There is, I fear, a little misunderstanding by some as to the nature of the appropriation. We were provided with \$500 the first year, and \$250 the second year, for equipment. This means that money was appropriated to organize and equip the apiary, but no money was appropriated for the salary of a bee-keeper. Hence the apiary, so far as the help and assistance are concerned, has been maintained by my department, out of the Entomological Assistance Fund. I have been able to do this because I was unable to procure a proper man until several months of the salary had elapsed. At the proper time I was then able to secure additional expert service in practical bee-keeping by employing your honored Secretary for a couple of months before the close of the fiscal year.

After the close of the fiscal year, Sept. 1, there will be no such funds, and we shall have to do the best we can in managing the apiary in a small way as a model for instruction. This we can hope to do successfully, but I fear not much time or funds will be available to devote to experimental work.

I have been especially fortunate in securing the services of Mr. Wilmon Newell as my assistant in the Department of Entomology. He is also an experienced bee-keeper, and you can fully rely upon his scientific accuracy as well as practical judgment in the future management and development of the apiary. I commend him to you and solicit your hearty co-operation in his behalf.

The \$500 for the first year has been practically expended. We have enclosed a beautiful ten-acre block of ground under fences. This block has a small, wooded ravine running through it, and an enticing natural grove, making it an ideal location for an apiary. Here has been built the beehouse, and equipped with everything that should be found in a well-equipped, up-to-date apiary. Some models are, of course, "dead timber," as it were, but they are important for teaching students, by comparison, the advantages of one hive or implement over another. Hence, I think we have all our apiary needs as a practical money-making apiary, and in addition many things which are important in a complete course of instruction in bee culture at the Agricultural College.

We had hardly started with the apiary on the College grounds when we found ourselves confronted by the very serious conditions of a sparse honey-pasturage, and it became at once imperative to study the honey-plants of Central Texas, systematically and thoroughly. This immediate section is not well provided with indigenous honey-plants at critical times in the production of surplus honey. Under direction of this Department Mr. Newell and Mr. Scholl have made quite a complete collection of the native honey-plants, and we shall constantly enlarge upon this. It is needless to state, therefore, that this Department at once began a systematic study of the honey-plants which might be tested on the College grounds with a view to determining their adaptability and successful introduction and cultivation. Some 30 or 40 different varieties have been sown each month during the season, and many valuable data have been already noted, some of which will enable us to secure a continuous honey-flow for this locality the coming year.

It is proposed to make a complete study of the honey-plants of the State and make a map of their geographical distribution. This will be accompanied by a map showing the time of best honey-flow in the various sections of the State for each leading honey-plant. Much can be done along this line, and it is the first important work which this Department proposes to investigate thoroughly.

F. W. MALLY.

The apiary, or bee-yard, referred to, has been located at the Agricultural and Mechanical College of Texas, at College Station, in connection with the Department of Entomology at that institution. It adds to the already large number of courses of study at the College, a course of instruction in up-to-date bee-keeping, both practical and scientific. It is now beginning to be realized that in the bee and honey interests of the State, Texas has a most important agricultural resource. Already Texas produces annually more honey than any other State or country in the world, and still thousands of square miles are annually furnishing in their trees and plants millions of pounds of honey which await only the bee-keeper and his faithful little workers—the bees. Already many firms and individuals are devoting their entire time and capital exclusively to this industry, one firm alone producing annually over one-half million pounds of honey. In addition thereto, this industry furnishes beeswax, vinegar, refreshing beverages, and derivatives for medicinal use.

Texas should be proud of what has been done, there being but three or four other States that have established an apiary in connection with their Agricultural and Mechanical College.

In concluding, Prof. Mally kindly asked the bee-keeping fraternity to lend freely their help by giving their suggestions and advice, which would be greatly appreciated, and would help the bee-keepers as well as the Department in conducting the study of bee-keeping at the College. He also requested the President of the State Bee-keepers' Association to appoint a committee to inspect and investigate

all that had been done, and report on the same, with suggestions and advices. Prof. Mally finished by remarking what a grand State Texas is for such a pursuit, and mentioned the wonderful things that could be done; also, how he expected to see to it that Texas bee-keeping should be brought up to a high standard. He will keep bees upon his extensive truck and fruit farms in East Texas, and in a few years expects to have a large number of colonies of bees.

The president, Mr. Udo Toepperwein, spoke a few words of thanks in behalf of the bee-keepers, for the pleasure afforded them by Prof. Mally's address. Pres. Toepperwein also appointed a committee of three, viz., L. Stachelhausen, F. L. Aten, and Mrs. C. R. West, to investigate and report upon the college apiary. Later, they reported as follows:

REPORT ON COMMITTEE ON STATE APIARY.

"Your committee has investigated the apiary upon the College grounds, and has found 16 colonies of bees in good and healthy condition, a very neat honey-house, and in it all necessary implements for the apiary. Our opinion is that the small sum of money at the command of Prof. Mally was invested in a very proper way for the purpose of creating the apiary, the object of which is to serve as a medium of instruction in apiculture to students of the College. Especially were we pleased with the orderly and systematic arrangement of the whole.

We hereby recommend that more money be expended on this apiary so that it will contain at least 50 colonies and the necessary implements, as we think that the present number of colonies is not sufficient for the proper carrying on of experiments.

Preparing Bees for Winter—When and How.

BY G. M. DOOLITTLE.

A correspondent writes me that he desires to do the best he can with his bees at all times of the year, and that he has been benefited much by my writings. He still wishes to benefit by them by me giving an article in the American Bee Journal regarding when to prepare bees for winter. He says his neighbor tells him that December is soon enough to get the bees ready for winter, but he has been wondering if it was not too late.

Well, I will do the best I can in the matter, but I will say that we do not all see alike in regard to the time when bees should be prepared for winter. Many seem to think that the latter part of November or December is early enough to prepare bees for winter; but some of our best apiarists have learned that the best results in wintering can be secured only when preparations are begun early in the season, so that the inside of the hive need not be disturbed after cold weather arrives. Therefore all colonies are to be looked after as soon as the honey harvest is over, to see that they have good queens, and that there is plenty of brood in all stages, for this brood is to produce the bees which are to live through the winter months; and if, for any reason, there is not plenty of brood at the end of the honey harvest, it is easy to tell what the result will be the following spring.

If any colonies are found that have been short of brood, the queen should be changed for a good one, and brood from those which have an abundance be given them so that they

can build up so as to be sufficiently strong in bees before cold weather sets in. If by any means, after all our precautions, the 20th of October finds us with weak colonies, they should now be united, for it is useless to attempt to winter very small colonies unless we have some special place to put them in, which has proven during the past to be sufficiently equal to the wintering of such small colonies.

Again, we wish to know that all have honey enough, of good quality for winter. *Good quality in honey* has much to do with the safe wintering of our pets; in fact, I believe *more* than any one thing which can be named; and he who does not pay any attention to this matter cannot expect to succeed to any great extent.

But what is good quality in honey? may be asked. If we look to Nature for an answer—that Nature which preserved our bees all through the thousands of years before man began to keep them for the profit in them—we shall find that, as a rule, the honey which a colony left undisturbed by man has in store, is that which has been on the hive long enough so that it is thoroughly ripened, having that rich, good quality we all like so well. Now such honey as this cannot be gotten just at the close of the season, where the extractor has been used till the very last thing, as many novices, and even older ones, persist in doing, leaving only the thin, watery stuff which comes at the time of the year when extracting is usually left off, for the bees to live upon. In my opinion, upon the injudicious use of the extractor has been chargeable much of the loss of bees in wintering during the past quarter of a century; for in nearly every instance where we have heard of large yields of honey taken with the extractor late in the season, we were almost sure to hear of a corresponding loss of bees by the same persons the next spring.

To overcome this difficulty it is better to set aside enough combs of thoroughly ripened and sealed honey during the season to winter our bees; and then, when the honey-yield is over, exchange combs with the bees; extracting all that is left in the combs taken this late from the bees, if we so desire, or carry it over in the combs to help build up the colonies in early spring, if this seems better in our sight. In this way we are sure that the bees have such honey as they ought to have to winter on. Of course, this applies only to those who are prone to extract too closely during the earlier honey-flows; but it is a good plan to work a few colonies for such combs of thoroughly ripened honey to be used in case of emergency, no matter how the bees are worked. Each fall finds me with an average of at least two full combs of such honey for each colony calculated to be wintered over.

Another reason why we should not put off preparing the bees for winter till cold weather comes, is that, if we do this, they cannot well get their winter stores near and around the cluster in time for them to settle down into that quiescent state so conducive to good wintering, as they should do prior to November 10th to 15th. To arrange these stores, and properly prepare them, requires warm weather, hence all will see the fallacy of putting off caring for them till cold weather arrives.

To be sure that all have enough honey for safe wintering, this can be ascertained by weighing a hive filled with empty combs, of the same pattern as those which the bees are in; or the frames can be taken out and the honey "counted off," as many prefer to do, myself among the number, as this gives you the whole of the wintering matter in only one manipulation.

To be absolutely safe, 30 pounds should be allowed for each colony to be wintered on the summer stands, and 25

pounds for each colony to be wintered in the cellar or special repository.

However, if we are willing to look after them when spring opens, 25 pounds for those out-doors, and 20 for those wintered under cellar protection, will do well enough; and in season of scarcity my bees have gone through safely from September till April on 20 pounds for those left out and 15 pounds for those carried in.

If there is not honey enough, after all are equalized in the apiary, to give sufficient stores to all, then draw on those combs you have set aside for emergency; and if not enough of these, then you will have to resort to feeding. As I go over the hives I carefully note the quantity of bees, age of the queen, amount of pollen in combs, etc., which is jotted down on a piece of honey-section, this piece being left on top of the hive, so that the next spring I can tell just what was in each hive the fall before, so that in case of loss I can form some idea of what occasioned it, and also tell what is the first thing to be done with each colony when spring opens. This little piece of section also helps me in deciding what queens to supersede during the next season, for on it I keep quite a record of when the colony swarmed, if it did so, how much honey it stored, etc.

After having the bees prepared as above, they are to be snugly tucked up in their chaff and sawdust cushions, at any time before the middle of November, when most convenient, after which they are left undisturbed till spring, or till placed in the cellar, according to where we winter our bees.

Onondaga Co., N. Y.

The Value of Honey as a Food.

BY PROF. SHUTT.

[The following is part of a very interesting address made before the Ontario Bee-Keepers' Association by Prof. Shutt, and reported in the Canadian Bee Journal. It would be a good thing if bee-keepers could have it copied in their local papers.—EDITOR.]

HONEY AS A FOOD.

With regard to this matter of the position of honey as a food, honey must be classed with the saccharine foods when considering its value. In order to appreciate its value intelligently, I shall have to say something with regard to the general food constituents as found in all foods. It will not take me more than a few minutes just to outline their nature and their composition and function in the animal system. We find that all foods comprise a greater or less quantity of the following classes of constituents: Protein or albuminoids, fats, starch and sugar, ash or mineral matter.

Now, first of all, with regard to protein or albuminoids: These materials all contain as an essential element of their constitution, nitrogen. Now, if you ask me for an example of protein or albuminoids I should at first name the white of an egg, which is pure albumen; it is one of the purest forms in which we can obtain protein; then the curd of milk and gluten of wheat are others. There are more or less pure forms.

Fat or oil I need not describe to you, because we have in so many articles, such as butter and various classes of oils, materials that you are perfectly familiar with. You know what I mean when I refer to and mention the word fat.

With regard to starch and sugars, those are known to the general chemist as carbo-hydrates. You have already learned from what I have said that starch and sugar are related chemically, so that all those substances which come underneath that head we call carbo-hydrates. Then there is also ash or mineral matter which, in the body, goes to form the bone. These substances you understand are present in greater or less proportion in nearly all our foods,

though not in all; we shall see in that respect honey is not a complete food.

I have said it is absolutely necessary that a complete food should contain these. First of all, the body requires something to build up its tissues continually. There is waste of our tissues due to muscular energy. Every time I speak a word or move my arm there is a certain waste of the system and this must be replaced; it is due to the protein or albumenoids that repairing of the waste of the body takes place, and consequently in order to restore life we must have foods which contain a certain proportion of protein or albumenoids. Such have this quality of being muscle-builders, body-builders. They contain nitrogen as an essential element. These other materials, fat, and starch, and sugar, and so on, do not contain any nitrogen. The chief intention with regard to protein and all albumenoids is to build up the body and repair the waste which hourly takes place.

With regard to the fats and sugars, we have materials which are useful in keeping up the heat of the body. If you put a thermometer in your mouth you will find that the temperature is somewhere in the neighborhood of 100 degrees Fahrenheit. How is that maintained? In the same way that heat in the stove is maintained. The wood is burned in the stove; the food is burned in the body. It is really a process of combustion; and the combustion of fat and starch and sugar within our bodies gives rise to heat. Heat is only another form of energy. We know that. Therefore we are able to convert the heat produced by the combustion of our foods into physical force or energy. So that we have in these two substances—fats and carbohydrates—those materials or constituents which have for their chief functions the development of heat and energy within our bodies.

Of course, the formation of fat takes place; a certain quantity of fat within the body is formed and we further find that that fat may be formed from either one of those three substances, but chiefly from the fat and carbohydrates of the food. It is important for us to know that a complete food must contain all those classes of constituents, and that protein or albumenoids differ, from those others, in possession of nitrogen, and that the latter are absolutely essential and cannot be left out of our daily diet, from the fact that it is necessary to build up the body and repair the waste which is constantly taking place. It is also necessary we should have a due portion of fat, starch, and sugar, in order to produce the necessary heat of our bodies, and for the purpose of developing energy.

There is also a certain proportion of mineral matter, or ash, required for the development of our bones.

Having said so much, where does honey come in? Honey is not a complete food, it does not contain any protein or albumenoids; it is not a body-builder, it does not contain any fat, but it is a substance of great value from a saccharine standpoint. It consists of sugars, dextrose and levulose, principally; consequently, we have a substance which from the food standpoint is strictly comparable with sugar.

The digestibility of food in a large measure limits or regulates value. It is not the food we eat that does us good, it is the food we digest and assimilate, that is, is converted into body-tissue or helps to develop heat and energy. When we take cane sugar or syrup into the mouth it is mixed with the saliva and converted into the form of glucose, and that is the form of sugar which is assimilated and passes into the blood and nourishes the body. We have that work already done in the case of honey; it is then already in the forms of dextrose and levulose, and therefore sugar in honey is what we may term a partially digested form; it is at once presented in a condition that is immediately assimilable and

may pass into the system. From this standpoint we may say that 95 parts of honey-sugar are worth 100 parts of cane-sugar for the purpose of assimilation.

We already have been saved the expense, so to speak, the physiological expense, of conversion of that sugar into assimilable forms. Honey as a food material, furnishes in a palatable, wholesome and readily digestible and easily assimilable condition, sugar which may act for the production of heat, for the development of energy, and also for the formation of fat within the body. From the foregoing considerations you see, we could not live on honey alone, no matter how desirable from many other standpoints, simply from the fact that it does not possess any of these protein or albumenoid substances which furnish the necessary nitrogen, neither does it furnish the bone-forming material. I think, however, it is one of the most digestible, most agreeable, most palatable, and most assimilable of all forms of sugar.

With regard to its position as a medicine I cannot say very much. It is used as a demulcent and as an anti-irritant for affections of the throat and coughs, and so on. It is slightly laxative in its character and it has some value as a medicine in that direction. But I think it is used medicinally principally for coughs and colds and affections of the throat, although possibly to some extent as a laxative. In former times it was employed medicinally to a much greater extent than it is now.

Rearing Queens—Another Jury Member Speaks.

BY E. S. MILES.

I have read the articles on "Rearing Long-Lived Queens and Bees," by Dr. Gallup, and since they do not seem to commend the queens as now generally reared I have been expecting to see some of our queen-breeders defending their methods. As the Doctor has left the case with the "jury," and seems to expect a verdict (see page 471), or at least a defense, I beg leave to give a little of my experience with queens.

Now, I cannot site the readers back to 30 or 40 years with bees, as I have had bees just 10 years this season. After having all kinds of queens, as to manner of rearing, and after having owned several dozen queens from several different breeders, I wish to say positively that my experience has been altogether different from Dr. Gallup's. When I first began with bees I noticed, every now and then, in the bee-papers, some one, like Dr. Gallup, who would tell how natural-swarmering queens were so much better than others, that for several years I was afraid to try to rear any queens except as I could save cells at swarming-time. After a few years' experience I found that there was a great difference in queens from swarming-cells, and I also found that a good, fair nucleus would sometimes rear a fairly good queen.

Now, I use the 8-frame hive, but don't think that I don't know a good queen, for I have had two stories and 10-frame brood-chambers, and have also known colonies to be in large boxes, box-hives, etc., so I know pretty well what a queen ought to do here in the way of producing bees.

I clip every queen as soon as she begins to lay, and keep a record, so I can tell, without any chance of making a mistake, whether a queen lives one year or six. Every purchased queen is clipped before being introduced, so there is no chance for superseding without my knowing it. Of all the queens I ever purchased or reared by artificial methods I never had one that did not get up to 5 Langstroth frames of brood; and all but one or two purchased queens filled from 6 to 8 of the combs in the 8-frame hives.

As to the longevity of the queens, I believe the transportation through the mails, or something that happens to

them between the place of rearing and their final home, does shorten their lives; but that it shortens the lives of their workers, I never could see.

One of the poorest queens I ever saw was a "super-seder." She could fill only 5 frames, and those scattering, nearly half the cells missed, and she gave out when less than two years old. Another one, I believe the poorest queen I ever had, was from a swarming-cell, and as fine and large a queen as I ever saw, but absolutely worthless, and lived less than a year.

I have had a great many "swarming and superseding" queens give out at two and three years. On the other hand, some of the most profitable colonies have been "mothered" by queens reared by the "Doolittle method" or modifications thereof. I have never had one such give out the second year, as the Doctor says they do, and I have had several do good, profitable work the third year.

So I write this not to argue with any one, not to criticize, but in the hope that some beginner may save valuable time in learning how good queens are reared.

I do not wish to be understood as claiming that natural-swarmering queens are not good, but only that there are poor ones among them; and that queens reared under artificial methods from the best stock are worth more than natural-swarmering queens selected haphazard as to stock. And, further, I would as soon have them as swarming queens from any stock.

I hope to hear from more of the "jury."

Crawford Co., Iowa, July 25.

The Bee in Law—Keeping of Bees; Damages—When, and When Not, Recoverable.

BY R. D. FISHER.

1. *Definition.*—Damages are the indemnity recoverable by a person who has sustained an injury, either in his person, property, or relative rights, through the act or default of another.

2. *General Principles.*—Whenever an injury is done to a right, actual, perceptible damage is not indispensable as a foundation of an action: but it is sufficient to show the violation of the right, and the law will presume some damage.

But no damages are recoverable for a mere inconvenience attending the existence of a public benefit; or for any lawful act lawfully done, which, if causing damage, is *damnum absque injuria*; or for any act causing no legal injury, which is *injuria sine damno*; or for an injury caused wholly or in part by the complaining party's own wrongful act, default, or negligence.

3. *Nominal Damages.*—Proof of the violation of any legal right entitles the injured party to some damages. If no actual damages appear, nominal damages are given for the technical injury.

4. *Substantial Damages.*—Where actual injury and the violation of a right are proved, substantial damages may be awarded as compensation to the injured party, and in certain cases as punishment to the wrongdoer. In arriving at the proper amount of damages, the courts follow defined rules.

5. *Remoteness.*—Immediate or consequential damages may be considered. No one is held responsible for all the consequences of his acts or defaults, but only for those which the law considers the natural consequences. These are either the direct consequences or they are indirect. For all direct consequences, whether they are such as inevitably ensue, or such as have naturally ensued in the particular case, the person guilty of the cause is held absolutely liable.

Such damages as the cause produced naturally but indirectly are called consequential.

In case of *tort* not involving malice, damages may be recovered; not merely for the direct consequences, but for such indirect results as might reasonably be expected to ensue by a person of ordinary intelligence, or for all the natural consequences of the wrongful act.

6. *Personal Property; Trespass.*—For asportation or destruction of his personal property, so that the owner is wholly deprived of it, he is entitled to recover its value at the time of the trespass. This is the measure of damages for the entire loss of the property. For an injury to it there is a right to a proportionate recovery.

The measure of damages for the conversion of property is the value of the property at the time and place of conversion. The element of damage to be considered in case of injury to the person is, the plaintiff's time of loss from business or employment; his loss of capacity to perform the kind of labor for which he is fitted; expenses for medical services, nursing, and mental and physical pain. The same rule will apply to injuries to animals.

We have set out the above principles of damages for the purpose of discovering, if possible, under what branch or branches damages may be recovered for injury or losses in consequence of keeping bees. In a previous article we reviewed the causes of damages growing out of the nuisances committed by bees. In this article we desire to review the rules regarding the bee as a trespasser. One who feels aggrieved by reason of trespassing bees may bring an action against the owner for damages, and may recover upon proper proof and identification of the trespassers for their original act of destruction; and successive actions may be brought to recover for damages for the continuation of their wrongful trespassing; but in all these cases damages are estimated only to the date of the bringing of each suit (*101 N. Y., 98*).

CAPACITY TO TRESPASS.

Courts judicially know that bees can not be stabled as other animals are: that to do so would destroy their value as property. If the owners of houses, grocers, and fruit-dealers and fruit-raisers were not careless in leaving attractions for them, bees would commit no trespass. They would go to pasture among forests, fields and amid flowers. But the grocers, fruit-dealers, and fruit-raisers say they are not required to screen against bees if domesticated and regarded as property; that the law should protect them from the ravages of trespassing bees the same as from any other trespassing animals. This is true only in so far as identification can be made positive. The instinct of bees is well understood, but their identification is difficult. The relation between fruit-growers and bee-keepers is said to be somewhat strained. The former claim it to be fair to compel the bee-keeper to feed his bees at home in seasons when they would otherwise prove a nuisance and damaging trespassers to his neighboring fruit-grower. Whether it would or would not be possible to keep bees at home by feeding them heavily is an open question. But this plan would entail a heavy tax upon the bee-keeper. Would it be just to make the bee-keeper pay this when, quite likely, the cracked and rotting fruit which the bees would take from the neighbor's orchard has been produced, at least has set, because of the labors in pollination of these same bees? When bees find a fair supply of nectar in the flowers within reach of the hive they prefer that to fruit, and few bees then attack fruit. But it is not at all sure that liberal feeding will keep all of the bees at home, or nearly all of them, from trying to get fruit sugar or juices.

The next suggestion is that of moving away if the cost would be less than feeding. But can the bee-keeper get

away from the fruit-grower? If the extensive fruit-grower can sue and collect damages for injuries to the fruit on his 1,000 trees, the owner of one tree, and 1,000 owners of trees within flying distance of an apiary, can also collect. If an abundant bee-pasture happens to exist a few miles away, the solution is easy and moving is practical. But this is usually of short duration; civilization and improvements, farms and fruit-gardens, soon follow, and the cry is again, "Move on!" On the other hand, it is claimed that the damages to fruit alleged to be due to bees is too remote and uncertain; and, as already stated, the benefits from pollination are equal to the damages. Few, if any, cases have reached the higher courts, and the judgment in the lower courts are largely based upon actual damages proved, and identification of the trespassing bees.

INJURY TO PERSON OR PROPERTY.

A small son of an Indiana farmer left the team he was driving, near some bee-hives, while he chased a squirrel. The horses backed the wagon into the hives, and the animals were so badly stung that they died. The boy was also stung so badly that he lost the sight of one eye. It was held that the boy's contributing negligence occasioned the injury and resulting damages, and no recovery could be had.

An Iowa farmer maintained a hitching-rack at the roadside in front of his residence. Near by, but within his inclose, he kept a number of stands of bees. A neighbor voluntarily hitched his horses to the rack. A swarm of bees settled upon the animals, causing them to break the tethers and run away. In their flight they collided with a team and vehicle going in an opposite direction, and both teams and vehicles were damaged. It was held that the hitching of the horses near the bees was a voluntary act, and the attack by the bees was too remote to justify a recovery from the bee-keeper for the joint damages suffered by the owners of the wrecked outfits.

In the case of *Earl vs. Van Alstine* (*8 Barbour, 630*), the New York Supreme Court held that the owner of bees is not liable, at all events, for any accidental injury they may do; that one who owns or keeps an animal of any kind becomes liable for any injury the animal may do, only on the ground of some actual or presumed negligence on his part. It was alleged in this case that defendant owned and wrongfully kept fifteen hives of bees in his yard adjoining the public highway, and that the plaintiff's horses, while traveling along the public highway, and passing the place where the bees were kept, were attacked and stung so severely that one died and the other was greatly injured. A judgment of \$71 was appealed from, and the court, in revising this judgment, said: "In an action against the owner of bees for an injury done by them to the plaintiff's horses while traveling along the highway where the bees were kept, it appears that the bees had been kept in the same situation for nine years, and there was no proof of any injury ever having been done by them, but, on the contrary, neighbors testified that they had been in the habit of passing and repassing the place frequently, without having been molested. This rebutted the idea of any notice to the bee-keeper, either from the nature of the bees or otherwise, that it would be dangerous to keep them in that situation, and hence he could not be made liable."

If damages be done by any domestic animal kept for *use or convenience*, the owner is not liable to an action, without notice (*13 John, Rep., 339*). The utility of the bees no one will question, and hence there is nothing to call for the application of very stringent rules in their case. However, the question whether or not the keeping of bees near a highway subjects their owner to a responsibility which would not otherwise rest upon him has not, to our knowledge, been passed upon.—Gleanings in Bee-Culture.

Questions and Answers.

CONDUCTED BY

DR. O. O. MILLER, Marengo, Ill.

The Questions may be mailed to the Bee Journal office, or to Dr. Miller direct, when he will answer them here. Please do not ask the Doctor to send answers by mail.—EDITOR.]

Getting Winter Stores—Denver Convention.

1. I started a new colony in June by taking out 2 frames of brood from an 8-frame hive. Now the old hive has the 2 outside frames full of honey, all capped over, and the most of the brood-frames are $\frac{3}{4}$ full of honey. I put on a super of sections, and they are working in them—have the middle rows filled and capped. What I wish to know is, if I take out 1 or 2 of the outside frames that are filled with honey, and put in a frame with a full sheet of foundation, can they draw it out and fill it before cold weather? and will it stop them from working in the supers? The reason I want to take it out is for feed in the new hive this winter. I would put it in the new hive about the last of October or first of November. This is my first season with bees.

2. I expect to be in Denver the first week in September, at our Letter Carriers' Convention. Could I attend one of the bee-keepers' sessions, while there? MISSOURI.

ANSWERS.—1. Whether the bees can fill up again depends entirely upon the harvest. The chances, however, are that storing will not yet stop with you, and in case the vacancy was not filled it would be an easy thing to return the combs removed. As two of the eight combs have no brood in them, and the remainder are only about one-fourth filled with brood, there is some danger that the colony may go into winter quarters weak in bees. Therefore when you take away the frames of honey, put the frames of foundation in the middle of the hive, so as to encourage the rearing of brood. There is danger that in taking away outside combs you may take away all the pollen in the hive. Taking away honey from the brood-nest will not stop storing in the super if there is enough storing for both, but, of course, what goes into the brood-chamber will be that much less in the super.

2. The sessions of the convention at Denver will be open to the public. At the same time it will be to your advantage to become a member of the Association.

Foul Brood.

I have had bees for some time, but never had any experience with foul brood until last spring, when I first noticed it in one colony, and they increased and threw out a swarm and left a good colony in the old hive. The brood that died was coffee-colored, and now almost all the other colonies have it. Will they breed and swarm with it? I thought at first it was chilled, as we have had so much bad weather. What shall I do with it? I do not want such a mess around. We are in need of an inspector here. If there is a cure for it besides fire, I would like to know it. OHIO.

ANSWER.—The best thing you can do is to get Dr. Howard's pamphlet on foul-brood, and also read up the instructions given in your text-book. You are entirely right in thinking a foul-brood inspector is needed. A good foul-brood law should be enacted in every State, with proper officers to carry it out.

Troubles in Introducing Queens.

1. I have some trouble introducing queens, but I never had so much before, with 3 colonies as follows: One swarm 1 month ago; I divided colonies and left one queen-cell; it did not hatch; and then I took a laying queen, placed over frames, as usual, and after being over frames 4 days I let

her out, expecting her to be all right, but she was crippled so she died before I could get her. Two queens were lost in fertilization, and the bees set to biting wires, and I know what that means. I considered it too late for dividing and cut out cells. The queen is lost. Now, is there any way to bring bees to time? There are plenty of bees in said hives. I am sure there is no queen as there are no eggs, nor laying workers, as yet.

2. Now suppose I buy queen-cells, placing them in hives, would that way be all right? I have no cells myself, but can get some.

3. Is it safe to carry them 4 miles, as I have found out it takes a very small jar to kill a queen in the cell.

ILLINOIS.

ANSWERS.—1. It is possible that the difference in the season had something to do with the trouble. When honey is coming in in a flood, bees are much more tractable about accepting a new queen than they are in time of dearth. Perhaps you might succeed better if you did not have to open the hive to liberate the queen. The opening the hive, especially in the time of scarcity, when robbers are ready to pounce in whenever a hive is opened, is likely to make the bees hostile to the new queen. Opening the hive in the evening, when robbers have stopped flying, is safer. It is also safer to have the queen liberated without opening the hive at all, letting the bees do the liberating by having them eat through the candy of an introducing-cage. You might try Simmins' method of direct introducing: Let the queen fast half an hour before introduction, and then smoke the bees at the entrance, open the hive and smoke a little on top and then let the queen run down between the top-bars.

2. Very likely the queen-cells would work all right, although you are never entirely sure what whims a stubborn colony may take.

3. Pack the cells in cotton, put them in a breast-pocket where there is no danger of their being chilled, and they will carry all right if you do not do any high jumping.

Bisulphide of Carbon for Fumigating.

1. How much bisulphide of carbon will it take to treat two or three thousand pounds of comb honey?

2. What is the cost of it? And could you get it for me? WISCONSIN.

ANSWERS.—1. I don't know as I can give a definite answer. Something depends on the size of the quarters that contain honey, and the closeness of the walls. In a large room much more would be needed than in a small space, and more will be needed if cracks allow the escape of the vapor. If honey is closely confined in small space I should say at a guess that a quart would be enough, perhaps less.

[2. We have investigated the matter and find that we can furnish bisulphide of carbon in pint (one-pound) cans, at 40 cents a pint, by express, not prepaid; 2 pint cans, for 75 cents. Address all orders to the office of the American Bee Journal.—EDITOR.]

A Queen Experience.

Desiring to Italianize my bees, I purchased 3 select-tested queens, and on receipt of them, June 26, removed the old queens and introduced the Italians by placing the cages over the frames of colonies 1 and 2, and started No. 3 by giving 2 frames of brood from No. 1, and one frame of honey from No. 2. No. 1 was a very strong colony of hybrids and had almost filled an "Ideal" extracting super at the time. July 4 I examined 3 colonies and found all three queens (how easy to find them compared with black ones). Nos. 2 and 3 had eggs and larvæ, but not No. 1; however, as the queen was there, I thought it was all right. July 12 I found my Italian queen missing in No. 1, and still no eggs and only a few capped brood. I looked over the frames carefully and found 2 small queen-cells, one opened naturally, and one torn open at the side. I did not know what to do, when,

after replacing all the frames. I found a bunch of bees on a piece of board on the ground, and on examination found a small, black queen, so small was she that I would never have found her among all the other bees. I removed her and sent for another queen at once, but as the breeder was out of his own queens I put in a frame of brood and eggs from No. 3, on July 16. Now this colony, No. 1, had been practically queenless for 21 days, up to July 16. Ten days later (the 26th), I found a big, yellow queen, one frame full of eggs, and some larvæ floating around in the milky food in several frames.

Now, then, isn't this a record-breaker for queen-rearing in 10 days time from brood to laying? and some of the brood from the new queen was surely several days old; it lay in the bottom of the cells curled up so as almost to complete the circle. What do you think of it? I clipped her wings at the same time.

NEW YORK.

ANSWER.—Your supposition is that from brood given July 16 a queen was reared which July 26 had brood several days old. Suppose the larvæ were only two days old; then the queen must have laid the eggs five days earlier, July 21. That leaves five days from the starting of a queen-cell to the laying of eggs. You are most surely mistaken in your supposition. No queen could possibly be reared in five days from the starting of the cell, to say nothing of an interval between hatching and fecundation, and another interval between fecundation and laying. It is a week from the time the cell is sealed till the young queen emerges, and if the queen emerges five days after the starting of the cell, the cell must have been started two days after it was sealed! You will probably ask me where that nice, laying queen came from. I don't know, but there are more ways than one to account for her presence, one way being that she was the same queen that was introduced; for you saw her in the hive eight days after she was introduced; for if the bees would tolerate her for eight days they might have kept her along till after the rearing and rejecting of the little black queen. It is also possible that the black queen was an interloper from outside, and that the yellow queen was reared in that properly opened cell that you found July 12, the egg having been laid by the introduced queen when she was first introduced.

Bees Turning Black.

Can you explain the following (to me) funny happening? Our bees last year were all Italians but this year they are, except a couple of colonies, black. Now there has been no black queen given them. No. 1 had, last year, a beautiful Italian queen. She superseded last summer and now still has that queen, but all the bees have turned black. We had two swarms from three colonies, a beautiful swarm of Italians, and they have turned black. Nearly every colony in the yard has turned to blacks. Some are bright Italian and some are blackish, but they all came from Italian mothers of our own, and the bees turn black whether the queen is bright or dark. We got a couple of queens this year—bright, golden-colored ones—and their bees are black too. Our beautiful, large Italians, which every one admired, are slowly but surely getting smaller and blacker every day. Will you kindly explain this?

ILLINOIS.

ANSWER.—If there were not internal evidences that your letter is from one of the gentler sex, I should be inclined to say, "My dear sir, you are quite mistaken in some of your views. Bees don't gradually become darker day by day. You must be more careful in your observations." But to get into controversy with a lady—never.

"I don't know why your bees have changed as they have," is the only answer I happen to have that will meet all the requirements of the case. I'll tell you, however, a little of my own experience, and then you may not feel that the bees are treating you so much worse than they do others.

Longer ago than you probably know anything about I got Italian blood, but I found it was changed to something a good deal darker, and in spite of obtaining from time to

time yellow blood by means of imported Italians, I found a constant tendency toward black. At the same time there seems to be a tendency on the part of the queens toward lighter color, and I think there must be something in this climate that makes the queens lighter than in Italy. As long as I did not clip queens, there was a chance to be mistaken in some things. A certain colony would have an Italian queen and three-banded workers. In a year or two the workers would average very much darker, although the queen would be just as light as ever—perhaps a little lighter. As a matter of fact, there had been a change of queens, and the new queen having met a black drone, her progeny resembled blacks as much as Italians. When this queen was again superseded (remember that every queen as a rule is superseded), the workers were darker still, and so long as black drones were in the majority in the surrounding vicinity this blackening process went on. Only by constant weeding out of queens with darker workers could the bees be kept respectably yellow, and yet the vexatious thing about it was that some of the very best harvests were made by those colonies that lack somewhat in color, and to-day I am breeding from a queen that is not pure yellow, just because I want honey more than color.

So I can only give you the doubtful comfort of saying that you may expect a continuance of a tendency toward darker color in the future as in the past.

Fastening the Queen on Foundation.

In your first answer in the first column of page 475, you seem to think it noteworthy, if not strange, that "California" didn't make a success of fastening queens on foundation in lower stories.

Why, how can it seem even noteworthy? I don't see how anyone could make a success of it. I am quite sure (although I never tried it) that the poor things would soon die, whether in the lower or upper stories, and no matter whether you fastened them with glue, melted wax or pins, on foundation or combs.

Don't you think you should be careful how you try to induce bee-keepers to try such risky practices?

SKEPTIC.

ANSWER.—I do not for a moment suppose it would be a success to fasten queens on foundation either "with glue, melted wax or pins." Indeed, it is reasonable to believe that no queen fastened in such a way could live more than eight or ten years. But has "Skeptic" the right to assume that I had any of these plans in mind? Before he is too hasty in condemning a thing which he himself admits he has not tried, let him try fastening the queen by some humane plan. Has he ever tried fastening one with a string!

The Buffalo Convention Report is issued in pamphlet form, size 6x8½ inches, 80 pages and cover. Besides a full report of the proceedings of the 32d convention of the National Bee-Keepers' Association, held in Buffalo, N. Y., Sept. 10, 11 and 12, 1901, it contains fine half-tone portraits of all the officers and directors of the Association; also the Constitution, a list of the membership up to the end of 1901, and the two latest bee-songs—"The Hum of the Bees in the Apple-Tree Bloom" and "Buckwheat Cakes and Honey." We believe it is the finest ever gotten out for the Association. Of course, all members of the Association receive a copy free, but there are thousands of our readers who are not yet members, but who should have this valuable Report. Better send for a copy, if you have not yet received one. Price, postpaid, 25 cents, or with the American Bee Journal one year—both for \$1.10. Send all orders to the office of the American Bee Journal. Better order soon, before all are gone.

QUEENS!

Buy them of H. G. QUIRIN, the largest Queen-Breeder in the North.

The A. I. Root Company tell us our stock is extra-fine; Editor York, of the American Bee Journal, says he has good reports from our stock from time to time; while J. L. Gandy, of Humboldt, Nebr., has secured over 400 pounds of honey (mostly comb) from single colonies containing our queens.

We have files of testimonials similar to the above.

Our Breeders originated from the highest-priced, Long-Tongued Red Clover Queens in the United States.

Fine Queens, promptness, and square dealing, have built up our present business, which was established in 1888.

Prices of GOLDEN and LEATHER-COLORED QUEENS, after July 1st:

	1	6	12
Selected	\$.75	\$4.00	\$7.00
Tested	1.00	5.00	9.00
Selected Tested	1.50	8.00	
Extra Selected Tested, the best that money can buy..	3.00		

We guarantee safe arrival, to any State, continental island, or any European country. Can fill all orders promptly, as we expect to keep 300 to 500 Queens on hand ahead of orders. Special price on 50 or 100. Free Circular. Address all orders to

GENERAL ITEMS

Buying and Rearing Queens.

I was very much interested in Dr. Gallup's articles about queens, and have just read what Mr. Alley says, on page 519. I have bought queens from nearly every queen-breeder in the United States, and my experience has been that 9 of every 10 queens I have purchased are worthless, while 50 percent of the queens I rear myself under the swarming impulse are fully up to the standard. I bought 5 queens in 1901 of a Texas breeder who is now out of business, the bees from one of these having produced for me, this season, 200 pounds of surplus honey, while the other four have not produced a single pound.

I believe that all queen-breeders, regardless of the methods they follow, will produce some good queens, and I think it wrong to condemn them, but rather we should encourage them, for what improvements we have made we are indebted to them for the same.

M. D. ANDES.

Sullivan Co., Tenn., Aug. 15.

Bees Have Done Poorly.

My bees have done very poorly so far, as it has been raining the most of the time since spring opened; in fact, I had to feed all through June, there being only one day the bees got to work on basswood, and there was so much water on the trees that they could do but little that day. They have been doing fairly well since July 20. So I hope I will not have to feed them this winter.

I winter my bees in an open shed where they are protected from the east, west and north wind, and are perfectly dry and well packed in straw, so nothing is exposed but the front. I have never lost any, and when I unpacked them the last of March they were all rearing brood, and have kept strong all summer. I got only 3 swarms, and those by dividing.

J. M. BUTLER.

Mercer Co., Ill., Aug. 10.

A Fairly Good Season.

This has been a fairly good honey season here, in North Idaho, and I think the honey crop will be very good. The season here is much shorter than in the Eastern States, owing to the cold rains late in the spring and early in the fall.

I started with 25 colonies last spring, and have increased to 70. Bees are filling supers with fine white clover honey.

The farmers here are seeding their farms to grasses to a great extent, such as red and white clover, alfalfa, etc., which makes fine pasturage for bees.

Is it a fact that bees do not gather honey after Aug. 10, to any extent, in any of the Eastern States, or, in fact, any part of the country? Do you know how much honey has been gathered by a colony of bees after that date? The statement has been made by a person

here, that bees do not gather any honey to amount to anything after Aug. 10, in any part of the country.

J. A. WATKINS.

Latah Co., Idaho, Aug. 3.

[Where there is a fall flow of honey, the bees gather after Aug. 10. May be some one will answer as to the amount a colony has been known to gather after that date.—EDITOR.]

Not Getting Much Honey.

Bees are not gathering much honey this year—too dry and cool. My late buckwheat is blooming nicely. I hope the bees will do better this fall. I started with 26 colonies last spring, now have 44, and two swarms went to the woods. My bees gathered some honey in May.

T. G. JONES.

Lyon Co., Ky., Aug. 16.

Small Crop of Honey.

I had to feed my bees the last half of June, when we had a sudden flow from basswood, which lasted but a few days. I have had only 5 or 6 swarms and a very small crop of honey. I am expecting a good flow this fall, as the weeds have grown very rank. We had so much rain that the farmers could not keep their fields as clean as usual. There is plenty of heartsease and all kinds of weeds.

C. P. MCKINNON.

Hardin Co., Iowa, Aug. 11.

Bees Dying from Spraying.

On page 503, I noticed an article on "Bees dying from spraying when trees are in bloom."

Away back in 1884 or 1885 our State Pomologist, Mr. P. M. Auger, requested that some tests be made to prove whether the spraying of trees while in bloom would be harmful to the bees, or of no benefit to the fruit, saying he thought it harmful to both. A discussion of the subject followed at that meeting of the Connecticut Board of Agriculture. The result of it was, I was requested to use all precaution necessary and make tests that followed for 4 or 5 years, selecting isolated locations, and these were the results, unlike the report of Mr. C. H. Lake:

1. It did not always kill the bees: sometimes a part of the young died in larva; others were further advanced.

2. The poison could be traced in the nectar carried to the combs, so that it was unsafe from a mercantile view. It was not analyzed, but fed to flies, etc., and they were killed by it.

3. The bloom was very much injured by the spraying, which in several cases was the cause of the whole crop of fruit being spoiled.

The report of results was never published in full, for two reasons, viz: 1st, it might help to induce the smart unbelievers to do considerable damage to Nature's pollenizers; 2d, evil-disposed persons could use it as a means to ruin a crop of fruit, and be out of the reach of detection.

There is a class of citizens in every place that are the worst criminals on earth: they occupy good positions in society, in the church, and in all organizations. They have strong influence, and they know they own the earth but have not yet fenced it in, and

they are the vilest enemies to every occupation and citizen, but they are out of the reach of the law. The law punishes not for the act, but for getting caught, and they do not get caught. To illustrate by a fact:

A certain minister in my vicinity found out that kerosene kills vegetation, and proclaimed it broadly, "When an obnoxious plant is in my way, a ½ pint of kerosene oil puts it out of my way."

Not long afterward, various shrubs and plants began to die, that were offensive to various persons. They followed that minister's advice.

Another person finding that sweetened Paris-green water would kill flies and other insects, exposed it for that reason, and killed off 20 colonies of bees. Some time afterward it leaked out that, "I made up my mind those devilish bees had to be gotten rid of." The bees were the things aimed for, some of their honey was eaten and the eaters were made sick.

The law does not reach that class of people, but they are everywhere.

Spraying really does more harm, as a whole, than it does benefit. I have worked at it, and I have studied it closely for more than 20 years. It does some good, but that good is limited.

H. L. JEFFREY.

Litchfield Co., Conn., Aug. 13.

Bachelor Bee-Keepers.

On page 488, I notice the question, "Why so many bachelor bee-keepers?" Now as I rank with a few of the best men, and as there are only a few who do not take the fatal step in early life, there is no reason why there should be bachelor bee-keepers, for they are the sweetest men in all the world. And, then, again, they are so wonderfully "stuck-up." Perhaps that is why the ladies would always be excused.

Now, if there are any old maids who can throw any light on the subject, it would be gladly received and highly appreciated.

C. E. STEVENS.

San Diego, Calif., Aug. 9.

Too Cold and Wet.

It has been too cold and wet this season for bees to store any surplus honey. Buckwheat is in full bloom here, but it does not appear to be yielding nectar in large quantities. I have 36 colonies of bees in Heddon hives.

Why do bees have a dislike to a certain color of hats? I never wear a veil, but I could not go through the apiary without getting stung, if I wore a neutral or mouse-colored hat. A large straw hat they do not mind.

SAMUEL HEATH.

Armstrong Co., Penn., Aug. 18.

(No one can tell why bees dislike dark colors, any more than any one can tell the why of many other things that exist. It has often been noticed that white or light colors are preferred by bees.—EDITOR.)

Honey-Supply Short.

The bees are working at present on sweet clover, red and white clover, heartsease and buckwheat. The honey supply here is very short and will not be enough for home consumption.

Up to date, my strongest colonies

of leather-colored and Golden Italians for sale in 9-frame hives, on Langstroth-Hoffmann standard frames. My leather-colors took first premium at the Minnesota State Fair last year. Delivery at any time before winter. (Amples stores guaranteed: Singly, \$5; in lots of 20, \$4.50 each, on car.

W. R. ANSELL,

34A2t Millie Leas Apiaries, MILACA, MINN.

have filled two supers of 28 one-pound sections, while the weaker ones have done about half as well, and still some of the weakest colonies have not given any surplus, and I think June 1, 1903, will be time enough to put on supers for them.

J. W. JOHNSON.

Stephenson Co., Ill., Aug. 11.

Light Crop—Too Cold.

The honey crop is very light; too cold. Bees are not making a living. Unless it gets warmer it will be necessary to feed for winter. C. M. TARR.

Wood Co., Wis., Aug. 9.

Light Crop of White Honey.

The present season will go on record as phenomenal, not only in the extreme rainfall, which has exceeded the recollection of the oldest inhabitant, but in the violence of its storms, which have caused washout after washout, rendering highways and railroads impassable at times. The aggregate rainfall in this place, according to the official report for the month of July, was 10.45 inches.

It is worthy of note, that "washout after washout" was not confined to highways and railroads, but has been most successful in removing the nectar from the blossoms, to the detriment of the honey-bee, and the consequently wretched impoverishment of the apiarist's pocketbook.

It is now a settled fact that no strain on the imagination is necessary to impress vividly the most casual observer that the apiarist's pocketbook, in this section at least, must this fall carry the impression of having either been unsuccessful in an attempt to "loop the loop," or of having been accidentally stepped on by the elephant, and no "baby elephant" at that.

We are sorry to have to report so light a crop of white honey; our buckwheat just commenced to produce nectar a few days ago. About 200 pounds of comb honey and 400 pounds of extracted will comprise our surplus from 66 colonies, present count; 47 spring count. We trust we will have a good flow of dark honey.

As a consolation to my fellow bee-keepers who are in the "same boat," and without any disrespect to the "Good Book," or the "sky pilots" who so earnestly and faithfully advocate its most excellent principles; neither do I wish to cast any reflection on the "gentler sex," for I ever have in mind that my mother is a woman. I would say, but you know it is on record that "a little nonsense now and then is appreciated by the wisest men." (Perhaps the quotation isn't verbatim). As a consolation to such poorly afflicted mankind (or it may be womankind), the story is told of a minister of the gospel, who, remembering the teachings of the Master, upon the sudden death of one of the oldest members of his parish, went immediately to offer his counsel and consolation to the newly-made widow in this her greatest bereavement.

"My dear madam," began the good man, "this is indeed a great affliction; but you know the Good Book teaches us that we must all some time go the way of all the earth, and that we should all be prepared, for we know not

Bee-Keepers—Attention!

Do not put your money into New Fangled Bee-Hives, but buy a plain, serviceable and well-made hive, such as the regular Dovetailed hive arranged for bee-way sections. Honey-producers of Colorado—one of the largest honey-producing sections in the world—use this style.

Thousands of Hives, Millions of Sections, ready for Prompt Shipment.

what hour we may be called in like manner."

"O, yes," she replied, "I don't know what I would do without the Good Book. There is one passage of scripture in particular that has been a great help to me through my present affliction."

"To what passage do you refer?" he asked, all attention at once as the subject of his daily study was mentioned.

"Well, now," replied the elderly matron, and the shadow of a smile appeared on her wrinkled features, at the fickleness of her memory, "I don't remember whether it is in Psalms or Proverbs, but I distinctly remember the passage."

"Perhaps I could recall the passage, and prompt your memory as to its location, if you would kindly repeat it," he quickly made answer, "as the deepest interest held him in rapt attention."

"Well," she replied to his request, as a hesitating uncertainty, plainly depicted on every feature, and in voice as well, seemed to take possession of her as she endeavored to recall the quotation verbatim to the learned man who stood before her. "The passage is, 'Grin and bear it.'"

Fellow bee-keepers, let us, without wavering, face the front, continue to take the "Old Reliable" American Bee Journal (which I have taken for nearly 19 years), study apiculture, look for a better season next year, and do not forget the old woman's quotation, whether it is in Psalms or Proverbs or not, but "Grin and bear it."

HONEY AND BEESWAX MARKET QUOTATIONS.

CHICAGO, Aug. 11.—Some comb honey produced in 1902 is now on sale. Fancy brings 15c; anything off in appearance or quality sells at 13@14c for white; amber grades, 2 and 3 cents per pound less. Extracted is selling at 6@7c for white; light amber, 5 1/2@6c; dark, 5@5 1/2c. There is a fair demand for all grades and kinds. Beeswax steady at 30c. R. A. BURNETT & CO.

KANSAS CITY, Aug. 16.—The receipts of comb honey are increasing; so is the demand. New fancy white comb, 14c; No. 1, 13c; No. 2 and amber, 12 1/2@13c. Extracted, white, 6c; amber, 5@5 1/2c. Beeswax, 22@25c.

C. C. CLEMONS & CO.

CINCINNATI, July 26.—Considerable stock of 1901 crop fancy comb on the market and sells at 14@15c; there is a call for new comb honey, as yet none on the market; this market demands fancy comb; all other grades discourages trade. Extracted is in fair demand at 5 1/2@6c for amber and 7@8c for clover. Beeswax, 28@30c. THE FRED W. MUTH CO.

ALBANY, N. Y., Aug. 22.—The demand for honey is improving with the unusual cool weather, the summer resorters returning home hungry. We quote: Extra white comb, 15@16c; medium, 14@15c. No other grades coming yet.

We want to caution shippers against shipping by express, as it arrives almost invariably broken. Express companies are stamping the cases "Received at owner's risk," which seems to cause their employees to "play ball" with it. Freight handlers are slower, more careful, and less broken, and much cheaper. We advise sending by freight only. H. R. WRIGHT.

NEW YORK, Aug. 11.—New crop comb honey from New York and Pennsylvania is beginning to arrive in limited quantities. There is a good demand for fancy white at 14c, and No. 1 at 13c, and exceptionally fine lots will possibly bring a little more. Lower grades quiet at from 10@12c. As to extracted honey, fancy grades are in good demand at from 6@6 1/2c for white, and 5@5 1/2c for light amber. Southern in barrels and half-barrels quiet at from 4 1/2@6c per gallon, according to quality. Beeswax dull at from 27@28c. HILDRETH & SEGLKEN.

CINCINNATI, Aug. 19.—New comb honey is not coming in so plentiful, so far. Whatever has come in, and is fancy water-white, has brought a good price, and sold to stores from 15@16c. Honey kept over from last year, fancy sells for 14c. The market for extracted is more lively and brings—amber, from 5@5 1/2c; alfalfa water-white, from 6@6 1/2c; white clover, from 7@7 1/2c. Beeswax, 30c. C. H. W. WEBER.

SAN FRANCISCO, Aug. 6.—White comb, 13@14c; amber, 10@12c; dark, 8@9c. Extracted, white, 5 1/2@—; light amber, 5@—; amber, 4 1/2@—; Beeswax, good to choice, light 27@29c; dark, 25@26c.

There is not much honey offering from any quarter, and market is decidedly against buyers, particularly for choice to select comb, which is in fair request on local account. Extracted has to depend on shipping demand to a considerable extent, and to secure shipping orders prices have to be regulated by values current in other centers. While there is not much extracted offering, buyers have not so far shown disposition to take hold at any material advance on figures lately ruling.

WANTED!

A Celluloid Queen-Button is a very pretty thing for a bee-keeper or honey-seller to wear on his coat-lapel. It often serves to introduce the subject of honey, and frequently leads to a sale.

NOTE.—One reader writes: "I have every reason to believe that it would be a very good idea for every bee-keeper to wear one [of the buttons] as it will cause people to ask questions about the busy bee, and many a conversation thus started would wind up with the sale of more or less honey; at any rate it would give the bee-keeper a superior opportunity to enlighten many a person in regard to honey and bees."

The picture shown herewith is a reproduction of a motto queen-button that we are furnishing to bee-keepers. It has a pin on the underside to fasten it.

Price, by mail, 6 cents; two for 10 cents; or 6 for 25 cents. Send all orders to the office of the American Bee Journal.

PROF. A. J. COOK.

Price,
Postpaid,
\$1.20

Price,
Postpaid,
\$1.20

This standard work on practical bee-keeping has just been thoroughly revised and brought down to date. About 100 pages and nearly 100 illustrations have been added, which makes it now a superb volume of 544 pages, with 295 fine illustrations. It is printed on clear white paper, and is bound in elegant brown cloth, gold-lettered.

Prof. Cook has been one of the leading contributors to the American Bee Journal for a quarter of a century. He is well known to bee-keepers everywhere. He is an authority on bees and related subjects. His book has had a large sale, which now bids fair to increase greatly.

In order that every reader of the American Bee Journal, who does not already possess a copy of Prof. Cook's work, may have it, we wish to make the following

FOUR LIBERAL OFFERS:

No. 1.—For \$1.75 we will mail the American Bee Journal one year and a copy of Prof. Cook's book.

No. 2.—Any one of our present subscribers whose subscription is now paid in advance, can have a copy of Prof. Cook's book mailed to him free as a premium for sending us two new subscribers to the American Bee Journal for a year (with \$2.00.)

No. 3.—Or, send one new subscriber for a year (at \$1.00) and 50 cents more (\$1.50 in all,) and we will mail to YOU a copy of the book and will send the American Bee Journal for one year to the new subscriber.

No. 4.—For \$1.00 we will send Prof. Cook's book by express or freight with other goods; or, if called for at our office, the price is \$1.00. But the post-paid price of the book alone is \$1.20.

Please remember that offers Nos. 2 and 3 of the above are made to those who are now subscribers to the American Bee Journal, and whose subscriptions are paid in advance. Offers Nos. 1 and 4 are made to any one who desires to take advantage of them.

Address all orders to the publishers,

* Editorial. *

Comb Versus Extracted Honey.—

The question is often asked by beginners, "Shall I produce comb or extracted honey?" The question is not one to be answered off-hand in a single word. The flora must be considered. Some kinds of honey, especially the darker and the stronger-flavored varieties, may find a ready market, even if not at a high figure, while the same honey in sections could hardly find sale at any price. The market must be considered. There are local preferences which can not be utterly ignored. Consumers in some localities may prefer extracted at the same price as comb. In other localities they will have none of it at any price.

The man must also be considered. One man has learned the trade of producing comb honey so as to make it more profitable, while another man in the same locality will make extracted more profitable. Perhaps the season should also be considered, although how is one to know in advance what the season is to be? If the season is unusually cool, the cool days, and especially the cool nights, will drive the bees out of the sections; and if honey be gathered in larger amount than necessary for the daily consumption of the colony it will be crowded into the brood-chamber, crowding out the queen; while with extracting-combs the honey would be stored above. As illustrating this, see the following editorial from the Rocky Mountain Bee Journal:

This is one of the seasons when it would have been paid to run all of our apiaries for extracted honey. A fairly good crop might have been produced even if all new combs had to be built. In one of our out-apiaries are rigged about 25 colonies for extracted honey, with the design of supplying our home city market. Full-depth extracting-supers were given with frames containing half-sheets of wired foundation. In every instance these supers (they hold 10 frames) have been filled and are ready for extracting. Comb-honey colonies in the same apiary have not finished one super apiece. The honey in the extracting-supers is all sealed and will yield 45 pounds apiece. In the section-supers three or four rows of sections in the middle are finished. The balance are unsealed and only half built out. The season, of course, accounts for this vast difference. In the extracting-supers a large cluster of bees could form, and comb-building was not seriously interrupted during the cold days and nights that prevailed during the first flow. In the section-supers the comb-builders had to divide up into 25 little clusters, and these literally "froze out" during the aforesaid cold weather.

The Fourfold Bee-Hive.—Mr. A. W. Smith, of Sullivan Co., N. Y., wrote us as follows Aug. 11:

EDITOR YORK:—I answered an advertisement in the New York Herald, of a wonderful bee-hive, and received the enclosed letter, which I thought might interest you. I do not think it any improvement on the common hives in use in this country.

A. W. SMITH.

A very interesting document is the circular enclosed, which might be worth printing here but for its length. It is hard to see what there is patentable about the "specially-constructed fourfold bee-hive," and hard to see what advantage it can have, although the circular assures us its advantages "are so obvious that even the layman can grasp and comprehend them at a glance."

It seems that in this hive there is no separate compartment for honey, at least the author says "there is no separate honey-section in my hive," and adds:

"The reason why, after years of experience, I can not endorse the separate honey-section is that the bees, in the first place, fill up with honey the empty nooks around the queen, and only after there is no more space here at all, they carry the honey into the section separated from the queen; this, however, greatly harms the breed, for the great quantity forces down the queen-bee from the bee-breeding perches to such an extent that the family often degenerates or entirely declines by reason of too much honey."

Isn't that richness for you? Just what the "breeding perches" are is not explained, although the writer of the circular says:

"My experience has taught me that the bees perform their work most industriously, and readily in an undivided section in which the queen-bee can freely move from perch to perch to arouse the population to industry."

What would happen if the queen should fall off one of the perches as she goes on her rounds "to arouse the population to industry" is not stated.

Is it possible that a sufficient number of dupes can be found to pay for the expense of issuing and advertising such a circular?

A Bad Case of Stinging.—Not long ago Editor Root had a little controversy with the bees, which he reported in *Gleanings in Bee-Culture*. Another fracas with bees has occurred at the Home of the Honey-Bees—this time no laughing matter. A horse belonging to Mr. Harrington was standing unhitched in a field in which was an unfenced apiary, and the horse got among the bees.

Pretty soon the horse began to kick, and then a regular stampede ensued. The more the bees stung her the madder she became. She kicked two hives over, and, as if out of revenge, she would walk right up to a hive in front of her, and stamp one of her front hoofs right through it. She actually ran one foot

right through one super of comb honey, down into the brood-nest, and, such a racket! Mr. Harrington arrived on the scene just in time to find the horse covered with bees and kicking everything in sight into smithereens. He managed to get her free, and started her for the open bars. He himself was literally covered with stings. He raked the bees out of his hair by the handfuls; and when he emerged from the yard there was scarcely a spot on his face or body that you could place a finger on without putting it on a sting; and the 'old mare'—well, she shared about the same fate.

Notwithstanding the dozens, and perhaps hundreds, of stings received, the curious part is that Mr. Harrington insists that after the first few stings the rest did not hurt, although he remembers feeling slightly sick.

As to the horse, Mr. Harrington treated it in the following manner:

He called for a pound of salt, and, in the meantime, proceeded to rake the bees off the horse. He wrapped the salt in a paper, and pushed paper and all down the horse's throat. She was beginning to swell, and it was evident she would die in a few minutes unless the salt would act, and something *did* act. Very soon the swelling began to ease up; the horse seemed easier, and, in the course of an hour, when given grain, she ate as if nothing had happened; and in two or three hours more she was driven home by Mr. Harrington, 2½ miles, in the very buggy in which she had been hitched, and from which she kicked herself clear. With some binding-wire the thills were made to hold together, and man, horse, and buggy went to town as usual.

Boxwood is spoken of very highly by S. E. Miller in the *Progressive Bee-Keeper* as a honey-yielder in Missouri. He has a fine lot of extracted honey from it, and says:

"June 10 is the date in my almanac for bees to commence on boxwood, but they commenced on June 9, and did good work on all favorable days until about the 20th. Little trees not over four inches in diameter—some of the same ones that I have husbanded in the past—were full of bloom, and the roaring of the busy bees in their tops was certainly good music to my ear."

There Are Other Fools, Too.—General Manager Secor sends us the following clipping, which originally appeared in the *New York Sun*:

THEY FOOL THE BUMBLE-BEE—HIS HIVE-
LOVING COUSINS TICKLE HIM AND
STEAL HIS HONEY.

The men who study insect life have found that the big, black and yellow humble-bee is often swindled of the results of his hard day's work at honey-gathering. The dapper little hive-bee knows how to play upon his weaknesses.

The hive-bee is a thoroughly city dweller, living in a bee-metropolis which has its bee-mechanics, builders and nurses, bee-boards of health that look after the ventilation of the city and the removal of the garbage—bee-policemen who guard the hive against moths

and other honey-thieves, with bee-queen to rule over all.

The clumsy, loud-buzzing bumble-bee, however, is a veritable farmer, and lives with a comparatively small family in his mud farm-house in the clover-fields. He is such a simple soul that the hive-bees look upon him as a hayseed.

Several of them will meet him when he is on his way home with a load of honey, and induce him to stop and have a chat in the bee-language. Then they pat him and rub him, and the bumble-bee loves to be tickled. Thus they work upon his good nature until he actually lets them take part of his bag of sweets—all of it sometimes.

When he has been robbed in this fashion the smart hive-bees bid him an affectionate good-by, acting just as if they were slapping him on the back, and probably telling him that he must come up to town and take dinner with them some day when he is not busy. Whoever knew a bumble-bee to have a day to himself?

Then the robbers go home and lay their plunder away, while the bumble-bee sets out for his farm-house, congratulating himself upon having such good friends, likely enough, and quite convinced that he is indeed a highly popular fellow.

Mr. Secor's only comment on the above was this: "I never caught them at it."

Weekly Budget.

MR. AND MRS. UDO TOEPPERWEIN, of Texas, called at this office recently, when on their wedding tour. They were expecting to go East, and possibly get back to the Denver convention. We wish the happy couple a long and useful life.

THE LONE STAR APIARIST, of Texas, has suspended publication. This is unfortunate, especially for those who had their money invested in it. But it will be no surprise to those who know what it means to publish a bee-paper. There are a good many people who just know they can make a great success in the apicultural literature line—until they try it. Then they learn better. We are really sorry for our Texas friends, for they *deserved* success, at any rate.

EDITOR E. R. ROOT seems to inherit some of his father's rural tastes. The father has gone into the wilds of Michigan and built him a cabin in the woods two miles from the post-office, and now the son, restrained by business cares from getting so near to the heart of Nature, has moved his family out upon a farm $2\frac{1}{2}$ miles from town, to get away from the smoke of factory and locomotives, and from the nerve-destroying shriek of whistles and clang of bells. He has an apiary on the farm where he can spend his evening hours.

THE DEATH OF MR. GEO. F. ROBBINS was announced a week or two ago. He was in the employ of Mr. E. T. Flanagan, in Texas. Mr. Flanagan wrote us as follows, Aug. 23:

FRIEND YORK:—I have just returned from a trip to southern Texas, where I was called by a telegram announcing the sudden death of my manager, Geo. F. Robbins, formerly of Mechanicsburg, Ill. It was a sad blow for me, as I will find it hard to replace him.

for it will be hard to find a more faithful or honest man than he was. Peculiar in some respects, even eccentric, he was faithful to a high standard of duty. Intelligent, well educated, keeping abreast with the advancement of his favorite pursuit, he was above all a sincere Christian gentleman. I respected and loved him as a friend and brother bee-keeper, and none will miss him more than I. Would there were more like him.

St. Clair Co., Ill. E. T. FLANAGAN.

CONSIDERABLY DOUBLED-UP is what you might call Editor Hutchinson, of the Bee-Keepers' Review. Quite a good many years ago he was a double father all at once—a pair of twin girls came into the home. A year or so ago these same "twin girls" were married at the same time, so Mr. Hutchinson became a double father-in-law. And now—think of it!—one of these twin daughters has a little boy and the other a little girl, making Mr. H. a double grandpa. If he isn't a much-doubled-up man we don't know who is. "Grandpa Hutchinson!" Sounds old, doesn't it? But he says he "Never felt younger or more energetic."

Many happy returns, grandpa!

MR. C. P. DADANT and youngest son, "Maurice," called on us last week when on their way home from Sturgeon Bay, Wis., where they had gone to settle up some business affairs of Mr. Dadant's father. It was the late Chas. Dadant's annual custom to spend a few weeks each autumn in Wisconsin, where he would be free from an attack of hay fever. One of his aged Iowa friends, also an octogenarian, who was always at Sturgeon Bay at the same time Father Dadant was there, when told of his death, decided to go there no more, as he would miss the companionship of Mr. Dadant too much to endure it. So this year he is going to the Pacific Coast for awhile. It only shows the strong friendships made by the late friend of bee-keepers.

Biographical.

1817 CHARLES DADANT. 1902

The news of the death of Charles Dadant came as a shock, notwithstanding the fact that at his advanced age it was a thing naturally to be expected. Many of those, however, who have enjoyed his youthful and vigorous style of writing were perhaps not aware that he was more than 85 years old at the time of his death, which occurred after a short illness, on July 16, 1902.

Charles Dadant was born at Vaux-Sous-Aubigny, in the golden hills of Burgundy, France, May 22, 1817. After his education in the college at Langres, he went into the mercantile business in that city, but ill-success induced him to remove to America. He settled in Hamilton, Ill., in 1863, and found a genial and profitable occupation in bee-culture, which, in his hands, yielded marvelous results. He soon became noted as one of the leading apiarists of the world.

In 1873 he made a trip to Italy to import the bees of that country to the United States

on a large scale. Later he began the manufacture of comb foundation, which has helped to make his name known.

It is true, however, that of late he has not written much, his son, Camille P., having come to the front as a writer of distinction to take his place. Neither is it in this country that Charles Dadant is best known as a writer. It is in the French journals that he was most at home; for in them he could use his native tongue, and although it might not be suspected by those who were familiar with his writings in the American journals, he never became so familiar with the English language as to converse freely in it. That the movable-frame hives with improved methods of management are to-day so much in use among French-speaking people is in a very large measure due to the strong influence of Charles Dadant, an influence used in the face of the opposition of the French journal, *l'Apiculteur*, for a long time the leading French bee-journal.

When 46 years old, Mr. Dadant came to this country, intending to make a business of grape-growing, a business with which he was familiar from childhood, but within a year he became so interested in bees that although he continued to do something with grapes the bees became the leading object of his attention. Dadant & Son made themselves known as large producers of extracted honey, as importers of Italian queens, and especially as the largest manufacturers of comb foundation in the world until recent years.

In 1886 he revised and republished the book of "Langstroth on the Honey-Bee," which has been styled "the classic in bee-culture." This work was published almost simultaneously in America, France, and Russia. The three latest editions were printed at Keokuk, Iowa, near his home. His teachings spread over the world, and there is not a civilized country where his name is unknown to progressive bee-keepers.

Charles Dadant married, in 1847, Miss Gabrielle Parisot. Mr. Dadant had two daughters, one of whom is the wife of E. J. Baxter, of Hancock Co., Ill., and one son, C. P. Dadant, with whom he has been in partnership since 1874, and with whom he lived till his death.

Mr. Dadant was of a cheerful disposition, and made friends of all who knew him. He had none of the infirmities of old age, and his death was but the flickering out of a lamp that has entirely used up its fuel, a worthy ending to a useful life.

Those who have had the pleasure of an acquaintance with Mr. Dadant in his own home will testify to his genial and cordial spirit, a spirit which it is a pleasure to know has descended to the son.

A Tribute from Mrs. L. Harrison.

The death of Charles Dadant has brought to my mind many pleasant reminiscences of a visit there, after the closing of the national convention of apiarists, held at Keokuk, Iowa. Carriages had been provided, and invitations to delegates to visit the home and manufactory of comb foundation of Charles Dadant & Son. I accepted the invitation, and it has been a pleasant reminder ever since. After a pleasant drive of three miles, more or less, from the town of Hamilton, Ill., with congenial companions, we entered the grounds where there was a fine residence where three generations lived in harmony and love.

It is not every one who, having spent time,

thought, and money in establishing a new business, would, as it were, give it away to those who might come in competition with them, as they did. They had called together their workmen, and had every department in full operation from the melting of the wax to the finished product. It was noticeable how much thought had been expended to reach the goal of perfection in all the small details, with the least expenditure of time and strength.

The senior Mrs. Dadant spoke the French language only, which I could not comprehend. The wife of the son had a large family and a little child to care for, so Father Dadant was delegated to entertain me. I remained over night, and in the morning he offered me his arm and showed me through the grounds, going among the buildings first; these were all upon substantial stone foundations, quarried from their own land. The buildings were quite numerous, and so far apart that if one burned the others would not. One was corrugated iron for storing wax, and Mr. Dadant said "it paid its own insurance." One building was devoted to the vineyard, containing implements for its culture and spraying; presses and other paraphernalia for the manufacture of wine; a large cellar beneath containing hogsheads of the fruit of the vine.

I saw the stables and barn, in which I noticed that all bins for holding grain were lined with tin, preventing rats or mice from destroying their contents; a honey-house containing all the appurtenances of a model apiary and storage for barrels of extracted honey. I was shown the apiary with its large, 10-frame hives, and from there we went to the vineyard, with its vines neatly trained to wires, showing care and culture.

Mr. Dadant then said, "Now, you must see John's home." It was the colored man's, who spoke French. As we drew near the pleasant cottage, the loud barking of the dog proclaimed our arrival, and a bright-appearing colored woman opened the door with a child in her arms, and gave us welcome. She appeared so comfortable and happy, and her countenance beamed with gratitude as she said, "Mr. Dadant built our home for us."

On our return across the field Mr. Dadant said, "John is too kind-hearted; he spent his wages every month. I said, 'John, you will be getting old after awhile, and you must save something.' But John could not do it. So he agreed that I should pay him only part of his wages, and I could save the rest for him, and now he owes a home. I encouraged my French workmen in like manner, and now they have homes of their own; and when we have no work for them they cultivate their vines, and work their ground."

What a philanthropist! Taking such kindly interest in those he employed. Though "the place that once knew him knows him no more forever," his kind deeds and loving counsel will continue to bear fruit upon the stony bank of the Great Father of Waters. May we profit by his example.

MRS. L. HARRISON.

Extracts from the Bee-Keeping Press.

Gleanings in Bee-Culture, besides having a fine picture of Mr. Dadant, published a biographical sketch written by Dr. C. C. Miller, from which we take these paragraphs:

As briefly mentioned in Gleanings for July 15, the death of Mr. Charles Dadant occurred July 16. A brief illness of 36 hours preceded his death, fulfilling a wish often expressed by him that he might never become childish, nor linger a burden to himself and others. Few men have lived to pass the 85th milestone of life's journey retaining such vigor of mind and body.

When he reached America [in 1863] he knew not a word of the English language. He established himself on a small farm near Hamilton, and subscribed to Horace Greeley's paper, the New York Tribune, denying himself any French books or paper. In this way he found himself compelled to follow the events of the day by the use of a dictionary; and so great was his ability to learn, that, although then 46 years of age, within three years he knew English well enough to write articles for the American Bee Journal, then

published in Washington, D. C. His articles on "How I Became an Apiculturist," published in Vols. III and IV of the paper for 1867-68, were eagerly read. In 1869 he undertook the task of fighting the routine of European bee-culture by writing for the French, Italian, and Swiss bee-keepers. In 1874 he published a small book, "Petit Cours d'Apiculture Pratique," in the French language.

Notwithstanding the clear and forceful manner of Mr. Dadant in writing English (although it never became easy for him to converse in that language), yet he wielded a pen of still greater power when writing in his native language; and the fact that the movable hive is to-day so much in use among French-speaking people is not a little due to the vigorous writings of Charles Dadant, the Dadant and the Dadant-Blatt hives being among the most common in France of movable-frame hives.

In this connection it is not out of place to say that his son, Camille P., bids fair to become, like his father, a power at long range, for he has lately begun to furnish monthly articles of ability and interest to that standard French bee-journal, the Revue Internationale.

In 1874 Mr. Dadant took into partnership with him his son, C. P. Dadant, and together

whose hive and system were more fully adopted than those of our late departed friend. He was a vigorous writer in English; but, as Dr. Miller says, his pen wielded a still greater power when writing French.

I met him some ten years ago, and well do I remember the cordial welcome he extended, and how, as I got into the carriage to drive to town, the old gentleman, with the warmth of feeling so characteristic of the man toward those he loved, leaned forward and grasped my hand and hung to it. I had not at that time written much on bees, and he knew me only through my father; but from his manner I took it he loved me because I was a son of A. I. Root, for, indeed, he and my father were very warm friends.

Years ago Mr. Dadant imported queens from Italy. Like all imported queens these were leather-colored, and rather inferior-looking compared with the ordinary, yellow queens of the same race in this country. It was not long before Mr. Dadant was accused of sending out hybrids for imported. At that time my father came to the rescue by saying that, if Mr. Dadant wanted to send out hybrids, he would mail mismatched Italian queens of a bright color rather than to send the dark-colored, genuine imported of Italy, which he did. This little act pleased Mr. Dadant, and I think he never forgot it.

Our business connection with the Dadants has always been of the pleasantest. Indeed, there are no better or more successful business men in our ranks than those same Frenchmen; and when they first advertised that every inch of their foundation would be equal to the samples, they lived up to the very letter of their guarantee.

I am not so sure but the death of Mr. Dadant will mean more to the bee-keepers of Europe than to those of America. Indeed, it is wonderful that he could wield such a mighty influence in modern apiculture at such "long range," and in a foreign country, even if it was his old fatherland.

It is gratifying to know that his son, Camille, is also able to influence, as did his much-respected father, at "long range."

E. R. Root.

FROM THE BEE-KEEPERS' REVIEW.

Chas. Dadant, at the advanced age of 85, passed away, after a short illness, on July 16. Forty years ago, when he came to this country from France, he was a poor man with a family, and no knowledge of our language. Notwithstanding these disadvantages, he and his son, C. P. Dadant, have built up a most prosperous business in the production of honey, and especially so in the manufacture of comb foundation. Not only have they done much towards the building up of bee-keeping in this country, but the mother country has not been forgotten—the name of Dadant being an authority in that sunny clime.

FROM THE CANADIAN BEE JOURNAL.

The bee-keeping world will learn with regret of the death of Mr. Charles Dadant, of Hamilton, Ill., on July 16, after a brief illness. Mr. Dadant was deservedly considered one of the fathers of American bee-keeping, and in his death the industry has lost one of its most faithful and devoted followers, and who, apart from his connection with the revisions and translations of that magnificent work, "The Hive and Honey-Bee," by L. L. Langstroth, has done much for its highest advancement.

FROM THE MODERN FARMER AND BUSY BEE.

The Modern Farmer and Busy Bee speaks thus of Mr. Dadant, through its editor, Emerson T. Abbott:

We are pained to be compelled to announce the death of one of our prominent bee-keepers and staunch friends, the senior member of the firm of Chas. Dadant & Son. Mr. Dadant was born in 1817, and died July 16, 1902, being in his 85th year. He was born in France, and educated in the language of his nativity. He never acquired an easy use of the English language in conversation, but, notwithstanding this, he was a very interesting conversationalist. He has been identified with the bee-keeping industry for more than a quarter

CHAS. DADANT IN 1873.

they increased their apiaries till they reached the number of 500 or more colonies. They harvested at different times crops of 40,000 to 45,000 pounds of honey. Later they went into the manufacture of comb foundation. In 1873 Mr. D. went to Italy for Italian bees, and became a most successful importer, having been the first to ascertain what was necessary to keep bees alive on such long journeys.

It is pleasant to know that the familiar firm name, Dadant & Son, is to be continued, the son becoming the senior, and the son's son, Louis C., the junior member.

C. C. MILLER.

Following the foregoing Editor Root has this foot-note:

Charles Dadant, almost the last representative of the Langstroth and Quinby generation, was probably the best-known bee-keeper of any man in the world, for his writings have been read in both hemispheres. Langstroth wielded a great influence in America; but perhaps there is no bee-keeper in all Europe

of a century, and we are probably safe in saying that his name is known wherever a colony of bees is kept.

He was a man of that high type of character with whom it is a pleasure to associate, and after whom no one can read without being benefited. His home life was ideal, and he was revered and loved by those who knew him best. The writer has found a hearty welcome in a great many homes, but in no home has he felt more at home than during his visits at the home of the Dadants, "Father Dadant," as we were wont to call him, was a capital host, and while he made no pretensions to being a religionist of any kind, we have no hesitancy in saying that his

outward life was that of an ideal Christian. It will be a long time before the bee-keepers pay the debt of gratitude which they owe to this venerable patriarch in the industry. He lived an excellent life, and at a ripe old age, without a lingering illness, no doubt died an ideal death. He has left us for something higher and better, we trust, but his work will remain to bless the untold generations yet unborn.

C. P. Dadant has been associated with his father in the comb foundation business from the start, and his son will now join him, and the firm name will be continued.

We shall miss the pleasant welcome of Father Dadant, and the interesting articles

from his pen, but there will be no change in the policy of the firm so far as the quality of their goods is concerned. We have done business with them nearly 20 years, and during all that time, if we have ever differed on a business deal to the amount of a nickel, we have not known it. To us, the word of a Dadant was always as good as a bond, and this has been true, because the goods have always been delivered according to the stipulation in the bond. The family has our profound sympathy in this, their hour of bereavement, and the best we can possibly wish them is that their lives may be like the life of the friend and father who has gone out of their sight for the time being.

Convention Proceedings.

Report of the Texas State Convention, Held at College Station, July 16 and 17, 1902.

BY LOUIS SCHOLL, SEC.

(Continued from page 550.)

The subjects regularly upon the program were taken up, and Prof. Wilmon Newell spoke as follows, on

The Preparation of an Apiary for a Honey-Flow.

This is a subject that is closely coupled with that of producing surplus honey, and together with the latter subject has received its full share of discussion in the bee books and periodicals.

The entire subject under present conditions is more adapted to a careful and full discussion by all, rather than a treatment by any one person. What I will have to say will be composed solely of facts and principles that are familiar to up-to-date bee-keepers, and therefore not of paramount interest.

I have nothing new to introduce, and shall only endeavor to review briefly those methods of operation that have been found essential to the proper handling of a honey-flow. On the other hand, it is to be expected that the experience of many bee-keepers, in various localities and under varying conditions, will bring to light many new ideas and methods of manipulation. For this reason I shall attempt no more than to introduce the subject, for the full discussion of which I feel sure will follow, and which, I hope, will bring to light many valuable points, that, at least to many of us, will be new.

HOW BEST TO PREPARE FOR A HONEY-FLOW.

The proper time to begin preparation for a honey-flow is the year before. All partially-filled sections, if we are producing comb honey, and all empty combs, if we are running for extracted honey, cannot be made better use of than by saving for use as "baits" the following season. For this purpose they should be placed in a tight super or hive-body and kept absolutely protected from mice, wax-moths, ants, and all manner of insects. It is also needless to say that they should be kept in a fairly dry room, where they cannot freeze. Many bee-keepers assert that these baits are worth their weight in gold; and, while I believe I would prefer the gold, they are at least worth more for coaxing the bees up into the super, at the beginning of the honey season, than could be realized from them if converted into wax and extracted honey.

At the approach of the honey season, there are three points to which I would call special attention:

The first is the gathering together of all tools and implements, getting the tools sharp and clean, and getting every thing into its place, where you can instantly put your hands on it when wanted. Of course in all well-regulated apiaries there is a place for everything, and everything in its place, but, alas, we are all human, and, once in awhile, or perhaps twice in awhile, tools are mislaid. This is likely to entail a waste of time and labor in hunting for them when most needed, and when strictly, as well as literally, time is money, to say nothing of the fact that it is liable to

be conducive to language very unbecoming to even a Texas bee-keeper.

In addition to this, a sufficient supply of supers, extracting frames, hive-bodies, etc., should be nailed up and painted. If using sections, the supers should be filled with their proper number of fences or separators, and if the honey season is not too far distant, the sections folded, comb foundation inserted, and all made for immediate transfer to the hives. I would not advise the placing of foundation in frames or sections more than a month previous to use, as it does not retain its form and freshness as well as when kept in the original boxes, to say nothing of the exposure to insect pests.

The second point to which I would call attention, and which, above all others, is of the most importance, is that of having strong, hustling colonies at the beginning of the honey-flow. It has been repeatedly demonstrated that unless a full force of bees is present little or no work will be done in the supers. To attain this result best the colonies should go into winter quarters with plenty of stores and bees in each hive. As soon as possible in the spring, the colonies should be examined, and any that are weak should be stimulated by feeding. In localities where a reasonably good honey-flow is expected there is absolutely no question as to the profitableness of feeding. Only a small amount of cane-sugar is necessary, when fed daily, to stimulate brood-rearing.

During the forepart of June we conducted some experiments in the College apiary to determine the amount of sugar necessary to stimulate. At this time there was little if any honey coming in, and as a result of the shortage all queens had ceased laying. Both nuclei and full colonies were fed an average of 3 ounces of sugar per day, made, of course, in the form of syrup. Within a week the bees were rapidly building comb, and all queens laying. We bought sugar at this time at the rate of 15 pounds for a dollar, or 6 $\frac{2}{3}$ cents per pound, making the cost of feed per colony 1 $\frac{1}{4}$ cents. Of course, earlier in the spring a larger amount would be necessary, owing to the increased consumption needed to maintain the temperature of the hive. It seems likely, though, that even then stimulative feeds should not cost on an average of more than 2 $\frac{1}{2}$ to 3 cents per feed for each colony.

The importance of thus feeding in order to have a strong force of bees at the beginning of the honey-flow, is readily seen when one realizes that approximately ten thousand bees are required to do the household work in an ordinary-sized hive. Suppose a colony to contain 40,000 bees, 30,000 of these will be field-workers—really the number which will be gathering surplus honey. On the other hand, suppose these 40,000 bees to be divided into two colonies of 20,000 each. In each hive will be required, as before, 10,000 bees for interior or household work, leaving but 10,000 field-workers to each colony, or 20,000 in all, as compared to 30,000 in the former case. The bee-keeper cannot afford to have weak colonies at the opening of the honey season, as a large part of the season at least will be required to build them up to a profitable working strength.

As a third important point, queens which are prolific should be used in all colonies; and while it may not be advisable to supersede poor layers during the honey-flow, this point should not be neglected, and as soon as a poor layer is found she should be replaced by a queen at as early a date as possible.

WILMON NEWELL.

In the discussion that followed, questions were asked as to which feeder was best adapted for this feeding. Of the different kinds used in the College apiary the division-board feeder, or "Doolittle Feeder," was found to be the best.

The required amount of syrup for feeding was discussed,

as some did not think the amounts as given by Mr. Newell would be sufficient after several weeks, on account of the increased number of bees that would then be hatching. The answer was that at about that time the amount would have to be increased, but in the case of the experiment at the College apiary a light honey-flow came on at this time, which increased the food-supply sufficiently to make further stimulative feeding unnecessary.

BUILDING UP NUCLEI BY STIMULATIVE FEEDING.

Relative to the building up of nuclei by stimulative feeding, and having combs built out, the question was asked:

"Where is the proper place in the hive to put the full sheets of foundation to have them built out?"

The replies developed that this requires some good judgment and care. When adding a frame filled with foundation, this should be placed next to the last frame containing brood, or, in other words, on the outside of the brood-nest, to have it well-built out. It should not be placed in the middle of the brood-nest as many are prone to do, as such does very disastrous work at times. When honey comes in very sparingly, and this is not drawn out, the queen is very likely to use only the set of combs on one side of this sheet of foundation, neglecting entirely the combs on the other side. Then, again, when honey is coming in plentifully, these combs are generally drawn out fast enough, but filled with honey before the queen has a chance to deposit any eggs in them. Then the same condition prevails as before: One side of the hive is neglected, the combs on that side are filled with honey, and the colony is in a cramped condition. The queen is restricted to but half of the combs, and as a result there is a decreased amount of brood, and finally a weak colony.

When putting in foundation be careful. Put it outside the brood-nest, next to the brood, with the combs of honey (if there are any) on the outside of this, and then, when the foundation is drawn out sufficiently, place in the middle of the brood-nest, *between combs of hatching brood*, for the use of the queen when she makes her next round.

Next a discussion on adding frames of foundation to full colonies, and in the spring, was also had. There is great danger when cutting the brood-nest, at this time, into two parts, as the bees are likely to neglect the queenless half or side on cool nights and during cool weather. This often results in a great loss of brood. It is better to give frames on the outside of the brood-nest, and then one need not lie awake on cool nights, during a cold, backward spring, and wonder if any brood is suffering, to entail a heavy loss for him later on.

Weak colonies and nuclei should have the brood placed next to one side of the hive, the west or sunny side being best, and then the other frames added towards the middle or other side of hive.

(Continued next week.)

No. 8.—Bee-Keeping for Women.

Dangers of Starvation—What and How to Feed.

BY EMMA M. WILSON.

One of the dangers that a beginner needs to guard against is the danger of starvation. She may think her bees bountifully supplied with stores in the early spring, and indeed they may have been, but she is not aware of the large quantity of honey needed to keep up the amount of brood-rearing that is necessary for the welfare of her colonies.

Perhaps the first intimation she has that anything is wrong, she notices the remains of larvæ dragged out of the hive, the juices all sucked out of them—nothing but the white skins left. She is very much alarmed, and wonders what disease has appeared among her bees, when the simple truth is, her bees are starving. If you should tell her so, she would be very sure you did not know what you were talking about. Starving, indeed! didn't she know that her bees had plenty of stores when she examined them only

two or three weeks before? She has very little idea of the amount of stores needed for brood-rearing. She has not taken into account the number of wet or chilly days when the bees were not able to gather any. Brood-rearing must go on just the same, and an extra amount of stores is consumed at such times in order to keep up the heat.

A good bee-keeper tries in every way to encourage brood-rearing in the spring, in order that the colonies may be as strong as possible and ready for the harvest when it comes. There can be no brood-rearing without the consumption of stores. Not only must the bees have enough stores for immediate needs, but they seem to look ahead and do better work if they have quite a surplus on hand. If the bees are allowed to come to actual starvation the danger is much greater, for not only is brood-rearing stopped, but much of the brood already started is destroyed. In this condition of affairs it pays to feed.

How shall we feed? By giving the bees combs of sealed honey, if you have them to give. There is no better way of feeding than this, but, unfortunately, we so seldom have enough of these combs. The next best thing is the feeder and the best granulated sugar.

I know of no better feeder than the Miller. With this feeder it is a very quick and easy job to feed. You can put the feeder on the hive, put in the dry sugar, making a little depression in the center, and then add a very little water (either cold or hot can be used, much depends upon the weather which is best; if it is cool, better use hot); let it soak through slowly, so that the first that goes through will be sweet enough for the bees to take readily; after that add the water as you please. You need not be very particular about the quantity of water used. If only a small quantity of sugar is used, use about the same quantity of water. If a large quantity of sugar is used, add as much water as you can conveniently, and more water can be added from time to time as the sugar gets dry.

Another way is to dissolve the sugar with hot or cold water, and pour the syrup into the feeder.

But you may have no feeder, and may not be able to wait to get one. Then the crock-and-plate feeder will do. Put into the crock equal parts of sugar and water, stirring until dissolved. Put over the crock one thickness of woolen cloth, or five thicknesses of cheese-cloth. Put the plate upon the crock, bottom side up. With one hand under the crock and one hand over the plate, quickly turn the whole thing upside down. Place it on the top of the brood-frames and put an empty hive-body over it. Cover it up bee-tight, so that no bees can get to it only as they come up through the brood-frames.

If there are no neighbors' bees near you that you are afraid of feeding, you can feed out-of-doors just as well, setting the feeder a few rods away from the hives.

Do not imagine that the only time that your bees are in danger of starving is in the spring. It sometimes happens that in the very height of the season, even when bloom is very abundant, because of a prolonged cold, wet spell, or some other condition of the weather, there is no nectar coming in, and unless you are on the alert the first thing you know your bees are dragging out their brood.

This year we had to feed our bees all through the month of June, and that with abundance of white clover in bloom all the time. Not a very encouraging prospect. Still, the bees must be fed. I must say I never realized before how much honey it took for their own consumption. It was a big relief, I can tell you, that the weather changed the first of July, and we had about ten days of very good weather, just at the time, too, that the bees had full benefit of the little basswood we have. They filled up their brood-chambers so that we have not had to feed up to the last of July, but I don't know how soon we may have to, if this wet weather continues.

Whatever you do, don't let your bees starve. See to it that they have at least two or three weeks' rations in advance. You may be sure if they have more than they need they will not waste it.

McHenry Co., Ill.

Necessity of Legislation Against Bee-Diseases

BY N. E. FRANCÉ,

State Inspector of Apiaries for Wisconsin.

FRIEND YORK:—I thank you for the editorial on page 531, on "Legislation Against Foul Brood." I find that bee-keepers are like other people—*selfish*—and seem to care little for others in general. Unless they are in some way in danger of their bees getting disease they seem to care

little about law or for others. Several times I have noticed the indifference of some good bee-keepers about diseases of bees, saying their bees and that part of the country had nothing of the kind; but when I showed them pictures I took only a few miles from them—of apiaries once profitable, 200 colonies reduced to 5, and another of 90 reduced to 1, and also diseased combs lying around on the grass—how anxious they were then to know what the law was, and whether the disease is endangering their bees.

Had it not been for importing foul brood into Wisconsin from other States, I could have had our State free of the trouble some time ago.

Each State can have just such laws on diseases of bees as its bee-keepers want, and will have them as soon as its bee-keepers will *together* ask for the same.

Now, the United States Census Report on bee-keeping in United States is to be had. I know the above to be true. I long for the day when every State will have legislation on diseases of bees, and no more importing of the same from other countries, or from one State to another. Foul brood and other diseases are not half as hard to handle as the behind-the-times bee-keeper.

Every State should have an experiment apiary conducted by a bee-keeper, said bee-keeper to be chosen by its State bee-keepers' association, and to conduct such experimental work as directed by said association. I hope to see such a day. Then bee-keeping will advance and be of great value.

Grant Co., Wis.

Evolution in Bees—"Nature and Nurture."

BY PROF. A. J. COOK.

I read with great pleasure the interesting article from Mr. L. Stachelhausen, on page 422. I always do read his articles with great interest. He knows a whole lot, and I usually find myself in hearty accord with his pen-strokes.

This matter of development in the bees has puzzled many abler than Mr. Stachelhausen or I. Even the great Darwin was staggered to harmonize fully his great discovery with our bees. Yet to me there seems no very great puzzle, nor any serious conflict with the laws of breeding or of transmission. Let us see:

In all organisms parents, either through some inherent tendency, as taught by Darwin, or more probably influenced by environment, are ever producing offspring varying from each other, which shows that it is more from "nurture than Nature." Thus while all parents tend surely to transmit their own peculiarities to their progeny—that is, all offspring tend surely to inherit the peculiarities—there is always as surely a like tendency to variation. And it is these two tendencies, coupled with "survival of the fittest," that has guided and controlled in all the developmental life-history of the World's evolution.

Let me make the case or example concrete. A man sires children. He gives to them strong characteristics, to all of them. One is to transmit to his possible children these same prominent traits. Let us suppose this is a very united family, and always works together for the common good—like the apostles of old, "have all things in common." Suppose there are two children. One marries and is happy in a family, which he is able to surround with the best environment, and is wise to give or withhold as the best needs of his children suggest. The other does not marry, is not encumbered with family cares, and thus shares the productive resources of his fruitful labors with his less thrifty but more fortunate brother. Who can surely say but that this is not better for the world, in scattering more broadly the grand, sterling characteristics of this family than though both had offspring? A good motto for college classes is, "Not how much, but how well." Here the bachelor brother supplies means for the best possible nurture that the benedict has leisure and opportunity to give it. More children less well equipped would surely not be a richer gift to the world. One unique, like a Gladstone, a Beecher, or a Washington, is worth scores of those who never touch their kind to bless and help. If, as I fear, the neglect of busy fathers sends fine, promising boys to the slums, then surely means to banish this neglect would be beneficent.

Could we say that the bachelor brother did nothing to elevate the future in his failure to leave children? Did he not help to a development which carried grandly his own very characteristics also, rich in the blood of his brother. into the life and work of the world? To doubt this is to doubt the grand work of nurture in the world's progression.

If, as seems likely, the whole work of sex-determination is dependent upon nourishment, who shall say that such division of labor as suggested here is not most influential in organic evolution?

If division of labor is the strongest factor in economic advancement, why, then, may not such division of labor as just suggested prove most potential in the best and most rapid development?

Do not all see at once the application of this example to our bees? Here, through varying the food, the bees develop a numerous "bachelor class"—the workers—which may never transmit their characteristics—for they shall never know descendants; but they may store such rich harvests of the best food, may prepare a food regimen so super-excellent that their own mother and fertile sisters shall the better transmit surely and generously all the good qualities which they bear and share. This mother-queen had the power to transmit them, else they would not possess them. She will hand her peculiarities as surely to her fertile daughters, and more richly because of their exceptional ministries.

Again, suppose, because of an exceptional environment, she produces workers of exceptional excellence. The exceptional environment may have come through better care and attention from her own sterile daughters. She will not only produce there excellent workers, but she will give to their fertile sisters, her own power—perhaps magnified—to produce also improved workers.

Thus the fact of sterile females is no bar to the work of development through "natural selection"—nay, may be its best aid. The fact is that differentiation has nowhere been so varied and marked, both anatomically and physiologically as in the honey-bees, and no less wonderful work of the queen in laying nearly double her own weight of eggs each day. To appreciate this latter we have only to fancy a Brahma hen laying some 15 pounds of eggs a day, or a Jersey cow producing milk that would furnish us say 1,500 pounds of the best Jersey butter.

Los Angeles Co., Calif.

The Causes of Swarming—Its Prevention.

BY C. P. DADANT.

I notice the quotation, on page 499, of Dr. Miller's statement in regard to the prevention of swarming. I wish to make some remarks about it, and as the paragraph I wish to quote is quite short, it is perhaps as well to repeat it here. Dr. Miller says:

"One way to prevent swarming is to get the bees to rear a young queen about swarming-time. Giving a young queen reared elsewhere won't answer. I had a swarm issue with a young queen that I had given not a week before, she having just begun to lay, but when a colony has itself reared a young queen, and that queen has begun to lay, I never knew or heard of such a colony swarming till the next year. Gravenhorst gave this as reliable without being able to explain why the young queen must be reared in the hive itself."

My experience tallies exactly with that of Dr. Miller, but the difficulty is to rear a young queen in a colony just at swarming-time, and get her to lay before the bees swarm. My experience is that when a populous colony is made to rear queens during the swarming season it will swarm with the first queen hatched, more readily than if it had not been caused to rear queens at all. If, however, the first queen can be brought to lay, the other queen-cells have all been destroyed, the swarming fever is over, and the interruption in the laying between the taking away of the old queen and the laying of the new one—making a period of some 20 to 25 days—is sufficient to deter the bees from swarming. After the young queen has begun to lay, the season is already far advanced. But a young queen has this particularity: If she is healthy, she lays drone-eggs very sparingly. My father held that a queen preferred laying worker-eggs whenever she was not tired by incessant laying, and according to his views the young queen avoids laying in drone-cells simply because she feels vigorous. The drones when numerous are a great incentive to swarming. I might say, perhaps, that they are the greatest incentive of all when circumstances are favorable. So if the hive has few drones the swarming will be less frequent. Open a hive that has just swarmed, and in nine cases out of ten, you will find a great many drones. They are noisy, they are in the way, they make the workers more or less uncomfortable, hence the swarming.

When we give the bees a young queen just at the time

of swarming, they usually notice the change from their own queen to a stranger. Ordinarily they accept the intruder, but in many instances it is only a temporary acceptance. I have seen this many times, when we used to import queens from Italy by the hundreds and introduced them in full colonies. Often the bees would accept them quietly, but would also quietly go to work rearing queen-cells with the intention of getting rid of the stranger at the first opportunity. At any rate that is what I thought was their purpose, for I have many times seen the bees rear queen-cells in a hive where a new queen had been introduced. As a matter of course, if this happens during the swarming-time, there are ten chances to one that the bees will swarm out with the queen instead of killing her. The bees have almost become reconciled to her and they are reluctant to hurt her. So out goes the swarm. That is why, as Dr. Miller says, a young queen may go out with a swarm from a colony to which she had been given not a week before.

In our efforts at domesticating the bees and making them bend to our will, we must put up with their natural tendencies. If our work does not contravene with their native instinct we will succeed, but there will probably always be some difficulties which we cannot overcome. Thus the very requirement to prevent swarming—the rearing of a young queen in the hive at the proper time—will be our undoing, if the bees conclude that the hive is too crowded at the time when the young queens hatch.

I would like to suggest to those who wish to avoid natural swarming, to rely mainly on good, young, prolific queens of the previous year's rearing, for two reasons: The first is, that the removal of the old queen and the rearing of a young one at the opening of the harvest is sure to result in a weakening of the colony by the interregnum of the greater part of a month, during which no eggs will be laid. The second is, the difficulty of preventing the swarm from issuing with the first queen hatched. It is true that the cells may be removed, all but one, but in a populous colony it is quite a task to make sure of all the queen-cells, and this would be practicable only in small apiaries, as it would entail a great deal of labor.

When all the conditions have been as favorable as possible to the comfort of the bees—shade, ventilation, and storing space amply provided, the production of drones reduced within the smallest possible limit—we find that there is but one very strenuous cause of swarming, and that is the superseding of an old queen by her bees. As the laying has been long protracted, the queen begins to show signs of weakening, or of decrease in her laying, and the bees build queen-cells in the prevision of her decrepitude. Should the queen retain enough vigor, as she often does, to resent this treatment, an excitement is produced, and swarming results, even though the other conditions may be satisfactory. So it is very certain that the older the queens are, the more probability there is of swarms.

Hancock Co., Ill.

The "Missing Link" in Queen-Rearing.

BY G. M. DOOLITTLE.

It was with more than usual interest that I read the articles on "Rearing Long-Lived Queens and Bees," by Dr. E. Gallup. And why? Because Dr. Gallup was about the only *personal* teacher I ever had in bee-keeping. Under date of the earlier '70's, I have a stack of letters nearly three inches thick, which the then Elisha Gallup wrote me, giving me the minutest instructions how to proceed along the different lines in bee-keeping I asked him about; and I have kept these letters all these years as a sweet memento of the man who had so much patience with a beginner in the mysteries of apiculture.

Brother Gallup and myself have aged nearly, or quite, 30 years since then, but I see by these articles on queen-rearing of his that he is quite as young on this theme as he was at the time he wrote me that "*Good, long-lived queens come only from cells in which there was a lump of royal jelly left after the queen had emerged from the cell.*" And that was 29 years ago. He was so emphatic in this matter, and made it so plain to me, that I soon discovered why I had so many queens lying dead at the entrance of their lives the spring before, for I had been rearing them on "the nucleus plan" recommended by some of the "leading lights" in queen-rearing of those days.

The next year found me rearing all my queens by natural swarming, coaxing colonies to swarm both early and

late in the season, that I might rear the more while the bees were under this magic of swarming. This I continued to do till into the early '80's, when I discovered a colony having two laying queens in it—mother and daughter. These two queens just filled that hive from end to end, and from bottom to top, with brood in May and June, and when the basswood bloom came on their workers filled the supers with honey equal to the way the hive had been filled with brood. The old queen died during the honey-flow. But the young queen lived to be nearly six years old, doing the best of work for five years.

This turned my head from queens reared by natural swarming to queens reared where two laying queens were tolerated in the hive at the same time, and the next time I found such a case—which was some two or three years later—I took away the young queen as soon as she commenced to lay, and then cut out mature queen-cells as fast as the bees built them. In this way I secured the finest lot of queens I ever had known before, and, later in the season, after I had discovered the "cell-cup" plan, I gave this colony a frame of prepared cups, which they accepted at once, and turned out from them as fine a lot of queens as I ever saw, every one of which was long-lived, and of the best quality. And each of these cells had a lump of royal jelly left in them, just as Elisha Gallup said there would be where good queens were reared.

From this sprung the plan as given in "Scientific Queen-Rearing," from which I have reared many queens that have given splendid service for four, five, and, in a few instances, well into the sixth year. And I wish to say to my indulgent teacher of the "gone-by" years, that in nearly every instance where I have cut open cells I have found that "missing link" present—that which Dr. Gallup pleases to term "an umbilical cord." I had noticed this cord many times in years gone by, when, in instances where I had more ripe cells than I needed for use, I would cut them open and critically examine the embryo queen to see in just what stage of development she was. And this cord has often been so strong that it would hold the queen-embryo suspended to the cell after I had rolled her out in my hand, or partially so, as far as the cord would allow, when it would take quite a little force to break it.

Since the Doctor wrote his articles I have examined more closely into this matter, and every cell which I could spare since has been carefully opened, only to find in each case the tendrils he speaks of, as they run from this cord up the inside of the base to the wax cell-cups, and all under and through the royal jelly in every conceivable direction. Therefore, according to my old teacher, the "missing link"—that which will produce the best of queens—is supplied in nearly every instance when using the plan of queen-rearing as given in "Scientific Queen-Rearing."

And this *best of queens* is as hundreds, if not thousands, have found it to be when using that plan, for I have hundreds of testimonials telling me that those using this plan now produce queens of far greater value than they were ever able to produce before using the same. And these hundreds and thousands can only smile a quiet, contented smile when told by Mr. Alley that queens so reared are "as worthless as so many house-flies." "The proof of the pudding is in the eating," and after having tasted of a really first-class article, none care to go back to the "makeshifts" of the past.

To say that "a colony of bees will not rear good queens while there is a fertile queen present," shows the fallacy of many of the other statements and assertions made by the writer, for a moment's reflection will convince any thinking, reasonable person that 99 out of every 100 queens were so reared prior to the Nineteenth Century, queens which brought our bees down to us in as perfect condition as they were when the Creator pronounced them as "*good.*"

And lest some may think that I have an "ax to grind" in this matter, I wish to say that I am in no financial way interested in "Scientific Queen-Rearing." The same is the property of the publishers of the American Bee Journal, to use and to do with as they please.

Onondaga Co., N. Y.

[The price of Doolittle's "Scientific Queen-Rearing" is \$1.00 bound in cloth; or with the American Bee Journal one year—both for \$1.60. Bound in leatherette, price 60 cents, or with the Journal a year—both for \$1.30. Order from this office.—EDITOR.]

The Premiums offered this week are well worth working for. Look at them.

"Quoting the Honey Market" Again.

BY "RIP VAN WINKLE."

I have read the comments of the honey-buyers and commission men made in answer to the Editor's request to "give me what I am after," etc., and I see no reason to change my position on the subject as given in my article, that is, that the honey-producers of this locality ought to have an organization for the protection of their interest in such matters. And the general conclusion I arrive at, after reading all the replies is, that all practically admit that the market has been misquoted, most of the articles being devoted to *explaining the reason why*.

And now allow me to examine some of the statements. The Editor says that it is better to l—, no. He says, "It is better to quote a cent lower rather than a cent above the market." So it is (for the buyer or commission-man). I don't dispute it; but I am looking at it, I frankly admit, from the selfish standpoint of the producer.

Mr. Muth "would suggest a broader range." That is, I suppose, from his standpoint, he being a philanthropist, and only in business for his health. Well, of course, it does make a difference, sometimes, which point of view you take, or whose ox is gored.

Then comes R. A. Burnett & Co., and, in a very moderate and conservative article, among other things repeats the Editor's statement: It is better to l—, to be a little lower in the quotations given, than a little higher. "It is the desire of the commission merchant to quote *as high as he dares*, etc." (The italics are mine). Depending on his conscience, I suppose. Well! well!

Then comes Hy. Segelken, all the way from New York (I didn't say anything about the New York market, but it seems the shoe fit him, too), and after facetious remarks about my being asleep, and afraid to sign my name, proceeds to say:

"We endorse emphatically every word of Editor York's reply, especially where he says 'It is better to l—, no, quote a cent lower,' etc. Exactly *this* has been our rule ever since we have been in business."

As I observed above, I had not included the New York market in my article, as I did not at that time know that Mr. Segelken had been misquoting it for so long; and as for my name, there is an old Greek adage which says, "Consider not so much who speaks, as what is spoken," and Mr. Segelken practically admits the truth of my statement as to ly—, no, misquoting the market.

Mr. Weber seems to be the only one of these combination buyers and commission men who honestly quotes the exact prices that he gets.

Another gentleman, Mr. H. R. Wright, has a word to say, who seems to be legitimately a commission man (not a buyer), and I wish to call attention to what he says. He has been in the business 30 years, and he does not quite agree with these buyers, etc., but says on page 486:

"It is not wise to quote honey too high or too low, for quotations are seen by buyers as well as the producers, and it is extremely difficult to sell above quotations." And again, near the foot of the same page; "I do not understand why any party would want you to quote market under price, unless they want to *use the quotation to help them buy in the country*."

Now, isn't it about time that some one mentioned it, even a sleepy Rip Van Winkle, when three prominent buyers and commission men admit that "It is better to l—, no, excuse me! better to quote the market differently from what it is? And, candidly, I would be not a little ashamed, even if I were a New Yorker, to admit that I had been ly—, excuse me again!—misquoting the New York market all these years, even if I had such an authority on commercial ethics as Editor York to wink at it.

But, gentlemen, what is the need of lying—excuse me—quoting the market lower, etc.? You don't need to; as Joe Jefferson makes my famous namesake say about his glass of liquor, "You'd be better mitout it."

There is a business here in Chicago conducted on similar lines. Shippers send stock to the commission man, on commission: stock is sold and returns made, etc. A journal is published in the *interests of the shippers*, wherein *actual sales* are reported. The editor publishes actual sales of all prominent transactions. He may make his comments on the state of the market, etc., but the shipper and stock-man who receives the paper can see for himself just what the market is, and can use his own judgment in his shipments. There is no lying or misquoting, and if his stock arrives on

a weak or falling market he *can't blame the commission man* for misleading him on quotations, at least.

There seems no good reason why this system could not be adopted by the bee-papers. Wouldn't it be better for all concerned? Gentlemen—combination-buyers-and-commission-men—why not try it and see if you will not thrive just as well by telling the truth, and have the added pleasure of a new sensation? Cook Co., Ill.

[And to think that all our symposium on quoting the honey market was lost on "Mr. Rip!" This certainly is discouraging. But we'll let him "call names" if he wants to, and accuse us all of lying, for it seems to amuse him, even if everybody else knows his charge isn't true.—EDITOR.]

Questions and Answers.

CONDUCTED BY

DR. C. C. MILLER, Marengo, Ill.

(The Questions may be mailed to the Bee Journal office, or to Dr. Miller direct, when he will answer them here. Please do not ask the Doctor to send answers by mail.—EDITOR.)

Feeding for Winter Stores.

I have had bees a long time, and this is the poorest year I have seen for honey, some of my best colonies not having enough to take them through. What is best to do with them, feed or not? And what shall I feed them, honey or sugar? and how shall they be fed? and when? I have about 10 colonies out of 63 in this condition. I started with 29 colonies in the spring and now have 63; they are strong in bees but have not enough honey to take them through the winter, and I do not believe they will get any more.

When I say to feed honey, I thought of taking out a comb that is well filled and putting it in for them; but even then they will not have enough for winter. IOWA.

ANSWER.—Increasing from 29 to 63, you have evidently had some after-swarms, and in a bad year it would have been the part of wisdom to prevent after-swarms or else to return them. It may be well to unite now any that are weak in bees and then feed those that need it. If you have enough combs of sealed honey to give the needy, nothing can be better. If not, then feed sugar and water in a Miller feeder or by the crock-and-plate plan. See page 567.

Catnip as a Honey-Plant.

What is the value of catnip as a honey-plant? I have a few bunches along the poultry-yard fence, and every day from morning until night the bees are working on the plants. Would it pay to plant out $\frac{1}{2}$ acre, or an acre, of catnip for bees? Could the leaves or seed be utilized in any way. ILLINOIS.

ANSWER.—Catnip is a superior honey-plant, but I have some doubt whether it would be a paying investment to plant half an acre with it. The leaves are used as a medicine, especially for children, and if a market could be found for these there might be profit in the planting. In the lifetime of Jesse Oatman, I saw at his place a cultivated patch of perhaps an eighth of an acre, but I think it was not considered wise to continue it.

Perhaps there are others who can answer definitely.

The Queen's Sting.

Last February I wrote for your idea in regard to the queen's so-called stinger being a feeler, to which you replied on page 153. When I read your reply I saw that I failed to express what I had meant.

My experience agrees with every condition in your reply. I should have written that my observation had been, and still seems to be, that instead of being a stinger it was a gauge, with power of feeling used to place the egg in a uniform position in each cell, as you find them. Your clipping in reply to Ohio, page 409, is about my idea.

To-day I saw two queens up close together that had been

out of their cells a short time, and the stronger, or older one, clinched the younger, or weaker one, and you would have thought she was pushing her stinger clear through her, right by the small connection of the two parts of the body. I rolled them around so I could have full view of what the process was. She tried to sting her, all right, or else bite hard. The so-called stinger seemed to be too soft to penetrate the body, and made a performance like one of your black wasps will when you hold him by the two wings, so he cannot sting, as we used to do at school.

But the queen died in a few seconds, either from a sting, bite, hugging or fright. I found this young queen in a worker-cell head first, where she had crawled for protection. I notice the weaker queen does not make any resistance in a meleé, so the victorious one could not very well get hurt.

This season I have found several queen-cells with the queen dead, and the head toward the bottom of the cell.

CALIFORNIA.

ANSWER.—Confronted with such good authority as T. W. Cowan, I have been obliged to change my view as to the possibility of the sting being used by the queen as an aid in laying. Moreover, it is likely that I was wrong in thinking there is no need of a "feeler" at both ends, for workers have them. Cheshire tells us that, notwithstanding the swift work a worker makes in stinging, it always feels first the spot where it stings.

Taking Off Supers—Stores for Winter.

1. When is the best time to take supers off, in middle Wisconsin?

2. Should all the frames in the brood-nest containing unsealed honey be removed when preparing for winter? If placed in the middle, and containing a little honey-dew, the bees will get the diarrhea, and if put towards the sides, for the bees to get at towards spring, the honey sometimes pops out. What is best?

3. Sometimes after the supers are taken off, the bees swarm. If such swarm is hived on empty combs and fed 20 pounds of sugar in syrup, will that carry a colony through the winter and until the next fruit-bloom?

WISCONSIN.

ANSWERS.—1. Take them off as fast as the sections are all or nearly all finished, whether that be in June or September. Take all off as soon as it is evident that storing for the season is over.

2. Honey-dew of such character as to give diarrhea should be removed from the hive and replaced with honey of good quality or with sugar syrup. In spring, after bees are flying daily, it may be safely returned.

3. That will be likely to carry them through if the bees are cellared. For out-doors a fourth more would be safer. But let the feeding be done early.

Carrying Out Sealed Brood.

1. Something has gone wrong with one of my colonies. Here is the history so far as I know, together with present appearances: It was a swarm, having been hived on July 3, hence it is only a few days over a month old. It was a very large swarm, and during the first three weeks not only built frames of comb in the brood-nest down to the bottom, but filled one and partly filled a second super of sections. Over a week ago I noticed an apparent lack of energy in this hive; bees did not seem to be working, and acted as though something was wrong. I examined the frames carefully, but could not find a queen, although there was brood in all stages, even eggs. I noticed that a lot of the sealed brood was "bareheaded." However, since I found eggs I felt satisfied. Still the bees did not go to work, and seemed listless, walking about on the alighting-board in front of the hive. Yesterday and this morning I observed the bees busily engaged carrying out brood, some of it quite dead, but a good part of it still living, so that the young bees dragged out of the cells and thrown out could still move their legs, and some of them could even crawl around.

I at once opened the hive and examined the frames. I find no cells empty, and most of the remaining brood have the caps torn off and the bees are at work hauling the brood out of the cells. Some of it is dead, and some living, and some of it is hatching out in the natural way. But in a day or two the bees will have every brood-cell empty. The brood which the bees are carrying out is all taken from capped cells (there is no other in the hive at present). With very

few exceptions it is not colored, but is shrunken and short. There is no sign of a queen in the hive at present, and evidently has not been for some days, as there are neither eggs nor unsealed brood. About 10 days ago there was brood in all stages, and a large quantity of it. The combs or cells out of which the bees are taking the brood are clean and apparently very dry. When empty I noticed 2 or 3 small wax-worms in the cells along with brood, but so far as I have examined, not enough to account for the very abnormal condition of things. Can you give me any hint as to what is the matter, and what to do in the case? I do not like to lose a colony which started out so well.

2. Would you advise me to put a new queen with this colony in its present condition, or what would I better do with it first? Of course, if I can get the colony in working order again I intend to feed it up for winter. I forgot to say that at present it has plenty of sealed stores.

ONTARIO.

ANSWER.—I don't know what the trouble is, but it looks like a case of poisoning. Being past the time of fruit-spraying it is hard to make any guess as to the source of the poisoning, if poisoning it be, so it is impossible to say what should be done, only to hope that the trouble may now be over. In any case it may be a good thing to supply the colony with a queen. If the trouble continues, try giving a frame of brood with some of it sealed, taking it from another colony, and see if they tear the brood out of the sealed cells the same as they do with their own brood. If it were only part of the brood that was carried out, it might be drone-brood, nothing being wrong, but from what you say it seems to be all the brood.

Are They Diseased?—Paralysis.

Last June I found 2 colonies of bees had rotten brood, nearly one-half of it; it is not rosy or stringy. It dried up and the bees carried it out of the hives, and now some of the larvæ that are sealed up are dry, and some are watery. I think it will dry up, and the bees will uncap it and carry it out. There does not seem to be over one-tenth or less of the brood affected now, and they seem full of bees and prospering. Yesterday and to-day I find I have 3 colonies of bees that seem to have made drone-comb out of the worker-combs, and they have dead dried, brood, and I think all the brood just before capping looks yellow. Are they queenless, or are they diseased?

I had two colonies that had paralysis; I changed the queen for queen-cells, and they appear to be all right now.

IOWA.

ANSWER.—The trouble seems a little like poisoning, and if it is poisoning it will disappear when the cause no longer exists. The rearing of drone-brood in worker-comb indicates drone-laying queens or laying workers.

Introducing Queens.

1. When a queen is introduced *how* is one to know whether the bees received her? Of course, one could wait until the brood already in the hive hatches out, and then examine for young brood, but that takes time—too much time.

2. I introduced a queen a few days ago (August 2) and would like to give her more bees. Can I take bees from another colony and give her? If so, will there be danger of their killing the queen? If so, how long after introducing the queen before that danger would be over?

KENTUCKY.

ANSWERS.—1. If the queen is introduced immediately after the removal of the old queen, it will be about three weeks before all the brood from the old queen emerges from the cells: but there is no need to wait so long a time. Three days after the removal of the old queen all her eggs will have hatched, and if you then find eggs in the combs you may know that the new queen is laying. But if you do not find eggs at that time it is not by any means proof that the new queen is gone, for sometimes she does not lay for a week. By a little looking over the combs you can generally see the queen.

2. Yes, you can give more bees from another colony, but it must not be recklessly done. Something depends on the strength of the colony to which you wish to add the bees, and a good deal depends on the harvest. If honey is not yielding there is more danger. If the colony is very

weak, you must not give many bees. If they have three frames of brood, you may give a fourth with adhering bees, but it would not be safe to add two frames. The safer plan is to give them queenless bees. If you have no queenless bees, take the queen with two frames of brood and adhering bees from one of your colonies, putting them anywhere in a separate hive. In two days' time you can take from this queenless colony one or more frames of brood with adhering bees, and give to the colony you want to strengthen. Of course it will be better to take brood that is sealed. Then return to the queenless colony the queen with the two frames of brood.

Reducing the Number of Colonies.

I do not want over 5 colonies to keep over winter—I don't need more for my use, and I cannot sell colonies here for any more than the hives are worth. I have been doing just what farmers do with cattle, which they keep for family use. Some I keep for milk (honey), some I keep for breeders, and others I kill. I use the movable-frame hive with full, well-wired foundation. Those I keep over winter, I call my "breeders" (5 of them). They have the surplus one-pound sections and always produce enough comb honey. These are allowed to swarm in the natural way. I have hives ready with complete comb, from last year's building, which receive the swarms, and as fast as they fill and cap these combs I extract, leaving perhaps one or two of the center ones untouched. At the end of the honey-gathering season I—don't get shocked—I kill them with brimstone, and after extracting what honey is still in the hives, set the brood-chamber on top of one of the breeders, with perforated-zinc between. The hatched brood will strengthen the old colony, and by the beginning of December, when there is no danger of the bee-moth doing mischief, I take off the brood-chamber and find the comb again entirely clear of brood, and in perfect order for the next year's work. Thus I keep 5 "breeders" and 5 completed brood-chambers for use as stated.

Do you think I could safely strengthen my "breeders," if needed, by putting them where new colonies are, and shake the bees out of the latter in front of the breeders? Do you think there would be a fight among them, and perhaps do more harm than good? I know your method of putting a frame covered with bees into another hive, but I do not want to use my "honey" frames in with the breeders, if there is another way.

Your article on "Strengthening Colonies," by putting one hive where another has been, while many are "afield," will not answer my purpose, because the "breeder" may be as strong as the "milker," hence I would lose as many perhaps by being taken away from the old colony as would be gained in the new.

If you have any suggestions to strengthen my "breeders" with those or some of those I would kill at any rate, you will greatly oblige.
PENNSYLVANIA.

ANSWER.—I confess I don't feel entirely sure I understand you. You don't say when you want to strengthen

your breeders, but I suspect you mean when storing is over. You speak of putting your breeders where your new colonies are, which would lose to a breeder its own field-bees, an idea that later on you repudiate, leaving it a little muddy what you do mean. In any case, your fears as to danger from fighting may be well founded. Supposing that you want to strengthen thus your breeder about the time the harvest is over, you might do this:

Remove the queen from the colony that is to be destroyed, setting the hive on top of the breeder or close beside it, leaving on the stand of the condemned colony a hive with the queen and one comb. This hive will catch all the older or field bees, and upon these you can wreak your sulphurous fury without loss, for these bees would not be likely to survive the winter; while the hive that has gone to keep company with the breeder has the younger and more valuable bees. Two days after this these bees will be fully conscious of their queenlessness, and there will then be no danger of their making any attack upon the queen of the breeder. Up to this time there must be no communication between the two hives—if the one has been on top of the breeder it still has its own bottom-board. After its two days of queenlessness, you are then to set it over the perforated-zinc as has been your custom, with no bottom-board between, but over or under the zinc put a piece of manilla paper or two or three thicknesses of newspaper, allowing no communication between the two stories except a hole through the paper large enough for one bee to pass at a time. The bees will gnaw away the paper, and when all brood is hatched out you can extract.

If I don't get your idea, come again and I'll try it over.

Feeding Bees—T Supers.

1. How did you feed that 1,000 pounds of sugar the past spring, in the hives or out of them?

Do you still adhere to the "T" super? and do you like them? Do they sag at all?

3. Do you use any dovetailed supers with section-holders? If so, how do they act with you? I have had great trouble with their sagging, in some cases so badly as to close up the bee-space between them and the queen-excluders, or one super and the other.

4. Can "T" tins be used in a dovetailed super without much changing?

ANSWERS.—1. By means of Miller feeders, which are always put on top of the hives. In some cases a second story was put on a hive with a feeder over it, and filled combs were taken from this upper story to give to other colonies.

2. I still use the T supers and like them as much as ever. There is not the least sagging, the upright part of the tin entirely preventing it.

3. I have not had the trouble you mention, but I have not used them to any great extent.

4. The super would have to be shortened inside, which could be done by putting in one end a board of sufficient thickness, or a thin board with two little cleats.

Prize = Winning Stock

Daughters of Moore's famous long-tongued red clover Italian Queen, which won the \$25.00 prize offered by The A. I. Root Co. for the longest-tongued bees; and also daughters of other choice long-tongued red-clover breeders whose bees "just roll in the honey," as Mr. Henry Schmidt, of Hutto, Tex., puts it. Bees Doing Fairly Well.

We had a very poor honey-flow the early part of the season, but it is now picking up and bees are doing fairly well. H. H. MOE.
Lafayette Co., Wis., Aug. 20.

Disposing of a Laying Worker.

I had a case of laying worker like that on page 503. I take an empty hive, without frames, and put in two of the most empty frames, from the hive where the laying worker is, and then put a good queen with a few of her bees in a new hive, then put the new hive with the queen in the place where the hive stood with the laying worker, and put the queenless one on top of the other. When the bees come from pasture they will find themselves in a strange place and will not fight the

The Emerson Binder

This Emerson stiff-board Binder with cloth back for the American Bee Journal we mail for but 60 cents; or we will send it with the Bee Journal for one year—both for only \$1.40. It is a fine thing to preserve the copies of the Journal as fast as they are received. If you have this "Emerson" no further binding is necessary.

queen. In 2 or 3 days the rest of the bees and frames can be transferred to the new hive. I did it in this way on July 5, with good success. The old bees were queenless since May 10; they are all gone now. I think it is the safest to introduce a new queen, only the old one must be taken away, and the first frames must be without brood. ANTON SIMON, Linn Co., Iowa, Aug. 18.

A Bulgarian Beginner.

It is not necessary to tell you that I am a beginner in bee-keeping, but I like it very much.

I am a teacher in the Orphan-House here. In it live about 100 children (70 boys and 30 girls), and the larger ones like very much to work with me in the apiary, which consists of 8 colonies in Dadant-Blatt hives.

In the Bulgarian language there are two or three books or guides for bee-keepers, among which the best is, Bertrand's "Bee-Keeper's Almanac." D. CHAKALOFF, Bulgaria.

Unfavorable Season.

This has been a very unfavorable season for the bee-keeper in this vicinity. The month of June was so wet that the bees stored very little, but July proved very favorable, and those that were so situated as to catch the milkweed flow reaped a nice harvest.

We are having very dry weather at present, and unless we get rain soon there will be no surplus from the fall flow.

I have about 10,000 pounds of white honey, mostly extracted. I hope for better weather soon. IRA D. BARTLETT, Charlevoix Co., Mich., Aug. 18.

Very Poor Honey Crop.

The honey crop is very poor in this locality. Buckwheat and goldenrod are blossoming, but the weather is so stormy and cloudy that the bees cannot gather honey.

A. W. SMITH, Sullivan Co., New York, Aug. 11.

Those Partially Filled Sections.

As the time of the year draws near when the disposition of partially filled sections becomes a question of importance to the average bee-keeper, I think the plan I used last year will be of interest, especially as it was very successful.

When the honey-flow ceased I took all the unfinished sections and divided them into two lots, according to the amount of honey they contained; those that were half completed or more in one lot, and those that had less than half in the other. The first lot I placed in supers in the ordinary way, and the others I put loosely in supers, breaking some of them so that the honey would run from the comb. This was to excite the bees to get them to do the work I intended them to do when I was ready for them.

I then nailed a lath on the top of a bottom-board in such a manner as to form a bee-space, leaving an opening of two inches in the front for an entrance. A patent bottom-board will do as well if the entrance is contracted to two inches.

I placed one of the supers, which had the sections in loosely, over a strong colony, and left it on until about noon the next day, when I removed it to the prepared bottom-board, with what bees it contained, and tiered up several other supers containing the same class of sections on top of it, and finished with a cover, being careful that there was no other opening for the bees except that which was made intentionally on the bottom-board, and on the colony I placed a super with the sections in properly.

Results began to show immediately. At first I thought there was going to be a case of old-fashioned robbing, but in a few minutes things quieted down except the bees from the colony which was intended should do the work. They worked the balance of the day,

and the next morning went back to work, and so continued, except when it rained, until I had all the honey in what sections it required, and the other sections cleaned ready for spring.

I found that it lost about 20 percent by being handled in this way, but I think that was better than having a lot of sticky combs around all winter, and the muss of putting them in supers in the spring.

Bees guarded the entrance to the supers as well as they did the entrance to their hive, and there was no signs of robbery after the first day, although I worked them about two weeks.

As fast as they would clean up a lot of sections I would remove them and put others in their place to be cleaned. On the colony I tiered up the same as I would in a honey-bow, only I used those sections which were more than half full.

As I was only experimenting I tried but one colony, but if I had many partially filled sections I would work enough colonies to do the work in a much shorter time, and I would use only very strong colonies.

C. M. BRADLEY.

Cook Co., Ill., Aug. 22.

Too Wet and Cold for Bees.

It was very cold and wet all through the spring, so the bees did not get built up very strong until the middle of June, and then there was nothing for them to do. It rained about half of the time, and it was too cold for them to fly the other half.

I never saw so much white clover in bloom in my life as this year, but not a bee to be seen upon any of it, and I do not see how they have done as well as they have, but they have found something, for they have stored some amber-colored honey, and some black as ink, which I think is honey-dew. We may get a short flow from goldenrod if the weather is so they can work.

JAMES QUINN.

Stratford Co., N. H., Aug. 19.

Foul Brood—The Rosemary Cure.

My first experience with foul brood was in the summer of 1890. I had never seen a case and did not know we had any in the community. I was working for extracted honey almost exclusively, therefore I had no occasion to go into the brood-chamber for examination, until I observed something of a serious nature was the trouble with some of my best colonies—they were on the decrease. Then I began to examine them. I had 49 colonies, and had been extracting and exchanging frames from one to the other, so I had scattered the disease thoroughly, through the apiary. Then I put on my thinking-cap, and wondered what was the trouble, and what would be the remedy. I began to read up, and was soon convinced that my bees had foul brood, and in the worst form.

The honey season about closed, and the robbers ready to get in their work as soon as I took the cover off the hive. I tried the shaking process but it was not a success. During the next season it closed the business out for me. My neighbors had a few colonies and I began to look at them and found a number of cases of foul brood, so I concluded I would better keep out of the business for a while, believing it would not be long before they would be out also. I knew they had had no experience with the disease, and as long as the disease was in our community it was useless for me to attempt to keep bees, so I laid off until 1899, and came through all right that year. One of my neighbors had 3 colonies, and one of them died with the disease that winter. The next season I had two cases of it; the honey season came on, and one evening after they had all come in from the field, I closed the hives and took them away about half a mile from the apiary. The next morning I built a fire near them, and set an empty hive beside them, with a few frames with narrow strips of foundation in them; I opened the hives and shook the bees in front of the clean hive, so the bees could enter it, and put the frames and combs, and unhatched brood, on the fire where the flames consumed them; then I returned the bees to their former place in the apiary. After 4 days I took away

QUEENS!

Buy them of H. G. QUIRIN, the largest Queen-Breeder in the North.

The A. I. Root Company tell us our stock is extra-fine; Editor York, of the American Bee Journal, says he has good reports from our stock from time to time; while J. L. Gandy, of Humboldt, Nebr., has secured over 400 pounds of honey (mostly comb) from single colonies containing our queens.

We have files of testimonials similar to the above.

Our Breeders originated from the highest-priced, Long-Tongued Red Clover Queens in the United States.

Fine Queens, promptness, and square dealing, have built up our present business, which was established in 1888.

the combs they had built, and gave them full sheets of foundation. They filled their hive full of brood and honey, and I saw no signs of the disease that season.

In the spring of 1901, I bought a colony that seemed to be in good condition and strong in bees; the combs were not straight in the brood-chamber, so I did not make an examination. When the honey-flow came I removed the honey-board to put on extracting frames, and there was some honey and wax adhered to it. I put it up on a shed, near by, for the bees to clean off, and they did it, and the result was that in a short time I found 4 more colonies affected with the disease. I applied the same remedy to them, and I saw no more of the disease that year.

In the spring of 1902 I started with 34 colonies. May 15 I discovered I had the disease in several colonies. I had seen an article in the American Bee Journal, on page 198, where the essence of rosemary had been used with good results in several colonies with foul brood. I resolved to give it a test, with the next thing to no faith at all in its doing any good. May 16, I bought half a pint, paying 50 cents for it. May 17, I commenced using it on every colony I had, to make sure that none would escape. I filled a small oil-can and dropped 30 or 40 drops on top of the frames in the brood-chamber, being careful not to drop it on the bees, for it will kill a bee as soon as you drop it on it. I used it 3 times a week for about 4 weeks, and at the end of that period I could not find any of the disease in the apiary, and have not seen any up to the present date, and my bees never were in better condition than they are at the present time.

The total cost of rosemary used on the 34 colonies was \$1.25. Some will say it may not have been genuine foul brood. Well, all I have to say is, it was the same as I had before, and I never have known a case of it to get well itself; and where they had it in the spring it increased very rapidly in June and July—it became so foul that it sent forth an odor so offensive that any one who had ever had anything to do with it before would not doubt its presence. HONEY AND BEESWAX

MARKET QUOTATIONS.

CHICAGO, Aug. 11.—Some comb honey produced in 1902 is now on sale. Fancy brings 15c; anything off in appearance or quality sells at 13@14c for white; amber grades, 2 and 3 cents per pound less. Extracted is selling at 6@7c for white; light amber, 5@6c; dark, 5@5½c. There is a fair demand for all grades and kinds. Beeswax steady at 30c. R. A. BURNETT & CO.

KANSAS CITY, Aug. 16.—The receipts of comb honey are increasing; so is the demand. New fancy white comb, 14c; No. 1, 13c; No. 2 and amber, 12½@13c. Extracted, white, 6c; amber, 5@5½c. Beeswax, 22@25c. C. C. CLEMONS & CO.

CINCINNATI, July 26.—Considerable stock of 1901 crop fancy comb on the market and sells at 14@15c; there is a call for new comb honey, as yet none on the market; this market demands fancy comb; all other grades discourages trade. Extracted is in fair demand at 5@6c for amber and 7@8c for clover. Beeswax, 28@30c. THE FRED W. MUTH CO.

ALBANY, N. Y., Aug. 22.—The demand for honey is improving with the unusual cool weather, the summer resorters returning home hungry. We quote: Extra white comb, 15@16c; medium, 14@15c. No other grades coming yet. We want to caution shippers against shipping by express, as it arrives almost invariably broken. Express companies are stamping the cases "Received at owner's risk," which seems to cause their employes to "play ball" with it. Freight handlers are slower, more careful, and less broken, and much cheaper. We advise sending by freight only. H. R. WRIGHT.

NEW YORK, Aug. 11.—New crop comb honey from New York and Pennsylvania is beginning to arrive in limited quantities. There is a good demand for fancy white at 14c, and No. 1 at 13c, and exceptionally fine lots will possibly bring a little more. Lower grades quiet at 10@12c. As to extracted honey, fancy grades are in good demand at 6@6½c for white, and 5@5½c for light amber. Southern in barrels and half-barrels quiet at 47½@60c per gallon, according to quality. Beeswax dull at 27@28c. HILDRETH & SEGELKEN.

CINCINNATI, Aug. 19.—New comb honey is not coming in so plentiful, so far. Whatever has come in, and is fancy water-white, has brought a good price, and sold to stores from 15@16c. Honey kept over from last year, fancy sells for 14c. The market for extracted is more lively and brings—amber, from 5@5½c; alfalfa water-white, from 6@6½c; white clover, from 7@7½c. Beeswax, 30c. C. H. W. WESEK.

SAN FRANCISCO, Aug. 20.—White comb, 13@14c; amber, 10@12c; dark, 8@9c. Extracted, white, 5½@5¾; light amber, 5@5½; amber, 4½@5. Beeswax, good to choice, light, 27@29c; dark, 25@26c.

Not much offering or arriving of any sort. While the market is firm throughout, current values are being better sustained on comb than on extracted, for the reason that the latter has to depend to some extent on outside demand. All the comb honey offering will be required locally. The shipment of comb honey has never proven satisfactory, and the production is in consequence restricted to small compass.

A Celluloid Queen-Button is a very pretty thing for a bee-keeper or honey seller to wear on his coat-lapel. It often serves to introduce the subject of honey, and frequently leads to a sale.

NOTE.—One reader writes: "I have every reason to believe that it would be a very good idea for every bee-keeper to wear one [of the buttons] as it will cause people to ask questions about the busy bee, and many a conversation thus started would wind up with the sale of more or less honey; at any rate it would give the bee-keeper a superior opportunity to enlighten many a person in regard to honey and bees."

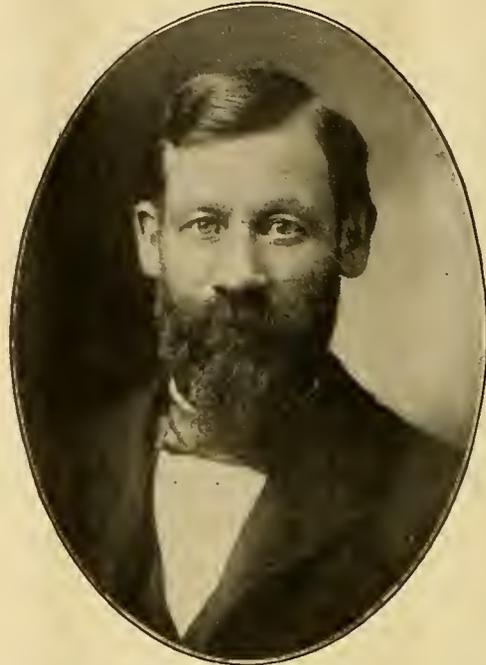

The picture shown herewith is a reproduction of a motto queen-button that we are furnishing to bee-keepers. It has a pin on the underside to fasten it.

Price, by mail, 6 cents; two for 10 cents; or 6 for 25 cents. Send all orders to the office of the American Bee Journal

PROF. A. J. COOK.

Price,
Postpaid,
\$1.20

Price,
Postpaid,
\$1.20

This standard work on practical bee-keeping has just been thoroughly revised and brought down to date. About 100 pages and nearly 100 illustrations have been added, which makes it now a superb volume of 544 pages, with 295 fine illustrations. It is printed on clear white paper, and is bound in elegant brown cloth, gold-lettered.

Prof. Cook has been one of the leading contributors to the American Bee Journal for a quarter of a century. He is well known to bee-keepers everywhere. He is an authority on bees and related subjects. His book has had a large sale, which now bids fair to increase greatly.

In order that every reader of the American Bee Journal, who does not already possess a copy of Prof. Cook's work, may have it, we wish to make the following

FOUR LIBERAL OFFERS:

No. 1.—For \$1.75 we will mail the American Bee Journal one year and a copy of Prof. Cook's book.

No. 2.—Any one of our present subscribers whose subscription is now paid in advance, can have a copy of Prof. Cook's book mailed to him free as a premium for sending us two new subscribers to the American Bee Journal for a year (with \$2.00.)

No. 3.—Or, send one new subscriber for a year (at \$1.00) and 50 cents more (\$1.50 in all,) and we will mail to YOU a copy of the book and will send the American Bee Journal for one year to the new subscriber.

No. 4.—For \$1.00 we will send Prof. Cook's book by express or freight with other goods; or, if called for at our office, the price is \$1.00. But the post-paid price of the book alone is \$1.20.

Please remember that offers Nos. 2 and 3 of the above are made to those who are now subscribers to the American Bee Journal, and whose subscriptions are paid in advance. Offers Nos. 1 and 4 are made to any one who desires to take advantage of them.

Address all orders to the publishers,

* Editorial Comments. *

Greatest Good to the Greatest Number.—Bee-keepers as a class are a progressive lot, always on the alert for any change that offers a reasonable prospect of gain. It is human nature for a bee-keeper to be interested in an improvement by which he may make more, even if some one else suffers a degree of loss by it. More commendable it is, even if not so much according to human nature, that he should be interested in an improvement likely to bring gain to bee-keepers at large; and most commendable it is to be interested in that which will be an advantage to the world at large.

Suppose a bee-keeper discovers that by making certain changes in his supers and sections he can produce honey in sections that, without making any difference in the total amount of honey sold, will make consumers prefer his honey to other honey on the market. If there is no difference made in price, he will have the advantage of a more ready sale for his product, but whatever that advantage may be it will be exactly balanced by an equal disadvantage to competing producers. If a difference in price is made, the final result will be more or less lowering of the price of competing honey. Then his competitors must make the same changes he has made, so as to bring up the price they obtain. When all is balanced there will be no gain either to bee-keepers or the public, and bee-keepers will bear the expense of changes in fixtures.

On the other hand, take such an improvement as the extractor. The public at large is the gainer by its use, for a pound of good honey can be obtained for a less price, while hundreds of bee-keepers will testify substantial gains by using the extractor.

So, in laboring for improvements and in advocating them, it will be well always to place the greater emphasis upon those improvements which will bring the greatest good to the greatest number. Just now there is probably no more promising field for improvement which shall be for the benefit of all—an improvement in which every bee-keeper in the land can take a part—than that of improvement of stock. Fortunately it is a field which gives promise of immediate personal reward to each bee-keeper engaged in it.

The Bee-Louse (*Braula cœca*) is an enemy of the bees that fortunately bee-keepers of this country know little about. In Europe it is considered by some a troublesome pest, while others think it not worth minding. It seems a little strange that it does not flourish in this country, having been introduced more than once on imported queens. As many as ten lice have been found on a single queen. Prof. Cook says in his Manual, that, compared with the

size of the bee, it is enormously large, hence it is no wonder that it devitalizes the bee "from which it sucks its nourishment."

Some European writers, however, assert that it does not suck its nourishment from the bee on which it dwells, but is merely a "table companion," partaking of the food that the bee takes by running down to the mouth of the bee. Prof. Benton is quoted in Cook's Manual as saying that "if hives are kept clean inside, and colonies kept supplied with young queens and kept strong, the damage done by the Braula is very slight, if anything."

Let us hope that in any case this pest may continue in its present mind and refuse to take out naturalization papers in this country.

Wax-Production.—The Australasian Bee-Keeper contains a symposium upon the production of wax, in which some of the writers think that it may be made a profitable thing to have wax the staple product, with honey a secondary matter, while a minority are of a different mind. G. Colbourne, Jr., says:

"One way to increase the production of wax is to space the frames wide and allow the bees to cap the honey well over; then, when extracting, cut the combs down level with the frames. In this way I have increased the yield of wax very much. I also find that it pays to insert a few empty frames in the extracting-super. I can not see any difference in the yield of honey from colonies so treated and those whose combs are left full thickness and all the frames full of comb. The extra amount of wax is quite an item at the end of the season."

E. J. Rien says:

"Always use bright, tin vessels if you would have a good-colored wax, and as the price varies as to color and clearness, there should be a constant aim to produce the best."

Box-Hives in Germany are in greater favor than here. Indeed, in some parts they are preferred by intelligent men who are experts in bee-keeping, and the bee-journal, which has the largest circulation of all German journals, has each month a chapter of instruction in "fixed" bee-keeping. Strictly speaking, however, the hives are mostly skeps made of straw.

Securing White Sections of Honey.—S. T. Pettit says in *Gleanings in Bee-Culture*:

On page 435, *American Bee Journal*, under the caption "Do not leave the sections on too long," the editor tells us how to get the sections all finished; but if I had to follow the directions I should never take comb honey. This pulling the supers to pieces during the honey-flow is just awful. I pity the poor bees and their good owner. Now, if the colonies are *strong* my best wishes would say, "Just try my system: use the wedges, or their equivalents, and my dividers."

Last year my son and I took thousands of sections. Mine in Aylmer averaged over 100 sections to the colony, and, with but very few exceptions, the outside sections were beautifully finished. In many cases the choicest sections were right next the dividers. Brother York's editorials are generally of the very best—well chosen, well written, and

right up to date; but this one is sadly astray. I quite agree that the sections should come off soon after the white-honey-flow ceases. Here, where the honey-flow is short and sharp generally, I leave all the sections on until the close of white honey.

If a system can be used that will get the outside sections finished as soon as the center ones, certainly that is a good thing. It is not entirely clear, however, what Mr. Pettit may have in mind when he pities the poor bees on account of "pulling the supers to pieces during the honey-flow." He takes off the super just the same, and it can hardly trouble *the bees* that two, four, or six of the sections are taken out of the super as unfinished. It is evident, too, that his conditions are different from those of many others. He generally leaves the sections on until the close of white honey. That may do very well with him, "where the honey-flow is short and sharp," but with many it would be leaving the sections on entirely too long, for before the close of the white-honey harvest the central sections of the first supers would be sure to be darkened. So long as whiteness of sections is a desideratum, take them off as soon as the super is entirely sealed, whether it be at the close of the harvest or before it is a third over, and generally it is better not to wait for the finishing of the corner sections.

Even with Mr. Pettit's system, getting outside sections finished as soon as inside ones, sections would be badly darkened if only taken off "soon after the white-honey flow ceases," when that flow continues as long as it does in many places.

The Apiary of H. E. Gale appears on the first page. He wrote thus when forwarding the picture:

I enclose a view of my home-yard of 111 colonies, situated in Chateauguay Co., Province of Quebec.

It also gives a view of the house, my wife, two daughters, youngest son, and myself. My nephew happened to be standing so that he is entirely hidden by me, with the exception of one of his shoulders.

I run the home-yard principally for comb honey, and the out-yard for extracted honey. My oldest son has had charge of the out-yard this summer.

This has been a very poor season with me. The first part was so cold and wet that the bees did not do very well on the clover flow. The basswood yielded next to nothing, and now there is very little for them until the buckwheat blooms.

I commenced to keep bees about 20 years ago, but did not put my whole time into the business until about five years ago.

I subscribed for the American Bee Journal in 1896, and in a single issue I have found articles worth to me many times the subscription price. I recommend it to all the bee-keepers with whom I come in contact.

I have the largest bee-yard in this vicinity. I was the only contributor in this Province to the display of extracted clover and comb honey made by the Ontario Bee-Keepers' Association at the Pan-American Exposition, in Buffalo, N. Y., which display won the Gold Medal, and from which I received a certificate of "Honorable Mention."

H. E. GALE.

* The Weekly Budget. *

BEES HELP AT A WEDDING.—The Chicago Tribune of Aug. 26 tells how some bees helped a bridal couple in Aurora, Ill.:

Guests at a wedding ceremony in this city to-day were put to flight by a swarm of bees. As the guests rushed out of the house laden with rice and old shoes when the couple left for their carriage the swarm of bees, which had built a nest by the walk, attacked the company and drove them into the house, while the bridal couple rode away in peace.

The bees entered the house, and the officiating clergyman was badly stung on the head and face.

Here is a suggestion for other bridal couples. Have a few bees to let loose on those who wish to "rice" and "shoe" them away. Great scheme!

Mr. F. DANZENBAKER called on us last week when passing through Chicago on his return trip from visiting some California bee-keepers. He is very enthusiastic over his hive, which he says is to be improved in its finish of the small wood parts. Mr. D. is an interesting conversationalist, and loves to dwell on the excellent qualities of his devoted wife, who passed away a few months ago.

"BEES IN COLORADO" is the title of a 48-page and cover pamphlet gotten up to boom the Denver convention. Its author is D. W. Working, the alert secretary of the Colorado State Bee-Keepers' Association. It is beautifully illustrated, and printed on enameled paper. It is a credit to Mr. Working, and will be a great help in acquainting those outside of Colorado with the bee and honey characteristics and opportunities of that State. Price of pamphlet, 10 cents postpaid. Address, D. W. Working, Box 432, Denver, Colo.

CIGARETTES KILL A BOY.—This is the heading of an item reported to the New York World from Easton, Pa., Aug. 21, and forwarded to us by R. J. Cary, of Connecticut, one of our subscribers. It reads as follows:

Charles Zane, aged 11 years, died to-day from brain fever, superinduced by excessive cigarette smoking. He was ill ten days, and while delirious he went through the motions of holding a cigarette to his mouth and imagined he was blowing smoke from his nose.

It pays to bring boys into the world. But it doesn't pay to allow them to be killed off in that way. The "killing off," however, ought to be applied to the human hyenas that make and sell cigarettes and similar body-and-soul-destroying things. But it pays in dollars and cents, don't you know? That's the test now-a-days. What does a few thousand boys amount to if some one can make a few more dollars! And then, you know, by licensing the evils, it saves a few dollars in taxes! It's cheaper to use up boys than to pay honest taxes. And, then, it's so nice for good, Christian people to get the license (blood) money for furnishing the boys! Great exchange, that!

We know this isn't about bees, but we believe boys are worth more than bees. How about *your* boy? Are you rearing him for the cigarette or saloon to kill off? God forbid.

The Buffalo Convention Report is issued in pamphlet form, size 6x8½ inches, 80 pages and cover. Besides a full report of the proceedings of the 32d convention of the National Bee-Keepers' Association, held in Buffalo, N. Y., Sept. 10, 11 and 12, 1901, it contains fine half-tone portraits of all the officers and directors of the Association; also the Constitution, a list of the membership up to the end of 1901, and the two latest bee-songs—"The Hum of the Bees in the Apple-Tree Bloom" and "Buckwheat Cakes and Honey." We believe it is the finest ever gotten out for the Association. Of course, all members of the Association receive a copy free, but there are thousands of our readers who are not yet members, but who should have this valuable Report. Better send for a copy, if you have not yet received one. Price, postpaid, 25 cents, or with the American Bee Journal one year—both for \$1.10. Send all orders to the office of the American Bee Journal. Better order soon, before all are gone.

Convention Proceedings.

Report of the Texas State Convention, Held at College Station, July 16 and 17, 1902.

BY LOUIS SCHOLL, SEC.

(Continued from page 567)

SECOND DAY.

The meeting opened at 8:30 a.m., with the reception of a number of new members, after which the committee on resolutions made their report, and the following were unanimously adopted:

REPORT OF COMMITTEE ON RESOLUTIONS.

Resolved, That we tender our thanks to Pres. J. W. Salyer for the efficient manner in which he has discharged his duties while in office during the year just closed.

Resolved, That, 1st, in recognition of the services of Prof. F. W. Mally in securing the experimental apiary at the College, and in view of the great services rendered by him in various ways to the bee-keepers of Texas, we tender him our warmest thanks and highest appreciation of his work; 2d, in view of the service rendered by Prof. Wilmon Newell, in the establishment and equipment of the experimental apiary, we tender him our thanks and full approval of his work, and heartily recommend him to the bee-keepers of Texas.

WHEREAS, The Hon. W. O. Murray did, at the last session of the Texas legislature, use his influence to secure an appropriation for the establishment of an experimental apiary at the A. & M. College of Texas; and

WHEREAS, The Hon. W. O. Murray did use his best efforts, and did persistently defend the interests of the bee-keeping industry in Texas; and, owing to the fact that the establishment of an apiary at A. & M. College, making possible the investigation of important problems in bee-culture, and offering to the students of the Agricultural College a course of instruction in the same, is largely due to his influence, be it

Resolved, That this body extend to the Hon. W. O. Murray its hearty and sincere thanks for the valuable services above mentioned. Be it further

Resolved, That the Secretary of this Association be instructed to forward to the Hon. W. O. Murray a copy of these resolutions, and they be spread upon the records of the Association.

F. J. R. DAVENPORT, W. O. VICTOR, H. H. HYDE, F. L. ATEN.	} Committee.
--	-----------------

DELEGATES TO THE NATIONAL AT DENVER.

Following the adoption of these resolutions, the Association elected the following delegates to the National Bee-Keepers' Convention, which convenes in Denver, Colo., Sept. 3, 4 and 5, 1902: Udo Toepperwein, Louis H. Scholl, W. O. Victor and H. H. Hyde. Alternate delegates were elected as follows: L. Stachelhausen, F. L. Aten, J. B. Salyer, F. J. R. Davenport, and Mrs. C. R. West.

A motion was then made relative to having special badges prepared for the delegates to wear to Denver. It was ascertained that the secretary had already ordered association buttons, but which had not yet arrived; it was decided to have ribbon badges printed, to be used with the buttons, and this combination could be used year after year by delegates elected.

PRES. SALYER'S ADDRESS.

Pres. Salyer having arrived, he was requested to deliver his annual address. He spoke on the importance of bee-keepers getting together for organization, and of united efforts in earnestly pushing forward bee-keeping until it should occupy its due place as an important industry. Earnest organization counts for much towards success. He made a direct appeal to every bee-keeper when he said, "Organize and get together all the bee-keepers in your neighborhood."

Pres. Salyer has been interested in Farmers' Institutes, and has been impressed with their good work in making

better farmers, better cattlemen, better truck-farmers, better fruit-growers, and better men in all lines of agricultural work. He argued that the same thing could be done in the case of bee-keepers. He also called attention to the rapid progress being made by the Texas Bee Keepers' Association, and to its importance in developing this resource of the State. He also discussed at length the benefits accruing to its members, both educational and financial, through their mutual support and co-operation.

He also called the attention of the members to a clause of the Association's constitution, which clause was adopted at the previous annual meeting, which requires all annual membership dues be paid in full at or before the time of each annual meeting. Members should be prompt in sending in their dues to the secretary in time, so that all amounts can be sent to the General Manager of the National Bee-Keepers' Association at the appointed time, thus lessening the work of the secretary and preventing more or less delay each year in keeping the accounts of the Association.

Therefore an earnest request is made that all members send in their annual dues at or before the time of the annual meeting in July, which annual meeting is held in connection with the Texas Farmers' Congress.

The regular program was then resumed, and Mr. F. L. Aten spoke on

THE PRODUCTION OF EXTRACTED HONEY.

Mr. Aten remarked that the subject had been gone over so many times that he feared he could add but little. He astonished some of his listeners by making the remark that this year he had not produced any extracted honey at all, but explained matters by stating that on account of the dry season he had no honey, the crop being an absolute failure.

He then related his methods of procedure in years when a honey-flow is to be had, when he is a heavy producer of extracted honey.

He uses 10-frame hives, with plenty of super-room, sometimes tiering up four or five stories high. He uses the regular full-depth body for extracting-supers, and allows the queen to go up in these as high as she desires. As the bees fill the supers with honey she will be crowded below, or to the regular brood-chamber.

M. M. Baldrige, of Illinois, said that, as a matter of course, honey could not be produced when there was no nectar to be gathered, but he said that he believed that when honey was to be had, rousing colonies and plenty of super-room about covers the subject of producing extracted honey.

H. H. Hyde's most important requisites for the successful production of large quantities of extracted honey are: A good locality, good honey-flows, strong colonies secured by the use of prolific queens, and plenty of empty combs.

ANNUAL ASSOCIATION EXHIBIT.

Under the head of new business the following was given attention:

H. H. Hyde spoke on the importance of having a bee-keepers' exhibit at each annual meeting of the Association at College Station, and that premiums should be offered, so that the bee-keepers would make the best showing possible, of what the bee-keepers are doing. He also mentioned the good results that would come to the Association through this plan. After a lengthy discussion it was decided that a committee should be appointed to consist of such persons as would give careful attention to working up the matter.

Udo Toepperwein spoke relative to a bee-keepers' exhibit at the San Antonio Fair, as Pres. Brown of the Fair Association had requested that the bee-keepers make an exhibit. Pres. Brown also asked that he be advised as to the exhibits the bee-keepers would have at the Fair, and the amount of space they would require, as the Fair Association had signified their desire to do everything possible to help the development of this industry within the State.

The question of providing a suitable premium list for use at fairs was then discussed.

H. H. Hyde was appointed a committee of one to take charge of and secure exhibits and premiums at the next meeting of the Association at College Station, in 1903; he was also authorized to correspond about and solicit premiums therefor.

Mr. Toepperwein and Secretary Scholl were appointed a committee to co-operate with the management of the San Antonio Fair Association, in adopting a suitable premium list, and determining the amount of space that would be required by the bee-keepers' exhibits.

A committee, consisting of those appointed later by the executive committee, was also appointed for the purpose of securing exhibits for the World's Fair at St. Louis in 1904.

and was given instructions to co-operate with similar committees from other sections of the Farmers' Congress.

As a standing committee to supervise and attend to any future needs of the experimental apiary, J. B. Salyer and F. L. Aten were appointed.

Prof. F. W. Mally, M. M. Baldrige, Dr. R. C. Buckner and Hon. W. O. Murray, were unanimously elected honorary members of the Association.

THE PRODUCTION OF COMB HONEY.

H. H. Hyde talked on this subject. Success in this is more dependent upon right conditions than in the production of extracted honey. With a good locality and fast honey-flows it is more profitable than the production of extracted honey. Here the importance of having good queens and strong, rousing colonies of bees, again comes in. Without these you will not succeed. The proper manipulation of the brood-nest in the spring is of great importance. It should be so handled as to induce the production of a great many young bees, so that at the beginning of the honey-flow the brood-combs will be filled with brood.

Shallow supers have their advantages over others, in that they produce more capped honey, and sooner than when deeper combs are used. Besides, in manipulating hives containing shallow supers, the handling of the frames individually is unnecessary, as all the handling is done by cases, or full shallow supers. Then, too, brushing off the bees is dispensed with, the shallow supers being easier to remove. The bees are smoked down, supers taken off, and jostled roughly, when only a few bees will be left upon the combs, and these will soon leave for home, freeing the combs of bees.

Mr. Hyde advocates using shallow supers with combs in shallow frames, on all hives at the beginning of the season. He allows the queen to lay in these, thus giving her more breeding space. Then, when section-supers are to be put on, he removes the shallow-frame super, and thus the bees go right ahead storing honey in the newly-put-on sections.

He also spoke in regard to having supers ready beforehand, to be immediately available when the flow comes on. Care should also be taken to have such supers, containing comb foundation, put away so they will be free from dust or dirt, as the bees are slow about entering dirty ones. Supers should not be put on until the flow is coming on, as the bees have a tendency to gnaw down much of the foundation given them if sufficient honey is not coming in. Mr. Hyde advises removing all comb honey from the hives as soon as well sealed over, and before it becomes soiled. The demand is more for comb honey in bulk, or, as formerly known, "Chunk Honey." He explained how it was produced, in shallow extracting-supers, then cut out and fitted into cans, after which extracted honey is poured over it to fill up the crevices. This packing is of much importance. If the honey is put up honestly and neatly, so that a gilt-edged article is produced, a good demand can be maintained at remunerative prices.

L. H. Scholl told the bee-men how he used the shallow extracting-super on all his hives the year around. In early spring the queen is allowed to go upstairs and use it for an increased amount of room. Then, as more or less honey comes in during the spring, before the main honey-flows, it is stored upstairs and crowds the queen down into the lower compartment; and by the time the main honey-flow comes on, the shallow super is about full. These are then raised up and the comb-honey supers inserted between them and the brood-chamber, when the bees go right ahead and fill them with a vim not shown by any treated in other ways. Thus a whole super of extracted honey is gained, besides being very essential in the spring in providing a place for the storage of all surplus, or honey not used in brood-rearing. It also prevents clogging of the brood-nest, which is likely to occur where no such room is given, and saves the honey which the bees otherwise would have had no use for, and no place to put.

He, like Mr. Stachelhausen, prefers the divisible brood-chamber hive, consisting of shallow-frame cases or supers, and these have brought the best results in every trial for several years by the side of several other kinds of hives.

The question was asked as to whether an entrance at the top of the super would be of advantage. The reply was that it would not be, as it would give too much ventilation, would interfere with the nice finishing of the combs, and that very few of the bees would make any use of such an entrance; hence it would be useless.

"Should an excluder be used on the brood-nest when the

comb-honey supers are put on?" Answer: "No, it is not found necessary."

F. J. R. Davenport related his experience in producing comb honey. He is not in favor of producing what he calls a "cap and ball" honey, *i. e.*, in shallow frames, or bulk comb honey. He wants his in sections, of which he can sell more than he can produce. He rehearsed the importance of saving every section containing foundation starters, drawn comb, and even the very small bits started in some sections, as they are the most valuable in getting the bees started when the honey-flow begins. He keeps these nicely stored away, safe from the ravages of mice, rats, moth-larvæ and dust, so that they are nice and clean when they go to the hives.

MARKETING HONEY.

M. M. Baldrige was called upon for a discussion of this subject. He uses frames seven inches deep for comb-honey production as well as for extracted. Then, instead of using pails or cans, he has manufactured for him shallow pans or trays which will hold just one comb when cut out of the frame. He also sells his extracted honey for the same price as comb honey—makes no difference in price—sells them in the same style of can regardless of kind. He said it was the bee-keepers' fault that a difference of price existed between extracted and comb honey, and the bee-keepers were foolish for ever having made any difference in price between the two. If this had not been done, extracted honey would today be selling at the uniformly higher price received for comb honey. His, of course, is a retail market, and under such conditions a uniform price for both extracted and comb honey would be satisfactory; but for a wholesale business it would not answer.

Mr. Davenport said that he wanted his honey in sections, which he packed in twelve-pound cases and sells in his home market. In regard to comb honey packed in pails and buckets, he told of the quantity shipped in from the North—adulterated goods with but a strip of comb put in each package to deceive the public. The people soon come to dislike this glucose mixture, and prefer to buy what they know to be pure honey, namely, that in the comb or in sections, which sells right beside the vile, adulterated stuff for very much higher prices. He calls all his yellow honey "Gold-Bug Honey," and all his white honey goes as "Free Silver Honey," and if he had 150 cases of it in his own town he could dispose of it in a few hours. "It knocks the 'cap and ball' honey out, every time." He related instances where comb honey, put up in cans, when opened would boil out as though it were all frying on the inside. He objects to the way in which bulk comb honey is put up by many bee-keepers, the cans being smeared with honey, dirt and dust, which certainly is anything but a good advertisement for the industry.

He believes in advertising, and advertising right; then in putting the best of goods on the market, and with a little talking they can soon be disposed of at good prices.

Prof. Newell arose to say that if there was anything by which to successfully advertise one's business, it was by one's mouth.

A motion was approved for the Association to purchase 144 copies of the Farmers' Congress Proceedings at 8½ cents per copy, this being the number allotted to each section of the Congress. Owing to the fact that the bee-keeping section was not as strong as some of the other sections, and owing to the fact that this number was not needed, the motion was amended so that the Association should take 50 copies at a price not exceeding 15 cents each. A sum was raised for payment of this number, and the Secretary instructed to mail copies to the members. [This matter has been referred to the executive committee.—SECRETARY.]

Concluded next week.)

Our Wood Binder (or Holder) is made to take all the copies of the American Bee Journal for a year. It is sent by mail for 20 cents. Full directions accompany. The Bee Journals can be inserted as soon as they are received, and thus preserved for future reference. Upon receipt of \$1.00 for your Bee Journal subscription a full year in advance, we will mail you a Wood Binder free—if you will mention it

Queenie Jeanette is the title of a pretty song in sheet music size, written by J. C. Wallenmeyer, a musical bee-keeper. The regular price is 40 cents, but to close out the copies we have left, we will mail them at 20 cents each, as long as they last.

Contributed Articles.

Forming Nuclei—A Review and Comment.

BY DR. C. C. MILLER.

In the American Bee Journal for March 30, 1899, page 198, a questioner proposed to make a nucleus by taking a frame of brood and eggs and one of honey, and asked whether a pint or so of bees would do. I replied:

"They may protect themselves against robbers, and they will be pretty sure to rear a queen, but the chances are that the queen will be a very poor affair."

On page 370 of the same volume, Mr. Doolittle objected to my answer, and said:

"If four quarts of bees are taken from any colony of the 14 our questioner says he has, and said 14 colonies are all in the same apiary where he is forming his nuclei, as it will be reasonable to infer, said four quarts will not be enough to make a decent nucleus of those two frames, providing no precautions are taken to make that four quarts of bees stay in that hive, for all but the very youngest, fuzzy ones will go back home, and the fuzzy fellows run out in the grass and all about the outside of the hive, where they will perish."

That statement surprised me very much, and I said on page 788:

"If I should take four quarts of bees without any precaution, and put them on a frame of brood and one of honey, I think enough would remain to make a fair nucleus; but as I have not actually tried for years taking bees from a hive with a laying queen to form a nucleus, I am not positive about it."

On page 484, Aug. 3, 1899, Mr. Doolittle was still more sweeping in his statement, where he said:

"As it is stated that 'Iowa' intends to take the bees which he is to use in forming his nuclei 'from the colonies with laying queens, shaking the bees from the combs and giving them directly to said nuclei,' I would reply that under such conditions *all* the bees there were in any one colony from which they were taken would *not* be sufficient to form a decent nucleus. . . . The proposition does not even hint at any precautions being taken to keep those bees in the hive with the comb of brood and honey, and unless such precautions *are* taken, there will not remain bees enough in that hive to make a decent nucleus 24 hours later, no matter if two bushels are put in by the plan proposed; for what can not get back home again will run out of the hive and scatter over the ground, through the grass and anywhere but stay with those two combs in that hive. I know what I am talking about, for I have tried it many times, even putting them in just at dark, only to find them scattered all over everything surrounding the hive early the next morning, with scarcely a bee inside on the brood and honey."

In a nutshell, if I understand him correctly, Mr. Doolittle teaches that if bees and brood are put on a new stand, the bees having been taken from laying queens in the same apiary, they will in no case remain where put unless previously imprisoned.

It would not be a very difficult thing to ascertain from the bees themselves whether Mr. Doolittle is correct or not, and yet, being very much occupied, I never made any direct experiment in the matter until recently. August 1 I formed two nuclei by giving to each of them three frames of brood with the usual number of adhering bees, the same being taken from normal colonies in the same apiary without any precaution whatever.

I may say by way of parenthesis, that I am not in the habit of making nuclei so strong as this, because I either use queenless bees or imprison the bees in the nucleus hive for a day or more. This time, however, the bees were not queenless bees, and no precaution whatever was to be taken to make them stay, and I thought a larger number of frames of brood and bees would be more successful.

I did not look at the nuclei till three days later, when I found a plenty of bees remaining to cover well the frames of brood.

Then I thought I would try having about the conditions that had been specially mentioned. I took a nucleus hive having three compartments, the two outside compartments large enough to contain three frames each, and the middle

compartment large enough to contain one frame. In the central compartment I put a frame of brood, and in each of the other two compartments a frame of brood and one of honey, and a dummy, all bees being brushed from the combs. Then I put the hive on a pair of scales, and after taking the weight, brushed upon the combs 2½ pounds of bees, allowing the bees to distribute themselves over the combs. Then covering up all, I put the hive upon an unoccupied stand and left it to its fate. Two days later I found all three nuclei robbed out, not a drop of honey remaining. Notwithstanding that, two of the nuclei had a sufficient number of bees remaining to make satisfactory nuclei (the central and one of the outside ones), while the third nucleus was deserted. I gave some honey to each of the two nuclei, stopping the entrances for a day or so, so that robbers could not enter, and they have held their own against the robbers since.

In this case it will be seen that there were less than a pound of bees to each nucleus, much less than "four quarts," to say nothing about "two bushels," and, according to Mr. Doolittle's assertions, they ought not to have stood a ghost of a chance for existence, and yet they did exist, and that after having all their honey taken away by robbers, and to-day—15 days after the formation of the nuclei—I find plenty of bees present in each of the two nuclei.

I do not want it understood that I advise forming nuclei with bees that are not queenless without taking any precaution against desertion, but I think I have proved that in this locality, and with my bees, there will not in all cases be such wholesale exodus as Mr. Doolittle speaks of. I prefer queenless bees for forming nuclei, as such bees will "stay put" more contentedly, but within the past two years I have formed many nuclei by taking them from colonies having laying queens, and imprisoning them in the nucleus hives for a day or more by stuffing green leaves into the entrance (green grass will not answer as well). I think they are thus safer from robbers than if first imprisoned after Mr. Doolittle's plan, and it is a good deal less trouble.

But I have lately formed new colonies (not nuclei) by simply taking brood and bees from laying queens, putting them in a hive on a new stand without any precaution whatever, and so far I rather like the plan. On the 8th of the present month of August, at the Hastings apiary, I put three hives on new stands, each containing four or five frames of brood and adhering bees taken from colonies with laying queens, and put in each hive a caged queen. Yesterday, Aug. 18, I was again at that apiary, and I found each of the three new colonies well stocked with bees, a moderate force of field-workers flying, and in each hive plenty of young brood and eggs. I do not believe they staid any better for the presence of the queen, for she was a stranger to them.

I wish Mr. Doolittle would try the experiment of putting in a hive four frames of brood with adhering bees, so as to see whether they would desert in his locality.

Why Mr. Doolittle's experience should be so different from mine I do not pretend to explain. The kind of bees may have something to do with it; but I am inclined to believe that for the majority of bees and the majority of places my teaching upon the subject has been sound.

Commercial Queens—Amount of Brood in Large Hives—Age of Workers at Different Seasons, Etc.

BY F. GREINER.

In the series of articles on queen-breeding, written by Dr. Gallup, the contention is that queens reared by artificial methods are greatly inferior to those reared naturally. The Doctor cites many instances to prove his position. He has had a most exceptional experience with bought queens. I have not had such disastrous results. These things are absolutely not true with the queens I have bought. The very worst case I have had was with six very yellow queens which did not go through the winter, and one other queen which laid only "dead" eggs, or such as would not hatch. Nearly all others were prolific enough to keep the combs of a 10-frame hive well filled with brood, and attained the age of three years.

It would not be fair to condemn all queens reared from worker-larvæ because Dr. G. has had such a singular experience. He says his bought queens would not lay

enough to keep three or four frames full of brood. The average commercial queens do a great deal better. Mr. Case, treasurer of the Ontario County Bee-Keepers' Association, says the queens reared from young worker-larvæ do just as well with him as those reared naturally or under the swarming impulse. At the present time I have only three bought queens in my yard. They brought their respective colonies to a high state of populousness early in the season, and when preparations were made for swarming I formed nucleus colonies with the queens in order not to run any risk of losing them. At this writing (Aug. 7) these nuclei have again reached full normal strength, and are ready for the buckwheat harvest. These are the rules, not the exceptions. I can not understand what kind of queens Dr. Gallup must have gotten hold of. I have no ax to grind, as I do not sell queens.

In speaking of longevity of bees, Dr. G. judges and condemns certain mother-queens because he finds a certain number of dead bees scattered around the hives. I wonder whether that is the way he judges this matter, or any other matter, for that matter. If it is, I don't give much for his opinion. The only certain way to test the longevity of bees of a certain queen is by changing queens or brood with other colonies of different blood. How could the Doctor tell whether or not the dead bees lying around were from those special hives? Admitted that the bees from his properly-reared queens live 90 days, as he says, does he claim that when the time comes for them to die—and it certainly does—that they have vitality enough to go away and die far off, while the offspring from his so-called degenerated stock dies in or near the hives? If his high-blooded queens are no more prolific than those of deteriorated blood, just as many bees of high-blood stock must die as are born, the same as in the colonies of inferior blood. If they are more prolific than his high-blooded colonies, they must lose more bees each day than the others, and he ought to find more dead bees around his rousing-big colonies. This seems as plain as twice two makes four. I don't think Dr. Gallup has claimed that his high-blood bees do *not* die. If they die, where do they die? (I do not mean to say that during the working season the bees die around their hives; they don't. They die in the field, as a rule.) We must be careful in our experiments and not jump at conclusions.

Dr. Gallup resides in California. From his writing it seems his locality is favorable for bee-keeping. In such a country a colony of bees requires a great deal more room. The same number of bees would make much more of a showing there than they would in a locality like mine, with its regular, poor honey seasons. Judging from the very poor results I have chronicled for a long term of years, I began to lose faith in my own ability; but the wonderful yield I have had in a distant out-yard—with the same stock of bees, mind you—shows very plainly that a good locality is the secret of success. When honey flows the colonies appear populous; they may occupy half a dozen of 10-frame hive-bodies. There is nothing wonderful about it.

As to Dr. G.'s bees living 90 days in the working season, I am skeptical, at the least. Mr. C. P. Dadant says, on page 485, in substance, that bees hatched May 22 will all be dead Aug. 1, thus making 70 days, the greatest age of a bee at that time of the year. It is well known that the Dadants, for many years, have used very large hives, and their bees ought to live as long as anybody's. Had Mr. Dadant, in his experiment, changed his black queen for a yellow one on June 1, instead of May 1, the chances are his bees would have lived but 60 days, or less. On the other hand, Mr. D. says that bees hatched Sept. 1 will live till May. With me they live till July, *i. e.*, just a few of them. Cellar-wintering might bring about this different result; I do not know.

Thus, it will be seen that different men have different experiences, and arrive at different conclusions.

Mr. Gandy, of Nebraska, is another example of how widely experience differs. He, like Dr. Gallup, is an advocate of large hives, because, as he says, bees will occupy two combs on each side of the hive for storing pollen and honey, anyway. This would leave but 4 frames of an 8-frame hive for brood, which, of course, is not enough. Two 8-frame hives would not suffice. They ought to be 10-framers, at the least.

In my hives of 10-frame capacity, sometimes one comb on each side is thus used for pollen and honey, but very often—yes, usually—brood is found in these outside combs, although not as much as in the others. In an observation glass hive, standing in the window in my house, I can now see brood again in each outside comb, the colony occupying it having swarmed, and the young queen—an *improperly reared one*—is again doing her duty, as it seems.

In a 12-frame glass hive, in my yard, the brood reaches the outside comb on one side; there is brood in 10-frames. These are the rules with my bees here, and my colonies have probably as much brood in one hive-body as Mr. Gandy's or Dr. Gallup's in two or three. It seems, anyway, that with good honey seasons I can produce very large crops, inferior queens and small, 10-frame hives notwithstanding.

The experience of Mr. Gandy as to longevity of queens differs widely from Dr. Gallup's. Mr. Gandy's queens can not stand the strain two seasons; Dr. Gallup's queens live six years. Both of these gentlemen give their queens unlimited room. In my yards queens seldom live much over three years.

The reason why the experiences of different men differ, must lie in their peculiar location, as well as in the different management. Some men may also be keener in making correct observations. I am not able to detect a great deal of difference in different stocks of bees, or in properly or improperly reared queens.

I have often used two 10-frame hive-bodies for brood-chambers, with both properly and improperly reared queens in them. It was no uncommon occurrence to find 16 frames with brood in them; but to obtain comb honey from such colonies—that has been a complete failure unless a severe change was made at the beginning of the main honey-flow, or soon after. In good honey seasons it may not be impossible to obtain comb honey from these double-deckers.

Ontario Co., N. Y.

Rearing Long-Lived Queens—Other Matters.

BY DR. E. GALLUP.

In reply to Mr. Baldwin, on page 493, I will say that last May or April (I have forgotten which) I received a queen of the long-tongued variety, cracked up to be extra, etc. Well, she turned out *entirely* worthless, not prolific, did not occupy two combs with as many eggs by one-half as she should have done, and with all the coaxing that I could do to have her rear bees enough so as to supersede her, she died the last week in June with feebleness and old age, and her bees failed to rear a queen to take her place. Now, I have no doubt she was reared from a good strain of bees, but she was reared out of season the fall before, and in an unnatural manner. It is a fact that a good strain of Italians can and do work on flowers that ordinary black bees can not reach. This fad of long tongues was gotten up by some queen-breeder in order to sell his queens, and the other breeders have taken up the cry in order to keep up with him. Long tongues, improperly or unnaturally reared, are a humbug, anyway.

The nearest right distance for frames is $1\frac{1}{2}$ inches from center to center in the brood-chamber, instead of $1\frac{3}{4}$. I have tried them both ways.

On page 509, "One Way to Improve Stock," is a good item to read carefully.

On page 502, in the article by F. Greiner, it seems that he did not get at my true meaning about extra-large colonies producing long-lived queens. An extra-large colony manufactures a large amount of electricity, heat or vitality, while an extra-small colony is lacking in all these essentials or necessities for rearing good queens.

Mr. Greiner says we should not ignore the fact that Mr. Doolittle and others are just as successful since practicing queen-rearing according to the new methods as they were when queens were reared naturally. Now, Mr. Greiner, are you sure that is a fact, or have you jumped at that conclusion without examining the facts? I have examined the facts, and do not find your conclusions correct. Mr. Baldwin says the truth should be spoken at all times. Well, I have begun on this line, and now I shall speak right out in meeting.

Being a prominent writer on bee-keeping, I have had a great many inquiries as to whom I would recommend as the best queen-breeder, and I almost invariably recommended Mr. Doolittle. I also had queens shipped in my name for different parties, and all that, reported said the queens did not turn out right. I have received private letters from queen-breeders, stating they had received queens from him, that they had paid an extra price for, and they did not turn out right, etc. I tried one queen from him myself, and she was no good. Four years ago, when so many were sending me queens to test, he sent me two for a present. I think I received them in August, and in the fall both colonies that I introduced them to had dwindled down very low in numbers

and both queens died before spring. They were probably reared the season previous, and consequently died of old age. Mr. H. Alley sent me two queens as a present the same season—they were his Adel strain—and both colonies perished out before spring.

Most people dislike finding fault with a queen-breeder to his face, and so do I, but now we are trying to get at facts. My motion is that queen-breeders, as a class, are as honest as I am, and I never had the least fear of being hung for my honesty. Mr. Doolittle and Mr. Alley both comply with all the necessary conditions but one for rearing queens, consequently their queens do fairly well the first season, but almost invariably fail the second season. There are exceptions to all general rules, I admit.

Now, gentlemen, if you can invent any plan in transferring common larvae to the cell-cups, whereby you can attach that umbilical cord, you will then come up to Nature, otherwise your queens will lack longevity. Look this matter up thoroughly, and see what conclusion you arrive at. Don't find fault with me for coming to the conclusion that I have.

Mr. Greiner went into a trifle of ridiculousness about Gallup's long-lived queens. I wish to ask him one question: Mr. Greiner, are you aware that ridicule is not argument? Neither you nor any one else can overcome facts by ridicule.

That colony of mine that sent out the extra-large swarm which filled three standard hives with bees, was not the only one I had, it was only one out of seven, all built on the same plan. I have said before that my colonies in extra-large hives all swarmed from 1 to 10 days before those in the standard hives, and I am foolish enough to attribute it to the fact that their queens were all reared in extra-large colonies, and on the superseding plan, as the previous season they did not swarm, and I honestly thought I had made a non-swarmer hive. I know that longevity of both queens and bees were above those in the standard hives.

When I started bee-keeping in this State, the bees were in 10-frame Langstroth hives, and, as I have before stated, I selected two colonies to rear queens from. I stimulated them to have them rear natural queens early. One reared 17 and the other 19 queens; all had had 20 frames, and each had 16 frames fully occupied with brood, and 2 more frames in each hive partially occupied. I managed to save every one of the 36 queens, and all turned out extra-good in every respect. They were good not only the first season, but good for four seasons.

Now, here is another thing: I do not know how many letters of inquiries I have received in regard to queens, prices of queens, etc., since commencing those articles, and I wish it distinctly understood that I never have reared queens for sale, and never expect to do so. So no one can truthfully say that I have an ax to grind, other than to benefit bee-keeping.

The "Old Reliable" seen through New and Unreliable Glasses.
By E. E. HASTY, Sta. B Rural, Toledo, O.

HASTY ON A HOP, SKIP AND JUMP.

With a hop and a skip and a jump a number of weeks have got to be gone over. (You see, I've been playing truant; but the teacher kind 'o intimated that he wouldn't whip me, and so I'm back again.) The writers in those numbers are lucky, or unlucky, just as they view things. If they deem it a favor to be reviewed, their case is sad. If they consider my reviews as a traveler considers the attentions of the custom-house officer, let them chuckle that their baggage has slipped through untouched.

A PIPING QUEEN.

We might guess that a queen piping up and down the hive would stop laying; but it is better than a guess to have so careful an observer as Doolittle tell us such is the fact. And a being-introduced queen, as long as she pipes, is not safe from attack. Page 423.

A SWARM-PROMOTER.

So Mr. Davenport "prevented" a considerable number of colonies from swarming by putting all brood above an

excluder—and every one swarmed. To my mind that ought to be expected. It *looks* just as if a lot of queen-cells, where the queen can not get at them, would be an almost sure swarm-promoter. Page 397.

HINTS ON BISULPHIDE OF CARBON.

Bisulphide of carbon, as described to us by Prof. Cook, on page 390, is not the stuff some previous writers caused us to think that it was. *Don't* pour it upon your food, or your clothes, or your person. I may add, from the book of my own foolishness, don't pour a lot of it into a well, thinking to sweeten up its ill-smelling water.

THE LITERARY FIGHTER.

The picture of the home and apiary of Thaddeus Smith (page 417) has a melancholy interest now that he has passed over to the other shore. His antagonism to one of our most cherished ideas—well, we are glad now that on our part the antagonism was no sharper than it was. A twinge of *something* (can it be regret?) comes when I remember that he *thought* I was a little too severe. Paul indeed said, "So fight I, not as one that beateth the air;" but we must also be able to say, "So fight I, not as one that smiteth his fellow servants."

THAT PAPER HONEY-HOUSE.

Apparently F. L. Thompson's paper honey-house has to be tried—and condemned, and accepted and laughed at, and praised, and be put through all the chequered experiences common to novelties. For some locations and uses I incline to think well of it. Light it by having one or more sections of the sides made of muslin—double, with air-spaces between, if a specially warm shanty is desired. So much easier to keep it bee-tight than a board shanty, is one prime good point. Still, if you trust honey in it at an out-apiary it will get punched, and the bees will carry all away in your absence. Page 428.

HONEY OF CIVILIZED AND NATIVE BEES IN BRAZIL.

Honey of the civilized bee to eat, and honey of a little native bee to make medicine of, is the way they fix things in Brazil, it seems. Said little native is kept to some extent. We get to thinking that quality in honey all comes from the flower; but in Brazil, where they have a dozen or more species of nectar-storing insects, the influence of the gatherer is too plain to be ignored. The honey is good, bad, or indifferent, according to the little paws and pipes it has come through. Page 438.

THE GASOLINE CAN FOR WORMS.

One of the very best little inventions of recent years—is the way I incline to put it. And all about what, sure? Why, Miss Emma Wilson's oil-can full of gasoline for worms. We (at least I) have been inspecting combs for years; have been picking out, or smashing in, or cutting away, as the case might be. Slow, disgusting, unsatisfactory work, and very apt to leave many of the larvae alive, even when we had killed 'em our prettiest. The gasoline slaughter-machine promises to make clean work where it goes, and to go much more rapidly than fingers and forks. Page 437.

BISULPHIDE OF CARBON TO PREVENT GRANULATION.

Yes, Mr. Davenport, find out, for it is an important thing, whether treating honey to bisulphide of carbon vapor does actually prevent granulation in the combs, or whether the one case you experienced was fortuitous. Seems to me we *have* had complaints that the vapor damaged flavor. Or is my memory at fault? Must not expect to transform the character of a thing without at least the possibility of transforming the taste also.

Why Not Help a Little—both your neighbor bee-keepers and the old American Bee Journal—by sending to us the names and addresses of such as you may know do not now get this journal? We will be glad to send them sample copies, so that they may become acquainted with the paper, and subscribe for it, thus putting themselves in the line of success with bees. Perhaps you can get them to subscribe, send in their dollars, and secure for your trouble some of the premiums we are constantly offering as rewards for such effort.

The Premiums offered this week are well worth working for. Look at them.

Questions and Answers.

CONDUCTED BY

DR. C. C. MILLER, Marengo, Ill.

(The Questions may be mailed to the Bee Journal office, or to Dr. Miller direct, when he will answer them here. Please do not ask the Doctor to send answers by mail.—EDITOR.)

Perhaps a Scarcity of Bees.

1. I had black bees in a box-hive, and drove them into an 8-frame dovetail hive. Then I waited until the bees hatched, when I put them, with their old combs, in the dovetail hive, and gave them eggs and hatching brood from a golden queen. They reared a queen from the first brood hatched, but since then $\frac{2}{3}$ of it has died in the larvæ state. There is no odor or ropiness, it just dies and dries up. The brood that is sealed hatches all right.

2. I reared 2 golden queens, and made nuclei; one shows dead brood, and the other one does not. There are very few bees here, and no disease anywhere around. I used new hives, and full sheets of foundation, bought queens and made the nuclei. My old bees are all sound. Now, what is the cause? and what shall I do? PENNSYLVANIA.

ANSWER.—It looks a good deal like nothing more than a scarcity of bees. If there are not enough bees to care fully for all the brood, the sealed brood will continue all right, but some of the young brood will be starved. If my guess is right there is nothing to be done now, as by this time no more brood will be dying.

Is It Foul Brood?

I would like information in regard to disease that has attacked some of my colonies. Last summer I noticed a weak colony that had lots of brood that died before it matured. This dead brood was brown in color, but did not smell badly, neither did it adhere to a toothpick if stuck into it. The colony was rather weak in the spring, and had to be fed, but it cast a swarm late in the season. This young swarm acted in the same way, only there was not much dead brood, but it did not store any honey, and finally swarmed. I put them back several times, but they would not stay, so I put them with another colony. I do not know whether the colony I have described before is the one I united those bees with or not. I know it was a weak colony when I took it from winter quarters, and I fed it partly-filled sections of honey on top in a super, and put a blanket over them; but we had a very cold spring and I believe the brood got chilled.

Please let me know what you think of it, and how to find out whether it is foul brood or not. MINNESOTA.

ANSWER.—In a matter of so much importance one cannot be too active in taking precautions, and a wise thing would be to send in a tin box a sample to Dr. Wm. Howard, Fort Worth, Tex., with a fee of \$2, and then you can know something definite.

Italianizing—Preventing Swarming—Uniting Nuclei.

Being desirous of Italianizing my apiary, and not feeling myself equal to rearing queens, nor wishing to purchase all I need, I concluded to try a plan which I have not seen described, but would like to have your approval or opinion as to its practicability.

To try my plan I took several colonies of black bees, that failed to give any surplus this season, and removed their queens. Then I took out all the combs containing brood or eggs and exchanged them for a frame of brood from a colony of Italians.

1. As they have no queen, and only Italian eggs, will they not rear an Italian queen?

2. If so, how will she be fertilized, as all the drones were killed off more than a month ago? Are there likely to be drones flying from other apiaries?

3. If more than one queen is reared by each colony, to which I have given brood or eggs, how can I preserve them from being killed? I would use them on other colonies of blacks.

4. How can I tell when to take measures to prevent a colony from swarming?

5. If nuclei are formed in the spring, and some of them do not build up to more than 3 or 4 frames, what do you advise doing with them? Unite, or carry over the winter by feeding. MISSISSIPPI.

ANSWERS.—1. You will not be able to tell any difference between the queens reared from Italian brood in the way you mention, and those reared by Italian bees.

2. I suspect you're fooled as to all the drones being killed off in your apiary; but if they are, there is little doubt that neighboring apiaries will supply them.

3. Only one queen will likely be reared in each, unless the colony is strong enough to think of swarming, for the first queen that emerges will kill all her royal sisters in their cradles. If you want to get more than one queen from each, take away the cells nine days from the time the brood was given, and give to nuclei.

4. By looking in the colony to see when queen-cells are first started.

5. Either dynamite or gunpowder would be a good thing to blow up any nucleus started in spring that failed to build up by winter, unless it was started too weak to have any chance, and then the bee-keeper needs—to be told to unite the weaklings, unless he is anxious to save the queens, in which case he may feed up and try to keep them over separately.

Sweet Clover—Foul Brood.

1. If I sow sweet clover in the spring of 1903 it will not bloom until 1904. The following winter it will die, and if it does not bloom until the second season of its life, how will it produce any bloom in 1905?

2. Would $\frac{1}{2}$ acre of sweet clover do much good for 25 colonies.

3. How long will a colony of bees live after they take the disease called foul brood?

4. Will they ever appear to get better?

5. Will they ever swarm?

6. Will they ever work in the supers? If so, would the honey be wholesome to eat?

ANSWERS.—1. I don't know of any possible way by which you can have bloom in 1905 from sweet clover plants that started from the seed in the spring of 1903. If you want bloom in 1905, the plants must begin their growth in 1904.

2. Yes, indeed.

3. There is no definite rule about it; they may be finished up within a year, and they may live several years.

4. Yes, if the disease is not very bad it may appear to be almost gone in a big yield of honey, but it's only fooling; it will be faithful about coming back again.

5. Yes, sometimes.

6. Yes, and the honey is not injurious to the human stomach, although death to a healthy colony of bees.

One Colony Joining a Neighbor Colony.

I may be taking up your time with something that other bee-keepers know all about, but the incident is entirely new to me.

I have a few colonies of bees, all numbered; the other morning my little boy came running to me with, "Papa, No. 5 is robbing No. 4." I found, when I got there, that there was no robbing going on, but a solid line of bees as wide as two fingers going from No. 5 into No. 4. These two hives stand on a platform holding 5 hives; they are about 4 feet apart. The bees in No. 4 made no objection whatever, and as long as they were satisfied I was, so I stood and watched them migrate until a fair-sized swarm had passed into No. 4. No. 4 was a small colony that I had made about 4 weeks before, and was not very strong, but had a nice lot of capped brood ready to hatch. There has been perfect harmony in No. 4 since the addition, and they are working nicely.

I have handled bees quite a number of years, and have read the most of the bee-books, but I don't remember ever having seen a like incident recorded. ILLINOIS.

ANSWER.—You do not say anything about the condition of No. 5. If No. 5 was in good condition, having a laying queen, the case is one perhaps unlike any previously reported. But if No. 5 was queenless, it is not such an

unusual case, except that it is very unusual for bees to pass over so much space as four feet. Even if the hives are four feet from center to center, they passed over a pretty long journey to be made on foot.

Virgin Queen.

1. How soon can a virgin queen's wing be clipped after she leaves the cell?
2. How soon will she commence to lay?
3. Will she mate if her wings are clipped as soon as she leaves?
4. How often do they mate?
5. How would it work to put the entrance-guards on during the swarming season, and not allow the queen to go with the swarm at all?
6. Are the queens mated that are sent out? Is it safe to clip their wings as soon as they are received?

IOWA.

ANSWERS.—1. A queen should not be clipped till she begins to lay.

2. She will lay at the age of ten days, sometimes sooner and sometimes later than that.

3. No.

4. Once.

5. It works all right if you take the proper care afterward. It will not do to leave the entrance-guard on permanently. The old queen must be allowed to take her wedding-flight.

6. Yes, unless it were specially stipulated otherwise, no queen-rearer would send out a queen that had not already commenced to lay, at least no honest one would. It is safe to clip the wing of any queen that has begun to lay.

Prevention of Swarming.

On page 499, under the heading "Prevention of Swarming," you say that you never knew of a colony of bees, after they had reared a queen and she had commenced to lay, to swarm that season. Now, if I understand the meaning of that item, I have had just such an experience this season. About May 20 I made a nucleus for 2 frames of brood, and all adhering bees, from a strong colony; they reared a queen, and in about 10 days after starting the nucleus I gave them 2 more frames of brood, but no bees, and in due time the queen commenced to lay, and, as soon as she got to laying well, I commenced to spread the brood until she had an 8-frame hive full, and they increased very fast. I gave them a super (shallow one) of drawn extracting-combs, and on August 5 they cast as fine a swarm as I have had this season; they stored a little honey in the combs, on top, but not to amount to much. They were given full combs all the time to work on, so they did not have to draw out any. The queen is from good Italian stock, but is mated with a black drone. I think this covers the case. If I am mistaken please let me know.

ILLINOIS.

ANSWER.—Referring to page 499, I find I am quoted as saying that one way to prevent swarming was to get the bees to rear a queen about swarming-time, and when a colony has itself reared a young queen (of course about swarming-time, as before mentioned), I never knew or heard of such a colony swarming till next year. The case you mentioned does not come within the requirements I have given. The queen was reared in a *nucleus*, not in a colony, and then with some aid it grew to a colony. It is possible there may be an exception to the rule given, but it was given by a man of no less experience than the lamented C. J. H. Gravenhorst; but you will notice that the young queen must be reared in a *full colony* about swarming-time.

A Failing Queen—Queens in the Mails.

1. July 10 I had a very strong colony to swarm, and in due time the young queen was mated, and she laid only a very small patch of eggs in 3 combs, and she has not, or will not, lay another egg. All the brood has hatched, and not a sign of an egg is to be seen in the combs. The queen is very small. Why is it that this queen will not lay any more? Do you think she will lay in the future?

2. I have some queens that are 3 years old. Would you remove them and introduce young queens? These old queens are extra-good stock.

3. Do you know of any queen-breeder who can rear

queens fully equal to natural-swarving queens? If you know of such a breeder, name him; I want to buy such queens. The queens that I buy are worth about as much as a one-cent postage stamp, and it cancelled.

4. Do you know that the American Bee Journal is the best paper published? WEST VIRGINIA.

ANSWERS.—1. I don't know why she should fail in such a sudden manner, but there is probably no hope that she will ever be good for anything.

2. A queen is never old enough to kill so long as she is doing exceptionally good work.

3. I suppose a number of them can, but it would hardly be the right kind of advertising to give their names here. It is possible, however, that no queen that reached you is as good as when mailed. The handling of mail pouches is worse in some places than others, as when a pouch is thrown from a mail-car when the train is going at the rate of 40 miles an hour, and all queens received by you through the mails may have an unusually rough experience.

4. Well, now—that is—you see, if I should say yes, the editor would have to get a new hat of a larger size; if I should say no, he'd get mad and hire some other fellow to answer these questions, and then I'd lose a lot of fun. I don't quite like to say I don't know, so I'll say I'm keeping it a secret.

Fastening Bees in Hives in Winter.

Do you think it is advisable to fasten bees in with wire-screen in winter, to keep mice out? I did that last winter but my bees were very uneasy. I carried them out-of-doors several days but that would only content them for a short time; they would come out and fill the entrance. They seem to be doing very well this summer. Of course our text-book tells us we must have our cellar mice-proof, but as we cannot all be so fortunate I would like to have some advice.

IOWA.

ANSWER.—It's all right to keep mice out with wire-screen, but all wrong to keep bees in. Use heavy wire-cloth with three meshes to the inch, and the mice will be kept out without fastening the bees in.

Dragging Out Young Bees.

I found your answer to my question, on page 473, regarding the whole destruction of "young bees" (I note your destruction to my term "brood"), and was disappointed that you could not explain it. At the time I wrote I forgot to say that not only were the young bees driven from the hive, but in many cases their wings were cut off, not a vestige of a wing to be seen, but in cases where there were wings there was no tremulous motion as you describe indicating paralysis. It could not have been from poisoning or there would have been old bees crawling about as well. It seems strange that you have never met with nor heard of such a case in your experience.

The colony I wrote you of, to which I gave an Italian queen, now has young Italians in the field, and yet occasionally I see a grown bee come out dragging with it a kicking, struggling Italian youngster, and either flies away with it or drops it near by. CALIFORNIA.

ANSWER.—I am sorry to say that I can do nothing more than to confess ignorance, and will be glad to yield the floor to any one who can help out. The mutilated wings suggest the work of wax-worms, but on page 473 you say "all are perfectly free from moths," and paralysis and poisoning are now ruled out. Can any one of the numerous American Bee Journal family give any hint as to the trouble of our good friend?

"The Hum of the Bees in the Apple-Tree Bloom" is the name of the finest bee-keeper's song—words by Hon. Eugene Secor and music by Dr. C. C. Miller. This is thought by some to be the best bee-song yet written by Mr. Secor and Dr. Miller. It is, indeed, a "hummer." We can furnish a single copy of it postpaid, for 10 cents, or 3 copies for 25 cents. Or, we will mail a half-dozen copies of it for sending us one new yearly subscription to the American Bee Journal at \$1.00.

QUEENS!

Buy them of H. G. QUIRIN, the largest Queen-Breeder in the North.

The A. I. Root Company tell us our stock is extra-fine; Editor York, of the American Bee Journal, says he has good reports from our stock from time to time; while J. L. Gandy, of Humboldt, Nebr., has secured over 400 pounds of honey (mostly comb) from single colonies containing our queens.

We have files of testimonials similar to the above.

Our Breeders originated from the highest-priced, Long-Tongued Red Clover Queens in the United States.

Fine Queens, promptness, and square dealing, have built up our present business, which was established in 1888.

Prices of GOLDEN and LEATHER-COLORED QUEENS, after July 1st:

	1	6	12
Selected	\$.75	\$4.00	\$ 7.00
Tested	1.00	5.00	9.00
Selected Tested	1.50	8.00	
Extra Selected Tested, the best that money can buy..	3.00		

We guarantee safe arrival, to any State, continental island, or any European country. Can fill all orders promptly, as we expect to keep 300 to 500 Queens on hand ahead of orders. Special price on 50 or 100. Free Circular. Address all orders to

GENERAL ITEMS

Prospect for a Good Fall Flow.

We had a very wet spring, but through June and the first half of July the bees stored steadily.

My 19 colonies, spring count, increased to 32 by natural swarming, and have stored almost 1000 finished sections to date.

A week ago it was dry and hot here, the bees had been out of a job for nearly a month, and corn and hay were drying up, but it has rained almost every day this week, and the prospect for a good fall flow of nectar is promising.

W. H. MEANS.
Greenwood Co., Kau., Aug. 23.

Buckwheat Harvest at Hand.

Our honey harvest has arrived. Field after field of buckwheat is white with bloom, with acres still to come in bloom. My bees are doing splendidly, are storing in the supers very fast, and I have the second super on almost all of my colonies. I think the honey-flow will continue for about three weeks yet, as the farmers were kept back on account of the wet weather, some sowing as late as the first of August—something I never knew of their doing before. As it takes from five to six weeks to bloom, our honey harvest should continue well into September.

J. A. MCGOWAN.
Butler Co., Pa., Aug. 22.

Honey Crop Will be Short.

We had 4 colonies of bees, spring count, and increased to 12 by the first of July. A prime, or first swarm, that issued June 13, cast a swarm Aug. 16. They clustered about one hour, and then left for the woods. I was not at home at the time, and was not thinking about swarms at this time of the year, so I was not prepared. It was the first swarm I ever lost in any way.

The crop of surplus honey will be short on account of the wet weather. There was plenty of white clover, but the bees did not work on it very much.

GEOFFREY A. HUNT.
Tipton Co., Ind., Aug. 25.

Beating Nature at Queen-Rearing.

Prepare the colony by removing the queen and all unsealed brood. In four or five hours give them cell-cups primed with royal jelly, and supply with larvae not over three days old, and feed abundantly from four to five days. By so doing you will have long-lived queens and workers. In my 23 years' experience I have watched the nature of bees. I find in a colony left to Nature's way, colony No. 1 swarmed with 3 capped queen-cells and 5 unsealed cells. Colony No. 2 swarmed without having started any queen-cells. Colony No. 3 swarmed with 2 sealed queen-cells, and 5 unsealed cells, and 2 unsealed cells started on drone-brood. Why should Nature make a mistake by starting queen-cells on drone-larvae?

ARTHUR STANLEY.
Lee Co., Ill.

Bees Did Well—Bee-Martins.

My bees have done well for this bad season, and are still at work. I had two prime swarms last Saturday, and two on Monday.

I wonder if I am a member of the American Bee-Keepers' Association? I sent Mr. Secor my dollar, but do not know for sure whether I was black-balled or not.

I want to tell you something about the bee-martin, that may be new to a great many bee-keepers. They are rightly named bee-martin—king-bird may be something else. The bee-martin will locate on a dead limb of a tree, on a high post, or on the comb of the house, near the bee-yard, and if you will watch him

GUS DITTMER, Augusta, Wis.

very closely you will notice that he acts very much like a dog in fly-time, snapping at flies above his nose and head. The martins attract bees to them similar to the way the dog draws flies. How? Well, I will tell you:

When God made man he provided for him—see? And when he made the martin he placed a nice, little, saffron-colored flower in the center of his head, and covered it over with a few long feathers, hinged to the scalp, that can be raised or parted. This pretty flower is seen by the bees a long way off, and when close enough almost to alight on the flower the bird throws up his head, makes a few quick snaps, and all is over—and the trap set for the next victim. These birds used to eat thousands of bees, no doubt, in by-gone days, but in late years they have all been chased away by the English sparrow.

Now, I suppose Prof. Cook and others will laugh at this as a poor joke. To all such I say, shoot one and examine his head closely. Peoria Co., Ill., Aug. 28. W. P. TURNER.

[It would be very easy to find out as to your membership, Mr. Turner, by writing to the General Manager, Mr. Eugene Secor, of Forest City, Iowa. He is the only man that can give you a definite answer.—EDITOR.]

Storing After Aug. 10—Kaffir Corn.

On page 556, J. A. Watkins wants to know if it is not a fact that bees do not gather any honey after Aug. 10, in any part of the country, and the Editor wishes some one to answer. Two years ago I did not get any surplus honey at all until after that date, and had one colony that gave me 96 sections of nice comb honey, another 72 one-pound sections, and several that filled two supers of 24 sections each; and they gathered honey until the first heavy frost, about Oct. 10.

We are right in the midst of the honey-flow—heartsease, goldenrod, sunflower, and various plants are in full bloom, with plenty of moisture to date. If the frost holds off I expect some of my colonies to equal those of two years ago.

If you want something to yield pollen in the fall, just sow two or three acres of Kaffir corn about June 1 to 10; the white variety is preferable, as it has larger heads, and, when it begins to head out, you will think your bees have all left their hives, by the hum they make in that field of Kaffir corn. It will pay you in feed, too, if you have horses, cattle or sheep to feed.

The American Bee Journal is all right, and no bee-keeper should be without it.

J. M. LINSOTT.

Gage Co., Nebr., Aug. 28.

A Comment on Queen-Rearing.

I note what has been said about artificially-reared queens, and queens reared under the swarming impulse. Dr. Gallup claiming the latter to be much superior to the former, while Mr. Alley claims superiority for the artificially-reared queens. Dr. Gallup's articles contain much which I heartily endorse. Mr. Alley, backed by 40 or more years experience, likewise is correct, and I have every reason to believe that if these two gentlemen were to spend a season in the same apiary rearing queens, their views on queen-rearing would harmonize.

Of late years I have come to the conclusion that there are three factors which must be present in rearing good queens, viz.: To have the cells started with the proper-sized larvæ; an abundance of royal jelly; and, last but not least, to have the cells reared and hatched in the proper temperature. These are the three essential elements to rearing good queens; should either one be absent, poor queens will be the result.

Great care must be taken in handling cells until maturity; not that shaking the cells will break the young queen's neck—the injury is not caused by the sudden jerk exactly, but it has the effect of shaking the embryo into the cap of the cell, and there it will simply starve, no difference how abundant the supply of jelly has been.

I have noticed that in cell-building a larva will drop down out of the jelly; the bees, in

Bee-Keepers—Attention!

Do not put your money into New Fangled Bee-Hives, but buy a plain, serviceable and well-made hive, such as the regular Dovetailed hive arranged for bee-way sections. Honey-producers of Colorado—one of the largest honey-producing sections in the world—use this style.

Thousands of Hives, Millions of Sections, ready for Prompt Shipment.

Please Mention the Bee Journal when writing Advertisers *****

their efforts to get it back, will keep on drawing out the cell, until sometimes it is twice the natural size; such a cell will never hatch. Whenever I handle cells, and if by accident I should jar them so that I think any of the larvae have dropped in the caps of the cells, I simply reverse the stick of cells and gently shake the larvae down into the jelly again. At one time I thought it quite necessary to shake all cells to get the bees off, and when doing so I always reversed the stick and shook back what larvae might have dropped out of the jelly; and I never had any trouble in the cells hatching.

It is now quite evident to me that there are many poor queens due solely to the fact that they do not get all the benefit of the jelly placed in the cells for them.

The above is simply one inkling of the many, showing why sometimes poor queens result from what appears to be a nice batch of cells.

The subject is altogether too inexhaustible to be thoroughly discussed in one or two issues of a bee-paper. H. G. QUIRIN.
Erie Co., Ohio.

Bees Have to Loaf.

It has been a backward season here. I had to feed my bees in June to keep them from starving. We have not had a pound of surplus honey this season. It looks as if we might get a little surplus from the heartsease, as the bees have just commenced to work on it. It rains every other day, so they have to loaf, like the farmers. ADAM WINROW.
Scott Co., Iowa, Aug. 27.

Late White Clover—Moving Bees.

White clover has bloomed later this year than ever was known in this locality; however, but little honey was obtained from it. The prospects are, that there will be a heavy bloom next year.

Bees have done moderately well here all the season through, but have swarmed entirely too much—just enough honey to keep brood-rearing under good headway, and to keep the bees swarming. The hives are full below, and but little surplus has been obtained, owing to so much swarming.

Next week is our State Fair—Aug. 29 to Sept. 5—to be held at Lincoln. Superintendent Whitcomb is expecting a big show this year in the Apiary Department. Some very handsome premiums are offered by the managers.

Last spring we moved our entire apiary two miles nearer town. Moving in March, the weather was rather cool, but the roads were smooth. The hives were all still packed with their winter packing. The entrances were closed, and then the hives were set in a wagon, one on top of the other, and all were moved in safety to their new location without the breaking of a single comb, or losing a colony. They were moved so carefully that the bees did not seem a bit restless, or hardly notice their removal. J. M. YOUNG.
Cass Co., Nebr., Aug. 27.

Results of the White Honey Season.

The story is told, the tale is ended, for the season, so far as the white honey crop is concerned. The season has been a most peculiar and unnatural one. The bees broke all known rules in regard to swarming, and almost everything else, for that matter. The season was a cold one, but it kept me warm the most of the time to handle them; in fact, they got the upper hand and were boss for awhile. But by putting in from 15 to 24 hours a day I soon got on top, and kept there.

The crop was light, but I got enough to buy food and clothes for another year, and will also be able to lay up a few hundred dollars for the long, rainy days that may come some time. So things might have been worse than they were.

Fall flowers have been in bloom for some time, and the bees appear to be doing a good business, but I have examined a number of hives and find they are barely making a living.

I have just finished delivering 7000 pounds of

—ITALIAN—

honey in a city 20 miles distant; it was hauled by team over rough roads, but not a comb was broken.

What has been said about queen-rearing lately is interesting, to say the least. I have just read, and had a hearty laugh over, Editor York's comments on the Wisconsin ex-bachelor who imported a "queen" of superior stock!

But now, when some of the highest living authorities disagree point-blank on the best methods of rearing queens, what are we common bee-keepers to do? We have to rear our own, for, according to Dr. Gallup, what we can buy are worthless. I hope Mr. Alley will give us his latest method. What he has said so far has kind of jarred me. Editor E. R. Root takes the matter coolly and calmly, and points out that somewhat different methods may be best according to conditions, but he does not devote much space to this matter, for he seems to have his hands full defending Mr. Gandy's recent assertions.

Well, I must quit and go to cutting grass and weeds around the hives again. I kept the entrances clear during the flow, but lately the bees in many of the hives have to crawl up the front and climb on the cover before they can fly away. It has been a great year for grass and weeds to grow.

C. DAVENPORT.

Southern Minn., Aug. 25.

Short Crop Expected.

After the heat and drouth of last summer I prepared 30 colonies of bees for winter on the summer stands. Twenty-nine of them wintered nicely, but 3 of them dwindled away, the spring being so cold and backward, as has been described in so many of the reports.

I fed the bees until fruit-bloom, and from that time on they were able to make a living. We had considerable rain and very cool weather, but they began swarming the last of May; it kept raining, and they kept swarming; sometimes two or three swarms would go together, and I would hive them, and they would go to work as though there was only one.

There was basswood and white clover in abundance, but it rained so much that the white honey crop here is rather short. My honey crop is still an unknown quantity; the late honey is just coming; the bees are working nicely, but it rains very often. The honey season is short here, and very late this year. We are afraid of being overtaken by the frost. MRS. PAUL BARRETTE.
Crawford Co., Wis., Aug. 30.

Long-Lived Queens.

I have succeeded in getting more honey and of better quality than any of my neighbors, and it is the reading of bee-books and bee-papers that has enabled me to do so.

Since reading Dr. Gallup's articles on "How to Rear Long-Lived Queens," I had a chance to examine 25 queen-cells the bees built after the queen was removed, and I found little threads running from the abdomen of every queen and fastened to the side and base of the cells.

I have some queens going on their fourth year, and, so far as I can tell, they do not show any signs of failing yet. They were reared by the Doolittle plan. A queen that is poor any way is not allowed to live in my apiary, because poor queens make poor colonies, which are unprofitable.

CHESLEY PRESSWOOD.

Bradley Co., Tenn., Aug. 25.

Getting a Bee-Tree.

I will give you a description of an adventure I had out of town the other evening, when we went to get a bee-tree, which we brought all right. We cut the tree down, plugged the hole where the bees went in and out, sawed off the lower end as well as the top, and brought home the chunk with the bees. It was about 4 feet long, with a cavity about 12 inches in diameter, and 3 feet 6 inches long. We sawed the lower end as close to the comb as we could without harming the comb. The bees were very well

marked Italians, and we had no trouble with them coming out; they clustered up in the top of the cavity, and stayed there. The man who found them has had blood in his eye ever since, and has been out on a still hunt for the man who reported the matter to the village editor; and he says he will turn the bees loose on him when he finds him (but that will not scare me any). The bees are doing well, and I think I will buy them before he finds his man, and then I will give him the laugh.

I am very glad I had the honor of superintending the getting of the bees, and I think I will transfer them in a week or two. I was very glad Editor C. R. Melleny, of our local paper, took as deep an interest in the affair as he did, for, by his writing the article, of which I send you a copy, he has caused the people to take more interest in bees and honey. I am positive that it has helped the cause a great deal. CHAS. MARTIN.
Ramsay Co., Minn., Aug. 26.

[The item referred to was quite well written—and all right for a local newspaper, but hardly of sufficient interest to our readers to copy in these columns. But thank you for sending it, Mr. Martin.—EDITOR.]

Wet and Cool Weather.

I have been exceedingly busy this season looking after 100 colonies, spring count, and doing carpenter work. I get the money from the latter, and the experience from the former.

It has been extremely wet and pretty cool. We had a good honey-flow for about a week the first part of July, but the bees have been getting only enough to keep up brood-rearing since. We still hope for winter stores, but may not get them.

I have been rearing queens since 1891, and never had as poor luck; I could not induce good work in upper stories, after having fed for weeks. I can get larger cells, and I think better queens, by using queenless bees. I have been a close observer, and have seen a good many things that look strange—drones with white heads, drone head, thorax and wings with *worker bodies and stingers*. Had a lot of the latter caught to send in last fall, but did not. I have studied the tent-mating problem for over 10 years, but have not tried it yet; I may some time.

I had expected to go to Denver, but the honey will not pay the bill.

I will try to give a full report later, if I can find the time. I dehorn cattle during the winter, taking the horns from 2657 last season, and one season from 3056. It is snorer pay than bee-keeping, but harder work.

THEO. S. HURLEY.

Tama Co., Iowa, Aug. 25.

CONVENTION NOTICES.

Utah.—The Utah Bee-Keepers' Association will hold the annual convention in the City and County Building, Salt Lake City, Utah, Oct. 6, 1902, at 10 a.m. Business of interest to all bee-keepers will be presented. All are invited.
J. B. FAGG, Sec.

CLOSE SATURDAYS AT 1 P.M.—Our customers and friends will kindly remember that beginning with July 1, for three months we close our office and bee-supply store at 1 p.m. on Saturdays. This is our usual custom. Nearly all other firms here begin the Saturday afternoon closing with May 1st, but we keep open two months later on account of the local bee-keepers who find it more convenient to call Saturday afternoons for bee-supplies.

SHEEP MONEY IS GOOD MONEY and easy to make if you work for us. We will start you in business and furnish the capital. Work light and easy. Send 10 cents for full line of samples and particulars.

**Langstroth on...
The Honey-Bee**

Revised by Dadant—1900 Edition.

This is one of the standard books on bee-culture, and ought to be in the library of every bee-keeper. It is bound substantially in cloth, and contains over 500 pages, being revised by those large, practical bee-keepers, so well-known to all the readers of the American Bee Journal—Chas. Dadant & Son. Each subject is clearly and thoroly explained, so that by following the instructions of this book one cannot fail to be wonderfully helped on the way to success with bees.

The book we mail for \$1.25, or club it with the American Bee Journal for one year—both for \$1.75; or, we will mail it as a premium for sending us **THREE NEW** subscribers to the Bee Journal for one year, with \$3.00.

This is a splendid chance to get a grand bee-book for a very little money or work.

GEORGE W. YORK & CO.

144 & 146 Erie Street, CHICAGO, ILL.

HONEY AND BEESWAX
MARKET QUOTATIONS.

CHICAGO, Aug. 11.—Some comb honey produced in 1902 is now on sale. Fancy brings 15c; anything off in appearance or quality sells at 13@14c for white; amber grades, 2 and 3 cents per pound less. Extracted is selling at 6@7c for white; light amber, 5½@6c; dark, 5@5½c. There is a fair demand for all grades and kinds. Beeswax steady at 30c. R. A. BURNETT & Co.

KANSAS CITY, Aug. 30.—The demand for comb honey is good. The receipts are not large. We quote fancy white comb, 14c; No. 1, white, 13@13½c; No. 2, 12@13c. Extracted, white, 6c; amber, 5@5½c. Beeswax, 22@25c.
C. C. CLEMONS & Co.

CINCINNATI, Aug. 30.—The demand for comb honey at present is very good; all shipments are sold quick at 15@16c for No. 1 and fancy. We advise shipping while demand is good and before the western carloads are here. In three weeks from now carloads will arrive, then demand is satisfied, sales harder to make, and prices demoralized. Extracted honey is selling as fast as it arrives, at the following prices: Amber and Southern in barrels, at 5½@6½c, according to the quality. White clover, 7½@8c. Beeswax is scarce at 30c.
THE FRED W. MUTH Co.

ALBANY, N. Y., Aug. 22.—The demand for honey is improving with the unusual cool weather, the summer resorters returning home hungry. We quote: Extra white comb, 15@16c; medium, 14@15c. No other grades coming yet. We want to caution shippers against shipping by express, as it arrives almost invariably broken. Express companies are stamping the cases "Received at owner's risk," which seems to cause their employees to "play ball" with it. Freight handlers are slower, more careful, and less broken, and much cheaper. We advise sending by freight only. H. R. WRIGHT.

NEW YORK, Aug. 11.—New crop comb honey from New York and Pennsylvania is beginning to arrive in limited quantities. There is a good demand for fancy white at 14c, and No. 1 at 13c, and exceptionally fine lots will possibly bring a little more. Lower grades quiet at from 10@12c. As to extracted honey, fancy grades are in good demand at from 6@6½c for white, and 5@5½c for light amber. Southern in barrels and half-barrels quiet at from 47. @60c per gallon, according to quality. Beeswax dull at from 27@28c. BILDRETH & SEGLKEN.

CINCINNATI, Aug. 29.—New comb honey is not coming in so plentiful, so far. Whatever has come in, and is fancy water-white, has brought a good price, and sold to stores at from 15@16c. Honey kept over from last year, fancy sells for 14c. The market for extracted is more lively and brings: Amber, from 5@5½c; alfalfa water-white, from 6@6½c; white clover, from 7@7½c. Beeswax, 28c. C. H. W. WEBER.

SAN FRANCISCO, Aug. 20.—White comb, 13@14c; amber, 10@12c; dark, 8@9c. Extracted, white, 5½@5¾c; light amber, 5a 5¼c; amber, 4½@—, Beeswax, good to choice, light, 27@29c; dark, 25@26c.

Not much offering or arriving of any sort. While the market is firm throughout, current values are being better sustained on comb than on extracted, for the reason that the latter has to depend to some extent on outside demand. All the comb honey offering will be required locally. The shipment of comb honey has never proven satisfactory, and the production is in consequence restricted to small compass.

“What Happened to Ted”

BY ISABELLE HORTON.

This is a true story of the poor and unfortunate in city life. Miss Horton, the author, is a deaconess whose experiences among the city poverty stricken are both interesting and sad. This particular short story—60 pages, 5x6 3/4 inches, bound in paper cover—gives somewhat of an insight into a little of the hard lot of the poor. Price, postpaid, only 10 cents (stamps or silver.) Address,

ISABELLE HORTON,

227 EAST OHIO STREET, CHICAGO, ILL.

Tip-Top Glass Honey-Jars

The picture shown herewith represents the best one-pound jar for honey that we know of. It is made of the clearest flint glass, and when filled with honey, and a neat label attached, it makes as handsome a package as can be imagined. Its glass top sets on a flat rubber ring, and is held in place by a flat steel spring across the top as shown in the picture. It is practically air-tight, thus permitting no leak,

which is an important thing with honey-sellers.

We can furnish these jars, f.o.b. Chicago, at these prices: One gross, \$5.00; two gross, \$4.75 a gross; five or more gross \$4.50 per gross.

If you try them once you will likely use no other kind of top or sealing arrangement for honey jars.

WEEKLY

APIARY OF WM. HOUSEL, OF MONMOUTH CO., N. J.
(See page 602.)

A STANDARD-BRED QUEEN-BEE FREE

To Our Regular Paid-in-Advance
Subscribers.

We have arranged with several of the best queen-breeders to supply us with **The Very Best Untested Italian Queens** that they can possibly rear—well worth \$1.00 each. We want every one of our present regular subscribers to have at least one of these Queens. And we propose to make it easy for you to get one or more of them.

In the first place, you must be a regular subscriber to the American Bee Journal, and your own subscription **must be paid in advance**. If it is not already paid up, you can send in the necessary amount to make it so when you order one of these fine Queens.

A Queen Free for Sending One New Subscriber

Send us \$1.00 and the name and address of one **NEW** reader for the American Bee Journal, and we will mail you one of the Queens free as a premium.

Now, go out among your bee-keeping neighbors and friends and invite them to subscribe for the old American Bee Journal. If you want some to show as samples, we will mail you, for the asking, as many copies of the American Bee Journal as you can use.

Should there be no other bee-keepers near you, and you desire one of these fine Queens any way, send us \$1.50 and we will credit your subscription for one year and also mail you a Queen. Of course, it is understood that the amount sent will pay your subscription at least one year in advance of the present time. So, if your subscription is in arrears, be sure to send enough more than the \$1.50 to pay all that is past due.

As the supply of these splendid Queens is limited, we prefer to use all of them as premiums for getting new subscribers. But if any one wishes to purchase them aside from the Bee Journal subscription, the prices are as follows: One Queen, 75c.; 3 Queens, \$2.10; 6 Queens for \$4.00.

We expect to be able to fill orders by return mail, or almost as promptly as that, so there will be no great delay at any rate.

Now for the new subscribers that you will send us—and then the Queens that we will send you! Address,

GEORGE W. YORK & CO.,

BEE JOURNAL

42d YEAR.

CHICAGO, ILL., SEPT. 18, 1902.

No. 38.

* Editorial Comments. *

The Denver Convention was held as announced, Sept. 3, 4 and 5. While it was not as largely attended as expected, it was a good meeting. The election of officers for 1903 resulted as follows:

President—W. Z. Hutchinson, of Michigan.
Vice-President—Jas. U. Harris, of Colorado.
Secretary—George W. York, of Illinois.

As soon as we can begin it, we will publish the report of the convention in full in these columns.

When to Cut Alfalfa.—M. A. Gill, in the Bee-Keepers Review, thus earnestly enters a protest against the idea that for best results in hay alfalfa should be cut before it comes into bloom. He says:

I say again that it is *not* a fact that alfalfa cut before it comes into bloom makes the best hay; and I know of many careful, thoughtful farmers who were once led into that practice, but who are now letting their alfalfa stand until it reaches that certain stage when it contains, and will retain, the most food-value.

Some years ago the Experiment Station of New Mexico, carried on a series of experiments to find out at what stage of development the alfalfa plant would make the most pounds of the best hay. As I understand it, they made four cuttings of the first crop. First, when about half grown; again just before it came into bloom; then while in full bloom; and again after it had gone to seed.

They then took four bunches of steers and fed them the same number of pounds from the four different cuttings, and weighed each bunch of steers every five days during the experiment, which lasted some 60 days.

He also thinks there is no danger that the alfalfa honey crop of the future will be any less important than it is now.

Number of Extracting-Combs Needed.—A wide difference prevails as to this in practice. A uses a single story of extracting-combs for each colony, extracting as often as necessary. B adds stories as often as needed, and does not extract a pound of honey till the season is over. If the harvest is at all large, B invests a good deal in combs that A saves—a saving that B considers very poor economy. A must necessarily extract before all combs are sealed, for after the combs are filled it will be some time before all of the honey is ripened sufficiently, and most bee-keepers can hardly compete with the bees in ripening honey. So storing will be hindered while awaiting the ripening and sealing. Then, when the combs are extracted and returned, there is some demoralization and no little delay; for the bees will not attempt to store in wet combs, and the combs must all be licked dry before any storing is done. In B's case there is no delay whatever. Before one story is filled another is put under, the work goes on steadily, and the

honey is thoroughly ripened, and of the best quality. B considers himself well paid for the investment in extra combs.

If one has not a sufficient number of extra combs, it is not a difficult thing to use frames filled with foundation, or with starters. Some, however, will prefer to take a middle ground. When the first story of combs is partly filled, let another story of combs or foundation be placed under it. Then extract the first story when it is completed, and return the wet combs on top. If the wet combs are placed next to the brood-nest, the bees will not readily pass through them to store in the story above until the wet combs are cleaned dry.

Even if only one story of extracting-combs is used, it is probably not best to extract the whole story at once. When half the combs are completed, extract them, putting the wet combs back, not in the center of the super, but at the sides. The center combs will be ready for extracting a little sooner than if at the sides, and each time half the combs are extracted the wet combs are to be placed at the sides. The bees will thus be allowed to go right on storing without interruption. Of course, it will make a good deal more work than to have more combs.

Mr. Abbott Retires from the General Managership.—We have received the following from Mr. Abbott for publication:

EDITOR AMERICAN BEE JOURNAL:—In view of the good feeling and harmony which prevailed at the Denver Convention, and being desirous of doing all I can to promote the interests of the National Bee-Keepers' Association, I have concluded to retire from the General Managership for the present. So far as my future official relations to the Association are concerned, I am perfectly willing to leave this with the membership, as I have every confidence in the good intentions of the bee-keepers of the United States, and believe that they will see to it that no injustice is done any one.

During the time that I was actively engaged in the work of General Manager, 83 memberships were received, and 40 of these were new members, if I am correct. My short experience has shown me that there is a world of work that a General Manager can do, all of which will tend to promote the interests of every bee-keeper on the continent; and, while I have not changed my mind in the least as to the correctness of the stand I have taken, yet I feel that our energies would much better be spent in promoting the interests of our industry than in discussing in a harsh way differences among ourselves.

I think I have said before that personally I could cooperate with any member of the Board in promoting the interests of the Association, and in the future I shall be just as ready and willing to do it as in the past. The Board has an excellent and efficient Chairman, and I can see no reason why the Association should not continue to grow and be a great power for good. New fields are opening up every day. The Government of the United States is showing an interest in our work, and is making it manifest that it is willing to cooperate with us, so that all that is needed now is a *disposition to work* on the part of the officers of the Association and the membership at large, and great good can be accomplished in a very short time. What the world needs is more men and women who *do things*—who are willing to work as well as to write and talk.

I have forwarded to the Secretary a list of the names of those who have joined the Association through me, and accompanied the list with my check covering the amount of membership fees, less expenses, etc., and I trust that the statement sent therewith may be found correct. If not, I stand ready to make it so.

In conclusion, I want to thank a multitude of friends for letters and words of encouragement which have come to me during the controversy, and I desire to say that in the future, as in the past, they will find my voice, pen and hands ever ready to promote the interests of bee-keeping in the United States and Canada.

EMERSON TAYLOR ABBOTT.

It gives us much pleasure to receive the above communication. It shows a magnanimous spirit on the part of Mr. Abbott, which, no doubt, will be appreciated by all, and especially by the membership of the National Bee-Keepers' Association. It ends all controversy over the General Managership matter, and leaves the way entirely clear for action in December, when the annual election takes place. And, should Mr. Abbott be elected General Manager at that time, by a majority of the votes cast by the membership, we can all unite in quoting, "All's well that ends well." If he is not elected, the utmost harmony will still prevail, and the National Bee-Keepers' Association will continue to grow and be a useful institution for the benefit of bee-keepers.

Strong Colonies and Nuclei for Queen-Rearing.—In the effort to devise plans for rearing queens without too much expense, there has been a tendency, if not toward starting cells in other than strong colonies, at least toward having the cells given afterward to small nuclei. The current now seems to be starting in the other direction. Dr. Gallup has been emphatic in protesting in this journal against the use of weak colonies or nuclei for the rearing of queens. Editor Root says, "I don't like to come down on the small nuclei, but I believe that they will prove only a disappointment and a vexation of spirit for the *average* bee-keeper." Editor Hutchinson says amen most heartily to this, and adds, among other things, "Our nuclei must always be of such strength that they will be able to *take care of themselves*," without the danger of their being robbed out.

Really, when one considers the very great importance of having queens of the very best, it seems poor economy to try to save bees either in the colonies in which the cells are started or in the nuclei in which the cells are afterward placed. Supposed the entire time of a strong colony and a number of strong nuclei be lost. What does the honey they would have gathered signify, if thereby such queens are reared that their workers will store an extra amount sufficient to replace the loss of the colony and nuclei used in queen-rearing? And this they may do many times over.

But there is no such loss as generally seems to be supposed. Queenless bees do not sit in dead idleness. It is true that bees in a nucleus will not store as much in proportion as in a strong colony, but they are by no means idle; they keep at work, and when a young queen emerges from her cell the field-bees of the nucleus work with intense vigor, if anything can be had to work on.

It can hardly be emphasized too strongly that the queen is the most important factor of a colony, and that a very poor place to practice economy is in her rearing.

Please send us Names of Bee-Keepers who do not now get the American Bee Journal, and we will send them sample copies. Then you can very likely afterward get them subscriptions, for which work we offer valuable premiums in nearly every number of this journal. You can aid much by sending in the names and addresses when writing us on other matters.

Convention Proceedings.

Report of the Texas State Convention, Held at College Station, July 16 and 17, 1902.

BY LOUIS SCHOLL, SEC.

(Continued from page 582.)

AFTERNOON SESSION.

The convention was called to order at 2:30 p.m., whereupon Mr. Toepperwein talked on the subject of the

ADVANTAGE OF HAVING PROPER SUPPLIES, GOOD QUEENS, ETC.

He called attention to the advantages of frame hives over the old-style box-hive; and of the various dovetailed hives, of which the 10-frame size seemed best adapted to Texas localities. He preferred the Ideal super for all purposes, and those containing the ten shallow extracting-frames, for the production of extracted and bulk comb honey; for sections, the Ideal, or 3 $\frac{5}{8}$ x5 $\frac{1}{2}$, on plain slats, with fences or separators, as these fill out the super better, and allow of more sections to each super.

It was thought that the Danzenbaker section super was a little better, in that it contained narrow sections, causing thinner combs to be built in them, which would be capped sooner.

The difference in depth in the different styles of supers was also discussed. The very shallow or 4 $\frac{3}{4}$ depth are too shallow, while a full-depth body is again too deep for tiering up, leaving the 5 $\frac{3}{8}$ -inch depth as the best super, and most satisfactory.

Mr. Newell asked if anyone had been able to prevent the bees from gnawing away the paraffin mats used above the Danzenbaker supers. As none present had used these mats, they could not reply.

QUEEN-REARING—CONDUCTING A QUEEN-BUSINESS.

Mr. Aten said that on account of the very dry seasons, which had been discouraging to queen-breeders, he had quit that phase of the business. Others were of the same opinion, and had to be coaxed to speak on the subject. Mr. Aten told why it did not pay to rear queens, on account of the fact that too many bee-keepers are already engaged in it, and prices have become so low that it is impossible to rear first-class queens at prevailing prices, and make a reasonable profit.

To this Mr. Victor said that Mr. Aten had hit the nail squarely on the head.

Mr. Aten uses the Alley plan of queen-rearing. Larvæ for this purpose should not be over two days old; and he insinuated that by grafting cell cups, as in the Doolittle method, there was danger of using larvæ that were too old, which would result in inferior queens. He takes a row of cells containing eggs and destroys the egg in every other cell. This strip or row of cells is then attached to the lower edge of the comb, cut out to receive it. By this method there is no danger of using larvæ that are too old. He makes his cell-building colony queenless on one evening and gives the prepared cells the next morning.

H. H. Hyde considered this time as being entirely too long, as the bees have almost lost their desire for constructing cells by that time. He gives his cell-cups within two or three hours, and in 30 minutes finds them to contain royal jelly. He uses the Doolittle method with some changes of his own. He described the methods he used the present season. He used drone-cells that are neither too old nor too new. In the case of very old drone-comb, he found that the cells were too tough and hard; and, on the other hand, new drone-comb would be gnawed down by the bees. Drone-comb about two years old is about right. The cells are shaved down to about half their original depth, after which a lead-pencil is twirled in each cell to give it the form of the queen-cell. These are then given to the queenless colony for a few minutes, when they will be gone over by the bees and nicely polished. They are then removed and "grafted," i. e., the young larvæ transferred into them. When placed in the queenless colony they are readily accepted.

For this cell-building Mr. Hyde selects a strong, rousing

colony, preferably hybrids, as they are found to be the best cell-builders. This colony is made queenless and broodless, the queen being removed and used somewhere else, or placed in a nucleus until wanted. The brood is distributed among other colonies in the apiary, or wherever it may be needed. In two or three hours after this the queen-rearing colony is ready for the grafted cells. To wait until the next morning would be waiting too long a time, in Mr. Hyde's opinion.

Mr. Victor's method differs from both that of Mr. Hyde and Mr. Aten. He considers that leaving the colony over night both queenless and broodless is too long a time. On the other hand, he thinks that three or four hours is entirely too short a time, as this period is only about sufficient for the bees to find out that they are queenless. At this time they are too much excited and confused to attend properly to the grafted cells. He makes instead the colony queenless one day, and about four o'clock the next afternoon removes all brood. Late the same evening he gives the cells, prepared much the same as by Mr. Hyde's method, and the bees are kept closely concentrated for the entire night, giving their attention to these cells. Out of 138 cells by this method he had 135 accepted, distributing them among different cell building colonies at the rate of about 38 cells to each one. For making cell-cups and grafting, he uses the Doolittle plan, together with some features of the Alley plan and some of his own. He has his own methods of manipulation, by which he is enabled to gain one day's time over the Alley plan.

"Is the use of the queen-excluder an advantage, or to the contrary, in honey-production?"

"No, not advantageous."

"Does it pay to keep a colony on scales?"

"No, not from a financial standpoint."

Under the head of General Business, at the close of the meeting, Mr. H. H. Hyde addressed the Association on the question of

STANDARD PACKAGES FOR HONEY.

He stated that heretofore no standard size had been adopted by the bee-keepers, which had led to much confusion and misunderstanding, especially between the producer and the dealer. Mr. Hyde advocated the adoption of standard-sized packages, so as to avoid this confusion in the future.

Heretofore, for extracted honey, cans with small screw tops have been used, having respective capacities of 6, 12, and 60 pounds. Under this arrangement they were crated so as to make either 60-lb. or 120-lb. cases or crates. The cans for comb honey have been made with 4-inch screw-tops for the 6 and 12-pound sizes, with 8-inch screw-tops for the larger sizes.

Of late a new-style package, known as "the friction-top can," has come into quite extensive use. This is better and cheaper than the old style so long used. But there are objections to it in its varying weights and capacities, and also the way in which it is cased.

It is made in sizes—2, 3, 5, 10, and 60 pounds—and put up in cases or crates of different weights, the larger size cases weighing but 80 pounds. This means mistakes in ordering, and general misunderstanding and confusion.

On motion, the Association adopted as standard size packages, the following: Cans of 3, 6, 12, and 60 pounds capacity, each and all to be crated in cases either of 60 or 120 pounds; the 3 and 6 pound cans to be crated in double tiers, each case containing 60 pounds, while the 12 and 60 pound cans are always to be crated in cases containing 120 pounds each. This secures a uniform sized package, and a simple method of putting honey on the market.

Pres. Toepferwein was instructed to meet with a certain can company and co-operate with them in the manufacture and supply of this new standard package. Southwest Texas alone will use, during the coming season, not less than 20 carloads of these cans, which will be filled with honey for strictly family use.

The bee-keepers' exhibit this year was not as large and complete as the previous year, but a grander exhibit than ever before is being planned for readiness at the next meeting.

Mr. H. A. Mitchell had on exhibition the finest sections of basswood honey that was ever exhibited at the Association meetings, and his exhibit carried off the medal.

A collection of honey-plants was shown by Louis H. Scholl, and was found to be very instructive. A similar collection of honey-plants of Central Texas was also shown by the Department of Entomology, of the College.

LOUIS H. SCHOLL, Sec.

(The End.)

Contributed Articles.

Old Bees Not the Best for Queen-Rearing.

BY G. M. DOOLITTLE.

A bee-keeper in an adjoining State and myself have been having a little correspondence regarding the giving of a colony, which has been queenless six or seven weeks, brood from which to rear a queen, I telling him that a first-class queen can not be reared that way, even where only eggs are given, as he seems to think that better queens can be reared from "the egg" than in any other way. One of the claims I made was that field-bees could not, from necessity, make good nurse-bees. In his reply to my last letter, he comes at me in this way:

"If field-bees make poor nurses, how about a colony that comes out of their winter quarters in the spring both queenless and broodless, as is quite often the case? If given choice brood, will they be prepared to care for it to the best advantage and rear a queen that is satisfactory? If so, why will not queenless bees do the same when of the same age? I have often seen it stated that we should give brood to such colonies as are queenless when put out from winter quarters. Or do you regard this, as you do the other, as a makeshift, when nothing else can be done? I should like to have your opinion in these matters given through the American Bee Journal, as others are interested."

In reply, I would say that there is quite a difference between old field-bees and the bees which come out of winter quarters as regards their making good nurse-bees. The vitality, or the different parts of the anatomy of the bee which perform different offices, become exhausted or changed in accord with the amount of labor performed, not in accord with the number of days which go by; hence, a bee which has seen five months of winter, where a colony has wintered to the best advantage, may be no older in reality than the same bee would be at from 10 to 20 days old, were the date of the season June or July.

It is a fact with which many are acquainted, that bees which have been wintered over become good nurse-bees, while many are as fully cognizant that a bee which has been in the field as a field-worker for two weeks is almost wholly incapacitated for such work; and if forced to nurse the larvæ, does it as a "makeshift," as our correspondent puts it.

I have found that a colony losing its queen soon after coming through the winter, will rear a very fair queen, though I have never found them to be among the best; but in order to rear such a fair queen it seems necessary that the nurse-bees should be feeding some larval bees before they set about rearing a queen. I have often taken a colony of queenless and broodless bees in the spring and built them up in this way:

As soon as possible after spring opens give them a frame of eggs and larvæ, and in eight or ten days open the hive and break out or cut off all the queen-cells they may have started, giving brood to them once a week if possible, until plenty of young bees emerge from the first brood given, when I give a frame of brood from my choicest colony, and allow them to rear a queen from the same. In this way I have succeeded in securing queens that would prove of value, and saved a colony which otherwise would have been lost. Had I allowed them to perfect a queen from the brood first given, she would have been a makeshift queen, and, in all probability, a drone-layer, as she would have been perfected quite a little before there would have been drones flying for her fecundation. I firmly hold to this belief, the same coming from long experience and deep study along the queen-rearing line, that good queens can not be reared except where there are nurse-bees in the hive, feeding larvæ at the time they are required to rear queens.

To force any bee, which is not in the habit of preparing chyle, to prepare immediately the same for a larva intended for a queen is out of the ordinary course of Nature, and the result can be only an apology for the better article, or a "makeshift," as our questioner puts it. And such colonies as have been queenless six or seven weeks in midsummer can have no chyle prepared, for it would be at least 30 to 33 days since the last larva in that hive had been sealed over.

and all of the bees would have to be field-workers for from four to seven days, consequently nothing but the very poorest kind of a queen could be reared by such bees.

But here is a point which I do not remember ever having heard any one speak about, namely, that so far as my experience goes the bees, when in the proper shape as to nurse-bees, can rear a really good queen from one of these very poor ones which only came about as a makeshift, so that any colony so rearing a queen from a poor one can become a thriving colony again, with a queen reared by supersedure from the brood of the very poor one. In fact, I have often found such queens to equal those reared from the very best of mothers, although I am far from advising using such queens as mothers for queen-rearing. In this we see how Nature has provided for the bees, so that there may be a perpetuation of the race, even under the most adverse circumstances.

I am frequently written to that queens gotten from certain queen-breeders prove poor layers, thinking, evidently, that I will condemn those sending them queens; but, instead, I always advise the rearing of queens from these poor layers, if gotten from any responsible queen-breeder, for it often happens that the very best of queens will not do as well after shipped away as she did when in her original hive; but if the stock is good, queens reared from her will prove equally good with those which were reared from her when she was in her first owner's hands. At least this has proven so in any and every case that has come under my notice.

No. 9.—Bee-Keeping for Women.

The Bee-Smoker—One of the Indispensables.

BY EMMA M. WILSON.

One of the indispensable things in the apiary is the smoker. Perhaps those of us who never knew what it meant to get along without a smoker hardly realize just how much of a comfort it is. Still, there are times when a smoker can be the cause of much discomfort.

You have a big day's work to do, and feel that you have not a minute to spare, and yet you are obliged to waste many precious minutes because the fire in your smoker will persist in going out.

You blow and blow for some time, in hopes of resuscitating it, but finally become disgusted and empty the whole thing out, and begin all over again, and it may be with the same result.

The very fact that you are in a hurry does not help the matter any, as you are very apt to fill your smoker too full and cram it down too tight, which proves disastrous, and out it goes.

Alas for your temper. By this time you are decidedly cross, and no doubt the bees, too, as you have been trying to work without a good smoke.

Well, what shall you do about it? Suppose we go back to the beginning and start right. If there is a fire in the kitchen stove, and you can get some nice, bright coals, that will be fine. Put enough in the bottom of the smoker to insure its starting promptly, and fill it up with fuel, and blow it up good. If your fuel is dry there ought to be no trouble in having a good fire. But you can not always get coals from the kitchen fire, so you must be ready in advance to light your smoker in a hurry.

To do this, put in a stone jar saltpeter and water in the proportion of an ounce of saltpeter to a pint of water. After the saltpeter is dissolved, throw in any pieces of old cotton-cloth that you may have handy. After they have thoroughly soaked, take them out and wring lightly, and spread out to dry. When dry they are ready for use.

Next time you want to light your smoker, have ready some nice, dry fuel. First light a good piece of your saltpeter cloth, and drop it in the bottom of your smoker; then quickly fill up the smoker with fuel, and blow "like sixty" until the fuel is well lighted. You may go right on with your work and feel sure that your smoker is not going to bother in the least, even if you did fill it up full and cram it down tight. If it burns too fiercely lay it on its side, but be careful that you do not put it out by leaving it that way too long.

It does not pay to be too economical with saltpeter cloth. Always have a good supply on hand, and use it liberally, and always have some in the apiary with you ready

for use. It pays to give your smoker a good cleaning out occasionally. If there is a valve, see that it is thoroughly cleaned, and it may be well to oil it a little.

Now, as to fuel: Fine, dry chips from the chip-pile are excellent. I don't know of anything better, as they burn well, make a fine smoke, and last well. Keep a box or hive full in the apiary so they will be handy. Keep it well covered, so that they will be perfectly dry. If at some special time you want a very dense smoke, you can add some wood that is a little damp, if you have a good fire in your smoker to begin with, or even some green wood at this time, will give you a dense smoke, and will be a help. If you are driving bees, or doing any work in which the smoker is kept constantly blowing, you will be helped, I am sure, by using green wood.

At such times I have had my smoker get so hot I could scarcely hold it without burning my fingers. Adding a little green wood was a great help, as I had a better smoke, and the heat was not nearly so great. When your smoker gets so hot, it is a good thing to empty it and start the fire over again, using only enough coals to start with. You will have a better smoke, and less heat.

Dry apple-wood is well worth saving for smoker-fuel. Almost any good, hard wood, if dry, will make a good fuel; the main points are to have it dry, and plenty of it.

McHenry Co., Ill.

Methods of Rearing the Best Queen-Bees.

BY W. H. LAWS.

The articles of Dr. Gallup, Henry Alley, and others, move me to write. Dr. Gallup has said many good things, and I doubt not that the venerable Mr. Alley, with his more than 30 years' experience in rearing queens, has learned many good tricks, the most of which have been generously given to an appreciative public. Mr. Doolittle, for nearly as many years, has devoted his best days in experimenting and rearing fine queens, and he, too, has made public all his best ideas.

But what I object to is mere assertions without proof. In recommending his own methods and queens, let Mr. Alley not condemn all others, and state as he does, on page 519, that, "I do believe fully 90 percent of all the queens reared are as worthless as so many house-flies." Pray, and how does he get his information? Can it be possible that with thousands upon thousands of queen-bees reared and sold by the leading queen-breeders of this country, Mr. Alley has had a report from even 1 percent of that number? And if his statement be true, then let the bee-keeping world know it, and we queen-breeders must either improve in our ways, or let the public buy all their queens from Mr. Alley.

Personally, as a queen-breeder, I have followed the advice of each of these pioneer queen-breeders and teachers, and verified their teachings as perfect by turning out thousands of first-class prolific queens, reared by either, or both, of their methods.

But permit me to say that as great a percent of large, fully-developed queens were obtained by the Doolittle method as by any method ever used. I dare say, that a majority of the queen-breeders will subscribe to this statement as their experience also. I am not writing this wholly in vindication of Mr. Doolittle's method, but to show that Mr. Alley's method is not the only one to give good queens, for poor queens can be reared by any and all methods.

For several years I have used a modification, or rather a combination, of the above plans, with the best results, and if it is the wish of the Editor I shall be happy to explain this in some future issue. Yes, let us rear our queens by Nature's method as far as possible, for Nature, when properly applied to the rearing of queens, cannot be beat, and is perfect, whether under the swarming impulse or the supersedure of old queens. The sudden realization of queenlessness, however, is not natural, but brings about conditions that are forced, and leads me to say that very few colonies are naturally fitted for the production of good queens. So many conditions must exist before good cells can be obtained, therefore the art of obtaining all good queens is the work of a professional rather than of an amateur.

The time is now ripe for an output of good queens, and the breeder who carelessly puts poor queens on the market will sooner or later pay the penalty, by finding his reputation and business gone.

Bee Co., Texas, Aug. 18.

The Bee in Law—Statutory Enactments.

BY R. D. FISHER.

1. Preface.
2. Offense against Private Property ; Unlawful Enticement of Bees.
3. Bees, Property in.
4. Bees, with Hives and Honey, Exempt from Attachment and Execution.
5. Poison—Exposing with Intent to Destroy Bees—Penalties.
6. Bees, Entering Premises to Disturb or Carry away—Penalty.
7. Prevention of Foul Brood among Bees—Michigan.
8. Same, Nebraska.
9. Same, Colorado.
10. Same, California.
11. Same, Utah.
12. Same, Wisconsin.

1. PREFACE.

It is the purpose of this article to supply in convenient form a digest of the whole body of statutory law concerning bees and bee-keepers. The code of laws for each State is supplied only by large libraries, and the wealth of material on most subjects is somewhat confusing. It has been said, "The difficulty is not so much to know the law as to know where to find it."

Our investigations during the preparation of previous chapters of this series of articles have led to the belief that it will be practicable to make a useful and satisfactory digest of the law providing for the propagation, preservation, and protection of bees and bee-keepers.

The concluding chapter is divided into such titles as seem capable of separate treatment. In so far as our investigations could discover, none of the statutory law referred to herein has been repealed.

A feature of the concluding chapter which seems worthy of particular mention is the collection of statutes providing for inspection of apiaries, and penalties. However, in this and other respects the work must speak for itself.

2. OFFENSE AGAINST PRIVATE PROPERTY ; UNLAWFUL ENTICEMENT OF BEES—PENALTIES.

Laws of Connecticut, 1882, Chap. 77, Central Stat. 1888, Sec. 1466, provide that every person who shall place upon the premises of another any tub, box or other contrivance for the purpose of enticing swarms of bees from the premises of their lawful owner shall be fined not more than seven dollars or imprisoned not more than thirty days.

3. BEES, PROPERTY IN ; DEPOSITS ON LAND.

Laws of Georgia, 1883, Chap. 2, Sec. 3074, Stat. 1895, provide that any deposit made by wild animals on realty belongs to the owner; thus honey deposited by bees in a tree belongs to the owner of the tree, though the bees may be hived by another; so the eggs and young of birds, or the increase of animals (bees), so long as they remain unable to leave the land, they belong to the owner.

4. BEES, WITH HIVES AND HONEY, EXEMPT FROM EXECUTION.

Statute of Vermont, 1894, Sec. 1805, provides that, among the goods or chattels of a debtor which are exempt from attachment and execution to satisfy a judgment debt, are three swarms of bees and their hives, with their produce in honey, provided the suit brought is not to recover payment for the purchase price thereof, or for material or labor expended on the same.

5. POISON, EXPOSING WITH INTENT TO DESTROY BEES—PENALTIES.

Section 1247, Rev. Stat. Kentucky (Carroll), provides that if any person on land or premises not in his possession or under his control shall lay or expose any poisonous substance with intent to destroy honey-bees he shall be fined not less than five nor more than fifty dollars.

Same, Code and Stat. Washington Sec. 7161 (Laws '97, p. 11), provides that it shall be unlawful for any person within the State of Washington willfully or maliciously to kill or poison any honey-bees. It shall further be unlawful for any person within said State willfully and maliciously to place any poisonous or sweetened substance for the purpose of injuring honey-bees in any place where such poisoned or sweetened substance is accessible to honey-bees within this State. Any person or persons violating said law shall, upon

conviction thereof, be punished by fine of not less than ten dollars nor more than one hundred dollars.

6. BEES, ENTERING PREMISES TO DISTURB, STEAL, OR CARRY AWAY—PENALTY.

Laws of Ohio (Rev. Stat. 1890 (S. & B.), Sec. 6840) provide that whoever unlawfully enters the premises of another for the purpose of disturbing or carrying away any box, gum, or vessel containing bees or honey, or injuring or carrying away any such property, shall be fined not more than five hundred dollars or imprisoned not more than sixty days or both (60 A. 5, Sec. 1, S. & S., 279).

Same, Laws of Nebraska, 1879, Sec. 81, provide that, if any person shall steal any hive, box, bee-palace, or other contrivance containing honey or honey-bees, the property of another, of less value than thirty-five dollars; or if any person shall steal honey from any such receptacle or other contrivance, or shall willfully and maliciously disturb, injure, or destroy any of the aforesaid receptacles or other contrivances containing honey or honey-bees, or if any person shall steal, or by art, device, or contrivance, or in any manner whatever, decoy from any such hive, box, bee-palace, or contrivance any such honey-bees, with intent to convert the same to his own use, or with intent to damage or defraud the owner thereof, or by any art or device injure, damage, or destroy any such honey-bees by means of poison and otherwise, such offender shall be fined not exceeding one hundred dollars, and confined in the county jail not less than ten nor more than thirty days, and shall be liable to the party injured in double the value of the property stolen, injured, or destroyed.

7. PREVENTION OF FOUL BROOD AMONG BEES.

(a) Laws of Michigan (Howell's Ann'd Stat., 1882, Chap. 62), 1881, p. 125, makes it unlawful for any person to keep in his apiary any colony of bees affected with contagious malady known as foul brood, and makes it the duty of every bee-keeper, as soon as he becomes aware of the existence of said disease among his bees, forthwith to destroy or cause to be destroyed by burning or interment all colonies thus affected.

(b) Wherever foul brood exists, or where there are good reasons to believe it exists, it shall be lawful for any five or more actual bee-keepers of any county of the State, to set forth such facts, belief, or apprehension in a petition addressed to the judge of probate, whose duty it is to appoint a competent bee-keeper of said county, as a commissioner, to prevent the spread of said disease and to eradicate the same; said commissioner to hold his office during the pleasure of the court; records of appointment and revocation shall be filed with the petition as a part of the records of the court.

(c) Upon complaint of any three bee-keepers in writing and on oath, to said commissioner, setting forth that said disease exists, or that they have good reason to believe it exists within said county, designating the apiary or apiaries, it is the duty of the commissioner to proceed at once to examine the bees so designated; and when satisfied that any colony or colonies of said bees are diseased with foul brood, he shall place a distinguishing mark upon each hive wherein exists said foul brood, and immediately notify the person to whom said bees belong, personally or by written notice, to remove or destroy said hives, together with their entire contents, by burying them or by fire within five days. In case no foul brood is found to exist in said apiary, the persons so petitioning, or either of them, becomes liable to said commissioner for the amount of his fees for such services.

(d) Any person neglecting to destroy or cause to be destroyed said hives and contents, after notice and time limited, shall be fined not more than twenty-five dollars or by imprisonment not more than fifteen days or both. For the second offense the fine may not exceed one hundred dollars or imprisonment more than 60 days or both.

(e) The commissioner is allowed two dollars per day for his services, and is paid by the county. But no fees are allowed unless foul brood is found.

(f) In all suits and prosecutions under this law, it is necessary to prove that said bees were actually diseased, or infected with foul brood.

8. SAME, FOUL BROOD, DISEASED BEES.

(a) Laws of Nebraska (Chap. 3, Act 1885, Chap. 8a, Ann'd Stat. Neb., 1901); makes it unlawful for any one to keep or have in possession in this State, any honey-bees, brood-comb, or honey known to possess or to be infected with the disease known as "foul brood," or any other infec-

tious or contagious disease peculiar to bees or honey, or to keep or have in possession any bee-hive or other receptacle in which any foul brood, diseased bees, or infected honey is known to have been kept.

(b) *Destruction. Penalty.*—Any honey-bees, brood comb, or honey owned or kept or found in this State, known to be affected or infected; and any bee-hive or other receptacle in which any bees, brood-comb, or honey shall have been kept, known to be, or have been infected as set out in section (a), shall be destroyed immediately and completely by burning. Any person who shall be the owner, possessor, or care-taker thereof, who refuses or neglects immediately to cause the same to be destroyed, as provided herein, shall be deemed guilty of a misdemeanor, and upon conviction thereof shall pay a fine of not less than ten nor more than one hundred dollars, or be imprisoned in jail not more than 30 days for each offense.

(c) *Inspection.*—Every person owning or keeping honey-bees in this State shall cause the same to be inspected at his own expense, at least once a year in infected districts. This includes each and every brood or colony of bees, brood-comb, and honey in his possession or under his control, and the procuring of a certificate of such inspection showing the true condition of each and every one of the above-named articles in his possession as to the existence of foul brood or other infectious or contagious disease, in duplicate, one of which duplicates shall be left with such person, and the other filed in the county clerk's office, where such bees or honey or brood-comb is kept.

(d) *Treatment.*—If, upon inspection, the disease of foul brood or other infection or contagion shall be found to exist, and the inspector shall be of the opinion that, by proper treatment, such diseases, contagion, or infection may be removed, he shall so certify officially in his certificate of inspection, and the owner or keeper of such bees shall be entitled to keep such bees for the period of six months for treatment; and if not eradicated at the expiration of such time, such bees shall be destroyed as hereinbefore described; and any person having in possession any brood-comb, bee-hive, honey, or apparatus used in connection with bee-culture, found in like manner to be infected, such person shall be allowed 30 days in which to disinfect the same; and if said disinfection shall not have been complete at the expiration of 30 days, such brood-comb, bee-hive, honey, or apparatus shall be burned as hereinbefore provided.

(e) *Penalty.*—Every person neglecting or refusing to cause all such bees to be duly inspected as provided herein, shall be deemed guilty of a misdemeanor, and shall pay a fine of not less than ten or more the one hundred dollars for each offense upon conviction thereof.

(f) *Inspector. Pay.*—Upon the application of the Nebraska Bee-Keepers' Association, or other person or persons interested in bee-culture residing in any county of the State, the Governor may appoint a suitable resident inspector of bees and honey of said county, whose sworn duty it is to inspect all bees, brood-comb, and honey, within said county, when requested, and shall receive two dollars per day for his services, to be paid by the owner, agent or lessee in whose possession such bees, brood-comb, or honey may be when inspected. Such inspector shall make certificates in duplicate as provided in section (c).—Gleanings in Bee-Culture.

(Continued next week.)

The Buffalo Convention Report is issued in pamphlet form, size 6x8½ inches, 80 pages and cover. Besides a full report of the proceedings of the 32d convention of the National Bee-Keepers' Association, held in Buffalo, N. Y., Sept. 10, 11 and 12, 1901, it contains fine half-tone portraits of all the officers and directors of the Association; also the Constitution, a list of the membership up to the end of 1901, and the two latest bee-songs—"The Hum of the Bees in the Apple-Tree Bloom" and "Buckwheat Cakes and Honey." We believe it is the finest ever gotten out for the Association. Of course, all members of the Association receive a copy free, but there are thousands of our readers who are not yet members, but who should have this valuable Report. Better send for a copy, if you have not yet received one. Price, postpaid, 25 cents, or with the American Bee Journal one year—both for \$1.10. Send all orders to the office of the American Bee Journal. Better order soon, before all are gone.

* The Afterthought. *

The "Old Reliable" seen through New and Unreliable Glasses.
By E. E. HASTY, Sta. B Rural, Toledo, O.

CHARLES DADANT.

From the title page of No. 30 a grave, wise face looks a good-by to us. Honor, and a place in our memories, to Mr. Charles Dadant. I understand that more people in France than in America realize his weight and worth. This is on account of the extent of his writings in French. Not long since apiculture was called a new craft, and its eminent men were mostly living. How soon it will be that most of those who first dignified apiculture as a vocation, and a semi-science as well as a vocation, will be mostly among the dead?

WHY SO MANY BACHELOR BEE-KEEPERS.

Worry, worry;
Frowns and flury;

And it's the old bachelors "Iowa" is troubled about when he (or she—horrid thought!) counts the noses of beedom! Half mankind get married when good sense would bid them not to. (There, now, let's see you deny that.) And the average sense of mankind is low; and the average sense of bee-keepers is supposed to be quite a bit higher. Or, if you don't like that, say that a man so full of ideas as the bee-man, must needs long for a mate of his own kind (like Adam, when the critters were paraded before him), and lady bee-keepers, both present and potential, are still quite insufficient in number to go round. Page 488.

WHY BEES VISIT PIG-STYS, ETC.

Anent the other "Iowa," page 489, I don't believe that bees go to privies and pig-stys for salt—that is, salt is not the main thing. All higher life on this planet is a life-and-death struggle with microbes. The excreta of all higher animals abound in antiseptics, which the proper internal organs have made and poured out to keep down microbe multiplication within. Much of this anti-microbe matter is not neutralized, and is capable of being used again. Bees seem to think they need all they can secrete and all they can gather, too. Salt is a mild antiseptic, and comes all in the same line; but you may salt never so wisely the water you offer them at the apiary, and they will still prefer their chosen watering-place where cattle stamp around.

MAXIMUM AGE OF QUEENS.

Ever since defending Virgil's seven-year age for bees, I have felt specially interested in the maximum age of queens. On page 494 we find that Edwin Bevins has a queen that has done service four whole years and two fractional years, six in all. If she should commence on next season she would be in a measure a seven-year queen.

GRAVENHORST'S SWARM-PREVENTION.

I think that to be sure of the Gravenhorst method of swarm-prevention you will have to get the bees to rear themselves a young queen *a little before the time of regular swarming*. If you should delay until the midst of the swarming season I should incline to warrant you that the queen that began laying in that hive would be queen No. 2—queen of a depleted colony. Page 499.

QUEENS WITH AFTER SWARMS.

So Doolittle has counted 15 queens with the last after-swarm of a series. Till some one else counts more, let's call that the record. Page 501.

DR. PEIRO AND MULBERRY-TREES.

And so Dr. Peiro, when he gets ready, and feels just like it, is going to make some of us presents of young mulberry trees. I'm going to try to look real pretty. Hope my duties won't require me to give him anything in the nature of a switching until after my tree arrives. Or is this just the rogue's crafty plan to keep his jacket untanned for about five years?

TOOLS FOR HOLDING QUEENS FOR CLIPPING.

The little tool which is shown on page 526, seems to be an excellent invention—that is, so far as can appear with-

out actual use it does. (Carved section-slip crossed by thread of rubber.) Has also the merit of being very easy to make. As but few bee-folks are clumsy in their mechanical doings, nearly every one can make it, and catch queens with a minimum of danger and nerve-strain.

Twenty-two years ago—the first year I owned the apiary here—I also invented a wonderful queen-catcher. Worked well the few times I used it; and would pick queens up instead of being restricted to holding them down. But as I am an anti-clipper my invention has languished from a total want of use, and I have never brought it forward.

Questions and Answers.

CONDUCTED BY

DR. C. O. MILLER, Marango, Ill.

(The Questions may be mailed to the Bee Journal office, or to Dr. Miller direct, when he will answer them here. Please do not ask the Doctor to send answers by mail.—EDITOR.)

Two Queens in a Hive.

I will give a little of my experience with a colony of bees. They are a cross between Carniolans and golden Italians. The first of May I opened this hive with the intention of dividing the colony, as they were getting very heavy, and in my work I found two queens, so I had one queen for each colony. I left the old one on the old stand, and looked in a week later and they had two more queen-cells, one finished and the other one almost done. July 12 I divided them again and had a nice young queen to go with the increase, but I do not think she was laying at this time, but she has spread herself since. The old queen keeps the hive running over with bees, and there are 7 frames of brood in the hive now, and two queens again. Now this is the third young queen she has reared this season, and I am going to leave it with her and see whether there will be two in the spring. I clip all my queens, and when I clip this last young one I will do it in such a way that I will know one from the other, and can see which one gets killed, if either. The question is: Why does she insist on having a helper when she is so good herself?

ILLINOIS.

ANSWER.—The probability is that in spite of her good work the bees have a presentiment that she is nearing her end, and it is not at all likely that you will find her alive next spring. Still it is possible. The case, however, is unusual, and if peculiarity extends to her offspring you have struck upon a valuable trait.

Can Bees See in the Dark?

I was asked the other day whether bees could see in the dark? I could not answer, and so refer it to you for answer.

GEORGIA.

ANSWER.—The word "dark" is a relative term, and does not always mean the same thing. There is probably no such thing as sight in the absolute absence of all light, but it is quite possible that bees can see where it is so dark that human eyes can not see. On the other hand, it is possible that they need more light than we do, and that the work of the hive is carried on mostly by the sense of feeling.

Why Did the Bees Do So?

I have a very strong colony of Italian bees with a super for extracted honey on the top of the brood-chamber, in which super they had commenced to store honey. By opening this super one day in order to find out how much surplus honey they had stored, I pulled out the center comb and found eggs and larvæ three or four days old with which said comb was pretty well filled on both sides.

I found that there was a little space left between the zinc queen-excluder through which the queen went up to the super.

I could not find the queen in the super, but I thought by using a little smoke from the top she went down into the

brood-chamber. However, I put the zinc in proper place and closed the hive.

The fourth day after this, I went to the same hive and looked through the super to see if I could find the queen there laying eggs, and found that she was not there; and upon reaching the comb which contained the eggs and the brood, I found it empty of eggs, and the larvæ partly gone, and some left starved without any food at the bottom of the cell.

Why did the bees leave this larvæ to starve, and dispose of the eggs?

NEBRASKA.

ANSWER.—I don't know. When honey is being gathered very rapidly there is a tendency to crowd out the queen. Put an empty comb in the center of the brood-nest. If honey is coming in slowly the empty comb will be filled with brood. If honey is coming in very rapidly the comb will be filled with honey. The same passion for honey might be carried still further, making the bees empty out cells already occupied by brood. But I don't know anything about it for certain.

White-Eyed Drones.

I had one colony out of 190 that had a few of those white-eyed drones that "Kansas" was inquiring about on page 489, but I have nothing particular to say about them excepting that it seemed like a white enamel scale which could be removed, as I practiced on one. I never saw one around the entrance (only inside the hive). I believe they cannot see until those scales get rubbed off. I think there were some with the same kind of shield on the back of the head, and I believe they were not long hatched.

MICHIGAN.

ANSWER.—I think the case you mention was exceptional, the common thing being a mere change in the color of the head, or the eyes, without any scale or other imperfection.

The Loose-Tin T Super and Propolis.

You tell us (on page 521) that you use T supers for comb honey, and I have understood from other writings of yours that you use the tins loose. Will you kindly explain how the loose tins may be an advantage to you over stationary tins in manipulating the supers? Also, do you find the T super any improvement over the P super with plain section-holders, especially in regard to the feature of propolis?

The amount of propolis which I find in the hives this season is enormous, and we all know your acquaintance with this article is "exceedingly intimate." Has the T super with loose tins given you any relief?

ILLINOIS.

ANSWER.—With T tins loose, the entire contents of the super are pushed out in one mass, the loose tins are picked off, and then the sections can be easily split apart. Possibly no arrangement will prevent the deposit of propolis. In the T super, however, there is less trouble than with some others, for the tops and bottoms of the sections are entirely free, so that the bees have no excuse for plugging glue into the cracks formed by having something touch either the top or bottom of the section. It is possible that a change of bees might help you, for there is a great difference in that respect as to the amount of propolis. The worst gluers I ever had were the Tunisians or Punic, from northern Africa. They were fine gatherers, but their liking for propolis and for cramming the cells so full that there was no air-space between the honey and capping made them utterly unfit for producing comb honey.

Confining Queens Below Excluders.

I notice, on page 475, and also in a previous number, that you are slightly off in your understanding in regard to what I said about confining the queens below with the excluder, while the brood was placed above. In both of my letters I stated that I was not using foundation this year—I used empty frames. In previous years I used foundation, but the bees failed to use it.

On page 474, I stated that "I think if foundation had been used I might have been able to get better results." The heading and also your reply would indicate that it was used in these experiments.

Now, in reply to the inquiries in your answer, I would caution a beginner, that if the nights are cold and the col-

ony not strong it would not be safe to put all the brood from another colony on it, without giving bees also, as the brood might get chilled. But in warm weather, and a strong colony, the more brood given the better. I could not say that the colony with its double load of brood *would not swarm*, but if the queen has room to lay below, and the bees room above to store, they will not be likely to swarm, or at least no more likely to than any other strong colony.

In regard to the colony swarming out when all the brood is taken away, I suppose you fear that under such circumstances they might be discouraged, and desert the hive. They might do so, but in my experience they never do. But if they would in your locality, leave one comb with a small patch of unsealed larvæ, and you will not be likely to lose any bees. In hiving natural swarms, I find they will sometimes leave a hive when given eggs and sealed brood, but have never had one leave unsealed brood.

CALIFORNIA.

ANSWER.—It's a pretty clear case that we will never be able to learn all about bees, for when we think we are settled upon some one thing, our bees or the bees of some one else, apparently with no other object but to get the laugh on us, topple over settled notions by doing just the reverse of what they have done before. I felt safe in saying that if there was foundation in the lower story the queen would use it, and you thought better work would be done with foundation than without it. Well, since the former words were written, I have had a case in which foundation was given and left untouched, and at the same time another colony had empty frames given below, not even starters, and the queen commenced laying with more promptness than any case I had with foundation! There are some things I know all about, but not about bees.

The practice of giving a frame of brood to the bees to prevent discouragement, is, I think, the practice of Mr. L. Stachelhausen. If the bees will not desert, it is no doubt better to omit the brood, for Mr. Stachelhausen, if I remember rightly, takes it away in a day or two, because the bees are likely to start queen-cells on it.

Storing a Black Liquid.

My bees for about one week after August I stored some black, or nearly black, liquid in part of the brood-combs. What is it? May it be from huckleberry or blueberry juices?

MASSACHUSETTS.

ANSWER.—Your guess is perhaps as good as can be made, providing such berries were ripe and within reach.

Drone-Eggs in the Super—Pollen in the Sections—Swarming, Etc.

1. Lately a question was asked, "What makes the queen lay drone-eggs in the supers?" To this you answer, "Want of drone-comb?" Now if this is the only cause in your location, and with your bees, I live in a much different locality, or else have a much different strain of bees, for those critters of mine will breed just as fast in the supers as they will in the brood-chamber, if the conditions are right, and not drones, either. For I have taken off the finest sections of worker-brood any bee-keeper ever saw—not a single cell missed, combs attached to three sides, not a drop of honey in them, but filled from top to bottom with worker-brood. Those sections not having brood in them had more or less pollen, which makes them unsalable.

2. How can bees be prevented from carrying pollen into the sections? The queen-excluding zinc does not prevent the bees from working in the sections, nor do I think it hampers them at all, for I have tried it on hundreds of colonies, side by side. But the zinc does not prevent the pollen from going into the sections, if the bees are determined to put it in there.

3. I had a singular occurrence recently, something I never saw before. Four supers of unfinished sections were placed on a hive, to be finished with extracted honey, over a queen-excluding zinc. On taking off those 4 supers, when finished, a few days ago, 4 of the sections had been emptied by the bees, the combs reduced to brood-comb depth, some pollen in them, and on the bottom of one of them a queen-cell ready to be sealed; and on another one a queen-cell cup with an egg in it, standing on its end as if deposited by a queen, but not another egg could be found in any other cell, and the queen was down in the brood-chamber, and is

a very good one. She was reared in 1899, and is so large that she never could go through the zinc. Could she have gone through, she would surely have laid more eggs in the sections than only 2. The difference in the age of the 2 eggs was about 8 days. I have seen it stated that bees would carry eggs to different parts of the hive, but I never believed it. But this experience put me at sea, and makes me almost believe they do.

4. Out of 75 queens reared in June about 50 swarmed in August, and the others would have done so, too, if it had not turned to the freezing-point at night.

WISCONSIN.

ANSWERS.—1. I wish you had given the page to which you refer, so that we could know just what was under discussion. For you are now talking about queens laying *worker-eggs* in sections, whereas you quote a question about *drone-eggs*. I suspect the answer was all right, for when there is no chance for drone-brood in the brood-chamber the bees will be likely to prepare drone-comb in the super if there is a chance for it, and the queen is likely to lay there if she can get there. There are, however, cases in which she will do as you say—enter the super and fill not only one, but many sections, full of worker-brood. Just why those exceptions occur where separators are used and sections filled with foundation, I do not know.

2. You are probably right, that perforated zinc has little or no effect in preventing pollen from being carried into the sections, and I am not sure I know what will prevent it, although it is very rare to find such a thing in my own experience. It is possible you can prevent it by use of a deeper brood-chamber, for I think the more shallow the brood-combs the more likely will the bees be to carry pollen into the sections.

3. Some one has suggested that when an egg is found in a story over an excluder, a laying queen being below, that an enterprising laying worker has been in the upper story. I don't know.

4. If those 50 queens were reared in the same colonies that swarmed with them, it is something different from anything on record. If they were reared elsewhere and introduced into the colonies with which they afterward swarmed, there is nothing so unusual about it.

The Apiary of Wm. Housel is shown on the first page. When sending the picture he wrote as follows:

I send a photograph of my bee-yard, or part of it, which contains 100 colonies; not all is shown, as the camera would not take all of them in.

I have been in the bee-business since 1888, and have had a few failures as well as success.

I have taken the American Bee Journal since 1889 or 1890, and have been well paid for the money invested.

At one time my bees were all Italians, but now they are hybrids and Germans. It has taken me just 12 years to find out that the Italian is no good for me for comb honey. I would not give my blacks for all the Italians in the land. I will give the Italian bees credit for one thing; that is, they are great swarmers. I find all alike as to swarming, as I have had bees from different breeders. I spent \$20 for Italian queens to breed from, and never found one of them equal to the ones I rear. I believe all queens are injured in the mails, or in caging. The blacks always give me the largest yield of comb honey, and not only the largest yield, but the finest honey. The Italians never fill the sections full, and do not cap the honey as white. Hurrah for the little black bee! I give the man praise who speaks up for the black bee, and if you were to change color—put the yellow bands on the blacks and the dark bands on the Italians, and let the temper and honey-gathering qualities be as they are—they would all jump for the blacks. It is the color and gentleness the most people are after, not fine work.

The Italians do no more work on red clover than the blacks, and not so much on buckwheat, and the blacks will hold them a good round on anything that is fit for honey. I often see it asked: "Why do the Italians store better honey than the blacks?" If those people just reverse the question they will come nearer right, according to my experience. I give the bee the credit it deserves, minus color or length of tongue. I do not know how long the tongues of my bees are, but the other end is plenty long enough!

A Celluloid Queen-Button is a very pretty thing for a bee-keeper or honey-seller to wear on his coat-lapel. It often serves to introduce the subject of honey, and frequently leads to a sale.

NOTE.—One reader writes: "I have every reason to believe that it would be a very good idea for every bee-keeper to wear one [of the buttons] as it will cause people to ask questions about the busy bee, and many a conversation thus started would wind up with the sale of more or less honey; at any rate it would give the bee-keeper a superior opportunity to enlighten many a person in regard to honey and bees."

The picture shown herewith is a reproduction of a motto queen-button that we are furnishing to bee-keepers. It has a pin on the underside to fasten it.

Price, by mail, 6 cents; two for 10 cents; or 6 for 25 cents. Send all orders to the office of the American Bee Journal.

GENERAL ITEMS

Rearing Good Queens.

Having a few spare hours I sat down and grasped my old friend (the American Bee Journal) by the—well, leaves, and gave Mr. Alley's contribution my attention; and I wish to say to him that he is tagging pretty hard, when he says on page 519, "I have found by actual experiment that a colony of bees will not rear good queens while there is a fertile queen present;" and then says, "I don't want any one to tell me it can be done, for I assert that it can not be done by any person." Now, Mr. Alley, I have had queens from a dozen different breeders, ranging from Texas to Wisconsin, and I am in position to know what a good queen will do, for I have one reared just the reverse of your experiment—over a laying queen. The bees of this queen have produced, of comb honey, 128 pounds, or filled sections, and helped build up a weak colony. You may say chance or luck—perhaps it is, and if it is so, it is a chance worth while to chance.

ROBERT J. CARY.
Fairfield Co., Conn., Aug. 24.

Report for the Season of 1902.

I read with a good deal of interest the articles from many correspondents in regard to their experience and prospects for a honey crop for this season, and as mine is in many respects nearly the same, I will add it to the others.

I have 71 colonies—41 old and 30 new. I wintered a part in the cellar, and (as an experiment) I left 12 on the summer stands. They were about 18 inches apart; I drove stakes 3 feet back of the hives, and these I boarded up 2 feet. I then filled in with clover-hulls between and back of the hives, packing the same until the hives were covered to the depth of one foot.

At the front, and resting on the porch of the hive, I put a board one foot wide, also kept in place by stakes driven in front to prevent the clover from falling off. I then covered with sough-grass, laid to shed water, and then I set a row of corn-stalks in front to protect from snow. The stalks I removed when the weather admitted of the bees taking an outing. The experiment proved a perfect success, the bees coming out in the spring in excellent condition, and also those wintered in the cellar, except 3 colonies which were dead. I took them out April 1, nearly all with a good supply of stores.

From that time until May 20 the weather was "all sorts," with many cold, wet days. About the middle of May I discovered that my bees were nearly destitute of honey, although I had fed perhaps 150 pounds of honey, but as they seemed to be working freely I concluded that they were all right. From that time on until the middle of June every pound of honey went into the brood-chamber, and the same is true of more than half of the colonies up to date. All my supers have glass strips in the sides, so I can easily examine the interior. July 2 there were 35 partially filled, 4 finished, and 10 finished all except a few sections. My supers hold 32 1/2 sections, and usually weigh 26 to 28 pounds net, so I estimated there is about 600 pounds on 70 colonies, about equally divided between old and new, or rather 35 colonies, the others having none.

For the past four weeks there has been little if any surplus honey stored. Buckwheat is just coming in bloom, and the bees have commenced working strong, and may yet store a fair average.

I have never seen such an abundance of "bee-pasturage" as this season. All pastures, roadsides, commons, and vacant places, were covered with white clover and alsike. There is plenty of heartsease, goldenrod, buckwheat, and many other "bee-plants."

To make cows pay, use Sharples Cream Separators. Book Business Dairying & Cat. 212 free. W. Chester, Pa.

QUEENS!

This is your last chance for this season to get Queens from Quirin's Famous Red Clover stock, so hurry in your orders. We have files of testimonials like the following:

Mr. J. Roorda, of De Motte, Ind., bought 4 dozen in the spring, and says the workers are hustlers; while E. L. Messenger, of New Haven, Conn., says the queen bought last season produced bees which beat anything in that part of the country.

Price of Queens for balance of season:

	1	6	12
Selected	\$.75	\$4.00	\$7.00
Tested	1.00	5.00	9.00
Selected Tested	1.50	8.00	
Extra Selected Tested, the best that money can buy..	3.00		

We guarantee safe arrival, to any State, continental island, or any European country. Can fill all orders promptly, as we expect to keep 300 to 500 Queens on hand ahead of orders. Special price on 50 or 100. Free Circular. Address all orders to

GUS. DITTMER, Augusta, Wis.

Nothing but the bad weather has prevented an unprecedented honey crop.

I have kept bees for 15 years, and have never seen or heard of foul brood in this vicinity, although there are a great many who keep from a few to 50 colonies. My bees are Italians, some hybrids, some brown, and some small, black bees. I have never been able to determine which are the best all-around bees.

My apiary is necessarily very close to the house, on account of limited space. My garden is full of shrubbery, and at the back a row of wild plum-trees. I do not clip my queens, but allow them to swarm naturally; they invariably cluster either on the shrubbery or on the plum-trees—in either case are easily reached from the ground. At night I remove the old colony and replace it with the new. It is not often that a second swarm issues when the old one has been removed, although I seldom remove the queen-cells, as I find that whenever I have done so there are a great many vicious bees ready for business, anxiously waiting for victims, and the hives being so near the house no one dares come into the yard, so in case a second swarm issues I give them in a living-box, and place a queen-excluder in front of the entrance to the hive from which they came. I empty them in front, and with the smoker drive them in and catch and kill the queen. It is very seldom that I have any further trouble. Of course, I know that I lay myself open to the charge of heresy, but with my environments I find my way the most convenient and satisfactory.

My bees did not commence swarming until June 8, and continued until July 12. I have never had any trouble on account of the queen laying in the super, although I do not use excluders. I put supers on three or four days after hiving. I put supers on old colonies about May 1, which they often fill before they cast the swarm. Whether or not it delays swarming I am not certain, but I do not think it makes any difference. I have had two instances where new colonies have swarmed 11 days after having been hived. I don't understand it. N. B. KNOWLES.

Winona Co., Minn., Aug. 9.

Rearing the Best Queens.

I am glad to see queen-rearing discussed, as discussion is a good way to bring out the best points of apianary work. I am only a green backwoodsman, but I must take a decided stand against Mr. Alley, on pages 519 and 533. I have tried his forced plan, and my experience is that when a colony becomes queenless all at once, that is, by taking the queen from them, that they build, in a hasty way, a lot of insignificant queen-cells that produce very poor queens. He says they will not rear good queens while there is a fertile queen in the hive. Is there not a fertile queen in the hive when cells are built under the swarming impulse? And that is where the best queens come from, he says.

Queens whose colonies fill 100 one-pound sections can not be called cheap queens. I have very few queens in my yard whose colonies have done that well, even in an ordinary year, and some of them have done much more—and all my queens are reared under the swarming impulse.

He speaks of colonies rearing queens under the swarming impulse, as if they did not care as much about the future welfare of the bees that are to be left in the hive, as they did for their own particular selves. If that is the

case, why do they build cells at all? The fact of the case, in my mind, is, that the very best queens are reared in a good, strong colony of our best bees under the swarming impulse.

I would like to ask Mr. Alley one question: He says the best queens he ever saw were reared in his small boxes that he speaks of; and that he does not use them for rearing queens, only for fertilizing them. Why doesn't he rear queens in those boxes if that is where the best ones he ever saw were reared? C. H. HAILMAN.

Kanabec Co., Minn., Aug. 25.

Introducing Queens with Tobacco-Smoke.

This method gives Editor Hutchinson more satisfaction than any other way. He says:

About two days before sending a queen I send notice to my customer when he may expect the queen, and below the notice are the following instructions:

"As soon as you receive this notice remove the queen from the colony to which you expect to introduce the new queen. When she arrives, put her away in a safe place until after sundown, just at dusk, then light your smoker, and when it is well to going put in a pipeful of smoking-tobacco, put on the cover, puff until you get an odor of tobacco, then puff three or four good puffs into the entrance of the hive. Wait two or three minutes, then send in another good puff or two, remove the cover, drive the bees down with a puff of smoke, open the cage and allow the queen to run down between the combs, following her with a puff or two of smoke, and put on the cover. Half an hour later light up the smoker again, put in the tobacco as before, and blow two or three more good puffs in at the entrance. If no honey is coming in, feed the colony a pint of syrup each night from the inside of the hive, but don't disturb the brood-nest for four or five days."

Brushed Swarms.

We have just had a brief visit from Mr. Danzenbaker, who is on his way to California on special business. In talking over the matter of the brushed-swarm plan, he mentioned the fact that he had practiced for years

that method of controlling swarms; and by it he is enabled to get a powerful colony in one of his shallow brood-nests for comb honey—and if there is any honey at all to be had, he is going to get it, and that with a small probability of swarming.

I have been looking up this matter of brushed or "shook" swarms; and in the face of the favorable testimony concerning it I am surprised that bee-keepers have not made more of it. Why, just think of it! if swarms can be controlled in small brood-nests when running for comb honey, it will be one of the greatest boons that ever struck modern apiculture. If any one else has had experience with brushed swarms I wish he would tell us about it.—Editorial in Gleanings in Bee-Culture.

Shaken Swarms as Good as Natural Ones.

M. A. Gill, in the Bee-Keepers' Review, says he examines his colonies each week, and "all colonies that are going to swarm will be shaken into new hives with starters, setting the new hive on the old stand and carrying the brood, with just enough bees to protect it till the brood hatches, to the new stand. This usually 'fixes' swarming as far as such colonies are concerned.

"I must confess that the longer I practice the shaking-off plan, when colonies are going to swarm anyway, the better I like it. Much has been said about a colony being a unit, and that we can not sort them with proper regard to age, but I find that is more in theory than in practice. I find little if any difference between natural or shaken swarms that are now two weeks old, and it's certainly a great advantage in out-apiaries."

A Dog that Watches for Swarms.

This is reported in Gleanings in Bee-Culture. Its owner, H. S. Ferry, says:

This dog is half Newfoundland and half St. Bernard, both thoroughbred. The kennel has a four-light window, where he can see the apiary; and if there is anything unusual going on in the apiary he is sure to notify us. If there should be a swarm, or an extra buzzing in the apiary, he is sure to call some of us before they alight or leave the yard. I never have had a swarm of bees leave the yard as long as this dog has been in charge. He weighs 150 pounds, has a good disposition, and understands the nature of the bees as well as any dumb creature can, and much better than some human beings. He will go among the bees. They do not seem to meddle with him. He is not afraid of them, and is kind to his owners and those who take care of him, but is proof against intruders. So far as value is concerned, he is beyond price. Money would not buy him.

Comb and Extracted in the Same Apiary.

This has been advocated by Mrs. A. J. Barber heretofore, but the experience of this year makes her more in favor of it than ever. She says in the Rocky Mountain Bee Journal:

All colonies that have been run exclusively for comb honey are full of honey in the brood-chamber, so full that in many cases there is not even a cell of brood or an egg. At first we thought there must have been a wholesale murder of queens, as there was no brood, but upon close examination queens are found

healthy and fine looking. The bees refuse to work in sections.

We had a warm winter, and the bees were very strong and active in March, and had hives full of brood. We had a cold May, and brood-rearing checked. In June we had a freeze that killed all bloom, and bees almost starved. During the freeze, and after, a great many bees went out and never came back in their hives. In spite of heavy feeding brood-rearing almost ceased, and bees nearly starved. About July 5 the alfalfa bloom seemed to begin to yield honey all at once, and the bees within two or three days filled every cell with honey, and as they had become somewhat weakened in June they were not in condition to fill the sections, so they are cramming every cell in the brood-chamber with honey and doing almost nothing in sections, and getting weaker every day. As there is now a very severe drouth we are likely to have our first experience in failure this year.

The colonies having a super of half-depth extracting-frames fared some better, as the bees began to fill them as soon as the honey came, and when I raised them and put sections under, the work went right on as long as the honey-flow lasted, and the brood-chamber was relieved so that those colonies are in fair condition. I have extracted some of the small frames and given them to the bees that had no brood, and it acts like a charm. The bees are storing in the extracting-combs and giving the queens room so that the colonies may be in condition for a flow if we have one.

I am getting to be a stronger advocate of producing both comb and extracted honey at

DIRECT FROM FACTORY

Immediately on receipt of this certificate we will ship this regular \$65 strictly high-grade Ball-Bearing 30 Days' Trial ARLINGTON Sewing Machine on 30 Days' Trial explained above. NOTE—If you send cash in full with your order we will refund your money, including the freight charges, if at any time within one year you become dissatisfied with your purchase for any reason.

THE BALL BEARINGS prevent friction and afford absolute ease to the operator. The balls are large size made from fine tool steel and run in an oil tempered steel cup which is adjustable.

PROMPT SHIPMENTS

There will not be any delay in filling your order, we have the machines, thousands of them, all tested and crated ready for shipment.

CASH BUYERS' UNION, Dept. M 609 CHICAGO, ILL.

IT IS VERY IMPORTANT THAT YOU MENTION THE AMERICAN BEE JOURNAL WHEN WRITING TO THE CASH BUYERS' UNION. PLEASE DO SO.

the same time, in the same apilary. I have believed in it for the last six years, and this year has decided the question for me. As soon as possible I shall have a super of small frames for every hive I possess. Some seasons there is but little advantage in them, and I should not use, perhaps, more than half of them after they were taken off in the spring, but even that half would pay for itself in getting the bees into the sections, and this other half would be used over and over on the colonies that were inclined to loaf, securing many a pound of honey that I should not get otherwise.

Greasing the Valve of a Smoker.

This is recommended by S. E. Miller. He says in the Progressive Bee-Keeper:

Probably every one knows that machinery works best if well greased, but I doubt whether many bee-keepers know that a smoker requires greasing. Yet they all know that at times a smoker gets choked up and wheezy. This is caused by the sticky, sooty accumulation being sucked back into the bellows, because the valve gets stuck and does not admit the air freely into the bellows. The more of this accumulation that gets sucked into the bellows the worse the valve will stick, and the worse the valve sticks the more of it is sucked back, so that we have an aggravated state of affairs. To keep the valve from cleaving to the inside of bellows, oil it freely with machine oil, or any good lubricant, and

as often as it shows a tendency to cleave give it more oil. If the valve has become thickly coated with the soot, it may be necessary to take the bellows apart and put in a new valve. Then keep the valve thoroughly oiled, and you will have very little trouble. This sooty accumulation is much worse in damp weather when the atmosphere is heavily charged with moisture, than it is in dry, clear weather. We should, therefore, watch the smoker to see that it does not get "stuck on itself" at such times.

CONVENTION NOTICES.

Utah.—The Utah Bee-Keepers' Association will hold the annual convention in the City and County Building, Salt Lake City, Utah, Oct. 6, 1902, at 10 a.m. Business of interest to all bee-keepers will be presented. All are invited.
J. B. FAGG, Sec.

Illinois.—The annual meeting of the Northern Illinois Bee-Keepers' Association will be held at the Court House in Freeport, Ill., on Tuesday and Wednesday, Oct. 21 and 22, 1902. All interested in bees are invited to attend.
Cherry Valley, Ill. B. KENNEDY, Sec.

New Jersey.—The first annual meeting of the New Jersey Bee-Keepers' Association will be held at 10 a.m., Thursday, Oct. 2, in the Club House on the Inter-State Fair Grounds, Trenton, N. J. We extend a most cordial invitation to all bee-keepers, and others interested in bee-culture, to be present.
GEORGE N. WANSER, Sec.

B. F. ONDERDONK, Pres.

PERSONAL TO SUBSCRIBERS

WE WILL SEND to every subscriber or reader of the American Bee Journal a full-sized ONE DOLLAR package of VIT-E-ORE, by mail, POSTPAID, sufficient for one month's treatment, to be paid for within a month's time after receipt, if the receiver can truthfully say that its use has done him or her more good than all the drugs and drops of quacks or good doctors or patent medicines he or she has ever used. READ this over carefully, and understand that we ask our pay only when it has done you good, and not before. We take all the risk; you have nothing to lose. If it does not benefit you, you pay us nothing. VIT-E-ORE is a natural, hard, adamantite rock-like substance—mineral—ORE—mined from the ground like gold and silver, and requires about 20 years for oxidation. It contains free iron, free sulphur and magnesium and one package will equal in medicinal strength and curative value 800 gallons of the most powerful, efficacious mineral water, drunk fresh at the springs. It is a geological discovery, to which there is nothing added or taken from. It is the marvel of the century for curing such diseases as Rheumatism, Bright's Disease, Blood Poisoning, Heart Trouble, Diphtheria, Catarrh and Throat Affections, Liver, Kidney and Bladder ailments, Stomach and Female Disorders, La Grippe, Malarial Fever, Nervous Prostration and General Debility, as thousands testify, and as no one, answering this, writing for a package, will deny after using. Give age, ill and sex.

This offer will challenge the attention and consideration, and afterward the gratitude of every living person who desires better health, or who suffers pains, ill and diseases which have defied the medical world and grown worse with age. We care not for your skepticism, but ask only your investigation, and at our expense, regardless of what ill you have, by sending to us for a package. You must not write on a postal card. In answer to this address:

HONEY AND BEESWAX
MARKET QUOTATIONS.

CHICAGO, Sept. 9.—Comb honey is beginning to come forward and is meeting with fair demand. The prices at present are 15¢/16¢ for the best lines of No. 1 fancy white; other grades are wanted at 2 to 5 cents less per pound, but they are scarce. Extracted sells at 6¢/6½¢ for white, according to the kind and quality; 5½¢/7¢ is obtainable for the amber grades. Dealers are seeking what they term a "honey" flavor more than ever before, as they say their customers demand more sweet taste in honey. Beeswax is scarce, and brings 30¢.

KANSAS CITY, Sept. 13.—The demand still continues good for comb honey, but receipts are very light and meet with ready sales at these quotations: Fancy white comb, 15¢; No. 1 white, 14¢; No. 2 white and amber, 13¢; dark, 12¢. Extracted, white, 6¢/6½¢; amber, 5¢/5½¢. Beeswax, 22¢/25¢. C. C. CLEMENS & Co.

CINCINNATI, Aug. 30.—The demand for comb honey at present is very good; all shipments are sold quick at 15¢/16¢ for No. 1 and fancy. We advise shipping while demand is good and before the western carloads are here. In three weeks from now carloads will arrive, then demand is satisfied, sales harder to make, and prices demoralized. Extracted honey is selling as fast as it arrives, at the following prices: Amber and Southern in barrels, at 5½¢/6½¢, according to the quality. White clover, 7½¢/8¢. Beeswax is scarce at 30¢.
THE FRED W. MUTH CO.

ALBANY, N. Y., Aug. 22.—The demand for honey is improving with the unusual cool weather, the summer resorters returning home hungry. We quote: Extra white comb, 15¢/16¢; medium, 14¢/15¢. No other grades coming yet.

We want to caution shippers against shipping by express, as it arrives almost invariably broken. Express companies are stamping the cases "Received at owner's risk," which seems to cause their employes to "play ball" with it. Freight haulders are slower, more careful, and less broken, and much cheaper. We advise sending by freight only. H. R. WRIGHT.

NEW YORK, Aug. 11.—New crop comb honey from New York and Pennsylvania is beginning to arrive in limited quantities. There is a good demand for fancy white at 14¢, and No. 1 at 13¢, and exceptionally fine lots will possibly bring a little more. Lower grades quiet at from 10¢/12¢. As to extracted honey, fancy grades are in good demand at from 6¢/6½¢ for white, and 5¢/5½¢ for light amber. Southe in barrels and half-barrels quiet at from 47¢/60¢ per gallon, according to quality. Beeswax dull at from 27¢/28¢. HILDRETH & SEGELKEN.

CINCINNATI, Aug. 29.—New comb honey is not coming in so plentiful, so far. Whatever has come in, and is fancy water-white, has brought a good price, and sold to stores at from 15¢/16¢. Honey kept over from last year, fancy sells for 14¢. The market for extracted is more lively and brings: Amber, from 5¢/5½¢; alfalfa water-white, from 6¢/6½¢; white clover, from 7¢/7½¢. Beeswax, 28¢. C. H. W. WEBER.

SAN FRANCISCO, Aug. 20.—White comb, 13¢/14¢; amber, 10¢/12¢; dark, 8¢/9¢. Extracted, white, 5½¢/5¾¢; light amber, 5¢/5½¢; amber, 4½¢/—; Beeswax, good to choice, light, 27¢/29¢; dark, 25¢/26¢.

Not much offering or arriving of any sort. While the market is firm throughout, current values are being better sustained on comb than on extracted, for the reason that the latter has to depend to some extent on outside demand. All the comb honey offering will be required locally. The shipment of comb honey has never proved satisfactory, and the production is in consequence restricted to small compass.

Home Visitors' Low-Rate Excursion.

Sentiment inspired by patriotism has, and it is to be hoped always will afford, a one-cent-a-mile rate to enable the "Boys in Blue" to assemble in reunion at least once a year, from all points of the compass. Such a rate is authorized from all points east of Chicago to Washington for this purpose in October, 1902. Such a rate has been afforded once a year since the first reunion of the veterans of the war of '61. This especially low rate has become popular, not only for the purpose for which it was established, but for other purposes, chief among which we recognize the opportunity thus afforded to visit friends, at or convenient to, the place of reunion, because of the low rate, and because of the favorable opportunity by reason of the liberal extension of time limit for return.

On dates authorizing sale of Grand Army Excursion Tickets to Washington, for the Reunion of 1902, are also authorized similar reductions in rates, from all points west of Chicago, with time limits the same as on such tickets to Washington, excursion tickets to any point in the territory of the Central Passenger Association, on or reached by the Nickel Plate Road. For full information call on your most convenient interline ticket agent by mail, wire, phone, or in person, or on John Y. Calahan, General Agent Nickel Plate Road, 113 Adams St., Chicago, Ill. 38A1t

APIARY OF MR. W. H. HORSTMANN, OF COOK CO., ILL.—(See page 612.)

A STANDARD-BRED QUEEN-BEE FREE

To Our Regular Paid-in-Advance
Subscribers.

We have arranged with several of the best queen-breeders to supply us with **The Very Best Untested Italian Queens** that they can possibly rear—well worth \$1.00 each. We want every one of our present regular subscribers to have at least one of these Queens. And we propose to make it easy for you to get one or more of them.

In the first place, you must be a regular subscriber to the American Bee Journal, and your own subscription **must be paid in advance**. If it is not already paid up, you can send in the necessary amount to make it so when you order one of these fine Queens.

A Queen Free for Sending One New Subscriber

Send us \$1.00 and the name and address of one **NEW** reader for the American Bee Journal, and we will mail you one of the Queens free as a premium.

Now, go out among your bee-keeping neighbors and friends and invite them to subscribe for the old American Bee Journal. If you want some to show as samples, we will mail you, for the asking, as many copies of the American Bee Journal as you can use.

Should there be no other bee-keepers near you, and you desire one of these fine Queens any way, send us \$1.50 and we will credit your subscription for one year and also mail you a Queen. Of course, it is understood that the amount sent will pay your subscription at least one year in advance of the present time. So, if your subscription is in arrears, be sure to send enough more than the \$1.50 to pay all that is past due.

As the supply of these splendid Queens is limited, we prefer to use all of them as premiums for getting new subscribers. But if any one wishes to purchase them aside from the Bee Journal subscription, the prices are as follows: One Queen, 75c.; 3 Queens, \$2.10; 6 Queens for \$4.00.

We expect to be able to fill orders by return mail, or almost as promptly as that, so there will be no great delay at any rate.

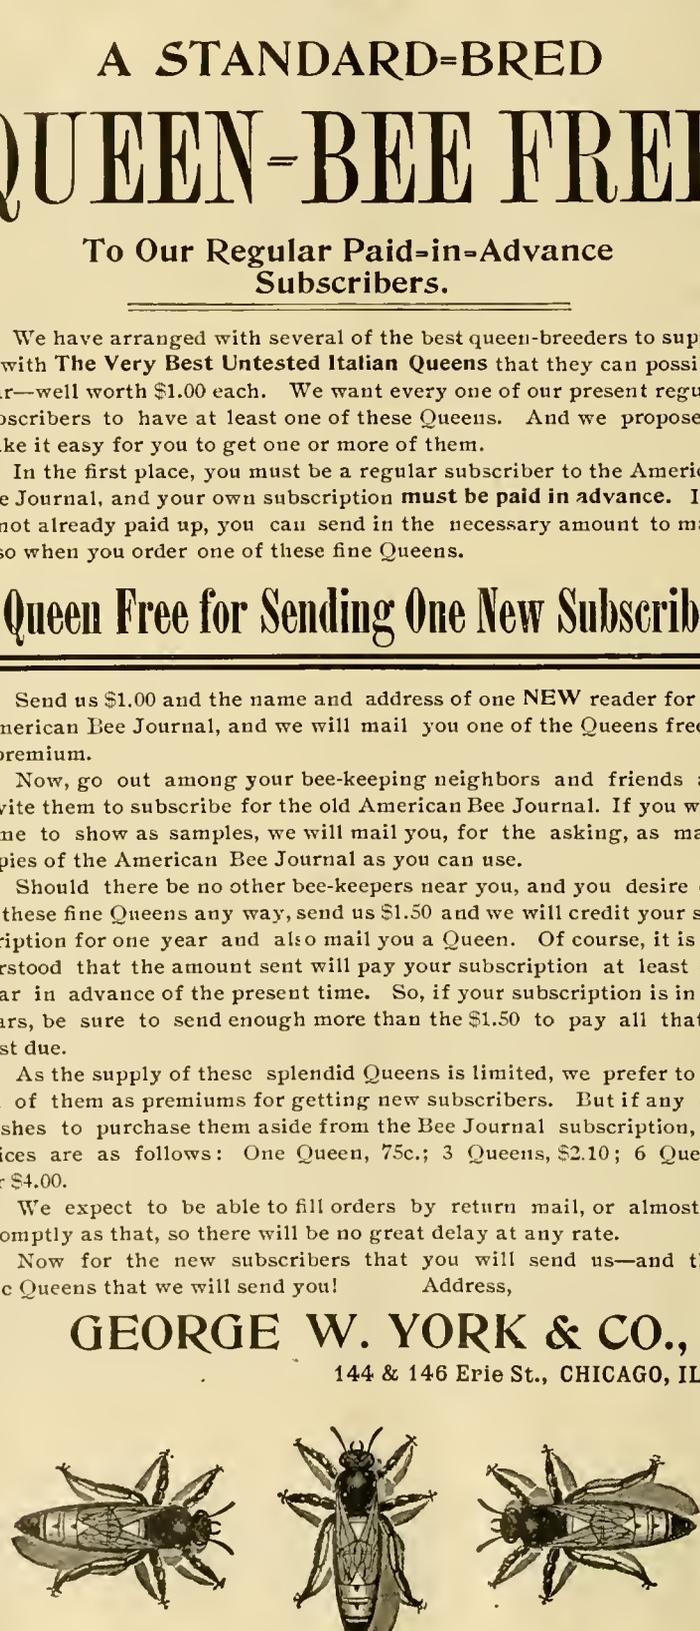

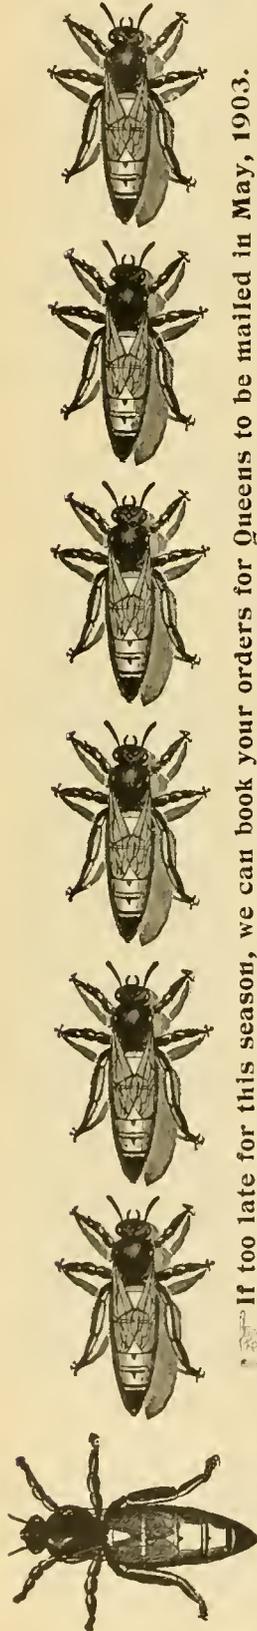

Now for the new subscribers that you will send us—and then the Queens that we will send you! Address,

GEORGE W. YORK & CO.,

144 & 146 Erie St., CHICAGO, ILL.

If too late for this season, we can book your orders for Queens to be mailed in May, 1903.

If too late for this season, we can book your orders for Queens to be mailed in May, 1903.

* Editorial Comments. *

The Denver Convention Report we expect to begin to publish next week. It will be interesting reading. It would be a good time now to get your neighbor bee-keepers to subscribe for the American Bee Journal, to begin with the number commencing the Denver convention report. Why not do it?

The National Bee-Keepers' Association.—In this number of the American Bee Journal will be found two articles which bear on the advantages or benefits to be derived from a membership in the National Association. In view of the statements made by Mr. V. Shebat, of Minnesota, it seems to us that instead of only 1000 bee-keepers being members at present, there ought to be from five to ten thousand members.

We do not see how any bee-keeper can feel that he can afford not to be a member. It costs only \$1.00 a year, and even if a member receives no direct benefits himself, he has the satisfaction that he is helping in a splendid cause.

The National Association has done more, perhaps, than all other bee-keepers' organizations combined, in this country, to place the industry of bee-culture on a firmer foundation, and secure for it the rights that it justly deserves. But its work has only begun. And yet, in view of its wonderful success with only a handful of members and dollars, what might it not do if it had five or ten times as many members and dollars?

We trust that all the readers of the American Bee Journal will join as soon as possible. We stand ready to receive their membership dollars and forward them promptly to the General Manager, if it is more convenient to send the money to us than to him direct.

Shall we not have a rapid stream of new members and dollars flowing in from this time on?

The Mission of Drones.—Prof. J. W. Spengel, of the University of Giessen, contributed to the Deutsche Revue an article of which a translation was published in the Literary Digest. This translation is copied in the Rural Californian, and at its close C. N. Wilson makes the following comment:

Dr. Joseph Warder, of Crydon, England, in his now rare work entitled, "The True Amazons, or the Monarchy of Bees," published in London in 1765, devotes a chapter on heredity of bees, and handles the subject from a practical standpoint, giving the drone-bee credit for generating the heat in the hive, whereby the temperature is maintained in the hive sufficient to hatch the eggs, both of queen, workers and drones.

The translator for the Literary Digest is therefore in error when saying, "The entire mission of the queen and

drone is reproduction of their species; the queen being assiduous in the deposit of eggs, the drones stupid and slothful." Dr. Warder understood the drone's duties and usefulness better in 1765 than the translator for the Literary Digest does in 1902.

It is just possible that the translator for the Literary Digest may be so ignorant about bees as not to know a drone from a worker, but is it fair to hold him responsible for the sins of Prof. Spengel? If he has made a faithful translation, he can hardly be said to be in error.

The question is whether Prof. Spengel or Mr. Wilson is in error. Prof. Spengel has plenty of company in believing that no special value attaches to the drone as a heat-producer. Does Mr. Wilson believe that by having a full frame of drone-comb in the hive there will be more heat produced than if no drone-comb was in the hive? An equal weight of workers will produce just as much heat as drones, and this heat costs nothing, for the workers will produce more heat while busily acting as nurses than while remaining idle like the drones. The time when the drones produce the greatest amount of heat is when they are out of the hive whetting their appetites for a fresh meal to be taken when they return, and this heat can hardly be said to be utilized.

How to Burn Foul Brood.—The editor of Gleanings insists strongly that it should be "burned at night, when the bees are all in the hive." If done in the day-time there is danger that some of the bees will carry the disease into other hives. He does not advise burning bees as well as combs, except in very bad cases, or when it is the only case known in the bee-yard. A detailed account of the way he treated one case when he could not throw all into a boiler-furnace is thus given:

Once, when treating a case of foul brood, or, rather, burning it up, in an outyard, I started a big blaze in a brush-heap near-by; but to make the blaze hotter I threw on a quart of coal-oil. Then I placed the hive as near the fire as I could, picked out the combs and the bees, and threw them one by one into that raging flame. When the bees flew up (for it was night) they would go right into the fire, of course, and that was the end of them. Then I took the hive, held it up by means of a pitchfork, and thoroughly scorched the walls inside and out. Next, in like manner, I treated the cover; but while the fire was raging I could see the melted wax running down between the fiery embers to the ground. I marked the spot, and when the brush-heap burned down I raked the hot coals right over that place, then pawed over the ground with a rake and pitchfork. I made up my mind that I would thoroughly disinfect the ground; and the next morning I found the live coals had been so hot that the clay was turned red—in fact, it was turning into common brick. I had no doubt the whole thing had been disinfected, including the hive.

Writing for the Papers.—Barring the high price put upon pen and pen-holder, the following words from the editorial columns of the Bee-Keepers' Review are well spoken:

A bottle of ink can be bought for five cents. A pen and wooden pen-holder for five cents more. There is no

excuse for not having these two articles in every house where there is any occasion for their use; and when they are provided, let them be used whenever there is a letter or postal to write.

One thing more, good writing paper is cheap enough so that there is no excuse for using the thin, slazy, spongy, dingy stuff that is sometimes used.

I am led to make these suggestions, as so many communications come to this office, and I presume it is the same at other offices, which are written in pencil on a postal, and the shuffling about in the mails often rubs the writing until it is scarcely visible. Then, to add to the difficulty, the writer often miscalculates the length of his communication, and, as he approaches the bottom of the card, he crowds the words closer and closer, and writes finer and finer, and the signature is so crowded that it is often impossible to decipher it. If you find that a postal will not hold all that you wish to write, throw it aside and take a sheet of paper. If one sheet will not hold it, take another.

Attention to these things will add greatly to the comfort of those with whom you have correspondence, and may be to your own advantage, as a communication that is undecipherable, or that is misunderstood, may result in a serious disappointment to the writer.

By way of postscript, however, it may be well to say that if you have learned some fact as to bee-keeping that has not before been given to the public, no matter how little a fact, editors will be glad to have you write upon "any old thing" in any old or new way, just so they get the fact, and they will appreciate it all the more if they can read it first time trying.

* The Weekly Budget. *

MR. FRANK B. WHITE, formerly of the well known Frank B. White Company, of Chicago, has been employed as Advertising Manager of the American Bee Journal, and will assume his duties at once. He recently disposed of his interest in the company which he organized, and which has been so successful under his able management. We have known Mr. White intimately for a number of years, and count him as one of our most highly esteemed personal friends. And in adding him to our force of helpers, we know we have secured the services of a gentleman whose knowledge of the advertising business will not only add to our patronage along this line, but whose original methods will make the American

Frank B. White.

Bee Journal more valuable to our patrons. With 16 years' experience as a promoter of good advertising, Mr. White knows how to originate effective methods of publicity, and the great business built up by the Frank B. White Company, while he was at its head, is the best evidence of his capacity in this direction. No man is better known among advertisers than Mr. White, and we are free to say no man

has built up and maintained a better reputation than he bears to-day.

We are pleased to introduce Mr. White to our readers and advertisers, and we trust the latter will feel free to confer with him in regard to their advertising, for he will likely be able to help make it more effective and profitable in every way, and thus not only be a great aid to the advertisers, but also to the old American Bee Journal.

We bespeak for our Advertising Manager the hearty co-operation and encouragement of all in his important work.

We feel like congratulating our advertisers, and ourselves as well, in being able to secure the services of Mr. White.

PRES. W. Z. HUTCHINSON AND O. L. HERSHISER called on us when on their return trip from the Denver convention. Mr. Hershiser is the vice-president of the National Bee-Keepers' Association for 1902. He is one of the big bee-keepers of New York State—both in number of colonies and in his avoirdupois.

MR. M. M. BALDRIDGE, of Kane Co., Ill., gave this office a pleasant call last week. He is one of the oldest bee-keepers in the ranks, and yet one of the liveliest in every way. He and Dr. C. C. Miller are a pair of "old timers," and yet in spirit and "git-up-and-gitness" they are as much "new timers" as any can possibly be.

DEATH OF FRANK BALCOM.—Mr. Francis H. Drake, of Worcester Co., Mass., wrote us as follows Sept. 11:

"I beg to inform you of the sad death of my esteemed friend and brother bee-keeper, Mr. Frank Balcom, of East Brookfield. He died Aug. 22, of typhoid fever. He started right by getting the "A B C of Bee-Culture" and the American Bee Journal, and showed great interest in the study of apiculture. I feel that we have lost one who would have been a credit to the craft. He was 21 years of age."

MR. THOS. CHANTRY, of Clay Co., S. Dak., recently met with a great misfortune, in the loss by fire of his crop of honey, worth about \$1200, and a house and contents worth as much more. Nothing was saved. Mr. Chantry was working at an out-apiary at the time of the fire, and the man who was working where the fire occurred had gone to dinner, and as there was no water-works all was destroyed. This loss will undoubtedly fall very heavily on Mr. Chantry, but he is a man not easily discouraged, and in time will be on top again. That's a way those South Dakotans have.

MR. WM. H. HORSTMANN, and his good little wife, are two of the best bee-keepers in this (Cook) County. And they have one of the prettiest apiaries we ever saw. We show a part of it on the first page this week. We visited it on Saturday, Aug. 16. In the center of the yard, as will be seen, is a miniature model of the National Capitol Building, at Washington, D. C. Mr. Horstmann made it all with his own hands last winter. Of course he is a genius, as well as one of Uncle Sam's numerous family of postmen.

There are three full colonies and one nucleus in this Capitol Building. Across each end (one named "Garfield" and the other "McKinley") is a colony having about 30 Langstroth frames, all in the brood-chamber; the center hive (named "Lincoln"), which extends from one end colony to the other, has about 40 frames. These three are really "Long Ideal" hives. The rear colony is a three or four frame nucleus. It will be seen that there is room in this unique fourfold "hive" for a good many bees. They were put in on July 4, and as the season has not been a good one, none of the colonies in it were strong. Undoubtedly it is the only "hive" of the kind in the world. The

whole building rests on a raised cement platform. It is indeed a curiosity, with its little columns and gilded dome surmounted with a miniature statue that reminds one a little of "Liberty Enlightening the World."

Mr. Horstmann has all his colonies named as well as numbered. For instance, there are Doolittle, Dr. Miller, Root, Dadant, Mason, Yates, Brown, Duff, Mary, etc. Some hives are double, and are set up on posts, as he used to cultivate the ground as a garden. Now it is all a beautiful lawn, but he has let the short posts stand just the same.

Last year he had a crop of 1700 pounds of comb honey from 19 colonies. This year he has some 30 colonies, but doesn't expect much of a crop of honey.

From Mr. Horstmann's apiary we went about two miles on street-cars to see Mr. P. N. Duff's beautiful apiary, managed by Mr. Frank Brown. But Mr. Duff was not at home. He has over 150 colonies. But we will have to go and see it again some time when Mr. Duff is at home, and then tell our readers all about it.

Convention Proceedings.

Some Facts in Favor of Joining the National.

Read at the last Minnesota Bee-Keepers' Convention

BY MRS. H. G. ACKLIN.

We were on the verge before of seriously discussing this very important proposition, and now that we are fully launched I trust we will remain in the turbulent waters until every bee-keeper in Minnesota has his or her name enrolled as a member of the National Bee-Keepers' Association.

If bee-keepers will commence thinking about this matter seriously and intelligently, and without prejudice of any kind, I feel sure that the result of such thinking will be to bring every one into the Association. Every one will admit that we need something of the kind; and if this Association does not quite come up to our standard in this, that or the other thing, let us bring it up to where we want it in every particular. The members have the power to do that very thing. The Association is wholly democratic. Its officers are elected by the members. If a change in the constitution is proposed, it must be ratified by a vote of the members. One person has just as much "say" as another, no matter if the other fellow can talk louder and longer.

There is no class of bee-keepers but need something more majestic, more awe-inspiring, as it were, to refer inquisitive people to, than their own State association. The millennium is not quite here; consequently we have with us yet some people who are envious and spiteful to a certain extent. They do not like to see their neighbor "get on" in the world; and if they can cause him trouble and expense without much trouble to themselves, they are happy. Bee-keeping seems to be such an easy business to attack. Some one gets stung, maybe by a hornet or wild bee; but there is a bee-keeper in the vicinity and he is made to suffer. The wrathful stinger comes to him and says:

"I got stung by one of your bees, and am going to take steps immediately to have them removed."

The chances are he would not use quite as mild language as the above. Then is the time, if the bee-keeper did not belong to the National, that his heart would go pit-a-pat. But he does belong to the National, and he calmly says:

"Very well, my friend; but before you commence proceedings it might be well for you to look into this thing a little. Every bee-keeper in the United States and Canada stands behind me with their money and influence ready to help if I am unjustly attacked."

The stinger grumbles some more, but goes away with a more serious look on his face, and the bee-keeper hears nothing more about it.

You may say that this supposititious case is overdrawn. Not so; I will cite you a circumstance of our own with the same result minus the sting.

The house next to us is rented. The tenant came in after the bees were put into the cellar. He was a shiftless fellow; his wife did washing to support the family. Before the bees were taken out in the spring he went to his landlord and said he could not live there on account of the bees; but if the rent could be reduced he would try and put up with the bees! Just remember, he had not yet seen the bees!

The landlady came to our house perfectly wild. We could not reason with her; in fact, she would not listen to a word from us. After about an hour we managed to get in a word about belonging to two bee-keepers' unions, while she was taking breath. The effect was magical. In a few minutes she cooled down, and we were able to talk with her. When she found that her tenant had not even seen the bees, she was disgusted and said he should not live there if he wanted to.

There is another instance of a disgruntled man. He was working for us, but did not do his work well. We let him go and he was angry. He and another envious person were planning to get up a petition to have our bees removed. Some of our friends told us about it, and we spoke about belonging to the National, and that news became circulated around, and we never heard anything more of the plot. These same people are as friendly to us now as of yore. We never speak of belonging to the National Association unless forced to do so.

Again, there are other good offices of as much importance as the above which a National Association can perform. The matter of adulteration is a very serious affair, and is being coped with successfully in several places, as we will see later. Dishonest commission men is another evil which the National must fight. Helping the bee-keepers to dispose of the honey crop to the best advantage is another branch of work which the National organization will take up more fully later on.

There is no limit to the amount of good this Association might do, if it only had the moral and financial support of every bee-keeper, but it can not work single-handed. There must be funds to meet the expense of all this work; and there must be co-operation and sympathy in the rank and file of bee-keepers to give the officers courage to go ahead and do the greatest amount of good in all branches of the work.

I think we have reason to be proud of the record made by the National Association in the past. And it need not take a prophet, nor even the son of a prophet, as we peer into the dim future, to see, nay, almost to realize, the great results for good which this organization can and will accomplish if not handicapped for funds.

Now, dear friends, I believe it would be an advantage to all of us to join the National Association in a body. That means 50 cents for our State Association and 50 cents for the National Association. That is a saving of 50 cents each, as the membership fee in the National is \$1.00 if we join singly.

After I was put on the program for this paper, it occurred to me that Mr. E. R. Root would be an excellent person to get some facts from, and I wrote to him to that effect, with the following result:

ADVANTAGES IN JOINING THE NATIONAL.

MRS. ACKLIN:—You ask for some facts in favor of joining the National Bee-Keepers' Association. Stating them off-hand, and on the spur of the moment, they come to my mind about as follows:

It is the only national organization that is putting up an effective and successful fight against adulteration. Through the efforts of the organization Illinois has a pure food law, and through the action of that law adulteration of every form has been practically driven out. When it is remembered that Chicago was the very hotbed of the honey-mixing business, the work of the organization stands out as something to be proud of.

But not only in Illinois, but in several other States, the organization has been doing effective work against adulteration.

Second—The National Bee-Keepers' Association has, through the operation of law, brought about many valuable precedents, so many of them, in fact, that bees would not be declared a nuisance, and in every city or incorporated village of the United States they are allowed to be kept. The organization brought about this result by appealing to the Supreme Court of Arkansas in the Arkadelphia case, and won in this court. It has defended the rights of bee-keepers in various kinds of suits, and in every case has won. You are doubtless familiar with the full facts con-

cerning the Utter vs. Utter case, that resulted in a verdict for the bees. Many other incidents might be cited, but I can not give them from memory.

Third—The National Bee-Keepers' Association is the only organization that is national in its general character. It is, therefore, the representative national body through which the interests of bee-keepers throughout the United States are cared for. Besides the annual meetings, which are a constant source of inspiration and help to the bee-keepers wherever it goes, it has added to its credit something like \$1000, and a membership of nearly 1000 bee-keepers. Its power is getting to be tremendous; but there are many things it can not do for lack of funds and lack of membership; and every one who is interested in advancing the interests of bee-keeping should enroll himself as a member. Your whole organization ought to join in a body, thus securing the privilege of the benefits at 50 cents per member: but to get this rate of 50 cents your society should *join in a body*.

Yours respectfully,

E. R. ROOT.

Mr. Root was president for two years, and has been one of the directors for a number of years of the National Association, and knows whereof he speaks.

We have attended the last three National conventions, and, I tell you, it is a treat no bee keeper should miss. If one ever comes your way be sure to make an extra effort to attend. The deliberations are interesting and instructive, and one realizes, as never before, the hearty good-will existing among bee-keepers.

Contributed Articles.

Benefits of Being a Member of the National.

BY V. SHEBAT.

I desire to say a few words through the American Bee Journal to the bee-keepers of America.

I have been a member of the National Bee-Keepers' Association for 12 years, but I have never appreciated the value of a membership in the organization until this summer.

I have lived in this city for many years, and for more than 13 years have kept about 60 colonies of bees on a lot that I own here, and have never had any complaint made to me about my bees doing any damage or being a nuisance in any sense of the word until this summer.

A large church is situated on the corner opposite the lot where my bees are located, but no complaint was ever made that they annoyed or injured any one. This summer a large church school for girls was commenced on the lot adjacent to mine, and a city ordinance was manipulated through our city council declaring it a misdemeanor for any one to keep bees in our city "within 600 feet of any church, schoolhouse, or other public building, or within 300 feet of any dwelling in said city." This ordinance was passed in the latter part of July, and within a few days thereafter two actions were begun against me under said ordinance, and one under our State law, which declares, "Any act or omission which injures, annoys, or endangers the comfort, repose, health, or safety of any considerable number of persons a public nuisance." These were all criminal actions, and I was arrested in each case.

The case under the State law was virtually abandoned for lack of evidence, and I was declared not guilty, but the case under the new city ordinance was prosecuted with bitterness and venom. The trial was in our Recorder's Court before a jury, and lasted the whole of one day.

My attorney, Col. J. T. Bowditch, defensed me on the following grounds, viz.:

1st. That the ordinance was not authorized by our city charter.

2d. That the city council had no power to make a nuisance of any act by passing an ordinance against it, unless the act itself was *in fact* a nuisance.

3d. That the ordinance in question resulted in taking and damaging private property for public use without just compensation to the owner, contrary to the Constitution of the United States and of this State; that it abridged the

natural rights of private citizens; that it was unreasonable and unjust.

4th. That if the keeping of bees contrary to the terms of the said city ordinance was a nuisance at all it was a *private nuisance*, for which all persons injured thereby had their redress in the courts, and was such a nuisance that could not be regulated by any general ordinance or law.

These were the main points in my defence, but, of course, each one was greatly elaborated by my attorney.

I am happy to say that the jury returned a verdict "Not guilty," and I have since received the congratulations of many bee-keepers on the happy ending of the vicious fight that was made against me.

My chief object in writing this communication is to thank the National Bee-Keepers' Association publicly for the valuable aid it rendered me in this fight, and to impress upon all bee-keepers the benefits derived from belonging to such an organization.

In the beginning I informed the officers of the Association of the passage of the ordinance and dangers threatening me. *They at once forwarded to me valuable briefs for the use of my attorneys, and suggestions how to proceed if I should be arrested. My attorney says the briefs furnished were of great assistance to him in preparing my defence, that, in fact, they lightened his labors fully one-half.*

After the case was decided I sent to the General Manager, Eugene Secor, a statement of the cases against me, and also a statement of the costs I had incurred in defending myself. I at once received a check for \$40, to pay a part of the expenses I had been put to. Surely, this is an Association worth belonging to, and it seems to me that we ought to do all in our power to support and aid any institution that does as much for us as the National Bee-Keepers' Association.

Flat vs. Grooved Top-Bars—Wiring Frames—Other Devices.

BY F. GREINER.

The ingenuity of man is always at work to improve on the things we use. The V-shaped top-bar was devised to secure straight combs. The wooden comb-guide was to accomplish the same object. But not until comb foundation came into general use did we secure the object sought for perfectly. The next question was, How best to attach the comb foundation to the top-bar of the frame? Different methods are employed. The simplest manner consisted of running melted wax along the top-bar where the comb foundation joined it. Many of us have practiced this for years. Then we thought a saw-kerf would come very handy; consequently we run our top-bars over a saw, placed the foundation in the groove, and fastened it with wax or a wedge. This brought the guide exactly where it was wanted, and appeared satisfactory. Others made top-bars of two halves and secured the foundation between them. This, also, worked well. However, when frames are used a second time a top-bar with a saw-kerf in it can not be so prepared as to make use of the kerf as when the frame was new. The saw-kerf is then nothing but a bother. Many bee-keepers have, therefore, come to the conclusion that a flat, smooth top-bar is best. They may easily be cleaned and made ready to receive again the strip or sheet of foundation.

In order to make a neat and quick job of running the starters on by hot wax a simple little implement comes very handy to dip up and administer the wax. Below is a drawing (Fig. 1) showing the little ladle as I made it. Any one

Fig. 1.—Ladle for Fastening Comb Foundation.

can fix up something of the kind from a piece of stout tin $1\frac{1}{4}$ inches wide by 5 inches long, and a piece of wood $\frac{1}{2}$ inch square and 4 inches long for the handle.

A tea-spoon may be used for the same purpose, but a ladle, like the one shown, is very much better, as the bowl of the same holds sufficient wax to run on a long strip of foundation, and with it one may direct the stream of wax just to the place where needed without the danger of spilling. It enables one to fasten foundation in the frames as rapidly as I have been able to do it by other methods.

WIRING FRAMES OF COMB FOUNDATION.

When full sheets of foundation are used, I find it at least desirable to wire the frames—even should this not be necessary in order to prevent any sagging. By wiring the frames the foundation is kept exactly in the center of the frames, just where it is wanted. Perpendicular wiring is a surer way to prevent bulging than the horizontal way. Under certain conditions foundation is quite apt to bulge. If, for instance, one wishes nucleus colonies to draw out foundation into combs it is almost necessary to wire perpendicularly. A sheet of foundation inserted in the center of the brood-nest is not likely to bulge out; just so when a young swarm is hived on full sheets. In these instances the bees go to work on both sides of the comb and draw out all cells uniformly, and at one time. Horizontal wiring answers in these cases, and as it is the easier way to wire horizontally, bee-keepers have adopted this system.

When wiring frames it is not necessary to draw the wires extremely taut; but when imbedding with the Spur wire imbedder (which I consider the best tool for the purpose), the forefinger of the left hand may be made to go in advance of the tracing wheel, pulling the wire down so that it will be curving instead of straight across, as Fig. 2 shows. When operating the Spur wire imbedder in this

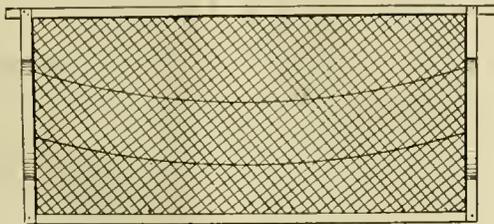

Fig. 2.—Plan of Wiring Frames.

fashion, it has to be pushed from the right to the left; not drawn from left to right. I have filled quite a lot of frames this way, and they have been built out into most beautiful combs without exception.

GETTING FOUNDATION INTO THE SAW-KERFS.

In buying our hive-material we often order the standard goods without making any specification. Top-bars with saw-kerfs come thus into our hands, although we might prefer flat bars. Sometimes these kerfs are not wide enough to let the foundation drop in readily. I just lay the sheet, or strip, of foundation upon the bench, and with a straight edge mash down the cell-walls along the edge. After this procedure the foundation will easily slip into the groove, and may be fastened in the usual way.

POINTED NAIL FOR HOLDING EXTRACTING-FRAMES.

Before closing, I wish to remind those who do any extracting, that a common 8-penny nail driven from the underside through the bar which runs across the uncapping-can is the best thing to rest the frames of honey on when uncapping them. The nail should protrude about 1½ inch above the bar and be filed sharp. I spoke of this at a bee-keeper's meeting several years ago.

These are simple little kinks, and perhaps not worth mentioning. I speak of them because we often plod along following old ruts, when a single word thrown into our path by way of advice by some friend changes our course to our advantage. I have often been helped in this same way by others.

Ontario Co., N. Y.

The Bee in Law—Statutory Enactments—
Continued from Last Issue.

BY R. D. FISHER.

9. SAME, COUNTY INSPECTOR OF BEES.

(a) Laws of Colorado, approved April 16, 1891 (Laws 1891, p. 41), provide for the appointment by the county court, upon application of the Colorado Bee-Keepers' Association, or any five actual bee-keepers resident in any county, of a competent, actual bee-keeper, resident of said county, to be county inspector of bees. Application shall be based upon information and belief that the disease known as foul brood,

or any other contagious or infectious disease, exists, and must name the actual bee-keepers of the country, so far as known to the applicants.

(b) *Oath of Office.*—The person so appointed shall, within five days, file with the clerk of the court his acceptance of the office, and the usual oath of office. The inspector shall hold office during the pleasure of the court, and until his successor is appointed and qualified.

(c) *Bee-keepers Give Notice of Foul Brood Penalty.*—A bee-keeper or other person aware of the existence of foul brood, either in his own apiary or elsewhere, shall immediately notify the county inspector, if there be one; if not, the Secretary of the Colorado Bee-Keepers' Association, of the extent of such disease, and in default of so doing he shall, on summary conviction before a justice, be liable to a fine of \$5.00 and cost.

(d) *Duty of Inspector; Owner; Treatment.*—On receiving notice from any source of existence of the aforesaid disease the inspector shall forthwith inspect each colony of bees and all hives, implements, and apparatus, honey and supplies used in connection with such apiary, and mark those he believes to be infected, and notify the owner or agent thereof; and the latter shall, within five days, carry out such treatment of the diseased colonies as may have been prescribed by the State Bee-Keepers' Association for such cases, and thoroughly disinfect, to the satisfaction of the inspector, all hives, houses, combs, honey, and apparatus used in connection with any such diseased colonies; or the owner or agent may elect, within the same time, to destroy said bees, hives, comb, comb-houses, and apparatus, by fire or burial.

It is the duty of the inspector and his assistants, after inspecting hives or fixtures, or handling diseased bees, before leaving the premises and proceeding to another apiary, to disinfect thoroughly their persons and clothing.

(e) *Box Hive—Transfer.*—The inspector may, in his discretion, order any owner or possessor of bees dwelling in box-hives in apiaries where the disease exists (being mere boxes without frames), to transfer such bees to movable-frame hives within a specified time, and, in default of such transfer, the inspector may destroy or order the destruction of such hives and bees therein.

(f) *Penalty for Selling Diseased Bees or Infected Appliances.*—Any one who knowingly sells, barter, or gives away, moves, or allows to be moved, a diseased colony or colonies of bees, be they queen or workers, or infected appliances, he shall, on conviction before any justice, be liable to a fine of not less than \$50 nor more than \$100, or to county-jail imprisonment for a term not exceeding two months.

(g) *Selling Infected Property; Exposing Infected Things—Penalty.*—Any person whose bees have been destroyed or treated for foul brood, who sells or offers for sale any bees, hives, or appurtenances after such destruction or treatment, before being authorized by the inspector to do so, or exposes in his bee-yard or elsewhere any infected comb honey or other infected thing, or conceals the fact that said disease exists among his bees shall, on conviction, be liable to a fine of not less than \$20 nor more than \$50, or imprisonment in the county jail not less than one nor more than two months.

(h) *Disobedience, and Resistance to Inspector—Seizure.*—When an owner or possessor of bees disobeys the directions of the inspector, or offers resistance, or obstructs said inspector in his duty, the latter may apply to a justice for special constable, to proceed with him to the premises of such owner, and assist the inspector to seize all the diseased colonies and infected appurtenances, and burn them forthwith, and, if necessary, cause the arrest of the said owner or possessor, and have him dealt with according to the provisions of section (g).

(i) *Inspector Must Read or Deliver Copy of Act.*—The inspector shall read over to such person the provisions of this act, or shall cause a copy thereof to be delivered to him before proceeding against him for its violation.

(j) *Annual Report.*—The said inspector shall include in his annual report to the president of the Colorado State Bee-Keepers' Association a statement of his work during the preceding year, the number of colonies inspected, the number diseased, the number destroyed by fire or otherwise, the names of the owners, and the localities where found, and the amount paid to him for his services and expenses for the year.

(k) *Compensation—Payment by County.*—The county inspector of bees receives four dollars per day, and two dollars for each half-day necessarily and actually employed, together with his necessary and actual expenses while so em-

ployed, payable by the county as other claims against the county are audited and paid.

10. SAME.

(a) *County Inspection of Apiaries.*—Laws of California (Laws of 1901, Chap. XXIV., Stat. 1901), provide that, upon petition of ten or more resident property-holders and possessors of an apiary or place where bees are kept, to the board of supervisors of any county, stating that certain or all apiaries within the county are infected with the disease known as "foul brood," or any other disease infectious or contagious, and injurious to bees, their eggs, or larvae, that an inspector be appointed by them to supervise the treatment of said bees and apiaries, the said board shall, within 20 days, appoint a suitable person, who shall be a skilled bee-keeper, inspector of apiaries. Upon petition of a like number of resident property-holders, and possessor of an apiary, the board may remove said inspector for cause, after a hearing.

(b) *Duties of Inspectors.*—It shall be the duties of inspectors in each county to cause an inspection to be made when he deems it necessary; and if any foul brood, infectious or contagious disease injurious to bees or their eggs or larvae be found, he shall notify the owner or person in charge of said apiaries, or place where the bees are kept, and he shall require such persons to eradicate and remove such disease or cause of contagion within a certain time to be specified. Notice may be served by an inspector, or by deputy, or after the manner of a summons in a civil action. Any and all apiaries or places where bees are kept, etc., found infected with disease are declared to be a nuisance; and neglect or refusal of the owner or agent to abate the nuisance within the time specified, it shall be the duty of the inspector to abate the same treatment or destroy the infected hives, bees and comb. The expense thereof shall be allowed by the board of supervisors, and paid out of the general funds of the county.

(c) *Salary.*—The salary of the county inspector of apiaries shall be three dollars a day when actually engaged in the performance of his duties.

(d) The act of 1883, approved March 30, providing for inspection of apiaries, etc., is hereby repealed.

11. SAME.

(a) *Bee Inspection; Inspector.*—Laws of Utah (Rev. Stat. 1898, Sec. 139 to 143 inclusive) provide for the appointment by the county commissioners of one or more qualified persons, inspectors of bees for their respective counties. Such inspectors shall hold office for two years, qualify and give bond. No appointment is made except on petition of a majority of the bee-keepers of said county.

(b) *Pay of Inspector; Tax on Bees.*—Inspectors shall be paid out of the county treasury for services actually rendered at such rate per day as the board of county commissioners may fix. Each colony of bees is assessed, and taxed in the same manner as other property is assessed and taxed, and collected by the county.

(c) *Duties and Powers of Inspector.*—All hives of bees in each county shall be carefully inspected at least once each year by a county inspector, where such inspector has been appointed; and, at any time upon complaint that disease exists among the bees of any person, the inspector to whom complaint is made shall immediately inspect the bees said to be affected. He shall have authority to take charge and control of diseased bees and their hives, and the tools and implements used in connection therewith for treatment; or to destroy such bees, brood, or hives and their contents, or implements, as may be infected. The owner may question a decision of the inspector concerning the presence of disease, and may appeal to three arbitrators selected from among bee-keepers of the county, one each by the owner and inspector, and the third by the two chosen, whose decision, concurred in by two of the number, shall be conclusive as to the condition of the bees at the time of such examination.

(d) *Obstructing Inspector—Penalty.*—Any person who obstructs or hinders an inspector in the performance of his duty shall, on conviction thereof, be deemed guilty of a misdemeanor, and fined for the first offense not less than five nor more than twenty-five dollars; and for additional offense, any sum not exceeding fifty dollars.

12. SAME.

Inspection of Apiaries; Inspector; Appointment, Duties, and Compensation.—Laws of Wisconsin (Wis. Stat. 1898, Sec. 1494f) provide for the appointment, by the Governor, for a term of two years, a State inspector of apiaries. He shall, when notified of the existence of the disease

known as foul brood among apiaries, examine all such as are reported, add all others in the same locality, and ascertain whether or not such disease exists; and, if satisfied of its existence, shall give the owner or person in charge of such apiaries full instructions as to the manner of treating them. Within a reasonable time after making such examination the inspector shall make another examination thereof; and if the condition of any of them is such as, in his judgment, renders it necessary, he may burn all colonies of bees and all comb necessary to prevent the spread of the disease. Such inspector shall, before burning, give the notice provided for, and otherwise proceed pursuant to the provisions of section 1492b (covering the slaughter of diseased animals). The inspector shall make a yearly report to the Governor, stating the number of apiaries visited, the number of those diseased and treated, and the number of colonies of bees destroyed, and of the expenses incurred in the performance of his duties. Said inspector shall receive four dollars for each day actually and necessarily spent in the performance of his duties, and be reimbursed in any sum not to exceed five hundred dollars per year.—Gleanings in Bee-Culture.

The "Old Reliable" seen through New and Unreliable Glasses.
By E. E. HASTY, Sta. B Rural, Toledo, O.

ROBBERS-BEES STINGING THE ROBBED.

I guess all will agree that *sometimes* robbers sting the bees they are trying to plunder. Probably a good many (on talking the matter over and refreshing their memories) will agree that sometimes they do not. Manifestly the off-hand expectation, judging bees by human beings, would be to expect the robbers to be first and fiercest to begin slaughter; but jumped-at conclusions are notoriously apt to be wrong. The point on which more reports of exact and careful observation would be welcome is, Do robbers *usually* make free to kill? In all cases where assailants and assailed are different looking bees, the dead lying around can be inspected. That's something; but the observed deportment of the two parties at different stages of the muss is needed also. Different races and strains of bees are liable to differ somewhat in their robbing manners. Also old, experienced robbers are liable to differ from those robbing a hive for the first time. Our more usual robbing is by bees that personally never robbed a hive before. Bee-life is short. Also the colony has not recently robbed—not often enough to keep up a continuous tradition and set of tactics.

ITALIAN BEES TURNING TO BLACKS.

On page 537, "Minnesota" thinks all the bees in his locality are from one parent lot of all-yellow bees. Dr. Miller doubts very strongly. The puzzle is, they're getting black. It occurs to me that we have had, first and last, rather too many such reports to ignore. I'm getting about ready to admit that Italians subjected to close in-breeding do sometimes let the black element of their blood come to the front. Not much doubt that Italians were in their origin a mixture of some yellow oriental race with blacks—the mixture being unified and modified by many centuries of time.

FEEDING HONEY TO PRODUCE WAX.

Loyalstone's practical work at getting nearly a pound of wax from five pounds of fed honey—especially the continued success for four years—that's getting things out of mere experimental science into the bread and butter regions. There are plants which produce much honey that the bees will accept although the human taste rebels a little at the flavor. Where prime extracted has to go for 5 cents, this stuff ought not to be figured more than 2 cents. Then we see (in case wax is 24 cents) one pound takes 12 cents in honey to produce it, and yields another 12 cents for bee-labor, man labor, and profits. As to Loyalstone's cloth feeder, one would naturally be somewhat suspicious about that, and ask for something better. Page 536.

SHAKING QUEENS OFF COMBS—BEE-LONGEVITY.

When combs are shaken a laying queen drops easier than the bees, but a virgin queen not so easy. These facts

can sometimes be utilized in hunting queens—dowager found with the first bees down, virgin with those remaining when most are off. This is a part of the article of Adrian Getaz, page 534.

QUERY.—Is it brood-rearing or outdoor labor that wears out the lives of bees? Whichever way you answer don't be too fanatically sure of it. I am pretty sure Mr. Getaz is getting "into the pictures" when he holds one of these views to such an extent as to pronounce extra longevity for the bee of no use. Actual and mechanical wearing out of their bodies (if that were all) would not occur so regularly at 42 days. Varied circumstances and conditions under which the work was done would vary it greatly. Bees little one-hoss shays, eh? I'll affirm that, had the deacon made a swarm of one-hoss shays, some would have dropped off at 100, some at 110, and some at 55.

ALLEY AGAINST THE WORLD.

"Athanasius against the world" did not come out second best after all, at least we are given to understand so sometimes, but Alley against the bee-keeping world will, I fear. Leastwise when the B.-K. W. says a pint colony in a nucleus hive will presumably rear a poor queen, and Alley says it will always rear a good one—well, we at least scratch our heads. Also, it's somewhat singular that all the queens our Nestor rears should be so good, while all the other fellows have to send out queens worth less than the postage stamp required to "hist 'em." Page 333.

EUROPEAN VS. AMERICAN BEE-CONVENTIONS.

Lots of wisdom in the Dadant article about conventions. Yet, if everything was remodeled in the light of these wise suggestions, American conventions might still be small. Getting a Yankee into a convention is like getting a day-old chicken into an egg-shell—don't fit him, somehow. I think most Europeans are more moderate in their expectations of a convention than we, and so less constantly disappointed. But once let the same persons get Americanized by coming across the Atlantic, and they, too, will drop off like big boys from Sunday-school. Page 533.

Questions and Answers.

CONDUCTED BY

DR. C. C. MILLER, Marengo, Ill.

(The Questions may be mailed to the Bee Journal office, or to Dr. Miller direct, when he will answer them here. Please do not ask the Doctor to send answers by mail.—EDITOR.)

The "Answerer's" Short Absence.

An absence of ten days on account of the National convention at Denver has caused no little delay in some of the answers in this department, a delay which is much regretted; and the assurance may be given that no National convention shall interrupt again for some months to come.
C. C. M.

Perhaps Foul Brood—Other Questions.

1. I have a queenless colony, and there are about 200 cells on each comb sealed, but the brood is putrid and somewhatropy, and looks brown, and does not give off a bad odor. Do you think it is foul brood? or is such condition common in an apiary?

2. On Aug. 5 a colony of hybrids cast a swarm, and I found the frames of the parent hive filled with brood clear to the wood, and not an ounce of honey in the brood-nest, and very little pollen, but there were two supers on top, filled. The hive contained six frames. The colony is very vicious. Would you breed such stock? The other colonies of the same breed have a tendency to crowd the brood-nest.

3. Do you keep dummies in the hive to contract all summer, and if so, what do you put in place of dummies when the season is over?

4. Do you think it better to hive swarm on eight frames in a place where there is a continual flow from July to September? Would you advise putting the frames that have the most honey in the center of the brood-chamber for winter?

5. The entrance to the chaff-hives is only 1/2 inch by 12 inches, and I am thinking of boring a 1 1/2-inch hole through the casing and brood-chamber, and put a wooden tube in the hole. Do you think it would improve the hives?

6. The frames in the chaff-hives are the old-fashioned Hoffman frames, and I am thinking of replacing with staple-spaced frames, but that would leave a bee-space of 1/8 inch. How would you arrange it?
NEW YORK.

ANSWERS.—1. The condition you mention is by no means common in a healthy colony, and the fear is that foul brood is on hand. Better send a sample to Dr. Wm. R. Howard, of Fort Worth, Tex., with \$2.00 to secure an analysis.

2. The viciousness makes it hardly desirable to continue the stock, but crowding the brood-nest is not objectionable, and is just what might be expected with a good queen and only six brood-frames.

3. No, dummies are not now used for contracting.

4. Yes, if full sheets of foundation are used. Some think it wise to give only half the number of frames at first, using shallow starters, and after ten days or more, when these frames are filled, giving frames filled with foundation to fill out the remaining vacant space.

5. Hard to tell. Better try only part, and see how they compare with the others.

6. I'm not sure I fully understand the case, but if bars are 1 1/8 inches wide there need be only 1/4-inch space. If I don't get the right idea, please write again.

Do Queens Carry Foul Brood?

Is it safe to take a queen from a foul-broody colony and place her with a healthy colony?
INDIANA.

ANSWER.—It is claimed that a queen will not carry the disease. I have had no personal experience.

Will Bees Store All for Surplus?

Is there any danger of bees storing all the honey in the supers and not storing enough below for winter use? My bees have the brood-chamber full of brood and pollen, and are storing honey in the supers very rapidly.
PENNSYLVANIA.

ANSWER.—You will find that although the combs may be so full of brood that not one-fourth enough honey is present for winter stores, as the brood advances and hatches out there will be a tendency to restrict the brood and increase the amount of honey toward the periphery of the brood-nest, allowing plenty of stores in the brood-chamber for winter. Still, it sometimes happens that in an 8-frame hive the stores will be so scanty that you must add to them.

Troubles with Queens and Bees.

1. A certain high and mighty editor has suggested that we write to you and get your opinion upon some very peculiar things, to-wit:

We bought two queens about a month ago. The weather being bad here we did not pay much attention to them, except to see that they were accepted. We look at our bees about every week, but this time, from one thing and another, we did not look at them thoroughly until we had had them a month. When we did we found one had filled the hive with drones, and the other had not laid one egg, and when we opened the hive and took out the frame she was on she gaily flew to the fence, and when I tried to catch her she sailed away as light and airy as you please, and we have not seen her since. We gave the drone-layer the "water cure." The only reason for this that I can give is, that the time for the queens to fly must have been when they were in the mails, and the time passing they did not mate at all. I think the queen that did not lay at all is the real conundrum.

We have an immense colony that will not work in the super, but I think we have gotten ahead of her. It was in a Danz. hive, and we took a Jumbo body and nailed their frames—out of their hive full of brood, etc.—to the top of frame of the Jumbo, and put them in, and put sections under them. That just fills a Jumbo body; those that the queen lays in we will leave until late, and when they fill these we are going to raise them up and put a super under

them with a queen-excluder between. Do you know of any better way to get ahead of the pesky things? If you do, you will greatly oblige me by telling it. ILLINOIS.

ANSWERS.—1. I don't know for sure the right answer to your conundrum. Are you entirely sure that the queens that behaved in such a naughty manner were the queens you bought? Unless specially stipulated that you were to receive a virgin queen, no queen-dealer should send you a queen that had not already begun to lay, and that laying should come so early in her life that there should be no question about her having mated. You do not explicitly say that you found the queen in the hive that was filled with drone-brood, but I take it for granted that you found her from some things you say, otherwise the question might be raised whether you did not have laying workers. It is not probable that a queen that was all right when mailed should immediately turn into a drone-layer; but such a thing is not entirely impossible. It might happen that a young queen was present and that the queen you introduced was killed, but that would still leave the question a puzzling one. With regard to the queen that did not lay any, if there is no doubt that she was the one introduced, the question is still more puzzling. A queen that lays eggs that never hatch is a rare thing, and a queen that never lays at all is still more rare. But such a thing has been known, and yours seems to have been one of the very rare cases. The flying out of the queen when the hive was opened looks a little as if she was a young queen hardly old enough to be laying.

2. I hardly dare say your plan is not a good one, since it is *your* plan, but you might try a plan that is at least easier. The usual plan with a colony that is slow to go into the supers is to put into the super one or more sections partly drawn out. Indeed, it is the practice of many to put a "bait-section," as such sections are called, in the first super put on every hive. More surely still, perhaps, in case of a stubborn colony, is the plan of putting in the middle of the super a section from another colony, bees and all, the bees having already put some honey in the section.

What Ails the Larvae?

I had 2 colonies of bees that had about $\frac{3}{4}$ to $\frac{1}{2}$ dead, rotten brood in July. I could not see that the rotten larvae was stringy, nor did it smell badly. The colonies were from two different apiaries. The rotten larvae dried up and the bees could pull out the most of it, but some they could not get out. Now the larvae is nearly all sealed over, but it dries up and is not fully matured, and they uncap it and drag it out; some have wings and some have not. I have 2 more—yes, 3 more colonies—affected the same way. What is the trouble with the bees? Is it contagious? and what is the best thing to do with them? About nine-tenths of the larvae hatches out all right, so the hives keep full of bees in all but one. IOWA.

ANSWER.—It does not seem like foul brood, and I don't know what the trouble is. It might be a good thing to send in a tin box a sample to Dr. Howard, of Fort Worth, Tex., who, for \$2.00, will make a microscopical examination and report to you.

Storing Surplus Honey after Aug. 10.

J. A. Watkins asks the question, "Do bees store any honey after Aug. 10, in any of the Eastern States?" Yes, indeed; were he living in Butler Co., Pa., he would find the bees gather more honey after Aug. 15 than all the rest of the season. I have one colony in an 8-frame hive from which to-day (Sept. 1) I took 40 sections of nice honey; it has 32 more almost ready to seal, and is drawing out foundation in 16 more; which I expect it will finish up, making 88 sections in all. This has all been started since Aug. 15, 1902. I have 13 other colonies that on Aug. 15 had no honey in supers at all, and now they have in round numbers 537 sections, on an average of 41 sections per colony, all of which will be completed in a few days.

There is no need to feed bees here, as there are hundreds of acres of buckwheat in full bloom, to make the busy bee glad all the month of September. PENNSYLVANIA.

ANSWER.—I am thankful to say that much the same thing can be said here as to the bees gathering since the middle of August, so there will be no need to feed for winter. But the hundreds of acres of buckwheat would not have prevented feeding in June.

Honey-Boards vs. Cloths—Comb Foundation—Merits of Different Kinds of Bees.

1. Are honey-boards better to use than gunny-cloth to within one-half inch of walls of hives? A man with 13 years' experience here says that he has tried each way, and the gunny-cloth is preferable.

2. I received some samples of Dadant's comb foundation, and find that between opposite angles the width of the cells is 8-32 inch, while some natural comb that I have is 9-32 inches. Would not a 9-32 inch-wide-celI foundation be the best?

3. How do bee-authorities stand on the respective merits of different kinds of bees in regard to honey-gathering? CALIFORNIA.

ANSWERS.—1. I don't know. I think I should prefer the board for summer and the cloth for winter.

2. Natural comb varies, and I think the cells of worker foundation will be found a trifle larger than the cells of average natural comb. At one time foundation was tried with cells considerably larger than made at present, but it did not prove satisfactory. It is not likely that you would find any advantage in having foundation with larger cells than those in common use.

3. There are more different opinions than different kinds of bees; but it is probable that the majority of bee-keepers in this country prefer Italians.

Introducing Queens—Moving Bees.

I introduced several queens last month, and looking 5 or 6 days afterward I found them laying, but in 2 or 3 cases there were queen-cells, which I cut out. In looking again 5 days later I found in one colony some queen-cells with the queens almost ready to emerge.

1. What do you think would have happened if I had not cut them out?

2. Is it necessary always to look for and cut out queen-cells after introducing? Last year I introduced a queen to a colony of dark bees, and after seeing that she was laying, I clipped her wing; next spring I found a dark queen with uncut wing there. If I had not cut the wing I should have blamed the breeder for sending me a bad queen.

3. I want to move some colonies a distance of 30 or 40 yards. When do you think is the best time to do it? We do not need to put bees in a cellar here.

BRITISH COLUMBIA.

ANSWERS.—1. The bees would likely have destroyed them. It is not an uncommon thing for the bees to start cells when a queen is introduced, destroying them afterwards. If the queen is unsatisfactory, however, a young queen may be allowed to supersede her.

2. No.

3. Move them quietly any time after they have stopped flying; preferably soon after they have taken a flight, and at a time when you think they will not again fly for some weeks.

Quiet Robbing—Honey in the Hive in Spring.

1. My bees swarmed, unexpectedly, last Sunday, and I now find that the old bees are robbing from the hive they left. What would, or could, you advise me to do? I have made the entrance very small, but it is of no use.

2. Honey that is still left by the bees in the spring, shall I leave it, or take it out and extract it?

MINNESOTA.

ANSWER.—This is one of those cases of quiet robbing in which it is difficult if not impossible to do anything, because you cannot have the co-operation of the bees. Making the entrance smaller will do no good so long as the bees make no attempt at resistance. Such cases—the bees robbing the mother colony—have seldom been reported, and I do not remember that any one has ever reported a cure. It may be that after a little while the individuality of the colonies will assert itself, when the robbed colony will no longer allow the robbers to enter, and you will have to feed enough for winter stores if sufficient has not been left.

The Premiums offered this week are well worth working for. Look at them.

THE AMERICAN BEE JOURNAL

PUBLISHED WEEKLY BY

GEORGE W. YORK & COMPANY

144 & 146 Erie St., Chicago, Ill.

Entered at the Post-Office at Chicago as Second-Class Mail-Matter.

EDITOR—George W. York.

DEPT. EDITORS.—Dr. C. C. Miller, E. E. Hasty, SPECIAL CORRESPONDENTS—G. M. Doolittle, Prof. A. J. Cook, C. P. Dadant, R. C. Aikin, F. Greiner, Emma M. Wilson, A. Getz, and others.

IMPORTANT NOTICES.

The Subscription Price of this Journal is \$1.00 a year, in the United States, Canada, and Mexico; all other countries in the Postal Union, 50 cents a year extra for postage. Sample copy free.

The Wrapper-Label Date of this paper indicates the end of the month to which your subscription is paid. For instance, "dec01" on your label shows that it is paid to the end of December, 1901.

Subscription Receipts.—We do not send a receipt for money sent us to pay subscription, but change the date on your wrapper-label, which shows you that the money has been received and duly credited.

Advertising Rates will be given upon application.

MEMBERSHIP DUES, \$1.00 a year.

If more convenient, Dues may be sent to the office of the American Bee Journal, when they will be forwarded to Mr. Secor, who will mail individual receipts.

A Celluloid Queen-Button is a very pretty thing for a bee-keeper or honey-seller to wear on his coat-lapel. It often serves to introduce the subject of honey, and frequently leads to a sale.

NOTE.—One reader writes: "I have every reason to believe that it would be a very good idea for every bee-keeper to wear one [of the buttons] as it will cause people to ask questions about the busy bee, and many a conversation thus started would wind up with the sale of more or less honey; at any rate it would give the bee-keeper a superior opportunity to enlighten many a person in regard to honey and bees."

The picture shown herewith is a reproduction of a motto queen-button that we are furnishing to bee-keepers. It has a pin on the underside to fasten it.

Price, by mail, 6 cents; two for 10 cents; or 6 for 25 cents. Send all orders to the office of the American Bee Journal.

GENERAL ITEMS

Bees Did Well.

I can not get along without the American Bee Journal. I would sooner lose my dinner one day in each week.

I have not seen any report from this locality, and do not know how well other bee-keepers here have done, but my bees have never done as well before, and I have kept a few bees for 20 years. I do all the work except taking them in and out of the cellar, and I claim the income from them.

The honey is almost all fancy white clover this year, and they were still at work in the supers yesterday when I examined a few of them.

I had 23 colonies, spring count, have increased to 42 by natural swarming, and have taken off 2500 pounds of honey up to date, with a few sections still on the hives.

I think the bees will go into winter quarters in good shape, for the hives are well filled now.

We had a great deal of rain here, and had we had less during the honey-flow we would have done even better than we have; but, all things taken together, we are well satisfied.

MRS. R. T. SMITH.

Fond du Lac Co., Wis., Sept. 15.

Common Snowberry.

The specimen flower sent by Edward Kortum, of Blue Earth Co., Minn., is the common snowberry, and belongs to the honeysuckle family. The snowberry is frequently cultivated in the East, but is seldom found west of the Mississippi River. It is probably a good honey-plant, as is the majority of the honeysuckle family.

C. L. WALTON.

Wintering Bees in Danz. Hives.

I have 2 colonies in Danzenbaker hives. I winter bees out-of-doors, with 2 inches of planer-shavings to protect from cold. Will these colonies winter as well as in Langstroth hives? I fancy the Danz. hive being so shallow must bring the bees near the opening of the hive, and so bring them nearer the outer cold.

I nearly lost my bees from starvation in May and June. Having no experience I did not know what was the matter. I lost three queens, and managed to require the three out of five I bought. Bees are building up now, and I think will be all ready for winter, but I started the spring with five colonies, and have only the same five now. I have had no new swarms so far, and only 70 pounds of honey. I think I may get another 25 or 30 pounds.

I get no profit this year, unless my experience counts as such. I hope I may bring my 5 colonies through the winter, when I do not think I will allow them to starve next spring.

H. BEER.

British Columbia, Canada, Aug. 20.

[It is generally considered that depth of frame is an advantage for wintering, but some have success with shallow frames.—ED.]

Bitterweed Honey.

I am sending you two sections of our honey which is gathered from bitterweed. This honey begins coming in about July 15, and lasts until about Sept. 1. It is in quantity enough for the bees to fill up with it for winter, and everything in the way of good honey could be extracted about July 1, thus securing all of the good honey. It is also convenient to get plenty of sections drawn out so they can be used for bait next year. I have one super for each hive filled with this honey, and next spring I shall uncap it and stack up the supers out about 100 yards from the hives, and let the bees clean out the sections; and

To make cows pay, use Sharples Cream Separators. Book Business Dairying & Cat. 212 free. W. Chester, Pa.

Tennessee Queens

Daughters of Select Imported Italian, Select long-tongued (Moore's), and Select, Straight 5-band Queens, bred 3/4 miles apart, and mated to select drones. No bees owned within 2 1/2 miles; none impure within 3, and but few within 5 miles. No disease. 20 years' experience. **WARRANTED QUEENS, 75 cents each; TESTED, \$1.50 each.** Discount on large orders. Contracts with dealers especially. Discount after July 1st

27 cents Cash
paid for Beeswax.

This is a good time to send in your Beeswax. We are paying 27 cents a pound—CASH—for best yellow, upon its receipt, or 29 cents in trade. Impure wax not taken at any price.

Address as follows, very plainly,

GEORGE W. YORK & CO., 144 & 146 Erie St., Chicago, Ill.

then when the honey-flow begins I will have plenty of drawn-out combs which should be filled much quicker than if the bees had to build the combs. One strange thing about this honey is that the comb and cappings are the same color as the honey, which is not the case with other honey here.

Take this along to Denver, and show it to your friends, if it reaches you in time. I should like to be with you. JOE S. WISE.

Copiah Co. Miss., Aug. 27.

[The honey did not arrive in time to be taken to Denver. It is not as bitter in taste as we expected to find it, but it is really too bitter to eat with any degree of relish. We prefer to be excused, and will take the fine alfalfa or sweet clover honey for our own use. However, many thanks, Mr. Wise, for sending us the sample sections.—EDITOR.]

Partridge Pea.

Enclosed find plant for name. It is in full bloom, and the bees are very thick on it now.

EDWIN BEVINS.

Decatur Co., Iowa, Aug. 6.

[The flower belongs to the pulse family, and is called partridge pea. It flourishes best in a warm climate on sandy soil, and its large, yellow flowers are very conspicuous. It is an excellent honey-plant. In "Bee-Keepers' Guide," page 429, will be found a cut and short description of the partridge pea.—C. L. WALTON.]

Excelsior as Smoker-Fuel.

I am surprised (and pained) to see by Miss Wilson's article, on page 598, that she, and by inference others, have trouble with smokers, as by my method there is no preparation necessary. I rarely use but one match to light it, one filling of a 3-inch Bingham smoker lasts over an hour, and it does not go out if kept upright.

The secret (?) is *excelsior*! Put a small wisp in the bottom of the smoker and drop a well-lighted match on top of it. Let it get to burning thoroughly and put in another larger wisp and blow up *well*. Now fill up and pack down as hard as you can—don't be afraid, so it is thoroughly lighted—and you are fixed (with an occasional pump at the bellows) for an hour at least. When nearly burned out, open up the smoker, poke what is left to the bottom with a stick, blow it up lively, take a fresh wisp from your pocket and fill and start over again with only a minute's delay.

I don't recollect where I "got on" to this, but I claim no originality. I think if Miss Wilson will try it she will soon abandon soaking rags and hunting good "smoke wood."

RALPH D. CLEVELAND.

Dupage Co., Ill., Sept. 18.

A Bear in a Bee-Yard.

A bear was in my bee-yard two weeks ago, and destroyed 2 colonies and damaged 10 more or less, in going through the yard.

The other day I found 6 queenless colonies. I started with 35 colonies, spring count, increased to 90, and got 2000 pounds of extracted honey.

JOHN BLEEM.

Wood Co., Wis., Sept. 11.

The Hamilton Co., O., Association.

The bee-keepers of this county met in response to a call by circular, and organized. Upward of 50 persons were present, and quite a number from Kentucky. Several ladies interested in apiculture graced the company with their presence and took a prominent part in the proceedings.

The following officers were elected for the ensuing year: President, Henry Shaffer; Vice-President, Ben Koicks; Treasurer, C. H. W. Weber; and this Executive Committee: Wm. M. Lehman, Frank Beck, Fred Muth, J. C. Froliger, Chas. Kuck, and E. A. Newell. Among the objects of the Hamilton County Bee-Keepers' Association is the inspiration of

egislation in Ohio to protect bees from the ravages of foul brood, which has already appeared in our midst. This State is rather tardy in looking after the interests of the beekeepers. It is estimated that this county alone contains about 500 apiarists whose interests are worthy of some legislative attention.

W. M. J. GILLILAND, Sec.

Hamilton Co., Ohio.

Mountain Mint.

I send you by this mail one of the finest bee-plants I ever saw. It is a stranger to me, and was discovered two weeks ago while crossing an old pasture, by the loud humming of the bees, as if robbing. I followed up the "bee-line" to a plant about 4 square rods which was just alive with bees, getting honey. I went back there yesterday to see whether the plants were still in bloom, but could see no difference from my previous visit two weeks before.

I have been over the country a great deal, but never saw this plant before. It is a mint, and may be the great horsemint of Texas; as I have never been in Texas I do not know. I shall keep my eye on that patch, and try to save the seed, then I hope to "go" the man that has the catnip and sweet clover "one better."

W. P. TURNER.

Peoria Co., Ill., Aug. 26.

[The specimen is a mountain mint, first cousin to the horsemint, and a very valuable honey-plant. The mountain mint is quite common eastward, but has not spread over the middle or western States to any extent.—C. L. WALTON.]

A Fair Fall Flow.

We have had a fall honey-flow here that is pretty fair. I will have 3 or 4 hundred sections from 20 colonies, spring count; but no swarms.

D. C. WILSON.

Linn Co., Iowa., Sept. 15.

Beard-Tongue.

I enclose stems and flowers of a perennial plant that grows among the rocks. Can you give the name of the plant? and is it of value for bee-pasture?

The spring and first part of the summer was cold and windy; it was hard on bees. I had 50 colonies, spring count, all doing well on sweet clover just now.

M. L. HELTZEL.

Lincoln Co., Wash., Aug. 22.

[The specimen is called beard-tongue, Pentstemon, grandinorus, and belongs to the figwort family. The figworts are, as a rule, honey-plants, and while I cannot speak positively of this one it probably follows the family trait and well repays the bees for an occasional visit.—C. L. WALTON.]

Rearing and Introducing Queens.

I have been reading with interest the articles written by Dr. Gallup and also those in reply by Mr. Alley. Now Mr. Miles, a member of the jury, as he puts it, wants to hear from the other members, and I will try to add my mite to the list.

I have always supposed that natural queen-cells were as good as any, and still think that to be the case. I know, too, that good queens can be reared with the cell-cup plan, or by Mr. Alley's method, because I have proved it; and also that poor queens are reared on the best plans used, and from the best breeders you can buy. I think the best plan to follow is to save nothing but the very largest and best cells, no matter what method you use. The best method to use is the one you have proved to be the most successful, and gives the best result, no matter who thinks differently.

I will give my way of introducing queens when received by mail: Remove the queen from the cage and put her in a cage that has not been used or been through the mail, so

QUEENS!

This is your last chance for this season to get Queens from Quirin's Famous Red Clover stock, so hurry in your orders. We have files of testimonials like the following:

Mr. J. Roorda, of De Motte, Ind., bought 4 dozen in the spring, and says the workers are hustlers; while E. L. Messenger, of New Haven, Conn., says the queen bought last season produced bees which beat anything in that part of the country.

Price of Queens for balance of season:

	1	6	12
Selected	\$.75	\$4.00	\$ 7.00
Tested	1.00	5.00	9.00
Selected Tested	1.50	8.00	
Extra Selected Tested, the best that money can buy..	3.00		

We guarantee safe arrival, to any State, continental island, or any European country. Can fill all orders promptly, as we expect to keep 300 to 500 Queens on hand ahead of orders. Special price on 50 or 100. Free Circular. Address all orders to

"What Happened to Ted"

BY ISABELLE HORTON.

This is a true story of the poor and unfortunate in city life. Miss Horton, the author, is a deaconess whose experiences among the city poverty stricken are both interesting and sad. This particular short story—60 pages, 5x6 1/4 inches, bound in paper cover—gives somewhat of an insight into a little of the hard lot of the poor. Price, postpaid, only 10 cents (stamps or silver.) Address,

ISABELLE HORTON,

227 EAST OHIO STREET, CHICAGO, ILL.

there will be no scent from it as there would be in the cage she came in, and leave no workers with her. Then go to the hive you wish to put her in, remove the queen they have, if any, and place the queen-cage with the queen you wish to introduce, with wire-cloth down, on top of the frames, first removing the slip of card off the end of the cage containing the candy. Some will object to putting the new queen in at the same time you take the old one out, but I do it that way and it saves disturbing the bees more than once, and I have lost only one queen that was introduced in that way. I suppose Mr. Alley will object to this; but never mind, I can do it that way if he can't.

I notice a writer in the American Bee Journal says 9 out of 10 queens he has bought were worthless. Now that has not been true in my case, and I have bought quite a number, and have never had one I called worthless; but some were better than others, and that is the case with those you rear. I am not writing this without knowing something about it. I have had queens from 5 different States, and imported some from Italy twice, and I have no cause to complain. I received a couple of premium queens from Editor York a short time ago that are beauties, and are doing well.

CHAS. W. CILLEY.

Merrimack Co., N. H., Sept. 4.

Age of Queens.

I indorse what G. M. Doolittle says about replacing queens every two years. If a queen is bad, replace her any time, even if less than a year old, but don't replace an old queen simply because she is old. I have a queen 5 years old that is to-day doing just about as good work as any other queen I have. A sufficient reason against replacing all 2-year-old queens, if there was no other, is that you can hardly decide the character of a queen until she is 2 years old; and if she has a good record when 2 years old, every year of good record after that increases her value as a queen to breed from.—Stray Straw in Gleanings in Bee-Culture.

Getz's Plan of Dividing.

After trying all the processes advised, I simply divide each colony in two, putting two-thirds or three-fourths of the brood in the new one, and leaving the rest on the old stand. Both hives are completed with empty combs or foundation. Three days later I look for the queen. Only the new colonies need be examined, and it takes but little time, since they are not strong in bees. Queens are then introduced where needed, and the cells cut out, if there are any.

Laying queens can be introduced anywhere, but the virgins, ready to mate, should be introduced only to the new colonies; otherwise there might be trouble. If necessary, take the old queen out of the new colony, and put her back in the old one, and give the virgin to the new colony.—ADRIAN GETZ, in the Bee-Keepers' Review.

Stimulative Feeding.

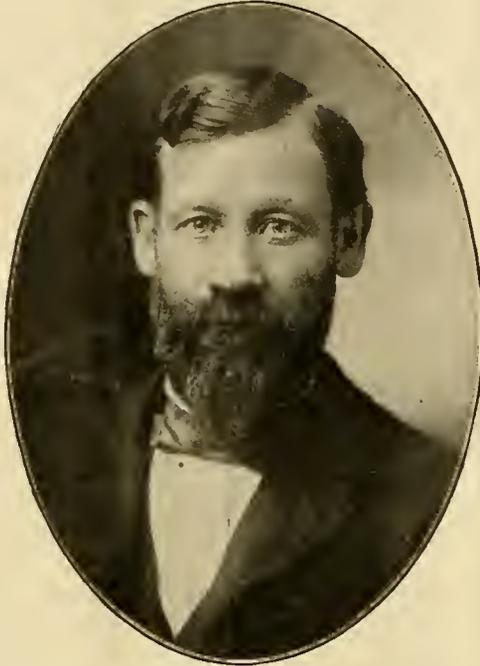

This has a strong advocate in the editor of the Rocky Mountain Bee Journal, and what seem to be good arguments are given in favor of it; but it seems that all Coloradoans are not of the same mind. F. L. Thompson says in the Progressive Bee-Keeper:

Stimulative feeding for spring is one practice whose value is unproved, hence it can not be included in the list of essentials. It has been said lately it is desirable in Colorado; but convincing proof has not been given. If feeding stimulates that does not prove that the stimulation is profitable. From the view-

Prof. Cook's Bee-Keeper's Guide

Or, Manual of the Apiary.

PROF. A. J. COOK.

Price,
Postpaid,
\$1.20

Price,
Postpaid,
\$1.20

This standard work on practical bee-keeping has just been thoroughly revised and brought down to date. About 100 pages and nearly 100 illustrations have been added, which makes it now a superb volume of 544 pages, with 295 fine illustrations. It is printed on clear white paper, and is bound in elegant brown cloth, gold-lettered.

Prof. Cook has been one of the leading contributors to the American Bee Journal for a quarter of a century. He is well known to bee-keepers everywhere. He is an authority on bees and related subjects. His book has had a large sale, which now bids fair to increase greatly.

In order that every reader of the American Bee Journal, who does not already possess a copy of Prof. Cook's work, may have it, we wish to make the following

FOUR LIBERAL OFFERS:

No. 1.—For \$1.75 we will mail the American Bee Journal one year and a copy of Prof. Cook's book.

No. 2.—Any one of our present subscribers whose subscription is now paid in advance, can have a copy of Prof. Cook's book mailed to him free as a premium for sending us two new subscribers to the American Bee Journal for a year (with \$2.00.)

No. 3.—Or, send one new subscriber for a year (at \$1.00) and 50 cents more (\$1.50 in all,) and we will mail to YOU a copy of the book and will send the American Bee Journal for one year to the new subscriber.

No. 4.—For \$1.00 we will send Prof. Cook's book by express or freight with other goods; or, if called for at our office, the price is \$1.00. But the post-paid price of the book alone is \$1.20.

Please remember that offers Nos. 2 and 3 of the above are made to those who are now subscribers to the American Bee Journal, and whose subscriptions are paid in advance. Offers Nos. 1 and 4 are made to any one who desires to take advantage of them.

Address all orders to the publishers,

GEORGE W. YORK & CO., 144 & 146 Erie St., CHICAGO, ILL.

point of this locality, there are two questions involved:

1. Which is better, a strong colony of old bees, whose vitality is unimpaired by previous brood-rearing, or a weak colony of young bees, 37 days before the flow, that being the time required to rear honey-gatherers from the egg?

2. When natural pollen (the best kind of a stimulant) begins, as it does here, more than 37 days before the flow, and continues without a break, is it any additional stimulation to feed thin honey?

In answer to the first question, one experience in cellar-wintering here shows that a comparatively late start in brood-rearing with strong colonies of vigorous old bees, which start was still, however, more than 37 days before the flow, produced results just as good as the usual handful of brood kept up from January on, resulting in weak colonies by the first of May. To be sure, natural pollen begins rather late here, not till the last week of April, and bees will take artificial pollen eagerly before that time, and it certainly does stimulate them; but it is very doubtful whether that stimulation is any real good.

As to the second question, any one familiar with the normal aspect of the brood-chambers here in the middle of May—broad sheets of brood with comparatively few bees—and who concludes that the bees can be stimulated more than they are, must have some considerations in mind which are not apparent to the understanding of this writer. If there is one thing in which theoretical views are dominant, it is in this matter of stimulation. Where are the proofs?

Size of Cells.

Doolittle says queen-cells should be rather more than five-sixteenths in diameter. Call it five and a third sixteenths—that's just a third of an inch. Then we have: worker-cells five to the inch, drone-cells four to the inch, and queen-cells three to the inch.—Stray Straw in Gleanings in Bee-Culture.

An Association Seal.

Some years ago the Ontario County (N. Y.) Bee-Keeper's Association decided to place their good, white honey under the seal of the Association. It was thought that a reputation for Ontario County honey could thus be built up. I do not know that it occurred to the instigators of the scheme at that time, that this seal might act as a guarantee of the purity of the genuineness of the article. In these times of mistrust against even the genuine product of the bee, it would seem all the more desirable that we should enact a scheme by which we could strengthen or regain the confidence of consumers of an article that we know is not, and never can be, successfully imitated. I do believe that, if a goodly number of the bee-keeper's societies all over our land would act in unison, adopt our system of sealing their honey, it would go a long way towards re-establishing the lost confidence.

Our rule is, not to send out any inferior honey under the seal of the Association. Fancy and No. 1 white only are admitted. This rule is all right if the object is to create a reputation for a No. 1 article; but it is a question whether this is the best course to follow, when we consider that all honey is to be guarded against any possibility of suspicion. If I send out a part of my honey without a seal, would not the purchaser naturally think this to be an adulterated article? I confess I do not know what is the wisest thing for us to do.

The seal we use consists of a strip of glazed turkey-red paper 4x14 inches, having the gold seal attached at the right of the reading matter, with the official seal of the Association impressed thereon. The reading is as follows:

"Ontario County, N. Y., Bee-Keeper's Association Honey Stamp. This case of honey has been inspected by the honey-inspector of the Ontario County, N. Y., Bee-Keeper's Association, and the honey within, if seal is attached and these stamps remain unbroken, is guaranteed to be grade No. 1 white."

From the reading it appears that the stamp

or seal is pasted around the case of honey in such a manner that the honey can not be removed therefrom without breaking the seal.

The honey-inspector's business is to go to the different honey-producers, on solicitation, and inspect the honey. If he finds it all right and up to the standard, he attaches a seal to each case. For this service he receives from the owner of the honey 8 cents per case, and 15 cents from outsiders. He also receives mileage.—F. GREINER, in the American Bee-Keeper.

CONVENTION NOTICES.

Utah.—The Utah Bee-Keepers' Association will hold the annual convention in the City and County Building, Salt Lake City, Utah, Oct. 6, 1902, at 10 a.m. Business of interest to all bee-keepers will be presented. All are invited. J. B. FAGG, Sec.

Illinois.—The annual meeting of the Northern Illinois Bee-Keepers' Association will be held at the Court House in Freeport, Ill., on Tuesday and Wednesday, Oct. 21 and 22, 1902. All interested in bees are invited to attend. Cherry Valley, Ill. B. KENNEDY, Sec.

New Jersey.—The first annual meeting of the New Jersey Bee-Keepers' Association will be held at 10 a.m., Thursday, Oct. 2, in the Club House on the Inter-State Fair Grounds, Trenton, N. J. We extend a most cordial invitation to all bee-keepers, and others interested in bee-culture, to be present. GEORGE N. WANSER, Sec. B. F. ONDERDONK, Pres.

One Fare for the Round Trip

to Boston and return, via Nickel Plate Road, Oct. 7th to 11th, account meeting of Brotherhood of St. Andrews. By depositing tickets at Boston and paying fee of 50 cents, extended return limit of Nov. 12th may be obtained. Through vestibuled sleeping-cars and first-class service in every respect. Cheap rates to all New England points. Write John Y. Calahan, 113 Adams St. Chicago, for particulars. 49—38A3t

Langstroth on... The Honey-Bee

Revised by Dadant—1900 Edition.

This is one of the standard books on bee-culture, and ought to be in the library of every bee-keeper. It is bound substantially in cloth, and contains over 500 pages, being revised by those large, practical bee-keepers, so well-known to all the readers of the American Bee Journal—Chas. Dadant & Son. Each subject is clearly and thoroughly explained, so that by following the instructions of this book one cannot fail to be wonderfully helped on the way to success with bees.

The book we mail for \$1.25, or club it with the American Bee Journal for one year—both for \$1.75; or, we will mail it as a premium for sending us THREE NEW subscribers to the Bee Journal for one year, with \$3.00.

This is a splendid chance to get a grand bee-book for a very little money or work.

GEORGE W. YORK & CO.

144 & 146 Erie Street, CHICAGO, ILL.

Queens at a Bargain

Because I have to move on the 1st of November, and have to double up my Nuclei by Nov. 1, Untested Queens, 50 cents each. I have 100 Tested Queens (think of it—Tested!) for 75 cents each. Tested Queen in a 2-frame Nucleus for \$2.01.

I also have 200 Chaff Division-Boards made up that cost 15 cents in the flat. I will take 14 cents each.

Also 200 Supers for 10-frame hives, filled with sections and starters—are worth 38 cents—will take 20 cents each. I am offering these on account of having more than a car will hold, and I haven't enough to fill two cars. Whoever gets them gets a bargain. This is a money order office.

DANIEL WURTH, THE QUEEN SPECIALIST, CARYVILLE, TENN.

The Emerson Binder

This Emerson stiff-board Binder with cloth back for the American Bee Journal we mail for but 60 cents; or we will send it with the Bee Journal for one year—both for only \$1.40. It is a fine thing to preserve the copies of the Journal as fast as they are received. If you have this "Emerson" no further binding is necessary.

GEORGE W. YORK & CO., 144 & 146 Erie Street, CHICAGO, ILL.

DAIRYMEN ARE DELIGHTED to meet those who work for us. Cow keepers always have money. We start you in business. You make large profits. Easy work. We furnish capital. Send 10 cents for full line of samples and particulars. DRAPER PUBLISHING CO., Chicago, Ills.

City ticket office, 111 Adams St., Chicago. Full information can be secured from John Y. Calahan, General Agent, 113-Adams Street, Chicago. 48—38A3t

HONEY AND BEESWAX

MARKET QUOTATIONS.

CHICAGO, Sept. 19.—Comb honey is meeting with good demand and the arrivals are easily disposed of at 15@16c per pound for that which grades No. 1 to fancy. Very little of the lower grades are offered, but bring within 2 to 3 cents of No. 1. Amber grades of comb are also scarce, with no buckwheat offerings. Extracted is steady, white bringing 6 3/4@8c; amber, 6@7c; Southern and odd lots of dark, 5@6c. Beeswax, 30c. R. A. BURNETT & CO.

KANSAS CITY, Sept. 13.—The demand still continues good for comb honey, but receipts are very light and meet with ready sales at these quotations: Fancy white comb, 15c; No. 1 white, 14c; No. 2 white and amber, 13c; dark, 12c. Extracted, white, 6@6 1/2c; amber, 5@5 1/2c. Beeswax, 22@25c. C. C. CLEMONS & CO.

CINCINNATI, Aug. 30.—The demand for comb honey at present is very good; all shipments are sold quick at 15@16c for No. 1 and fancy. We advise shipping while demand is good and before the western carloads are here. In three weeks from now carloads will arrive, then demand is satisfied, sales harder to make, and prices demoralized. Extracted honey is selling as fast as it arrives, at the following prices: Amber and Southern in barrels, at 5 1/2@6 1/2c, according to the quality. White clover, 7 1/2@8c. Beeswax is scarce at 30c.

THE FRED W. MUTH CO.

ALBANY, N. Y., Aug. 22.—The demand for honey is improving with the unusual cool weather, the summer resorters returning home hungry. We quote: Extra white comb, 15@16c; medium, 14@15c. No other grades coming yet.

We want to caution shippers against shipping by express, as it arrives almost invariably broken. Express companies are stamping the cases "Received at owner's risk," which seems to cause their employes to "play ball" with it. Freight handlers are slower, more careful, and less broken, and much cheaper. We advise sending by freight only. H. R. WRIGHT.

NEW YORK, Aug. 11.—New crop comb honey from New York and Pennsylvania is beginning to arrive in limited quantities. There is a good demand for fancy white at 14c, and No. 1 at 13c, and exceptionally fine lots will possibly bring a little more. Lower grades quiet at from 10@12c. As to extracted honey, fancy grades are in good demand at from 6@6 1/2c for white, and 5@5 1/2c for light amber. Southern in barrels and half-barrels quiet at from 47 @60c per gallon, according to quality. Beeswax dull at from 27@28c. HILDRETH & SEIGELMAN.

CINCINNATI, Aug. 29.—New comb honey is not coming in so plentiful, so far. Whatever has come in, and is fancy water-white, has brought a good price, and sold to stores at from 15@16c. Honey kept over from last year, fancy sells for 14c. The market for extracted is more lively and brings: Amber, from 5@5 1/2c; alfalfa water-white, from 6@6 1/2c; white clover, from 7@7 1/2c. Beeswax, 28c. C. H. W. WEBER.

SAN FRANCISCO, Aug. 20.—White comb, 13@14c; amber, 10@12c; dark, 8@9c. Extracted, white, 5 1/2@5 3/4c; light amber, 5@5 1/2c; amber, 4 1/2@5. Beeswax, good to choice, light, 27@29c; dark, 25@26c.

Not much offering or arriving of any sort. While the market is firm throughout, current values are being better sustained on comb than on extracted, for the reason that the latter has to depend to some extent on outside demand. All the comb honey offering will be required locally. The shipment of comb honey has never proven satisfactory, and the production is in consequence restricted to small compass.

Wanted—Extracted HONEY

Mail sample, and state style of package and price delivered in Chicago.

AMERICAN

BEE JOURNAL

GEORGE W. YORK,
Editor.

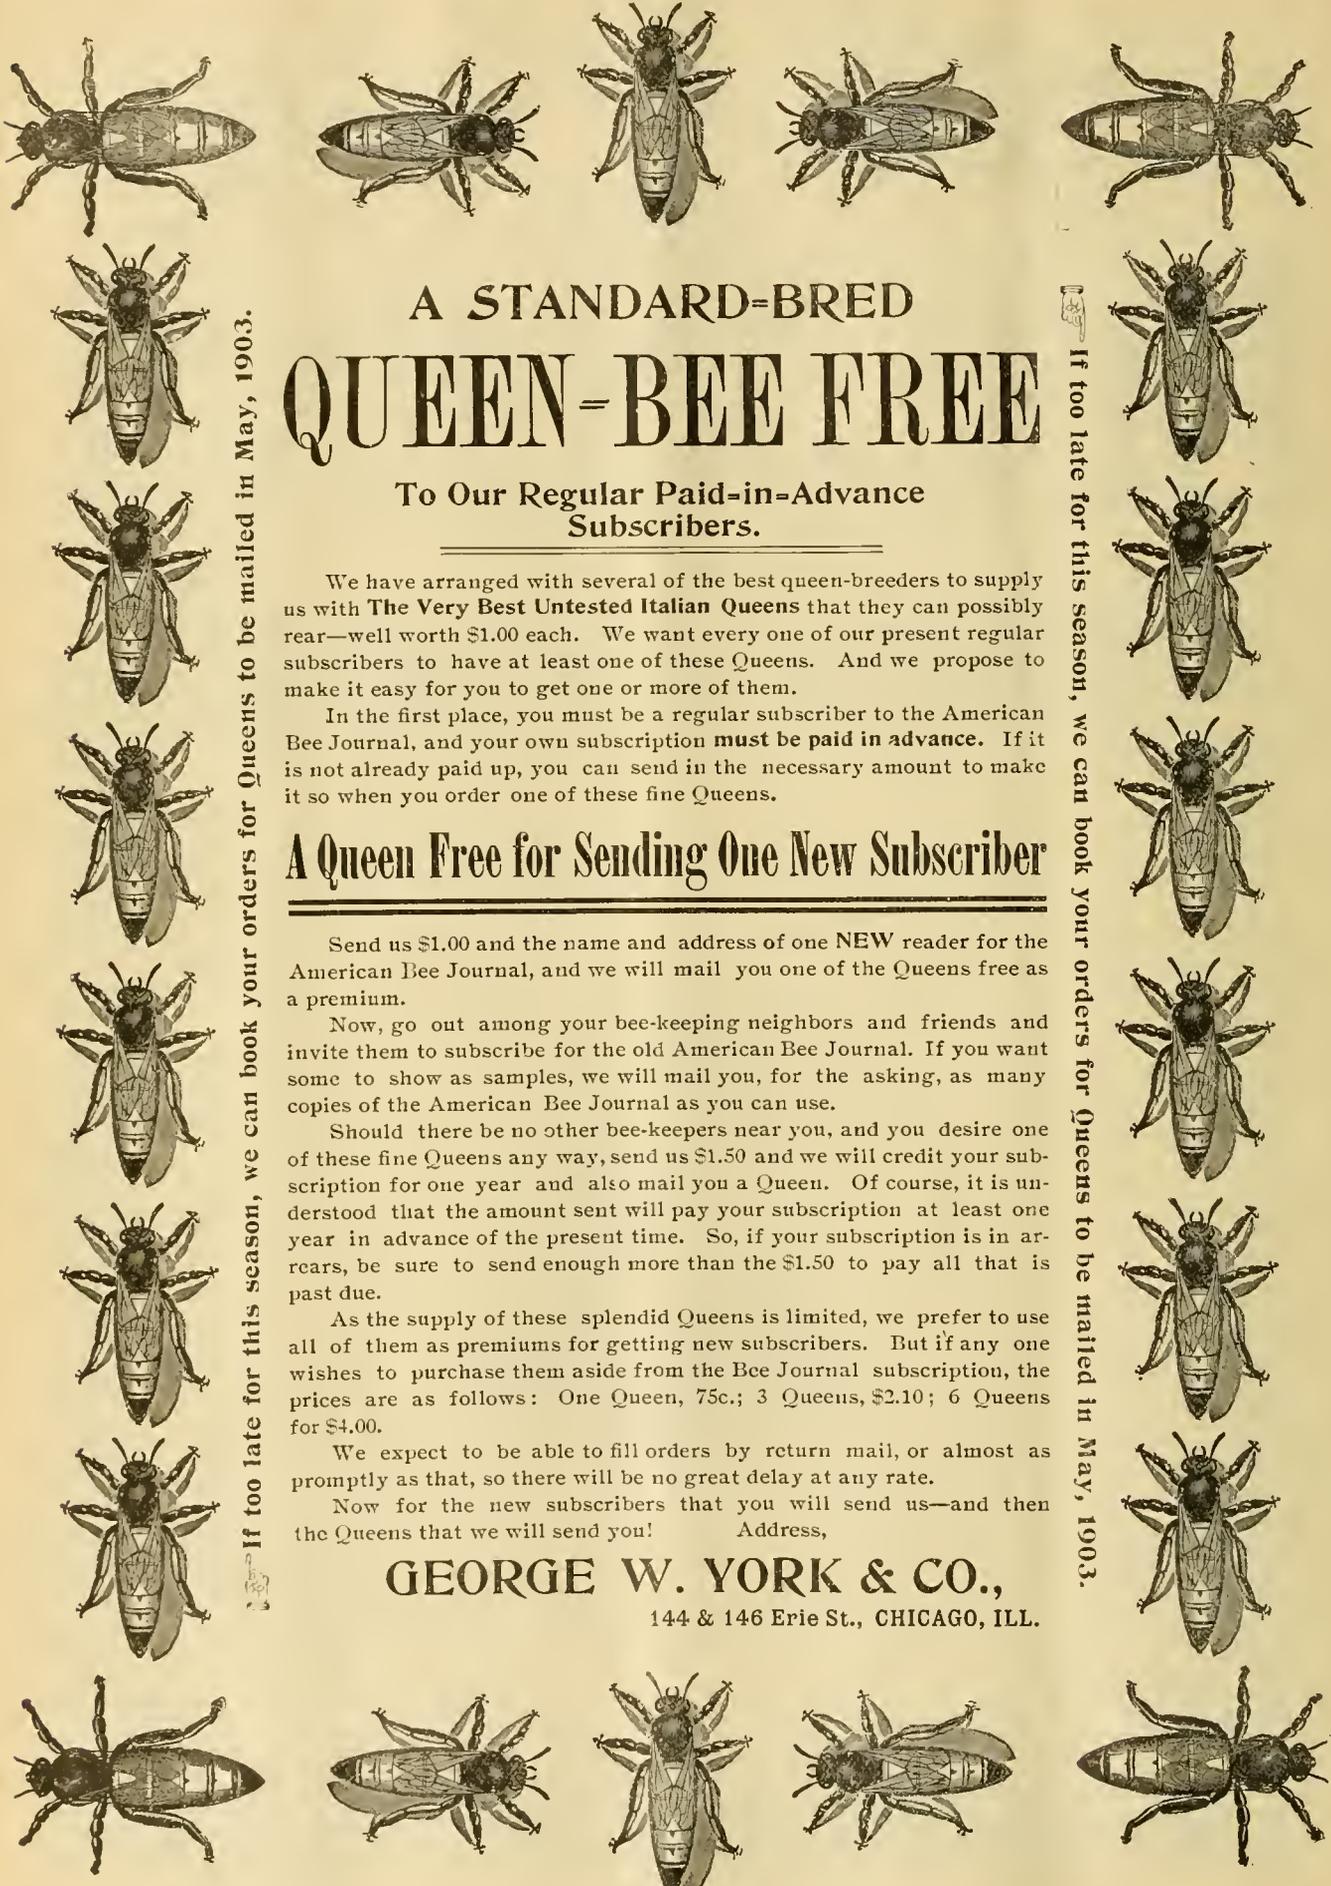

CHICAGO, ILL., OCT. 2, 1902.

FORTY-SECOND YEAR
No. 40.

WEEKLY

JAMES U. HARRIS,
President of the Colorado Bee-Keepers' Association.

If too late for this season, we can book your orders for Queens to be mailed in May, 1903.

If too late for this season, we can book your orders for Queens to be mailed in May, 1903.

A STANDARD-BRED QUEEN-BEE FREE

To Our Regular Paid-in-Advance
Subscribers.

We have arranged with several of the best queen-breeders to supply us with **The Very Best Untested Italian Queens** that they can possibly rear—well worth \$1.00 each. We want every one of our present regular subscribers to have at least one of these Queens. And we propose to make it easy for you to get one or more of them.

In the first place, you must be a regular subscriber to the American Bee Journal, and your own subscription **must be paid in advance**. If it is not already paid up, you can send in the necessary amount to make it so when you order one of these fine Queens.

A Queen Free for Sending One New Subscriber

Send us \$1.00 and the name and address of one **NEW** reader for the American Bee Journal, and we will mail you one of the Queens free as a premium.

Now, go out among your bee-keeping neighbors and friends and invite them to subscribe for the old American Bee Journal. If you want some to show as samples, we will mail you, for the asking, as many copies of the American Bee Journal as you can use.

Should there be no other bee-keepers near you, and you desire one of these fine Queens any way, send us \$1.50 and we will credit your subscription for one year and also mail you a Queen. Of course, it is understood that the amount sent will pay your subscription at least one year in advance of the present time. So, if your subscription is in arrears, be sure to send enough more than the \$1.50 to pay all that is past due.

As the supply of these splendid Queens is limited, we prefer to use all of them as premiums for getting new subscribers. But if any one wishes to purchase them aside from the Bee Journal subscription, the prices are as follows: One Queen, 75c.; 3 Queens, \$2.10; 6 Queens for \$4.00.

We expect to be able to fill orders by return mail, or almost promptly as that, so there will be no great delay at any rate.

Now for the new subscribers that you will send us—and then the Queens that we will send you!

THE OLDEST BEE-PAPER IN AMERICA

BEE JOURNAL

42d YEAR.

CHICAGO, ILL., OCT. 2, 1902.

No. 40.

* Editorial Comments. *

The Producer's Name on Comb Honey.—An experience that we had recently suggests the wisdom of referring again to this subject, which was quite thoroughly discussed in the Chicago-Northwestern convention last December.

We received a nice lot of white comb honey a few weeks ago. It came in excellent condition, because the producer who shipped it followed our instructions as to packing. But when we opened it, we found that not only on every case, but on every section as well, he had rubber-stamped his name and address. Of course we had to spend the time necessary to scrape off all the marks. Had we wanted the producer's name and address on the honey we would have requested him to put it on.

It is not a safe rule to put your name and address on comb honey unless you are retailing it yourself. Then it would be all right. Or, if the dealer buying your honey wanted it on.

We have worked up a demand for "York's Honey," and not Smith's, or Miller's, or Nelson's honey.

It would simply be foolish for us to create a demand for Nelson's honey one year, and then the next year he would likely have no crop. Where would we be then? Again, Nelson couldn't produce the tenth part of what we would need to supply our trade. Then, where would we be again?

The best way when wholesaling honey is to omit the name and address from every case and every section.

Packing Comb Honey for Shipping.—Now is the time to repeat the directions for packing comb honey for safe shipment. There are always a number of new readers who need to learn how to do it properly, and then a good many not so new need to be reminded occasionally lest they become careless.

We prefer to pack say about a dozen 12-pound cases, or eight 24-pound cases, in a large crate, first putting about four inches of straw in it. This will act as a cushion, and prevent breaking down of the combs from jarring or jolting.

The glass fronts of the cases should show through the crate so that freight-handlers can easily see what it is, and handle accordingly.

Then, there should be two long strips nailed near the top of the sides of the crate (one on each side), and extending out six or eight inches, forming handles by which to carry it.

Another good thing is to tack on top a large card having on it in plain letters: "COMB HONEY. HANDLE WITH CARE."

When so prepared, comb honey should go almost anywhere by freight in good condition.

Shaken Swarms, or brushed swarms, are much talked about nowadays. It is really little more than anticipating the action of the bees by making them swarm a little in advance, and at the same time making a more thorough job of it by leaving with the swarm a larger proportion of the bees. A caution as to one point may not be out of place. Some say to brush off all the bees, setting the beeless combs on a stand by themselves, and trust to the young bees hatching out to take care of the brood. While this may work all right when days and nights are continuously warm, with a continuous flow of honey, it would most surely result in disaster in some cases. A chilly night with no bees on the combs would be sure death for thousands of larvæ, and a let-up in the honey-flow would be the signal for an attack from robbers. In any case, there would be no bees present at first to feed the larvæ, and it is likely a good many of the older unsealed larvæ would starve before the hatching bees would be sufficiently mature to feed them.

Shall Extracted Honey Be Strained or Skimmed?—

A discussion of the question in the Ontario convention showed that while some preferred straining and some skimming, the weight of sentiment seemed to be in favor of both. After the most careful straining there will still be a lack of clearness caused by small particles of comb and pollen and bubbles of air. After standing a week these can be skimmed from the surface. Objection was made that allowing the honey to stand for a week would result in a loss of aroma, but it was thought the gain would be greater than the loss.

Denver Convention Notes.—With us, the Denver convention began about two weeks before we got aboard the train at the Chicago & North-Western station at 6:30 p.m., Monday evening, Sept. 1, and ended several days after arriving at our office again on Sept. 12. It was necessary to put in a good deal of rush work in order to get the business and office affairs in shape to be left for ten days. This was no easy matter, as it was necessary to prepare copy for over two numbers of the Bee Journal in advance, and also explain many matters so that the clerks could keep things going during our absence.

Well, by careful planning and hard work, when the train was ready to start, we had completed all arrangements, and with Mrs. York got aboard for Denver. There were also in the same Pullman coach, Dr. C. C. Miller and Miss Emma Wilson; Editor E. R. Root and Huber Root; C. H. W. Weber and Mr. Klocks; W. L. Coggshall; and Mr. and Mrs. Geo. Angus, the last two being from Canada: Mr. Angus having been employed to report the convention for the American Bee Journal.

We all started off feeling well, and in good time. But the first four named of our party were destined to be separated from the rest of the company. At Omaha, the next morning, we four had to get round-trip tickets from there to Denver. We expected to find the tickets all ready for us

at the railroad office, having written ahead to the agent. But through some misunderstanding, the tickets were not there, and, as it took so long to make them out, and there being other travelers as well who also wanted tickets, our train simply pulled out of the station, and left us in Omaha! Think of it! Our baggage was all in the car on the way to Denver, and we four strangers "left" in a strange town until 4:25 p.m., when the next Denver train would leave. There we all were—Dr. Miller, Miss Wilson, and "Ye Editor" and "frau."

We walked around the town until nearly noon, when we had breakfast and dinner all in one. It was a good, big one, we may assure you. In the afternoon we went out to Hanscom Park, which is a beautiful spot indeed.

When the 4:25 train came rolling in, you may be sure we all were waiting for it. And we weren't bothered with any baggage, either—all the extra baggage we had was two combs that the "girls" bought in Omaha! But we didn't worry any about our baggage that was on its way to Denver ahead of us, for we knew that those two Root "boys" would care for it all right. And they did. When we reached Denver, which was about noon of Sept. 3, we found they had taken it all up to the hotel, where it was awaiting its owners. Easy way to travel, wasn't it? Nothing like having your baggage looked after well, and lugged around to just where it is wanted!

Of course, we all were twitted quite a little during the convention over being left in Omaha, but we simply replied that we preferred to travel leisurely and see the country as we went along. And we did. Besides, as our long journey of nearly 1100 miles was thus broken in two near the middle, when we did arrive in Denver we all felt rested and ready for the convention.

Next week we will go on with these notes. It may take almost as long to write them out as it did for us to get to Denver. But we got there, and had a good time, too. Dr. Miller said it was the best and greatest trip of his life. Of course, as he is only a little over 70 years old, he "don't know" much more about trips than he does about bees!

American and British Styles of Frames.

BY F. W. L. SLADEN.

Though American bee-keepers may not have much to learn from British methods, which are often more or less the result of the peculiar climate of the British Island than anything else, it will at least be of interest to study points about bee-culture in comparison with one another, and the two plans of which involve differences of principle. In this connection there is perhaps no important article used in bee-keeping in the two countries which differs so much in principle as the brood-frame. As regards shape and size of frame the British seem to agree with their American brethren in preferring a somewhat shallow frame, one that is considerably longer than it is deep. The same variety of opinion is expressed in England as in America on this much-discussed question, but in a decidedly less-pronounced manner, most bee-keepers being satisfied that the size and shape decided upon and adopted by the British Bee-Keepers' Association is the best. This is a small frame, 14 inches long and 8½ inches deep, and there has always been a party of bee-keepers who would like to make it deeper, although in the light of recent tendency in America it would seem that if it can be improved on it would be by lengthening it rather than deepening it.

A very remarkable thing about the British Standard frame is the great length of the top-bar in comparison to that of the frame itself. The former is 17 inches long. The

top-bar therefore projects 1½ inches at either end, while the latter is only 14 inches long. Shorter top-bars have been tried but they have been abandoned by almost universal consent in favor of the long ones. The only way such a long top-bar can be accommodated in the hive is by having the walls of the brood-chamber, on which the ends of the

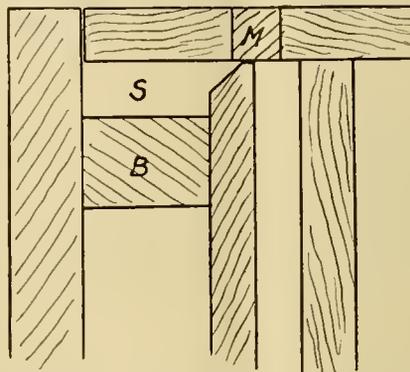

Fig. 1.—Vertical section through the top of the brood-chamber wall in the British hive, showing part of the frame fitted with metal end resting upon it.

top-bars rest, of double thickness, with a space between them, closed by means of blocks. (See Fig. 1). The chief reason why the long top-bars are preferred in England is, apparently, ease of manipulation, and certainly this is a great advantage.

It will be seen on reference to the figure that the upper surface of the top-bar is flush or level with the top edge of the outer walls of the brood-chamber. There is no beespace above the frames as is the case in most American hives. (I do not say that this is an advantage in itself, but it brings other advantages.) The frames are spaced the correct distance from one another by means of a folded tin metal-end (M) which slips on to the top-bar from the end. It is difficult to convey a clear idea of the English bee-keepers' metal-end in a few words, but it is sufficient for the present purpose to say that it projects about ¼ inch on either side of the top-bar, and touches the metal-end on the next bar over the whole surface of "M" shown in the figure. These metal-ends in fact, being in contact with one another, form an impassable barrier to the bees, so that they are unable to enter the space "S," and thus they cannot mess with propolis the ends of the top-bars, which are in this space. This is an advantage, for the top-bar can be made to fit close between the outside walls of the brood-chamber without fear of propolization, thus end-spacing is secured without driving staples into the end-bars.

But the greatest advantage that results from this large bee-excluded space is ease of manipulation of the frames.

On referring to the figure it will be seen that the block "B," is fixed a little distance below the end of the top-bar;

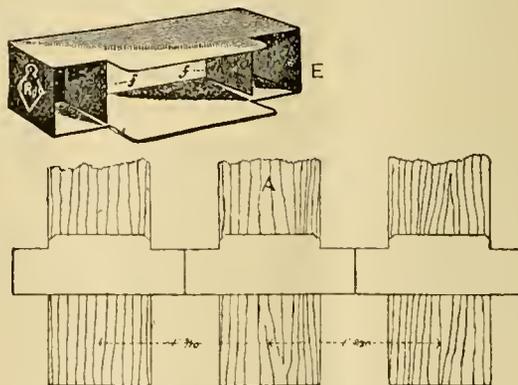

Fig. 2.—The "W. B. Carr" Metal Frame-End.

this leaves a thumb-and-finger space (S) which is most useful, as affording the finger such leverage that it is never necessary to use a tool for separating or lifting the frames. The regular thick top-bar Langstroth frame is, I believe, supposed to be handled somewhere in the top-bar between the uprights; but those operators that I have seen at work

with them generally handle them at or about the uprights. In whatever way they are handled (and especially if it be the latter way), a certain amount of propolis or bee-glue is bound to get on the fingers in time, and this is a distinct annoyance. With the British frames there are neither bees nor propolis on the part where the frames are to be handled, and if two hands are used this part is the very best part for readily getting a good grip of the frame, especially with the room that is given for it. I have handled both the regular up-to-date Langstroth, and the British Standard frames, in my apiary, and I must say I can work more quickly and easily with the latter.

The projecting ends of the top-bars in the British Standard frame are also very handy if one wishes to carry one or two frames a short distance. Two of them can be carried by the projecting lugs top to top between the thumb and fore-finger of one hand, and the smoker being carried in the other hand. It is astonishing how quickly work can be done. Of course, I am more used to handling British frames than American frames, and it may be that if I were as accustomed to handling the latter as I am the former I might not find them so inconvenient.

There seems to be a movement on foot in favor of double-walled hives in America. In such hives the opportunity might be taken to give a longer top-bar a trial. It is difficult to see how the top-bar can be lengthened in the regular dovetailed hive now in use without bringing on serious troubles. Even in such a hive there would still be the drawback—perhaps of little real moment—of the possibility of propolis and bees getting into the part where the frame is to be handled, and the only way to get over this would be to use quilts, and no bee-space, over the frames, as the British do. This might be all right for some queen-breeders, but it would not do for honey-producers and the bulk of bee-keepers.

England.

Wintering Bees—Some Experiences.

Read at the last Minnesota Bee-Keepers' Convention

BY J. B. DEXTER.

About 50 years ago, while living in Picataquis Co., Maine, I had my first attack of "bee-fever." With lots of pains and some danger I obtained 20 colonies of bees. I had them in nice, little box-hives on a raised platform. I thought at that time that they were very beautiful and interesting. They were large, with bright black and yellow stripes around the bodies.

Well, they worked and multiplied until fall, but then they were attacked with—not springdwindling—but "fall" dwindling, and I did not winter one. They were bumble-bees, and I was 9 years old.

The next fall a lady gave me a colony of honey-bees, but by the following spring they were all dead. Since that time I have kept bees a good many years, and my thoughts have often been turned to the welfare of my bees in winter. I will now mention a few of the many ways I have known bees to winter.

While I lived in Maine, as far as I knew, bees were always wintered on the summer stands. I have known the snow to drift six feet deep over the hives, and in the spring, when a crust formed on top, we would count the holes that the heat from the hives melted through the snow. I never knew a colony to die and leave honey in the hives those years.

From 1870 to 1882 I kept bees in Floyd Co., Iowa. My bees did well in the summer, but I lost more or less each winter, owing, as I thought, to a very damp cellar and to the large amount of honey-dew in the fall. One fall, when I considered them in bad shape, I let one-third of the bees stay on the summer stands, and another third I put into the cellar. For the other third I opened a long, deep trench in a large bin of oats and put the colonies in there and covered them deep with the oats. When spring came I found all the bees in the cellar dead, and also all on the summer stands. I supposed that all would be dead in the oats, and so did not open them until the first of May. Then, to my surprise, I found the hives full to overflowing with bees, and all the frames that were emptied of honey were full of brood. I never had bees do as well as those bees did that summer, and I noticed that the oats was cut up under the hives, as though mice had nested there.

One lady wintered one colony with the hive inclosed in a tight box under the kitchen table, and another wintered a colony behind the doors of a room used as a sleeping-room.

I know a man who keeps a small apiary in his chamber, and finds that not more bees die from 15 colonies than I could hold in my hands.

For the last ten years I have lived in Todd Co., Minn. My bees have wintered (1898 excepted) without loss, in a cellar kept at a temperature of about 33 degrees, Fahr. Mr. M. Osborn, of Wadena County, has wintered bees directly under his stationary engine, which was running most of the winter.

To sum it all up, bees with plenty of stores of light, sealed honey, will come through a long winter under circumstances that would prove fatal to bees with dark, poor honey.

The Denver Convention.

Report of the Proceedings of the Thirty-third Annual Convention of the National Bee-Keepers' Association, held in Denver, Colo., on Wednesday, Thursday and Friday, Sept. 3, 4 and 5, 1902.

The first session began Wednesday evening, at 8:30 o'clock, with J. U. Harris, president of the Colorado State Bee-Keepers' Association, in the chair, and, after the invocation by the Rev. R. H. Rhodes, and the rendering of a musical selection by the Æolian Quartet of the College of Music, Denver, Gov. James B. Orman was introduced to the convention in the following words:

Mr. Harris—Ladies and Gentlemen: It gives me great pleasure this evening to have one speak to the National convention the words of welcome who has done more as a Governor of this State in the interests of bee-keepers than any Governor it has ever had since its in-

auguration as a State. I have pleasure in introducing to you our chief executive, the Hon. J. B. Orman.

Address of Welcome by Gov. Orman.

Mr. President, and delegates to the National and State Bee-Keepers' Convention:

On behalf of all the people of the great State of Colorado, I wish to extend to you a most hearty welcome. I consider the bee-industry one of the greatest and noblest in the United States to-day. In traveling over the State of Colorado, and other States which I have been in during the past 10 or 15 years, and, more particularly, the past 4 or 5 years, I have noticed bee-culture on nearly all of the farms

and ranches. Take it north of Denver, up and in and about Boulder, Greeley, and along the Platte River, you can hardly find a ranch or a farm but has more or less bees. Take it along the Arkansas River, in and about Rocky Ford, and all the way from Pueblo to the State line, and almost every farm or ranch has its bee-hives. This is something that is very noticeable in traveling over the State.

Take it on the western slope, at Grand Junction and Montrose, and a number of other places along the Grand River, and along the Gunnison and other rivers and streams where there are a number of ranches, and you will find bees on almost every ranch and farm. Gentlemen, as I have already stated, the industry is one of the largest that we have at the present time, and it is becoming larger yearly: it is something that is becoming very noticeable, much more so than it was some years ago; and these conventions and gatherings tend to help along and increase the industry. The people of this State are taking more or less interest yearly; their meetings here are advertised well all over the State, and not only in this State, but all over the United States. The newspapers are advertising it, the people are reading about it; they know it is

something for all to become interested in and know about.

I hope while you are in the city of Denver, if there is anything that I can possibly do for you, you will not hesitate to call on me at my office, and I shall be glad to extend any courtesies or do anything for you I may be able to. I thank you. (Applause.)

Mr. Harris—I again have the extreme pleasure of introducing to you Mr. Malone, president of the Denver Chamber of Commerce, one who is always on the alert to do everything for every one who is interested in the State of Colorado, its people or its interests. President Malone.

Address of Mr. Malone.

Mr. President, Ladies and Gentlemen:

It is a pleasure to me to be with you to-night, although rather suddenly called upon. I, as president of the Chamber of Commerce, the largest and oldest commercial body in the State, extend to you who come from other States, a hearty welcome to our State. To you who come to Denver from our State, let me also extend a hearty welcome, and at our Chamber of Commerce—were it not that our home has been burned—we would be glad to receive you and extend to you any courtesies or favor that we might be able to grant, or that you might be able to ask.

On Saturday we are going to take the Letter Carriers' Convention to the Globe Smelter; a train has been chartered by the Chamber of Commerce, and I see no reason why it should not be a pleasure to you, as it certainly would be to us, to have you join us on that occasion at 1:30 p.m., when we leave the Union Depot.

In regard to bees, I must confess I am ignorant upon the subject. I have had brought to my mind to-night, by the song that was sung about sitting upon the bee, the only incident where I have any remembrance of having had experience with bees. In my childhood days I was venturesome, and they told me that honey was good; that there was a lot of it under the sidewalk that the bumble-bees had placed there. I went after it, and I remember the business-end of the bee; I had both eyes blackened, and everybody believed I had been in a fight, and, in fact, I had been, and I got the worst of it. From that time I have never robbed a beehive, but one has suffered, as my friend Krueger, here, knows.

At the Letter Carriers' Convention the other night I had occasion to say that it was our duty, as well as pleasure, to gather information throughout this State, and to extend that information not only to our own citizens, but throughout the United States and Europe; and in England at one time our Chamber of Commerce had an office in London, and our literature was distributed there. At that time the letter carriers were discussing the question as to whether Uncle Sam would raise their wages from \$1000 (which is the salary he pays) to \$1200. I told them it made me think of the story of the preacher who had been for many years in a small country town. He came one Sunday night and said to his parishoners: "It is with regret and sorrow that I must to-night make an announcement to you," and tears

began to flow as his voice trembled. He said, "I have received a call to a neighboring town, and I must leave."

The old deacon in the rear arose and said:

"Parson, how much are they going to pay you over in the new town?"

"\$1200."

"And we pay you \$1000?"

"Yes."

"Parson, that's not a call; that's a raise!" (Laughter.)

I then said to the letter carriers, if you are struggling with Uncle Sam—the most liberal government upon the face of the earth—to get a raise, and you don't get satisfaction in your Eastern and Western districts, come to Colorado and join our agricultural industry, our manufacturing industry, our mining and our grazing industry. I left out the bees, and I will tell you why. I then saw by statistics that I had, that a man had put in six acres of potatoes which had earned him a net profit of \$900, and from which, at a better time, he could raise from \$1000 to \$1200 worth. Again, the Hon. Governor sent to the Chamber of Commerce statistics showing farmers in his district were earning year by year from \$3000 to \$9000 a year on their farms from 40 to 160 acres of land. Since I came into this room to-night I have learned that there is in your midst one who has a great number of bee-hives, and who has netted from one colony in a year \$22.50. I know that that party worked at the business.

I see no reason why the bee-industry should not be better advertised than it is. If you will give to us at the Chamber of Commerce statistics so that we can get them out for you in pamphlet form; or, if you will give them to me this week, I will see that they get in the letter carriers' journal of the United States, which will go into the home of every letter carrier in the United States; 105,000 men will distribute that throughout the broad lines of the United States.

A few years ago I was in business in this city, and I remember with pleasure when a friend whom I see in the rear came to me and asked why I didn't buy the honey that I was shipping in Colorado, and I said, "They haven't any to give us; they couldn't sell me the quantity I want." He said, "Will you let me sell you some?" I bought from him, and I think there was never a year thereafter that I didn't buy all of his surplus. I shipped from the State of Colorado over three cars to firms in which I was interested, from here to Chicago. At one time I shipped three cars of honey, and at another time I had bought for them out in Idaho as high as ten cars of honey, because I couldn't get it in Colorado.

Ladies and gentlemen—because I feel the ladies can do this as well as the gentlemen—if you will put your shoulder to the wheel, and take the trouble to give us some statistics, we can show you that it is possible to do great things for the bee-industry in Colorado. Let us assist you, and I am sure that Colorado will never have to go to Idaho again to buy ten cars of honey to ship to the East.

And, as I have said before, the Chamber of Commerce, the Board of Trade, and the city of Denver, stand ready to offer to you not only the glad hand while you are here now, but for-

ever after, at any time that they can be of service to you and to your industry, as well as all other industries not only of Denver but of Colorado. Call on us, and you will not only favor yourselves but you will favor us. It is to our credit to assist you, and we want to assist ourselves as well as you.

I thank you for your attention.

Address by President Harris.

Mr. President and Members of the National Bee-Keepers' Association:

I feel proud on behalf of the State Bee-Keepers' Association of Colorado to greet you here to-night. We have in this State a large honey industry, which, by the probable statistics next year, will amount to nearly \$800,000. Within the next two years I think we will be shipping out of the State of Colorado something like 200,000 pounds of honey. The industry in the past, perhaps, has not been recognized as it should have been, for the simple reason that it has not been known how large the industry has grown. You come from the East, you strike the borders of our State, you strike the cattle on a thousand hills, and away on the barren peaks from one side of our State to the other you find there are mines from which millions of dollars have come; and yet the mining proposition is in its infancy. We have a State here that is yet a baby, only 22 years old. Making comparison of it with any other State in the Union, with its unbounded resources, and I will say to you it is simply remarkable. You take the agricultural sections of the State, you take Greeley to the north on the potato proposition, and hundreds of cars each year go away, and bring back to the farmers much money. Take it on the west and southwest, in the rocky country, and there we have the Rocky Ford cantaloupe that is known the world over, hundreds of cars going East each year to the markets.

Take our coal industry in this State; we have coal enough in the various counties to supply the world for years. Take the city of Denver, grand in itself, and in its welcome, the people from the outside all know of it as the great convention city. You then go from the city of Denver to the city of Pueblo, where we have a monster rising up. Then go into the sections on the western slope, where you get the great fruit interests. From that section, taking Montrose, Delta and Grand Junction, there will be over 600 carloads of fruit this year.

Taking all these into consideration, you can have some conception of the immensity of the resources of the State of Colorado, young yet, as I have stated before. With an inter-State canal that will cover something like 200,000 acres of land, there we will successfully land 10,000 people, or 10,000 families, in other words; and where there is a barren desert to-day it may be grown up in flowers, and the farmers will be reaping the alfalfa, and the crops, and bees gathering the honey from the same, and car after car of honey will be shipped, as well as from the other districts.

The half has never been told of Colorado. The people in the East think, in a manner, that we were but a few years ago a set of barbarians. To-day

in Colorado you find one of the most enlightened classes in the world. Take our educational matters, we are second to none in the United States, and each and every individual who lives within the confines of the State feels proud of the education that a young man or young woman can get in the State of Colorado.

We hope, ladies and gentlemen, that when you view our State and look at its wonderful resources and return to your Eastern, Western, Southern, and Northern homes, you will think your trip has not been for naught, but you can go to the people there and tell them that there are still homes here for hundreds; they can come here and make a good, comfortable living. They can do what a great many can not do in the East. And we as bee-keepers, as citizens, all bid you welcome to our State. (Applause.)

Mr. Harris—I have the pleasure of now introducing to you Dr. Mason, who will reply to the Governor's address of welcome.

Dr. Mason's Response.

Mr. President and Brother Bee-Keepers:

It is a very nice thing to listen to such nice speeches as we have been having, but to call upon a man like me, who is not accustomed to speaking in this way at all, is very embarrassing. You see, I am so easily embarrassed, anyway! But I can say to you that we certainly appreciate the addresses of welcome that we have heard, and it is with pleasure that in the name of the members of the National Bee-Keepers' Association to-night, and especially of those from outside of Colorado—for we have them here from Texas, Washington, D. C., New York, Ohio, Michigan, Indiana, Illinois, Wisconsin, Missouri, Kansas, and other States—I heartily thank the Governor for his address of welcome.

Some of us have not yet fully appreciated the beauty and the grandeur of your scenery, but we have met with a warm, open hand and a warm heart, and we can most cordially return these hand-shakes and these heart-welcomes. It has often been said, you know, that those of us who live in the East are tenderfoots; but let me assure you to-night that all who live in the East are not tenderfoots, and that all of the tenderfoots do not live in the East. I think you can appreciate that fact. But we realize that a great many of your people here who are not tenderfoots did come from the East, and some of us who have come in more recently, within a few hours perhaps, may find to our pleasure that we have been welcomed by more than the one

class of society, both of them grand and noble in their place.

A few years since, the Hon. Eugene Secor responded to an address of welcome in words so noble and grand that I can not in any way do better than to read to you what he said on that occasion, and, with a few word changes in it, it is applicable to this time and place. [Here followed the poem.]

Mr. Harris—I have just been informed that of the interests of this State the agricultural shows the largest increase, the manufacturing comes next, and the mining last. I now have the pleasure of introducing to you Dr. Miller, who will reply to Pres. Malone of the Chamber of Commerce.

Dr. Miller's Address.

It wasn't necessary for Pres. Malone or anybody else to get up here and tell us we were welcome; we knew it almost before we ever got here; we knew what the people of the State of Colorado were doing from the press; we knew enough to know we were thoroughly welcome; that was the notion I had when I started from home, and I have had no occasion to change it—I don't expect to.

I am glad to be here, but, I tell you one thing, I have gotten over some of the notions I had. My wife was afraid to have me come here, and yet I find it isn't anything like as dangerous as I expected. I find that the president of the Chamber of Commerce looks like a white man. Of course, I know from all that is being brought in about the 22 years and different things, and by his straight hair, that he is an Indian, but I expected to find him with a blanket on instead of like a white man; and I don't believe I would be afraid to sleep in the same room with him at night, and to have a Waterbury watch! I think I might be safe. But, I tell you, some things I have been disappointed in, in another way—the tremendous distances here make it a dangerous place for anybody as short as I am. It has fooled people before my time. I don't know whether any of you know it, because it has not gotten out, perhaps, that there was a man here once who came over from England. He had gone with some of his friends to see the different places of interest, and there is a little hill called Pike's Peak that showed up big, and he thought he could go there immediately; but he found it a great deal further than he expected, and he found everything else the same way. So he was going along, and his friends were going with him, and they came to a little bit of a stream; he began to take off his clothes, and they said, "What are you doing?" He said, "I am going

to swim across." But, they said, "That is only a little way." "You don't fool me," he said; "by the time you start you will find it's a mile across!" (Laughter.)

When we got out to Omaha there was too much room there, our baggage lost us! Then, after we got here I saw a place where I thought there was more room to stay, and some of our friends were there, and I went there—a nice place. And then Pres. Malone said something about my coming down from the gallery, and I started to come; I knew I could get here in just a little while, and I started out there, and I ran with all my might, and I ran that way, and the other way, and when I got down here the soles of my shoes were all worn out; I was a tenderfoot for certain, and if I ever get home I believe I will stay in some little place.

But I want to tell you I am glad you welcomed us here, very glad, and I am glad to shake hands with a civilized Indian. (Applause.)

Pres. Malone—Dr. Miller says I am a civilized Indian. Let me tell you when I first came here to the State of Colorado I worked with a crew that moved all the dirt from Long's Peak, and filled that hole and made it Pike's Peak! (Laughter.)

Dr. Miller—You are bigger than I suspected.

Mr. Harris—I present to you Pres. Hutchinson, of the National Bee-Keepers' Association, who will reply to Colorado's address of Welcome.

Pres. Hutchinson's Address.

Ladies and Gentlemen:

I am not a speech-maker, and I can not reply to this address of welcome, and I shall not attempt to. I can say that we people from the outside know we are thoroughly welcome. We can't object to that.

I wish to say that Mr. Ernest Root will show us, with his stereopticon, views taken from the Atlantic to the Pacific, and I know if he shows those and tells us all he has to say about them he will have to commence pretty soon, and I shall just simply say I know we are welcome, and sit down.

The remainder of the evening was taken by Mr. E. R. Root, of Ohio, who delivered his interesting lecture (illustrated by means of the stereopticon) on "Bee-Keeping from the Atlantic to the Pacific as Seen Through the Camera and Stereopticon." This lecture was very much enjoyed by those who had the pleasure of listening to it, and seeing views projected upon the screen.

At 10 o'clock the convention adjourned to meet the next day, Thursday, Sept. 4, at 9 o'clock a.m.

(Continued next week.)

* The Afterthought. *

The "Old Reliable" seen through New and Unreliable Glasses.
By E. E. HASTY, Sta. B Rural, Toledo, O.

GOOD QUALITY OF HONEY FOR WINTER STORES.

Notice that Doolittle also says that good quality of the honey counts more than any other one thing in wintering a colony of bees. If he had said more than all other things combined, I don't think I should have pitched in. Page 550.

BEE'S DARKER WHEN HUNGRY.

Dr. Miller might have added to his excellent answer on page 555 this further suggestion: When bees are in real and literal fact "slowly but surely getting smaller and blacker every day," it is because nectar in the flowers is getting scarce. The bees are shutting up—not the shop, but themselves. The sections of which a bee's body is composed are yellow on the inner edge (if anywhere) and dark-colored on the outer edge. Lots of beginners have never heard or thought of this. Most bees look pretty dark when hungry and totally empty—and small also, the sections being slid in to the utmost. And pretty decided hybrids may rejoice their owner's appetite for yellow when distended as far as possible. The amount of honey the home bees habitually carry declines, and I presume the other

fluids of the body decline some also, as the harvest ceases and famine times come on. Often the enterprising apiarist wishes to select the large bees and breed from them till all the bees are larger. It seems to be rather a tough-job to select correctly. When two colonies seem to differ in size April 1st, how shall we tell how much is real difference in size, and how much is difference in distention?

KILLING OFF BEES ON THE SLY.

I rather think that kind of dirty-souled people are not very common—the people who kill off their neighbors' bees more or less on the sly. If the bee-keeper himself is unwisely inclined to go on the war-path he may awaken passions of this kind which would otherwise remain dormant. In one case, long since, I remember wondering if some one was not infecting certain bees with foul brood on the sly. When it comes to keeping discoveries secret for fear a bad use may be made of them—that sort of thing is liable to be greatly overdone. Don't keep a new and better way to kill flies secret for fear some one will use it to kill bees. Page 557.

THE PAIN OF BEE-STINGS.

And so Mr. Harrington thinks that after the first few stings the rest of the hundred or so didn't hurt much. I rather think that that is a genuine and not very uncommon phenomenon. It's queer. Same thing appears when one gets a multitude of small wounds in succession, I believe. As to the why of it, call it one of the wonderful results of nerve-power. Do we rise above pain by sheer inner force? Or do some of the nerve trolleys get off, and the nerves kind o' forget to bring up the pain reports? My best guess is that it takes a magnetic current to carry the impression of pain to the brain (otherwise no pain at all), and that whenever we get into a general and miscellaneous rumpus there are so many other uses for the current that there is very little left to carry pain reports with. Page 563.

QUEEN-REARING AND SWARMING.

I felt comfortably assured that I was right before; but yet I'm glad so strong an authority as C. P. Dadant says the same:

"My experience is that when a populous colony is made to rear queens during the swarming season it will swarm with the first queen hatched more readily than if it had not been caused to rear queens at all."

So a little too late and your bees swarm; and if you are not late you weaken the colony badly and decrease the harvest. In fact, any seasonable application of the method weakens the colony badly. Probably Mr. Dadant is right, that the only practical application of the principle is to have the young queens reared the season before. Helps some to discourage swarming even then.

THE STING-TROWEL THEORY—OTHER STINGS.

Well, well! From the warrior feeling for a position to stab home, and the queen troweling the egg into position with her sting, how many miles is it to the "sting-trowel theory" which we have pelted with garbage?

"Always" is a big word. And all the bees that sting did not sting Mr. Cheshire. I prefer to believe that there is now and then an exceptional bee that stings without any poking around to locate.

Questions and Answers.

CONDUCTED BY

DR. C. C. MILLER, *Marengo, Ill.*

(The Questions may be mailed to the Bee Journal office, or to Dr. Miller direct, when he will answer them here. Please do not ask the Doctor to send answers by mail.—EDITOR.)

Feeding Back.

I have a few colonies of bees that are without winter stores and must be fed. I also have some colonies that are stronger and have a full supply, and it is my opinion that if they were to find any more they would put it in the sections. Would they do this if the honey is fed to them? If they would, would it not be wise to feed them, as there is a good demand here for section honey, retailing at from 25 to 30

cents during a light crop? Or, would what is fed to them diminish in quantity enough to leave no profit at all. If you think that there would be a margin, would you advise feeding a No. 1 article, or would the bees not convert an inferior honey to a superior lot? MARYLAND.

ANSWER.—Unless you have had a good deal of experience you will find it unprofitable to feed honey to have it stored in sections. Some say they have made it pay, but most bee-keepers, even those of much experience, have not been successful at it. If you feed back, use only the best honey if you want a good article. The bees will not improve the quality of honey you furnish them.

Not Working in Sections—Knowing Queens—Feeding Bees.

My bees swarmed once in July, so I have 2 colonies, and neither works in the sections. The colony that is left in the old hive does not seem as large as I think it should be. There are acres of goldenrod, ironweed, highbush, smartweed, and corn, as well as vines. Now that is all right for them, and there are no other bees in the country. I fear the old colony has not a fertile queen? How may I know her? Shall I feed the bees? If so, how?

ANSWER.—Possibly you have been expecting your colonies to be stronger than they ought to be. The swarm can have no young bees hatching out for three weeks, and during all that time the bees will be dying off daily, so it will be getting weaker during all of that three weeks. The mother colony is likely to be left quite weak, but will gain rather than lose during the first three weeks. Then will come a falling off for some days, until the progeny of the young queen begins to emerge. Lift out the combs and see whether you can find eggs or unsealed brood. The presence of these is proof that the colony has a laying queen.

Look up the matter of feeding bees in your text-book, and if anything in that is not understood, feel free to ask questions about it in this department.

Storing in the Supers—Fears Short Stores.

Does it deprive the bees of their winter supply to let them continue storing honey in the supers until they quit of their own accord? If so, please tell me how to stop them, and at what time. IOWA.

ANSWER.—Generally bees of their own accord will gradually contract the brood-nest and fill up the brood-chamber with honey. Of course you can prevent them from storing any more in the supers by taking supers off. A better plan is to have a supply of combs of sealed honey, and then after supers are taken off one of these combs can be given wherever needed. You will find good use for a number of them next spring.

Eggs that Failed to Hatch.

During the month of August I brought 3 select queens. The last one I introduced by the wire-screen method. She had commenced laying before I gave the bees free access to her. They accepted the queen all right, but would not accept her eggs—at any rate they failed to hatch into larvæ of any kind. Plenty of eggs can be found at any time; they are laid in as nice rotation as any queen could lay them, but there seems to be something wrong. On opening the hive the bees will commence a low hum or moan, not just like a hopelessly queenless colony, but something similar. I put on a feeder and commenced feeding, but that has not changed matters a bit.

1. Can she be a drone-layer?
2. What becomes of the eggs?
3. What would I better do in the case?

WEST VIRGINIA.

ANSWERS.—1. It is possible, but not probable, that she is a drone-layer.

2. I don't know. Likely the workers eat them, after they have been in the cells two or three days.

3. It is not an uncommon thing for bees to stop breeding toward the last of September, and sometimes as early as the date of your letter, Sept. 15. It is generally supposed, I think, that the queen takes the initiative in this matter, the bees continuing to take care of the eggs as long as the

queen lays; but I have noticed quite a number of cases in which the queen continued to lay for some days after the workers stopped hatching the eggs. So the best thing for you to do may be to do nothing; trusting that the bees may be ready next spring to take care of the brood. There is such a thing sometimes as a queen laying eggs that never hatch; but such cases are very rare (I think I never had more than one such queen), and as your queen was a tested one, she should not come under that head.

Perhaps Paralysis or Poisoning.

On June 2 I sold to one of my neighbors a swarm of bees that came out May 30, and he hived them in a hive on the old combs on which a colony had starved out last winter. He moved the bees right away to his place one block distant from my place. They worked well and put up considerable honey in the brood-combs, and have it about all filled up with brood and honey.

About two weeks ago he advised me his bees were dying; some of them would crawl out and roll down on the ground, while others were carried out by the bees, unable to fly, but would crawl around on the ground and finally become too weak to crawl, and after from 2 to 12 hours would die. Upon mashing them there is a dark-yellow substance comes out about the size of two wheat-grains. The ground is all spotted up around the hive with this dark-yellow substance. They are not working very much the last few days. The queen looks all right.

Can you give some idea what is the matter with them? and is there any remedy for it? What is it?

My bees, one block away, are working well, and do not appear to have anything the matter with them.

KANSAS.

ANSWER.—I am not sure that I know what the trouble is. It looks a little like paralysis, in which case you will find the diseased bees with trembling wings, some of them having a shiny, black appearance. It looks rather more like a case of poisoning. I am sorry to say that in either case I can offer no remedy.

Probably the Result of Worms.

What causes the following: Nearly every morning I find young bees of a whitish color lying on the alighting boards of the hives; sometimes there is just enough life to cause the legs to move, but generally they are dead.

ILLINOIS.

ANSWER.—It is probably because of the presence of worms in the hive. It might be well for you to examine, and kill the larger worms.

Screening Grapes Away from Bees.

Perhaps you would like to hear how bees are getting along in Virginia. Upon the whole it seems to be an off year. My best colony stored 60 pounds of comb honey in pound sections, and did not swarm. This was all stored in June. Since then they have filled only the sections with comb, but stored no honey.

My other colony stored but 6 pounds of honey, and swarmed once in June. The old colonies are in Langstroth hives; the swarm I got I put into a Danzenbaker hive. This colony has no honey in the super yet, but has filled the most of the sections with comb. Now, you know it is claimed for this hive that the bees will store no honey below. I took it all apart a few days ago, and there is a circle of cells filled with honey from 2 to 4 inches wide, both at the top and at the sides of the 10 brood-frames, with the center built out in worker-cells.

I am only a beginner, this being my first year. I like it very much. I find, however, that the good people who claim that bees will not cut into fruit are away off, at least as far as grapes are concerned. My bees have been on a spree for two weeks, working on my grapes, and have caused considerable loss. I have watched them very closely and have seen them go from berry to berry, especially the thinner-skinned sorts, and cut them. Another year I must surely cage them during this season. Now, will you please tell me the best way to accomplish that? Of course I would expect to feed them during this time, and perhaps allow them a flight late in the evening. Would not an empty super spanned with wire-cloth, and the same over the en-

trance, be safe? Besides the damage they do in the vineyard they are a real nuisance in the wine-house, stinging and getting into the must, and in and on everything that has any grape-juice on it. They now neglect everything in favor of the grapes, even smartweed and buckwheat. I have a field of black cowpeas, but I have never seen a bee on the bloom. Although there is an abundance of the so-called honey-plant bloom, and the bees get all the grape-juice they can make away with, they have brought in no honey. All honey stored was white clover and poplar.

I do not know about the truth of bitterweed making bitter honey, but certainly the bees work on it for at least three weeks, and as this was before they stored in the super, both the nectar and pollen was either fed to the brood or stored below.

VIRGINIA.

ANSWER.—I do not believe you can imprison your bees during the grape season without heavy loss, unless you put them in a cellar where they can be kept in the dark at 50 degrees or less. Some have been very positive that bees cut into grapes, but upon closer observation have always found that no bee ever cut through the skin of a sound grape. After the skin has been broken through, the bees will make rapid work sucking out the juices. Some grape-growers prefer to have the bees work on the grapes, as the grapes they work on would only sour if left on the vines in their broken condition. The bees can be kept away from the grapes after they are off the vines in the same way they are kept from cider-mills, by putting wire-cloth in all doors and windows.

Perhaps Worms in the Hives—Ants.

I wrote you a few days ago that my bees were killing the young bees; they still kill them. I am feeding them sugar every day; they don't eat the sugar very well—some days they eat it all, and other days they leave it. The bees seem very uneasy. Some nights the black ants bother them. I scalded the ants' nest to-day with hot soap-suds, to try to drive them away. They are gnawing at the joints of the cover, trying to get into the hives.

ILLINOIS.

ANSWER.—If the number of young bees carried out is not large, it may be because there are worms in the hive.

If the hot water has not made a finish of the ants, you might try pouring gasoline into their nests.

Feeding for Winter Stores.

1. This has been a poor season for honey here. The bees have held their own, but no more. Last spring I increased my bees from 10 to 25 colonies, so I have some small ones that will not gather enough to winter on. Would it not be best to pick out a few of the best ones, put on second stories filled with frames of full foundation, and feed them? Then after the frames have been filled and sealed give them to the needy?

2. Can I feed sealed honey stored in odd-sized frames, by setting them in an upper or third story, after cutting the cappings open?

3. About how many pounds would the bees store from every 100 pounds fed? Or, what would there be in the transfer from the old to the new frames?

4. Or, is it better to feed sugar?

5. If both are good, which is the cheaper when they cost the same per pound?

MICHIGAN.

ANSWERS.—1. Yes, your plan is all right.

2. Yes, but unless there is much empty space in the brood-frames you may find the bees making very slow work carrying it down. In some cases they will leave it where it is and seal it over again.

3. I don't know the amount of loss in transferring from one set of frames to the other, but I think it would be very small.

4. I don't know which is best. Some authorities in Europe think it unwise to use sugar except as a matter of extreme necessity, claiming that bees reared on such food will have a weakened constitution. On the other hand, some good authorities in this country think sugar better than honey for wintering. Something may depend on the way the sugar is fed. If fed early, having as much water as sugar, or more water than sugar, so that the bees can make the proper chemical changes, the results may be very different from feeding late, so that there shall be only a third as

much water as sugar. Whether fed thick or thin, it is not well to feed late.

5. Five pounds of sugar made into a syrup with two pounds of water is supposed to be of about the same strength as honey; so you will see that at the same price per pound it ought to be cheaper to feed sugar.

An Experience with Bees.

I have had quite an experience with that colony since I wrote before. I think I said I had examined it carefully three times during 10 days, after first noticing something wrong, and the last two times I could find neither eggs nor unsealed brood in the hive. A greater part of the sealed brood was dead also, the bees busy carrying it out and tearing down comb, and of course there was no sign of a queen. I therefore concluded it was queenless, and wrote for a queen. It was about 10 days later (Aug. 15) when, the queen having arrived, I opened the hive to introduce her. What was my surprise to find a splendid-looking young queen, and 4 frames packed with eggs in the most approved style, every cell having an egg, and no skips. She evidently had been laying a couple of days, as there was no hatched brood. I knew it to be a new queen for I had seen the old one several times, and she had ragged wings.

1. But where did she come from? I examined every frame carefully on Aug. 6, and found no trace of any queen-cells, and no unsealed brood, and no queen; and now, on Aug. 15, I find a young queen at work laying for 2 or 3 days. Did I overlook her on the 6th? or was there a queen-cell in some corner that escaped my search? At all events there she was, and I was then in a dilemma. I had 2 queens on hand. I disliked destroying either; and yet I did not want both. The young black was doing such good work, the caution seemed to say, "Let well enough alone;" but, then, I would rather have the Italian. So I caught and caged the black and set the yellow one in her cage (unopened) over the brood-frames. I waited 2 days and then opened the hive and destroyed 15 queen-cells which they had started. I waited another day and destroyed 8 more, then I let the bees at the candy. In two days more I looked in again and found the bees trying to kill my pretty Italian queen. They had evidently been abusing her for some time. I found her on the bottom of the hive, and about two dozen bees mauling her. Her wings were nearly bitten off and she looked altogether in a pitiable plight. I immediately caught and caged her again. The next morning she looked much better, and I thought I would try again; once more I examined the frames and destroyed 2 very small queen-cells, and I was now satisfied there was no more brood in the hive young enough to start queens from; so I let the bees at the candy end of the cage again. This was on Saturday. On Monday I again looked after my queen, and again found her nearly dead, and the bees still balling her; her wings were now in strips and her legs quite stiff. I knew she could not live, so I let her go and gave back to them (in a cage) their own black queen. I had kept her caged for 10 days while experimenting with the Italians. So you observe that is victory number one for the bees. But if they scored the same, I have learned a great deal about bees. I also learned something else. I discovered what was, and is yet, the matter with my colony. Shortly after the 4 frames of eggs above mentioned (laid by the young black queen) had been sealed, I observed the bees again tearing down the comb and hauling out the brood, the most of it dead. I determined now to make a thorough examination, and to my chagrin discovered that the cells were full of worms (bee-moths). They had gotten under the capping and had tunnels right over the heads of the young bees, and in many places I dug a worm right out of a cell right alongside of the nymph. Fully one-half the brood is destroyed. The rest is hatching out all right.

2. Now, why don't they (the bees) destroy those worms? The colony is strong, and I never saw larger and finer looking bees. They are not the little black bee, but a very large brown bee. I think they must be a cross with an Italian drone, for last year they were certainly all blacks. They have done very little at gathering honey for several weeks past. It takes them all their time tearing down the comb, and even part of the foundation, and carrying out the dead brood.

3. What about the wintering of this colony? Will the bees get the worms killed before time to put them into the cellar, or will the worms remain in the hive all winter and destroy bees? What would I better do in this case? The

bees do not seem to be able to get at the worms; and they do not like to "tackle" them when they can get at them.

4. I have also something else to tell you, doubtless not a new experience to you, but rather strange to me. The first queen I got was let loose in the hive on the first day of August. She has done well, and the hive is packed full of fine-looking, bright-colored, young Italians. But here is what surprised me. On Aug. 29, I examined this colony to see how the new queen was getting along, and, as I said, found it packed full of young Italians and plenty of sealed brood, but I found, along with the old queen, and close by her, a fine, long, energetic and very graceful-looking young queen as bright in color as her mother, and apparently on terms of mutual agreement existing between them. Now what does this mean? Does it mean that my new red clover queen which has been laying just about one month, and laying well, too, is now going to be superseded? If so, Dr. Gallup may be right, after all.

5. Shall I leave those two queens in the hive for winter (there can be no more swarming here now this season)? or shall I destroy the young one? Of course, she cannot be mated pure, here, and I dislike to see my beautiful colony of bright Italians go back to blacks again.

I forgot to say that the black queen that I kept caged for ten days while trying to get the bees to accept the Italian, is again laying well. If they can only get the worms destroyed, it may pull through all right yet.

ONTARIO.

ANSWERS.—1. I don't know where she came from. Sometimes a young queen reared in the hive escapes the most careful search; sometimes a virgin queen from elsewhere enters the hive; and in a few cases I have known a laying queen from another colony to enter.

2. The character of the bees has much to do with the matter; blacks will suffer the presence of moths when Italians would clean them out, and some blacks are worse than others. The great number of worms would make the bees somewhat discouraged, for blacks will give up when too many worms are present.

3. With the help that you can give them, they may winter all right. If you dug out all the larger worms, they may take care of the smaller ones, so as to winter pretty well. Take the sharp point of a wire-nail, or the point of a penknife; start at one end of the webbed gallery of a worm, and tear it open perhaps half an inch. Then start at the other end and tear it open the whole length. When the worm, driven by you, comes to the hole first made, it will come out, and you can then deal with it as your judgment dictates.

4. It looks like superseding. Yet it is possible that the old queen has a considerable lease of life before her, for when a queen is introduced the bees are sometimes dissatisfied with her for a time, long enough to start a successor, and afterward she proves all right.

5. Leave both for the winter. If the old queen has disappeared by next year, then you may be thankful you did not destroy the young queen. If both are still alive, then divide the colony as soon as strong enough, letting each queen set up an establishment of her own.

Send all the questions you like without any feeling you are intruding, but please don't send anything for postage. When I open a letter and find postage stamps enclosed, it always gives me a sort of chill, for the first thought is that an answer is expected by mail, and although you did not want an answer by mail I want to be spared the chill.

"The Hum of the Bees in the Apple-Tree Bloom" is the name of the finest bee-keeper's song—words by Hon. Eugene Secor and music by Dr. C. C. Miller. This is thought by some to be the best bee-song yet written by Mr. Secor and Dr. Miller. It is, indeed, a "hummer." We can furnish a single copy of it postpaid, for 10 cents, or 3 copies for 25 cents. Or, we will mail a half-dozen copies of it for sending us one new yearly subscription to the American Bee Journal at \$1.00.

Why Not Help a Little—both your neighbor bee-keepers and the old American Bee Journal—by sending to us the names and addresses of such as you may know do not now get this journal? We will be glad to send them sample copies, so that they may become acquainted with the paper, and subscribe for it, thus putting themselves in the line of success with bees. Perhaps you can get them to subscribe, send in their dollars, and secure for your trouble some of the premiums we are constantly offering as rewards for such effort.

THE AMERICAN BEE JOURNAL

PUBLISHED WEEKLY BY

GEORGE W. YORK & COMPANY
144 & 146 Erie St., Chicago, Ill.

Entered at the Post-Office at Chicago as Second-Class Mail-Matter.

EDITOR—George W. York.
DEPT. EDITORS.—Dr. C. C. Miller, E. E. Hasty.
SPECIAL CORRESPONDENTS—G. M. Doolittle,
Prof. A. J. Cook, C. P. Dadant,
R. C. Aikin, F. Greiner, Emma M. Wilson,
A. Getaz, and others.

IMPORTANT NOTICES.

The Subscription Price of this Journal is \$1.00 a year, in the United States, Canada, and Mexico; all other countries in the Postal Union, 50 cents a year extra for postage. Sample copy free.

The Wrapper-Label Date of this paper indicates the end of the month to which your subscription is paid. For instance, "dec01" on your label shows that it is paid to the end of December, 1901.

Subscription Receipts.—We do not send a receipt for money sent us to pay subscription, but change the date on your wrapper-label, which shows you that the money has been received and duly credited.

Advertising Rates will be given upon application.

The National Bee-Keepers' Association.

OBJECTS:

To promote and protect the interests of its members.

To prevent the adulteration of honey.

To prosecute dishonest honey-dealers.

MEMBERSHIP DUES, \$1.00 a year.

If more convenient, Dues may be sent to the office of the American Bee Journal, when they will be forwarded to Mr. Secor, who will mail individual receipts.

A Celluloid Queen-Button is a very pretty thing for a bee-keeper or honey-seller to wear on his coat-lapel. It often serves to introduce the subject of honey, and frequently leads to a sale.

NOTE.—One reader writes: "I have every reason to believe that it would be a very good idea for every bee-keeper to wear one of these buttons! as it will cause people to ask questions about the busy bee, and many a conversation thus started would wind up with the sale of more or less honey; at any rate it would give the bee-keeper a superior opportunity to enlighten many a person in regard to honey and bees."

The picture shown herewith is a reproduction of a motto queen-button that we are furnishing to bee-keepers. It has a pin on the underside to fasten it.

Price, by mail, 6 cents; two for 10 cents; or 6 for 25 cents. Send all orders to the office of the American Bee Journal

GENERAL ITEMS

Getting Fall Honey.

I cannot keep bees without the American Bee Journal. I have 23 colonies, some working in the third super. The bees here worked well on red clover. We are getting lots of fall honey. I did not get much white honey as the bees needed it to start housekeeping after stargation during the month of June.

A. J. GIFFORD.

Cass Co., Mich., Aug. 29.

Phacelia Tanacetifolia.

Liedloff writes about phacelia as follows: "All bee-papers are full of praise about Phacelia tanacetifolia. It is not only a good honey-plant for the bees, but it furnishes with its juicy green stems and leaves also a very excellent green fodder, which horses, cattle, goats and hogs eat with the greatest relish. Cows and goats give, when fed with phacelia, great quantities of milk. The crops of seed are also rich, one acre (American measure) producing in Prussia 400 to 500 pounds of seed. It takes about 5 pounds of seed to sow one American acre. We recommend to all bee-keepers and farmers to try this plant yet this year. The plant does well in almost any kind of soil. The seed can be sown similar to grain after the grain-fields have been plowed. After six to eight weeks the plant is in full bloom."

OTTO LUDORFF.
Tulare Co., Calif.

A Visit to Dr. Gandy, in Nebraska.

FRIEND YORK:—The extraordinary yield of honey in Richardson Co., Nebr., as reported by Dr. G. L. Gandy through the columns of Gleanings in Bee-Culture recently, has created no little interest in the matter of artificial pasturage, and more especially that of catnip as a honey-producer. To determine more clearly these matters of interest, E. R. Root, W. Z. Hutchinson and myself visited the locality and spent several days viewing the different apiaries and the home of the catnip in Nebraska, during which time both Mr. Root and Mr. Hutchinson took many photographic views, and will doubtless be able to illustrate to their readers what they saw while on the ground.

During our stay we were royally entertained by Dr. Gandy and his excellent wife, and no pains were spared to show us the surrounding country. The Gandys own some 20,000 acres of the fertile soil of Richardson and surrounding counties, and the Doctor is, without question, the owner of the greatest number of bees within the great State of Nebraska. While there are some differences of opinion as to the yield of honey during 1901, as reported by the Doctor, and the statements made by residents in and around the locality, and as none of the honey reported is now in sight, of course we had no means of determining which side of the question was the correct one. We are of the opinion that some misconstructions have been placed upon the Doctor's statements, that he was the owner of some 3,000 colonies of bees, and that this whole number had produced the wonderful yield of honey reported by him. While the Doctor has in his home apiary at this time about 137 colonies, he meant, as he stated to us, only to infer that the yield reported came from this apiary alone, and that from many of the out-apiaries he received less surplus, and from some of them none at all. From present appearances there will be a very light yield from this home apiary for this year, and those located in the surrounding country show but little evidences of a copious honey-flow.

At one of the Doctor's farms, occupied by Mr. Bryant, some six miles south, we found the best conditions where there are about 50

colonies of bees, and where could be gathered from 1000 to 1500 pounds of surplus honey, although none had been taken from these up to date. The honey-flora, as we were able to see it, consists of sweet clover, heartsease, catnip, white clover, horehound, wild cucumber, buckbush, and in some localities a sprinkling of linden. The farming in the vicinity where Dr. Gandy lives, is too good to expect any considerable flow from the heartsease, and the buckbush, wild cucumber and linden are confined almost entirely to the streams of timber skirting along either side of them. Sweet clover grows along the roadsides and waste-places, but not in so great an abundance, as this plant is to be found in many other localities in this State.

Catnip and horehound have been sown by the Doctor and his tenants, and is to be found along the roadsides peeping out from under the hedges, and up to this time no attempt to produce this plant in any considerable quantities out in the open has proved successful, and it is yet an experiment whether this can be accomplished or not, inasmuch as the catnip appears more to desire the shade of other plants rather than the pure sunlight. We were unable to procure a single sample of pure catnip honey, yet we did procure some extracted honey produced on the Missouri River, some 25 miles east of where the Doctor lives, which was mixed with sweet clover and other nectars, and with sufficient catnip to impart a flavor of this plant to the honey.

Dr. Gandy is very enthusiastic over the prospects of the future for producing great quantities of honey from the catnip bloom, and the result of his efforts will be watched with a great deal of interest during the years which are to follow; and while we and others may be a little skeptical upon this point, yet we believe that if there are any good results to be gotten out of this plant the Doctor is pretty sure to find it.

In the manner of hives, and the method of tiering up, as practiced by the Doctor, we do not care to take issue, inasmuch as about the same results can be attained with the same care with any of the movable-frame hives; yet the production of what is called chunk honey, as practiced by Dr. Gandy, is not that class of producing honey which is considered up-to-date by most bee-keepers, but is considered by most of them as having been handed down from the more primitive days of bee-keeping. During our brief stay we did not see a single apiary which might be considered up-to-date in many particulars.

We departed, feeling that whatever might be the results of Dr. Grandy's experiments in growing catnip, horehound and buckbush, and howsoever others might differ from him in these matters, that both he and Mrs. Gandy were excellent entertainers; and that to the visitors who drop in upon them the latch-string of hospitality will always be hanging outward. E. WHITECOMB.

Saline Co., Nebr., Sept. 13.

Not a Good Location for Bees.

I would not be without the American Bee Journal as long as I have bees. My bees have not done well this season; they have increased from 14 to 22 colonies. I will probably have to feed later on.

This is not a good location for bees—too cold and windy, and too many bees for the amount of pasturage. ROSCOE WHEELER.
Alameda Co., Calif., Sept. 8.

Light Yield of Honey.

The honey harvest is over, and the yield has been light, take the county right through.

From 35 colonies, spring count, I harvested 1000 pounds of white comb honey, with no fall flow of yellow honey. Fourteen miles east of here bee-keepers got no white honey, but all yellow.

I lost over half of my young queens this season. They would fly out to meet the drone, but in place of returning to the hive they would drop down in any old place. I found and returned 10 or 12 to their hives, but they were no good. Not one of them ever laid an egg.

Originally my bees were black, but now they have one or two yellow rings on the

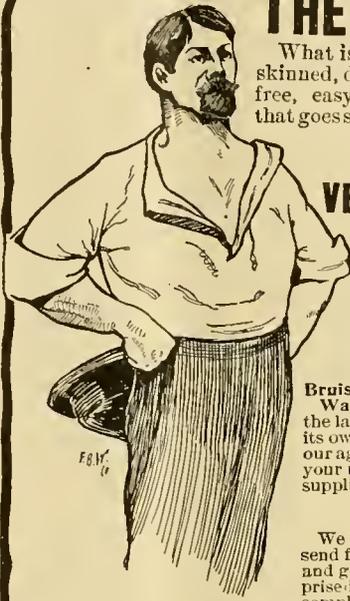

BEE-KEEPERS--ATTENTION.

Do not put your money into New Fangled Bee-Hives, but buy a plain, serviceable and well-made hive, such as the regular Dovetailed hive arranged for bee-way sections. Honey-producers of Colorado—one of the largest honey-producing sections in the world—use this style.

THE GLORY OF HEALTH.

What is more pleasing to the eye than an athletic, clear skinned, deep chested man, ready to toil or play, with the free, easy grace of perfect health? The kind of man that goes singing about his work, because he feels that way.

WATKINS' VEGETABLE ANODYNE LINIMENT

will not make a lazy man muscular, but it will keep the body in such perfect condition that the food you eat, the work you do, will all help to build up a big, strong body. It is the cold in the chest, followed by a troublesome cough that breaks down so many strong bodies. A dose of Watkins' Liniment will stop it all before the harm has been done. **No running for Doctor, no paying big doctor bills.** Use internally or externally for Colds, Coughs, Colic, Diarrhoea, Dysentery, Cholera Morbus, Indigestion, Cuts, Burns, Bruises, for man or beast.

Watkins' Liniment is good for so many diseases because of the large number of valuable ingredients, each of which does its own work, and does not interfere with the others. Let our agent leave a bottle at the house. If there is no agent in your neighborhood, write to us, and we will see that you are supplied.

A Valuable Gift.

We have a beautiful Cook Book and Home Doctor that we send free to all. It is full of valuable recipes and good wholesome advice. Everyone is surprised that we can afford to send out such a complete and beautiful book free. Write today. Send your name and address on a postal card.

abdomen, so they must have crossed with Italians.

All that I have done is to take queens from my best honey-gatherers for increase. It is five years since I commenced to keep bees.

We get 12½ cents per pound for our honey at home.
JOHN F. HUNTER.
Morrison Co., Minn., Sept. 12.

An Arizona Report.

We have about 400 colonies of bees that are run for extracted honey. This season they have averaged about 85 pounds per colony, and will extract once more, and should we get a good fall flow it will give us a big crop of honey.

Our first nectar was gathered from catelaw, which is of a beautiful white color and fine flavor; our next was from alfalfa, which commenced to yield about June 20, and lasted until the first part of September. I am sure we will get one more good crop from it. The first honey from alfalfa was amber, then there came a light shower of rain, and after that came the nectar, and it was almost water-white.

The dry summer, I think, was an advantage to bee-keepers, as the alfalfa did not grow high enough for the farmers to cut it, on account of the scarcity of water in the Gila River, and it just bloomed from June 2 to Sept. 1. Then the rains commenced and it was cut, but will commence to bloom in a few days.

We have about 200 colonies which we run for comb honey, but can not give an estimate of the crop. This valley is now well stocked with bees, and I think overstocked around here.

We run our bees in eight different apiaries. We have over 600 colonies in 8 and 10 frame Langstroth hives; I prefer the 10-frame hive, and I think I would like 12, or even 14, frames better for this county. I will give 25 of each a trial next season, as I always find the most honey in the large hives, and plenty of bees.
W. D. JEFFERSON.
Graham Co., Ariz., Sept. 7.

Late Honey-Gathering—Queen-Rearing.

Some one has asked in the Bee Journal whether bees stored honey after Aug. 10. In this locality our fall flow comes after Aug. 10, and some years bees will store 50 pounds of comb honey per colony. Just now we have from two to four supers on, and if the honey keeps on until Sept. 10, as it may, we have no idea what the best will be. After the worst summer season that I have ever seen in this State, we have the best honey-flow just now that I ever saw; and should warm days and nights continue we can not tell what the end will be.

Bees are swarming (when not kept down) as in good May and June honey-flows; this I never saw in this State, nor in Indiana (my old home State), as late as this.

I watch with interest what some have to say about degenerate queens, two-cent queens, and worthless queens. The breeders are keeping silent, and some wondering why. It strikes me that if the breeders should make reply on the subject it would be very interesting and instructive reading, and would be just the thing to do.
D. J. BLOCHER.
Stephenson Co., Ill., Aug. 30.

Queen Improved—Honey Report.

I received a queen sent me about a week ago; when I saw her in the cage I was disappointed, she looked so small and inferior, and I took out a fine, large queen to make room for her, and thought I would give her a fair trial. I looked at her yesterday and I was surprised to see how large she had become after she got filled out and over her journey, and I think she will be all right.

August has been a poor month for honey—too wet. I got 900 pounds of basswood honey that is fine and well filled. I think I will have 1000 pounds more of comb honey. I extract the partly-filled sections and save them for next year. I have a few colonies that I got three supers of basswood from, but

QUEENS!

This is your last chance for this season to get Queens from Quirin's Famous Red Clover stock, so hurry in your orders. We have files of testimonials like the following:

Mr. J. Roorda, of De Motte, Ind., bought 4 dozen in the spring, and says the workers are hustlers; while E. L. Messenger, of New Haven, Conn., says the queen bought last season produced bees which beat anything in that part of the country.

Price of Queens for balance of season:

	1	6	12
Selected	\$.75	\$4.00	\$ 7.00
Tested	1.00	5.00	9.00
Selected Tested	1.50	8.00	
Extra Selected Tested, the best that money can buy..	3.00		

We guarantee safe arrival, to any State, continental island, or any European country. Can fill all orders promptly, as we expect to keep 300 to 500 Queens on hand ahead of orders. Special price on 50 or 100. Free Circular. Address all orders to

they were large colonies, nearly a bushel of bees in each colony. There were two or three swarms that came out together and alighted on the same hive. I put them into one hive and had to put on three supers before the bees could get into them. This is the kind of colony I like. I think I will have more honey to sell than all the other bee-keepers put together in our county.

I have a home market for all the honey I can produce, and more too. I have developed a market in the past by peddling honey from house to house. When the children see me coming they run and tell their mothers, and I hear them tease, "Mamma, buy some; do, mamma." So, if the stores do not come to my terms, I start out with a couple of cases of honey on a wheelbarrow, and I will dispose of them in two or three hours.

I will write again when I take off the last honey, and the season is over.

WM. CLEARY.

Kossuth Co., Iowa, Sept. 1.

Bees Did Not Do Very Well—Keeping Combs.

The bees have not done very well this year. They are storing a little from fall flowers now. I think of changing my location, going to Texas. I have kept bees here for 30 years or more, and have taken the American Bee Journal the greater part of the time.

Since I have written this much I wish to speak of saving comb honey from the moth. Combs hung up separately in a barn or open shed will never be disturbed by moths. Bee-moths works on the same principle as other moths. I keep hundreds of combs in this way; I never had the fumes of sulphur do any good.
GEO. STINEBRING.
Wayne Co., Ohio, Aug. 29.

Late Gathering—A Fair Crop.

On page 556, J. A. Watkins, of Idaho, says that the statement had been made there that bees in the Eastern States do not gather honey after Aug. 10 to any extent. In a note at the foot of the article a request is given to answer, by giving the amount a colony has been known to gather after that date. I will give my experience on the subject. Two years ago, on Aug. 3, 1900—I had a prime swarm issue, which I hived on full sheets of foundation. As my bees were bringing in honey quite freely, I thought they would store enough honey to carry them through the winter. On Aug. 11, I examined the hive to see how they were progressing, and, to my surprise, I found that they had the foundation all drawn out, and were sealing over the honey along the top-bars, and the queen was laying freely. I then put on a super (my supers hold only 21 sections), and on Aug. 19 they had it filled and capped over; I raised the super and put on another, and on Aug. 30 they had that filled. In just 19 days they had filled 42 one-pound sections of beautiful white honey, and all capped over as white as

snow. I then put on the third super, and they filled 11 sections; the remainder were only partially filled; they would have completed the third super if it had not been for the Texas cyclone, which reached here about Sept. 10 or 12; after that the weather changed, and they did not store any more surplus honey. But I was satisfied; they had filled 53 one-pound sections with as nice white honey as any one could desire, besides storing enough in their hive to winter on.

Last year that colony stored 169 pounds, the most of it from red clover; they would have stored over 200 pounds if it had not been for the cold, windy weather that we had the latter part of August and in the month of September.

I get my best flow of honey during August and September, if the weather is fair and warm enough; mostly from goldenrod and wild asters, which always yield honey very freely. Within about two miles from where my bees are located there is about 200 acres or more which, at this season of the year, is one mass of wild flowers, mostly goldenrod and wild asters.

I have kept bees for 10 or 12 years, but this has been the poorest season I ever saw; thus far I have taken off only one super of 21 sections. During June, July, and the first part of August, I had to feed some of them to keep them from starving.

The weather has been fair for the last week, and bees are working freely on the early goldenrod; there are several varieties, and usually the season lasts about six weeks. With warm, pleasant weather for the next three weeks, I will be able to report a fair crop of honey.

GEORGE H. WEAVER.

Langstroth on... The Honey-Bee

Revised by Dadant—1900 Edition.

This is one of the standard books on bee-culture, and ought to be in the library of every bee-keeper. It is bound substantially in cloth, and contains over 500 pages, being revised by those large, practical bee-keepers, so well-known to all the readers of the American Bee Journal—Chas. Dadant & Son. Each subject is clearly and thoroly explained, so that by following the instructions of this book one cannot fail to be wonderfully helped on the way to success with bees.

The book we mail for \$1.25, or club it with the American Bee Journal for one year—both for \$1.75; or, we will mail it as a premium for sending us THREE NEW subscribers to the Bee Journal for one year, with \$3.00.

This is a splendid chance to get a grand bee-book for a very little money or work.

* Add 10c per hive for fdn-starters in these two hives.				
† Covers and bottoms over 7 inches wide to be in two pieces, and may be shipped together. This is made necessary by the increasing difficulty of finding wide boards for making covers and bottoms in one piece.				
12-in. 4-row cases have had 2-piece covers and bottoms for years; we are extending this to other sizes as well.				

THE A. I. ROOT CO., MEDINA, OHIO.

HONEY AND BEESWAX

MARKET QUOTATIONS.

CHICAGO, Sept. 19.—Comb honey is meeting with good demand and the arrivals are easily disposed of at 15¢/lb. per pound for that which grades No. 1 to fancy. Very little of the lower grades are offered, but bring within 2 to 3 cents of No. 1. Amber grades of comb are also scarce, with no buckwheat offerings. Extracted is steady, white bringing 6 1/2¢/lb.; amber, 6¢/lb.; Southern and odd lots of dark, 5 1/2¢/lb. Beeswax, 30c. R. A. BURNETT & Co.

KANSAS CITY, Sept. 20.—The demand still continues good for comb honey, but receipts are very light and meet with ready sales at these quotations: Fancy white comb, 15¢; No. 1 white, 14¢; No. 2 white and amber, 13¢; dark, 12¢. Extracted, white, 6 1/2¢/lb.; amber, 5 1/2¢/lb. Beeswax, 22¢/25c. C. C. CLEMONS & Co.

CINCINNATI, Aug. 30.—The demand for comb honey at present is very good; all shipments are sold quick at 15¢/lb. for No. 1 and fancy. We advise shipping while demand is good and before the western carloads are here. In three weeks from now carloads will arrive, then demand is satisfied, sales harder to make, and prices demoralized. Extracted honey is selling as fast as it arrives at the following prices: Amber and Southern in barrels, at 5 1/2¢/lb., according to the quality. White clover, 7 1/2¢/lb. Beeswax is scarce at 30c. THE FRED W. MUTH CO.

ALBANY, N. Y., Sept. 24.—Honey receipts are light here so far, and good demand for comb honey. We quote light comb, fancy, 16¢; A No. 1, 15¢; No. 1, 14¢; mixed and dark, 13¢; buckwheat scarce at 12¢/lb. Extracted, light, 7¢; mixed, 6 1/2¢; buckwheat, 6c. Beeswax, 28¢/30c. H. R. WRIGHT.

NEW YORK, Sept. 20.—Comb honey is in good demand; fancy white at 15c, and some exceptionally fancy lots may bring a little more. No. 1 sells at 13¢/lb.; amber at 12c; no arrival of buckwheat as yet, the season being late. Extracted firm at 6 1/2¢/lb. for white, 6c for light amber, and 5 1/2¢/lb. for dark. Beeswax firm at 27¢/28c. HILDRETH & SEGLER, N. Y.

CINCINNATI, Aug. 29.—New comb honey is not coming in so plentiful, so far. Whatever has come in, and is fancy water-white, has brought a good price, and sold to stores at from 15¢/lb. Honey kept over from last year, fancy sells for 14c. The market for extracted is more lively and brings: Amber, from 5¢/lb.; alfalfa water-white, from 6¢/lb.; white clover, from 7¢/7 1/2¢. Beeswax, 28c. C. H. W. WEBER.

SAN FRANCISCO, Aug. 20.—White comb, 13¢/lb.; amber, 10¢/lb.; dark, 8¢/lb. Extracted, white, 5 1/2¢/lb.; light amber, 5¢/lb.; amber, 4 1/2¢/lb. Beeswax, good to choice, light, 27¢/29c; dark, 25¢/26c.

Not much offering or arriving of any sort. While the market is firm throughout, current values are being better sustained on comb than on extracted, for the reason that the latter has to depend to some extent on outside demand. All the comb honey offering will be required locally. The shipment of comb honey has never proven satisfactory, and the production is in consequence restricted to small compass.

1-lb Keystone ... Honey-Jars

These are clear flint glass jars holding just one pound, and the shape of a keystone. They are 7 $\frac{1}{8}$ inches high, and very pretty when filled with honey. The corks can be sunk a trifle below the top, and then fill in with beeswax, sealingwax or paraffin. We can furnish them in single gross lots, with corks, f.o.b. Chicago, at \$3.50; two gross, \$3.25 per gross; or five or more gross, at \$3.00 a gross. These are the cheapest glass one-pound jars we know anything about. We have only about 30 gross of them left. So speak quick if you want them. Address,

A Celluloid Queen-Button is a very pretty thing for a bee-keeper or honey-seller to wear on his coat-lapel. It often serves to introduce the subject of honey, and frequently leads to a sale.

NOTE.—One reader writes: "I have every reason to believe that it would be a very good idea for every bee-keeper to wear one [of the buttons] as it will cause people to ask

questions about the busy bee, and many a conversation thus started would wind up with the sale of more or less honey; at any rate it would give the bee-keeper a superior opportunity to enlighten many a person in regard to honey and bees."

The picture shown herewith is a reproduction of a motto queen-button that we are furnishing to bee-keepers. It has a pin on the underside to fasten it.

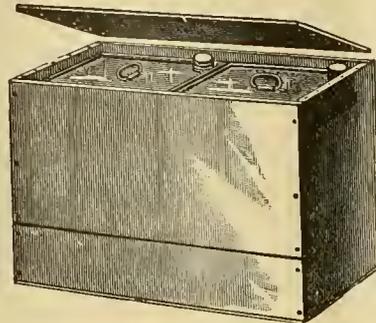

Price, by mail, 6 cents; two for 10 cents; or 6 for 25 cents. Send all orders to the office of the American Bee Journal

BEST Extracted Honey For Sale

ALL IN 60-POUND TIN CANS.

Alfalfa Honey

This is the famous White Extracted Honey gathered in the great Alfalfa regions of the Central West. It is a splendid honey, and nearly everybody who cares to eat honey at all can't get enough of the Alfalfa extracted.

Basswood Honey

This is the well-known light-colored honey gathered from the rich, nectar-laden basswood blossoms. It has a stronger flavor than Alfalfa, and is preferred by those who like a distinct flavor in their honey.

Prices of Alfalfa or Basswood Honey:

A sample of either, by mail, 10 cents, to pay for package and postage. By freight—two 60-pound cans of Alfalfa, 9 cents per pound; 4 cans or more, 8½ cents a pound. Basswood Honey, ½ cent more per pound than Alfalfa prices. Cash must accompany each order. You can order half of each kind of honey, if you so desire. The cans are two in a box, and freight is not prepaid. **Absolutely Pure Bees' Honey.**

Order the Above Honey and then Sell It.

We would suggest that those bee-keepers who did not produce enough honey for their home demand this year, just order some of the above, and sell it. And others, who want to earn some money, can get this honey and work up a demand for it almost anywhere.

GEORGE W. YORK & CO., 144 & 146 Erie St., Chicago, Ill.

The Novelty Pocket-Knife.

Your Name and Address on one side—Three Bees on the other side.

(THIS CUT IS THE FULL SIZE OF THE KNIFE.)

Your Name on the Knife.—When ordering, be sure to say just what name and address you wish put on the Knife.

The Novelty Knife is indeed a novelty. The novelty lies in the handle. It is made beautifully of indestructible celluloid, which is as transparent as glass. Underneath the celluloid, on one side of the handle is placed the name and residence of the subscriber, and on the other side pictures of a Queen, Drone, and Worker, as shown here.

The Material entering into this celebrated knife is of the very best quality; the blades are hand-forged out of the very finest English razor-steel, and we warrant every blade. The bolsters are made of German silver, and will never rust or corrode. The rivets are hardened German silver wire; the linings are plate brass; the back springs of Sheffield spring-steel, and the finish of the handle as described above. It will last a last-time, with proper usage.

Why Own the Novelty Knife? In case a good knife is lost, the chances are the owner will never recover it; but if the "Novelty" is lost, having name and address of owner, the finder will return it; otherwise to try to destroy the name and address, would destroy the knife. If traveling, and you meet with a serious accident, and are so fortunate as to have one of the "Novelties," your POCKET-KNIFE will serve as an identifier; and in case of death, your relatives will at once be notified of the accident.

How appropriate this knife is for a present! What more lasting memento could a mother give to a son, a wife to a husband, a sister to a brother, or a lady to a gentleman, the knife having the name of the recipient on one side?

The accompanying cut gives a faint idea, but cannot fully convey an exact representation of this beautiful knife, as the "Novelty" must be seen to be appreciated.

How to Get this Valuable Knife.—We send it postpaid for \$1.25, or give it as a Premium to the one sending us THREE NEW SUBSCRIBERS to the Bee Journal (with \$3.00.) We will club the Novelty Knife and the Bee Journal for one year, both for \$1.90.

GEORGE W. YORK & CO.

No. 41.

* Editorial Comments. *

Methods of Clipping Queens' Wings.—Bee-keepers differ in their practices, and each one is perhaps a little too much inclined to think his own way is the best, if not the only way worth considering. Clipping may be done by means of scissors or knife, or clipping device. The way one starts out with, and becomes accustomed to, is perhaps his best way. Those who have for years used either scissors or knife without having tried anything else may not be willing to potter with any kind of a clipping device, but if they had begun in the first place with a device of some kind, they might have quite a different feeling. There are some so nervous that it is almost torture to attempt to take hold of a queen, and for such persons some clipping-device is a boon. There are others—and their number may be larger than supposed—who have no nervous feeling in the matter, but whose hands are so shaky, or the sense of touch so dull, that a queen may be mashed in the catching. Such persons must have some kind of clipping-device, or refrain from clipping altogether.

Probably most bee-keepers use scissors for clipping. Others use a knife, and of these some are inclined to speak as if it were a great mistake for any one to use scissors. While allowing that the knife may be the best for those who have always preferred that plan, there may be no harm in making some defense for those who are addicted to scissors.

One argument in favor of the knife is that it is not necessary to handle the queen at all except to take her by the wings, and thus no foreign scent will be given to the queen to make the bees attack her. But one is not supposed to have anything but clean fingers, except as they are daubed with propolis, and no harm would come from this latter. If one's fingers have such an objectionable odor as to endanger the queen, even taking her by the wings might not be safe, for the same odor would be given to the wings, and if that objection be valid it will rule out knife as well as scissors.

The great point claimed in favor of the knife, is that every one has a pocket-knife—so it is always handy. This ignores utterly nearly all bee-keepers of the female persuasion; for they are not supposed to carry pocket-knives, and are much more likely to have scissors somewhere about their persons. Leaving them out of the count, however, a knife, to make good work at clipping, must have a keen edge to cut off a wing laid against a finger or thumb, and one does not always have handy a knife that is very sharp. To be sure, one can in a pinch use a dull knife, cutting the wing against the edge of a board, but no one recommends this as a desirable way, and if the fact that one has nearly always present some kind of a knife be a sufficient argu-

ment in favor of the knife, the same argument might make finger-nails come off victors over knives, for finger-nails can be made to mangle off a wing, and they are more sure to be on hand than knives.

But the scissors-clippers may reply that it is just as easy to have a pair of scissors constantly on hand as to have a knife, and the knifers must admit the truth of the reply for all who are willing to be to the trouble of having the scissors constantly on hand.

If the scissors-clippers should not be satisfied with remaining on the defensive, but take up the aggressive, they might say that however the queen's safety might be concerned, the operator would be in many cases much safer with scissors. One of the veterans with finger-tips calloused with handling frames might safely cut an appreciable distance into the skin without danger from a sharp knife, but one with tender finger-tips, especially if a little nervous, would feel much safer with scissors. To put it in stronger terms, with the scissors there is no possible danger of cutting the fingers, and there is danger with the knife.

There, now, it may not be best to say anything more against the knife for fear of being knifed by the knifers.

Moving an Apiary a Short Distance.—The apiary at the Hawkesbury Agricultural College in Australia was moved a short distance the last week in December, that date corresponding to the weather of the last of June in this country. The result is thus given in the Australasian Bee-Keeper:

On the morrow not one percent of the bees returned to the site of their old home, although it was in such close proximity. This is the way it was done: All things being in readiness, a moonlight night was selected. The entrance to each hive was closed by means of damp rags, and the hives were placed on hand-barrows and carried to the concrete stands; these were all in place beforehand; pieces of board, two or three bricks, bushes, in fact anything, was placed in front of each hive; these, when the bees came, caused them to study their new location, and at the same time caused them to forget the old. A clean sweep had been made of their old homes. Every piece of loose wood, brick, bush, etc., had been removed. There was really nothing left to indicate that an apiary had ever stood there.

Any one wishing to remove an apiary to a new site near by, if he follows his plan, need have no apprehension that the bees will return to the locality where they came.

Denver Convention Notes.—In our notes last week we had just arrived in Denver. We were met at the Union Depot by Mr. F. H. Hunt, and at once escorted to the State House, where the Colorado Bee-keepers' Association was in session, with Pres. J. U. Harris in the chair. There was a good attendance. At their closing, or afternoon, session, those from outside of Colorado were called forward and introduced to the convention, among them being Dr. Miller, Editor Root, Frank Benton, Dr. Mason, W. L. Cogshall, W. F. Marks, O. L. Hershiser, E. T. Abbott, C. H. W.

Weber, E. S. Lovesy, W. Z. Hutchinson, F. E. Brown, and Louis H. Scholl.

Perhaps it is unnecessary for us to refer to the convention proper, as about all of interest will appear in the very full report of the proceedings which is now running in these columns.

But we must speak of the banquet which was tendered those residing outside of Colorado. It was an elaborate affair, and delightfully carried out. Mr. D. W. Working was the witty toast-master, and his introductions of the various speakers were superbly done. Among those who responded were Messrs. Harris, Hutchinson, Hershiser, Benton, Rhodes, Booth, Mrs. Grenfell, and Mrs. Martin. It all was indeed a treat, and lasted almost until midnight.

Very small sections, perhaps the smallest sections of honey ever produced in such quantity, graced the table at the Denver banquet. One of these sections was placed at the table of each guest, and they were carried away as souvenirs. They were beautiful in appearance, each one being a plain section measuring 2 $\frac{1}{8}$ x2 $\frac{1}{8}$ x1 $\frac{1}{4}$, four of them thus occupying the space of an ordinary pound section. But instead of being one-fourth as heavy as a pound section, each of them contained only about two ounces of honey. Mr. Jas. U. Harris, vice-president of the National Association, was the man who produced them, and he said it was done only by crowding the bees very hard, and giving them only one case of sections, while other colonies had two cases of ordinary sections. He thought such sections could only be afforded at two or three times the price of the pound sections. Which serves as additional proof that the usual size section is small enough.

The Colorado bee-keepers did themselves proud in every way during the whole of the convention. Mr. Working, and those who worked with him, must have been glad when it was all over. We do not think they will want us all to come again very soon. But it was thoroughly enjoyable throughout, especially for those who came a long distance, and will never be forgotten so long as their memories endure.

Next week we will begin to tell of a few side-trips that we took after the convention. We really had never seen much mountain scenery, so, of course, it was entrancing. The only regret we now have is that we are unable to compel our pencil to do justice to the wonderful sights that we were permitted to behold and enjoy during the three or four after-convention days.

* The Weekly Budget. *

ALEXANDER, JOURIER, of Ural, Russia, writing us Sept. 1, sent the following in addition to a letter extending the sympathy of the bee-keepers of Russia to the family of the late Chas. Dadant:

"The book, 'Langstroth on the Honey-Bee,' revised by Chas. Dadant, after translation into the Russian language, had great influence in extending the movable-hive system in Russia, first introducing the Dadant hive. Here in Ural we adopted one for our apiaries in 1893, and the great advantages from its use are now plainly visible."

THE HOME APIARY OF A. COPPIN appears on the first page. He wrote us as follows concerning it:

My home bee-yard consists of three grape-arbors, as shown in the picture, all of which are 104 feet long. The

posts are 8 feet apart each way, and a grape-vine by each post. The first side-rail is about 4 feet from the ground, and the vines are spread on this rail and turned up to cover the top.

This cover is excellent shade for both bees and operator, there being no vines in the way of the bees flying in and out. In the center the side boards are left out between two posts, so that we can have a cross road from one arbor to the other.

The hive-stands are made from fence-boards 8 feet long, three hives to the stand. It will hold 216 colonies, but we never keep that many at home. The house seen at the other end of the arbor is the honey-house.

The alighting-boards are made from lath and shingles, which are just the right length to reach from the entrance to the ground with good slope.

The two persons seen in the picture are my wife and myself. The backs of the hives all face in where my wife stands, thus making a very pleasant place to work with bees.

Bee-keepers often say, while visiting me, "What is the reason I don't get stung here the same as I do at home? Is it because the bees are gentler, or is it because we are under the grape-vines out of their way?"

This apiary is run for comb honey. We run our out-apiary for extracted honey.
A. COPPIN.

NOMINATIONS FOR GENERAL MANAGER.—We have received the following from Herman F. Moore, which needs no further introduction:

To the Membership of the National Bee-Keepers' Association:

The undersigned views with alarm the unkindly spirit that seems to have animated some of the officers and members of the National Bee-Keepers' Association. The results of the discussion about the General Managership, if continued in the present spirit, may be serious, or even fatal, to our beloved Association.

Since my nominee for this position, Mr. York, has been elected to the Secretaryship, I, as a plain member, and in the interest of harmony, hereby appeal to the membership to decide this question; not by personal feeling or animosity, but according to the will of the majority, and the lasting welfare of the National Bee-Keepers' Association.

I hereby nominate the following for the office of General Manager of the National Bee-Keepers' Association, to be voted for at the next election, arranging them in alphabetical order:

EMERSON T. ABBOTT, of Missouri. NEWELL E. FRANCE, of Wisconsin.
CAMILLE P. DADANT, of Illinois. R. L. TAYLOR, of Michigan.

Very respectfully yours,
HERMAN F. MOORE, of Illinois.

There remains less than two months yet until the annual election to be held by the National Association, at which time three Directors and a General Manager are to be elected. The business ability of the four candidates for General Manager, presented by Mr. Moore, can not be questioned. Any one of them should be able to handle the affairs of the Association as General Manager in an acceptable manner to the membership. We suppose other candidates will be nominated also. Then when the time comes to vote, those who are entitled to cast their ballots will do so, and the one receiving the highest number of votes will be the General Manager for 1903. Whoever is the successful candidate will suit us. We will not champion any one in particular in the American Bee Journal, as we believe in a fair deal, and that the voting membership know well enough for whom they want to cast their votes.

But please don't vote for the editor of the American Bee Journal, as he is not a candidate for any office in the National Association. When he accepted the office of Secretary, at the Denver convention, that ended his candidacy for the General Managership. He does not believe in one person holding two offices in the Association when there are so many excellent men in the ranks who should have a chance to show their ability and fitness for positions of responsibility and trust.

The Denver Convention.

Report of the Proceedings of the Thirty-third Annual Convention of the National Bee-Keepers' Association, held in Denver, Colo., on Wednesday, Thursday and Friday, Sept. 3, 4 and 5, 1902.

(Continued from page 631.)

SECOND DAY—THURSDAY, SEPT. 4.

At 9:35 a.m., Pres. Hutchinson called the convention to order, and delivered the President's annual address on

The Future of Bee-Keeping.

FELLOW BEE-KEEPERS:—Has there ever crossed your mind the thought that modern bee-culture has advanced by distinct stages? When Father Langstroth's invention laid bare the secrets of the hive, allowing man to turn one more page in the book of Nature, then began what might be called the mechanical stage. In this were brought forth hives, smokers, sections, comb foundation, and the honey-extractor. Minor mechanical improvements, like the bee-escape, the queen and drone trap, the solar wax-extractor, the wax-press, perhaps an uncapping machine, may be occasionally added to our list of implements, but the fundamental, mechanical improvements were made long years ago.

Next came the methodical stage, when, with the aid of mechanical inventions, were developed methods and systems of management. Bee-keepers learned to control increase, to rear, ship and introduce queens, to secure the largest amount of the best honey in the most marketable shape—learned the numerous operations that come under the head of manipulation. Some of our present methods will certainly be improved upon, but it is doubtful if future bee-keepers will secure their crops with much less labor than we now bestow upon ours. Our hives, implements and methods leave little room for improvement.

In another respect bee-keeping is not now what it was years ago. The invention of improved hives and implements, allowing the adoption of more profitable methods, but calling for greater skill, has gradually led bee-keeping from mixed husbandry to that of specialty. Of course, there are, and probably always will be, people whose tastes impel them to keep a few bees, but the great mass of people have found it more profitable to buy their honey, the same as they have learned that it does not pay them to make their own cheese.

Bee-keeping has become a distinct branch of agriculture, and is largely in the hands of specialists. These specialists have implements and methods that answer well their purpose, and the natural question is, "What next?" What will be the next stage? What will be the future of bee-keeping?

The answer is not far to seek. The history of kindred industries will be the history of bee-keeping. First came

discovery, invention and development; next came specialty, and now comes ORGANIZATION and CO-OPERATION.

Most emphatically is this an age of organization. An industry without organization is practically helpless—at the mercy of all other organizations. Organization saved the citrus fruit industry of California. But we need not go that far for an illustration. Right here, in this good State of Colorado, with its fields watered from the eternal hills, and robed in the royal purple of alfalfa, bee-keeping would have lan-

W. Z. HUTCHINSON.

guished, and been robbed of its commercial charm, had not organization come to the rescue.

Organization has already done much for bee-keeping. It has fostered a fraternal spirit, helped to scatter apicultural wisdom from ocean to ocean, protected its members from unjust persecution, and secured favorable legislation. But the dear old Association, of which we are all so proud, is even now but the nucleus of what it is destined eventually to become.

Perhaps the next great work of this organization will be the timely gathering of statistics regarding the prospective harvest, and the reporting of the supply and demand in different localities, thus preventing glutted markets and unprofitable sales. From this the good work will go on until, if the Association does not actually control the bulk of the sales, it will be a potent factor in the regulation of prices.

Honey may never be higher in price

than it is now, but it will be produced at less cost. The continued development of specialty and of organization will lessen the cost of production. The number of bees will be increased, but not the number of bee-keepers. They will "keep more bees." Few bee-keepers will be content with simply the home apiary. There will be an out-apiary for each day in the week. With this style of bee-keeping organization will be an easy matter.

Commercial bee-keeping of the future will be in the hands of specialists. In the hands of men who have carefully selected and thoroughly understand their respective localities. Of men who keep enough bees to employ fully their hands, their brains, and their capital. And among these men there will be complete organization and co-operation.

As a foundation for the more perfect organization of the future, let us cherish and foster the dear old Association of which we are now members. Let us pay our dues promptly. Let us encourage others to join. Let us lay aside self and selfishness. And of the talents that we possess let us give that which will the most quickly and surely help to build up, to strengthen, and to broaden its scope. Let us rest not until every bee-keeper, from ocean to ocean, has rallied under its banner, and all can co-operate as the members of one great family.

W. Z. HUTCHINSON.

Pres. Hutchinson—I don't know as it is customary to discuss the President's address, but I would like to hear it discussed. I think it is a subject worthy of discussion.

R. C. Aikin—I think I shall not say very much relative to this subject, except on one particular phase of it—organization. I believe that there are many bee-keepers, both East and West, because of some things I have said in print, and because of my remarks in convention and in private conversation, have their eye upon me to learn something about organization, and I look upon this subject as one of no mean importance. Every one of you who are to-day reading the papers and observing the trend of business affairs, understand that organization and co-operation to an extensive degree are being practiced; the great railroad concerns, the manufacturing concerns, and many others, have taken an interest in one another, and in relation to one another are uniting under what is known as trusts or combines. The foundation or idea in all these is the correct, is the proper thing. Two large manufacturing concerns will go together because the two concerns united under one management can be handled more cheaply and more successfully than as two organizations. So it is we are combining and co-operating, and with bee-keepers it is the same thing. And let me give another thought here: All mankind are dependent more or less upon one another; and in these days the disposition is for me to produce one thing, and a neighbor to produce another thing, and so on all along the line, each having his special line of production, becoming an expert in that one thing; and as specialties increase we become more and more dependent. That is the way it is that

the large corporation, or trust, or combination, gets it within their power to oppress those who are not organized. Colorado bee-keepers will recall how, from year to year, I have urged and pressed for organization, not as a monopoly, but as a means of protection, and to facilitate our business; and I am tempted from day to day, and in my private conversation, to recall and point out the work of the fruit organization in Southern California. I know very little about it only by the published reports, principally those given by Prof. A. J. Cook, which you all know has brought about a distribution of the product, putting it in the markets where it is most needed; in short, an intelligent distribution of the product. Now we want to follow those lines; we want to co-operate; we want to produce as specialists, each one of us filling our place in the grand machinery of the whole. Last night some of the speakers referred to the magnificent distances of Colorado, and the one thing, gentlemen, those magnificent distances necessitate is co-operation and united work and effort. We can not, as small producers, ship our product to the market that needs it in less than car-load lots to the same advantage that the extensive shipper can do, and we need an intelligent distribution of our product, which can only be accomplished by one of two ways, either by government management, they doing this business for us, or by co-operation amongst ourselves directly. I am in hopes that this spirit of organization, co-operation and combination that is now taking possession of the business world will eventually reach where I think it ought to reach—the point where the Government will take control of it, and man-

age it to the interest of all the people, and not to the few who are in the combine. This may perhaps be combatted by some, but the student of business relations and conditions will be forced, sooner or later, to come to this conclusion, that somehow these affairs in this vast country must come under some grand, general agency and be manipulated in that way; and this thought has been enforced upon me more and more of late, and I recall one of the last public speeches, I believe it was made by our lamented President McKinley, in which he said that nations are coming so closely together in these days that old methods are practically out of date. A few years ago it was one nation against another; there was no brotherly feeling, there was no co-operation; but to-day trade relations are such that what destroys or kills one nation is bound to affect every other nation, and trade with it. Now, the principle applies everywhere, and these influences are becoming so general, and so far-reaching, that to-day there must be co-operation not only of the individuals in a community, not only among the people of the State, but State with State, and nation with nation. And when we will so co-operate there will be such a demand for every product as we little dream of. I have contended for years that if there were ten times the honey produced that we now have there would be a better market than there is to-day. Go with me into Iowa, Indiana, Illinois, Kansas, Nebraska—countries where corn and hogs and cattle are the principal products—and there the buyer will come right to your door and buy your hogs and your corn: or, if you choose to load some of them on the wagon and go to town, you will find a market

for every day in the week; you can dispose of them any time you haul them to market. How is it with our honey product? You all know that you have to get out on the market; there is no real, established market for honey. I think a few of us have pretty nearly established a market in our communities, but I am speaking in a general sense. Now, our President has outlined for us some of these thoughts, that we are going to keep more bees; we are going to produce more honey; we are going to organize and co-operate; and the community that produces any one line of produce is the community that has a market for that product. That is true of any line, it doesn't make any difference what it is; but the community that has just a little bit of any one thing is the community that has no real, settled market for that product. So we are going to keep more bees, and keep them more in a co-operative way. I would produce extracted honey; another will produce comb honey; and we will follow the thought of specialism more and more as the years go by, and as we follow specialism we are becoming more and more dependent, and as we become more and more dependent upon one another we are compelled to organize and co-operate. I am heartily in sympathy with almost if not every thought that has been put before you in the address of our President.

It was moved by Mr. York, and seconded by Mr. F. H. C. Krueger, that 3 o'clock this afternoon be fixed for the election of the officers, and that it be made a special order of business for that hour. Carried.

(Continued next week.)

Contributed Articles.

Uniting Colonies of Bees in the Fall.

BY G. M. DOOLITTLE.

QUESTION.—Two or three of us who take the American Bee Journal, have some colonies we wish to unite this fall, and we wish you would tell us in that paper one or two of plans for doing this. One of our number says you have written on this subject before, but we cannot find it now. Please give us an article on the subject, and, even if you have written on the subject before, there are many younger readers of the Bee Journal who will be benefited by the same, even if the older ones care not for it.

ANSWER.—In all localities where there is a promise of fall flowers yielding honey, it is generally better to wait till this yield is past about uniting, for the two colonies, separate, will generally rear more brood at this time of the year, and often store more honey, than would be the case were they doubled during the flow, or just before it began. But where there is no prospect of any such yield, as is the case with many localities with which I am acquainted, then the sooner the bees are attended to the better. If your colonies are strong in bees, the question might arise whether it would not pay to buy sugar and feed them, did they not have stores enough, so as to have a greater number in the spring; but where colonies are both light in bees and in stores there is only one correct solution of the problem, which is to unite the bees till all colonies are strong, and then if stores are still lacking they may be fed.

I have two plans for uniting, which I have picked out as

the best from the scores of plans which I have tried, the first of which I use on colonies that are quite fair colonies as to bees, so that only two are to be put together, and the second on those which are a little more than nuclei, or where two, three, four, or five, may be united profitably down to one.

Having decided to unite colonies like those first spoken of, I hunt out the poorest queen, if there is any choice, and kill her, when I leave the colonies as they are for from three to eight days, according to the weather and the pressure of business.

When I am ready I take the now queenless colony to the colony having the queen, and select from each hive the frames having the most honey in them, to the number I wish to winter them on, and set them in the hive which has not been moved, alternating them as far as possible so that the bees may be mixed up as much as possible. In moving the colony of queenless bees they are first thoroughly smoked at the entrance, pounding on the top of the hive as smoking, so as to arouse them thoroughly, when they are placed on a wheelbarrow in no gentle manner, and wheeled rapidly to the hive where they are to be united, confining the bees to their hive after smoking, and doing the whole on some dark, cloudy day, or near sunset, when the bees are not flying, as bees are less disposed to take wing at such times, and return to their old location when uniting.

Having the hive filled with combs containing the most honey, I next shake the bees (which are on the remaining combs) off at the entrance, taking one frame from one colony, and the next from the other, and so on, so as to mix all bees up as much as possible. When all are off the combs see that all the bees run inside of the hive, when the work of uniting is done.

Now remove anything and everything which may be left at the old stand where the queenless colony was, so that there will be nothing to look homelike to any bee which may chance to fly back there on the first flight afterward, and no loss will occur from bees returning.

The making of the colony queenless, which is to be removed when uniting, has much to do with the bees not returning, for bees having a queen, and especially queenless bees which have found a queen, are far more likely to adhere to the location of the colony having the queen than otherwise.

The other plan that I use with smaller colonies, requires the taking away of all queens but the one where the united colony is to remain, and this is done, as I said before, that the bees may the better adhere to the place where the united colony stands. In taking away these queens, I take all the combs from the hives but two or three having the most honey in them, the uniting of these colonies being left till the brood has all emerged from their cells. In leaving these two or three combs of honey they are spread about an inch apart, setting them out two or three inches from the side of the hive, so that the bees may all be clustered on these combs, instead of hanging to the sides or any part of the hive.

The hive which is to receive the bees and the combs, and the one having the queen, is also to be prepared beforehand, by taking away all the combs but two or three, the same as with the others, only these are left bee-space apart and close to one side of the hive.

Having all thus fixed, I wait as before for the colonies having their queens taken away to realize their queenlessness, and till a day occurs when it is so cool that the bees cluster together for warmth between the spread-apart combs, something as they do in winter. When the right day occurs, or on some cold, frosty morning, I light the smoker and put on a veil, for when using this plan we cannot use the hands should a stinging bee suddenly come for the eyes.

Being thus prepared, I go to the hive having the queen, and uncover it, giving the bees a little smoke to keep them quiet; and leaving the hive open, so that I can set other frames right in without hindrance, I go to one of those from which I took the queen, blowing plenty of smoke in at the entrance while I uncover the hive, when more smoke is blown over and around the frames, doing all as quickly as possible before the bees become aroused much. Quickly setting down the smoker, I place the two front fingers between the first two frames near their ends, then the large fingers between the second and last frames, while the third and little fingers are placed beyond the third frames, when by closing up the thumbs and all of the fingers, the frames with the bees all clustered on them are lifted out of the hive in a body and carried to the open hive, where they are to stay, and put in it all together in a body, as they were taken from their old home, pushing all up close to the frames of bees that are in this hive.

I now go back and get the smoker, and blow enough smoke on the bees to keep them down, while I arrange the frames as I wish them, when I go to another hive and get another lot in the same way, until two, three or four of the little queenless colonies are all put into this hive having the queen.

If the day is right, and I have worked as I should, I will have done this with scarcely a bee taking wing, which means the loss of none. Should any of these little colonies be so strong that a few of the bees are clustered on the side of the hive, this hive can be taken immediately to the united colony, holding it above it, when with a little smoke used on the colony below to keep them down, these can be brushed down on the frames of the united colony. Having all in and the hive closed, clear away all that looks like home from the vacated stands, as in the first plan, and the work is done.

Both plans are very simple, and accomplish just what is desired, the latter being a little easier where the colonies are small enough so that the bees can all cluster on three combs well spread apart.

Condensed Method of Classifying Knowledge.

BY C. P. DADANT.

A very interesting and to me very novel suggestion on bee-subjects, is the arrangement of all bee-journal articles under a classification represented by number, to enable any one rapidly and easily to find all that has been written on any one subject. This comes to me from the Editor of *L'Apicoltore*, of Milan, Italy, Mr. A. DeRauschenfels, in the shape of a pamphlet, printed in Italy, in very good English. The suggestion is based upon Melvil Dewey's bibliographic system, employing the ten figures of arithme-

tic for different subjects, and subdividing the subjects *ad infinitum*, by the decimal addition of numbers.

It appears that this idea of the American originator, Melvil Dewey, has been adopted by the Brussels International Bibliographical Institute, and that this Institute has appointed Mr. Vermorel—known the world over by his inventions for automatic spraying for the destruction of fungi and insects, a very able and scientific agriculturist and inventor—to prepare tables on agricultural sciences according to the above-mentioned system. This work was completed and published in 1900, under the title of "Manuel du repertoire bibliographique des sciences agricoles, établi d'après la classification decimale."

By Dewy's system the entire human knowledge is divided into ten groups, each represented by one of the ten figures. No. 6 is taken to represent the useful arts. By adding one of the ten figures to this number 6, he again subdivides the arts into ten subjects, as follows:

60 Generalities.	65 Commerce.
61 Medicine.	66 Chemical Industries.
62 Engineering.	67 Manufactures.
63 Agriculture.	68 Mechanical Industries.
64 Domestic Economy	69 Buildings.

Taking the word "Agriculture, 63," this is again subdivided into 10 additional figures, and 638 is meant to represent the subjects of apiculture and sericulture. The little pamphlet then takes up this subject of bees, and proposes to re-subdivide all questions pertaining to bee-culture in the same manner. It would be too long to go into details, and the reader can understand the system by what I have already outlined.

The principal advantage of such a system would be the ability to classify almost any subject by a few figures, and this of course would enable the student to find promptly the subjects he might seek, referring to classified tables.

I don't know how this system will strike the readers of the American Bee Journal. It certainly has some very good points, but it makes one dream of the possibilities of the future. It has also a funny side. Just think of the possibility of some day classifying all countries, States, counties, cities, and individuals, by a decimal number!

No. 10.—Bee-Keeping for Women.

Cleaning Sections for Market—How to Do It.

BY EMMA M. WILSON.

Of all the bee-work that has to be done during the entire year, I don't think of anything just now that I dislike to do as much, as getting the honey scraped and ready for market, and it is doubtful if there is any work I feel as much like shirking.

It is a hard, dirty, disagreeable job, for all the honey looks so dainty and pretty when the work is done, and I often wonder, as I stand and look at the finished product, if the people that eat it ever dream of the number of times it has to be handled over and over, and the amount of hard work connected with it before it reaches them in all its beauty.

It is for the bee-keeper's own interest to put his honey on the market in as dainty a condition as possible, for its attractiveness will have much to do with making a good sale.

Really good honey, if put up in a slovenly manner, will go begging for a market.

It is not an easy matter to remove all propolis and stain from the sections, especially if the weather is warm, and for that reason it is better to put off getting honey ready for market until the weather begins to get a little cool, if your market will allow of it; but in some cases it might be a loss to do so, for it might be to your advantage to have your honey on the market at an earlier date.

If the work must be done early in the season, do it early in the morning when it is coolest. It will make it easier, as the propolis is brittle and breaks off easily when cool, and is very sticky and hard to remove when warm.

Formerly I used only a case-knife in scraping honey. I had a board just large enough to hold comfortably on my lap, and a little block to set the section on while scraping. I considered 1,200 sections a pretty good day's work.

In the last few years I think we have improved a good deal in our methods of scraping honey. We have not only

simplified and made it a good deal easier to get our honey ready for market, but we have made it possible to have it look a good deal better when done, which is always a satisfaction.

We use the T super, and in emptying use a push-board which forces the sections out in a solid block, leaving them lying on a board bottom up when the super is removed.

We then remove the T tins and slip over the sections a frame very much like a super, only it is shallow to allow the sections to come about an inch above the frame. It is long enough and wide enough to slip over the sections easily. Then it is thoroughly wedged at one side and one end until everything is tight as a drum.

Now with a case-knife, which is kept very sharp, we can quickly and easily, if the weather is cool, remove all propolis from the bottom of the sections of the whole super at one time. It does not take very much more time to scrape the bottom of the whole super than it would to scrape one or two sections. Next, with a small piece of sandpaper we sandpaper the bottom of the sections. This removes all stains from the wood and also obliterates all marks that the knife may have left in scraping, leaving a smooth, pretty surface.

We now pull out the wedges (but not the follower), put a board over the sections, put one hand under the board on which the sections are standing, and the other hand on the board over the sections, and reverse the whole business, leaving the tops of the sections up, wedge them up tight again, and treat the tops the same way we did the bottoms. If there is any difference we are a little more careful in sandpapering the tops, as they show the most.

Now all that is left is the sides and edges of the sections to be done separately. Instead of the board on my lap I use a little table to scrape on, just high enough and wide enough to slip over my lap. It is strong and solid—an ideal little table to work on for many things besides scraping honey.

McHenry Co., Ill.

* The Afterthought. *

The "Old Reliable" seen through New and Unreliable Glasses.
By E. E. HASTY, Sta. B Rural, Toledo, O.

INVENTIONS AND INVENTIONS.

That is a good idea expressed editorially on page 579. Some inventions do good. Some inventions do no good, but only give an advantage to the person using them first. I suppose we have no right to forbid the latter class of devices, but we can look a little cross at them. Don't ask us to look pleasant when we are compelled to extra expenses just for nothing at all. Then there is another class of devices and plans which do harm, really, but do it to the benefit of somebody's pocket-book. I think we ought to look ferocious in concert at these.

THE BEE-LOUSE AND THE QUEEN.

So the fat bee-louse which sometimes inhabits the queen, is still regarded as in the land of the may-be-so-and-may-be-not, as to how he gets his dinner. Running down to the queen's mouth, and sharing her victuals, doesn't sound very reasonable; but may be it's all right—for the louse—and the scientist. Though we set a very "big bug" to observing a little bug, observing Sir Louse for a dozen hours without subjecting the queen to unnatural conditions must be in the nature of a puzzle. Page 579.

HALF-DEPTH FRAMES AND COMB HONEY.

A Texas plan on page 582 is not very familiar elsewhere, I think. (Some half-depth frames first filled to extract and then sections put on.) For a location with a light harvest of inferior honey just before the main harvest of white honey, the method would seem to offer special advantages. On general principles, I don't admire half frames and whole frames in the same hive; but I can see a chance for certain advantages. Getting the queen at work above early, and having the honey itself drive her down, looks like a taking scheme. Good plan if it works. It doesn't appear that any unsealed brood is to be put into the extractor. No kindly word from me for that abomination. In my field I wouldn't want to spare honey to fill a set of

half frames before the sections; but in different and just-right conditions it will do, I guess. In so far as one may wish to run for bulk honey, half-depth frames are presumably just the thing.

THE MOUTH AS AN ADVERTISING MEDIUM.

I see that on page 582, man's mouth has a puff as a valuable advertising medium. According to Solomon, as reported in one place, it consumes all the results of labor. If so, it looks as if it ought to turn to and help make a living. Still, there is a place where it says: "In many words there wanteth not sin. And many a good man will earnestly say, my wife and my mouth shall not blow trumpets."

CHARACTERISTICS OF NUCLEI.

It's the right way to do things to have some actual experiments when critics challenge our statements. This is anent Miller and Doolittle, on page 583. I suppose many of us often speak from general impressions, gathered during long years of continual work with bees. I guess that's all right; yet at times it may lead us to say things that will turn up at odds with the first experiment. If, in the style of the landscape-insulting advertisers, the words, "Sometimes and sometimes" could be painted on a big barn so we would have to look at every day, it would do us good. We all know 'em; but somehow they don't even yet ring in our ears loud enough or often enough. It's easy for me to believe that a good lot of bees will often all desert, as Mr. Doolittle says. 'Pears like, in times gone by, I've had 'em do it. And, of course, we believe, also, that Dr. Miller's nuclei survived not only the desertions but an attack of robbers, also. But say, wouldn't an attack of robbers, if made just at the right time, and with sufficient strength and suddenness, stop the desertions, and turn every bee's mind toward defense? And my impression is that after we get above say two quarts, perhaps less, the more bees we put in, the less our prospects of success. The excitement is bigger, and the young bees which do not know the way home have the more guides, and to the ones that can't fly at all the skedaddle looks more fearful. I'm not a queen-breeder, and for many years one great object before me has been to keep from having too many colonies; so, naturally, I haven't much recent experience with nuclei; but my impression is that my bees are somewhere between Dr. Miller's and Mr. Doolittle's in their inclinations when set alone.

QUEENS—DEAD BEES.

And Mr. F. Greiner, who does not deal in queens, has found most of his purchased queens to be good ones. Stick a pin there—just as good a pin as the one we stuck where somebody realized a shocking proportion of worthless queens. As to whether bees die around the hives or at a distance, we must look at our "Sometimes" barn again. Usually the ground around my hives is pretty clear of dead bees; but sometimes there are lots of them. These occasions when lots of dead bees scatter near by I am inclined to lay to a sort of poisoning—bees working on a nectar which is slightly poisonous—buckwheat, for instance. And cool weather at the time will very greatly increase the evil, I believe.

I can back Mr. Greiner that my bees do not leave two frames on each side unoccupied with brood. I run seven frames; and June 1 finds brood in all of them, as a general rule.

And so, in Mr. Greiner's yards, queens reared in ways said to be improper ways live nearly as long as the others. Can swallow the assertion without even a wry face. p. 583.

"The Hum of the Bees in the Apple-Tree Bloom" is the name of the finest bee-keeper's song—words by Hon. Eugene Secor and music by Dr. C. C. Miller. This is thought by some to be the best bee-song yet written by Mr. Secor and Dr. Miller. It is, indeed, a "hummer." We can furnish a single copy of it postpaid, for 10 cents, or 3 copies for 25 cents. Or, we will mail a half-dozen copies of it for sending us one new yearly subscription to the American Bee Journal at \$1.00.

Please send us Names of Bee-Keepers who do not now get the American Bee Journal, and we will send them sample copies. Then you can very likely afterward get them subscriptions, for which work we offer valuable premiums in nearly every number of this journal. You can aid much by sending in the names and addresses when writing us on other matters.

Questions and Answers.

CONDUCTED BY

DR. C. C. MILLER, *Maréngo, Ill.*

(The Questions may be mailed to the Bee Journal office, or to Dr. Miller direct, when he will answer them here. Please do not ask the Doctor to send answers by mail.—EDITOR.)

Granulation of Syrup—Miller Feeder.

1. In feeding sugar syrup to bees it granulates in the cells of one of the combs. Is this harmful? If so, can it be prevented?

2. Do you find the Miller feeder the most convenient thing for feeding small quantities of sugar syrup to nuclei, or to stimulate brood-rearing in a colony? If not, what do you find more convenient? ILLINOIS.

ANSWERS.—Granulating is bad, because the bees cannot utilize the granules, and it is about the same as wasting so much sugar. Acid in the syrup will prevent granulation—an even teaspoonful of tartaric acid for every 20 pounds of sugar, stirred into the syrup about the time the sugar is dissolved. The tartaric acid is first dissolved in a little water. Another year, however, feed early enough so that no acid will be needed. If you feed early and give as much water as sugar, the bees will furnish their own acid (formic) better than you can do it for them. To be sure, you can have it thin when you feed late, but in that case there is danger that the bees will not have time to evaporate it.

2. For feeding a small quantity each day, I know nothing more convenient. In that case put in sugar enough for a number of days, and then all you have to do is to put in a little water each day. It is less trouble to put in water than syrup.

Queen-Rearing—Propolis in Wax.

I have concluded to try rearing a few queens, so I commenced studying my text-book on the subject, but as usual I run on a snag about every paragraph.

1. In the first method I find "a cell-building colony to be preferred above all others... is one having a queen which it is trying to supersede... one or more will be found in a large apiary." Please let me know how the "find" is made.

2. In the next method I am directed to "select... a frame of eggs almost ready to hatch." How can you tell when a bee-egg is "almost ready to hatch"?

3. Some days ago I removed the queen from a colony and pinned two sealed queen-cells from another colony to one of the combs. Two days later I found the cells torn open and the queens destroyed. I also found 3 new queen-cells started. I opened them, removed the embryo queens, and placed in the jelly at bottom some of the smallest larvae I could find from an Italian colony; but the bees destroyed them also. What was the trouble?

4. How are queens reared now fertilized? I have not seen a drone about my apiary for two months.

5. When a queen is superseded, does the dowager resign peaceably, or does the princess have to fight for her throne? If the abdication is voluntary, what becomes of the old queen? Does she just go off and die?

6. Can you tell if wax is adulterated with propolis, or does it matter? MISSISSIPPI.

ANSWERS.—1. If you look in a hive and find queen-cells started, only one, two, or three in number, and especially at a time when bees are not inclined to swarming, you may consider such a colony as trying to supersede its queen. You will generally find superseding colonies among those with queens quite old.

2. I don't know. But if you find a considerable number of eggs in a comb, and very small larvae also, you are pretty safe in concluding that there are in the comb eggs nearly ready to hatch. According to some authorities, I believe, eggs that are lying flat on the bottom of the cells are those ready to hatch, while eggs just laid stand on one end.

3. I infer from what you say that you gave the cells at the time of removing the queen. In such a case the bees may be relied on to destroy the cells, for they are not yet aware of their queenlessness. Either wait till the bees are

fully conscious of their queenlessness, or else put the cells in a cell-protector of some kind.

You say you opened the cells and removed the embryo queens, from which I infer the cells were sealed. In that case the jelly present would be utterly inappropriate for a young larva, if indeed it would suit any larva, and the bees would be sure to cast out the larva of your placing.

4. There can be no fertilization without drones; but I venture to guess that plenty of drones have been in your apiary within the past two months, even if you have not seen them.

5. It is not so very uncommon a thing to find the old queen still in the hive after the young queen is present, sometimes both laying eggs at the same time, so the abdication seems to be peaceable. Just where the queen goes to "shuffle off this mortal coil," I don't know.

6. I think propolis would show in wax by its color. If melted, the propolis would separate from the wax on cooling, and settle to the bottom.

Moving Bees to Cuba.

Bees have done only middling well this year, it has been so wet, and not very warm except at times; about 2 weeks ago we had a few warm nights.

I have about 60 pounds of honey not capped over yet, and the bees are working on goldenrod and sweet clover. The mice got in and destroyed 3 nice colonies last winter. I just had a new queen and placed in one of the colonies and they had built up nicely; that left me with only one colony. I had 2 swarms, the last one in July. The June swarm has done as well as the old colony. I may get a few sections off the last one; I have had 90 off so far from the other two. The fact is, I have been kept so busy this summer I do not get time to see them more than once a week.

I have a notion to go down to Cuba this fall. I have a tract of land at LaGloria, and I want to go down and see it. From all accounts it is a fine country, a good place for bees, and I thought I would take along the few colonies I have, and get started. How would you advise taking them, in a full hive, or only a frame or two of brood with the bees on? Sometimes I think I would divide the brood-frames, and put new queens on them so as to double them up. How would that work? PENNSYLVANIA.

ANSWER.—I'm not sure about it, but incline to the opinion that it will be as well to take them in full colonies, making sure there shall be no lack of ventilation, and then do the dividing and giving fresh queens after you get the bees through.

Questions on Wintering Bees Outdoors.

The time of honey-gathering is nearly at a close, for this year, and the time for preparing our bees for winter is near at hand. The one subject of most practical interest is how to prepare our bees for winter, as we in this country winter out-of-doors; so my questions will be along this line, as there are various ways of preparing for winter. There are some principles involved which I would like to understand. One is this: Will bees go better up or down for their stores in winter?

For wintering in single brood-chamber hives:

Plan No. 1.—Leave the hive on the summer bottom-board; place over the frames thin domestic or burlap; put on an empty super filled with chaff or cut straw; place sticks or cobs under the cloth on the frames to give the bees passage over the frames.

Plan No. 2.—Like the above, with the addition of a T super, empty of course, under the hives, the bottom-board giving space for bees to cluster under their stores.

Plan No. 3.—Giving space of 1½ or 2 inches above the brood-frames; hive on the summer bottom-board 3 inches deep, well packed above. Will they get their stores from below all right?

1. Would it not be an improvement, on all three ways, to put dummies in place of outside frames, and let them extend to the bottom-board, virtually making a double-walled hive, letting them extend up in No. 3 to make the desired space above?

2. Would a super-board be better on top, over the brood-frames, than the cloth? It would give ¼ inch space over the frames; and place the super and packing on it.

3. Should all the honey be in the top brood-chamber, or in both alike?

4. Is there need of any device over the frames of double brood-chamber?
5. Is there need of any packing above a double brood-chamber?
6. Would it do to sow sweet clover, say in October, harrowing it, to be ready to grow in the spring?
7. What is the best way to keep a few extra queens over winter?
8. Please tell me what you think is wrong in any of these plans, and what you think is the best way to prepare bees for wintering out-of-doors.
9. I sowed some red clover last spring; it grew well, but did not bloom well. Will it live over winter, and bloom in the spring?
10. What time in the season does phacelia bloom? and how long does it continue in bloom? MISSOURI.

ANSWERS.—1. I am not sure that I understand your third plan. Bees left to themselves store their honey so that they must work upward or backward to reach it, although they will manage to get it from any direction. If you mean there is an air-space of 1½ or 2 inches above the brood-frames, that would not hinder the bees from getting the honey, as they would probably cluster upon the combs rather than in the air-space, but it is doubtful that there would be any advantage in such space above the frames.

I don't know whether the dummies would be an improvement. The best way to decide the question would be to make the trial on a small scale.

2. Opinions are divided. Some prefer the board with the ¼ inch space over top-bars, while others prefer the cloth.
3. Better have honey in both, the upper one having the most.
4. No.
5. The matter of packing should probably be the same with a double brood-chamber as with a single brood-chamber under the same circumstances.
6. It would probably do well, especially if the ground be made hard by rolling or by tramping of stock.
7. In nuclei, two or more nuclei being kept in one hive separated by partitions.
9. It may live over, and if it does it will bloom; but it may winterkill.
10. I have had no experience with phacelia. It is most praised as a honey-plant and also as a forage plant across the sea, and is said to have been obtained from California. Can any of our brethren from the Golden State inform us about it.

Swarming of Young Queens Reared in the Hive.

In your answer to my question, on page 538, you request me to let you know if I have had any swarms issue in such cases, as late as June. In reply I will say that I had a fine colony of Italians from which I desired to breed. They swarmed June 9, 1902 (and the swarm gave me 100 finished sections this year). I had other colonies which swarmed a few days before, and some a few days after. In order to furnish all colonies with a queen of this particular breed, I cut out all cells from the others and introduced cells from this choice queen. I had five hatch, mate and swarm the past season, under the above circumstances. One queen was not 6 weeks old when she and her colony swarmed out. NEW YORK.

ANSWER.—This seems a plain violation of the rule, and there seems nothing left but to say that, at least in some cases, a swarm may issue with a young queen reared in the hive the current season. Thanks for the information, even if the fact is one to be regretted.

Forming Nuclei.

I notice what you say on page 583, in answering Mr. Doolittle in regard to forming nuclei, the bees leaving the hive and returning home. Now, my experience is exactly the same as yours. I, for some cause, am not troubled very much with swarming, only last July I had the most I ever had, but I killed what queens I could get my hands on in returning prime swarms (which was about half). I could expect when the young queens hatched out to have what you may call after-swarms. The reason for putting back the prime swarms this year was because it was too cold and wet in June for the bees to do anything; and July 1st came in bright, and the weather was lovely from that on, and

what honey I would get I knew must be secured in the next 10 days. So I returned all prime swarms. The plan worked to perfection; quite a number of the colonies that I returned, and having failed to get the queen, did not bother about swarming again, but went to work with a will. The plan will be tried further next season.

Now, as I said, I am, as a general thing, not getting the increase desired, without making nucleus colonies in some manner; and as I usually run one-third of my bees for extracted honey, after the last extracting, which is not done very close, I go to all the extracting supers, and in those that have no sealed brood I insert a frame, then in a few hours after the bees have found it above, I break the super off (which is always a hive-body the same as the brood-chamber below), and carry it to a new location, closing the entrance until after dark. When it is opened, and in the morning of the next day, I can notice no bees leaving for home, and am not troubled in the least by having the colony dwindle.

I made several 2-frame nuclei last month, and few bees, if any, returned. I usually make them in the afternoon, close the entrance until dark, then open, and all is well with them. OHIO.

ANSWER.—Your practice is a little different from the usual way of taking bees and brood from a hive containing a normal queen. If you take out of such a hive, directly out of the brood-chamber, two or three frames of brood with adhering bees, and put them in an empty hive on a new stand, I feel pretty sure you will find a goodly number will return to the old stand. But your plan is to put brood over a colony and let the bees collect on it. Why such bees should stay any better on a new stand I do not know, but in a number of instances I have found they did so, although I think I have never seen it mentioned in print before.

Heating Extracted Honey—Market for Combs—Drone-Trap.

1. Is it necessary to heat extracted honey from 150 to 170 degrees, for any other reason than to prevent granulation? Would it keep without fermenting or souring if put up in jars cold and sealed?
2. Is there a market for new combs in Langstroth frames? If so, what are they worth?
3. About the last of July, wishing to go away over Saturday and Sunday, I looked one colony through, Friday night, and cut out all queen-cells; on Monday morning when I looked through the hive, before six o'clock, I found they had swarmed and gone, after starting new cells, but not one was sealed, as I caged all and I knew when the first one was hatched. This same colony had cast one swarm May 24, and the second came out about 2 weeks later, and I returned it. Is this right, to occur so often?
4. If I use the Alley drone and queen trap to cage the queen when the swarm issues, is it not necessary to empty the trap of drones every night? If so, this trap would not be practical to use in an out-apiary, if not visited oftener than every 3 or 4 days, would it? I mean practical to use as a preventive from losing swarms.

MASSACHUSETTS.

ANSWERS.—1. Well-ripened honey ought not to ferment or sour if put up in jars cold and sealed, neither ought there to be any trouble if it is unsealed unless it be in a place that is damp or otherwise objectionable.

2. There is no regular market for them, but if you have any to dispose of you could probably find customers by applying to other bee-keepers near you, or by advertising in this journal. I don't know what the price ought to be, and I suppose it would vary greatly in different places, say from 15 to 25 cents each.

3. It is an unusual thing for bees to swarm before they have sealed queen-cells when they are left to themselves; but when they are baffled in their preparations by having queen-cells cut out, they are not so particular about their preparations, and may even swarm without any cells started at all.

4. The Alley drone-trap is successfully used without being seen more than once a week. The suppression of drone-comb within reasonable limits does not leave enough drones present to make much trouble.

The Premiums offered this week are well worth working for. Look at them.

GENERAL ITEMS

Bees Did Fairly Well.

My bees have done fairly well, considering the wet summer we had. From some colonies I have taken 60 pounds, while others had no surplus, but all are well provided for winter supplies. There is no complaint in this vicinity of a short crop.

I can, and always do, sell my honey at home, and get 15 cents per pound. The honey is of good quality, and a light amber color. The bees are gathering honey from smartweed, which is very plentiful this year.

Many colonies of bees have starved to death. Early in the spring I lost one, before I noticed it. I would have lost more if I had not noticed it in time, but sugar syrup brought them through all right.

R. C. STUPE.

Woodson Co., Kans., Sept. 29.

Bees Still Storing.

Our honey-flow has been very good the past 4 weeks. I have some colonies that will give 125 pounds of surplus honey which I did not expect. I started out with 20 colonies, spring count, but had the worst spring dwindling I ever saw or heard of. They got so weak that I had to double up, which left me 10 colonies, and I did not think that would amount to very much; but in July they commenced to pick up, and they did it fast, too—before I knew it they had the super full, when I put on 24 one-pound supers and they filled them in 5 days. So I had to repeat it. They are storing honey right along, and the prospects are good for more.

P. H. HARBECK.

Lasalle Co., Ill., Sept. 24.

Poorest Season in Years.

Our season for honey has been the poorest we have had for years. We will have perhaps a ton of fall honey (extracted) to sell; that is, after all colonies have a good supply for winter. I have 244 colonies.

O. H. TOWNSEND.

Allegan Co., Mich., Sept. 26.

Cleome or Rocky Mountain Bee-Plant.

We have raised cleome (Rocky Mountain bee-plant) for chickens and bees for over 20 years, and we raise about two acres annually. It is equal to any grain crop for chickens, and the bees work on it from daylight until dark, when warm enough; from 10 until 3 o'clock, mostly for pollen. We do not value it for pollen (they can obtain pollen from corn and other plants more easily), but believe it to be the greatest of plants for honey. It blooms about the first of July, and blooms constantly for two months, keeping the bees breeding from basswood until heartsease. For beauty's sake nothing can excel this plant for a background cover to fence or hedge in garden work, for when in bloom it is a solid bank of pink, and grows from 4 to 6 feet high.

It is best raised in rows, the same as potatoes or corn, but will grow and take care of itself anywhere, even among the rankest weeds. The seed should be sown by all means (so as to freeze it) in the fall, or on the late snows of winter. I have succeeded in sprouting it in the spring by soaking the seed for several days in water, changing the water every day.

It may be plowed under from 4 to 6 inches deep in the fall, and will force its way through, but I believe the plants are more vigorous if just sown on any loose spot and allowed to work their way under cover with the action of frosts and storms. It may be transplanted the same as cabbage. If taken up when small, though I have changed plants in my garden

Plant Seeds of Flowers

that bees will work on. The "BELZEMERE" has pretty flowers, grows anywhere, blooms from June to October, and yields white honey, 10c per pkg. Motherwort seed, 6c. H. S. DUBY, ST. ANNE, ILL.

Please mention Bee Journal when writing.

when over a foot in height. I transplanted, this year, over 3,000 plants.

I have about 10 colonies of bees in Dadant hives, and double supered. They are now filling the second super and all have from 100 to 200 pounds of honey. I will have to extract a few frames from the body of the hive to give them room to rear bees for winter and spring. I just weighed the lightest of 11 Dadant frames of one hive, some weighing 10 1/2 pounds. In this hive there is not enough brood to fill one frame, nor eggs to cover one's hand. The cold and windy weather has worn the bees down to at least half a colony; they cannot generate heat enough to build comb, and they simply fill every cell with honey. Four days ago I looked at a beautifully egged comb, and it is now beautifully filled with honey. I would rather have had the eggs left in the comb, and the honey in the field.

W. J. LONGSDON.

Ogle Co., Ill., Sept. 10.

[We have some of the cleome seed, and can furnish it by mail, postpaid, for 15 cents an ounce.—EDITOR.]

Practically No Honey.

We have no honey here this year for the first time in ten years. I have 150 colonies of bees, and will have only 500 pounds of comb honey.

I could not get along without the American Bee Journal.

OLIVER CARON.

Red Lake Co., Minn., Sept. 27.

Good Prospects for 1903.

I have never seen the prospects so flattering for a great honey crop as they are now for 1903. The ground all over is covered with white clover—yards, lanes, fields, orchards, in fact all spaces not tilled, have a fine growth. It looks now as if the bee-keeper that is prepared, and has his dish right side up, will get some sweet next season.

I have 75 colonies in good shape, hoping to winter them so they will come out strong in the spring.

W. D. SOYER.

Jackson Co., Mich., Oct. 1.

Eating Boiled Honey.

I can eat honey that has been heated to the boiling point. Now this may seem a small matter, but let me tell you, I once tried to overcome its bad effects by eating half a teaspoonful of honey at each meal for 30 days, and had 90 doses of colic. I accidentally found out that I can eat boiled honey, and eat as much as two large table-spoonfuls at a meal without a dose of colic thrown in; and as I have never seen boiled honey spoken of in this way I hope it may be a benefit to others.

Rain and mud we have in plenty. I wish those people who are suffering with drouth in Texas had a part of it; I would be willing to give them two-thirds of it.

LEWIS LAMKIN.

Woodbury Co., Iowa, Sept. 24.

Suggested Cause of Bees Dying.

I have noticed the letter from J. Lother Bowers, page 518 and 519, giving an account of his bees dying, and suggesting that it is on account of buckeye bloom. I see that Prof. Cook rather holds that buckeye is not the fault, but says that spraying fruit earlier in the season might account for the mortality.

Now for my story: I had about 200 colonies in Placer Co., Calif., and during the time buckeye was in bloom a good many bees died in a good many colonies (not all), and seemed to depopulate them considerably for a time. The trouble seemed to subside after the buckeye ceased to bloom.

Being away at the time the bees commenced dying, the man I had in charge wrote me of the trouble, and said he thought the trouble was caused by ants troubling the brood, as the dead looked more like nearly matured brood. But as soon as I returned and looked over a few colonies I told him I did not think the ants were to blame. I could see a few bees crawling around which had the appearance of bee-paralysis. I thought that was more than

BEE-KEEPERS--ATTENTION.

Do not put your money into New Fangled Bee-Hives, but buy a plain, serviceable and well-made hive, such as the regular Dovetailed hive arranged for bee-way sections. Honey-producers of Colorado—one of the largest honey-producing sections in the world—use this style.

Thousands of Hives, Millions of Sections, ready for Prompt Shipment.

PERSONAL TO SUBSCRIBERS

WE WILL SEND to every subscriber or reader of the American Bee Journal a full-sized ONE DOLLAR package of VITE-ORE, by mail, POSTPAID, sufficient for one month's treatment, to be paid for within 1 month's time after receipt, if the receiver can truthfully say that its use has done him or her more good than all the drugs and dopes of quacks or good doctors or patent medicines he or she has ever used. READ this over again carefully, and understand that we ask our pay only when it has done you good, and not before. We take all the risk; you have nothing to lose. If it does not benefit you, you pay us nothing. VITE-ORE is a natural, hard, adamantite rock-like substance—mineral—ORE—mined from the ground like gold and silver, and requires about 20 years for oxidation. It contains free iron, free sulphur and magnesium, and one package will equal in medicinal strength and curative value 800 gallons of the most powerful, efficacious mineral water, drunk fresh at the springs. It is a zoological discovery, to which there is nothing added or taken from. It is the marvel of the century for curing such diseases as Rheumatism, Bright's Disease, Blood Poisoning, Heart Trouble, Diphtheria, Catarrh and Throat Affections, Liver, Kidney and Bladder Ailments, Stomach and Female Disorders, La Grippe, Malarial Fever, Nervous Prostration and General Debility, as thousands testify, and as no one, answering this, writing for a package, will deny after using. Give age, ill's and sex.

This offer will challenge the attention and consideration, and afterward the gratitude of every living person who desires better health, or who suffers from, pain, ill's and diseases which have defied the medical world and grown worse with age. We care not for your skepticism, but ask only your investigation, and at our expense, regardless of what ill's you have, by sending to us for a package. You must not write on a postal card. In answer to this, address, THEO. NOEL COMPANY, Dept. J. P., 527, 529, 531 W. North Ave., CHICAGO, ILL.

likely the cause, but they were not much in evidence. Then this caused the said man to call to mind what had been told, by another party (who had tried to keep bees in this same locality), that his bees always died off considerably during buckeye blooming time.

It is a great peach-growing center, and as far as growing radishes and lettuce is concerned I don't think there is any to speak of; these crops have a large acreage in Mr. Bowers' locality. There is a great amount of spraying of fruit-bloom, but whether there is any poisonous substance used in the spray I cannot say; so, according to my story, buckeye would be to blame. But I will further say that I had moved about 30 colonies from my Placer County apiary, a little after the first of June, to a new location in Sutter County; this was before mortality commenced, and 2 or 3 colonies were depopulated in the same way in the new location. The new location has no buckeye bloom, and the bees may have been affected by one of the forms of paralysis.

I have just been told that arsenic is used in the spray used in the orchards, but no mortality during spraying. C. D. BROWN. Sutter Co., Calif.

Poorest Season Known.

We have had the poorest season here I have ever known. No honey has been taken this year. I have 33 colonies, and they have no honey. I have been feeding them for the past month. I hope to have a fall flow, which will supply them for winter. S. F. SAMPSON. Greenbrier Co., W. Va., Sept. 19.

Thoroughwort or Boneset.

I enclose a specimen of a large weed which is now in bloom here (Sept. 15). It grows in neglected fields, and seems to be a great favorite with honey-bees. What is it? EAST TENNESSEE.

[The specimen is a Thoroughwort or Boneset, although not the common boneset of our Northern States. It belongs to the great Composite family and will no doubt sustain the reputation already established by this family in sweet beedom.—C. L. WALTON.]

How to Treat Quiet Robbing.

In answer to "Minnesota," page 618, I will say that I had the same experience the past season. My bees swarmed, and the swarm commenced quietly to rob the old colony. My remedy is this: Sprinkle a little flour on the bees that are doing the robbing, in front of the stand robbed, so that you can locate the robbers. Then with any fine spray, spray the robber-bees by opening the hive and spraying the bees; also spray them at the entrance with diluted peppermint essence. The change in scent in the robbers will cause the colony to protect themselves. Also make the entrance quite small, and your trouble is done.

LEONIDAS CARSON.

Trumbull Co., Ohio., Sept. 26.

A Proposition on Queens.

I wish to reply to Mr. Henry Alley's article on page 533, in regard to the queens that be can rear in those little boxes. I have read all of Dr. Gallup's articles on queen-rearing, and all of Mr. Alley's and others, but this one caps the climax. Dr. Gallup has got it down as nearly right as any one, according to my notion.

I rear all my queens in swarming-time; all the queens that do not come up to what I think they should, I kill and replace with good cells from my best colonies.

I work principally for honey, and get it. There was a queen-breeder that kept sending me his catalog, and I was a little "sore" on buying queens, so I wrote to him that I would give him \$5.00 if he would send me a queen whose bees would store more surplus honey than any one of my queens. He did not take me up.

I have bought queens from 6 different queen-breeders—the leading ones—and I have

not had one that would come up to those that I rear in swarming-time.

Now, Mr. Alley, I want to make a trade with you for 100 of your queens; I will give you \$100 more than you ask for them, if you will guarantee that your 100 queens will produce more honey, reared in those boxes, than my queens that I rear in swarming-time. I will furnish everything, and pay your man \$20 per month and board him. Ship your queens through the mail; I will furnish the hives to put them in; I to get all of the honey and the queens if you do not get the most honey. I will take care of them the first year; you can select your man. Now, I think this is the cheapest way to start an out-yard. I will pay for all the hives, foundation, paint and everything, except the queens. I will put out 100 colonies with queens reared in swarming-time, and you are to rear yours in those little boxes; I am to get the honey and queens if your man does not get the most honey.

I have about \$800 worth of honey from 120 colonies, spring count; 200 acres in cultivation, and 125 acres in corn under irrigation, and as fine as I wish. I have no queens for sale, nor anything else excepting honey and wax. I just want to start another out-yard, and I take this step as I think it will be a good investment. I don't want any one to write to me; if you do, you will lose your time and postage stamp.

EDWARD SCROGGIN.

Eddy Co., New Mexico, Aug. 28.

Sweet Clover—Wood Sage—Partridge Pea.

Enclosed find what is said to be sweet clover, but it is not according to Dr. Miller's description of sweet clover. Also No. 1 and No. 2; they are purple and pink, and commence to bloom about June 1. The purple one has not yielded any honey this season. It has been so wet that the tubes are much deeper than common. No. 3, the yellow sample, yields pollen and some honey, and commences blooming about July 15, and will continue a week or ten days longer. CHAS. M. DARROW.

Vernon Co., Mo., Sept. 15.

[The specimen you call sweet clover is surely the genuine article. I cannot account for the discrepancy between the Doctor's description and your flower. Consult "The Bee-Keeper's Guide," page 417. I have not been able to identify No. 1, as no flower was on the plant. You might send a sample to Prof. Cook. No. 1 is a Wood-Sage, which belongs to the mint family, and is a good honey-plant. No. 3 is the Partridge Pea, a really valuable bee-plant. In Prof. Cook's Manual, page 429, is a drawing of it.—C. L. WALTON.]

Introducing Queens—Determining Sex.

I wish to give my way of introducing queens. During the last days of June I received a California queen worth \$2.50, which I took from the shipping-cage and placed her in another cage, giving her some young bees about three days' old, from the colony to which I intended to introduce her. I corked up the cage and hung it in the hive for one hour, then pulled out the plug.

On July 1 I got another queen from Ohio—a \$4.00 one—and introduced her the same way.

On July 21 received a \$5.00 queen from a New York breeder, and introduced her the same as the others.

About Aug. 15 I received a long-tongued queen from an Illinois dealer, and introduced her as follows:

I brought a comb into the house for the purpose of getting young bees to place in the cage with the queen. The bees on the comb began to cry for a queen, and I turned her loose among them. They met her in a friendly manner, shook hands, then treated her to California white honey and escorted her over the comb: crossed to the other side. Then I placed the comb back in the hive, queen next to the wall, with the division-board on the inside of the frame, and left a

Or, Manual of the Apiary.

PROF. A. J. COOK.

Price,
Postpaid,
\$1.20

Price,
Postpaid,
\$1.20

This standard work on practical bee-keeping has just been thoroughly revised and brought down to date. About 100 pages and nearly 100 illustrations have been added, which makes it now a superb volume of 544 pages, with 295 fine illustrations. It is printed on clear white paper, and is bound in elegant brown cloth, gold-lettered.

Prof. Cook has been one of the leading contributors to the American Bee Journal for a quarter of a century. He is well known to bee-keepers everywhere. He is an authority on bees and related subjects. His book has had a large sale, which now bids fair to increase greatly.

In order that every reader of the American Bee Journal, who does not already possess a copy of Prof. Cook's work, may have it, we wish to make the following

FOUR LIBERAL OFFERS:

No. 1.—For \$1.75 we will mail the American Bee Journal one year and a copy of Prof. Cook's book.

No. 2.—Any one of our present subscribers whose subscription is now paid in advance, can have a copy of Prof. Cook's book mailed to him free as a premium for sending us two new subscribers to the American Bee Journal for a year (with \$2.00.)

No. 3.—Or, send one new subscriber for a year (at \$1.00) and 50 cents more (\$1.50 in all,) and we will mail to YOU a copy of the book and will send the American Bee Journal for one year to the new subscriber.

No. 4.—For \$1.00 we will send Prof. Cook's book by express or freight with other goods; or, if called for at our office, the price is \$1.00. But the post-paid price of the book alone is \$1.20.

Please remember that offers Nos. 2 and 3 of the above are made to those who are now subscribers to the American Bee Journal, and whose subscriptions are paid in advance. Offers Nos. 1 and 4 are made to any one who desires to take advantage of them.

Address all orders to the publishers,

GEORGE W. YORK & CO., 144 & 146 Erie St., CHICAGO, ILL.

space of one frame; next day I shoved the other frames up, removed division-board, and the queen was all right. This beats keeping them confined in the little shipping-cage for a week.

My introduction of virgin queens is to pick them off of the comb as soon as hatched and let them run in at the entrance; or lift back the corner of the blanket and let them run down from the top. Very often a very young virgin will supersede an old queen, if given in this way, without destroying the old queen yourself.

WHAT DETERMINES SEX?

On page 502 Prof. Cook has an article on this subject. These professors are always getting their foot into something. Look at the argument, read between the lines. First, animals on the earth are sexless. If a male offspring is desired, give the mother a dose of pills, or make her sick some other way, and the desired result will be obtained. If a female is desired, the mother must enjoy good health, and be fat. Wonder if all of our stalwart young men had weakly, sickly mothers, and all our weakly, sick, young American women had stalwart, healthy mothers. If the mother's meal does not digest it will be a male; if it digests well it will be a female. Just as though the food and sperm entered the same channel.

Prof. Loeb gives chemicals instead of male sperm, and the conception is perfect. It seems to me that a man is very closely crowded for logic, knowledge, and science, and even for argument, that will thus reason. I wish to say, with the highest regard to the professors, that I have mastered the science of controlling the sexes of animals, and have good knowledge of plants, and that his theory is not true by any means; and that my art never does fail. I can take his subject (the mother) and give him all the advantages his theory calls for, and will check up a thousand dollars that the results he desires will fail him; or I will bank on another thousand dollars that my art is true, and will develop either sex without a failure.

DR. W. A. JOHNSON.
Los Angeles Co., Calif.

Unfinished Sections—Foul Brood.

The honey season is over with about half a crop. It was too wet and cold. There are a good many unfinished sections and plenty of foul brood.

FRANK RASMUSSEN.
Montcalm Co., Mich., Sept. 29.

Nature's Way of Rearing Queens.

Regarding the discussion between Mr. Alley and Dr. Gallup (page 519) where Mr. Alley says that a colony will not rear a good queen when there is a fertile queen present, I must say that by my experience he is entirely mistaken; because if that is true I have not a good queen in any of my colonies, for they are all reared that way, by Nature's unchangeable law, which has seemed to be best, with the exception of one which I got April 20, 1901, from an Ohio breeder, and I do not know how she was reared, and yet I have first-class queens, and have several colonies each of which have filled 3 supers of 28 pounds of honey since July.

It was a very unfavorable season, very wet and cold up to the time of basswood flow, and they even worked in frequent drizzling showers.

Four years ago I had a queen whose colony filled seven 24-pound supers—which I can prove by my neighbors—and this queen was reared during swarming-time, and there was a fertile queen present in the hive. I had her almost 6 years, and she was as active and prolific the last year as the first. I still have several of her daughters that are 4 and 5 years old, and I doubt if Mr. Alley has any queen that he can match with her, in prolificness and honey-gathering qualities.

I am 52 years old, and have worked among bees since childhood, and have often wondered how it was possible for Mr. Queen-Breeder to rear good, prolific queens in a nucleus with only a handful of bees.

My father was a capable and experienced bee-keeper in Germany, and his bees brought him up from being a poor man to a well-to-do

Langstroth on... The Honey-Bee

Revised by Dadant—1900 Edition.

This is one of the standard books on bee-culture, and ought to be in the library of every bee-keeper. It is bound substantially in cloth, and contains over 500 pages, being revised by those large, practical bee-keepers, so well-known to all the readers of the American Bee Journal—Chas. Dadant & Son. Each subject is clearly and thoroly explained, so that by following the instructions of this book one cannot fail to be wonderfully helped on the way to success with bees.

The book we mail for \$1.25, or club it with the American Bee Journal for one year—both for \$1.75; or, we will mail it as a premium for sending us THREE NEW subscribers to the Bee Journal for one year, with \$3.00.

This is a splendid chance to get a grand bee-book for a very little money or work.

A Free Trial Proposition.—We desire to call our readers' attention to the free-trial offer made in another column by the Stratton Mfg. Co., Erie, Pa., on the Dandy Bone Cutter. This standard machine has been before the public for 9 years, and many of our subscribers have used it with perfect satisfaction; such as have not now have the opportunity of trying one for 15 days before they pay for it. The Company requires no deposit in advance. All you have to do is to try the Dandy and then decide whether you want to keep it or not. We need not urge upon poultry-raisers the importance of cut green bone as a poultry food; it has the advantage of costing almost nothing and certainly it is one of the greatest egg producers in the world. It will pay you to "get a Dandy."

The Emerson Binder

This Emerson stiff-board Binder with cloth back for the American Bee Journal we mail for but 60 cents; or we will send it with the Bee Journal for one year—both for only \$1.40. It is a fine thing to preserve the copies of the Journal as fast as they are received. If you have this "Emerson" no further binding is necessary.

GEORGE W. YORK & CO.,
144 & 146 Erie Street, CHICAGO, ILL.

man, but he never tried to rear a queen by any artificial way, but always followed Nature's way. And now comes Mr. Alley, who claims he can beat Nature's plan. I would like to refer him to a certain man who was always finding defects in Nature and trying to improve on her, and he could not understand why a small acorn could grow on a big tree, and a large pumpkin grow on a slender vine; and on a warm day he laid down in the shade of a large oak-tree to sleep, and as it happened an acorn loosened by the wind fell down, striking him on the head and waking him up. Springing to his feet, he exclaimed, "Oh, how could I have such a foolish idea about Nature, for had it been a pumpkin instead of an acorn that struck me I would not be standing on my feet now."

Here is my advice to beginners; *Rear your own queens* from a good, prolific mother, during the swarming impulse, and you will be certain to have queens perfect in all particulars. Why should we send away for queens when (as I have) we find them to be almost worthless, with the exception of the one I got from Ohio?

Now, if Mr. Alley claims he can rear better queens by the force method, then he must have proof for what he says on page 519, that there is quite a difference between artificial and forced methods in rearing queens, or this statement is false, for if a colony is going to swarm the bees know well enough that the queen leaves too, and that they must have another or they will be destroyed. If it were as Mr. Alley says it is, do it as you please, they would not prepare queen-cells beforehand, and protect them so carefully.

Now, the proofs that I have for my method of rearing good queens are:

1st.—That the old mother's whole duty and care is centered on the welfare of the old colony, else she would lay drone-eggs in the queen-cells, for it is very hard for her to leave her old home.

2nd.—That the old mother deposits the eggs with more care in the queen-cells than in the other cells, for this is proven by the young queens hatching at regular intervals, that is, a certain length of time between them.

3d.—That a queen-cell has a different shape or form inside from any other cell. This proves that Nature means to produce a perfectly shaped, perfectly formed, healthy, strong, and prolific mother-bee.

Now, this is no new method, that Mr. Alley claims that he has in his head (but which he is careful enough not to explain), but an old, old rule, followed by Nature for ages and ages. Let us follow her, too, for she knows what is best.

H. B. STUMPE.
Stephenson Co., Ill., Sept. 15.

Very Short Honey Crop.

We have just taken off our honey, and about one colony in five filled a super. Fully one-half are in a starving condition; no increase, and I will commence feeding at once to prepare them for winter.

Last year the Bank here said they paid out for honey, \$36,000; this year 1½ cars is all there is.

J. F. BROADBENT.
Boulder Co., Colo., Sept. 20.

Not a Heavy Surplus.

Our surplus honey crop will not be as heavy as expected; the wet weather continuing so long, just a few days of good work, then the frosts of the 11th and 12th cut them short. All except my very late swarms go into winter with full supplies.

S. P. DRINNIN.
Platte Co., Nebr., Sept. 25.

A Fair Honey Crop.

I am pleased to be able to report a fair honey crop, the first one in three years. I have about 60 pounds of comb and 75 pounds of extracted honey per colony.

Those that run their bees in a haphazard manner, or rather let them run themselves, got very little honey. They don't read the newspapers—don't need to! They know more than the writers or editors do. When we have a good year they all go wild, and

rush into bee-keeping; but the first "off year" knocks them out; they don't last much longer than a certain new bee-paper did.

By the way, it was the most expensive bee-paper I ever subscribed for—\$1.00 for three copies. It just lived until grass, then died; but I notice its publishers still run their "ad." in some of the journals, catching more "sneakers" like me, I suppose.

J. T. HARRISTON,
Cherokee Nation, Ind. Ter., Sept. 22.

Kuhnia Bees Doing Fairly Well.

I enclose a plant or weed that grows on the roadside or on unoccupied land that attracts the bees in the afternoon until night. Please give a name for the same.

My bees are doing fairly well at present. Central Kansas is free from bee-disease so far as I know.

FRED DRESSLER,
Ellsworth Co., Kan., Sept. 17.

[The plant is a composite, and goes by the name of Kuhnia. It is quite common east of the Mississippi River, and is spreading westward. September and October are the best months for bees to work on composite flowers.]

More Nectar this Year.

This is said to be the banner honey and wax producing county in the State. It's not much now if that be true, for the last two winters have wiped out more than one-half of the bees.

I think it is a fact that there was more nectar this year than in any of my five years' experience in bee-keeping.

The old bee-keepers got but little honey, but the up-to-date man has a good crop.

From 85 colonies, spring (May 15) count, I have increased to 130, and I took 5,000 sections of honey, and the frames have enough for winter.

D. C. BACON,
Bradford Co., Pa., Sept. 28.

About a Half Yield.

We had only about a half yield of honey here this season. From some unknown cause sweet clover has invaded this portion of the Yazoo Delta, within the last two years, and is very abundant in the waste-places near my apiary. I consider it the best of honey-producing plants. It grows here in the weeds and grasses where there is no cultivation.

O. M. BLANTON,
Washington Co., Miss., Sept. 29.

BEE=BOOKS

SENT POSTPAID BY

GEORGE W. YORK & CO.,

144 & 146 Erie St., - CHICAGO, ILL.

Bee-Keeper's Guide, or Manual of the Apiary, by Prof. A. J. Cook, of Pomona College, California. This book is not only instructive and helpful as a guide in bee-keeping, but is interesting and thoroughly practical and scientific. It contains a full delineation of the anatomy and physiology of bees. 544 pages, 295 illustrations. Bound in cloth. 1902 edition—19th thousand. Price, \$1.20.

Langstroth on the Honey-Bee, revised by Dadant.—This classic in bee-culture has been entirely re-written, and is fully illustrated. It treats of everything relating to bees and bee-keeping. No apianian library is complete without this standard work by Rev. L. L. Langstroth—the Father of American Bee-Culture. It has 520 pages, bound in cloth. Price, \$1.25.

A B C of Bee-Culture, by A. I. Root.—A cyclopedia of 400 pages, describing everything pertaining to the care of the honey-bees. Contains 300 engravings. It was written especially for beginners. Bound in cloth. Price, \$1.20.

Scientific Queen-Rearing, as Practically Applied, by G. M. Doolittle.—A method by which the very best of queen-bees are reared in perfect accord with Nature's way. Bound in cloth and illustrated. Price, \$1.00; in leatherette binding, 60 cents.

Bees and Honey, or Management of an Apiary for Pleasure and Profit, by Thomas G. Newman.—It is nicely illustrated, contains 160 pages, bound in cloth. Price, in cloth, 50 cents; in paper, 30 cents.

Advanced Bee-Culture, Its Methods and Management, by W. Z. Hutchinson.—The author of this work is a practical and entertaining writer. You should read his book; 90 pages, bound in paper, and illustrated. Price, 50 cents.

Bee-Keeping for Beginners, by Dr. J. P. H. Brown, of Georgia.—A practical and condensed treatise on the honey-bee, giving the best modes of management in order to secure the most profit. 110 pages, bound in paper. Price, 50 cents.

Bee-Keeping for Profit, by Dr. G. L. Tinker.—Revised and enlarged. It details the author's "new system, or how to get the largest yields of comb or extracted honey." 80 pages, illustrated. Price, 25 cents.

Bienen-Kultur, by Thomas G. Newman.—This is a German translation of the principal portion of the book called "Bees and Honey." 100-page pamphlet. Price, 25 cents.

Apiary Register, by Thomas G. Newman.—Devotes two pages to a colony. Leather binding. Price, for 50 colonies, \$1.00.

Dr. Howard's Book on Foul-Brood.—Gives the McEvoy Treatment and reviews the experiments of others. Price, 25 cents.

Winter Problem in Bee-Keeping, by G. R. Pierce.—Result of 25 years' experience. Price, 30 cents.

Foul Brood Treatment, by Prof. F. R. Cheshire.—Its Cause and Prevention. 10 cts.

Foul Brood, by A. R. Kohnke.—Origin, Development and Cure. Price, 10 cents.

If you want the Bee-Book

that covers the whole Apicultural Field more completely than any other published, send \$1.25 to

HONEY AND BEESWAX
MARKET QUOTATIONS.

CHICAGO, Sept. 19.—Comb honey is meeting with good demand and the arrivals are easily disposed of at 15@16c per pound for that which grades No. 1 to fancy. Very little of the lower grades are offered, but bring within 2 to 3 cents of No. 1. Amber grades of comb are also scarce, with no buckwheat offerings. Extracted is steady, white bringing 6 1/2@7c; amber, 6@7c; Southern and odd lots of dark, 5 1/2@6c. Beeswax, 30c. R. A. BURNETT & Co.

KANSAS CITY, Sept. 27.—The demand for both comb and extracted honey is good, especially comb, at the quotations. We quote fancy white comb, 14@14 1/2c; No. 1 white, 13 1/2@14c; No. 2 white and amber, 13@13 1/2c. White extracted, 6 1/2@7c; amber extracted, 6@6 1/2c. Beeswax, 22@25c. C. C. CLEMONS & Co.

CINCINNATI, Aug. 30.—The demand for comb honey at present is very good; all shipments are sold quick at 15@16c for No. 1 and fancy. We advise shipping while demand is good and before the western carloads are here. In three weeks from now carloads will arrive, then demand is satisfied, sales harder to make, and prices demoralized. Extracted honey is selling as fast as it arrives, at the following prices: Amber and Southern in barrels, at 5 1/2@6 1/2c, according to the quality. White clover, 7 1/2@8c. Beeswax is scarce at 30c. THE FRED W. MUTH Co.

ALBANY, N. Y., Sept. 24.—Honey receipts are light here so far, and good demand for comb honey. We quote light comb, fancy, 16c; A No. 1, 15c; No. 1, 14c; mixed and dark, 13c; buckwheat scarce at 12@13c. Extracted, light, 7c; mixed, 6 1/2c; buckwheat, 6c. Beeswax, 28@30c. H. R. WRIGHT.

NEW YORK, Sept. 20.—Comb honey is in good demand; fancy white at 15c, and some exceptionally fancy lots may bring a little more. No. 1 sells at 13@14c; amber at 12c; no arrival of buckwheat as yet, the season being late. Extracted firm at 6 1/2@7c for white, 6c for light amber, and 5@5 1/2c for dark. Beeswax firm at 27@28c. HILDRETH & SEIGELKEN.

CINCINNATI, Aug. 29.—New comb honey is not coming in so plentiful, so far. Whatever has come in, and is fancy water-white, has brought a good price, and sold to stores at from 15@16c. Honey kept over from last year, fancy sells for 14c. The market for extracted is more lively and brings: Amber, from 5@5 1/2c; alfalfa water-white, from 6@6 1/2c; white clover, from 7@7 1/2c. Beeswax, 28c. C. H. W. WEBER.

SAN FRANCISCO, Aug. 20.—White comb, 13@14c; amber, 10@12c; dark, 8@9c. Extracted, white, 5 1/2@5 3/4c; light amber, 5@5 1/2c; amber, 4 1/2@5c. Beeswax, good to choice, light, 27@29c; dark, 25@26c.

Not much offering or arriving of any sort. While the market is firm throughout, current values are being better sustained on comb than on extracted, for the reason that the latter has to depend to some extent on outside demand. All the comb honey offering will be required locally. The shipment of comb honey has never proven satisfactory, and the production is in consequence restricted to small compass.

1-lb Keystone ... Honey-Jars

These are clear flint glass jars holding just one pound, and the shape of a keystone. They are 7 3/8 inches high, and very pretty when filled with honey. The corks can be sunk a trifle below the top, and then fill in with beeswax, sealingwax or paraffin. We can furnish them in single gross lots, with corks, f.o.b. Chicago, at \$3.50; two gross, \$3.25 per gross; or five or more gross, at \$3.00 a gross. These are the cheapest glass one-pound jars we know anything about. We have only about 30 gross of them left. So speak quick if you want them. Address,

MEMBERSHIP DUES, \$1.00 a year.

If more convenient, Dues may be sent to the office of the American Bee Journal, when they will be forwarded to Mr. Secor, who will mail individual receipts.

A Celluloid Queen-Button is a very pretty thing for a bee-keeper or honey-seller to wear on his coat-lapel. It often serves to introduce the subject of honey, and frequently leads to a sale.

NOTE.—One reader writes: "I have every reason to believe that it would be a very good idea for every bee-keeper to wear one (of the buttons) as it will cause people to ask questions about the busy bee, and many a conversation thus started would wind up with the sale of more or less honey; at any rate it would give the bee-keeper a superior opportunity to enlighten many a person in regard to honey and bees."

The picture shown herewith is a reproduction of a motto queen-button that we are furnishing to bee-keepers. It has a pin on the underside to fasten it.

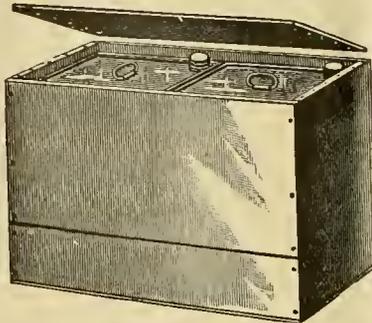

Price, by mail, 6 cents; two for 10 cents, or 6 for 25 cents. Send all orders to the office of the American Bee Journal

BEST Extracted Honey For Sale

ALL IN 60-POUND TIN CANS.

Alfalfa Honey

This is the famous White Extracted Honey gathered in the great Alfalfa regions of the Central West. It is a splendid honey, and nearly everybody who cares to eat honey at all can't get enough of the Alfalfa extracted.

Basswood Honey

This is the well-known light-colored honey gathered from the rich, nectar-laden basswood blossoms. It has a stronger flavor than Alfalfa, and is preferred by those who like a distinct flavor in their honey.

Prices of Alfalfa or Basswood Honey:

A sample of either, by mail, 10 cents, to pay for package and postage. By freight—two 60-pound cans of Alfalfa, 9 cents per pound; 4 cans or more, 8½ cents a pound. Basswood Honey, ½ cent more per pound than Alfalfa prices. Cash must accompany each order. You can order half of each kind of honey, if you so desire. The cans are two in a box, and freight is not prepaid. Absolutely Pure Bees' Honey.

Order the Above Honey and then Sell It.

We would suggest that those bee-keepers who did not produce enough honey for their home demand this year, just order some of the above, and sell it. And others, who want to earn some money, can get this honey and work up a demand for it almost anywhere.

GEORGE W. YORK & CO., 144 & 146 Erie St., Chicago, Ill.

The Novelty Pocket-Knife.

Your Name and Address on one side—Three Bees on the other side.

[THIS CUT IS THE FULL SIZE OF THE KNIFE.]

Your Name on the Knife.—When ordering, be sure to say just what name and address you wish put on the Knife.

The Novelty Knife is indeed a novelty. The novelty lies in the handle. It is made beautifully of indestructible celluloid, which is as transparent as glass. Underneath the celluloid, on one side of the handle is placed the name and residence of the subscriber, and on the other side pictures of a Queen, Drone, and Worker, as shown here.

The Material entering into this celebrated knife is of the very best quality; the blades are hand-forged out of the very finest English razor-steel, and we warrant every blade. The bolsters are made of German silver, and will never rust or corrode. The rivets are hardened German silver wire; the linings are plate brass; the back springs of Sheffield spring-steel, and the finish of the handle as described above. It will last a last-time, with proper usage.

Why Own the Novelty Knife? In case a good knife is lost, the chances are the owner will never recover it; but if the "Novelty" is lost, having name and address of owner, the finder will return it; otherwise to try to destroy the name and address, would destroy the knife. If traveling, and you meet with a serious accident, and are so fortunate as to have one of the "Novelties," your POCKET-KNIFE will serve as an identifier; and in case of death, your relatives will at once be notified of the accident.

How appropriate this knife is for a present! What more lasting memento could a mother give to a son, a wife to a husband, a sister to a brother, or a lady to a gentleman, the knife having the name of the recipient on one side?

The accompanying cut gives a faint idea, but cannot fully convey an exact representation of this beautiful knife, as the "Novelty" must be seen to be appreciated.

How to Get this Valuable Knife.—We send it postpaid for \$1.25, or give it as a Premium to the one sending us THREE NEW SUBSCRIBERS to the Bee Journal (with \$3.00.) We will club the Novelty Knife and the Bee Journal for one year, both for \$1.90.

GEORGE W. YORK & CO.

Chicago, Ill.

Please allow about two weeks for your knife order to be filled.

BEE JOURNAL

42d YEAR.

CHICAGO, ILL., OCT. 16, 1902.

No. 42.

* Editorial Comments. *

Uniting Colonies, where necessary, may in many places be done now as well as at a later date—perhaps better. It is better that the bees have a chance to arrange matters to their liking, and get quietly settled down some time before winter sets in.

Heartsease has always been counted an important honey-plant in the low grounds of the Mississippi valley, especially in Nebraska, but farther east it has not been considered of much value. This wet year, however, it has been reported as yielding quite a late harvest in northern Illinois, and perhaps in other parts east of the Mississippi.

Uniting Colonies in Autumn.—F. Volkman, gives in *Leipzig Bztg.* a plan which may suit those who have the time for it: Lift out the combs of the colony to be united and put them in an empty hive, replacing them with empty combs. After about 15 minutes brush the bees from their combs back into their hive with its empty combs, making sure to remove the queen. In not more than half an hour, the bees will begin to run out of the hive, having discovered their queenlessness, when the hive must be moved close to the hive to which it is desired that the bees shall enter. If it be desired to give the bees to two or more colonies, the hive must be moved accordingly, as soon as each receives its quota.

White Clover, in northern Illinois, yielded nothing in its usual season—June and July; indeed, bee-keepers were at that time feeding to prevent starvation; later on, however, white clover blossoms kept gradually increasing in number, and apparently in condition, for the bees began working on clover to some extent after the middle of August, and were still to be found on clover at the close of September. It is not an unusual thing to see a sort of second crop of white clover, upon which bees do not work, but this year it did not seem so much like a second crop as a continuation of the first, the very sparse early bloom gradually becoming more and more plentiful, showing more bloom in October than in June.

Treatment of Laying Workers.—As a rule, the best thing to do with a colony of laying workers is to break it up, distributing the bees where they will do the most good. If the affected colony be given to a colony with a laying queen, a new colony can afterward be made from the colony thus strengthened, and the outcome will be better than if an attempt had been made to keep the faulty colony intact. Some may like a variation of this plan thus given by W. Hickox in the *Rocky Mountain Bee Journal*, only it is pos-

sible that others may not be so favored as he in having cells always started:

Take two or three combs, containing eggs and brood in all stages of development, from a strong colony, replacing with same number from the queenless one. Put a queen-excluder on top of the strong colony, and upon this place the hive with the laying workers and brood. Queen-cells will be built; when these are sealed place the hive upon a stand by itself, or remove the lower hive to a new location, leaving the top one in its place, as preferred. I have not had a failure so far in saving the colony by this method.

Queen Introduction.—When a new queen has been introduced, the failure to find such a queen several days later, or to find eggs laid by her, is by no means proof positive that she is not present. It is not such an unusual thing for a queen to remain for a week without laying after being introduced, and then to do good work afterward. Speaking on this subject, L. S. Crawshaw says in the *British Bee Journal*:

For instance, I have introduced by direct introduction—or the “Simmins” method—queens which have been confined in postal cages, and several days have sometimes elapsed before they settled again to lay. This may not be unusual, the ovaries are to be stimulated afresh. Take the case of one young queen, in my own experience. She was a traveled “tested queen,” of different race from my own or neighboring bees, and was introduced at night to a strong colony. She “piped” for some time as though frightened or roughly treated, and an examination three days later failed to reveal any signs of her.

I made an examination on the fifth day, and failed to discover eggs or enlarged cells, and a frame of younger brood was therefore added. On again examining the hive next day I found some addition of eggs to this comb and also in the one adjacent.

Sugar Syrup Granulating.—There is a difference of opinion as to this matter. Some maintain that no precaution is necessary to prevent granulation, while others report that sugar syrup stored in the comb by the bees has granulated badly. All depends on circumstances. If the feeding be done early, and if there be as much water as sugar, or more, the bees themselves will make all the change necessary, and the syrup will not granulate. But this will not do for late feeding.

If thin syrup is fed late, not only will the bees fail to make the proper chemical changes in it, but they will fail to evaporate it, leaving it unfit for winter stores. So the syrup must be made of about the consistency of honey, or about five parts of sugar to two of water. The bees can not be relied on to ripen this so it will not granulate. The addition of an even teaspoonful of tartaric acid for every 20 pounds of sugar will be necessary to prevent granulation.

It is better to feed the thin syrup, providing you feed early—and the early feeding is the better—but if you are unfortunate enough to be late about your feeding, then give the syrup thick, and add tartaric acid. Still better than the acid is adding extracted honey to the syrup, if you are so fortunate as to have that article.

* The Weekly Budget. *

A. I. ROOT has started an apiary in the woods of Michigan. At latest advices the apiary consisted of two colonies, one being a brushed swarm made from the other, and he was carpeting their entrance with burlap to keep the feet of the bees from slipping.

"THE WABASH VALLEY Poultry, Pigeon and Pet Stock Association" will hold its Sixteenth Annual Show at Evansville, Ind., Dec. 15 to 20, 1902. For any further information desired, address the Secretary, P. L. R. Crowder, Oakland City, Ind.

REV. W. F. CLARKE, some 30 years ago editor of the American Bee Journal, passed away on Sept. 25, 1902. He was for many years a resident of Guelph, Ontario, Canada, at which place he died. We have not received any further particulars, but will likely have them for publication later. Mr. Clarke was a writer of most excellent English, and had more or less to do with bee-keeping for a great many years.

THE GREAT INTERNATIONAL EXPOSITION, to be held at Vienna, from the 4th to the 26th of next April, will comprise six great groups: Living bees, hives, implements, bee-products, books of instruction, and literature. Items to be exhibited in any one of these classes are solicited from all parts of the earth, and especially such items as are little known in Austria. Further particulars can be obtained by addressing: Der Centralverein fuer Bienenzucht in Oesterreich, Wien, I., Schauflegasse 6.

MR. G. W. BELL, of Clearfield Co., Pa., a bee-keeper of considerable prominence in his locality, is a candidate for the State Legislature. It beats all how some bee-keepers do run for office. Some of them have practiced running, with a bee after them—that was before they were real bee-keepers—and they haven't forgotten how to run. As the bee then succeeded in running down the boy, some of those grown-up boys now succeed in running down the office. We say, Go it, boys: and may the right and righteous always win.

MISS PICKARD MARRIED.—Yes, Miss Ada L. Pickard, of Richland Co., Wis., was married on Wednesday, Sept. 24, 1902. Here is the notice that appeared in the Richland Democrat a few days later:

The pleasant farm home of Mr. and Mrs. W. J. Pickard was the scene at noon Wednesday last of a most happy event in the lives of two well-known and worthy young people. At that time Rev. J. W. Irish spoke the words which joined in matrimony the lives of Miss Ada L. Pickard and Mr. Nathan Boggs, both well and favorably known in the city and county. The ceremony was witnessed by a select company of relatives and intimate friends, after which all were regaled with a sumptuous wedding feast.

The happy couple departed Thursday morning for Chicago, where they will make their home, temporarily at least, and where Mr. Boggs will pursue his medical studies. A long list of friends will join with the Democrat in hoping for them the best this earth affords in the way of contentment and prosperity.

On the Saturday following the wedding we received a telephone call from Mr. Pickard (who, we supposed, was alone in Chicago), saying that he would call to see us in a little while. He did so, but along with him came Mrs. Pickard and Mr. and Mrs. Nathan Boggs. Well, weren't we surprised? We didn't think that Ada Pickard would do

such a thing without saying a word to the Bee Journal readers! But we will have to forgive her, even if she doesn't promise not to do it again!

We are sure that all will unite in heartiest well-wishes to Mr. and Mrs. Boggs, and congratulations to Mr. and Mrs. Pickard. Wisconsin loses one of its fairest maidens, and apiculture one of its best lady bee-keepers. But this life is full of changes—'twould be very monotonous if it were not thus.

THE ILLINOIS STATE FAIR PREMIUMS.—The following is a list of awards given in the department of bees and honey at the Illinois State Fair held about Oct. 1, at Springfield:

Display of comb honey—1st, C. Becker; 2d, Geo. M. Rumler; 3d, James A. Stone & Son.

Collection of labeled cases containing honey from different flowers—1st, Geo. M. Rumler; 2d, C. Becker; 3d, James A. Stone & Son.

Collection of labeled cases of amber or dark honey—1st, C. Becker; 2d, James A. Stone & Son.

White clover comb honey—1st, James A. Stone & Son; 2d, C. Becker; 3d, Geo. M. Rumler.

Sweet clover comb honey—1st, C. Becker; 2d, James A. Stone & Son.

Basswood comb honey—1st, Geo. M. Rumler; 2d, C. Becker; 3d, James A. Stone & Son.

Display of extracted honey—1st, James A. Stone & Son; 2d, C. Becker; 3d, Geo. M. Rumler.

Honey extracting on the grounds—1st, C. Becker; 2d, James A. Stone & Son.

Frame of comb honey for extracting—1st, James A. Stone & Son; 2d, Chas. Kingan; 3d, Geo. M. Rumler.

Display of candied honey—1st, C. Becker; 2d, James A. Stone & Son; 3d, Geo. M. Rumler.

Display of beeswax—1st, Geo. M. Rumler; 2d, C. Becker; 3d, James A. Stone & Son.

Observatory hive of dark Italian bees—1st, C. Becker.

Observatory hive of Golden Italian bees.—1st, Chas. Kingan; 2d, Geo. M. Rumler.

Honey-vinegar, with recipe for making—1st, Chas. Kingan; 2d, James A. Stone & Son; 3d, C. Becker.

Display of designs in beeswax—1st, James A. Stone & Son; 2d, C. Becker.

DENVER CONVENTION NOTES.—Saturday morning, Sept. 6, gave promise of being a most beautiful day in Denver. So the quartette of Illinoisans (Dr. Miller, Miss Wilson, Mrs. York, and the writer) packed and checked their belongings at the American Hotel, and prepared to spend the day taking the great "Loop Trip" to Silver Plume, 54 miles up in the mountains, at a point nearly 9000 feet above sea-level.

The train was composed of windowless cars, simply openings extending clear to the top of the car, so as to permit an unobstructed view of the mountains and scenery when passing along on the narrow-gauge railroad that wound around through the canyons up, up, and still up. It seemed almost impossible that one engine should be able to pull the train of several cars filled with people up such steep grades. But it did it, with some puffing.

Many, many times, on looking ahead, we would conclude that the railroad track must run right into a mountain, and we must stop. But upon arriving almost there the track would wind around a sharp curve, and on we would go, only to repeat the same thing over and over.

Perhaps the most interesting sight on this trip is the "Loop," where the railroad track extends across a very narrow valley several times after running along the sides of the opposite mountains, and all the time getting up higher and higher. At one point the track winds around so that in crossing the valley it extends directly above where we had been but a few minutes before, thus forming what is known as the "Georgetown Loop," as a place called Georgetown is very near where the "Loop" is found. This town lies in a depression between two mountains, seemingly about a mile wide. In looking down upon it

from the "Loop" point, the town has the appearance of being built in a sort of bowl formed by the mountains surrounding it. It is a typical mining town. Everything must be brought into the place on the railroad, as there is no farming land anywhere near.

All along the sides of the mountains could be seen places where some precious-metal prospector or miner had dug his sort of woodchuck-like hole, and boarded up the front, often closing it with a door.

We think we wouldn't care to live in Georgetown. It's too "hilly" there to suit us.

We reached Silver Plume about 12 o'clock, and remained only long enough to eat lunch.

Silver Plume is simply "no place"—only a mining camp away up on and in the mountains. And it seemed as if there was nothing but mountains in every direction as far as the eye could see.

The return, or downhill, trip was made in a shorter time. The train simply whizzed around the curves. At Georgetown it stopped a few minutes, when we were entertained by three or four small, poorly-clad children who sang one or two Sunday-school songs, one being "In the Dawning of the Morning." It seemed strange to hear such sweet music coming from such forlorn-looking children and in such a God-forsaken place. But it would have done your soul good to have seen those children jump for the nickels and dimes that were thrown to them from the car windows.

The rest of the return trip to Denver was uneventful,

except the scenery seemed grander than when first seen on going up. It seemed to grow on one. It is simply wonderful. It was also about the cheapest side-trip we took after the convention, as it cost only \$2.00 for the round-trip. We thought it was the most for the least money of anything we struck in or near Denver—except it was that excellent banquet (which was free to all from outside of Colorado) with its quarter-pound souvenir sections of honey at each plate. But we didn't know it until after we had eaten all our section of honey near the close of the banquet, that it was to be carried away as a "souvenir." The reader can imagine how we felt with a souvenir inside of us! No doubt there was at least one of those sweet souvenirs carried away—and completely invisible, too! But if any one doesn't want us to eat honey, it is always safest not to put it near our plate on the table. If within reach it is almost sure to disappear—or at least a goodly quantity of it. A "quarter section" is just right!

Well, we all reached Denver again about 3:30 p.m. We at once secured our baggage at the hotel, and boarded the train for Colorado Springs at 5 p.m. We arrived there about 8 o'clock, a tired-out quartette, you may be sure. But we found an excellent hotel, and after a good meal all went to our beds and "slept like a log" all night.

And this seems to be a good place to rest our pencil also for this time. Next week we will tell of a restful Sunday in Colorado Springs, and about our Pike's Peak trip on Monday following.

The Denver Convention.

Report of the Proceedings of the Thirty-third Annual Convention of the National Bee-Keepers' Association, held in Denver, Colo., on Wednesday, Thursday and Friday, Sept. 3, 4 and 5, 1902.

(Continued from page 646.)

Pres. Hutchinson—The next thing on the program is a talk by Dr. C. C. Miller, on

The Most Hopeful Field for the National Association.

MR. PRESIDENT:—I do not often make apologies—I do not like to; but sometimes I tell the truth when I can't help it. The Secretary wrote to me quite early desiring me to prepare a paper in accordance with the statement on the program. Very promptly I wrote the paper; then I immediately sent it to the Rev. E. T. Abbott, who was to make the response. I sent that paper without making any copy of it, and if I could say he never returned it to me it would have been a great kindness on his part. Unfortunately, Mr. Abbott returned the paper very promptly to me, so I can't make that as an excuse, and I suppose I put the paper away very carefully—so carefully I have never seen it since; but I will give you just a few points. I don't know whether they are the same points that are in the paper, and I don't know whether Mr. Abbott intends to reply to what I wrote formerly, or whether he will reply to what I say to-day, so that if we get all jumbled up don't blame Mr. Abbott. I am the one to blame

for it; but as this is the first time I ever made a mistake it must not count this time.

The President has told you about organization, and very properly comes next the question as to what is the best thing for the organization to do? I want to emphasize his paper by saying that the very best thing that the organization can do is to organize some more. There is a whole lot of material that is not organized, and I believe the first and most important thing that can be done by the Association is to organize a little farther and get a new and larger number of bee-keepers. Numbers do count, there is no question about that. If you want to have any moral effect in the way of securing legislation, or doing anything of that kind, if you can say, Here is an organization composed of 5000 members, that counts a good deal more than if you say it is composed of 1000 members.

Now, I am not sure just which is the best way to do to get in a larger number of members. I very much doubt the justice of allowing it to be done so largely as has been done by the bee-journals. They have done a lot of good work in that direction, and they have done it freely. Perhaps they are willing to do it. Well, it is right enough for them to do it if they want

to. I am not so sure whether we ought not ourselves, as an organization, and perhaps through our officers, to do something more in that line; and I am not ready to say what is the best way to do that. That is not my business; my business is to tell you *what* ought to be done, not *how* it ought to be done.

The matter of adulteration is an important thing. I suppose if you were

DR. C. C. MILLER.

going to be very strict you might call me to order. I ought to be allowed to mention but one thing, for the question is, "The Most Hopeful Field for the National Association," and I am going into several fields, if the fences are not too high to keep me out.

You can hardly strike anything of more importance than the matter of adulteration; but that is a question that has been threshed over pretty well, and it is hardly worth while for me to say much about it.

As to the matter of legislation, I believe that the Association can do a great deal to help in that. Of late

years there has been a good deal done in the way of legislation in a few of the States—only a few of them—and more ought to be done. Take the matter of foul brood alone: without legislation foul brood is going to spread, and spread, and spread, you may count on that, because here is a man who has foul brood in his apiary, and if he can go on with it without let or hindrance from any officer of the law, he may be such a man as to do so, and the thing will spread into the apiaries of his neighbors.

Now, I don't know just how, but I think possibly the Association might do something to help secure legislation in the different States; for, remember this, friends, if you have a good foul-brood law in your State you will be perhaps to a certain degree safe from it, but you will be a great deal safer from it if every State touching your borders has just as good a law; and the man who lives in Colorado ought to be anxious that there should be a good foul brood law in Florida.

Another thing that I think might be done by this Association is, as was suggested to me by one of the members, to originate a propaganda. I am not sure whether I know exactly what the word means, it is a big word—a propaganda to help make the public understand, and feel, and know, that honey is a good thing, and that the use of honey as a sweet is a great deal better for the public health than the use of so much sugar.

Now, I could make a whole, long speech on that, but I have a little human nature about me, and I wouldn't be so hard on you as to give it to you now. I do not believe, however, that the public knows anything, comparatively, about that matter, and the Association could do something, perhaps, towards getting into the public prints information that would possibly be accepted as reading matter by some of the leading journals, and in that way it would be spread abroad throughout the whole land. You know very well that the public press does influence. You know there have been certain statements made that have gone the rounds of the press that have helped to bring down the price of your honey. You know it, don't you? And if a simple statement that has gone the rounds of the press, saying that in Chicago you mix up a mess and get up comb honey and sear it over with a hot iron—if that statement can have an effect to hurt the market a whole lot, then counter statements telling about the purity of honey and the wholesomeness of it might have a good deal of effect in helping the market. The Association may be able to do something in that direction.

Just one more thing, and that is, I believe, that there is not—and I am not sure whether I am not getting over a higher fence than I ought to just now—but I will say that I believe there ought to be a closer connection between this Association and the Government. I believe the Government, through the apicultural investigator, Prof. Frank Benton, is doing a good work. I believe it might possibly do a better work if it had the hearty cooperation of this Association. On the other hand, I believe that this Association might do better work if it were

more closely in touch with the work going on in Washington.

Now, there is not the close acquaintanceships that there ought to be, I think, between those two parts. It may be I am wrong; it may be it is a good thing to keep them apart. But I don't believe it. I believe they ought to be close together. I believe I ought to know what Prof. Benton is doing, and I believe he ought to be willing to tell me what is going on, what he wants to do, what he would like to do, what he thinks can be done, and ought to be done; and I don't believe he is averse to letting me know that. I don't know that anybody has ever asked him. (Turning to Prof. Benton.) Prof. Benton, I would like to have you tell me all about what you are doing, and if, at the same time, you would be willing to tell the Association, we will go in together, and it will cost us less to put that information before the bee-keeping public than to have you write a whole lot of letters to each of us separately. I believe there ought to be a whole lot of good work done in Washington, and we, as an Association, ought to be in harmony, and we ought to work together.

Now, if out of all those fields you know the answer to the question, "Which is the most promising field?" you know more than I do I don't know.

C. C. MILLER.

Rev. E. T. Abbott then followed with a response on the same subject:

The Most Hopeful Field for the National Association.

Ladies and Gentlemen, and Members of the Association:

I do not know but that I owe the chairman an apology. I do not know that he waited for me, but I got here late. It was a case of sickness. That is the reason I was a little late.

Now, about that lost paper: I will say that I copied it immediately, or I had my helper do it, and stowed it away in a pigeon-hole very carefully to bring to the convention. It is in the pigeon-hole yet; I haven't seen it since!

The question of the productiveness of a field is purely a question of proper cultivation. There are various fields of work that might be productive, if they were properly cultivated. It is not a question of cultivation *only*, but of *proper* cultivation. There may be a number of reasons why a field will not yield proper returns. Every farmer who has studied modern farming carefully understands that there is fertility enough in any soil that has ever been cultivated in the United States to produce a crop; and there is also fertility enough in a great deal of soil that has never been cultivated at all to produce a crop where people suppose now that nothing will grow. It is only a question of knowing how to unlock the fertility and bring it to the surface so that it can be appropriated by the plant that may grow in the soil. Now, this is just as true in our work as it is in real soil-work. Some farmers do not succeed; they do not live in Colorado. All in Colorado succeed; you can tell that by the clothes they wear, and the way the women are dressed. They do not get that kind of clothes out of nothing.

A good friend of mine said, "I would like to know where they got the material to build this city. There is nothing around it; I came across a great desert, or what looked as barren as one; I can not understand it." I said, "If you go back into these hills and unlock their treasures, and understand the fertility which is in these valleys, you would know something more about it. You would know there was fertility some place, that there were fields properly cultivated somewhere, by looking at this well-dressed crowd of people, or those you meet on the streets of Denver, or any place in Colorado."

There are farmers who do not succeed, and there are reasons for that lack of success, a few of which I want to mention.

One is ignorance. There are two kinds of ignorance—one is culpable

REV. E. T. ABBOTT.

ignorance; it is willful, persistent, downright ignorance, of the kind I have no sympathy with; there is some of that in the world. There is not as much of it, however, as we are inclined to think, sometimes. I think that some of the ignorance comes from following only the special line in which one is interested. The mind does not act on a thing until it has something to awaken it to activity in that special channel, or along that special line, so that it comes to pass that there are many people in the country who have no knowledge of a multitude of things because the activities of their brains have never been centered on that special thing. That is true with regard to the subject of honey. That is true with regard to the popular ignorance of the ordinary reporter; I do not blame the ordinary reporter for not knowing anything about bees, any more than I do the young man we heard sung about last night, who sat on the bee, and had trouble with his girl because he did. They did not tell us what the trouble was, but the probabilities are there *was* trouble. Now, I do not blame that young man for not knowing about that bee, because he was more interested in the girl than he was in the bee.

It is possible, however, for the National Bee-Keepers' Association to spread such a lot of information from one side of this continent to the other, or from the middle of it, as shall circle the entire country and do away with a great deal of this ignorance.

There is another kind of ignorance which is simply a lack of knowledge, and a lack of knowledge because there has been no opportunity to get the proper information.

Then, again, there is another thing that makes the farmer not succeed in the cultivation of the soil, and that is indifference. You will see a great, burly, well-built, finely-fed fellow sitting back in an old rocker with a broken arm, his beard as long as it can possibly grow, for it has never been clipped; his hair running a race with his beard, unkempt, and his face dirty, a kind of swaggerish way about him, who says: "Let her go; we have got enough to live on, that is all that a man can get in the world, anyway. Let 'er go!"

There is a great deal of indifference in the world, and this is characteristic of a certain class of farmers. If a farmer just eases back and puts his thumbs behind his suspenders, and says, "Let her go," she will go, and there will not be anything done; there will not be anything accomplished. There is that kind of indifference all over the country with regard to the work this Association has to do.

A gentleman, who is a judge, came into my office with his brother, an attorney, an intelligent man, who is probably worth half a million of dollars, and who has four colonies of bees. The judge is a member of the National Association, and he said to his brother, "Steve, you better join; they might want to drive you out of the city; the Association will defend you." Just as though a family of lawyers needed any defense!

His brother said, "Well, I would not mind to join, but I do not know as it would do me much good; I guess they will not drive me out with three or four colonies."

The judge said: "You better help the matter along; it is not much; it's only a dollar a year."

But he did not join. He belongs to the class, figuratively speaking, who have their thumbs behind their suspenders, so far as the interests of this Association are concerned, and he is "letting it go." There are a whole lot of people like that, I believe, in the United States, and something must be done to get them into a different way of thinking, if possible.

Then there are other people who say they have so much to do that they have no time to attend to the business of the Association. Now, friends, I tell you frankly, with emphasis and with real earnestness, that I have no sort of patience with a man who belongs to an Association, or is identified with any industry, who has no time to promote its interests. I believe you will not misunderstand me if I say I have no use for a man who will accept a position of trust, or identify himself with any body and neglect the interests of that body. So long as I am a member of the National Association, so long as I am identified with its work in any way, I expect to be present at all its meetings, let the cost be what it

may. You can hold it in Denver, in New York city, in Philadelphia, or San Antonio, as I hope you will next year, and I will be there and take my part, and hold up, if possible, my end of the whiffletree. Every farmer knows what that means.

R. L. Taylor—You must have a pass.

Mr. Abbott—Did you ever know a hotel that would accept a pass? Did you ever find a place where you could pay \$2.00 a day with a pass? Did you ever know a Pullman sleeper that would carry you with a pass, or a man riding for a week across the continent without sleep, or sitting square up in a common car and sleeping, as nervous as I am?

Mr. Taylor—I have seen railroads that would take passes.

Mr. Abbott—I have, too, and I can get one on almost any railroad in the United States. [Applause.] And I pay for it in value received.

Dr. Mason—I would go, too, if I could get a pass.

Mr. Abbott—My pass is worth money, and I exchange a commodity that is worth money, and of as much advantage to the railroad as the ticket is to me, so I do not owe the railroad anything. I have had the ride and they have had the space, which is worth in the Modern Farmer what they pay for it.

There is great danger in people concluding that the whole field has been worked over and cultivated. Dr. Miller rightly said that the matter of adulteration had been threshed over. Well, it has been threshed over like the boys used to thresh with the old-fashioned flail, leaving most of the grain. When a boy, I cut wheat with a sickle, and pretty nearly cut my shin off—if that is the proper thing to call it in company. Then I began with a cradle, and then I went to binding, and finally we got self-binders, and that let me out. And so we learn.

A man is apt to think because he has cultivated his own field properly that all fields have been threshed over, just as the boy threshed around with a flail and got out but little wheat. The farmer who threshed with a flail got some wheat, and after a while they got headers, and threshers, and they got all the wheat.

We are inclined to think that if we have done all the work in our immediate neighborhood we have done a great deal. Colorado is a big State, and Texas is still bigger, but North America is a great country. Every man who is a thorough gardener goes into his garden and cuts his own weeds. Perchance his neighbor takes pattern after him and cuts his weeds, and then he looks around, and when he sees what he has done he thinks everything is done. He thinks it is the cleanest garden you ever saw, and he swings the hoe over his head and says, "Hurrah boys! We have done it. We have exterminated all the weeds!" But further up the road, a mile or so, the weeds are as high as your head, and over there, in that other State, in that other State, and that other State, and that other Province, Canada, still the weeds grow, and still the work of adulteration goes on.

I will bet four dollars against a pewter spoon that I can go right down in the stores in Denver and find a quantity of adulterated extracted honey to-

day. I am sure there is not a town in Missouri that has two thousand inhabitants in which at least four or five grocerymen have not adulterated honey on their shelves; and it does not come from Missouri. They do not have any in Chicago because they have a strict law there, but the Chicagoans put it up and send it down to Missouri. Then we talk about having covered the field!

I had some experience for a short time acting as General Manager, and I know more about many things than I did before I had this experience. For two or three months I was trying to find out about some things; I was trying to do the work of the General Manager of the National Association, and wrote scores of letters, here and there, and everywhere. I went out after this thing and after that, and I have piles of stuff lying on my desk that tells the story of the multitude of work that there is for a live, energetic, earnest, up-to-date, enthusiastic, go-ahead Association to do.

There is no question about there being a field, my friends; there is no question about there being an opening; there is no question about the work, but it is a question of *where are the reapers?* Where are the men who have the nerve, the determination to do the work, and who will do it with enthusiasm, and without any regard to the results? What we need is men who do not consider the question of dollars and cents. Now, a dollar is an excellent thing. It will get you a good bed in Denver over night, when you are real sleepy, and I tell you that is a fine thing. If you get one like I had last night, right along by the railroad track, you might wish you had your dollar back in the morning. But a dollar is a good thing; it will do a lot in the world; but there are some things dollars will not accomplish, and you can not do them with dollars. The man who goes at the Association work with the thought of the paltry sum that may come to him in dollars and cents as an inducement to do the work will not accomplish much.

There has never been a great reform in this world, or a great work done, without a man who was willing to lay himself on the altar, to sacrifice his time, his life, if need be, to the work. Ever since the day when Jesus of Nazareth cried upon the cross upon the hill, "It is finished!" the work has been finished by self-sacrificing and noble people who were willing to die, if needs be, for the work they had in hand: and that is the kind of men we need, and that is the kind of work we must do, if we ever expect to succeed.

The only hopeful field is the field that is *wisely cultivated*, properly cultivated, a field that is cultivated every day, every hour, and during all the months of the year. Every time we go into a new field like this we find new men. I knew there were great things out here in Colorado, but I had no idea there were such men as there are here, that there was as much material to make Association workers as there is here; and, mark me, my friends, we will hear from these Colorado people in the future with regard to the work we have to do, and we will have that much more help to carry on the great work that is before us.

So then, in conclusion, our most

hopeful field is the field that is *worked properly*; and may God give us strength and knowledge to do that work aright.

EMERSON TAYLOR ABBOTT.

Contributed Articles.

Bees and Bacteria—The Spread of Blight.

BY PROF. A. J. COOK.

Of course all bee-keepers are interested in plants. Plants are so important to their success that even from a financial point of view they must take a deep interest in flowers and the plants that bear them. I hope and believe that with most bee-keepers the interest does not stop here. They know how valuable plants are to others and the feeling of kinship to all about us makes us look with interest on whatever touches others' welfare. I believe also that there is almost always an aesthetic influence that is perhaps dearer than all else. Dr. Miller loves and cherishes his roses, and who shall say that their ministrations to him is not of a kind most blessed? I need not make any apology, then, if this article, which is the substance of a talk given at a late Farmers' Institute, is strongest on the plant side.

Prof. Waite, of the Department of Agriculture—the same who did such admirable work proving that bees were a necessity in the orchard—has now done equally valuable work in showing that our bees also are chief agents in spreading pear-blight. Prof. Waite has proved this beyond any question. He shows that the micro-organisms which cause pear-blight can only live in a liquid or semi-liquid medium. They therefore reach only to the outside of the plant when carried by some secretion or exudation of the same. The bacteriologist has only to visit the plant with a pin-prick, and then insert the same pin into another plant to carry the disease. The tip of the stigma bears the sticky secretion whose natural function is to catch and hold the pollen. This liquid, or semi-liquid, also domiciles the microbes. The bee in quest of nectar touches the stigma and bears away some of the liquid with the microbes, as it does also the pollen-grains. It then hies away to other blossoms, possibly on other trees. Here it leaves not only the pollen but also some of the bacteria. Thus the inoculation is as certain as in case of the pin-prick.

Again, the tender buds are protected by the thin film of liquid resin, which also attracts the bee, as it is here that it gets its propolis or bee-glue. Without doubt the microbes are also in this semi-liquid secretion, and as the bee flies to other buds for more of the resinous secretion, the inoculation is again performed, and so we understand how pear-blight spreads in the nursery rows and how young trees which have never yet blossomed may die of the blight.

In California, we have another tree which is victimized by what Prof. Pierce, one of our best vegetable pathologists, has determined to be this same germ of pear-blight. The loquat we regard as one of our most desirable fruits, and thus we are as interested in preserving this as our pear-trees. The loquats about us have generally died. The loquat is an evergreen, and is really one of our very beautiful trees. It has a strange fashion of blossoming in mid-winter, and so gives us fruit in April—a time when fruit, from its scarcity, is very much appreciated.

HOW TO DIAGNOSE BLIGHT.

When the leaves of a tree wither, and we suspect that some blight or microbe is robbing it of vitality, or may be life itself, we should first examine the root and see if gopher, squirrel, insect or lack of, or too much, water have not disabled these most important parts of the plant. Without the roots, the plant cannot receive the needed water and mineral elements. Without these the plant will soon be sapless, and the leaves must wither and die. In case the roots are all right we should examine for insects on the leaves themselves, or possibly borers working inside the twigs. Many leaf-eating insects feed only on the chlorophyll layers of the leaves, and thus, while they do not take all the leaves, they do rob them of their working part. The leaves, then, of course, are gray and worthless, and suggest blight. The pear-slug and the canker-worms, which destroy apples, other

fruit trees, and elms, are of this kind. What observer has not noticed dead twigs from the presence and attack of twig-borers? It may be the roots are all right, that no insects are preying upon the plant above ground, and yet the plants fall down because of lack of nourishment in the soil. In such case we should apply nitrate of soda, and will be glad to see our plants immediately revive. If such is not the case, we are then sure that the trouble is not from lack of soil-fertility, and we may pretty surely ascribe the damage to the insidious microbe.

WHAT SHALL WE DO ABOUT IT?

The most potent fungicide, or bacteriacide, yet discovered is the Bordeaux mixture, which consists of water holding in solution lime and copper sulphate. The formula I usually give is one easy to remember: 4-4-45. This is easily made as follows:

Four pounds of fresh quick-lime are slaked, put in a bag and hung in enough water to dissolve it. The copper sulphate is dissolved in the same way in other water. When dissolved they are placed together and enough water added to make forty-five gallons. This is a quick cure for many blights. It does not, however, prove effective against pear-blight. We can easily see why. The germs remain inside, almost entirely, and so are not reached by the liquid.

The second remedy for blight is the only one, which, so far as we now know, will aid us in combating this terrible disease of the pear and loquat. It is to prune, and pull, and burn. In case of pear and loquat blight we watched for the withered leaves, which are apt to appear soon after the resinous buds attract the bees or the flowers open their showy petals, and cut them off a generous distance below the blight as soon as they appear—the sooner the better. If we have been so vigilant as to discover the trouble at the first onset, before the microbes are carried far from the bloom, we shall have stopped the blight entirely. It is safe in case we use our pruning-knife or shears, more than once, to disinfect them before each successive cut, by dipping in a dilute solution of carbolic acid. I hope and expect to save my pear and loquat trees by careful attention to this method. The tomato of California suffers severely from a blight. Great watchfulness and careful pulling of any vine as soon as the blighted leaves make any show, will frequently stop the blight at once, and save nearly all our vines.

Another method that is sometimes very successful in treating blight is to change the locality of the plant. The melons in some parts of California are grievously injured by bacteria that work in the crown and upper roots, causing them to rot. If we go but a short distance from where the blight destroyed the previous year and plant our vines, we often will escape entirely, whereas, if we had planted on the old ground, we might have lost all our plants.

The last remedy comes from the fact, as often noted, that some varieties resist blight much more than others. The Bartlett pear suffers terribly from pear-blight, while the Flemish beauty often escapes without harm, and the Le-Conte is often said to be more resistant. We may then, often, by growing varieties resistant to the blight, be saved from its ravages. In some parts of our region the very valuable English walnut is stacked with blight. Prof. Pierce has been growing varieties of walnuts very extensively, hoping to secure a variety that shall be utterly blight-proof. I hope that these suggestions may enable our readers to preserve their pet plants from these diminutive but terrible foes.

A word about the size of these bacteria: They are so small that in order to study them well, we must magnify them very highly. We wish to make them look at least half an inch long. Were we to magnify ourselves in like degree, we would stretch up something more than seven miles. The microbes vary in size from six to twelve hundred thousandths of an inch in length.

It only remains to be said that the moving of bees from any section, while it will work terrible mischief in preventing pollination, will probably avail not at all to lessen the pear-blight. We must remember while it takes thousands of visits of insects to pollinate the flowers of a single tree properly, less than a score are necessary to inoculate a tree thoroughly with this blight virus. There are always enough insects other than bees, not to speak of the unowned bees in rock, crevice, hollow trees, walls of houses, or even in holes in the ground, to spread the virus of the blight so abundantly that we can never hope to prevent the spread of disease by keeping the insect away. On the other hand, in case of a large orchard, where thousands of trees are often gathered in one block, it is utterly impossible to secure

thorough pollination except we have apiaries in the near vicinity. I have known several cases of bees working in holes in the ground the present year. Such would seem very poor hives. Have others noticed this?

INTERESTING LECTURE.

Prof. Fletcher, late of the Washington Agricultural College, has perhaps given the most extended and intelligent study to the matter of pollination of flowers that has been given by anybody in our country, certainly if we except Prof. Waite, of the Department of Agriculture. His bulletin on this subject would be a proud monument to any scientist. He was with me at three of our late institutes. I have never heard the value of bees as pollinators, more extolled than they are by Prof. Fletcher. He is soon to leave this coast for the East. It is greatly to be regretted that we cannot keep him among us.

Los Angeles Co., Calif.

The Prevention of Natural Swarming.

BY C. P. DADANT.

SINCE my article on the prevention of increase by returning swarms to the parent hive has been published, I have had a number of enquiries from bee-keepers as to the best method of preventing the bees from swarming. One gentleman in particular says that it is very well to keep down increase by that method, but that it only answers a part of the purpose, as there is all the labor attached to this method that would have to be performed if one wanted increase. He therefore thinks that this method of prevention of increase is lame in its main feature.

I agree to this, and for the benefit of this person and others, I will give our method for the prevention of natural swarming, which we have found successful in an extensive practice of many years on hundreds of colonies. This method has already often been mentioned in the American Bee Journal.

I must begin by saying that it is out of the question to find an infallible preventive for swarming. With the very best management, we must expect from 5 to 10 percent of swarming each year. But the number of swarms harvested by us in 30 years or more of this practice has not been sufficient to keep up the number of colonies in an apiary at the same point, and we have had to resort to artificial increase or by division. This is in itself a very clear proof that our method is successful—as successful, probably, as can be expected of any method that interferes with the natural ways of Nature.

Swarming is very much like emigrating among the human race—caused by a feeling of discomfort—the population of the hive becoming too great for the space at their disposal. Hence, small hives cause more swarming than large ones. For that reason, and many others, we have always favored a very large hive—a hive capable of accommodating the queen in her brood-rearing and the worker-bees in their honey harvest.

Our hive, which is nearly one-half larger than an ordinary 8-frame Langstroth hive, is arranged for half-story supers of which one, two, or more, may be used at one time. We put these supers on the hive with frames full of comb, saved by extracting the honey the previous season, and keep adding room in the shape of empty combs from time to time during the entire harvest. When the harvest is over we extract the honey and return all these combs to the bees to be cleaned up for another season. During the winter these combs are put away to be used again the following year. Thus we have used combs for 25 years, one season after another, for producing extracted honey, and an almost total prevention of swarming has been the result.

But plenty of space is not the only desideratum for the prevention of natural swarming. We must also have other conveniences to make the bees comfortable.

The hive must be well sheltered from the direct rays of the sun. A colony of bees in the busy season is usually overflowing with inhabitants; they hatch daily by thousands, and although there is also a regular daily loss of bees from accidents and the natural wearing out of an insect which is everlastingly at work and on the wing, yet the numbers in the hive increase to such an extent that it is quite difficult for them to keep the interior of the hive well ventilated. If you watch a populous hive of bees on a warm day, and even at night in hot weather, you will see a file of bees ranged in front of the opening, fanning the en-

trance by a rapid motion of their wings with an incessant roar. These bees are forcing a current of air from one end of the hive to the other. Their work is indispensable, for its cessation only during a few minutes, when the thermometer registers 100° in the shade, means the raising of the inner temperature of the hive to an unsafe point, when the combs are liable to break down, owing to the heat and the weight of the honey combined.

Exposure of the hive to the direct rays of the sun increases the danger and makes it more imperative for the bees to send out a swarm. Thus the able-bodied members of the hive accompanied by the queen leave for a new abode, allowing the young bees to remain and rear a queen. Usually the preparations for emigration are begun several days ahead, by the rearing of queen-cells, and, when the bees leave, the young queen is about to hatch. These preparations, when once made, are likely to be followed by an exodus, even if the apiarist has changed the conditions by enlarging the hive, giving it empty combs, more ventilation, or more shelter. It is therefore advisable to make the necessary changes for the accommodation of the increasing numbers several days ahead of the need.

As soon as the honey harvest comes, the entrance of the hive, if the colony is strong, should be enlarged to its fullest capacity; a hive should never be allowed to stand in a position that will compel its bees to cluster on the outside. The fact of their clustering in that way is an evidence of their ill-comfort, and unless the season is poor, or the crop nothing, it is a good indication of their intention to swarm. It is true that many colonies cluster thus and yet do not swarm, but this is only owing to adverse circumstances.

A great number of drones is also a very frequent cause of swarming. These burly, idle fellows, which are reared by the thousand to provide for the reproduction of the bees by the fertilization of young queens, are very much in the way. They are noisy, cumbersome and lazy, and a colony which is well stocked with them, and otherwise crowded, will swarm more readily than one in which the drones are missing.

There are then three or four absolute requirements for the prevention or diminution of natural swarming, viz.:

A large hive capable of accommodating the most prolific queen.

Enough surplus combs to receive the crop of the workers as they bring honey home from the field.

Plenty of ventilation, enabling the bees to work comfortably inside the hive at all hours.

Shelter against the rays of the sun during the hot hours of the day.

Lastly, a removal of the drone-combs, replacing them with worker-combs in the brood-chamber, early in the season.

As a matter of course all these requirements are more complied with in the management of an apiary for extracted honey, but even when producing comb honey the apiarist can readily see that these requirements, if complied with, will diminish the number of natural swarms, while if the matter is neglected the number of the swarms will be in direct ratio to the greater inconvenience to which bees will be submitted while the harvest lasts. Hamilton Co., Ill.

* The Afterthought. *

The "Old Reliable" seen through New and Unreliable Glasses.
By E. E. HASTY, Sta. B Rural, Toledo, O.

"GOING FOR" THE QUEEN-BREEDERS.

Shall we call him by name when a particular breeder's queens do not come up to our mark? We are not *allowed* to call names much in praise—that's "commercial," free advertising—and one would fain have rules work both ways. On the other hand, scolding indefinitely about the poor quality of queens conveys the impression that it must mean the small fry, and not the most prominent men. Bad to waste good ammunition in that way—and isn't it wrong to increase the difficulties in the worthy small operator's path? So if we have any Davids, young or old, looks like we had better let them name their Goliaths. But, then, Goliath will in return throw his spear. "which is like a

weaver's beam." And ye Editor may be jostled in his chair; and combat-hating readers may take to the quiet and umbrageous woods. Page 584.

CAUSE OF YOUNG BEES DYING.

As to California's hard puzzle, page 587, I would suggest that poisoning *does* sometimes affect numbers of young bees when the old ones show little or no effects of it. Other creatures ditto. Human baby will die from an amount of opium the effects of which the grown man would probably not notice. I'll guess also that the wings were not cut off from the wingless young, but that their development in the cell stopped before the wings were formed. The formation of the wing is about the last thing, I believe. So, as the novelist would say, the plot deepens. Whether poison or disease, it appears to have begun in the cell, allowing the young bees to develop enough to come out, although not allowing them to complete their development. And that, in turn, looks a little more like a constitutional disease than it does like poison. Say a form of microbic disease much like paralysis, but lacking the trembling motions.

THE BEE-MARTIN AND IMITATION FLOWER.

If you should place the nicest little genuine flower that could possibly be found on the top of a post how many bee-visits would it attract in a whole day? It would be lucky if it got one. Therefore, I do not tumble to the theory of W. P. Turner about the bee-martin with an imitation flower on the top of his head. Nothing intrinsically absurd in bees being attracted by a decoy flower and snapped up by a bird. There are lots of such things in Nature. The trouble is, I can't believe Nature would proceed with a scheme which no bird could make a living at. Bees don't rush to posies and the grave in any such style. Page 588.

HANDLING QUEEN-BEES.

H. G. Quirin reminds us, on page 589, that in case we accidentally bump a lot of sealed queen-cells so hard as presumably to cause some of the young inmates to drop, we can reverse them and gently tap them back again. I guess that's so. Will they not, however, drop the second time with such great ease that there's not much in it? Seems to me I would keep those particular cells reversed until the queens emerged. May be Mr. Q. means just that himself.

DENVER'S CONVENTION ATTENDANCE.

Aha! Denver also "regrets to report"—regrets to report that the Millennial attendance of a full convention, like it was going to be when told about beforehand, is not yet here below. Never mind. Lots of things are certainly going to be here below which the sun has not risen upon yet. Page 595.

Questions and Answers.

CONDUCTED BY

DR. C. C. MILLER, Marengo, Ill.

[The Questions may be mailed to the Bee Journal office, or to Dr. Miller direct, when he will answer them here. Please do not ask the Doctor to send answers by mail.—EDITOR.]

Feeding for Winter.

1. I purchased 21 colonies of bees August 1, in 10-frame Simplicity hives, with movable frames, comb built on wired foundation. After examining them I found only 5 with sufficient stores for winter, some only containing about 6 pounds of honey. Will it pay to feed such colonies for winter? They all contain an abundance of both bees and brood, excepting two which I shall unite.

2. I have fed them about 150 pounds of granulated sugar. They should each have about 25 pounds of stores for winter. Is it necessary that this be sealed?

3. I have made syrup of 5 parts sugar with 4 parts water, and have reckoned that one pound of this syrup would make $\frac{3}{4}$ pound of honey for winter stores. Is this right?

When I have fed the required amount to a colony they do not seem to seal it. I leave the 10 frames of comb in each hive. Will they winter on these stores, even though

they are not sealed at present? I shall winter them out-of-doors, packed in clover chaff in winter-cases. I have had fine success wintering this way, but have never had to do any feeding before. OHIO.

ANSWERS.—1. It ought to pay big.

2. Five pounds of sugar is considered equivalent to 7 of honey, according to which a pound of your syrup would be equivalent to 7-9 of a pound of honey, making your estimate very close to the mark.

3. It takes time to ripen and seal syrup as thin as you have fed, and the cooler the weather the longer the time. The fear is that you fed too late to allow the bees plenty of time to get the syrup evaporated to the sealing point. It is better to feed syrup even thinner than you gave it, but in that case it should be fed in August or early in September. When fed late, there should be 5 parts sugar to 2 parts water. If the weather should be warm enough in October, the syrup may yet be ripened; and in any case all you can do is to pack the bees warm and hope for the best.

Common Bumble-Bee.

Is the insect which accompanies this letter a bee or wasp?

I found it this morning at the entrance of one of my purest Italian colonies. The workers were dragging her out of the hive. You will see they have pulled off one of her wings. I never saw anything in the bee-line that was so intensely black. While she has some of the appearance of an old queen-bee, yet her color and length of legs are something I never saw in a queen-bee before.

KANSAS.

ANSWER.—The specimen sent is a *Bombus*. I do not wonder that you do not recognize it; for the bees have stripped it of all its gay plumage, making it a glossy black, and at the same time making its legs appear abnormally long. Its common name is bumble-bee.

Moving Bees Home from an Out-Apiary.

I have some bees to move home from an out-yard, and wish to know whether a screen over the entrance would give sufficient ventilation, if moved on a cool day, say just after frost, or when too cold for the bees to fly. The entrances are the full width of an 8-frame hive.

I think I have moved them with no other ventilation, years ago, but have forgotten. If no screens are needed over the tops of the hives we can get them all ready to load any time, except nailing screens over the entrances. I wish to move my bees home soon. MICHIGAN.

ANSWER.—For many years I have hauled bees to out-apidaries in the spring and back again in the fall, and all the ventilation they have is wire-cloth the full length of the entrance. For some years past the entrance is two inches deep, which makes quite a difference; but then they are hauled sometimes when it is a good deal warmer than the time you are talking about. With weather too cool for bees to fly, a full-width entrance needs to be only $\frac{3}{8}$ -inches deep.

Bee-Keeping as an Exclusive Business.

I am thankful for the good the American Bee Journal has done me. My partner (an experienced bee-man) and myself started into the business last May, with 47 colonies, in chaff hives. Until the first of August the bees barely made a living. Since then they have produced about 2,000 pounds of comb and extracted honey, 1,500 pounds of the former. The honey in sections has been of high grade, with white capping. I have had a little of greasy or dark capping. Although we have only given our spare time to the bees, we feel amply repaid. I believe this place can be made to produce large crops of honey, and would like to go into the business exclusively.

I can secure a location at the junction of the Kankakee and Iroquois rivers. The surrounding woods are rich in basswood and sweet clover, heartsease, Spanish-needle, and many wild flowers grow in profusion. I feel that with care and attention a large apiary could be made to pay. We have made a good name this year. We have sold all our extracted honey at 10 cents a pound, and could sell more. Our comb honey is about all disposed of. We get 12½ and 13½ cents cash, from local dealers. Kankakee seems to be a

good market. By honest dealings a fancy market can be built up among private customers. Now the object of all these details is to get advice from a man of experience.

Would you advise me to go into the bee-business exclusively? Could I handle an apiary of 250 colonies? I would expect to begin with about 40 or 50 colonies and build up to that number, at the same time adding to my fund of experience. I have enough cash to support myself and wife for two years. My partner and I expect to divide our apiary soon.

ILLINOIS.

ANSWER.—It is impossible for any one to say in advance what your success would be. Some men making a success with 50 colonies would make a failure with five times that number, while others might succeed with ten times that number. If your sole aim is the money that is in it for you, the probability is that the same amount of brains and muscle put into some other business would bring greater returns. But if you have a real love for bee-keeping, the happy and healthy life you would live would be worth a whole lot of money, and if you couldn't make so much in a year you would have more years to make it in. So if you have a born taste for bee-keeping, it would in all probability be a good thing for you to follow the plan you have outlined, beginning with 40 or 50 colonies, and increasing till you felt you had reached a fair limit. With increased experience you would very likely have no more trouble with 250 than with 50 colonies, and it would not be a hard thing to hire some help when you felt it was needed.

Wintering Bees.

1. I have read all of the American Bee Journals and in all the remarks on different things it does not tell the space between the hive and the winter casing.

2. I would like to know whether I could put a shallow brood-chamber on the old hive in the spring. The frames are 5½ inches deep. I have the 8-frame Langstroth hive, and I was thinking that if I could put a shallow brood-chamber on the hive in the spring it would give the queen a better chance for the next honey season.

ONTARIO.

ANSWERS.—1. In the chaff hive the space is two inches. Where the outside case is separate from the hive, the space varies from two to six inches, according to the different views of bee-keepers, the tendency being hardly as much toward the larger space as formerly.

2. It will be all right to add the shallow brood-chamber in spring, only it must not be put over the story already occupied till that is fully occupied, for it would be a loss of heat to have a story put over before needed. If the added story be placed under, then it does not make so much difference if it is given before needed.

Producing Section Honey—Wintering Questions.

1. It is claimed that the main drawback in the production of comb or section honey (versus extracted honey) is that the bees dislike to build and store in such small boxes as a one-pound section. Therefore, would it not be a good plan to have the bees produce their comb honey in frames (full or half depth, with or without separators, and if separators, only perforated ones), and then transfer the honey into sections, allowing the bees to fasten it in securely, clean up drip, etc.? We would thus have few or no pop-holes, all cells would be sealed, and we would obtain more honey than if the bees had built and stored from the beginning. There would be less swarming; the bees would not have to be crowded, etc. The question is, Would the extra amount of honey obtained, the advantage of not being bothered with swarms (of course there might be a few), etc., pay for the time used in transferring the honey to sections?

2. In regard to out-of-door wintering, do you recommend sealed covers (board or quilt), or porous coverings, the hives in each case to be packed on the top and sides?

3. How large should the winter entrance be?

4. If the bees on a cool night cover only 4 or 6 frames, would you leave in the other 4 to 2 of the 8-frame hive?

6. How much top packing do you recommend? What kind? Cork sawdust seems good, and I have enough of that.

7. Is the pepper-bush (white alder) known by any other name?

MASSACHUSETTS.

ANSWERS.—1. I think that something of the kind you suggest has been tried and condemned as unprofitable. It will be an easy thing for you to try it on a small scale for

yourself. In some parts, especially in Texas, "chuck" honey is strongly advocated, and many tons of it are sold. The honey is cut out of the frames, packed in cans, and the spaces filled with extracted honey. No separators are needed.

2. The weight of opinion at present seems to favor some kind of packing that will allow an upward passage of air, but in very small quantity.

3. Perhaps the equivalent of three square inches.

4. Yes.

5. Hardly.

6. Two inches of cork sawdust can hardly be beaten.

7. Besides its botanical name—*Clethra alnifolia*—it is also called "sweet pepper-bush."

Phacelia Seed.

Where can I get phacelia seed?

SUBSCRIBER.

ANSWER.—I do not know where it can be obtained, unless it be the seed offered among flower-seeds. It may be found in any considerable catalog of flower-seeds, but I do not know whether that is the forager-plant so highly praised. It is, however, a beautiful flower, and bees seem to have a great liking for it.

Superseding Queens.

1. I have 25 colonies of bees into which I introduced untested Italian queens last summer, and I want to know if there is any probability of them being superseded this summer?

2. Do bees as a rule supersede queens that are only one year old?

3. Please explain to me the way they supersede a queen. Do the bees build the queen-cells and then the queen lay in them? or do they build cells around larvæ that are already hatched out?

4. What is the plan of rearing queens from a colony which wants to supersede their queen? Do you take away the cells as soon as they are sealed over and give to queen-less colonies, and let the bees build more?

5. Will the bees of the superseding colony kill the old queen before a young queen is hatched and fertilized, or just as soon as she is hatched?

6. I have had a very good flow of honey from bitterweed during the last of July and all of August, until about Sept. 10, and several of my colonies have reared late drones. Is this any indication that they want to supersede their queen?

7. Would not this be a splendid locality for rearing queens, on account of having a long honey-flow, beginning April 10 and lasting until Sept. 10 without stopping?

MISSISSIPPI.

ANSWERS.—It would be nothing strange if some of them should be superseded.

2. No, but queens that are introduced are more likely to be superseded than if they had been reared in the same hive.

3. They may be so hostile to the new queen that they never allow her to lay at all, in which case the bees start cells from larvæ present; or they may allow the queen to lay, in which case the queen-cells will be built before the eggs are deposited in them.

4. Yes, your guess is the right one, only the cells may be left any length of time after being sealed till near the time of hatching.

5. If the introduced queen is accepted and allowed to lay, she will generally continue till the young queen emerges and sometimes both queens will be laying together for some time.

6. It hardly means superseding so much as a general feeling of prosperity which allows the indulgence of such luxuries as the presence of drones.

7. Yes, it ought to be a favorable place.

"The Hum of the Bees in the Apple-Tree Bloom" is the name of the finest bee-keeper's song—words by Hon. Eugene Secor and music by Dr. C. C. Miller. This is thought by some to be the best bee-song yet written by Mr. Secor and Dr. Miller. It is, indeed, a "hummer." We can furnish a single copy of it postpaid, for 10 cents, or 3 copies for 25 cents. Or, we will mail a half-dozen copies of it for sending us one new yearly subscription to the American Bee Journal at \$1.00.

Up a Stump 10 MILES TO A DOCTOR Watkins' Liniment all Gone

Enough to discourage anyone. Ill health, big doctor bills, no pleasure in life; blue and discouraged. What's the matter? Simply this. You can't work well, play well or sleep well until your body is in good healthy condition, and you can't keep the body in good healthy condition if you allow disease to once get a foot-hold. It is for this reason that a bottle of

Watkins' Vegetable Anodyne Liniment is so valuable in the house. It is ready when the first sign of cold or chill is felt. A few drops then does what a doctor would charge many dollars to do later. We receive numberless letters like the following:

MANAWA, Wis., July 5, 1901.
I have used Watkins' Vegetable Anodyne Liniment for colds and cramps with very best results.
H. F. ORA.

The Best Remedy made for

Colds, Coughs, Colic, Diarrhoea, Cholera Morbus, Dysentery, Indigestion, Cuts, Burns, Bruises, etc.

An especially strong point about Watkins' Liniment from the farmers' view-point, is that it is equally good for

MAN AND BEAST.

Our agent will furnish you with any of Watkins' Remedies, or if we have no agent in your neighborhood, write to us, and we will see that you are supplied.

GIFT FOR 1903.

GENERAL ITEMS

The Aster as a Honey-Plant.

The wild asters are now in full bloom. Bees are just tumbling over each other between showers, gathering nectar from them. The aster is to the bee-industry here what sweet clover is around Chicago. To look about and see the corn standing in the shock, the leaves on the trees turning brown and red, and to hear the crickets sounding the near approach of winter, it seems to one almost like a turning back of the natural order of things for the bees to be gathering such quantities of honey. Truly, the aster is a wonderful plant in its secretion of nectar.

W. W. MCNEAL.

Scioto Co., Ohio, Sept. 30.

A Rather Poor Season.

This has been a rather poor season in this section. There was too much wet weather and cold winds. The fall flow from motherwort, catnip, figwort and heartsease has been quite good, and the bees go into winter quarters in good shape. The prospects for a good season next year have never been better.

Linn Co., Iowa, Oct. 2. JAS. R. SMITH.

Poorest Year in 27.

I have kept bees ever since I was a boy of 16 years, which is 27 years. I have never seen such a poor year as this has been. I had 42 colonies, spring count, increased to 65, and from these I received 492 pounds of honey. The white clover is in bloom yet, but not a drop of honey is coming in.

H. LUEDLOFF.

Carver Co., Minn., Oct. 2.

Better Results than Expected.

A few weeks more will tell the story of another honey-year. No doubt many of the hopes that were builded in the early part of the season have been filled with disappointment. Who has seen a season like this? First too dry, and then too cool; with plenty of brood and plenty of bees in June. With all the ups and downs the season will end better than one could expect.

My bees kept swarming along from June 20 until almost the first of September. The last swarms have nearly filled their hives.

Some fields are white with white clover, and smartweed is almost beyond all records, but it has been too cool to gather to any great extent. The best day for one colony on the scales this fall (Aug. 28) was 8 pounds; and Sept. 7, 5 1/2 pounds.

The prospects are fine for another year. I never saw a better setting of white clover than there is this fall.

How do you do, Dr. Gallup? I am so glad you have taken the floor and told us so many startling facts about queen-rearing. Then, the other side justifying themselves by saying we agree with Dr. Gallup, but have improved these old methods! The experience with the queens one buys speaks louder than all the plausible theories queen-breeders are pleased to write. I never have received a queen through the mail that lived more than one year. They were all fairly good queens. But their daughters were much more prolific, yet hardly any longer-lived.

I think I have one experience that requires a new record. I had a colony that cast a swarm June 20, then a week later I sent out all queen-cells and gave them a frame of brood, from a fine queen I got from Ohio. On that frame they built one queen-cell, a very poor looking cell. I paid but little attention to them, only I noticed, to my surprise, in about five weeks they were getting very strong, and I thought what a difference in the colony of bees. Then about the middle of

To make cows pay, use Sharples Cream Separators. Book Business Dairying & Cat. 212 Free. W. Chester, Pa.

August they cast as the a swarm as any one could wish to see. I first thought there must be something wrong with them, but on examination I found the hive full of brood from top to bottom and side to side. I never saw a hive so completely filled with brood as this one was. Such queens must have more room. This is one of Dr. Gallup's kind.

"Long-Tongued" advertisements have seen their day; next year's will be "Long Lived Queens."

H. W. HECHLER.
Keokuk Co., Iowa.

Bloom but No Honey.

Dandelion, clover, heartsease, Spanish-needle, and some other plants are in bloom, and still no surplus honey. We will have to feed some 20 pounds per colony. Extracted honey is 12 1/2 cents here, and comb 20 cents. I got only 500 pounds from 130 colonies, and it is poor in quality. JOHN C. STEWART.
Nodaway Co., Mo., Oct. 5.

Cleansing Flights in Winter.

I have practiced taking my bees out for a cleansing flight from one to three times each winter for five years. The reason I commenced it was because my cellar was too changeable in temperature. I have not lost a colony except from queenlessness.

C. C. BEERS.

Scotts Bluff Co., Nebr., Oct. 2.

Northeastern Wisconsin Convention

The bee-keepers of northeastern Wisconsin held a convention at the residence of John H. Terens, in Manitowoc Co., Wis., Sept. 20, 1902, and the following officers were elected: President, John H. Terens; vice-presidents, C. H. Voigt and Fred Trapp; secretary, Dr. J. B. Rick; treasurer, John Cochems.

The total number of colonies reported to exist within a circle of 10 miles was found to be 1000. The regular order of business being taken up, the following topics were discussed: Introducing Queens, Wintering and Ventilation, Health and Longevity of Queens, Is the 8 or 10 Frame Hive Preferable? Each subject was discussed with great earnestness, and all present seemed deeply interested, and listened with much attention while each speaker gave his experience and opinion, with reasons for such.

Pres. Terens then appointed a committee of three to draft a program for the next meeting, which committee submitted the following: Wintering and Ventilation, Fred Trapp; Prevention of Absconding Swarms, C. H. Voigt; Marketing Honey, Chas. W. Voigt; Hives Best Adapted to This Climate, J. Cochems; Are Black or Italian Queens Preferable? J. H. Terens; Which is the Most Successful Way of Rearing Queens? L. C. Koehler; Bee-Pasturage, V. Chlonpek; Mating of Queens, Dr. J. B. Rick.

The date and place of holding the next meeting was decided to be at 10 o'clock a.m., Nov. 8, 1892, at the residence of John H. Terens, in Mishicot. C. H. Voigt, Sec.
Manitowoc Co., Wis.

Poorest Season in 8 Years.

The honey season of 1902 closed with heavy frosts on the nights of the 11th and 12th. It was the poorest season in 8 years here. The bees, however, got enough for winter, and from about 65 colonies, spring count, I got about 1,000 pounds, mostly comb honey, and an increase of 28 colonies. There would have been a fine crop from heartsease, I think, if the fall had been warm and dry, but we had no steady warm weather here either in the summer or fall, only an occasional nice day or part of day. There is more white clover here now, as a result of the wet season, than ever before; so the bee-keeper's hopes for "next year" will be large and lively.

There was one point in Dr. Gallup's articles on "Rearing Long-Lived Queens and Bees" that I hoped to see discussed further, but failed to bring out fully enough in a former communication; and it has been totally ignored in the discussion thus far. What I have reference to is the claim that the worker

BEE-KEEPERS--ATTENTION.

Do not put your money into New Fangled Bee-Hives, but buy a plain, serviceable and well-made hive, such as the regular Dovetailed hive arranged for bee-way sections. Honey-producers of Colorado—one of the largest honey-producing sections in the world—use this style.

New Work on Queen-Rearing!

Send for prospectus of book on QUEEN-REARING by new method that produces queens superior to those reared at swarming-time.

41At HENRY ALLEY, Wenham, Mass. Please mention Bee Journal, when writing

progeny of an improperly reared and short-lived queen will inherit that defect, and be shorter-lived than bees from a properly-reared queen. I have never been able to notice any difference in the strength of different colonies from a like amount of brood. Where one had a queen that was 4 years old, or afterwards lived to that age, and the other had a queen that gave out at one or two years old, I remember particularly one instance last year: Colony No. 39 gave me the most surplus of any I had, yet they superseded their queen when she was only a month over two years old. If there was any truth in that theory—the longer-lived the queen, the better and stronger the colony ought to be in the spring, other things being equal. But is this the case? Not according to my experience. Let us hear from more of the "jury."

E. S. MILES.

Crawford Co., Iowa, Sept. 30.

Worms Dragging Out Bees.

On page 587, under the head of "Dragging Out Young Bees," that had been crippled, such as parts of wings missing, etc., I will say that it is moth-worms, as I have proved to my own satisfaction. And it will take quick and close observation to catch them. They (the worms) eat a channel through the foundation, or partition, of the comb, and feast on the young brood and pollen. When frightened they go backward or forward, as the case may be. By looking closely, at day-break, if there are worms in the hive, young bees and parts of bees can be found on the ground in front of the hive. When I see such work going on in my apiary I go for a smoker and gouge, made of small, stiff wire, and hunt the combs good; and I never fail to find them.

A. J. ALLEN.

Johnson Co., Ark., Sept. 18.

Filling Combs for Feeding.

It is about 3 years since I got to thinking quite strongly on the question of how to get liquid honey, or dissolved sugar, or mixture for food for bees into honey-comb in some better way than pouring on the comb from a teapot. I hit upon the plan of dipping the comb into the liquid by holding the frame square up and down, and settling it down slowly so as to let the air pass out of the cells at the upper side while the liquid enters the cells at the lower side. When this plan was thought of I took a comb to the water-tank and tried it. I found the experiment quite satisfactory as to the amount that would enter the cells. So I had a tinsmith make a box 3 inches wide, and long and deep enough to take in the largest frames that I have (Quincy) in use, so as not to have to prepare a large amount of food at one time. The feed will not go in as readily as one might suppose, on account of the dryness of the comb, but with slow movement up and down it will go in. The feed should be warm and limber, and not too thick. It is necessary to have some place to hang the combs to drip a little.

A hive with a bottom-board nailed on, that has had bees in it, will generally not leak, and it is handy to carry the frames to where they are to be used. By holding the comb over the box a short time there will not be much drip.

I have thought that a piece of tin large enough to go under about 10 frames, and turned up a little at the ends and outside, might be soldered on this box on one side so that the drip would run back into it, but I have not had it put on yet. It would need a frame above to hold the combs, and legs below. This would make the plant complete.

It is a matter of history that a boy was playing with some pieces of comb by dipping them into water and giving them a whirling throw; hanging on to it he threw out the water. His father seeing this, invented the extractor, but the other part of the boy's play has been overlooked. That was an unsophisticated boy. He had never read a description of how to pour water into a comb, nor had he seen some of the Chicago daily papers with a picture of a person pouring from a teapot into a comb as it appeared not long ago, or as copied into the American Bee Journal. He simply dipped

the comb into the water to get it in, and threw it out again.

The question might be asked, what of it? While I have not experimented very extensively with this plan, it is, in my opinion, an easy way by which any colony of bees may be fed, in almost any place, out-of-doors, or in the cellar, at any time or place where they can be fed comb honey or candy.

CALEB L. SWEET.

Cook Co., Ill., Sept. 22.

Dot Queen-Rais Peesness.

MR. EDITOR NEW YORK:—Ay bean tak American Bee-Paper and ay see on Page five-tyrty-tre dat henry alley him don't like Mr. Gallup to ride him on de gallup bot his neuculus Quvens. Crouse, Alley him bean rite. I just bean dar summer rais me tre Bees Quvens in Neuculus, an dom bean just som big, and som yellow, som any svorn Quvens. now if Little hives rais little Quvens, and big svarns rais big quvens, Deu Mr Gallup better rais all his Quvens in de barn an dem bean big youst like horses, so he can ride dem to town. Den he can go on a Gallup down de Alley just a hooping. By ying, ay tank dat bean fine!

Now ay got von Great big chaf hive vat got von owful yellow 5-banded Gold-bug Svrens in it. ay don't lak dom 5 storries Quvens. Dom bees bean de lasiest bees vot never vos. Dom don't vill make any honies a tol in de up stairs, but dom yust sit around in front and tell storries. Dom dont even got sens nuf to svarm. Vell, ay Tank me self for lung time vat ay shal do ma dem. Shal ay fine dem tre dollars and cost? It don't bean no use, and if ay send dem to vork-hous; dom von't vill vork. So by an by ay git plent spunk an ay take out two frams mit bees and broods, and some broods vot got little eggs, and put in new hive. ay don put new hive on ole place an maw she help me cary big hive vay off. Den next day ven dom sasy fellers go out to fly aroun little to fine some new storries to tell, an dom get hungry and tank dinner bean ready, and comes home, an by ying! dom bean fooled. Dom have only two combs and no quvens. Den dom bean sorry plenty bad, and dom be gin to saw vood for supper, and dom vork hard all day, and dom rais von plenty good svrens, and dom bean at times good now, and dom big chaf hives dom mack new combs an dar quvens he pack him full of eggs for easter, and dom bees dom go up stairs an lay down dom plenty big pile of honey, and dom quvens he hund allround down stairs for some more holes to pack away more eggs for easter, and now ay ben git long fine; ay bin sen for some clover Quvens mit long tongs, but ay dont know vat kind of clover hay to feed dis vinter. Say, Mister New York, do you tank dom clover bees vill eat corn-fodder das vinter?

But ay vont to say to mr. Alley ay tank you mak some Plenty big mistake ven you say on Page 519 of American Bee-Paper, you say 90 per sent of Quvens no better as flies. now ay have bean ete some of das pudden, an ay can Profe you bean vay off. ay bean had severl Quvens vot come by post-office, an dome all bean some putty gud; but ay can rais yust some gud Quvens in neuculus, som no body els, if ay bean got gud stok. Ay bean had beas bout 16 yrs, and ny git some times 150 pounds come honey in de up stairs from von hive. Ay tank svarming or neuculus bote bean nature; ven you git better as nature dan you bean most to gut for das vord. Ay tank sometimes you have to sleep, but nature he never sleep; nature he do every ting, you only help nature, he bean boss—ve bean de hired hand. Ay can ho corn but ay can't make him to grow. Now ay tank you bote bean rong, an you bote bean rite, but ay tank you bote Gallup to fast. Ay tank you bote better clime back in das botes an den trade botes. You make plenty big mistake and git in de rong bote. Ven you bean got in de rite boat den if nature is villing you can have big race, an just go hooping, an, by ying, de you vot bote can have von of my best Quvens, an ay vill ete all der pudden.

Now a tank you bote bean yust so gud som no body. An you bot rais gud Quvens, an you bote is honest yust like me. But das trouble is you bote got each others boats, an

dan you bote jump out in de water, an may be got some little water on de brain. All gud Queens is gud. Dont for git dat, but better ones are just so gud an may be litle better, and ven you git some of dem better kinds let me know, and ay vil buy von dat bean de pudden vot ay like.

Vel, gud py, Mister New York, an if ay dont go bak to Svoden may be ay rite agin sometimes.

My address ven it don't rain is—
YON YONSON.

CONVENTION NOTICES.

Chicago - Northwestern.—The executive committee of the Chicago-Northwestern Bee-Keepers' Association have planned to hold the best convention ever convened in Chicago. The date is Dec. 3d and 4th, Wednesday and Thursday. Five eminent bee-keepers have been invited, and are expected to attend. More definite announcement later. Watch for it. Reduced rates on account of the fat stock show, which is held Nov. 29th to Dec. 6th
HERMAN F. MOORE, Sec.

Illinois.—The annual meeting of the Northern Illinois Bee-Keepers' Association will be held at the Court House in Freeport, Ill., on Tuesday and Wednesday, Oct. 21 and 22, 1902. All interested in bees are invited to attend.
Cherry Valley, Ill. B. KENNEDY, Sec.

A Far-Reaching Institution.—The J. R. Watkins Medical Co., of Winona, Minn., one of our advertising patrons, does business on a grand scale. Since the founding of the institution upwards of 35 years ago, the spread of the Watkins remedies has been phenomenal. At the present time, the two immense 5-story and three 3-story buildings, erected and devoted to the manufacture and sale of these remedies, give them a working floor-space of two acres. The equipment in the line of power, machinery, laboratories and appliances, is one of the most modern and approved character, affording the most perfect facilities for carrying on the work. Yet comprehensive and modern as their great plant is, it is only in keeping with the demand for its famous products which for many years have been growing in favor all over the country.

But the Watkins Institution is not all comprehended in the home plant. The Watkins wagons are almost as familiar sights in the country as the mail carrier. These wagons are not to be confounded with the ordinary huckster or peddler, but are a part of the great Watkins Company, in charge of bonded employees, carrying and distributing the Watkins preparations and nothing else, directly among the people. People patronizing these wagons are buying at first-hand from the Company. The Company is thus calling in person, not occasionally, but regularly, at the homes of their patrons, securing permanent customers, building still wider for the future and extending trade in the most open and fair, and at the same time, the most effective means that could be employed. Any agreement made with a Watkins agent as to credit, etc., is a contract with the Company itself, and is always faithfully carried out. Any errors that may be made are cheerfully corrected. There is no hazard in dealing with the Company through their own employees. The latest edition of the Watkins Home Doctor and Cook-Book is just off the press. It would pay our readers to send for a copy and get better acquainted with the Watkins idea of doing business. See the advertisement elsewhere, and kindly mention the American Bee Journal when writing.

BEE=BOOKS

SENT POSTPAID BY

GEORGE W. YORK & CO.,

144 & 146 Erie St., - CHICAGO, ILL.

Bee-Keeper's Guide, or Manual of the Apiary, by Prof. A. J. Cook, of Pomona College, California. This book is not only instructive and helpful as a guide in bee-keeping, but is interesting and thoroughly practical and scientific. It contains a full delineation of the anatomy and physiology of bees. 544 pages, 295 illustrations. Bound in cloth. 1902 edition—19th thousand. Price, \$1.20.

Langstroth on the Honey-Bee, revised by Dadant.—This classic in bee-culture has been entirely re-written, and is fully illustrated. It treats of everything relating to bees and bee-keeping. No apiarian library is complete without this standard work by Rev. L. L. Langstroth—the Father of American Bee-Culture. It has 520 pages, bound in cloth. Price, \$1.25.

A B C of Bee-Culture, by A. I. Root — A cyclopedia of 400 pages, describing everything pertaining to the care of the honey-bees. Contains 300 engravings. It was written especially for beginners. Bound in cloth. Price, \$1.20.

Scientific Queen-Rearing, as Practically Applied, by G. M. Doolittle.—A method by which the very best of queen-bees are reared in perfect accord with Nature's way. Bound in cloth and illustrated. Price, \$1.00; in leatherette binding, 60 cents.

Bees and Honey, or Management of an Apiary for Pleasure and Profit, by Thomas G. Newman.—It is nicely illustrated, contains 100 pages, bound in cloth. Price, in cloth, 50 cents; in paper, 30 cents.

Advanced Bee-Culture, Its Methods and Management, by W. Z. Hutchinson.—The author of this work is a practical and entertaining writer. You should read his book; 90 pages, bound in paper, and illustrated. Price, 50 cents.

Bee-Keeping for Beginners, by Dr. J. P. H. Brown, of Georgia.—A practical and condensed treatise on the honey-bee, giving the best modes of management in order to secure the most profit. 110 pages, bound in paper. Price, 50 cents.

Bee-Keeping for Profit, by Dr. G. L. Tinker.—Revised and enlarged. It details the author's "new system, or how to get the largest yields of comb or extracted honey." 80 pages, illustrated. Price, 25 cents.

Bienen-Kultur, by Thomas G. Newman.—This is a German translation of the principal portion of the book called "Bees and Honey." 100-page pamphlet. Price, 25 cents.

Apiary Register, by Thomas G. Newman.—Devotes two pages to a colony. Leather binding. Price, for 50 colonies, \$1.00.

Dr. Howard's Book on Foul-Brood.—Gives the McEvoy Treatment and reviews the experiments of others. Price, 25 cents.

Winter Problem in Bee-Keeping, by G. R. Pierce.—Result of 25 years' experience. Price, 30 cents.

Foul Brood Treatment, by Prof. F. R. Cheshire.—Its Cause and Prevention. 10 cts.

Foul Brood, by A. R. Kohnke.—Origin, Development and Cure. Price, 10 cents.

HONEY AND BEESWAX
MARKET QUOTATIONS.

CHICAGO, Oct. 9.—The advance noted in our last quotation has been maintained and there is a very good demand for honey at the present time. No. 1 fancy white comb brings 15¢@16c per pound, with the lower grades selling at from 2 and 3 cents less; this includes the light amber. Dark grades of amber sell at about 10¢@11c, and buckwheat 9¢@10c. Extracted is steady with white bringing 6¢@6c, according to color, flavor and quality; the amber brings from 6¢@7c; dark, 5¢@6c. Beeswax in good demand at 30c.
R. A. BURNETT & Co.

KANSAS CITY, Oct. 11.—The demand for both comb and extracted honey is good, especially comb, at the quotations. We quote fancy white comb, 14¢@14½c; No. 1 white, 13½¢@14c; No. 2 white and amber, 13¢@13½c. White extracted, 6¢@6½c; amber extracted, 6¢@6½c. Beeswax, 22¢@25c.
C. C. CLEMONS & Co.

CINCINNATI, Oct. 4.—The demand for extracted honey is good at the following prices: Southern and amber sells at 5½¢@6½c; better grades, 7¢@8c. Comb honey is scarce; fancy and No. 1 sells on arrival at 16¢@17c. Beeswax weak at 28c.
THE FRED W. MUTH Co.

ALBANY, N. Y., Oct. 14.—Honey is selling well with no accumulation. We quote: White fancy comb, 16c; A No. 1, 15c; No. 1, 14c; mixed, 13c; buckwheat, at 13¢@13½c. Extracted, white, 7¢@7½c; mixed, 6¢@6½c; dark, 5¢@6c. Beeswax, 28¢@30c.
H. R. WRIGHT.

NEW YORK, Oct. 10.—We are having a good demand for comb honey and receipts are quite plentiful. We quote fancy white at 15c, and some exceptionally fine lots will bring from 15½¢@16c; No. 1, white, 13¢@14c; amber, 12c.

Buckwheat is late arriving, and none has been on the market as yet to cut any figure. We expect large receipts next week, and it will sell at from 10¢@12c, according to quality and style of package.

Extracted in fairly good demand at 7½c for white, 6½c for light amber, and 5½¢@6c for amber. Southern in barrels at from 55¢@65c per gallon. Beeswax nominal at 28c.

CINCINNATI, Oct. 7.—Comb honey is in good demand, the supply is short and very little offered. No. 1 fancy water-white sells at 16c; other grades less, according to quality. The demand for extracted is very active and prices are a little better; amber sells for 5½¢@5½c; alfalfa from 6¢@6½c; water-white white clover, 7½¢@8c. Beeswax, 30c.
C. H. W. WEBER.

SAN FRANCISCO, Oct. 1.—White comb honey, 12¢@12½c; amber, 8¢@10c; dark, 7¢@7½c. Extracted, white, 5½¢@6c; light amber, 5¢@5½c; amber, 5¢@5½c. Beeswax, good to choice, light, 27¢@29c; dark, 25¢@26c.

There were comparatively heavy shipments outward the current week for a light crop year. A sailing vessel, with mixed cargo for London, took 315 cases extracted. A steamer in the new German line took 150 cases for Germany. Spot stocks and offerings are small, and especially is high-grade water-white honey in limited supply, with market for this description decidedly firm.

PUBLISHED WEEKLY BY

GEORGE W. YORK & COMPANY
144 & 146 Erie St., Chicago, Ill.

Entered at the Post-Office at Chicago as Second-Class Mail-Matter.

EDITOR—George W. York.
DEPT. EDITORS.—Dr. C. C. Miller, E. E. Hasty.
SPECIAL CORRESPONDENTS—G. M. Doolittle,
Prof. A. J. Cook, C. P. Dadant,
R. C. Aikin, F. Greiner, Emma M. Wilson,
A. Getaz, and others.

IMPORTANT NOTICES.

The Subscription Price of this Journal is \$1.00 a year, in the United States, Canada, and Mexico; all other countries in the Postal Union, 50 cents a year extra for postage. Sample copy free.

The Wrapper-Label Date of this paper indicates the end of the month to which your subscription is paid. For instance, "dec01" on your label shows that it is paid to the end of December, 1901.

Subscription Receipts—We do not send a receipt for money sent us to pay subscription, but change the date on your wrapper-label, which shows you that the money has been received and duly credited.

Advertising Rates will be given upon application.

The National Bee-Keepers' Association.

OBJECTS:

To promote and protect the interests of its members.

To prevent the adulteration of honey.

To prosecute dishonest honey-dealers.

EUGENE SECOR, General Manager and Treasurer, Forest City, Iowa.

MEMBERSHIP DUES, \$1.00 a year.

If more convenient, Dues may be sent to the office of the American Bee Journal, when they will be forwarded to Mr. Secor, who will mail individual receipts.

A Celluloid Queen-Button is a very pretty thing for a bee-keeper or honey-seller to wear on his coat-lapel. It often serves to introduce the subject of honey, and frequently leads to a sale.

NOTE.—One reader writes: "I have every reason to believe that it would be a very good idea for every bee-keeper to wear one [of the buttons] as it will cause people to ask questions about the busy bee, and many a conversation thus started would wind up with the sale of more or less honey; at any rate it would give the bee-keeper a superior opportunity to enlighten many a person in regard to honey and bees."

The picture shown herewith is a reproduction of a motto queen-button that we are furnishing to bee-keepers. It has a pin on the underside to fasten it.

Price, by mail, 6 cents; two for 10 cents, or 6 for 25 cents. Send all orders to the office of the American Bee Journal.

—BEST—

Extracted Honey For Sale

ALL IN 60-POUND TIN CANS.

Alfalfa Honey

This is the famous White Extracted Honey gathered in the great Alfalfa regions of the Central West. It is a splendid honey, and nearly everybody who cares to eat honey at all can't get enough of the Alfalfa extracted.

Basswood Honey

This is the well-known light-colored honey gathered from the rich, nectar-laden basswood blossoms. It has a stronger flavor than Alfalfa, and is preferred by those who like a distinct flavor in their honey.

Prices of Alfalfa or Basswood Honey:

A sample of either, by mail, 10 cents, to pay for package and postage. By freight—two 60-pound cans of Alfalfa, 9 cents per pound; 4 cans or more, 8½ cents a pound. Basswood Honey, ½ cent more per pound than Alfalfa prices. Cash must accompany each order. You can order half of each kind of honey, if you so desire. The cans are two in a box, and freight is not prepaid. **Absolutely Pure Bees' Honey.**

Order the Above Honey and then Sell It.

We would suggest that those bee-keepers who did not produce enough honey for their home demand this year, just order some of the above, and sell it. And others, who want to earn some money, can get this honey and work up a demand for it almost anywhere.

GEORGE W. YORK & CO., 144 & 146 Erie St., Chicago, Ill.

The Novelty Pocket-Knife.

Your Name and Address on one side—Three Bees on the other side.

[THIS CUT IS THE FULL SIZE OF THE KNIFE.]

Your Name on the Knife.—When ordering, be sure to say just what name and address you wish put on the Knife.

The Novelty Knife is indeed a novelty. The novelty lies in the handle. It is made beautifully of indestructible celluloid, which is as transparent as glass. Underneath the celluloid, on one side of the handle is placed the name and residence of the subscriber, and on the other side pictures of a Queen, Drone, and Worker, as shown here.

The Material entering into this celebrated knife is of the very best quality; the blades are hand-forged out of the very finest English razor-steel, and we warrant every blade. The bolsters are made of German silver, and will never rust or corrode. The rivets are hardened German silver wire; the linings are plate brass; the back springs of Sheffield spring-steel, and the finish of the handle as described above. It will last a last-time, with proper usage.

Why Own the Novelty Knife? In case a good knife is lost, the chances are the owner will never recover it; but if the "Novelty" is lost, having name and address of owner, the finder will return it; otherwise to try to destroy the name and address, would destroy the knife. If traveling, and you meet with a serious accident, and are so fortunate as to have one of the "Novelties," your POCKET-KNIFE will serve as an identifier; and in case of death, your relatives will at once be notified of the accident.

How appropriate this knife is for a present! What more lasting memento could a mother give to a son, a wife to a husband, a sister to a brother, or a lady to a gentleman, the knife having the name of the recipient on one side?

The accompanying cut gives a faint idea, but cannot fully convey an exact representation of this beautiful knife, as the "Novelty" must be seen to be appreciated.

How to Get this Valuable Knife.—We send it postpaid for \$1.25, or give it as a Premium to the one sending us THREE NEW SUBSCRIBERS to the Bee Journal (with \$3.00.) We will club the Novelty Knife and the Bee Journal for one year, both for \$1.90.

GEORGE W. YORK & CO., Chicago, Ill.

Please allow about two weeks for your knife order to be filled.

No. 43.

* Editorial Comments. *

Time to Bring Bees Home from Out-Apiaries.—At this time of the year inquiries arise as to the right time to bring home bees from out-*apiaries*, said bees to be cellared at home. It is bad policy to bring them home too early, for there will generally be a few late flowers on which the bees can work, and the bees may just as well have the benefit of this late pasturage by being left at the out-*apiary* as late as possible. Another reason why it is not best to be in too much haste is that it is not so safe for weak colonies. In a time of scarcity, let a colony be put in a new place, and a careful investigation will be made by marauding bees to see if any weak point of attack can be found. A weak colony that has stood unmolested in an out-*apiary* for days or weeks, is sure to have its proper measure taken when set down in or near the home *apiary*, and, if the weather is fair for a number of days in succession, it stands a fair chance of being robbed out. If brought home after the weather has become so cold that only an occasional day offers the opportunity for flight, its chances for safety are much better.

But it will not do to defer the matter till all flight days are over. To be sure, some say there is no objection to hauling bees home and putting them directly into the cellar, but others report loss therefrom, and it looks reasonable that the excitement of hauling the bees home will make them consume an extra quantity of honey, equivalent to a longer degree of confinement. At any rate, it is well to be on the safe side.

So let the bringing home be delayed, only not so late but that the bees will have a chance for a flight before being put into the cellar. In the North the last of October will not be far out of the way.

A Short Crop in England.—D. M. M. says in the *British Bee Journal* :

“Not only is there no surplus worth naming at the end of this sunless summer, but a very large percentage of colonies will require less or more feeding to preserve them for another season’s work.”

Although in this country there has been a summer more nearly sunless than usual, yet in many places where a dearth prevailed in the early part of the season a late flow came in most opportunely, and contrary to earlier expectations, the hives are heavy with winter stores.

The Proper Province of a Bee-Paper is sometimes not rightly understood, especially by beginners. Occasionally a subscriber writes to the effect that he has read the *American Bee Journal* carefully for so many months and has never seen any instruction given upon a certain point in

bee-keeping upon which he desires information, there being an implied suggestion that the *Journal* is not performing its full duty. A bee-paper has, however, its limitations, beyond which it can not go without loss to its readers. It should be clearly understood that its province is *not* to give such information as is considered absolutely necessary for every beginner in order to work in even a moderately intelligent manner. That is the province of the text-books on bee-keeping.

There are, however, constantly coming up more or less new things not in the nature of the case to be found in the text-books, and the bee-paper furnishes the proper field for their exploitation. There are also things given in the text-books about which there may be some point not entirely clear, even after careful study, and upon such points information in the bee-papers can generally be had for the asking.

Instead of being wronged by not finding in a bee-paper the matter found in a text-book, the reader would be wronged if its columns were filled with such matter. For example, every bee-keeper should know that when a queen lays an egg in a certain kind of cell a worker-bee will be produced, there being so many days for the egg, so many for the larva, and so many from the laying of the egg to the emergence of the young worker-bee, and that after so many days it will begin work in the field, etc. If he expects to find these things in a bee-paper, and if he is not disappointed in his expectations, there will be new subscribers within a year who will want the same things repeated; and so it will come to pass that every year there will be much space taken up with things that all but the latest comers will have already learned, and the very ones who have complained at not finding the things desired will be the ones to complain that space is taken up with things already learned.

So it is a real kindness to beginners to urge persistently that they study carefully the text-book, and then let the bee-paper take its proper place as supplementing the text-book.

Stock Eating Sweet Clover.—Some complain that stock will not eat clover. On the other hand, some complain that they eat it too much for the good of the bee-keeper. *Sonnambulist* says in the *Progressive Bee-Keeper* :

“The great trouble in regard to sowing sweet clover in this vicinity is that the stock will not let it come into flower, they keep it cropped off and only a stray stalk here and there ever reaches the blossoming period.”

The Honey Crop in Canada.—Secretary Couse, of the Ontario Bee Keepers’ Association, says this in the *Canadian Bee Journal* :

About a week ago there was mailed to each member of the Ontario Bee-Keepers’ Association a circular asking them to report on their honey crop. At this date about one-half have reported; from these reports there can be some idea formed as to the crop in the Province. Twenty-eight report a light crop, six of these say equal to, and 22 say less than the two previous years; 21 report an average crop

nine of these say equal, eight better and four less than the two previous years; 11 report a large crop, better than the two previous years; 50 report their bees in as good or better condition than usual.

One of the very difficult things in the line of statistics is to learn somewhere near the exact size of the honey crop. At best it can only be a guess, at least, until some careful plan of gathering statistics is evolved and carried out. We think that the only way to find out at all definitely is to have the Government take hold of it, and have the honey crop report the same as oats, wheat and corn.

* The Weekly Budget. *

MR. C. P. DADANT writes us that he is not a candidate for the office of General Manager, and desires his name taken out of the list proposed by Mr. Moore, on page 644. He says he would have neither the time nor the inclination to do the work that is required of such officer.

CLEOME IN THE SOUTH.—M. Wilkins & Co., of Marengo Co., Ala., wish to know whether cleome, or Rocky Mountain bee-plant, will grow in their locality. Also, whether there is any trouble in exterminating it when one cares to do so. Will some one answer who knows?

THE CHICAGO-NORTHWESTERN expects to hold the biggest bee-keepers' convention of the year, on Dec. 3 and 4. And Secretary Moore is planning great things, as will be seen by the following:

SPECIAL NOTICE.

The management of the Chicago-Northwestern Bee-keepers' Association are making extra efforts to have a grand, good meeting, Dec. 3 and 4, 1902, at the Briggs House, Chicago.

All within the territory embraced by the Association are requested to send questions (to be answered at the meeting) on postal cards to the Secretary immediately. (See address below.) Six eminent bee-keepers have been invited, and five have promised to be present. (Names later. Watch for them.) The questions will be assigned to the eminent people to answer, which will add greatly to the interest of the meeting.

HERMAN F. MOORE, Sec.

Park Ridge, Ill.

DENVER CONVENTION NOTES.—We spent Sunday, Sept. 7, in Colorado Springs. In the forenoon we attended the preaching service at the First Methodist church, and in the afternoon the Sunday-school at the same place. This church building is the finest we had ever seen, especially the interior arrangement and decorations. It cost about \$90,000, and was completed but recently. The organization has a membership of about 800.

From Colorado Springs Pike's Peak seems only about one mile away. We asked a resident, who said it was 16 miles away! A kind of 16 to 1, wasn't it?

Well, Monday morning we set out for Manitou, and a trip up to the Peak on the Cog Wheel Route. By the way, here, in a sentence, is Manitou upon which the Indians bestowed the revered name of "Great Spirit."

A graceful vale encompassed by cathedral hills; pure, invigorating atmosphere swept from snowbound heights, perfumed with piney odors and tempered by a genial sun; clear, crystal waters rollicking in stony beds, and effervescent fountains sparkling and delicious, and offering health and life as well; delightful parks, romantic, winding paths; cool, arched nooks; a very world of scenic beauty crowded all about."

Cog Wheel Depot at Manitou.

As we would be utterly unable to do justice to the trip up to Pike's Peak, we will make an extract from a publication which at least attempts to tell something about this "Monument of the Continent:"

Authentic lore of this wonder dates from Nov. 13, 1806, when Major Zebulon M. Pike, a gallant soldier and a daring adventurer, then heading a small exploring party of United States soldiers, sighted the mountain's whitened crest when many miles distant upon the plains. It cost him ten days' marching to reach its base; and, after vigorous attempts to scale it, Pike abandoned the project with the declaration that "No human being could ascend to its pinnacle."

The Manitou & Pike's Peak Railway (familiarly known as the Cog Wheel Route) was completed in the autumn of 1890. As an engineering achievement it is remarkable, and in many respects it is the most wonderful railway in the world. In general terms it is an Abt system cog road, though that conveys little idea of what it really is. The road is within a fraction of nine miles in length, and in this distance it overcomes 1½ vertical miles. It is standard gauge, and with a roadbed that is all in point of excellence that it is possible to make it. Where this is not cut in the solid rock, it is most thoroughly ballasted. On the heavy grades the track is securely anchored at frequent intervals to guard against any possible displacement from the effects of extreme variations of temperature. The mean grade is 16 percent, the maximum 25 percent (a rise of one foot in four), and the sharpest curves are 16 degrees. The outside rails are of the ordinary T pattern, and here the similarity

Half-Way House and Cog-Track.

to the ordinary railroad ends. The T rails serve merely to guide the train and bear its weight. It is the rack rails in the middle of the track upon which the propulsion and safety of the train depends. The rack rails are double every inch of the way from the valley to the summit. They are made from superior Bessemer steel, and are of extra heavy weight on the steeper grades.

The locomotives are an exciting novelty to any one with an interest in machinery. These powerful mountain climbers are constructed with the utmost nicety of detail. There are five of them in the road's equipment, all of the four-cylinder Vaucrain type, weighing about 30 tons each. Two double cog wheels underneath the locomotives engage the toothed rack rails. The locomotives are provided with brake power in abundance—hand-brakes, steam-brakes, water-brakes, and automatic brakes.

The coaches are observation cars. Each seats 50 passengers. They precede the locomotives on the ascent—which is an advantage in the matter of observation—and follow them on the descent, thus being always protected by the latter. The two, however, are never coupled together, and the coaches are provided with powerful individual brakes that operate through cogs on the rack rail. By this arrangement the coach can be stopped instantly and independently of the locomotive.

Through scenes of ever-changing beauty, the Half-Way House, which is far from half way to the summit, is reached. It is a rustic mountain hotel surrounded by a

Phantom Curve on the Way Up.

grove of stately pines, and, towering above it, the pinnacled rocks of Hell Gate, through whose portals the train passes on.

There are six stations on the line, besides the terminals, and three water tanks—for the engine is a thirsty monster. At one of these may be strikingly seen the apparent phenomenon of water flowing uphill in an open trough. Another illusion that excites comment is in the grade. Every inch of the road is up; yet, when approaching a moderate from a steeper grade, any one would declare that the track ahead was a down grade.

Quaint beauties, grotesque shapes and strange illusions fairly crowd the way. The conductor shows them all. Among the surprises is a printing-office perched on the mountain side. Here a souvenir daily paper is issued with the news of Pike's Peak—the names of its visitors, illustrations, descriptions, etc.

The climbing is unceasing. Ere long the scene expands. The verdured hills shrink back and leave the big, bleak peak a towering monument. The trees desert the landscape, and groups of stunted aspens shiver in the breeze. Grand vistas open everywhere. A sense of awe transcends that of delight.

The scenes of near-by interest now are gone. Rocks, gaunt and jagged, only line the way. The train now gains in elevation rapidly. The air grows chill; windows must be shut and outer wrappings donned. Away below—itself high in the hills—is spread out like a mirror the crystal, placid Lake Moraine, about whose shores tradition weaves

some thrilling legendary tales. Thick, billowy clouds—unless the day be strictly fair—float far below. In the early season snow is everywhere, and forms some strange effects. The opening of the road in the spring involves cutting through enormous depths of snow and ice. The locomotive labors sturdily and heroically on; and presently, and quite unexpectedly, the train halts on the Summit, and Colorado is spread below.

And that magnificent, sweeping view! How futile is description! Here is sublimity; here is immensity incredible! There, to the west, stand a thousand towering peaks in spotless white—majestic, beautiful awful! On the east a mighty ocean of plain, superb and placid, stretches infinite. The eye is strained, the senses dazed, in grasping the proportions of that stupendous sea. And the sun shines golden on its glimmering sands, while purple shadows wander here and there beneath the shifting clouds.

Aroused at last from awesome contemplation, there are interests of the summit that must not be overlooked. Upon the top of the new Summit Hotel is a steel tower, and here is on duty a powerful telescope through which the gorgeous landscape may be studied in detail. Eighty miles away to the north Denver can be recognized by the telescopic aid; to the south, Pueblo (the Pittsburg of the West) crowned by the smoke-clouds of its furnace fires; to the west, Cripple Creek, Victor, Goldfield, Independence, and the dozen lesser towns of the busy Cripple Creek gold-mining district. Manitou peeps out from its nest at the eastern base of the mountain; and, beyond, Colorado Springs lies like a vast checker-board on the border of the plain. Colorado Springs is 16 miles distant, as a bird would fly; yet so near does the telescope bring it to the observer, that signs on the stores may be read.

The top on the peak comprises several level acres thickly strewn with big rocks that are principally in cubes and other rectangular shapes. One might easily imagine it to be the scene of some Titanic building project—the materials all assembled but construction abandoned.

The Bottomless Pit and the Abyss of Desolation are great shuddering rents in the mountain, into which the sun never finds its way, and where the snows of centuries lie in unconjectured depths.

The Summit Hotel is a very substantial, commodious and comfortable building, and it furnishes entertainment for the many pilgrims that remain over night to view the glories of the sunrise. Sunrise excursions, which are run weekly in the latter part of the summer, have also become very popular, sometimes the entire equipment being required to handle the crowds.

Within the hotel building is a Western Union office, the highest telegraph station in the world; also a lunch-room and souvenir store.

The locomotive blows a warning note; a photograph is made of the passengers grouped about the train; the time is up; the conductor says his say.

And then they come down.

Yes, we all came down again, after the most wonderful railroad ride we ever took. We shall never forget it. And yet we would not care to repeat it. Once is enough. The next time (if there should ever be a next time) we hope to walk up. Many go up that way. But it must be a great climb!

Why Not Help a Little—both your neighbor bee-keepers and the old American Bee Journal—by sending to us the names and addresses of such as you may know do not now get this journal? We will be glad to send them sample copies, so that they may become acquainted with the paper, and subscribe for it, thus putting themselves in the line of success with bees. Perhaps you can get them to subscribe, send in their dollars, and secure for your trouble some of the premiums we are constantly offering as rewards for such effort.

“**The Hum of the Bees in the Apple-Tree Bloom**” is the name of the finest bee-keeper's song—words by Hon. Eugene Secor and music by Dr. C. C. Miller. This is thought by some to be the best bee-song yet written by Mr. Secor and Dr. Miller. It is, indeed, a “hummer.” We can furnish a single copy of it postpaid, for 10 cents, or 3 copies for 25 cents. Or, we will mail a half-dozen copies of it for sending us one new yearly subscription to the American Bee Journal at \$1.00. 

The Denver Convention.

Report of the Proceedings of the Thirty-third Annual Convention of the National Bee-Keepers' Association, held in Denver, Colo., on Wednesday, Thursday and Friday, Sept. 3, 4 and 5, 1902.

(Continued from page 664.)

Pres. Hutchinson—Is there some one else who has some views to advance upon the subject before us?

Mr. York—Dr. Miller has made the suggestion, in his address, and I, for another, would like to hear from Prof. Benton.

Prof. Benton—I am not an eloquent speaker by any means, and I can tell you only of a few facts merely in a plain, simple way.

The Government and Bee-Keeping.

I was appointed, after having been abroad some years in private work entirely, to undertake to do something for the apiarian industry of the country at the United States Department of Agriculture. The first proposition, perhaps, on which my services were demanded, was to undertake to secure from the East Indies and China the race of bees existing there; there were, however, a number of technicalities in the way of taking up that work at once, and it was shelved for the time, and it rests there still, I am sorry to say, because I think it ought to be undertaken. It will come forward, however, in the future.

Now, meanwhile, there were various things that could be done, and the Department thought most of all that there were in this country large numbers of people that were interested in apiculture, but knew nothing of it, or how to get at it, or how to get at the information; in fact, there were many people who did not know that there were works on apiculture that could be had readily; they did not know how to begin the business, therefore they commissioned me to prepare one or two little pamphlets on the subject which should connect those people that were really on the outside track with the industry itself. I did that work, and it has proved acceptable, I think, in general since; those publications have gone through many editions, and are constantly called for, more, in fact, than the law has permitted us to issue, and there are daily calls for that information.

Now, a great deal of the work, since I have been connected with the Department, has been to answer inquiries from just this class of people. We get daily queries from different portions of the country, from your far West and from the East and South. One man wants to know which is the best race of bees adapted to his locality; still another man asks what honey-producing plant he should put out in his neighborhood; and he asks a specific question, perhaps. To all of these, to each and every one, I have to give some reply, the best information I can obtain concerning it, and as you know

this is such a wide country, all kinds of climates from Maine to Southern California, from Minnesota to the Gulf States, from the Atlantic to the Pacific, and all manner of conditions and combinations occur. Each one must have, then, a special reply.

Now, when it comes to the matter, for instance, of bee-forage, I had just the other day an inquiry from a man in Minnesota, who asked what plant he should put out on the shore of a lake where the water had receded and the ground was but a foot above the level of the water, and had grown up with swamp-grass, and he didn't know what would grow there that would blossom to fill in a gap in his honey crops.

Now, in order to answer just such questions, my proposition has been, and we are doing that work, collecting information concerning every known honey-producing plant, its area, the soils that that plant may be found on, where it will thrive, then mapping these areas where the plant is found naturally, and setting down the amount of blossoming, and determining what crops could be cultivated to fill in the gap in any given locality, so that with the outlined maps filled in with the areas of the leading honey-producing plants, we are able to give an opinion, and say such and such plants are common; we know just what a man's honey resources are when we locate him, and we know what may be cultivated to advantage.

We get a great many inquiries about bee-diseases, and people ask also what they can do towards securing State Legislation, and we tell them what has been done in other States, and what measures seem to us most advisable to adopt with the laws covering that. There is foul brood, and then also the adulteration of honey. I don't know that we have sufficiently attempted to influence legislation in favor of laws governing the adulteration of honey, so far as at least requiring that honey should be labeled and sent out under its own name; and I have co-operated with the National Pure Food Congress, which has assembled in Washington, and have given information to members of congress that were on the committee also on Pure Food Legislation.

The Department, on my recommendation, has imported various races and strains of bees, the bees of distant Cyprus, West Austria—Carniolans, known as very gentle bees. It has also imported about twice the number of Italians than any of the other races, because I conceive many of the Italians brought to this country are not of the preferable strain, but we should have bees from the more northern districts of Italy, and those bees have been sent

to various experimental stations that were prepared to do something with apiculture, and to leading bee-keepers in different parts of the country who were competent to test them and render good opinions, and who were willing also to rear queens from this stock and sell them at a reasonable price to bee-keepers. In that way we reached a larger number than we could by attempting to breed queens and make a general distribution, and for my own part I have never recommended such a general distribution of queens as there has been of seed at the Department.

I have been testing, and have been given time by the Department to test all known systems of rearing queen-bees, to determine what seemed the most practical, simple and easily applicable method, and that by which we could produce the largest number and best queens with the least expenditure. In connection with that I think I had the honor of suggesting the first removable queen-cells that could be used over and over. Others have taken that up and developed it in a commercial manner. I think since that the suggestion was brought forward at that progressive bee-keepers' society, known as the Ontario County, N. Y., Bee-Keepers' Association, and from that it has spread far and wide. In connection with this work I have developed a nucleus hive for the care of the queen-cells and the holding of the queens until they are mated and ready to send out. Now, that nucleus hive has various features considered likely to prove valuable, and I am testing it this year with thus far eminent success; and a further point is, I am of opinion I can winter readily very small nuclei over full colonies; in other words, by wintering a queen in the body of the hive, and two nuclei above double wire-cloth, I can winter three queens to the hive; and I think that would be a practical feature for honey-producers who themselves are not queen-sellers, and have no opportunity, perhaps, to sell queens in the spring, but who would thus have a reserve for every colony intended to be put into harvest, of two extra queens to select from, in the spring, enabling a man to select that one which he believed would develop his colony to the highest standard for honey-production.

The collection and dissemination of information of a statistical nature concerning the bee-industry I consider of great importance, since, I think, most bee-keepers are agreed the information contained in the census reports is not in all respects to be relied upon. I think we have deficient reports regarding the status of the industry in the country, and that, were a full report obtained, the importance and value of the industry to the country would be greater than it appears now. Following that, the collection of and the issuance of regular reports regarding our honey crop I have recommended for a number of years, but have been unable to carry that through. There is more prospect of our doing that in the near future, especially if bee-keepers would demand it—a regular collection of statistics concerning the condition of the crops and the issuance of monthly or bi-monthly reports in the same way as the crop reports regarding the staples of the country. I have not believed it could be done through the preparation

of statistics by the Department without a special corps of bee-keeping reporters that would be willing to report the crop of their locality in such a way that we could compile figures and issue something like reliable statements; and there have been various suggestions that the National Society should undertake it, but when you stop to think that there are more than 3000 counties in the United States, and we should have several reports from each county, and the sending out of monthly queries to the number of 10,000 perhaps would mean quite a little expenditure for printing, stationery and postage, it is hardly feasible for any society to undertake that, since all of that could be done under Government frank requiring no postage, and they could be printed in very large numbers, and the Government has its great printing-offices there that are at the disposition of the members of the Department if they order anything from them.

Now, I may be pardoned for adding a word. I think I have scarcely touched upon the many suggestions I have made, some of which have been carried out, but I want to say a word as to how this society could assist in these various things, or in any other work that the society might think was an advisable thing to undertake—how it might assist me in doing that work, or assist the department in doing it through any other agent or individual, and that is by a hearty support of what little I have been able to undertake; and the seconding of the suggestions that I might make, or the making of independent suggestions to be perhaps

submitted to me, since they would ask my advice regarding them; and, directly, to appeal to the Secretary of Agriculture, and to the Chief of the Division of Entomology under whom I work, to make this work, in so far as possible, somewhat independent in the department; that is to say, to give the direct control of a certain fund, not of course the handling of the money, but the say as to how and in what direction that money shall be applied; and that a certain sum shall be set aside to be devoted to these industries directly. The Chief of the Division of Entomology, Dr. Howard, is a graduate of Cornell University, a very intelligent man, and understands, through numerous conversations with me, something of the status of the industry, and is willing and anxious to have this done; but he does not know, himself, exactly how to go about it, but he will defer to this society and to recommendations I may make; and if he sees there is a genuine union and demand for any line of work, he is willing to authorize and recommend it to the Secretary; and he has made many recommendations in accordance with suggestions I have made.

In any of these lines I am willing to co-operate with this Association, and I believe with a little more freedom in the application of such a sum as could be devoted to the interests of apiculture at Washington, we might do a great deal in the furtherance of the work, in assisting organization, in disseminating information concerning our pursuit, and showing its importance to legislators, who would then be willing to grant us more liberal

appropriations. I thank you for your attention.

Dr. Miller—Just upon that one point of statistics I want to endorse heartily the thought of Prof. Benton, that if we can get statistics through the Government that is the way to get them; they are in the business of gathering statistics, we are not; and we might do something. I perhaps know more, personally, about gathering statistics than any other one man here, because a good many years ago the National Association—I don't know whether it was the National Association or somebody else—at any rate, I tried to get hold of our United States' reports, and it amounted to about that (a snap of the finger). Prof. Benton, I am sure, could get two reports more than I could, and, perhaps, 2000 more, and if that can be done I believe it would be of a great deal of advantage. I want very heartily to thank Prof. Benton for answering the question that he ought long ago to have answered personally to me. I hold him responsible for that. I will never forgive him for that, and that he didn't write me a letter and tell me all he was doing; but for the answer he has made this morning I want to thank him heartily.

Dr. Mason—Better forgive him while you are about it.

Dr. Miller—Do you want me to forgive you?

Prof. Benton—Yes.

Dr. Miller—All right.

Prof. Benton—I would not want a good man like Dr. Miller to hold such a grudge against me.

Preparing Bees for Outdoor Wintering.

BY C. P. DADANT.

MR. C. P. DADANT:—I have been much interested in reading your writings in the American Bee Journal, and have profited by your advice at different times, and if not asking too much I would like you to write an article on outdoor wintering, and give full description as to how you would prepare the bees—I mean, how to prepare and winter them without putting each hive in a separate winter-case. I think you wrote on this subject a few years ago, but as I recollect it I failed then to grasp exactly your meaning on some points. If you could give another article on the subject I am sure it would be appreciated by many bee-keepers.

I have over 60 colonies sitting somewhat scattering, and facing in different directions. Would it do to group these close together late in the fall, and front them all one way for wintering? Would they not get badly confused when they would fly out on warm days? And, after getting used to their winter location, would they not again get confused when set farther apart in the spring.

The season here has been poor for bees—too wet and cold. They did not work in supers until late in June, and then were hindered a great deal by rain. Basswood bloomed very heavy, but owing to the rain and cold they stored no honey from it. I got about 1,500 pounds of very fine clover honey in sections (including a little extracted), but I am entirely sold out already, and could sell that much more. I sold nearly all the comb honey at 16 and 17 cents per pound; extracted and "chunk honey" at 13 cents. This last sold the most readily of all.

Huntington Co., Ind., Sept. 18.

A. H. SNOWBERGER.

Replying to the above enquiries, I will say first that I have never seen any good come from bringing the hives together in the fall and spreading them apart again in the spring. I have, however, been told of some bee-keepers doing this and being well pleased with the result, but I do not accept these statements without some doubt. Many people take too many things for granted, and make superficial ob-

servations which they would see in a very different light if they took the pains to investigate more thoroughly.

It is a fact that any one can ascertain with very little trouble, that the bees get so accustomed to their location that if the hive is moved but two inches, the bees when they alight will at first almost invariably notice that two inches of difference. If you move the hive forward, they will at first almost invariably notice that two inches of difference. If you move the hive forward, they will of course alight as usual at the entrance, but if the removal is two inches to the right or to the left you will see them alight to the side formerly occupied. If the hive is moved back that distance, they will fall short of the entrance about the distance moved. As one might easily conceive, they will soon become used to so small a difference in the distance, and not all the bees will notice it, but enough of them will be annoyed by it more or less to show the practical apiarist the danger of moving bees without notice.

If you have the patience and the opportunity of moving your hives from two to six inches every day to get them together, the inconvenience to the bees will be less than the advantage gained from their being brought together for shelter. But so very few people have the time and opportunity of doing this that one can hardly advise it as a practical thing. If you move them two or three feet, especially when many hives are in the same spot, there will be much confusion, a great deal of fighting, and, if you are a practical bee-keeper, you will regret it.

When bees are moved a great distance, say beyond their usual field-range, they easily recognize the spot at their first flight and remember it, especially if the apiarist has taken care to place in front of the alighting-hole some sort of obstruction that will show them that something is changed in their whereabouts. The old, experienced bee, that usually flies out of its hive in a "bee-line," will then face about and reconnoiter before going away. But if it has left the hive in the usual bee-line, there are many chances that it will get disconcerted in coming home. Although some reliance may be placed on the "home" call, many bees will have alighted in the wrong place, and perhaps have been destroyed. Bees may be changed from one spot to another within a short distance, if they are given a very decided

notice of the change, by disturbance of alighting-spot in the placing of an obstruction as stated, but it is not advisable to try these things when they need their whole force in the hive to keep warm during cold weather.

The most important requirement in wintering is good food. A strong colony with honey-dew or fruit-juice is worse off for winter than a comparatively weak colony with good, healthy stores. If the confinement is of long duration, the bees of the hive that contains unhealthy food will become restless, owing to their intestines being loaded with an excess of feces. They will then either leave the cluster and become chilled, or be compelled to discharge their excrements in the hive, and thus soil the brood-combs and the other bees, causing the speedy loss of a good portion of the swarm. On the other hand, the colony which is supplied with healthy stores will keep clustered together and will be able to pass through a very long period without much suffering or loss.

If our colonies are strong in bees and have plenty of good food, the next requirement is a good shelter. It is well to have the inside of the hive so arranged that the moisture arising from the bees may pass off without causing the hive to become damp on mild days. For this purpose absorbents, such as chaff, sawdust, etc., are used. We use forest leaves, because they are plentiful where we keep our bees, and also because these leaves are usually neat and may be placed over the combs without soiling anything. Chaff and sawdust must be put in sacks, and the bees sometimes gnaw a hole in the sack or cushion so provided, and when you remove it it allows a quantity of sawdust or chaff to fall in the hive among the combs. Dry oak-leaves are much more easily removed.

I have heard the objection that dry oak-leaves are not as good a non-conductor of heat or cold as the chaff. This may be correct, but they are much better than many people think. Did you ever try to dig a hole in the ground, in the woods, when the ground was frozen? If you did, you must have noticed that when there is a thickness of leaves of three or four inches over the soil, you are able to dig into that soil long after the bare ground has been frozen over. This shows how much shelter there is in forest leaves, though they may not be as efficient as sawdust or chaff.

I have sometimes heard people say that this matter of absorbents above the bees was nonsense. It is not to me, because I have seen the matter tried on hundreds of colonies, and I will here say what the experience was. We used to put leaves in the caps of our hives, not to absorb the moisture but to keep the heat from escaping, just to help keep the bees warm. When we did this, we used an enamel cloth over the bees and placed the leaves on top of this enamel cloth. During a very hard winter, many of our bees died, the hive apparently wet from one end to the other, in the brood-chamber, from the moisture that had escaped from the bees. Nearly every colony found in that condition was dead. But we had a number of colonies in which the oil-cloth was partly gnawed away by the bees, large holes having been cut into it by them. These colonies almost invariably wintered safely, but the leaves in the upper story were soaked with moisture, and in some instances mouldy. The larger the holes were, in the enamel cloth, the better the condition of the bees. This was an eye-opener to us, and from that time on we have uniformly removed the enamel cloth for winter.

We place over the frames a mat made of what is commonly called here "slough-grass." It is a very coarse grass which grows on the Mississippi lowlands, and is used in some places as hay. This is tough and wiry, and lasts longer than straw, for straw-mats are easily broken when dry. This mat allows the moisture to escape through it into the upper story, which we still fill with leaves as formerly. We do not believe that anything surpasses the straw-mat in usefulness, both as winter and summer shelter. While it acts as a warm cover for frames during the cold days, it is the very best shelter against the rays of the July sun during the hot summer days. Here, in Illinois, we cannot leave our hives exposed to the direct rays of the sun in the hottest weather, as they do in countries where the altitude gives a relief from the scorching heat, or where the sun's rays are less perpendicular. Cool summers, like the one just past, are an exceptional occurrence.

Now as to the outside shelter: I am very free to say that although we have used our method for years, there are some better ways, though perhaps more expensive, of sheltering the hives. We simply wrap up each hive on the three cold sides—north, east and west—with forest leaves held together by a frame-work of lath and twine, which is tied around the hive, like a cloak. Some people use corn-

stalks for the same purpose. Others use this same slough-grass already mentioned by me, and make each hive look like a little hay-shock, the front only being open.

If all the other conditions are complied with—good food, plenty of bees, sufficient amount of stores, and absorbents in the super—the bees will be likely to winter well, if not too much exposed to the high, northern winds. But the additional shelter is not to be disdained, whether it is of leaves, or corn-fodder, or simply a tight board-fence, or in snow countries a big pile of loose snow around and over the hive.

But, by all means, I would give the bees a fair opportunity of taking flight as often as the weather will permit during the winter.

Hancock Co., Ill.

Rearing Long-Lived Queens and Bees.

BY DR. E. GALLUP.

NOW, Mr. Greiner, I may as well pitch into you as any one—good naturedly, understand. I wish to ask what I call quite important questions, and would like them answered as candidly as they are asked.

You seem to fear that our bee-supply dealers may have to get up a different style of hive, etc. Now, if a queen reared in an extra-strong colony, such as I have mentioned, will fully occupy 16 Langstroth frames with brood, eggs, etc., in all stages of growth, in 21 days, are you perfectly satisfied with an 8-frame hive for such queen? Do you really think two 8-frame hives, one on top of the other, every frame fully occupied with brood, is the best and most satisfactory style of hive? Now you must understand that both stories must be double-walled, at the sides *especially*, or the two outside combs in each story will not be occupied. With double walls and dead air space the outside frames will be as fully occupied with brood as the center ones. Now we have 16 combs occupied with brood, and no place to store honey, and if we wish to examine the lower story we have to lift off the upper story. Then, with a good queen we are compelled to go on up to 4 or 5 stories, in order to give such a colony surplus room to store during the height of the season. In one case I worked a 10-frame Langstroth hive 4 stories high. I would certainly, for myself, prefer 12-frame hives to 8-frames.

You seem to think that the dead bees in front of that hive I mentioned, might have come from other hives in the yard. Well, at the time I was making that observation I had only one other colony in the yard, and that was over 100 feet away. I also had a 3-comb starved-out black colony, but not near the one spoken of. But the black colony kept on increasing in numbers, while the others decreased in numbers. Since you have accused me of jumping at conclusions, I have partially jumped at the conclusion that dead bees in front of that hive in the morning might have come from a neighbor's, over one block away, and come in the night on purpose to fool me in my observations.

You say that queens of my own rearing live to be 6 years old, simply because I mentioned one living that long, that I had received from Adam Grimm. Now, do you suppose I have never tested the longevity of bees by changing from blacks to Italians, at different seasons of the year? Well, I have, and I came to the same conclusions that you and Mr. Dadant did; but sometimes we are compelled to modify our conclusions, not by actual facts. In my 70 years' actual experience, and as close observation as I have been able to make (for I commenced when I was 12 years old, and am now past 82), I would certainly be a dull scholar not to have learned something in all that time. Mr. Dadant, Mr. Hetherington, and Mr. Quinby—all successful bee-keepers—used large hives, but they did not use hives four times as large as a 10-frame Langstroth hive. When I made that experiment I did not experiment on one single hive, but I made 7. I also made 2 long-ideal Adair hives, containing the same number of cubic inches as my other large hives.

Well, I have told you before, that the second season after putting bees in them none of them swarmed, and I *jumped* at the conclusion that I had a non-swarmer; but the third season all of them sent out rousing swarms, before the standard hives did. Mind you, all of them had superseded their queens, and reared queens to suit the capacity of the hive. I was then keeping all Italians, and I had one of those queens *impurely* mated, so I killed the queen, and gave a cell from a purely-mated queen, cut out all cells from the old colony and gave a good cell, and here I had a grand opportunity to examine for the missing link, and I found it in every case. This change of queen was

made the first week in May, and lots of those hybrid bees lived 90 days; and I had held previous to this, that bees lived only 60 days, during the height of the working season. All of those cells were extra large, and contained a large amount of royal jelly.

I have also thoroughly tested, to my own satisfaction, some of the colonies from those degenerate queens, as to their longevity, and they lived only from 30 to 40 days, and your belief or unbelief *will not* affect the facts.

I never did double up swarms in order to rear queens, but I put two swarms into my large hive so as to be sure to have it filled with worker-comb for next season, as I did not have ready-made combs to fill up with. This fall the intention is to kill the hybrid queen, and next winter take out the division-board, then I shall have 20 Langstroth combs; remove nearly all the honey and commence stimulating with diluted sugar, as granulated cane-sugar costs, at retail, 20 pounds for \$1.00. Understand that bees gather pollen all winter here. By stimulating just right I can rear a rousing colony, and have them rear drones early, swarm early, and have my queens purely mated before impure drones are out.

Now, Mr. Greiner, have you any objections? If so, please state them before I commence operations. I certainly have no objections to your making a large hive and doubling up swarms until you rear a 30-year-old queen, if you wish to.

What induced me to experiment with large hives was, seeing the large colony in the basswood log, out of which were taken enough bees to stock strongly four 10-frame Langstroth hives; and where I saw the largest queen I ever saw, up to that time, and the very largest queen-cells that I had ever seen, and I reasoned that there must be a cause, and by experiments I have demonstrated what that cause was, to my own satisfaction. I reasoned that those bees *must* be longer-lived than bees reared in small hives, or they could not be so extra-numerous; all were the progeny of one queen. In the aforesaid basswood log was where I first discovered the missing link, attached to the embryo queen.

You can have no idea how I have enjoyed the stirring up that I have made in the camp of bee-keepers. Speak up, gentlemen; don't be afraid of irritating or harming the "old gent;" you will find out he is "no spring chicken," on this queen-rearing question. He has more to say on this subject hereafter, as it is a subject of vast importance to the bee-keeping fraternity, for upon the quality of the queen hinges the success of bee-keeping.

Because you reared one inferior queen in one of your colonies, I do not jump at the conclusion that you claim that all your queens are of that class.

How to Preserve the Fine Flavor of Honey.

BY EMMA M. WILSON.

WE are all anxious that our honey be of the very best quality and flavor, but, perhaps, we are not all of us aware that we ourselves have much to do in bringing about the desired result, as well as the bees. The bees may give the honey into our hands in the very best condition, yet it is possible for us, by our ignorance or carelessness, to injure it much, if not utterly ruin it.

It is a fact that not many people, aside from bee-keepers, know how to keep honey properly.

One of our neighbors bought a case of honey from us. She used one section for tea, and put the rest of the case in the cellar for safe keeping, and only to be used upon state occasions. Some time afterward company came unexpectedly, and as she knew they were very fond of honey she went to the cellar for a section, thinking, as she went, how fortunate she was in having such nice honey to offer them. You can imagine how she felt on finding her honey utterly ruined, not much like the beautiful white honey she had put there. The cellar was damp—the very worst place she could have possibly put it; and yet it is a very common thing for people who do not know any better to put honey in the cellar. They naturally think it a nice, cool place for it, not knowing that the hottest and driest place you can find is the best place in which to keep honey.

If you can find a place for it in the kitchen near the cook-stove, that is an ideal place in which to keep it. If kept in such a place long enough the honey will string from

the knife when it is cut, and the flavor will be uninjured. Neither will you be likely to have any trouble with the honey candying in the comb, as it may do if kept in a cold place, even if the place be dry.

Just the other day a lady telephoned me to know what she should do with her honey that had candied in the comb. I told her the only thing she could do was to melt it up and use it as extracted honey; gave instructions as to how she could do it, saying:

"Put the honey in a dish or jar, set it in hot water, but be careful not to let it get too hot, as that would spoil the flavor. When it is all melted, set it aside to cool. When cool, remove the cake of wax which has risen to the top, and the honey is ready for use. After washing the honey off, put the wax in a dish with some hot water, and melt it over again, and when it is cool you will have a nice cake of wax."

If the public knew more about taking care of honey it might be that they would use more of it. As it is, if they spoil the honey by not taking the right care of it, they are not likely to blame themselves for it, but think they have been cheated by having an inferior article palmed off on them, and they make up their minds that they will not again invest much in honey right away. And they may be honest in it, too, as they don't know any better.

The kitchen will do very well for a small quantity, but if a large quantity has to be stored, some place else must be provided for it. An attic or a garret is a good place—one of those attics on which the sun beats down so fiercely in the summer time that it makes it such a hot place that you feel as if you could scarcely breathe in it, that's the place for your honey. There it will thoroughly ripen. □

It may not be generally known, but honey that has been kept for a sufficient length of time in such a hot place will be able to stand the freezing of the severest winter without the comb cracking, as it usually does when frozen.

After the thorough ripening the honey gets by being in such a hot place it never granulates, and perhaps it is the granulating that cracks the comb. Some have special rooms made as honey-rooms, with dark walls and roofs, to attract the rays of the sun.

In piling up your supers of honey in such rooms, or in the attic, it is a good thing to place small blocks between them at the corners, making a space of about an inch between the supers, for a free circulation of air to pass through.

McHenry Co., Ill.

Nice Flavor in Extracted Honey—Waxing Barrels.

BY G. M. DOOLITTLE.

A CORRESPONDENT writes me that it does not seem that his extracted honey has as good flavor as it should be, and wishes to know what is the best plan to preserve the flavor of extracted honey. I am of the opinion that he has been extracting unripe honey, and then putting it up without paying any especial attention to a further ripening of it. The best plan to secure the best flavor of extracted honey, or of any other, as for that matter, is to leave it on the hive till it is fully ripened by the bees.

I think it pays well to have sufficient combs in number so that colonies can be given two, three, or four stories if need be, enough so that all of one kind of honey can be stored in them before any is extracted, and then leave these combs on the hive till just at the commencement of the flow of nectar from some other honey-yielding plant or tree, when it should all be extracted, or enough of it at least, so that the needed combs for the next yield can go on again. In this way the honey is thoroughly ripened on the hive, giving the honey the best possible flavor for its kind, and be all of that kind, as no other is stored with it. And if it can stay on the hive until all of the cells are capped over, or very nearly all, it will be ready to put up for market as soon as it has stood long enough for any impurities to rise or settle. In this way we secure the best possible honey from our locality.

In any event, honey must be thoroughly ripened to give it a fine flavor. If any one thinks he must extract honey every few days during the honey-flow, then let him procure an evaporator, either sun or otherwise, through or over which this green honey should be run, until it is of the consistency of that nicely ripened by the bees, when he will have something approaching, as nearly as possible, that ripened by the bees, both in quality and flavor.

That which has been left on the hive till thoroughly ripened by the bees will be so thick that it will "almost stand alone" when a dish of it is turned over, and any artificial ripening which leaves it short of such thickness is faulty, to say the least. Of course, it is more work to extract such thick honey, but by keeping it in a room whose temperature is nearly or quite 100 degrees hot for five or six hours, or by extracting on some very hot day, it will come out of the comb very nicely. Then, when extracting, all honey should be stored in tin or earthen vessels and kept in a dry, warm atmosphere that is free from odors. Loosely cover with some thin fabric like cheese-cloth, something which will let the air circulate somewhat freely over it, and at the same time keep out the dust, and let it stand in this dry, warm store-room till all of the air-globules have disappeared, the scum which arises being skimmed off, when the honey can be put into glass or tin vessels, ready for market or family use; and it will retain its fine flavor for years, if kept in a proper place.

WAXING KEGS AND BARRELS.

This same correspondent wishes also to know what is the best method of waxing kegs and barrels for holding extracted honey, and whether it is necessary that all barrels and kegs should be waxed when used for storing honey. Before waxing any keg or barrel it should be kept in a dry, hot room, or out in the sunshine on hot days for two or three weeks till it is thoroughly dried out. In other words, the barrel should be as dry as it is possible to make it, or for it ever to become, at the time of waxing.

Having it thus dry and warm, the hoops should be driven as tight as possible, and short nails, or those broken off so they will not reach through into the inside of the barrel, driven a foot or so from each other at the rear of the last hoop, so that the hoops shall not get loosened or misplaced in handling.

Now pour in, at the bung-hole, from five to ten pounds of very hot, melted wax, or, what is much more preferable, paraffine, and quickly drive in the bung. Now, turn the barrel over and over, and twirl it around on each end till you are sure all cracks are filled. Then take out the bung, pour out the wax, and heat it over again for the next.

The reason for having everything as hot as possible is, that the hotter the wax the more it penetrates the wood, and also so as to use as little wax as possible, as the waxing of kegs and barrels is quite costly at best.

It may sound a little strange to talk about saving wax by having it soak into the wood, but far less is used in this way than where everything is cooler so that a coating is taken on all over the inside of the barrel, with not nearly so good a job being done, either.

In removing the bung be careful to see that it does not strike you when it flies out, as the heated air sends it out with great force, sometimes.

Now, having told how to wax barrels, allow me to ask, in answering the latter part of the query, why not use those made of soft wood, which need no waxing, providing the cooperage is good? Leaky kegs and barrels can never be made entirely safe by waxing them. The shrinking and swelling of the wood, as exposed to wet and dry, will sooner or later break the wax, and sometimes a heavy jar in handling something so heavy as a barrel of honey will often crack the wax, especially if the weather is somewhat cold, and start the honey to leaking. Good workmen with soft timber can make tight vessels, and they cost no more than leaky ones. A keg or barrel properly made of the right kind of wood needs no waxing, so this expense is saved.

And in conclusion I will say that I prefer properly-jacketed tin cans to anything else for either storing or shipping honey.
Onondaga Co., N. Y.

Our Wood Binder (or Holder) is made to take all the copies of the American Bee Journal for a year. It is sent by mail for 20 cents. Full directions accompany. The Bee Journals can be inserted as soon as they are received, and thus preserved for future reference. Upon receipt of \$1.00 for your Bee Journal subscription *a full year in advance*, we will mail you a Wood Binder free—if you will mention it

Queenie Jeanette is the title of a pretty song in sheet music size, written by J. C. Wallenmeyer, a musical bee-keeper. The regular price is 40 cents, but to close out the copies we have left, we will mail them at 20 cents each, as long as they last.

* The Afterthought. *

The "Old Reliable" seen through New and Unreliable Glasses.
By E. E. HASTY, Sta. B Rural, Toledo, O.

WHEN TO CUT ALFALFA.

A story of the bear and the fiddle, begun and left off before it got to the middle, we find on page 595. We'd like to know how those four bunches of steers weighed up. Then we would have something to set before the alfalfa-raising neighbor who proposes to cut it all before it gets to blooming. Howsomever, it's not always wise for manifestly interested parties to reason with a farmer—might make him learn still more t'other way—some men being so got up.

BEE BUILDING QUEEN-CELLS.

Mr. H. H. Hyde, of the Texans, removes a film, if not a hide, from my eyes by what he says of starting bees to building cells, on page 596. Mr. Aten (as most of us would have done, I surmise) made his bees queenless and broodless at night, and gave them the wherewith to rear queens in the morning. Mr. Hyde claims that their first and best enthusiasm to replace their loss is on in only two or three hours; that at that time they will have work begun and royal jelly visible in half an hour after the needful start is given them. Wonderful, isn't it? If this is correct, of course dilatoriness causes a double loss, loss of hours, and loss in the amount of work done each hour. But may this not be another case of "sometimes"—sometimes ready to do the best kind of work in two hours, and sometimes inclined to rush around and neglect the young larvæ given them for many hours? (Didn't think to notify *professional* queen breeders that they might skip this paragraph. Now, they've gone and read it, they may skip with wrath if they want to—yes, sir, they may.)

KEEPING A COLONY ON SCALES.

I'm ferocious at that fellow on page 597, who asked, Does it pay to keep a colony on scales? Did he contemplate the queen as coming out with a couple of nickels and paying the weigh-master. Apparently his question was simply a *plea*—a plea against investigation and study. Some people are so constituted that knowledge kind o' hurts 'em. Anxious to keep clear of it as far as possible. They do not tell us what then it is which they expect to put into that great emptiness—that great emptiness which they actually want us to call a brain. It may be that some such persons actually gain in dollars by exactly that course—refusal to see anything else but the paths which visibly lead to the dollar. Sorry. As a piece of my mind, however, two of them lose dollars and sense both for each one who gains dollars by the sacrifice of sense. The man who has a fund of general knowledge in his knowledge-box is the man more likely to succeed, I think—not to speak of its being more enjoyable to know a few things. We don't want to forget entirely that man was made in the image of God. How would it sound to inquire whether it pays God to keep a *world* on the scales? See Isaiah 40:12, and Job 28:25.

MISS WILSON'S SMOKER-FUEL.

Yes, Miss Emma Wilson, if you start with nice, industrious coals (more lazy coals you get the worse you are off), but get the right quantity of industrious coals, put on fine, dry-chip fuel, and "blow it up good," and you have "got there" for the time being. But, strange to say, I incline to turn my aft-think-atorial smoker on the whole proceeding and "blow it up good." What's the use of those of us who live in the country makeshifting along with anything else than the standard good fuel—rotten wood? I know woodlands are getting small and few, and that the superabundance of rotten wood to be found anywhere no longer surrounds the most of us. What then? Just "watch out" a little, and keep the subject on your mind, and seasonable supplies will turn up, if you seize them when they do turn up. Every stump is wood, and sooner or later will be rotten wood.

As to their decay, most of the thousand and one kinds of tree seem to fall in two grand divisions. The rotten wood of one division is ash-colored, soft, and breaks up as a mass of fiber. The other kind is brown, hard, and its fracture rudely approximates to cubical blocks. The first

kind catches instantly from a match, and smokes splendidly, but burns out rather too fast. Second kind lasts pretty well, but is sometimes a little hard to start with a match alone. Keep a supply of both kinds, well dried, and mix them according to wind and weather—and thereby forget that the smoker is the plague of one's life. Of course, you can stay in the wilderness if you want to. Saltpeter can save you (in the form of saltpetered rags), but wherefore? A zinc oiler full of kerosene will start you off; but is it the best one can do? Throw the saltpeter and the kerosene where some literary worthy was going to throw physic—to the dogs. Page 598.

COLLECTING BEE-LAWS.

To have all the laws relative to bees collected together apart from the bewildering mass of the laws in general is a good idea. Page 599.

Questions and Answers.

CONDUCTED BY

DR. C. O. MILLER, Marengo, Ill.

(The Questions may be mailed to the Bee Journal office, or to Dr. Miller direct, when he will answer them here. Please do not ask the Doctor to send answers by mail.—EDITOR.)

Making an Observation Hive.

Please describe the best observation hive to one who wishes to study scientifically the workings of the bees. I have built a glass hive, and then removed the brood-frames with bees from a regulation hive; but then I can only observe the comb formation on the outside frames.

IOWA.

In some respects the ordinary hive is the best observation hive, for in that the bees are not prevented from carrying on their regular work in the ordinary way. What you desire, however, is a hive that will allow you to see what the bees are doing without being obliged to lift the frames out of the hive. The hive you have made allows you to see only one side of each outside comb, so the thing to do is to have none but one outside comb: in other words, make your hive for one comb only.

Keeping Robbed-Out Combs During Winter.

Will the bees winter just as well if I set a hive with combs that have been robbed out, under their hive, taking the bottom-board from between? I wish to do this to keep the combs from the moths; and then I am planning to keep them there until they have enough brood in the lower hive to make a colony, then set them off. It is all because I feel so badly because my bees robbed out 12 colonies out of 32 that a neighbor brought to me to take care of (on shares), as circumstances prevented her caring for them herself. The combs are in such shape that they cannot be lifted without more trouble and expense than I can give them.

COLORADO.

ANSWER.—Your plan will work, but you need not feel obliged to keep the combs in the care of the bees all winter in order to protect them from the moth. It will soon be so cold that there will be no danger from moths laying eggs, and even if larvae of the moth should be present they will do little or no harm in cool weather. As soon as freezing weather comes, the freezing will destroy both larvae and eggs, and there will be no more danger until it is warm enough next summer for fresh eggs to be laid by moths.

Black Honey Gathered by Bees.

"Massachusetts" says his bees stored a liquid nearly black, after August 1, and asked if it might not be gathered from huckleberries or blackberries, and you reply perhaps his guess is as good as any. If "Massachusetts" had noticed his bees closely in the morning, while the dew was on the flowers, and the goldenrod was so wet that the bees were not working on the flowers at all, he would have found them hustling about as if they were robbing. That was the

way mine were doing, and I started out to discover the source of their supply. When I neared the oak-trees I could hear their busy hum and see them alighting on the leaves, which were covered in places with a sticky, shiny substance that the bees were gathering. One colony that I had standing on scales, gathered 12½ pounds in one day—not all from the oaks but part from goldenrod; and now as I open the hives I find nearly all the hive with a mixture of the two kinds of sweets, tasting strongly of goldenrod, but not salable, it is so dark and inky.

Several years ago I had one colony gather some 60 pounds almost black and very inferior to the honey this fall. The colony I had on the scales has gained about 50 pounds during the goldenrod flow; never but one year since 1856 have I had a colony store more during the fall flow.

NEW HAMPSHIRE.

ANSWER.—Whether the chief yield was from the goldenrod or honey-dew from the oak, is left a little in the dark. Goldenrod seems to be one of the most variable honey-yielders. It is very abundant in this region, but bees never seem to work upon it.

Transferring and Dividing—Finding the Queen.

1. I have 3 colonies of bees, one being in a square hive, and they are always building crooked combs. The bees are numerous, for one swarm returned after a short while. When would it be best to transfer them?

2. Could they be divided into two colonies?

3. How can I catch the queen for re-queening? I am a beginner and have read about re-queening but nowhere have I read about how to find the queen. The frames in my hive are firmly glued in.

MINNESOTA.

1. Better wait until next spring or summer.

2. Yes. Perhaps the best way to do that, and likely the best way anyhow, is to wait till the bees swarm next summer, giving the swarm in a hive with movable frames, and then transferring the remainder about three weeks after the issuing of the swarm. In the meantime read up well in your text-book, so as to be well informed on general principles.

3. Most of the catching of queens is done by simply putting the thumb and finger down over the queen, pressing her lightly on the comb, then letting the thumb and finger slide together over the back of the queen, and holding firmly the wings. A wire cage may also be placed over her, removing the cage when she runs up into it. If your object is to clip the queen, you might like the Monette clipping device.

Learning Bee-Keeping—Florida vs. Pennsylvania.

1. To a woman contemplating bee-keeping would it be to her interest to help a bee-keeper, for the experience she would receive?

2. Are there bee-keepers who would want help of that kind, if she were willing to give her time for the experience?

3. Is it more profitable to keep bees in Florida than in Pennsylvania?

FLORIDA.

ANSWERS.—1. Yes, it would be to her interest so to do: spending a short time at it if she expects to keep bees on a small scale, and a longer time proportionately if she expected to do more at the business.

2. Yes, some bee-keepers employ such help every year. Watch for their advertisements, or else put in a short advertisement yourself.

3. I don't know. Some bee-keepers in Pennsylvania do better than some bee-keepers in Florida, and vice versa. In general terms, it probably might be said that the opportunities for successful bee-keeping on a large scale were better in Florida than in Pennsylvania.

Please send us Names of Bee-Keepers who do not now get the American Bee Journal, and we will send them sample copies. Then you can very likely afterward get them subscriptions, for which work we offer valuable premiums in nearly every number of this journal. You can aid much by sending in the names and addresses when writing us on other matters.

The Premiums offered this week are well worth working for. Look at them.

BEE-KEEPERS--ATTENTION.

Do not put your money into New Fangled Bee-Hives, but buy a plain, serviceable and well-made hive, such as the regular Dovetailed hive arranged for bee-way sections. Honey-producers of Colorado—one of the largest honey-producing sections in the world—use this style.

GENERAL ITEMS

A Young Bee-Keepers' Report.

I am a beginner in the bee-keeping business. I have 4 colonies. The first part of the season of 1902 was cold and rainy, and I had to feed them. The fall was very poor, and they produced only 25 pounds of honey per colony; one colony alone filled three supers. I will have more to say some other time. I am but 16 years old.

WM. COVERDALE.
Jackson Co., Iowa, Oct. 10.

Had to Feed for Winter.

There has not been any frost here this fall, and catnip, white clover, and dandelions are still in bloom. My bees did not store enough honey to winter on, so I fed sugar syrup.

FRANK KITTINGER.
Racine Co., Wis., Oct. 13.

Worst Season for Bees.

I have kept bees for 25 years, and find that the past season has been the worst one for bees, in this locality, I have seen.

Last spring I had 21 colonies. I fed them \$3 worth of sugar to stimulate them, and it just kept them from starving. Two colonies did starve before I noticed them.

I got no swarms, but caught two that had been driven out by some cause; they had come some distance, as there are no bees within five miles of this village. I had to double them up or they would have starved, although they were large swarms.

My bees hung out all summer, and they seemed to do but little good. There was so much rain and cold wind they could not do much, and it continued cold all through June and until July 25, when it cleared up and turned warm. The smartweed bloomed in abundance with the catnip, and they went to work with a will—they were all on the move. It lasted only 10 or 12 days; the weather got colder, and a light frost coming set them back and drove them down from the sections. If they could have had ten days more of good weather they would have filled everything, but as it is some of the sections were filled. I think they are in good shape to winter; the hives are heavy with stores.

S. T. CRIM.
Sangamon Co., Ill., Oct. 10.

Clipping Queens—Moving Bees.

Referring to the editorial on page 643, on clipping devices, I will say that I use a pair of surgeon's scissors (or finger-nail scissors) for clipping queens' wings. The points curve, and by holding them with the points curving up, the wing can be clipped easily without removing the queen from the comb, and without the least danger of injury to her legs. I never hesitate to pick her up, and have never had one injured by so doing. I have always carried a pair of scissors since I was a boy. I have a pair that shut up like a knife. I could

PERSONAL TO SUBSCRIBERS

WE WILL SEND to every subscriber or reader of the American Bee Journal a full-sized ONE DOLLAR package of VIT-E-ORE, by mail, POSTPAID, sufficient for one month's treatment, to be paid for within 1 month's time after receipt. If the receiver can truthfully say that its use has done him or her more good than all the drugs and doses of quacks or good doctors or patent medicines he or she has ever used, READ this over again carefully, and understand that we ask our pay only when it has done you good, and not before. We take all the risk; you have nothing to lose. If it does not benefit you, you pay us nothing. VIT-E-ORE is a natural, hard, adamantine rock-like substance—inherent—ORE—mined from the ground like gold and silver, and requires about 20 years for oxidation. It contains free iron, free sulphur and magnesium, and one package will equal in medicinal strength and curative value 800 gallons of the most powerful, efficacious mineral water, drunk fresh at the springs. It is a geological discovery, to which there is nothing added or taken from. It is the marvel of the century for curing such diseases as Rheumatism, Bright's Disease, Blood Poisoning, Heart Trouble, Diphtheria, Catarrh and Throat Affections, Liver, Kidney and Bladder Ailments, Stomach and Female Disorders, La Grippe, Malarial Fever, Nervous Prostration and General Debility, as thousands testify, and no one, answering this, writing for a package, will deny after using. Give age, ill, and sex.

This offer will challenge the attention and consideration, and afterward the gratitude of every living person who desires better health, or who suffers pains, ills and diseases which have defied the medical world and grown worse with age. We care not for your skepticism, but ask only your investigation, and at our expense, regardless of what ills you have, by sending to us for a package. You must not write on a postal card. In answer to this, address:

THEO. NOEL COMPANY, Dept. J. P., 527, 529, 531 W. North Ave., CHICAGO, ILL.

Please mention Bee Journal when writing.

not think of cutting a queen's wing with a knife, as I have seen recommended, by holding the wing on the corner of the hive, and sawing it off by drawing the knife across it. I would as soon think of taking a hatchet and chopping-block.

I notice another item on the same page, respecting moving bees a short distance and none going back. Here is a little experience of my own:

Last spring (March 25) I moved my whole apiary about 130 rods, finishing up about noon. After dinner I opened up the whole 47 hives; the air was full of bees, as though they were swarming; there was no robbing, no fighting, but not a bee went back to the old location. They had been flying for the last two days before moving, so it was not as if they had been confined to their hive and had forgotten their old location. There was not a single device adopted to cause them to mark their new location, unless it be that they were put on the stands without the least regard to their former relative position.

WM. M. WHITNEY.

Walworth Co., Wis., Sept. 15.

An Aster.

Find enclosed a sample flower from which the bees gather honey and pollen. It begins to bloom about the first of September, and continues until frost. Please tell me the name of the plant.

GEORGE OSHA, JR.

Davies Co., Ind., Sept. 26.

[The plant is an aster—*Aster puniceus*, and is a good honey-plant, as are nearly all the asters, and the whole composite family, to which the aster belongs.—C. L. WALTON.]

But Little Surplus Honey.

There was very little surplus honey in this locality, and some are losing colonies from starvation. I understand that some beekeepers have not taken off an ounce of honey.

Mrs. C. A. BALL.

Oneida Co., N. Y., Oct. 15.

Wet Summer—Report for 1902.

The season for honey is over, and I have cleaned up and have the bees ready for winter. This has been the wettest summer. We got no fall honey to speak of. I started in the spring with 45 colonies, and I did my best to hold them back from swarming, and partly succeeded, but I got several late swarms, increasing to 75 colonies. I got 1440 sections of basswood honey completed, and about 700 partly filled and partly sealed. I extracted them and saved the sections for next year. I think it pays better than to try to finish them out by feeding, and I will not feed sugar, as I have a reputation for having pure honey, and sell it all in my own town. I sell those that weigh 11 to 13 ounces at two for 25 cents. I peddle them out all over town, and have built up a taste and demand for honey. I sell the others to the groceries for 13 cents cash, and 15 cents in trade, so I have disposed of all my honey except about 400 pounds of extracted. I "took up" all the light colonies I had and extracted the honey out of them. I have now 46 colonies in good shape for winter.

The Emerson Binder

This Emerson stiff-board Binder with cloth back for the American Bee Journal we mail for but 60 cents; or we will send it with the Bee Journal for one year—both for only \$1.40. It is a fine thing to preserve the copies of the Journal as fast as they are received. If you have this "Emerson" no further binding is necessary.

GEORGE W. YORK & CO.,

144 & 146 Erie Street, CHICAGO, ILL.

We have quite a lot of sweet clover around town and some cutnip.

I believe in strong colonies. The last of June I had several swarms issue at the same time, and two or three of them went together. I lived them, and weighed one that weighed 9½ pounds. I had to put on three supers before they could all get in, and they filled them in two weeks. When I have a swarm, in a day or two I take about four frames of brood from the old colony and put it in the new hive, and that insures keeping up the strength of the colony until they can have young bees of their own rearing. I aim to keep the drones down to the minimum.

I use the simplest hive I ever saw. It is 14x19 outside; 9½ deep inside; top-bar 18 inches; super, 14x19 outside, 17¼ x 14¼ inside; 4½ deep, with tins across. It holds 28 sections, 7 to the foot. So you see I do not have a lot of trappings to look after. It is the outcome of 20 years' experience, and it suits me. It is simple and practical. I prefer basswood frames to pine, some critics notwithstanding. WM. CLEARY.

Kossuth Co., Iowa, Oct. 6.

Cleaning Unfinished Sections.

At this time of year it will be convenient to try a plan that has been given heretofore, and is thus given in American Bee-Keeper:

Take a hive-body and fill full of such sections or combs as you wish to have cleaned out. Carry one section to a colony that needs feeding and place it inside of the hive for a few moments. When well covered with bees take it back to the hive prepared before, which should be a short distance from the apiary. You will thus start a case of robbing. Adjust cover bee-tight and contract the entrance so that but one or two bees can go in at a time. It is said that the robbing bees will protect the robbed hive against other bees as they would their own. One colony might, in this manner, be utilized to clean out a good many sections, or a number of colonies might be set at work at one time, each one having their own feeding ground. The thing looks almost incredulous; we will try it next year.

Strong Colonies for Winter.

I cannot get a colony too strong in numbers for winter, for, given plenty of bees, there is plenty of warmth, and plenty of warmth means less consumption of honey. If the bees are much reduced in numbers they become consumers of honey to generate heat. I think it is less expensive in stores to winter and spring a strong colony than a weak one. There is certainly much less risk in wintering a strong colony than a weak one.—Editorial in the Australasian Bee-Keeper.

Foundation Versus Drawn Combs.

G. M. Doolittle has little sympathy with the idea that foundation is preferable to drawn combs. He says in the Progressive Bee-Keeper:

And this poor season has shown that some surplus honey can be obtained where we have combs to give the bees, when little or none could be obtained where the surplus arrangement was filled with foundation instead of comb. Colonies having combs gave from 10 to 20 pounds of honey, while those having frames of foundation did not even draw out the same, say nothing of giving out surplus. And where sections were used, those having "baits" in were filled and finished so as to be in marketable shape, while those having only full sheets of foundation remained untouched. And yet there are those among our number who would have us believe that it is to the bee-keeper's advantage to cut the combs out of

Prof. Cook's Bee-Keeper's Guide

Or, Manual of the Apiary.

PROF. A. J. COOK.

Price,
Postpaid,
\$1.20

Price,
Postpaid,
\$1.20

This standard work on practical bee-keeping has just been thoroughly revised and brought down to date. About 100 pages and nearly 100 illustrations have been added, which makes it now a superb volume of 544 pages, with 295 fine illustrations. It is printed on clear white paper, and is bound in elegant brown cloth, gold-lettered.

Prof. Cook has been one of the leading contributors to the American Bee Journal for a quarter of a century. He is well known to bee-keepers everywhere. He is an authority on bees and related subjects. His book has had a large sale, which now bids fair to increase greatly.

In order that every reader of the American Bee Journal, who does not already possess a copy of Prof. Cook's work, may have it, we wish to make the following

FOUR LIBERAL OFFERS:

No. 1.—For \$1.75 we will mail the American Bee Journal one year and a copy of Prof. Cook's book.

No. 2.—Any one of our present subscribers whose subscription is now paid in advance, can have a copy of Prof. Cook's book mailed to him free as a premium for sending us two new subscribers to the American Bee Journal for a year (with \$2.00.)

No. 3.—Or, send one new subscriber for a year (at \$1.00) and 50 cents more (\$1.50 in all,) and we will mail to YOU a copy of the book and will send the American Bee Journal for one year to the new subscriber.

No. 4.—For \$1.00 we will send Prof. Cook's book by express or freight with other goods; or, if called for at our office, the price is \$1.00. But the post-paid price of the book alone is \$1.20.

Please remember that offers Nos. 2 and 3 of the above are made to those who are now subscribers to the American Bee Journal, and whose subscriptions are paid in advance. Offers Nos. 1 and 4 are made to any one who desires to take advantage of them.

Address all orders to the publishers,

these partly filled sections, run the same through the sun wax-extractor so as to separate the honey from the wax, and burn the sections, that we have the privilege of using new sections filled with foundation when working for section honey. Will it be too strong language if I say: "Away with such nonsense?" I should hardly have gotten a single section filled up to this time (August 5) had it not been for these partly-filled sections or baits, left over from last year. As it is, it looks as if I should be able soon to take off from 400 to 500 pounds of the same before buckwheat commences to yield nectar.

Then drawn combs have a value in helping to control swarming, as many of the colonies having such combs did not swarm at all, in this year of excessive swarming during July, when the bees secured just enough honey to keep up a large amount of brood, but not enough to do much storing or to start them to drawing out foundation.

Wax-Presses.

There are a great many inquiries as to which is most convenient, rapid and thorough—pressure under hot water, pressure in steam, or pressure on wax that has been heated in another vessel. With hot water one can get the same amount of wax as with steam, other things being equal; but it takes longer, and is more complicated. It has been suggested that the hot water will do better work than steam because of the fact that, since wax floats on water, the minute that a particle of wax is pressed out from the cheese-cloth it will rise to the surface out of the way—acting on the principle of "taking in the slack." Those who suggested this, however, had not tried both plans, and admitted that the idea was a simple theory. If they would try they would find, as we have done, that the wax will drop down from the slungum when steam is used, just as readily as it will float up in the hot water.

We have not had success with the third method, although some may have had. It is very difficult to keep the wax from burning when heated in another place unless it is heated in hot water. If this is done, part of the wax will melt out and come to the surface, just enough of it to cause trouble, and yet too much to throw away entirely. After burning one's fingers in getting the hot wax transferred from the heating-pan to the press, a great deal of heat will be lost; and when the wax comes in contact with the cold press it is so chilled that not all of it can come out; and what does come, often sticks to the cheese-cloth, and refuses to run.—An Editorial in *Gleanings in Bee-Culture*.

Management for Comb Honey.

"How One Man Managed 500 Colonies for Comb Honey in Out-Apiaries" is the title of a paper by W. Z. Hutchinson, reported in the Canadian Bee Journal as read at the Ontario convention. Chas. Koepfen was the man in question, his management being as follows:

In the spring the bees are looked over, stores equalized, and all extra combs removed, the bees being crowded up on as few combs as possible. When the packing is removed, each alternate hive is moved ahead a little way, and the other hives moved back a little, and then in a few days the distances are increased until the hives are sufficiently scattered. As soon as the bees are crowded for room the combs are spread, and empty combs are put in the center. This is usually done for the first time just before the harvest from white clover. A week or ten days later the colonies are again gone over, and the combs of sealed brood in the center shifted to the outside; the outside combs, that are largely filled with honey, being moved to the center of the brood-nest. At the opening of the basswood flow the brood-nests are again overhauled, and this shifting process gone through with; but, in many instances, in fact in most instances, that is, if the colony is strong enough, two combs of bees and brood are taken away and used in starting a nucleus, their places in the centre of the brood-nest being filled with empty combs. Each nucleus is furnished with a queen-cell,

plenty of which will be found in overhauling the colonies. The empty combs that are placed in the center of the brood-nest at the last overhauling, are usually filled, to a great extent, with honey; but as the flow begins to slack up, the honey will be removed and used in filling what sections may be on the hives. It is astonishing how a colony so treated will go on finishing up the sections after the flow from basswood is over.

With this management there is very little swarming, and as the queens are clipped, the swarm always returns, and usually the queen gets back into her own hive. If she does not, the fact is shown at the next examination. Mr. Koeppen says that if he can get around and examine each colony as often as once a week there is practically no swarming. Upon reaching an apiary, if there is not time to go over the whole number of colonies, the strongest ones are selected for that purpose.

Watermelons for Bees.

At the Ontario convention the question was offered, "Has any one got watermelon honey?" The following is part of the discussion:

Mr. Fixter—They will work on watermelon all right if there is an opening made for them. When they are testing watermelons at the experimental farm they have to get inside a building that the bees won't crowd around them.

Mr. Tender—That is a bad thing for bees. With me, they went up to work and filled up everything where the brood that has been hatched was, with watermelon honey, and, of course, the consequence was I didn't know anything about it. This was in the center all the time and the sealed comb honey was on the outside; and when I came to look at them this spring I found I had lost 16 colonies with diarrhea. Mr. Armstrong came along and said that was what was wrong.

CONVENTION NOTICE.

Chicago - Northwestern. — The executive committee of the Chicago-Northwestern Beekeepers' Association have planned to hold the best convention ever convened in Chicago. The date is Dec. 3d and 4th, Wednesday and Thursday. Five eminent bee-keepers have been invited, and are expected to attend. More definite announcement later. Watch for it. Reduced rates on account of the fat stock show, which is held Nov. 29th to Dec. 6th

"What Happened to Ted"

BY ISABELLE HORTON.

This is a true story of the poor and unfortunate in city life. Miss Horton, the author, is a deaconess whose experiences among the city poverty stricken are both interesting and sad. This particular short story—60 pages, 5x6 1/2 inches, bound in paper cover—gives somewhat of an insight into a little of the hard lot of the poor. Price, postpaid, only 10 cents (stamps or silver.) Address,

ISABELLE HORTON,
227 EAST OHIO STREET, CHICAGO, ILL.

**Langstroth on...
The Honey-Bee**

Revised by Dadant—1900 Edition.

This is one of the standard books on bee-culture, and ought to be in the library of every bee-keeper. It is bound substantially in cloth, and contains over 500 pages, being revised by those large, practical bee-keepers, so well-known to all the readers of the American Bee Journal—Chas. Dadant & Son. Each subject is clearly and thoroughly explained, so that by following the instructions of this book one cannot fail to be wonderfully helped on the way to success with bees.

The book we mail for \$1.25, or club it with the American Bee Journal for one year—both for \$1.75; or, we will mail it as a premium for sending us THREE NEW subscribers to the Bee Journal for one year, with \$3.00.

This is a splendid chance to get a grand bee-book for a very little money or work.

The Page Fence Co.—In a recent letter from the Page Woven Wire Fence Co., of Adrian, Mich., they say:

"We were never so well equipped as at present to furnish Page Fences. Having our own steel, rod and wire mills, and having largely increased our weaving capacity; with about 1400 employes on our pay-roll, converting the iron into high-carbon steel, the steel into ingots, blooms, billets, rods and wire, and with double the number of looms that we had Jan. 1, 1900, we feel that we are in pretty good shape to supply the demand for 1903.

"We make a standard style of fencing for every farm, poultry, stock or railroad requirement; use double-strength wires in all these styles, coil or spiral every one of them from end to end the whole length of the fence, thus providing for expansion and contraction, and Page Wire will retain this coiled shape even after it has been drawn out a thousand times.

"No locks, staples, or other devices are used to hold the horizontals and cross-bars together, because Page Fence is a real woven wire fence. Horizontals and cross-bars woven together is all there is of it."

Their advertisement appears regularly in our columns, and if you have not investigated the merits of their fencing, you should write for catalog, descriptive matter and prices now. Address as above, and be sure to mention the American Bee Journal when writing them.

HONEY AND BEESWAX
MARKET QUOTATIONS.

CHICAGO, Oct. 9.—The advance noted in our last quotation has been maintained and there is a very good demand for honey at the present time. No. 1 fancy white comb brings 15 1/2 @ 16c per pound, with the lower grades selling at from 2 and 3 cents less; this includes the light amber. Dark grades of amber sell at about 10 1/2 @ 11c, and buckwheat 9 1/2 @ 10c. Extracted is steady with white bringing 6 1/2 @ 8c, according to color, flavor and quality; the amber brings from 6 @ 7c; dark, 5 1/2 @ 6c. Beeswax in good demand at 30c.
R. A. BURNETT & CO.

ALBANY, N. Y., Oct. 14.—Honey is selling well with no accumulation. We quote: White fancy comb, 16c; A No. 1, 15c; No. 1, 14c; mixed, 13c; buckwheat, at 13 @ 13 1/2c. Extracted, white, 7 @ 7 1/2c; mixed, 6 @ 6 1/2c; dark, 5 1/2 @ 6c. Beeswax, 28 @ 30c.
H. R. WRIGHT.

KANSAS CITY, Oct. 11.—The demand for both comb and extracted honey is good, especially comb, at the quotations. We quote fancy white comb, 14 @ 14 1/2c; No. 1 white, 13 1/2 @ 14c; No. 2 white and amber, 13 @ 13 1/2c. White extracted, 6 1/2 @ 7c; amber extracted, 6 @ 6 1/2c. Beeswax, 22 @ 25c.
C. C. CLEMONS & CO.

CINCINNATI, Oct. 4.—The demand for extracted honey is good at the following prices: Southern and amber sells at 5 1/2 @ 6 1/2c; better grades, 7 @ 8c. Comb honey is scarce; fancy and No. 1 sells on arrival at 16 @ 17c. Beeswax weak at 28c.
THE FRED W. MUTH CO.

NEW YORK, Oct. 10.—We are having a good demand for comb honey and receipts are quite plentiful. We quote fancy white at 15c, and some exceptionally fine lots will bring from 15 1/2 @ 16c; No. 1, white, 13 @ 14c; amber, 12c.

Buckwheat is late arriving, and none has been on the market as yet to cut any figure. We expect large receipts next week, and it will sell at from 10 @ 12c, according to quality and style of package.

Extracted in fairly good demand at 7 1/2c for white, 6 1/2c for light amber, and 5 1/2 @ 6c for amber. Southern in barrels at from 55 @ 65c per gallon. Beeswax nominal at 28c.
HILDRETH & SEBELKEN.

CINCINNATI, Oct. 7.—Comb honey is in good demand, the supply is short and very little offered. No. 1 fancy water-white sells at 16c; other grades less, according to quality. The demand for extracted is very active and prices are a little better; amber sells for 5 1/2 @ 5 3/4c; alfalfa from 6 @ 6 1/2c; water-white white clover, 7 1/2 @ 8c. Beeswax, 30c.
C. H. W. WEBER.

SAN FRANCISCO, Oct. 8.—White comb honey, 12 @ 12 1/2c; amber, 8 @ 10c; dark, 7 @ 7 1/2c. Extracted, white, 5 1/2 @ 6c; light amber, 5 1/4 @ 5 1/2c; amber, 5 @ 5 1/2c. Beeswax, good to choice, light, 27 @ 29c; dark, 25 @ 26c.

Considering the limited quantities offering, and the firm views of holders, there is a fair amount of business doing. The firmness of the market, however, is confined principally to high grade stock. Offerings of water-white honey are of especially light proportions.

A Celluloid Queen-Button is a very pretty thing for a bee-keeper or honey-seller to wear on his coat-lapel. It often serves to introduce the subject of honey, and frequently leads to a sale.

NOTE.—One reader writes: "I have every reason to believe that it would be a very good idea for every bee-keeper to wear one [of the buttons] as it will cause people to ask questions about the busy bee, and many a conversation thus started would wind up with the sale of more or less honey; at any rate it would give the bee-keeper a superior opportunity to enlighten many a person in regard to honey and bees."

The picture shown herewith is a reproduction of a motto queen-button that we are furnishing to bee-keepers. It has a pin on the underside to fasten it.

Price, by mail, 6 cents; two for 10 cents, or 6 for 25 cents. Send all orders to the office of the American Bee Journal

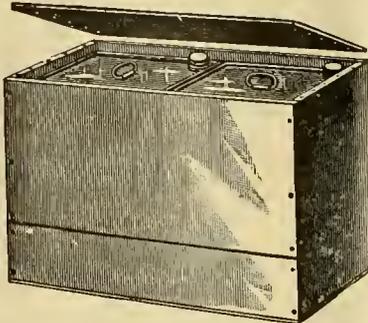

BEST
Extracted Honey For Sale

ALL IN 60-POUND TIN CANS.

Alfalfa Honey

This is the famous White Extracted Honey gathered in the great Alfalfa regions of the Central West. It is a splendid honey, and nearly everybody who cares to eat honey at all can't get enough of the Alfalfa extracted.

Basswood Honey

This is the well-known light-colored honey gathered from the rich, nectar-laden basswood blossoms. It has a stronger flavor than Alfalfa, and is preferred by those who like a distinct flavor in their honey.

Prices of Alfalfa or Basswood Honey:

A sample of either, by mail, 10 cents, to pay for package and postage. By freight—two 60-pound cans of Alfalfa, 9 cents per pound; 4 cans or more, 8½ cents a pound. Basswood Honey, ½ cent more per pound than Alfalfa prices. Cash must accompany each order. You can order half of each kind of honey, if you so desire. The cans are two in a box, and freight is not prepaid. Absolutely Pure Bees' Honey.

Order the Above Honey and then Sell It.

We would suggest that those bee-keepers who did not produce enough honey for their home demand this year, just order some of the above, and sell it. And others, who want to earn some money, can get this honey and work up a demand for it almost anywhere.

GEORGE W. YORK & CO., 144 & 146 Erie St., Chicago, Ill.

The Novelty Pocket-Knife.

Your Name and Address on one side—Three Bees on the other side,

[THIS CUT IS THE FULL SIZE OF THE KNIFE.]

Your Name on the Knife.—When ordering, be sure to say just what name and address you wish put on the Knife.

The Novelty Knife is indeed a novelty. The novelty lies in the handle. It is made beautifully of indestructible celluloid, which is as transparent as glass. Underneath the celluloid, on one side of the handle is placed the name and residence of the subscriber, and on the other side pictures of a Queen, Drone, and Worker, as shown here.

The Material entering into this celebrated knife is of the very best quality; the blades are hand-forged out of the very finest English razor-steel, and we warrant every blade. The bolsters are made of German silver, and will never rust or corrode. The rivets are hardened German silver wire; the linings are plate brass; the hack springs of Sheffield spring-steel, and the finish of the handle as described above. It will last a last-time, with proper usage.

Why Own the Novelty Knife? In case a good knife is lost, the chances are the owner will never recover it; but if the "Novelty" is lost, having name and address of owner, the finder will return it; otherwise to try to destroy the name and address, would destroy the knife. If traveling, and you meet with a serious accident, and are so fortunate as to have one of the "Novelities," your POCKET-KNIFE will serve as an identifier; and in case of death, your relatives will at once be notified of the accident.

How appropriate this knife is for a present! What more lasting memento could a mother give to a son, a wife to a husband, a sister to a brother, or a lady to a gentleman, the knife having the name of the recipient on one side?

The accompanying cut gives a faint idea, but cannot fully convey an exact representation of this beautiful knife, as the "Novelty" must be seen to be appreciated.

How to Get this Valuable Knife.—We send it postpaid for \$1.25, or give it as a Premium to the one sending us THREE NEW SUBSCRIBERS to the Bee Journal (with \$3.00.) We will club the Novelty Knife and the Bee Journal for one year, both for \$1.90.

GEORGE W. YORK & CO.

Chicago, Ill.

Please allow about two weeks for your knife order to be filled.

ESTABLISHED IN 1861

AMERICAN

THE OLDEST BEE-PAPER IN AMERICA

BEE JOURNAL

42d YEAR.

CHICAGO, ILL., OCT. 30, 1902.

No. 44.

* Editorial Comments. *

White Clover for Next Year seems all right, at least in northern Illinois. Never before, perhaps, has there been a stronger growth of white clover in October than at the present time. Its very luxuriance will help to protect it against a severe winter, the dense foliage forming a close covering, and the corresponding strength of root will also be a help. Bee-keepers are a hopeful lot, and they will at least enjoy the prospect throughout the winter, even if the winter should be so severe as to kill out all the clover. But that is not likely to occur.

The Weather has been exceptionally favorable of late, giving every opportunity to have the bees get into good shape for winter. This very favorableness, however, will in some cases act unfavorably, for there are some who will see no immediate need for action so long as the weather is so fine, and so the little things needed will be put off. Let all such remember that fall weather is well along, and almost any day may close up our beautiful days and nights, so it is wise to be provided against whatever may happen. If you did not see that your bees were well stocked with provisions in September, see to it at once that the delay be no longer continued. Each day longer is one day worse.

Building Combs to Separators.—G. M. Doolittle writes very fully upon this subject in *Gleanings in Bee-Culture*. To avoid having the bees build the comb of sections to the separators, he advises having the hives carefully leveled with a spirit-level, at least in the direction in which the combs run in the sections; to see that the starters are thoroughly fastened so that one of the corners can not drop down; to make sure that the starters are true in the sections, preferably using full sheets as starters; to avoid giving sections to colonies too weak to occupy them fully; and to avoid putting sections on too early, or leaving them on too long at any time when the bees are not storing.

To all this Mr. Doolittle might profitably have added that those who use bottom starters and fill the sections with foundation will not be likely to have combs built to separators, no matter what the other conditions may be.

Nomenclature of Forced Swarms.—Of late the plan of anticipating swarming by reducing a colony to the condition of a swarm before it has actually reached the swarming point has received much attention, especially in *Gleanings in Bee-Culture*. Editor Root classes it as an important discovery, although he does not claim there is anything new about it, for years ago it was given to the public by the late German leader, C. H. J. Gravenhorst. From the number that have been practicing the plan, it seems probable

that others besides Mr. Gravenhorst have struck upon it independently, for it is a thing that would naturally suggest itself.

Just what should be the right name for a swarm thus made seems a matter not entirely settled. Mr. Gravenhorst called it a "fegling," a German word that might be translated "brushling," or a "brushed swarm," and "brushed swarm" has been the term used in this country to some extent. Editor Root, however, used the term "shook swarm," and the term has been used to such an extent that it is likely to stick. Deference to Mr. Gravenhorst would suggest the propriety of following his example by using the term "brushed swarm," but those in this country who have used the plan do a good deal more shaking than brushing in removing the bees; so it seems more appropriate that the name should be one suggestive of shaking rather than brushing.

There can hardly be any objection raised to the term "shook swarm," except that it is very bad English, and on this account Dr. Miller has protested against it very earnestly, saying that when one shakes anything that thing is shaken, and so a swarm that is made by shaking should be called a "shaken" swarm. To this Mr. Root replies that the word "shook," to his mind, has a stronger meaning than the word "shaken." It seems a little strange that so well-informed a man as Mr. Root should make an idiosyncrasy of his own mind a sufficient reason for using a term that grates harshly upon the ears of others, and it is likely that he has had some feeling of the kind, for in the last number of *Gleanings* he shows a disposition to desert the term "shook," saying:

"I would suggest that we use the word 'forced' swarms, for that will describe either shook or brushed swarms, and avoid at the same time the ungrammatical adjective 'shook.' When we get the bees out of the hive by any of the processes named we *force* them out—we *make* them swarm, and if reports are to be believed, we make them think that they have actually swarmed, and that, therefore, they must get down to business."

No one in this country has championed more earnestly than Mr. Root the plan of swarming in question, and whatever term he uses will be likely to be adopted by bee-keepers who use the English language. If he should continue the use of "shook swarms," Dr. Miller may content himself with the thought that this is one of the cases in which "might makes right"—eventually—and however bad it may sound to say "shook swarms," it will be good English when *every one* says it.

Age at Beginning of Field-Work.—M. Devauchelle says that most authors agree upon 15 days as the age at which bees begin to forage in the fields, but he has made experiments which show that bees can gather honey at 8 days old and pollen at 10. These, however, he considers as only special cases which do not disprove the rule.

In this country the general agreement seems to be 16 rather than 15 days as the age at which worker-bees begin

to work in the field; but it seems pretty certain that under stress of circumstances they may be forced to begin work at considerably less than 8 or 10 days of age. Only to give one well-authenticated instance:

For the sake of caution a valuable queen was put in a hive containing sealed brood, much of it just ready to emerge, but not a bee was left in the hive except the queen. The hive was placed over a strong colony, so as to receive the heat therefrom, but wire-cloth prevented the passage of any bee. The hive was kept closed bee-tight for 5 days, and then the entrance was opened, the hive being so placed that there was no danger of the entrance being confused with the other. On that day young bees were seen entering the hive with loads of pollen, showing clearly that when necessity requires a worker may gather pollen at 5 days of age.

* The Weekly Budget. *

MR. W. P. HOGARTY, of Wyandotte Co., Kans., who is an old soldier, called on us when on his way home from attending the G. A. R. encampment recently held in Washington, D. C.

W. Z. HUTCHINSON has been appointed Foul Brood Inspector for the State of Michigan, John M. Rankin, the former inspector, having secured a steadier and more profitable position with some business firm.

MRS. J. J. GLESSNER—one of the wealthy society ladies of Chicago—returned Oct. 11 from her summer home in the mountains of New Hampshire, where she has her bees. She had 7 colonies in the spring, and secured over 700 pounds of comb honey and about 160 pounds of extracted, besides increasing to 13 colonies. Of course, she keeps bees only for the pleasure it affords her. There are one thousand acres in their place, and no other bees near. Mrs. Glessner attended them personally this season, and enjoyed it immensely. There are a lot more society ladies that could do likewise, if they desired to add to their stock of pleasure and good health by useful outdoor exercise.

THE CHICAGO CONVENTION—Dec. 3 and 4—promises to be a regular hummer. If any bee-keeper within say 200 miles of Chicago doesn't attend, he (or she) is going to miss it. See what Secretary Moore has to say about it now:

THE NEXT CHICAGO CONVENTION.

There should be a very large attendance of lady and gentleman bee-keepers at the next meeting of the Chicago-Northwestern Bee-Keepers' Association to be held at the Briggs Hotel club room all day Wednesday and Thursday, Dec. 3 and 4, 1902. Six well-known bee-keepers are expected to be present.

E. T. Abbott says: "I thank you for the invitation, and will see if I can arrange my matters so I can attend."

C. P. Dadant says: "I shall be glad to accept the invitation unless unexpected circumstances prevent."

N. E. France says: "I will be there with drawings and samples of foul brood. I am always glad to speak to bee-keepers on this important subject."

Pres. W. Z. Hutchinson says: "It affords me pleasure to accept your invitation to be present at your coming convention. I will come prepared to address the convention on "Commercial Organization Among Bee-Keepers."

Dr. C. C. Miller says: "Providence permitting, I shall be with you at your annual meeting, Dec. 3 and 4."

Mr. E. R. Root says: "My brother Huber has been making a long series of experiments in melting up old combs under pressure. He will give a paper on 'Wax-Presses: Their Construction and Their Uses.' In case he can not come I will take his place. If I can get away perhaps both of us may come."

With all this talent we can have the best convention ever held in Chicago, if the 300 bee-keepers near by will also come and bring their wives and sisters.

HERMAN F. MOORE, Sec.

Wouldn't it be a joke on the National, if the Chicago convention should exceed the one held in Denver recently, both in size and interest? That is entirely possible. Many agree that Chicago is the best bee-keepers' convention city on this continent. It would not do for us to say that, but we can easily coincide with that opinion.

There is quite a little time yet before the Chicago convention meets, so that everybody can begin to plan to be here on Dec. 3 and 4. It is expected that all the railroads centering in Chicago will offer excursion rates at that time, on account of the International Live Stock Exposition that will be held here beginning Nov. 29 and continuing for a week or more. Ask your nearest railroad ticket agent concerning it, say about Nov. 25. He will know all about it by that time, if not sooner.

J. L. ANDERSON, of McHenry Co., Ill., gave us an exceedingly pleasant call on Tuesday, Oct. 21, when attending a meeting of the Presbyterian Synod in Chicago. Mr. Anderson is one of the oldest bee-keepers we know, and has been a reader of the American Bee Journal for over 30 years. And still he is well and happy! He has about 80 colonies of bees, but this has been a discouraging year for him, as he has taken only about 500 pounds of honey.

THE APIARY OF MR. J. J. DUFFACK is shown on this page. When sending us the picture he wrote as follows:

"My apiary contains 18 colonies of bees. They are in the resident part of the city, and so far I have not had any trouble with my neighbors concerning the bees.

"I commenced bee-keeping four years ago with one colony. My average yield of comb honey, for 1901, was 50 pounds per colony. My bees are wintered in a cellar specially built for them, in which they have done very nicely, as the temperature varies very little.

"You will notice that I did not have my picture taken with the bees, as I am not as good looking as the majority of the bee-keepers who appear with their bees."

APIARY OF J. J. DUFFACK, OF YANKTON CO., S. DAK.

Convention Proceedings.

THE DENVER CONVENTION.

Report of the Proceedings of the 33d Annual Convention of the National Bee-Keepers' Association, held in Denver, Col., on Wednesday, Thursday and Friday, Sept. 3, 4 and 5, 1902.

(Continued from page 679.)

THE GOVERNMENT AND THE ASSOCIATION.

Dr. Miller—Prof. Benton said he was ready to receive suggestions. I want to suggest one thing. I believe he can do not a little towards increasing the membership of this Association. I believe that in his letter-heads that he sends out if there were possibly a hint that there is such an Association, that would go to many a one who otherwise might never dream that there was such an Association. I merely throw out the hint for him to think about.

Prof. Benton—That calls to mind that particular point. You must understand, so far as the Department is concerned, nothing of the kind could appear in a letter-head; there are ways that it could be brought to the attention of the public, but in all of this work I think there is some misunderstanding on the part of people regarding a certain feature of it: There can be no special legislation; we can not secure special legislation. Many have wanted the National Congress, for instance, to establish a law for stopping adulteration. There can not be anything of that kind. Again, they have wanted an appropriation of money for a National society. There can be nothing of that sort; legislation of that kind must be general; and in the case, for instance, of a pure-food law, Senate and Congress would be glad to establish a law regulating interstate commerce and commerce within territories, directly under the National Congress; the appropriation of money should be made for the industry through those channels that are regularly appointed as a part of the Government, but not through any society which, so far as the National Government is concerned, is like an individual; that is, this society is looked upon by the Government in this way. There could be no appropriation by the National Government of money directly for this society, but the aims of this society can be forwarded through the Department of Agriculture, through a special appropriation which has been asked for, and which has sometimes been granted, it seems to me, in a niggardly manner. Why? Because the people in the States did not ask their members of Congress for it; and for that reason you will have to ask the people to write to their members and tell them they want so and so.

"Well, my letter doesn't amount to anything;" but if he gets 20 such letters he sees his constituents are thinking about it, and other members in Congress get similar letters and they begin to think about it. Any one member would not like to stand up and broach the subject all alone, but if every member in Congress found there were 20 behind him pressing for it, it would positively come. If you only ask on every hand, and every member, then there won't be any one there to back down, and they have to go ahead and speak for their constituents, and they are going to do what their people want them to do; and if they thought there was anything in this industry, or any considerable number of people interested in it, or that it had any real, vital influence over the agricultural interests of the country, they wouldn't turn it down, that is all.

Now, there was a little thing overlooked that I want to go back to, and that was when I spoke of adulteration. Just as soon as these honey canards appear where there is some man that thinks, Now, there is a bee-keeper on the one hand who says this thing is not possible, and here is a newspaper reporter that has written it up in great style that they are manufacturing combs and filling them with glucose, sealing it over and sending it out; and he doesn't believe one or the other exactly, but he wants an impartial statement of it, and he writes to the Secretary of Agriculture. That letter is referred to the Division of Entomology, and lands on my desk. I answer that, stating the facts as

they are known to me, and that letter is received as the statement of the Department of Agriculture; it carries weight with it, and he believes that statement, and he is willing to publish it. There have been numerous requests of that kind for real information which I have taken pains to answer at length, and I think they have had some influence in counteracting views expressed by those who thought they saw a great thing in adulteration.

E. T. Abbott—I am going to ask a question of Prof. Benton. He says there can't be any special legislation for the good of this society. Now, just a short time ago, if my memory serves me right, Congress appropriated \$500,000 to help some people that do not even belong to the United States. They gave them \$500,000 down there in that Island. I used to tell my wife I was afraid to live on any of those islands, I was afraid they would sink. I guess I was about right. One sunk down there, and Congress appropriated \$500,000 and sent a vessel down there, and they did it because they wanted to. I rather guess if we want it real bad they would put up a little money for the bee-keepers, or anything they took a notion to. They appropriate some \$20,000 or \$30,000 to bury some dead Senator, or some man that gets on a booze. Those are special appropriations. The truth of the matter is, the people of the country have not awakened up to these things; they don't seem to know about these things. If they just let Congress know that if there is any appropriating along those lines they would like to have a slice, I believe they would change their mind about special appropriations. [Applause.]

E. R. Root—I wish to testify to the good work done by Prof. Benton in answering those canards. I had a good deal of work in connection with it, and they wouldn't take my statements, as I was interested in a paper; but all I had to say to them was, "Please write to the Department of Agriculture, and they will tell you the true facts of the case." They did so; and some of the worst papers that had been publishing stories about bee-keepers, and what they would do, have retracted handsomely; but only after they wrote to the Department of Agriculture.

Dr. Miller—Prof. Benton refers to one thing, in regard to getting an expression from this National Bee-Keepers' Association as to what we would like from the National Government, or the Department of Agriculture. I don't know, but I think it would be proper to have a committee to draft such resolutions to get an expression from this Association showing what we would want. I don't know that that is a wise thing, but if this matter of negotiation could go on record and give help to the Government in its work, and help us, we ought to have something of that kind.

O. L. Hershiser—Here is a query: Why would it not be the best way to have formulated a form of petition asking Congress for any reasonable and proper aid through the Department of Agriculture, to be placed in the hands of the National Association and your State Association, to be signed by the members thereof, and transmitted through the proper channels to Congress. That would bring the matter before Congress from all parts of the country for this National Association, and would give it such character as to induce Congress to act favorably upon it.

Mr. Harris—I move you that a committee of five be appointed by the chair to take these matters under consideration, and report later to this convention.

Dr. Mason—I second the motion.

Mr. York—I would like to amend that, and suggest that the Board of Directors prepare a list of requirements to be presented to the Department of Agriculture. The Board members are our representatives, and there is a great deal of wisdom collected there. I think they ought to be able to form a good list of requirements, and if we back them up I think it may amount to something.

Mr. Harris—We will embody Mr. York's idea and let it go at that.

Dr. Miller—There is this advantage in the motion as first offered. A committee could be chosen of the directors who are here; they are all here, and you can promptly have the matter acted upon if you call the directors aside.

Mr. Taylor—it seems to me the amendment should prevail. If a committee is appointed we will have no report for a year, or have a report made hastily, a report of a comparatively few number of members. Now, if this is referred to the Board of Directors, under the amendment, they are men who are supposed to have an interest in all these things, and to have spent a great deal of thought upon them, and they will have time to consider it, and they can all consider it, though they are not here. It is not necessary that this body, as a body, should act upon it if it is referred to the Board of Directors; the directors may take a month

or two, or even three, and make up a thorough, well-digested report, and forward it to the proper office in the Government. It seems to me that is much more preferable.

Dr. Mason—I think, with Dr. Miller, that the motion of Mr. Harris is a good one. We can refer this matter to a committee that can consider it briefly, and they will probably come to the conclusion that the best thing that can be done is to give the Board of Directors time; they can so recommend it to us, and then we can request the Board of Directors to do this work; then they have some authority; when they report to the Government they will say, "At the request of the Association, we, the Board of Directors of our Association," do so and so. I would be in favor of referring to the committee at the present time, and then letting it go into the hands of the Board of Directors.

Mr. Taylor—Am I to understand the motion is withdrawn as made by Mr. Harris, and that the amendment is before the house?

Mr. Harris—I rise to a point of order. We are all out of order at the present time, as the motion has not been stated; the gentleman who seconded my motion did not consent to its withdrawal, therefore the original motion is before the house.

Mr. Abbott—I rose to say I did not give my consent.

C. P. Dadant—As a member of the Board of Directors I know something about the difficulties encountered in having an understanding by correspondence. The directors present can have a talk and achieve a great deal more among themselves while they are present face to face than they can when they have to write. The letters all have to go to the chairman, and resolutions have to be proposed. For that reason I am very much in favor of a committee being appointed, whether it is of the Board or out of the Board, and do what we can here. One of the directors will make a proposition; that has to go to the chairman, then he has to send that proposition to each of the members; then the members make additions or corrections, and that takes a great deal of time. It is not satisfactory at best. We can not have a meeting anywhere else. We each go home, living in a different State very often, and it is very difficult to carry on business with the Board. Therefore, I would be in favor of doing all the business we can do right here in the convention.

W. F. Marks—There are certain phases of this question that can be settled here to-day. This committee could be appointed to take up this question of statistics, and it seems to me that is the proper way to do it. I am not in the least in favor of referring this matter to the Board of Directors. The resolution can be passed here to-day asking the Department of Agriculture that they be requested to take up this matter of statistics and furnish us with statistics in regard to the apicultural industry. I see no reason why it should be referred to the Board of Directors.

Prof. Benton—I think Mr. Marks has misunderstood the scope of the proposed recommendations; they were to be more general, not merely one particular subject, but to cover the field of what connection there ought to be between the Governmental work and the work of this Association, and how they could assist each other. The whole general subject, with a series of recommendations, and as to whether it would be wise to settle that here or not, it seems to me it would be rather advisable to have the committee, and the committee to suggest that the Directors should take it up in more general manner.

Dr. Miller—I am very ready to admit that there would be that advantage in having the Board of Directors to act, and I am very sure that the Board, as individuals, will readily fall into Mr. Dadant's thought, and be glad to have some one else do the work; but it has occurred to me that possibly we might have both of these things done and have a committee here consisting of the Directors who are here, then have that committee refer the thing to the whole Board. It does not come, perhaps, from one of the Directors with very good grace to have such a thing proposed, and yet we must not be too modest. I am rather of the opinion that a good plan would be to have a committee now consisting of the members of the Board who are here, and let that committee refer the matter to the whole Board.

Mr. Taylor—Mr. President, as it strikes me, it would be manifestly absurd—

L. Booth—I rise to a point of order. I have not heard any question stated by the chair; I don't know what is before the house.

Mr. Taylor—I am going to make a motion. Mr. President, I was about to say that it would be manifestly absurd to refer this to a committee and expect that committee to make a report that would be worth anything during the

life of this convention. This is a matter that would require some thought; after the thought is matured it would require some time in order to put the thought in shape and make it presentable. If we are going to deal with this matter intelligently, we ought to do it in such a way that we shall get a result that is intelligent. Now, the last suggestion of Dr. Miller, it seems to me, is a very good one, and I move to amend the original motion by substituting this, "That the question be referred to a committee to be composed of the members of the Board of Directors here present; that they consider the question while they are together, and that after this convention is adjourned they refer it further to the other members of the Board of Directors, and that they make a final report and have it submitted to the Government."

Dr. Mason—Mr. Taylor moves to amend by substitution. Is that proper?

Mr. Taylor—Certainly.

Mr. Harris—I rise to a point of order. There is nothing here for discussion, and I, as the mover of the original motion, would like to talk on the motion when properly put by the chair.

Dr. Mason—If that is proper, that we can have such a motion to amend by substituting, I want still to say that I believe the best thing we can do is to put this before a committee composed of those not directors, and I believe we have the ability to mature enough of a plan to be submitted to this convention so that we can get it right before the Directors, and they before the Government, and make it count.

Dr. Miller—I rise to a point of order. I believe Mr. Harris is right. There is nothing before the house at all; the President has not stated the motion.

Pres. Hutchinson—I don't know that I can remember it.

Dr. Miller—The stenographer will read it, and then you ought to repeat it.

Dr. Mason—That is pretty small, but you are a small man.

The stenographer read the motion, after which the president stated it.

Mr. Harris—The object of this motion was this, that to expedite business, and, as one of the gentlemen here has said, not to go into the correspondence and delay this matter from time to time, let this committee be appointed if necessary; then they make suggestions; let it go to the Directors thereafter on the suggestions that this committee may make, then you will get down to proper business in such a way that you will work in an intelligent manner, and know just what the desire of this convention is.

The President put the motion, which, on a vote having been taken, was declared carried.

Pres. Hutchinson—I will appoint the committee after dinner.

A PROPAGANDA FOR HONEY.

Mr. York—I want to speak on that big word Dr. Miller used, "propaganda."

Mr. Taylor—You are out of order.

Pres. Hutchinson—I think we can hear from Mr. York.

Mr. York—I wanted to go back to the subject before the convention, "The most hopeful field for the Association." Dr. Miller suggested that one of his views was a propaganda for advertising honey. A little while ago I noticed Mr. Abbott was reading a newspaper; perhaps he was trying to look up the meaning of that word.

Mr. Abbott—That means the propagandering among the geese!

Mr. York—I suppose it is a sort of scheme, or system, for advertising honey, and I believe the Association can do a good deal along that line. As some of you possibly know, I am interested in getting people to eat more honey. I think most people here to-day would like to have the demand for honey developed so that they can sell their honey at a better price. I can hardly agree with Mr. Hutchinson in his paper, where he said he thought honey would not sell for any higher price than at the present. I believe when people come to understand the real value of honey as a daily article of food that its price is going to be higher, because there is not enough to-day to supply the demand at the present. For several years I have been endeavoring to get more people to eat pure honey, and I think the Association, if it had a larger membership, could do a great deal along that line, and I believe that the first most hopeful field is that of increasing the membership of the Association. I believe if we had 5000 or 10,000 members, and would send a recommendation to Mr. Benton, in Washington, backed up by that number of members, it would have a great deal

more effect and weight than with 1000 members. I think he made a good suggestion when he said we ought to write to our representatives and senators in Congress when anything relating to bee-keeping, or anything else we are interested in, is up for discussion; and if we could have 5000 or 10,000 members in this Association, and order the General Manager, or Secretary, at a certain time, to notify all members to write to their representatives and senators, they would do it, and it might have great effect. I also believe in working up the propaganda for advertising honey, and that much can be done among the newspapers of the country. They will not do it for me alone, or for you who have honey to sell, but the Association has no honey to sell. If they would get up a line of articles on the use of honey, and mail it to certain newspapers in the country, I believe they would publish it, and it would create a greater demand for honey among the people. You would be surprised to hear the reports I am hearing in Chicago nearly every day about the honey I am trying to put out. Of course, it is pure honey. What will help one will help the whole membership of the Association. I wish the Board of Directors would take up this matter, or this committee that is to be appointed now, and try to get information about honey before the people more generally.

Mr. Abbott—On that matter of propaganda, there is a thing comes to my mind that I intended to say, and I didn't. I heartily agree with Mr. York, and we have before us here a striking illustration of what can be done by a little energetic advertising; and, not to be personal, the illustration is so good I can not help but refer to it. This little book which the Colorado Bee-Keepers' Association, or Mr. Working himself, individually, got out, ought to make the National Association a little ashamed of the only thing it has ever issued in years. It looks very cheap by the side of that beautiful illustration that was gotten up to advertise this meeting, and it has fine half-tones in it, and it is gotten up in good style; and I noticed, when a gentleman came into my office, four or five of them were lying on my desk; the gentleman took one up and looked at it, and said, "What is that?" I said, "That is issued by the Colorado Bee-Keepers' Association." He said, "Could I have that?" "Yes, sir, with pleasure. That is what it was sent for." And they were all called for in a very short time. The last report (referring to the annual report of Buffalo convention), as it appears, and as it is, is as good as we provided money to make it. I am not complaining of Mr. York; he made a real good book for what he got for it, and people are wanting it, and there are inquiries, and in about a month I had 50 inquiries for this book, wanting to know if they could get a copy of it, and there was an opportunity to advertise the Association, and I didn't know where there was a copy to be had. This Association never has had good literature of that kind; it has always been afraid somebody would find out it was at work; it was afraid to let the newspapers know it was in the city. We have gone to great cities and they never knew we were there; and we never had a committee to go and tell the reporters that five or six "queen-bees" had come to town. But there were members live enough here, and, five or six weeks before, let them know, and we were besieged for photographs. And that is what propaganda means. If we could get a little more into the National Association there would be more honey sold.

Mr. Taylor—In talking about propaganda, and that the Association should teach propagandi, it seems to me that one propaganda that covers this question of advertising as well as the question of the price of honey has, so far, not been mentioned. I think that it is in the hands of the bee-keepers, if they will, to raise the price of honey 50 percent over what it is at the present time, if this suggestion would be carried out. I don't know as it will be. We are like that farmer that Mr. Abbott described—we put our thumbs under our suspenders, and when we can get a crop of honey we say, "Let her go!" and we ship it off to Chicago, or some other large city, and let somebody else sell it for us. That is the way I had always done till last year; it is the way most bee-keepers have done; there are a few here and there—no doubt our chairman could name some of them—who, instead of doing that, have taken their honey and their wagons and have gone out and have asked 50 to 100 percent more than they could have gotten in any other way, and they have sold their honey readily, and they have gotten rid of it without any trouble in getting their pay from the commission men or anybody else; they have, at the same time, educated a taste for honey, and they have spread the market, they have enlarged the market. Of course, there are exceptions; there are men who produce so much honey that they could not think of anything of that kind, their

honey would go to supply the demands of the cities; but there are thousands of small towns in our country that have no supply of honey simply because the men in the neighborhood of such a town who produce honey of any amount will pack it up and ship it off in order to get rid of the trouble of doing anything further with it. We have an immense market in this country for honey, if we would cultivate it. There is no question at all in my mind that if bee-keepers would take up this point and try to cultivate this market that perhaps the price of honey could be increased 50 percent in a very few years without any difficulty at all. I think we can do more for ourselves than the Government in any way can do for us.

W. L. Hawley—I wish to indorse what Prof. Benton has said with regard to sending letters to your representatives. We have had some experience in that line in sending letters to our representatives, members of Congress, and personal friends, and the influence was such that you would be astonished. Word came out from Michigan, saying, "Boys, do all you can; write from one to a dozen letters a week and keep it up constantly; keep it up." Well, I wrote two letters, then I wrote two more, then I increased it to five, then I wrote five more; I kept that up for the entire six weeks, and I was only one of 15 that did that. Michigan, California, Colorado, Nebraska, and every place where they have a beet-factory, did that very same thing. You know the reason why; there was an agitation trying to reduce the tariff upon sugar on the raw material, and, consequently, we beet-men did not want that. It is the same way with this honey. Mr. Benton says fire 20 letters in. Double that, make it 40, make it 60, 80, 100; you can't get too many there; the more you get there the better; every man, every woman, every child, every bee-keeper, keep it up, and then you will find that your work is accomplished; and until you do that you will accomplish nothing.

The convention then adjourned until 1:30 o'clock p.m.

(Continued next week.)

How to Distinguish a Perfect Queen.

BY DR. E. GALLUP.

HOW to distinguish the difference between a perfect queen and an imperfect one by the looks, shape, etc., is the question. A perfect queen is usually (now mind I don't say *always*) larger than an imperfect one. She has a large and perfect abdomen, tapering and pointed, while the imperfect one has a smaller abdomen, more blunt; and there is usually quite a difference in the shape of the workers; in examining the queen nymph, the one having the "missing link" attachment, and the other not having that attachment, both of the same age, the difference in size is very marked to the most casual observer. Even where both are equally supplied with a large amount of royal jelly, the difference in size is plainly visible after they are hatched, and all their lives plainly showing that the embryo does draw substance through the umbilical cord.

Many queen-breeders notify their customers not to be alarmed if the queen appears small, as she will increase in size after she commences breeding, etc. All those degenerate or improperly reared queens do appear small, and they are small even after they commence laying, in comparison to one rightly reared. I have occasionally had a very small queen that appeared to be prolific for a short time, but they invariably do not hold out for any length of time.

On page 596, W. H. Laws says: "Permit me to say that as great a percent of large, fully developed queens were obtained by the Doolittle method as by any method ever used." In recommending Mr. Doolittle as a queen-breeder, all the queens that I have seen and received from him have been fully developed and large, to all appearances, but the fault found with them was this: They did not prove prolific, and I have repeatedly had to explain why, etc. Years ago I received queens from different breeders, recommended as extra-prolific, but they in no case turned out as recommended. Now, I did not jump at the conclusion that said parties falsely represented their queens as prolific, but I had a theory in mind which was this: That queens shipped

through the mails, after testing, did not turn out prolific afterwards. Dr. Hamlin, of Tennessee, and myself, were having a friendly correspondence, so we came to an agreement to test the matter. I was to ship him a very prolific queen, and he was to return one that he knew was prolific. Well, we exchanged four queens each—not all at once, but at different times—and not a single one of the eight proved prolific. All, without an exception, were very unsatisfactory as to prolificness. I then lived in the extreme north end of Iowa, and the Doctor lived within 6 miles of the capital of Tennessee. Since then nearly all of the queens I have received have been untested.

Of 16 queens last season, only two proved to be impurely mated. I have an impression that a prolific queen, suddenly stopped from laying, even when caged or shipped while breeding up to her full capacity, is injured ever afterwards, for prolificness. But I have not fully tested the above theory to my own satisfaction. Now you can understand my reason for preferring untested queens.

I have received two queens from Florida, three from Louisiana, sixteen from Texas, and all were good except two from Texas. Some may say, "All those worthless queens you have received were injured in the mail." Not a bit of it; I know better. It is quite an easy matter for a thoroughly experienced person to distinguish the difference on sight. A number of years ago I jumped at the conclusion that I might as well do up all my swarming in a couple of days as to wait and watch for natural swarming; so I divided and nearly doubled my number. The result was I had 36 queenless colonies in September, and 15 more in the spring. I jumped at another conclusion, and that was that rearing queens in the above manner was thoroughly unnatural, and unscientific.

I have lived long enough to know that some people can learn as much by their mistakes as by their successes. A near neighbor of mine, last spring, had some 15 colonies; he was away at work through the day, and no one at home, so he made his swarms by dividing. This fall he had four queenless colonies, and was wondering to me why he lost so many queens. He said he would look through the hives, and saw that all had laying queens, and shortly afterwards found four of them queenless. He then gave them queen-cells and then more "came up missing." I explained to him that they might as well come up missing, as they were worthless any way he could fix it, and gave him my reasons. Still he has kept bees and ran quite an apiary for several years.

Please carefully read the letter on pages 494 and 495, by Edwin Bevins.

Now, I do not wish to be understood as saying that all queens reared under the swarming or superseding impulse are perfect, as there are exceptions to all rules in bee-keeping as well as in some other occupations. I will say to Mr. Greiner, that I watched that feeble queen and her colony very closely, both inside and outside the hive. The queen was quite feeble, and the bees were so feeble and were dying rapidly both night and day, and the workers were so feeble that they could only drag a dead bee out of the hive and drop on the ground with it; they could never fly off with it as bees from other colonies do.

They reared two superseding cells, and I cut them out and saved them, and they have both turned out fairly well so far, but not extra, for I could not expect the best kind of stock from such a feeble queen. I cut them out hoping that they would rear more, and they did rear more in a manner that I never saw before. They lengthened out worker-cells to about twice the usual length, and did not increase the size one particle. On examining them, the embryo lay clear outside of the worker-cell, behind the nymph, and not one particle of royal jelly in the cell behind. I cut off about a dozen and examined them thoroughly; the queen failed entirely, and I allowed two of them to mature, and both hatched out at the same time, and both were the smallest queens I ever saw, not even as large as a common worker. They both lived together for three days on the same comb they hatched on. I then had to move my bees on account of starting to dry fruit near me, and I have not seen them since. Now, you might say, "I told you so; queens under the superseding impulse are no better than others;" but I call them freaks, nothing natural about them.

I informed the Editor, when I commenced these articles, that I expected to stir up a hornet's-nest, and I have not been disappointed; yet I think when the crisis is passed, good will result.

The Premiums offered this week are well worth working for. Look at them.

Long-Lived Queens and Bees.

BY E. F. ATWATER.

HURRAH for Dr. Gallup's new fad! Long-lived bees are what we need, and such men as J. B. Hall, of Ontario, E. A. Morgan, of Wisconsin, and many others, are working along that line. But as to the difference between the artificially-reared queens, and naturally-reared queens, many will be sure to differ from Dr. Gallup, and I am one of the many, though my experience does not cover half a century.

When located in South Dakota, operating but few colonies, we had "native" stock, and these artificially reared queens produced colonies that excelled the natives almost every time, in pounds of honey produced.

In addition to this, the hardy (?) natives were seriously weakened by "pickled brood," while the Italians were practically immune.

In the several years that I have tried them, the queens reared by Atchley, Doolittle or Alley plans proved their right to replace the hybrids and blacks, and this in spite of the awful (?) handicap—artificial cell-cups, "fuss and feathers."

Upon my removal to Idaho I sold my bees, buying more upon my arrival here, starting with 150 colonies of Italians with naturally reared queens. All these queens of various ages were clipped in April and May of 1901. Upon examining the colonies in April, 1902, I found that fully half of these queens had been superseded by the bees, making it appear that the average life of these naturally reared queens was about two years, although I admit that an occasional queen may live four or five years. Some (inexperienced amateurs) may say that clipping caused the queens to be superseded at this age, but I will say that in South Dakota, having two races, and being able to tell the age of the queens by mating (queens from abroad mated purely, queens reared at home mated with blacks or hybrids), I found the average life of the queen to be about two years.

Now, the larger part of our bees are run for extracted honey, with little or no swarming, and I find, like Mr. Chapman, of Michigan, that it takes a very good queen to live two years, or more, when given an abundance of room for egg-laying.

In May, 1901, I received several queens from different breeders; two soon died, but the others have equalled the naturally reared stock as honey-getters, although it is yet too early to judge of the longevity of the queens themselves. We have the testimony of such practical men as Alley, Doolittle, Hutchinson, and Heddon, that the artificially reared queens are equal, or superior, to the natural ones; and among other observers I may mention F. L. Thompson, A. I. Root, and the Dadants, who have touched on this matter in their writings.

If such men as these, eminently practical, have found no difference in results between queens reared from an egg laid (presumably) in a natural queen-cell, and those carefully reared from worker-eggs or larvæ, then, in spite of the arguments of Dr. Gallup, the great majority of practical honey-producers will continue to rear and purchase queens reared by these artificial methods.

If bees will, in time, rear queens to suit the capacity of the hive, how shall we explain the fact that the Dadants have so little swarming with their large hives?

We have apiaries here where the queens have for years been confined to an 8-frame brood-nest. Surely, these queens "bred to suit the capacity of the hive" can never fill two 8-frame bodies with brood! But, astonishing to say, when given the opportunity, they respond nobly, with 10, 12 or 15 frames of brood.

If the bees will rear a queen to suit the capacity of the hive, where will the limit be found?

More light, please. I am willing to learn.

Ada Co., Idaho, Aug. 16.

Queen-Rearing of 1859 vs. 1902.

BY HENRY ALLEY.

IN the spring of 1859 I first saw a queen-bee. To me it was a big thing. Before the summer was over I had reared my first queen-bees. In those days we knew only about black bees; later on the Italian bees came in, and then queen-rearing grew to a big business.

Well, the first queens I reared, though they were black, proved to be first-class in all respects, and they were nucleus-

reared queens, at that. At that time I knew as much about rearing queens as I now do about building telescopes. But the know-how didn't bother me much, as I never let such small matters trouble me, when I have a scheme to push through. However, I had had sufficient experience with bees to know that if a colony was deprived of its queen the bees would soon provide another. Of course I worked on this theory.

How this must surprise my friend, Dr. Gallup. Why, the idea of anyone rearing good queens by the nucleus system, even before the Doctor got acquainted with bee-keeping! Isn't it funny that such a thing could be done? Such was a fact. After half a century's experience in queen-rearing we can rear no better queens, or, in a word, no improvement has been made in the quality of the queens, notwithstanding the fact that the rearing of queens has been brought down to a science.

In my first attempt to rear queens, a piece of comb 2x3 inches, in which were eggs and quite young larvæ, was fastened to the top-bar of a Langstroth frame by strings. The frame was then placed in a single-comb observatory hive, in which there was glass on either side, so that any movement of the bees could be observed; only about a pint of bees were used.

In those days queens were not reared for sale—merely for experiment and amusement, and that is why a glass hive was used. This was the starting-point in my queen-rearing experience.

In 1860 I commenced to rear queens in 3-frame nuclei. This is how it was done: One of the 3 frames contained brood in all stages, from the egg just laid to capped brood. The 3 combs were removed from a strong colony and all the bees adhering to the combs, minus the queen, were placed in the hive. The bees were then confined to the hive from 12 to 24 hours, and water was supplied. Bees thus prepared would commence to build from 3 to 8 or more queen-cells. As some of the bees would return to the parent hive, when released, other bees were given the nucleus each night for 3 or 4 days. By this operation I at once saw how bees could be induced to rear quite a number of queens on one comb, as I found that each fresh lot of bees given the nuclei would commence a new lot of cells. The bees built the queen-cells in positions of their own choice, and selected either eggs or larvæ for the coming queen.

Now, Dr. Gallup, with all due respect to your opinion and experience with nucleus-reared queens, I want to say that queens reared by the above method were in all respects equal to any swarm-reared queen ever produced. For rearing queens on a small scale there is no better method known than the nucleus system, as above described. In those days no one ever heard of short-lived queens; all queens, as above reared, were first-class.

Now, can any-one give a method so simple, and perhaps so scientific, for rearing a few queens? Does it not come as near Nature's way as it is possible to reach? So far, so good.

But right here comes the trouble in rearing queens on a large scale by the above plan. When the time comes for the queens to hatch, then the trouble begins. It will be seen that if bees are constructing new cells for 4 days continuously, it will be 4 days before all the queens will hatch out. It will be impossible to cut out and save all the cells, if one desires to transfer them to other nuclei, or to the nursery, as the cells are built on both sides of the comb, and many of them are very near each other. So it will be seen that there is a disadvantage in this last method for rearing queens. For the above reasons I had to abandon that method, and adopt the strip-of-comb plan, and have used this latter method many years.

In the days of 1859 to 1870 we knew little or nothing about the "missing link;" more in fact, there was no "missing link." All we then lacked was a way to rear queens so that all the cells could be preserved, and the strip-of-comb method does it. All went well in those days; everybody seemed pleased with the queens they purchased, yet knew nothing about science as applied to queen-rearing; nor did we care to know the scientific part, beyond adopting Nature's way, and by so doing only the most perfect queens were produced.

Since 1870 advancement has been made in many respects in queen-rearing, but when it comes down to the quality of queens no advance has been made. In fact, many queen-breeders are not up-to-date.

Mr. Doolittle says hundreds and thousands are quietly smiling at my statements. I am glad to know this. I always make it a point to keep people good-natured, and if I have succeeded in thousands of cases, as evidenced by Mr.

Doolittle's statement, I can only say I am well pleased at the result. I know of many bee-keepers who do not smile at all, and, 'tis "Amen" with many of them. I refer to the class of bee-keepers who write me thus: "Send me a queen-bee. Have bought queens of all the breeders and never got a good queen." Who does this strike? The names of these people are all new to me; not one of them has ever "smiled a smile" at my statements.

I have no time to reply to Mr. Doolittle's article on page 569, but I will do so before spring. In fact, I don't know that I can get time to write all that is necessary on the subject of queen-rearing. It is the biggest and most important subject connected with bee-culture, and volumes can be written. I will say, however, that I am ready to back up any statements I have made, notwithstanding Mr. Doolittle takes no stock in them.

Dr. Gallup also remembers me when he says, "I have two queens of Alley and they petered out before spring." Does any one who has had any experience in queen-rearing and shipping queens see anything unusual in this? I have reared queens as Dr. Gallup says they should be reared (the correct and Nature's way), and they didn't even peter in; they were worthless, and of course were destroyed as soon as tested. The queens I sent to Dr. Gallup were reared by the method I am now so strongly condemning. The methods then used were long ago abandoned by me, but other queen-breeders still use them. I call upon those who have purchased queens of me in 1902 to speak of their quality: yea, I call upon those people who have written to me the past summer to say the same in public as they say to me privately, as to the quality of the queens I have sent them in years past. [Of course the American Bee Journal is not going to publish a lot of testimonials for any queen-breeder, unless paid for at regular advertising rates.—EDITOR.]

Now, all queens sent out, however reared, do not prove to be good ones, but of this and the reasons why, we speak later on. Dr. Gallup knows as well as others, that the fault of this "petering out" is not always the method of rearing queens. Why, bless you, Dr. Gallup, bees are subjected to diseases as well as the human race. We all know, too, about how queens are treated in going from Massachusetts to California in a mail-bag. Such treatment may improve the quality of the queen, but I cannot think so.

One more reference to Dr. Gallup and Mr. Doolittle: Mr. Doolittle would have the readers of this paper to understand that he can rear good queens as he "learned the trade" of Dr. Gallup (page 579). Now, Dr. Gallup says on page 585, that "Mr. Doolittle's queens fail the second season." How's that, gentlemen? Doctors seem to disagree. At any rate, I can't seem to make the two statements harmonize.

When Dr. Gallup says my queens fail the second year, that is, if he includes any number of them, he makes a decidedly wrong statement. Some queens do fail the second year, yes, some fail the first year, and they will continue to do so, and it won't matter who rears them, or how they are reared.

I first observed the lump of royal jelly in the cells of the first queens I reared, and I am not only "on to" that point as indicating good queens, but on to many others that no one has mentioned, and none of them are new to me.

Who is getting bit when Dr. Gallup and Mr. Doolittle speak about rearing queens in nuclei? Surely it can't be this man, as I was obliged to abandon that system years ago, that is, long before any bee-keeper of the present day knew anything about rearing queens. If it were practical to rear queens on a large scale by the nucleus system I surely would use no other method, as I know by actual experiment that just as good queens can be so reared as can be reared by any method ever given the public.

Now, the reader can easily decide whether or not I am right, by simply testing the nucleus system. Try a few queens by the nucleus plan given at the beginning of this article. Of course, this statement does not agree with the theory of Dr. Gallup, but it is an easy matter to prove or disprove my theory early in the year 1903.

I am not writing for the fun of it, but am in dead earnest in what I say, and I'll risk my reputation as a queen-breeder on the result. Essex Co., Mass.

Please send us Names of Bee-Keepers who do not now get the American Bee Journal, and we will send them sample copies. Then you can very likely afterward get them subscriptions, for which work we offer valuable premiums in nearly every number of this journal. You can aid much by sending in the names and addresses when writing us on other matters.

Questions and Answers.

CONDUCTED BY

DR. C. C. MILLER, Marengo, Ill.

[The Questions may be mailed to the Bee Journal office, or to Dr. Miller direct, when he will answer them here. Please do not ask the Doctor to send answers by mail.—EDITOR.]

Sulphuric Acid for Cleansing Beeswax.

How much acid should be used for 25 pounds of wax? Is it put in water or wax for cleansing? MICHIGAN.

ANSWER.—Sulphuric acid is the acid used in cleansing wax. Ordinarily about one part of acid is used to every hundred parts of water. If little cleansing is needed half as much acid will do, and twice as much may be needed if the wax is very dirty. Put the wax in the acid solution and heat all to about 180 degrees, Fahr., and keep it hot half an hour; but look out it doesn't boil over.

Honey-Plant for Railroad or Wagon-Road.

What plant would you name for a deep cut on a railroad, and also on highway wagon-road? I sowed sweet clover, but the bees do not seem to work on that freely for a long time. MICHIGAN.

ANSWER.—Most emphatically I should say sweet clover is the right thing either for a wagon-road or a deep cut on a railroad. With enough of it I should have little fear as to the bees working on it. Not many plants will grow well in the subsoil of a deep cut, but sweet clover will grow there luxuriantly. It is not at all likely that you can secure a good growth of catnip on a roadside or in a deep cut, but, if you have hedges, sow catnip directly in the shade of the hedge and it will flourish.

Getting Bees Out of a Chimney—Feeding for Winter.

1. I have a colony of bees that are in a chimney, that is not in use during the summer, only in winter; they are not very far down from the top, about 4 feet. How can I get them out? I would like to save the bees, and keep the honey to feed the rest of the bees.

2. I have quite a few unfinished sections, and would like to know whether I could feed it back to the bees. Would they clean them out, so I could save them for another season for bait-sections? About what time could I feed them back before very cold weather?

3. How much honey should a colony of bees have, to last them from October until the following May, without feeding them? I am going to winter my bees out-of-doors in light chaff hives. How can I fix them over the brood-frames? And what shall I use for packing.

NEW YORK.

ANSWERS.—1. Without being on the spot it is a difficult thing to say what is the best plan, and even when on the spot it is not easy, as each case is a separate problem. The best way would be to tear away the chimney sufficiently to reach the bees, but most likely that plan can not be considered. Possibly something like this might be tried:

Make enough fire below to smoke the bees so they will fill themselves with honey and be perfectly subdued, but of course there should not be so much fire and smoke as to make the bees fall down into the fire. Then with some kind of a tool such as is used in tile-ditching, reach down from the top of the chimney and take up what you can lift, combs, bees and all. Continue this till you have got all out. It will not be a nice or satisfactory mess; the honey will be mashed, the bees will be daubed, and some of them killed; but the honey will at least be good for feeding, and very likely the queen will be safe.

If any one can suggest a better plan, he can have the floor.

2. Any day when bees are flying you can get the bees to empty out your partly filled sections. Put the supers of sections in a pile of five or six supers each, closely cover up, only allowing a place for one or two bees to enter at a time. Let the bees still have them for a day or two after they have

emptied them, so that they will make a thorough job of getting them cleaned.

3. They ought to have had 30 pounds or more of honey. Lay a piece of burlap or other open cloth over the top-bars, and then put your packing on top. If you can get cork-dust, nothing is better for packing. Dry leaves, planer-shavings, chaff, etc., are also good.

The Afterthought.

The "Old Reliable" seen through New and Unreliable Glasses.
By E. E. HASTY, Sta. B Rural, Toledo, O.

TWO QUEENS IN A HIVE—SHAKEN SWARMS.

Two queens in a hive, *a la* page 601, are indeed exceedingly handy for dividing.

Twelve years is quite a long lesson; but doubtless there are still some in-plain-sight lessons unlearned when a man has kept bees for more than 12 years. Mr. Housel is very likely sound on black hybrids for fine comb honey—if *he thinks so*—no bee is worth a cent if his boss thinks ill of her. Page 602.

It's a phrase to conjure with, "shaken swarms," or would be were it not for that dreadful "sometimes." Sometimes look a little out for infuriated bees and a grist of queenless colonies. Page 605.

WHAT CAUSED THE POOR HONEY CROP?

"Nothing but the bad weather has prevented an unprecedented honey crop." Page 604. When Mr. Knowles has conned his book 12 years over that lesson he will have an inkling that there is a mysterious *something* back of the weather.

But I'll admit we have had some fantastic weather this year of grace 1902, and plenty of "something," too. As per page 607, it's famine to the extent of stopping brood-rearing, then rush of nectar filling the empty brood-nest full, then dearth again to keep a normal-sized brood-nest from ever getting started. Three such items constitute a queer situation.

THAT SWEET CAPITOL, AND MAST-HEAD INDEX.

The Capitol as a bee-palace, eh? Would that all capitol-tombs might be as sweet-savored internally, and furnished with as ready weapons against impudent wrong.

And say, that new plan of having a mast-head index of special things to be found inside is not a bad plan. Page 609.

WHEN THE HEAT OF THE DRONE IS HELPFUL.

It is true that the poor drone makes heat and wastes most of it on the summer air, and that what he makes in the hive is mostly when there is too much heat there already. Just once, however, his heat may come in proper-good play, and that's the first night or so after swarming, in which performance the workers mostly depart and the drones mostly stand by the old home. Page 611.

CREMATING FOUL BROOD.

Not so sure that Ernest Root's cremation, on page 611, is entirely absolute. What's to hinder some individual bees from alighting on the damp leaves of adjoining brush, sticking there till morning, and then for want of a home wandering off and carrying that many drops of infected honey into the nearest hive? Still, the disposition of most insects to dash at a light may save the situation.

WIRING FOUNDATION IN FRAMES.

As to the frame shown on page 615, I suppose the droop of the wires was drawn much exaggerated lest the reader might not notice *any* droop. The impression first made on my mind was: Here's somebody who thinks drooping wires will hold up foundation better than straight ones. Guess that's not the idea. Rather, wire with a moderate pull, not hard enough to spring the ends, and tighten moderately by pulling down the wire while imbedding. If that's not it, Mr. Greiner can get back at me. Very drooping wires would hardly resist swaying bodily over to one side as well as tight ones.

Langstroth on... The Honey-Bee

Revised by Dadant—1900 Edition.

This is one of the standard books on bee-culture, and ought to be in the library of every bee-keeper. It is bound substantially in cloth, and contains over 500 pages, being revised by those large, practical bee-keepers, so well-known to all the readers of the American Bee Journal—Chas. Dadant & Son. Each subject is clearly and thoroughly explained, so that by following the instructions of this book one cannot fail to be wonderfully helped on the way to success with bees.

The book we mail for \$1.25, or club it with the American Bee Journal for one year—both for \$1.75; or, we will mail it as a premium for sending us THREE NEW subscribers to the Bee Journal for one year, with \$3.00.

This is a splendid chance to get a grand bee-book for a very little money or work.

and doubtless have, a tendency to awaken such a condition.

Why two or three persons should insist on having their own views adopted when scores of those who are equally intelligent and well-posted think they should not be, I can't understand. It is very evident to me that Mr. Moore has not heard both sides, for if he had he would not have said what he has.

Lucas Co., Ohio. A. B. MASON.

Bee-Keeping in Connecticut.

I feel it my duty to use my pen in behalf of others as they have done for me. So I will start off with the production of section honey. I am an advocate of calling the three forms of honey produced in the apiary thus: Section honey, in sections; comb honey, in the combs, or as you would cut it out of an extracting frame; and extracted honey, in the liquid form. I believe in calling section honey "section honey," but I do not like the term sometimes used for comb honey—"chunk honey."

From Sept. 15 to Oct. 20 is the time to begin to prepare if you would get good results the following season. You should see that your bees have plenty of good honey and pollen. Put a division-board on each side of the brood-combs, then stuff old bags or anything of that sort on the outside of each division-board between the side of the hive. Now put the super on, but do not put a chaff cushion in them, or anything over the frames until the bees have fastened the super firmly to the brood-chamber. When they have glued all air-tight put four short sticks over the frames about 1/2 inch by 6 inches long, and place the sticks so they will be 1/2 inches apart; then put two thicknesses of burlap over them, then the cushion stuffed with chaff—that which blows farthest away from the fanning mill. Now place on the cover, then stand boards slanting up against the entrance from the ground. With the protection and a good quantity of honey, we will have a good force of young bees and brood in the spring, which we can not procure without plenty of good honey and protection.

We will say it is the first of March; gently tip the hive up and look through them from the bottom, spreading the frames if necessary to see to the middle, and if you see no brood notice the quantity of bees, pollen and honey, and if plenty of the three do not be alarmed, but clean the bottom-board and wait a week or ten days, and examine again, noticing the three things mentioned above, and if no brood let the hive down, providing the results are the same as at the first examination, namely, honey, pollen and bees.

I would examine them again about the first of April, and if no brood, but plenty of honey and pollen, I should then give them a frame of brood from each of three different colonies, giving three from the poor one that has some honey in place of the brood taken. Now, after you have satisfied yourself that all colonies have a good, laying queen (which you can very easily determine if you have followed these instructions, as each and every one that is worthy of the name queen will be making great strides toward preparing the colonies for the production of section honey, or any other kind), and those that have no queen you have provided for so they can rear one. I say, do not bother them, if you do not want your labor thrown away, as in the spring, when the weather is chilly, by opening the hive you may destroy thousands of eggs, larva, and brood. I will tell you why, as probably the beginner would wish to know how so much damage would be done in so short a time. Take an incubator, and put it where it is cold (but not windy); turn up the lamp and see how high the temperature goes, which will be about 98 degrees; no matter if it goes to 105, as long as you have on every bit of heat you can put on (we will call it 98, which is near right). Now, if you open the door only as long as it takes to open a hive and take out two or three frames, note the temperature, which will be several degrees lower, shut the door, and you will find that it will take several hours to register 98 degrees again; and if it is near sundown your machine may not register 98 before the next day at noon, or at the warmest part of the

The Emerson Binder

This Emerson stiff-board Binder with cloth back for the American Bee Journal we mail for but 60 cents; or we will send it with the Bee Journal for one year—both for only \$1.40. It is a fine thing to preserve the copies of the Journal as fast as they are received. If you have this "Emerson" no further binding is necessary.

day. Now, if it requires from 98 to 100 degrees inside of the hive (or about the cluster), what would be the result to open the hive and allow the temperature to fall to 60 degrees? And suppose we have a very cold night, the bees may draw up together in a more compact form than they were and leave the brood to perish, or they may stay spread out and try to protect the brood and perish with it; thus you see it is with the bees as with the incubator, it must become several degrees warmer on the outside before it can affect the inside; the same rule holds with the bees. All must wait for Nature to turn a bright smile on us, which, by our foolish fussing, may cause the destruction of thousands of our first field-force before she shines on us again. So, again, I say, *don't bother your bees*. Only on warm days, when they can fly freely, and not then if you know the colony to be in the aforesaid condition, queen, honey, pollen, and bees.

I have a way of feeding back partly filled sections, which, if there are other bees in your neighborhood, or in robbing time, can not be excelled. The way I proceed is to move the colony on the bottom-board far enough to leave a 3/4-inch space open at the back. Now take the box or hive-body, or, perhaps, your hives are on the ground, but no matter, all that is necessary is to place a bottom-board at the back of the hive, and close up to the other bottom; be sure to have the bee-spacing cleats on the bottoms come just even in height and square. Now, place a hive-body on the two, and if you have arranged them properly the body will sit on the two bottoms. Move the body forward enough so that there will be a 3/4-inch space at the back and bottom of the brood-chamber, and 1/4-inch space at the front and bottom of the hive-body. This 1/4-inch space should be on the inside of the empty body, which I, when so arranged, call my "back feeder." Two or three hive-bodies may be used in placing one on the other by covering crosswise the hive which contains the colony. I have fed back from brood-combs 37 pounds, and secured 22 pounds, net weight, in sections with drawn combs to start with. This colony has about 9 pounds in the brood-combs more than the others; this shows that 31 pounds out of the 37 were placed in the combs of honey to be placed in the hives over and above the other colonies that sit on the same bench. This

Hauling Corn-Fodder.—With the biggest and perhaps the heaviest crop of fodder ever harvested, and with the fields cut up as they are by the unusual fall rains, farmers are puzzled to know just how to take care of their fodder. In this emergency we want to call your attention to the low-down broad wheel Handy Wagon made by the Electric Wheel Co., of Quincy, Ills. This wagon at all times is one of the most convenient and useful articles a man could have on the farm. Is particularly useful in getting in the fodder and other late, fall work.

Most of our readers who have used this wagon are profuse in their praises of it. Some say they would not be without a handy wagon for three times what it cost. Those of our readers who do not feel that they wish to make the necessary outlay to buy one of the wagons at the present time, may have a low-down, broad-tired wagon by simply buying a set of the Electric Wheels such as are shown in the cut. They are made in a great variety of heights, and are made to fit any wagon. The simple removing of the old, high wheels and substituting a set of the Electric's makes a handy, convenient, low-down wagon at a very small item of cost. All the goods turned out by the Electric Wheel Company are made of the best material, and they are the kind of people we have talked so much about in the past. That is to say, they are wise enough to know

that the way their success has been achieved is by making every buyer a loyal enthusiastic exponent of their goods.

We suggest that you get one of their free catalogs, and see if their proposition does not impress you as being a particularly good one at this time of year. Write for the catalog to-day, and please mention the American Bee Journal when writing to them.

Prices subject to market changes. Single pound 5 cents more than the 5-pound rate, and 10 cents extra for postage and sack. Add 25 cents to your order, for cartage, if wanted by freight, or 10 cents per pound if wanted by mail.

CASH BUYERS' UNION, Dept. M 609 CHICAGO, ILL.

colony was at work in the fields at this time, and so were the others.

My bees are in Danz. hives. They have averaged, up to date, 56 pounds per colony, or 140 pounds apiece for the two that I managed to save out of six after a 12-mile move in the spring. Those two were in the best shape I ever knew bees to be in at that time of the year (March 26), but the others were only fair, but soon went almost like the wind (with a rush); but I am well satisfied with the result. I will close by giving a leaf from my diary:

LIST OF BLOOM.

ROBERT J. CARY.

Fairfield Co., Conn., Oct. 4.

The Burning Bush

An Illustrated Weekly Paper for all Classes.

It contains food for the hungry, throws floods of light into darkness and upon the depravity that so generally abounds, and maintains an uncompromising war against all sin. All that is of prime importance in the realm of spiritual thought and action is ably presented and attractively illustrated by men who have the gift, and at least some of the gifts, of the Holy Ghost.

This periodical fills a unique place in the field of literature, and is of such a nature as to make it interesting and profitable to Christians of all denominations.

Price, \$1.00 per year. Samples free. Special terms to agents. THE BURNING BUSH, 223 NORTH KEDZIE AVE., CHICAGO, ILL.

sell to our readers, if you will mention the American Bee Journal, at absolutely wholesale prices.

The firm of H. Leonard & Sons, to whom we refer, have been in business a half century, but have hitherto confined their efforts to the wholesale trade. Now they are selling direct to the consumer, and if you will write them at once they will mail you a copy of their Holiday Catalog containing a selection of household goods suitable for Holiday purposes.

Your dealer buys his furniture in Grand Rapids because it is the largest furniture manufacturing city in the world. You have the opportunity in dealing with this firm of buying at the same prices and in the same way. It is safe to say that you would save at least 25 percent, and in many cases more, on anything that you bought from H. Leonard & Sons. Please mention the American Bee Journal when writing.

“IMPROVED QUEEN-REARING,”

Or, how to rear large, long-lived, prolific queens. A new work, giving in minute detail all the latest improved methods. Illustrated. No fault found with my queens in 1902. I challenge the world to equal queens reared by this new process; queens live from three to five years. Send for prospectus. 44A2t HENRY ALLEY, Wenham, Mass.

Queen-Clipping Device Free....

The MONETTE Queen-Clipping Device is a fine thing for use in catching and clipping Queen wings. We mail it for 25 cents; or will send it FREE as a premium for sending us ONE NEW subscriber to the Bee Journal for a year at \$1.00; or for \$1.10 we will mail the Bee Journal one year and the Clipping Device. Address, GEORGE W. YORK & COMPANY, Chicago, ILL.

FOUR PERSONALLY CONDUCTED EXCURSIONS FROM CHICAGO, COUNCIL BLUFFS AND OMAHA TO CALIFORNIA WITH CHOICE OF ROUTES.

These excursions leave Chicago every Tuesday, Wednesday, Thursday and Friday at 11:30 p.m., and Omaha every Wednesday, Thursday, Friday and Saturday at 4:25 p.m. in Pullman Tourist Sleeping Cars, over the Union Pacific. The cars are accompanied all the way by conductors skilled in the service of excursion parties. The Union Pacific is the only line from Omaha running four excursions to California every week.

These excursions can be joined at any point enroute.

For full information call on or address W. G. NEIMYER, G.A., 193 South Clark St., Chicago, Ill.

Buy by Mail. — Doubtless many of our readers have adopted the custom of buying direct from large mail order institutions for various and good reasons, particularly because the mail-order houses issue magnificent catalogs which may be perused carefully, and the greatest thought and consideration given before the purchase is made.

Your local merchant buys his goods in a way commonly called “at wholesale.” It has always been supposed that he had the advantage of the consumer, but things have changed, and we are pleased to present an illustration of a large establishment in Grand Rapids, Mich., who

sell to our readers, if you will mention the American Bee Journal, at absolutely wholesale prices.

What Yon Yonson Thinks

Vell, dom big bee mans dom bean to see Dr. Gandy, an dom find he bean offul nice feller. Catnip, he bean all rite for ideal bee-keeper, but dat feller don't vas born yet; mebbly him goan to com from Sweden. And de catnip, he don't vas growed very much yet eder. Vell, dat bean plenty bad, but now don't cry, an ay tank ve can fix it up all rite.

Ay bean have catnip here in Illenois for 20 years; he don't bean much for cats, but dom bees dom vork on him all summer every year, and dom don't vas tierd of him yet. Ay bean sow him in brush-piles an hedges, an old rale fens, and he grow plenty nice, an dom bees hav plenty big time ven every ting els bean play out, an ven da bean plenty bass trees and clover, dom don't hardly hav time to vate till dinuer bean ready, but dom don't tell catnip to go vay back und sit down, but dom like him catnip yust so gud some nutting else; but dom never bean give ue an pure catnip honey in de up stairs. Ay tank ma be it bean so gud dom feed it to dom little bees down stairs, but das year dom put some in de up stairs for me, but dom bean kine o' triky, an mix him ma smartveed honey; mebbly dom tank ay git smart nuf to sow more catnip. Men, my ying, it bean awful good hunny—youst white like paper, an ven ve ete him it youst go down like to poor vater in a rat hole.

Las fall ay bean plant von aker in to catnip. Ay bean sow him tre times alreddy, an ay goan to sow him vons more, den him surely moste com up plenty much nex summer. Dom seed bean so fide it moste be more as a million in von ouns, an ay von can sow lots many places ma 50 cents a vort of seeds, and dom ole brush-piles and ole fens som look so bad can yust so vell bein catnip. Course, it don't be nuf, but you better believe dom bees bean plenty tickled ven da don't be nutting elst to vork on.

Now, ma name bean Yoo Yonson, ay bean kech bee-fever from A. I. Gleanings bout 20 ears ago. Gleanings be da bean offul nice ole man, an he sen me a b c d book, an ay kech bee-fever plenty bad. But Gleanings be plant so much onyuns he bean plum cured by das time. But ay tank if he stay in mishegan and see dom bees vork on rossberrys an buckveat, an now meby he goan to plant som catnip. Den I is fraid he goan to have touch of bee-fever agin.

Bout six seven years ago ay git some prise taker sets of Gleanings, an ay rais offle big onyuns, but dom don't kin cure bee-fever on svede man. Now ay don't bean som offul rich like Young Morgan or Vauderbilt, but ay got von billion dollars nearer nuf dan all dem big mans put together. Now ay bean have plenty big orchard 1800 trees, pears, an all kines of frute. Now ay bean goan to take tre four akers for experiment station. Ay bean got alreddy lots of rossberrys. My bees svarmed von rossberrys das year. Ay got catnip, sveet clover, fig wort, an some odder kines. Nex year I goan to have some cleome, an som phacelia. Ay tank if it pay Celia it mebbly pay Yon Yonson to. Ay goan to make big experiment ma rossbers. Som hav ful ma blossoms all summer, tree four kines. Ay goan to give you fellers all de essence. Course Yon Yonson he git de honey essence, dat mean experence boiled till it bean all dried up on print in merican bee-paper.

Dom big bee-mans dom don't got time to fool ma catnip or any kine of honey plants. Dom youst rassel ma dem selves bout quveens and difers hives, an dom don't fine out yet dat de bees don't can yust roll in de honey ven da don't bean ay honey to roll in.

Mr. New York, vot make das bee-paper, he live in chicago, an don't hardly hav room to hang his hat up on de vall, it yust bean town all over, an dom houses bean so tick dom houses partneer to run over each odder; an he bean so bissy to ma't das bee-paper, an he have so big apatite for new subscribers, he don't could vork in de garden. So dom all hav to depend on little bee-mans lak Yon Yonson to settle das bisnes bout honey-plants. Coggs shall he put locality first, an man he

come in for putty close second. Course he bean rite, but he don't go for nuf. You Yonson he say if man don't hav good locality he don't bean in it atoll, an he goan to git left ever time.

Dr. Gandy he say any place can be good locality if ve so nuf sweet clover and cutlip. Course he bean rite, too, but he don't go fur nuf eder. Ay say, ve moste have lots ma ross-berry, catnip, sweet clover, alsike or vite clover, smartveot, or buckwheet; den if ve can have odder good plants and buss trees, and den have good quvens, ve sure goan to bean in it evry year. Don't you tank it bean better to have lots of honey if it do cost some ting, den to cost notting an git notting? Ay tank ve can rais alfalfa in Illeois yust so gud some noplace elst. If all dom fellers vat live in Illeois vil send to experiment station, Urbana, Ills., an ask dom to sen your Bulletin No. 76, it tell all about alfalfa in Ills. He bean offol nice book ma 40 side, an you git it fre for nutting. If you ask dom to put your name on mauling list den, you git dem rite long. Ay been git dom long time.

If it don't rain ay bean com over nex week. Yours for luts of honey.

YON YONSON.

CONVENTION NOTICES.

Chicago - Northwestern.—The executive committee of the Chicago-Northwestern Bee-Keepers' Association have planned to hold the best convention ever convened in Chicago. The date is Dec. 3d and 4th, Wednesday and Thursday. Five eminent bee-keepers have been invited, and are expected to attend. More definite announcement later. Watch for it. Reduced rates on account of the fat stock show, which is held Nov. 29th to Dec. 6th.

HERMAN F. MOORE, Sec.

Illinois.—The 12th annual meeting of the Illinois State Bee-Keepers' Association will be held at the State House, Tuesday and Wednesday, Oct. 18 19, 1902. On account of the Odd Fellows' meeting at the same time, the fare on all the roads in this State are quite sure to be an open rate of one fare for the round trip. We always have an open, free discussion on any and all subjects interesting to bee-keepers.

JAS. A. STONE, Sec.

Route 4, Springfield, Ill.

A New Bee-Keeper's Song—

“Buckwheat Cakes and Honey”

Words by EUGENE SECOR.

Music by GEORGE W. YORK.

This song was written specially for the Buffalo convention, and was sung there. It is written for organ or piano, as have been all the songs written for bee-keepers. Every home should have a copy of it, as well as a copy of

“THE HUM OF THE BEES in the APPLE-TREE BLOOM”

Written by

EUGENE SECOR and DR. C. C. MILLER.

PRICES—Either song will be mailed for 10 cents (stamps or silver), or both for only 15 cents. Or, for \$1.00 *strictly in advance* payment of a year's subscription to the American Bee Journal, we will mail both of these songs free, *if asked for.*

Bee-Keeper's Guide, or Manual of the Apiary, by Prof. A. J. Cook, of Pomona College, California. This book is not only instructive and helpful as a guide in bee-keeping, but is interesting and thoroughly practical and scientific. It contains a full delineation of the anatomy and physiology of bees. 544 pages. 295 illustrations. Bound in cloth. 1902 edition—19th thousand. Price, \$1.20.

Langstroth on the Honey-Bee, revised by Dadant.—This classic in bee-culture has been entirely re-written, and is fully illustrated. It treats of everything relating to bees and bee-keeping. No apiarian library is complete without this standard work by Rev. L. L. Langstroth—the Father of American Bee-Culture. It has 520 pages, bound in cloth. Price, \$1.25.

A B C of Bee-Culture, by A. I. Root.—A cyclopedia of 400 pages, describing everything pertaining to the care of the honey-bees. Contains 300 engravings. It was written especially for beginners. Bound in cloth. Price, \$1.20.

Scientific Queen-Rearing, as Practically Applied, by G. M. Doolittle.—A method by which the very best of queen-bees are reared in perfect accord with Nature's way. Bound in cloth and illustrated. Price, \$1.00; in leatherette binding, 60 cents.

Bees and Honey, or Management of an Apiary for Pleasure and Profit, by Thomas G. Newman.—It is nicely illustrated, contains 160 pages, bound in cloth. Price, in cloth, 50 cents; in paper, 30 cents.

Advanced Bee-Culture, Its Methods and Management, by W. Z. Hutchinson.—The author of this work is a practical and entertaining writer. You should read his book; 90 pages, bound in paper, and illustrated. Price, 50 cents.

Bee-Keeping for Beginners, by Dr. J. P. H. Brown, of Georgia.—A practical and condensed treatise on the honey-bee, giving the best modes of management in order to secure the most profit. 110 pages, bound in paper. Price, 50 cents.

Bee-Keeping for Profit, by Dr. G. L. Tinker.—Revised and enlarged. It details the author's "new system, or how to get the largest yields of comb or extracted honey." 80 pages, illustrated. Price, 25 cents.

Bienen-Kultur, by Thomas G. Newman.—This is a German translation of the principal portion of the book called "Bees and Honey." 100-page pamphlet. Price, 25 cents.

Apiary Register, by Thomas G. Newman.—Devotes two pages to a colony. Leather binding. Price, for 50 colonies, \$1.00.

Dr. Howard's Book on Foul-Brood.—Gives the McEvoy Treatment and reviews the experiments of others. Price, 25 cents.

Winter Problem in Bee-Keeping, by G. R. Pierce.—Result of 25 years' experience. Price, 30 cents.

Foul Brood Treatment, by Prof. F. R. Cheshire.—Its Cause and Prevention. 10 cts.

Foul Brood, by A. R. Kohnke.—Origin, Development and Cure. Price, 10 cents.

Please Mention Bee Journal when writing advertisers.

HONEY AND BEESWAX MARKET QUOTATIONS.

CHICAGO, Oct. 9.—The advance noted in our last quotation has been maintained and there is a very good demand for honey at the present time. No. 1 fancy white comb brings 15@16c per pound, with the lower grades selling at from 2 and 3 cents less; this includes the light amber. Dark grades of amber sells at about 10@11c, and buckwheat 9@10c. Extracted is steady with white bringing 6@6½c, according to color, flavor and quality; the amber brings from 6@7c; dark, 5½@6c. Beeswax in good demand at 30c. R. A. BURNETT & Co.

ALBANY, N. Y., Oct. 18.—The market is having the best demand for honey it ever had, largely on account of the near-by bee keepers' colonies having been destroyed by foul brood and State officers. We quote fancy white comb, 10c; No. 1, 15c; mixed, 14@15c; buckwheat, 13½@14½c. Extracted, buckwheat, 6@6½c; white, 7½c; mixed, 6@7c. Beeswax, 30c. H. R. WRIGHT.

BOSTON, Oct. 20.—Our honey market remains firm, with good demand and fair stocks on hand. Honey is not coming forward as fast as usual, and the tendency of prices is steady. We quote our market as follows: Fancy white 1-pound sections in cartons, 16c; No. 1, 15c; No. 2, very light supply, 14c; glass-front sections generally one cent less than this. Extracted, light amber, 8c; amber, 7½c. BLAKE, SCOTT & LEE.

KANSAS CITY, Oct. 20.—The receipts of comb and extracted honey are light, and demand steady at quotations: Fancy white comb, 14½@15c; No. 1 white, 14@14½c; No. 2 white an 1 amber, 13@13½c. White extracted, 7@7½c; amber, 6@6½c. Beeswax, 24@26c. C. C. CLEMONS & Co.

CINCINNATI, Oct. 4.—The demand for extracted honey is good at the following prices: Southern and amber sells at 5½@6½c; better grades, 7@8c. Comb honey is scarce; fancy and No. 1 sells on arrival at 16@17c. Beeswax weak at 28c. THE FRED W. MUTH CO.

NEW YORK, Oct. 10.—We are having a good demand for comb honey and receipts are quite plentiful. We quote fancy white at 15c, and some exceptionally fine lots will bring from 15½@16c; No. 1, white, 13@14c; amber, 12c.

Buckwheat is late arriving, and none has been on the market as yet to cut any figure. We expect large receipts next week, and it will sell at from 10@12c, according to quality and style of package.

Extracted in fairly good demand at 7½c for white, 6½c for light amber, and 5½@6c for amber. Southern in barrels at from 55@65c per gallon. Beeswax nominal at 28c. HILDRETH & SEGRLEN.

CINCINNATI, Oct. 7.—Comb honey is in good demand, the supply is short and very little offered. No. 1 fancy water-white sells at 16c; other grades less, according to quality. The demand for extracted is very active and prices are a little better; amber sells for 5½@5¾c; alfalfa from 6@6½c; water-white white clover, 7½@8c. Beeswax, 30c. C. H. W. WEBER.

SAN FRANCISCO, Oct. 15.—White comb honey, 12@12½c; amber, 8@10c; dark, 7@7½c. Extracted, white, 5½@6c; light amber, 5½@5¾c; amber, 5@5½c. Beeswax, good to choice, light, 27@29c; dark, 25@26c.

There are no heavy offerings of any description, either at this center or at producing points. Comb honey is in better spot supply, however, than extracted. Stocks of latter have been greatly reduced by recent shipments outward. Current values are being well maintained.

Wanted—Extracted HONEY Mail sample, and state style of package and price delivered in Chicago.

1-lb Keystone ... Honey-Jars

These are clear flint glass jars holding just one pound, and the shape of a keystone. They are 7 $\frac{1}{2}$ inches high, and very pretty when filled with honey. The corks can be sunk a trifle below the top, and then fill in with beeswax, sealingwax or paraffin. We can furnish them in single gross lots, with corks, f.o.b. Chicago, at \$3.50; two gross, \$3.25 per gross; or five or more gross, at \$3.00 a gross. These are the cheapest glass one-pound jars we know anything about. We have only about 20 gross of them left. So speak quick if you want them. Address,

GEORGE W. YORK & CO.

MEMBERSHIP DUES, \$1.00 a year.

If more convenient, Dues may be sent to the office of the American Bee Journal, when they will be forwarded to Mr. Secor, who will mail individual receipts.

A Celluloid Queen-Button is a very pretty thing for a bee-keeper or honey-seller to wear on his coat-lapel. It often serves to introduce the subject of honey, and frequently leads to a sale.

NOTE.—One reader writes: "I have every reason to believe that it would be a very good idea for every bee-keeper to wear one [of the buttons] as it will cause people to ask questions about the busy bee, and many a conversation thus started would wind up with the sale of more or less honey; at any rate it would give the bee-keeper a superior opportunity to enlighten many a person in regard to honey and bees."

The picture shown herewith is a reproduction of a motto queen-button that we are furnishing to bee-keepers. It has a pin on the underside to fasten it.

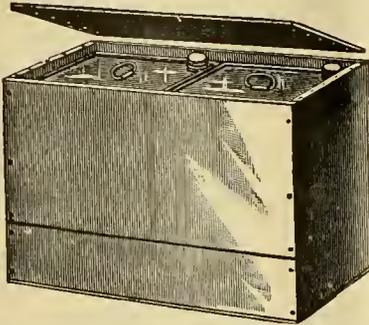

Price, by mail, 6 cents; two for 10 cents; or 6 for 25 cents. Send all orders to the office of the American Bee Journal.

BEST Extracted Honey For Sale

ALL IN 60-POUND TIN CANS.

Alfalfa Honey

This is the famous White Extracted Honey gathered in the great Alfalfa regions of the Central West. It is a splendid honey, and nearly everybody who cares to eat honey at all can't get enough of the Alfalfa extracted.

Basswood Honey

This is the well-known light-colored honey gathered from the rich, nectar-laden basswood blossoms. It has a stronger flavor than Alfalfa, and is preferred by those who like a distinct flavor in their honey.

Prices of Alfalfa or Basswood Honey:

A sample of either, by mail, 10 cents, to pay for package and postage. By freight—two 60-pound cans of Alfalfa, 9 cents per pound; 4 cans or more, 8½ cents a pound. Basswood Honey, ½ cent more per pound than Alfalfa prices. Cash must accompany each order. You can order half of each kind of honey, if you so desire. The cans are two in a box, and freight is not prepaid. **Absolutely Pure Bees' Honey.**

Order the Above Honey and then Sell It.

We would suggest that those bee-keepers who did not produce enough honey for their home demand this year, just order some of the above, and sell it. And others, who want to earn some money, can get this honey and work up a demand for it almost anywhere.

GEORGE W. YORK & CO., 144 & 146 Erie St., Chicago, Ill.

The Novelty Pocket-Knife.

Your Name and Address on one side—Three Bees on the other side.

[THIS CUT IS THE FULL SIZE OF THE KNIFE.]

Your Name on the Knife.—When ordering, be sure to say just what name and address you wish put on the Knife.

The Novelty Knife is indeed a novelty. The novelty lies in the handle. It is made beautifully of indestructible celluloid, which is as transparent as glass. Underneath the celluloid, on one side of the handle is placed the name and residence of the subscriber, and on the other side pictures of a Queen, Drone, and Worker, as shown here.

The Material entering into this celebrated knife is of the very best quality; the blades are hand-forged out of the very finest English razor-steel, and we warrant every blade. The bolsters are made of German silver, and will never rust or corrode. The rivets are hardened German silver wire; the linings are plate brass; the back springs of Sheffield spring-steel, and the finish of the handle as described above. It will last a last-time, with proper usage.

Why Own the Novelty Knife? In case a good knife is lost, the chances are the owner will never recover it; but if the "Novelty" is lost, having name and address of owner, the finder will return it; otherwise to try to destroy the name and address, would destroy the knife. If traveling, and you meet with a serious accident, and are so fortunate as to have one of the "Novelties," your POCKET-KNIFE will serve as an identifier; and in case of death, your relatives will at once be notified of the accident.

How appropriate this knife is for a present! What more lasting memento could a mother give to a son, a wife to a husband, a sister to a brother, or a lady to a gentleman, the knife having the name of the recipient on one side?

The accompanying cut gives a faint idea, but cannot fully convey an exact representation of this beautiful knife, as the "Novelty" must be seen to be appreciated.

How to Get this Valuable Knife.—We send it postpaid for \$1.25, or give it as a Premium to the one sending us THREE NEW SUBSCRIBERS to the Bee Journal (with \$3.00.) We will club the Novelty Knife and the Bee Journal for one year, both for \$1.90.

GEORGE W. YORK & CO.

Chicago, Ill.

Please allow about two weeks for your knife order to be filled.

No. 45.

* Editorial Comments. *

"Our Bee-Keeping Sisters" is the heading of a new department that we begin in this number of the Bee Journal. It is conducted by Miss Emma M. Wilson, a lady beekeeper of long and varied experience, and one who knows how to express on paper, in a clear and interesting manner, the results of her years of work in the apiary. We are certain our readers of the feminine persuasion will be pleased to read the new department, and will also be glad to accept Miss Wilson's invitation to send to her anything they can that may be helpful to the other sisters in their work with bees.

"Our Bee-Keeping Sisters" is to be a department that the sisters can have all to themselves. Of course, it is to be expected that occasionally a man may try to break into it, but he will not likely repeat the attempt.

Care of Extracting-Combs.—In this country it seems to be the general opinion that it is better to have the honey entirely cleaned out of extracting-combs when the season is over. Even a small trace of honey left in a cell, if left there to granulate, will encourage granulation in the honey that is stored there the following season. It is not too late yet to leave such combs exposed so that the bees will rob them out some warm day. No special care need be taken in the North against the work of the moth in extracting-combs. The weather is too cold for their development, and all that is needed is to leave them throughout the winter where they will have the full benefit of severe freezing, which destroys both the larvæ and the eggs of the moth.

Feeding Weak Colonies First.—W. L. Davey reports in the Australian Bee-Bulletin some experience in feeding that is suggestive. He fed in a time of scarcity, treating all colonies alike, whether weak or strong. A mania for robbing was started, "with the result that the longer the colonies were fed the greater were the losses from starvation caused by robber-bees."

The philosophy of the matter is not given by Mr. Davey minutely, but it is not difficult to understand. The giving of feed produces two effects: It excites bees to start out after other stores in the most eager manner, making them fiercely attack any weaker colonies that may be found; it is also true that when a lavish supply of feed is in the hive the bees are not as carefully on the defensive, and in many cases will make no resistance to robbers, even though the colonies thus fed may be very strong. So it is no great wonder that the continuance of feeding in a bad time resulted in much robbing.

Made wiser by this experience, his next feeding was on a different plan, being entirely successful, and is given in full as follows:

The feed in this case was cheap honey, brought to the boiling point and then emptied into four gallons of boiling water and allowed to boil for about 10 minutes. This was drained off into the extractor, and a 70-pound bag of the best sugar was boiled in six gallons of water. This was then run into the extractor, and the contents of the extractor were then churned by revolving the extractor machinery. This blend of honey, sugar and water, was exactly like new nectar.

After blending up 90 gallons of syrup, it was taken 15 miles to the out-apiary, where 30 strong colonies and 24 of weaker strength had to be fed. The collecting and filling of 100 drawn combs with 4 pounds each of syrup occupied until midnight. These were distributed amongst the weakest colonies before daybreak, with the result that these weaker colonies had lost that madness that usually draws the robbers to them, and instead they were on the offensive; eager for more, they tackled the stronger colonies.

Now these strong colonies were given 2½ gallons down to one gallon of feed, in a vessel made of the half of a kerosene tin, with about two inches of straw placed on top of the syrup to prevent the drowning of bees, and the feed was then placed on top of the brood-chamber and covered by an empty super-lid, etc. This second stage of the feeding was done as soon after the daylight as possible (should be done during the night if possible).

He found, after leaving them for a fortnight, that the artificial nectar had been capped over. The strong colonies had completed their task, no robbing had taken place, no bees, so to speak, had been killed in battle, the weak colonies, being the aggressors, were in a mood to look after their home, and the strong colonies were too strong to be affected by the weaker.

Alley's System of Queen-Rearing is strongly championed in the American Bee-Keeper by Arthur C. Miller as the best, and he says that Mr. Alley is testing some changes not yet made public. L. Stachelhausen also uses the Alley plan and has less trouble than the cell-cup plan. There is no doubt that good queens can be reared by either method. The small frames used in nuclei do not necessarily form a part of either plan, but not all will agree with the first part of his statement when he says: "As fine queens as any one should desire can be reared with a cupful of bees, and as poor queens as ever lived may be produced by a bushel of bees." Unless he means that the cells are to be first reared in a strong colony.

Alfalfa in Illinois.—An interesting article in the Orange Judd Farmer is in part as follows:

Farmers who have tried to grow alfalfa in Illinois have met with somewhat indifferent success. Theoretically, the soil ought to produce large crops. The Illinois Experiment Station, several years ago, began a series of experiments to determine what was lacking. Alfalfa was grown in pots and treated in various ways. A little later field experiments in 25 different sections of the State were inaugurated. The results of these tests, published in Bulletin 76, indicate that alfalfa can be successfully grown if the soil is infected with the bacteria which are found in tubercles on the roots of the alfalfa. If these are not present the soil must be exceedingly rich, and receive a liberal application of barnyard manure or nitrogenous fertilizers. Even the rich, black soil of Illinois does not furnish sufficient available nitrogen to produce profitable crops of alfalfa.

In some sections of the State alfalfa has been grown

successfully for some years. The soil from these fields is thoroughly infected with the alfalfa bacteria, and can be used for inoculating new areas. In the experiments conducted by the station, this infected soil was applied at the rate of from 320 to 1920 pounds per acre, the heavier applications being the most effective. Prof. C. G. Hopkins states in the bulletin that where lime is applied at the rate of 400 pounds per acre in connection with 100 pounds of infected soil, the inoculation will be very satisfactory in a year or two. The infected soil can be secured from Kansas or Nebraska, if it does not seem desirable to get it from Illinois.

The Experiment Station advises farmers to try a few acres of alfalfa, and to apply infected soil to at least a small plot. The infection enables the alfalfa to feed upon the supply of free nitrogen in the air, greatly enriching the land on which it grows, as well as producing heavy crops of forage. On the limestone soils of the State it will not be necessary to add lime.

This information will come a little in the nature of a surprise to those who have been in the habit of thinking that the main, if not the only, difference between Illinois and Colorado, as to producing alfalfa, is the matter of irrigation. As a better understanding prevails, it is likely that better success will attend the cultivation of alfalfa, and it is perhaps not too much to expect that some time it may be practicable to create conditions whereby alfalfa may be a honey-plant east of the Mississippi River, even if not so valuable as farther west.

The Poison of the Bee.—A clipping received speaks of formic acid as the basis of bee-virus, saying, "To this formic acid, in all probability, the therapeutic value of the honey-bee is mainly, if not entirely, due." While it is true that formic acid plays an important part in the economy of the hive, it should be remembered that the latest investigations show that the real virus is a thing separate and apart from formic acid.

Perforated-Zinc.—A French writer says the measurement of perforations should be very exact, as a bee not filled with honey passes through a perforation of 4.06 millimeters, but is stopped if loaded with honey. The true dimension, he says, is 4.19 millimeters, or 165 thousandths of an inch, the measurement favored in this country.

Five Requisites for a Good Honey-Yield, particularly where there is an early and short harvest, are thus given in *Leipziger Bienenzeitung*: 1. Colonies strong in time. 2. Limiting the brood during harvest. 3. Reprising drone-brood as much as possible. 4. Giving sufficient room. 5. Having a good strain of bees.

A Cough Mixture given by E. J. Rien, in the *Australian Bee-Bulletin*, is as follows:

"Castor oil, honey, one dessert-spoon of each; the white of one egg, juice of a lemon. Dose: One spoonful a few times a day."

* The Weekly Budget. *

HON. R. L. TAYLOR, who was nominated as a candidate for General Manager of the National Bee-Keepers' Association, wrote us as follows on Oct. 25:

EDITOR AMERICAN BEE JOURNAL.—

Please allow me, through your Journal, to thank Mr. Moore for thinking me worthy to be named in connection with the office of General Manager of the National Bee-

Keepers' Association; and to say for the benefit of the voters of that Association, that I have no desire for the office, and could not serve if elected. Yours truly,
R. L. TAYLOR.

Mr. Dadant having expressed himself similarly to Mr. Taylor, leaves only Mr. Abbott and Mr. France as candidates for the General Managership up to this time. We are ready to announce further nominations in these columns, should there be any, but we must decline to publish any electioneering matter in the interest of any particular candidate, as we consider such publication would be unfair. We prefer to have each candidate stand on his own merits, and then have the voting membership of the Association make their own choice.

To be just and fair, any bee-paper that mentions one candidate must mention all candidates. An editor's personal feelings have no bearing in a matter of this kind.

RULES ON ASKING QUESTIONS.—We have decided to make the following rules, which must be followed hereafter if any one desires to have his or her questions answered in the "Question and Answer" department.

1st. The questioner must be a paid-in-advance subscriber to the *American Bee Journal*.

2d. The questioner must sign his or her full name and address each time when sending in any question. Of course, we shall continue to give only the State as a signature to the question or questions asked, as that is all that is necessary, and does not "give away" the ignorance of the questioner as one's name might do sometimes.

We now have several questions from some one in Urbana, Ill., who simply signs himself "Ills." If the "Question and Answer" department is worth patronizing it is worth signing your name and address in full when sending in the questions, and also keeping your subscription to the *American Bee Journal* paid in advance.

AN INVITATION FROM THE ONTARIO.—We have received the following from Secretary Mason, of the National Bee-Keepers' Association:

EDITOR AMERICAN BEE JOURNAL—

Dear Sir:—I received the enclosed communication several days ago, and have been waiting to learn the time of meeting, but as Secretary Couse will probably give notice of the time in all the bee-papers, I'll wait no longer.

Very truly yours,

A. B. MASON, *Secretary.*

Here is the communication referred to by Dr. Mason:

DR. A. B. MASON,

Secretary of the National Bee-Keepers' Association—

Dear Sir:—I am directed by the Executive Committee of the Ontario Bee-Keepers' Association to extend to the officers and members of your Association a very cordial invitation to attend the annual meeting of the Ontario Bee-Keepers' Association at Barrie, early in December. The date not being finally set yet, we can not be definite; but hope soon to know, when we will advise you.

We look forward to having a very pleasant meeting.

Yours truly,

W. COUSE, *Secretary.*

We trust that a goodly number of bee-keepers of the United States can accept the invitation thus kindly extended.

Why Not Help a Little—both your neighbor bee-keepers and the old *American Bee Journal*—by sending to us the names and addresses of such as you may know do not now get this journal? We will be glad to send them sample copies, so that they may become acquainted with the paper, and subscribe for it, thus putting themselves in the line of success with bees. Perhaps you can get them to subscribe, send in their dollars, and secure for your trouble some of the premiums we are constantly offering as rewards for such effort.

Convention Proceedings.

THE DENVER CONVENTION.

Report of the Proceedings of the 33d Annual Convention of the National Bee-Keepers' Association, held in Denver, Col., on Wednesday, Thursday and Friday, Sept. 3, 4 and 5, 1902.

(Continued from page 695.)

SECOND DAY—AFTERNOON SESSION.

At 2:30 o'clock Pres. Hutchinson called the convention to order.

THE LOUISIANA PURCHASE EXPOSITION.

Mr. Taylor—I understand, and I suppose you all understand, that there is, in the year 1904, to be held a great fair at St. Louis, Mo.; it is a World's fair. All preparations are taking place for the purpose of making it a great fair, and it is instituted for the purpose of commemorating this great strip of land between the Missouri and the Rocky Mountains, the purchase of it by the United States Government from Napoleon I, one hundred years ago.

Now, most of our members are specially interested in representing our pursuit at this great fair, so I arise to make a motion with regard to it, if desirable, that this Association should be heard with regard to the appointments to office concerning the exhibit that will surely be made by the bee-keepers of the whole country. I, therefore, move that for the purpose of making such provision and overseeing all matters pertaining to it that this whole matter be referred to the Executive Committee of this Association, and that they act as a committee for that purpose, and to see that all proper action, so far as this Association is concerned, be taken.

J. C. Carnahan—I second the motion.

The President put the motion, which, on a vote having been taken, was declared carried.

Pres. Hutchinson—The first thing on the program is a paper by Mr. C. A. Hatch, on "Reporting of the Honey Crop: When and How It Should be Done," to which Mr. Frank Rauffuss was to respond, but as he can not be here this afternoon, in place of that we will hear from Mr. F. E. Brown, on

THE CALIFORNIA PEAR-BLIGHT.

F. E. Brown—It is not often that we hear California spoken of as blighted, but to-day I have something to present before you on that line. We have not the blight altogether; it is not all blight, but we have a blight there that promises to destroy our bees. You have already heard more or less regarding the blight question; it has been published through, I think, perhaps all the leading journals, and you are all more or less familiar with the subject, therefore I will not take any more of your time than is necessary to bring it before your minds just about as it appears to-day.

In the spring of 1901—I think it was, perhaps, in March—one of the Board of Horticulturists came into my office and inquired for the Secretary of the Bee-Keepers' Association, stating to me that our bees were destroying their pear-trees. That I think is the first mention I ever had made to me that bees were responsible for the spread of pear-blight. The pear-blight that exists in our district is what is commonly known as the Eastern pear-blight, so I suppose you are all familiar with this blight that exists among the pear-trees, apple-trees, and quince-trees.

I asked the gentleman how he knew our bees were responsible for this blight; he did not speak directly to that, but asked if I would be so kind as to meet him before the Board of Supervisors that afternoon. In that meeting that afternoon the Board of Horticulturists brought complaint, stating that the bees were responsible for the spread of the blight which was fast destroying the pear-trees, and unless the bees were removed from the pear districts, which virtually meant from our county, that within a very short time there would be no pear, apple, or quince trees left in the

vicinity. The gentleman, the speaker from the Board of Horticulture, went on to state how this blight was carried by the bees; he stated that it was a germ that was small, could not be seen with the naked eye, like small particles of smoke that went in the wind; the bees being of a hairy, fuzzy nature, flying through the air to the tree, would gather up this germ and contribute or carry it to the blossom thereof, reaching the nectar, and from there to the sap of the tree, finally killing the tree.

After he had made his speech the Board asked if I had anything to say. I simply told them no; that it was new to me, that I knew nothing about the fact, and never had had our bees accused of such a thing before.

The matter went on for about three or four weeks, when the Board of Supervisors telephoned me one afternoon asking if I would come into their room, when I found the same committee as before—and they had the same complaint up, asking the Board if they would not pass laws by which bees could not be kept in that section of the country. This was perhaps in May, 1901.

After they had made their complaint the bee-men were asked if they had anything further to say, and I simply asked the Commissioners how the bees distributed the blight. At this time the Commissioners had sketched a picture of the insect which they called pear-blight, stating that it came out on the body of the tree in the pores of the bark in a gluey or gummy shape, and that bees crawling over the body of the tree in search of the blossoms gathered up the pear-blight and communicated it to the flower. That was the position that was taken then, and when I was called upon, after they made the statement upon my question—of course, you understand people that are not familiar with the habits of bees would not know but what the statement was correct, which was the case with our Board of Supervisors—I told them that any man who was familiar with the habits of the bee would know better; that the bees did not crawl about over the body of the tree in pursuit of the flower, but when a bee went to a tree that was in blossom it lit directly upon that blossom, and from that blossom to the next one, and the next one, and so on, but never in any case were they found upon the body of the tree.

Now, when our trees in California blossom, especially the pear-tree, there are no leaves; they blossom before the time of leafing, and the tree is simply one great snow-ball of white blossoms, and the bees, of course, go over the trees, flying directly from blossom to blossom.

However, there were one or two other bee-men there who made some remarks regarding the matter. The matter was passed over; the Board did nothing.

A little later there was a mass-meeting called of fruit-growers, the pear-men and raisin-growers all together; they came together in the Superior Court room of King's county. In this meeting there were no bee-keepers supposed to be present. However, we had a delegation there. One of the most prominent men in that Board of Agriculture came before that mass meeting and urged that they would poison the insects that were infesting the trees—they were spreading the blight from tree to tree. This was said in an open mass-meeting of the fruit-growers of our county and vicinity. The gentleman that was addressing the meeting advocated that they use cobalt and honey as a matter of poison; that by poisoning them that way the bee would die before it reached the hive, therefore there would be no danger of the poison getting into the honey.

I think it was about this time, perhaps, that Mr. E. R. Root visited our locality, and he visited almost all the prominent pear-growers in our vicinity; he visited the orchards; he met Prof. Pierce, and had a good influence over the situation, and it was proposed by Mr. Root that we try to compromise the matter by making a test.

Now, the bee-men did not believe that their bees were in any way responsible for the spreading of the blight at that time. However, Prof. Waite and Prof. Pierce had both suggested that it was possible, and I think they have spoken more directly since then.

The first part of July of last year the bee-men called a meeting and passed resolutions agreeing to make a test case, and that we would move our bees out of the pear districts that we might test the matter. This was suggested by Mr. Root while he was with us. This was done the first day of July, 1901. We handed our resolution to the committee of the fruit-growers; they accepted it and said nothing.

It went on until some time in the fall, when one of the fruit-growers came to one of our men and said it was about time we were doing something with regard to moving the bees. At that time, however, I was away in San Francisco, but shortly afterwards I returned. Nothing further was

done until the very last days of February of the present year, when there was a mass-meeting of the fruit-growers and bee-men again called. In this meeting the bee-men were asked to go on and carry out the intention of their resolution which was passed the year before, in July. Our pear-trees begin to bloom about the first week in March, and this, perhaps, was the last week in February.

In that meeting our committee got together and agreed to clear up a certain district two miles square, and move our bees three miles from that line, as a matter of test. In our resolution the summer before we had agreed to move them clear out of the district, away from the pear-trees, but now, for want of time, as it was within a few days of the time when the pear-trees would bloom, we agreed to move out of this one district only. This was done, but before this meeting adjourned the bee-men asked the pear-men to see that they moved *their* bees.

Now, there are some of our pear-growers there that have a few bees, and some of our fruit-men have bees, and farmers have bees, and there are bees in the fence-corners—bees all around. I suspect you have them the same way here. So, we did not want to be responsible for the moving of the bees which belonged to the fruit-men; we left that to the fruit-men's committee, and this fruit-men's committee agreed to do it.

After the meeting adjourned we went to work moving our bees, and the Central California Bee-Keepers' Association moved every bee that belonged to them, and moved them the distance they agreed to move them—three miles from that line—clearing up a territory two miles square right in the heart of the pear-blight district.

On visiting the pear-trees after they came in bloom there were bees all over the trees very nearly as numerous as ever before, and, on coming to investigate, the fruit-men had their bees, had them still; men who had pear-trees upon their ranches, quite good-sized orchards, had bees, and so the test was spoiled.

Now, then, I believe, gentlemen, that the bee-men of Central California have done all that they could do in respect to this matter; they desired to make a test of the matter, but they did not believe that the bees were responsible for the spread of the blight at that time. The test was spoiled, but the trees were seemingly infected.

Now, in the winter-time our pear-growers prune down their trees quite closely, pruning off all signs of dead wood and blight, leaving the tree in the spring to come out new; you would scarcely see there had been any blight except the top is not quite so large. That was the case this time. The trees were in blossom, the bees were working upon them two weeks, and there was not a blight to be seen, and people thought for some reason there was not going to be a blight. But, seemingly, all at once, like a thunder-clap from the clear sky, the trees were all wilted, the blossoms just appeared to topple down, bow down their heads under the blight; nearly everything in sight was blighted, and it took it all at once. That is something that we as bee-men do not understand, or how it is so affected, but there was no blight seen upon the trees anywhere except in the blossom. I investigated it myself; I was on the ground; went amongst the large orchards and saw it with my own eyes; that blight attacked the trees directly in the blossom. About a week later than this the leaves began to shoot out amongst the blighted blossoms, and then the blight ran down the little stem that held the blossom and would affect the leaf and limbs, going on down the limbs.

About the time that we had our joint meeting of fruit and bee men regarding the moving out of the bees, the Board of Supervisors of our county appropriated money by means of which certain trees might be put under mosquito-netting to make a test that way. After we had seen the other test had failed, we thought quite likely we had a test under this head that would prove beneficial. I visited these trees and saw that they were not as reported. Perhaps you are not familiar with the report, but the Board of Horticulture published an article in our county paper stating that the trees which were under mosquito-netting were unhurt by the blight, while all the trees around them were blighted; stating further that the fruit on these trees that were under this protection was good, the trees were full of fruit, while all around them was otherwise.

I immediately went to these orchards and examined these trees under mosquito-netting, and I found that they were much blighted; I found that they had very little fruit; but I found that there was more blight existing on the trees outside the mosquito-netting than under it. But on examining those trees later in the season, after the pears were perhaps half-grown, I found that there were no more pears

upon those trees than the trees around them. This experiment was conducted in the Charles Downing orchard, the largest pear orchard in the State. You saw a picture of that orchard last night upon the screen, which was taken during the last days of June, a year ago last June, but to-day that orchard is half dead, and this winter, perhaps, three-quarters of that orchard will be dug up. This is only one. The pear-growers claim that they lose enormous sums of money. There is one grower claims he loses at least \$10,000 a year from the loss of pears alone. That was in the year 1901. If he lost \$10,000 from the loss of pears alone in 1901, this year, if this statement is correct, he has lost three times that amount; but whether it is or is not correct, the pear interests in our country are large and extensive. There are one or two pear men who have stated that they lose pears enough in a single year to buy up the whole bee-industry of the State. That is not correct. All the pears that are grown in Kings county or Central California, perhaps, would not amount to the honey industry of the State; but of the two industries growing side by side in Kings county, the pear industry is the greater, or was before the blight struck it.

The question as it stands to-day, is that the Board of Supervisors probably will do nothing. However, they are electing a new Board at this present election. But we fear this, that the fruit-growers will place notices upon their fences, "Poison about. Take care of your bees." We expect that will be done; in fact, it has been done; that is, the poison has been put out and bees have been poisoned, but the notices have not yet been posted.

The way the pear-blight is now existing and spreading rapidly, consuming the orchards, it will not be two years before there will not be a pear-tree left of the variety of the Bartletts. In view of this, our bee-keepers in our convention held the 24th of August last, passed a resolution and gave it to me to bring to this convention, which I have with me and will read. It is as follows:

The Central California Bee-Keepers' Association, assembled in regular session in Hanford, Kings Co., Calif., this 27th day of September, 1902, for the purpose of transacting business and discussing matters relative to the best interests of the Association, including the pear-blight and bee-question, which is so prominent with us at present; and

WHEREAS, The National Bee-Keepers' Association convenes at Denver, Sept. 3-5; and,

WHEREAS, It is an organization, organized for the protection of its members; and,

WHEREAS, There is in this vicinity an existing malady known as pear-blight, which is fast killing the trees and destroying the fruit crops thereby; and,

WHEREAS, The bee is accused of spreading said blight, and is alleged to be responsible to a great extent for the cause of failure in the pear crop, which loss is placed as high as \$10,000 per annum for a single grower; and said growers have made reported efforts to get the County officials to pass certain ordinances prohibiting the keeping of bees where pears are grown; and,

WHEREAS, There are threats of wholesale poisoning of the innocent bee, and said threats have, in a measure, been carried out, to the damage of some of our growers; and,

WHEREAS, This Central California Bee-Keepers' Association's members are members of the National Association, and are very desirous that the mother Association take up the matter, and in case there is further trouble, that the National Association will give us the advice and protection that is usually done in cases like this. Therefore, be it

Resolved, That we pass on this set of resolutions and preamble to the National Association assembled at Denver, Colo., asking them to consider its merits, and to discuss its contents, and that they take up the matter and give us the protection herein asked for. And be it further

Resolved, That Mr. F. E. Brown, our present Secretary, is our regular authorized representative to that body.

F. E. BROWN, *Secretary*. JOSEPH FLORY, *President*.

Pres. Hutchinson—You have heard the description given and the resolution which has been read. What shall we do with it?

S. Francis—I move the adoption of the resolution.

R. L. Taylor—Does that meet the point? This is a resolution of the California Association with regard to their troubles there, and a request that this Association examine into the matter and extend to them such advice and aid as they may need. Now, the adoption of that would not help them out any. It seems to me that motion should be put in some different form.

Mr. Abbott—Mr. Chairman, was there a seconder to that motion?

Pres. Hutchinson—I did not hear one.

Mr. Abbott—If there was not I will make another motion. This is a question which will involve the expenditure of money, and belongs exclusively to the Board of Directors. I move that the whole matter be referred to the

Board of Directors. The discussion of it may go on, but the final action will have to be taken by them.

Mr. York—I second that motion.

Dr. Mason—I had thought this would be a good plan, that we refer these resolutions to a committee, and that committee can report to-morrow and make such recommendations as may seem proper. We can hardly tell by hearing it read just what we had better do. Wouldn't that be a good plan, to put such men as Mr. Abbott, and men who can work fast, and think fast, on a committee of three with him? I move an amendment, that a committee of three be appointed to which those resolutions be referred, and they report to us during the session of this afternoon, making such recommendations as they think proper.

Mr. Rhodes—I second the motion made by Dr. Mason.

Mr. Abbott—I have no objection to the amendment. If I was on that committee I would simply go on about my business and recommend that it be referred to the Board of Directors, where it would have to go. I am a great stickler for us doing anything we can do, but while we are working under a Constitution like we have, I don't see how we could do any more than to recommend that the Board of Directors do so and so, and the presumption is that they know what is best to do. We want to draft a resolution in such shape that these people ought to be taken care of; I think that is their thought. That is my candid opinion.

Dr. Mason—I think so, too; I think we ought to attend to this, and my suggestion was simply to get it in line with what I thought was the best, the same as Mr. Abbott does; he thinks one way would be best, and I think another. In that way we get our views before you, and if you do what you think is best, that will be satisfactory to him and to me.

Mr. Ivy—I think the amendment made by Dr. Mason is a good one. This California Association did not go to the Board of Directors; they have come to this convention, and I think this convention should indorse it and recommend that those people be taken care of.

There being no further discussion, the President stated the amendment, and on a vote being called for and taken declared the amendment carried. The motion as amended was then put, and, on a vote having been taken, was declared carried.

ELECTION OF OFFICERS.

The election of officers for 1903 was held at this time, and resulted as follows:

President—W. Z. Hutchinson, of Michigan (re-elected).
Vice-President—James U. Harris, of Colorado.
Secretary—George W. York, of Illinois.

(Continued next week.)

No-Drip Shipping-Cases for Comb Honey.

BY G. M. DOOLITTLE.

QUESTION.—Do you use what are called the "no-drip" honey-cases for sending your honey to market? If so, will you please tell the readers of the American Bee Journal how you make the paper trays? I saw somewhere that I was to lay the paper on top of the case, and then, with a "follower," push it down to the bottom, when the tray would be in place and just as it should be. But after trying, and trying, I can do nothing that way, as in every case I have tried the paper becomes torn more or less, so that it would leak honey, if any dripped down on it. Please tell us all about the little kinks necessary in making and using, so that it may be plain even to the novice.

ANSWER.—Yes, I use the paper trays and have done so for more than twenty years. I have also, like you, read that all that was necessary to make these trays was to push the paper down to the bottom of the case with a board that would loosely fit the bottom of the case; and, again, like you, I never could so push one down without tearing the paper, and have often wondered if those who recommended such a procedure had ever tried the same themselves. If so, there was some part of it which has been left out, it seems to me.

Well, I will try to tell how I make these trays, use them, etc.

The first thing wanted is the paper. After testing

many different kinds I have come to the conclusion that none is equal to that known as "manilla," for this purpose, and that having the glossy finish is the best. This will hold honey a year without wetting or soaking through. Such paper can be bought by the quantity for from five to six cents a pound at the present time, but I used to have to pay from ten to twelve cents.

The next thing is the cutting to the size you wish, which you can generally get done where you buy the paper. If this is not handy then lay it on a table or bench, and after marking where you wish it cut, lay a saw or square on it where the marks are, and tear the same as you would tear it by a ruler, the back of the saw or square being used in place of the ruler, as it is longer. After a little experience you will be able to tear from six to ten sheets at a time, thus getting along quite rapidly. The paper should be cut from $1\frac{1}{4}$ to $1\frac{1}{2}$ inches larger each way than the bottom of the case you use, so as to turn up nearly $\frac{3}{4}$ of an inch on all sides.

Having the paper cut and ready, the next thing needed is a board one inch in thickness, and of a size so it will just nicely slip into the bottom of the case, but not so tight but what you can readily jar it out by turning the case bottom side up. Spend some little time on this board, getting it out true and having each and every corner true and sharp, for you will wish to use it for years, or so long as you use the same size sections and cases. If it is made of hard wood the corners will stay sharp longer and the board keep smoother.

Now lay one sheet of paper on the work table or bench, and place this board in the center of it each way, which will make your paper project about $\frac{3}{4}$ of an inch on all sides of the board. Put your finger under the paper on one side and one end and bring it up next to the edges of the board, rubbing it a little so as to make it fold at the sharp or lower edges of the board, when you will work both hands up to one of the corners which will make the point of the paper stand out in front of the corner. Now fold this point toward you, when you have what is known as the "baking-tin" joint, one which will not leak until the paper is full.

Now do all the other sides and corners the same, folding each corner toward you each time, when you will lift the board out of the tray which has thus been formed, and which will be the exact size on the outside as the inside of the case.

Now place a case on the table in front of you and beyond the paper tray, when you will take the tray by the two corners next the case, pressing the baking-tin joints to their places, and slip these joints into the open side of the case next to you, which holds the joints from spreading out or bothering you while you are placing it in the case. Now take the two remaining joints between your thumbs and forefingers, raising the tray a little till it is of the right height, when by a little gentle pushing motion the tray can be readily slipped into its place in the bottom of the case, the joints all coming into place nicely.

With the hand smooth the paper down on the bottom of the case, when you have something that will not leak unless the honey is broken badly enough to run over the top. Now should I stop here, I would leave out the part which used to bother me the worst, especially where the case is made so that a certain number of sections fit so they will not shake around any when handled, as all cases should be made. The trouble came when I went to put the middle or last tier of sections in the case. All the others could be placed up against the sides of the tray in such a manner that they would not catch on the paper, but rather come so as to hold it in place; but when I came to slip down the last sections next to the end of the case, the sections were almost sure to catch on the upper edge of the tray, and after tearing, carry the paper down to the bottom, which makes things about as bad as did that torn by pushing it down with the follower.

I studied on this matter for some time, when one day it occurred to me to get a very thin piece of tin, just a little narrower than the thickness of the section, when I placed this strip of tin within an eighth of an inch of the bottom of the case, and bent what stood above over the top of the case, cutting off what came out beyond the end of the case. Now when I came to put in the last sections at the back, I hung this strip of tin down in the case over the edge of the tray, which put the tray behind the tin so that the sections could not touch it, when the section was slipped into place, the tin lifted out by the bent-over end, and all done so smoothly and nicely that there was great rest and pleasure in it, over the former way. In writing out all the

minutiae of these matters they seem long and tedious, but in actual practice only just a moment suffices to do the whole thing, and the more anyone becomes used to such work the faster it can be accomplished.

Disposing of the Honey Crop Advantageously

Read at the Minnesota Bee-Keepers' Convention.

BY MR. SHEPHERD.

HOW to dispose of the honey crop to the best advantage?" is the question asked by the enterprising bee-keeper. Some say through the commission man, because they do not want to be bothered by selling in small quantities—they want their money all in a lump. Others peddle honey because they can realize a larger price. I prefer to work on that line, for I want that larger price, and by so doing I help keep a little off the city market, and sweeten up my neighbors.

I work on the exchange order or plan. I place in my local paper an "ad," something like this:

"Wanted—To exchange extracted honey for oats, corn, potatoes, eggs, or silver dimes."

When I commence peddling, I notice that a good many would not buy if they had to pay money, but if I would trade, "Why, yes, I will take some." By so doing I found a market for honey that would otherwise go to the commission house.

While living on the farm I would take all the eggs that I could get hold of, in exchange for honey, because I could take them to the store and exchange for something for the family, thereby accommodating my neighbor as well as myself.

You should be prepared to give your prospective buyer a taste of your honey.

Another way is to bottle it, and put it in the grocery stores. Put in jelly tumblers, or square bottles fill the bill quite well. This point should not be overlooked: Advertising your honey by having your name in as large letters as the word honey. Look at the bottled goods in the grocery stores for an example. When you buy butter, you look at the reputation of the maker, somewhat. It is the same in your honey-production.

Produce "A, No. 1" honey, so that it will "taste like more."

The "Missing Link" in Queen-Rearing.

BY HENRY ALLEY.

FOR the life of me I cannot reconcile the articles of Dr. Gallup (page 584) and Mr. Doolittle (page 569). Mr. Doolittle gives Dr. Gallup all the credit it is possible to give anyone for teaching him how to rear long-lived queens, and Dr. Gallup upsets the entire thing by telling the readers of the American Bee Journal that Mr. Doolittle's queens are worthless; that is, in the second year. Maybe I did not read those two articles understandingly. I do not agree with Dr. Gallup on this point, that is, if Mr. Doolittle rears queens by the method he says he does. I know his queens must be good, as I have reared for years more or less queens in that way, and they are always good; but if I remember correctly, Mr. Doolittle has not always reared queens in that way. I would like to ask Mr. Doolittle whether, after he commenced the cell-cup way of starting queens, did he recommend placing them in the top-story over the brood-nest of a strong colony?

As stated in a previous article, three queen-dealers appeared to make that discovery at the same time. We all thought that a marvelous thing had been discovered, but with me it proved to be the worst thing that ever happened to me in my queen-rearing experience. I found it the cheapest way to rear the cheapest queens, many of the cells so built out that they had all the appearances of containing extra-large queens, and would contain a half-grown worker-bee. Why was this so? Because the cells were built out and larvæ nursed by bees having a fertile queen. The lump of jelly was found in nearly all the cells, but, as before stated, the composition of the food was not the kind given to larvæ in cases where no queen is present. In fact the bees were not "broody," they saw no need of other queens, and would not "set" on the eggs.

The first milk a cow gives for nursing its offspring is

of a different quality from what it is several months later on; and so it is all through Nature's ways. Queens reared in the above way are "forced" queens; but queens reared in the way Mr. Doolittle and Dr. Gallup say they rear them are necessity queens. Quite a difference between the two kinds when they are put into colonies of bees.

Now, when I reared queens in the year 1860, I thought it was a waste of bees and time to use a full colony for rearing queens, and so the nucleus system was used; and, if practical to rear queens by the nucleus system, I would use it to-day; and as was the case 40 years ago, I could rear just as good queens by that system as any one would care to pay for.

"Necessity is the mother of invention," and as I found that queens could not be reared at a profit by either the nucleus or full-colony plan, as given by Dr. Gallup, I commenced to experiment, and soon discovered a way that combined all the good and essential points of the full-colony system; in fact, only full colonies were used, and have been used, by me for 38 years for rearing queens. I found that I could rear queens that were first-class in all respects by another plan. Last season I tested something entirely new, and now can rear queens that I think are superior to any reared in previous years; but the main point in this last plan is economy in bees, and quality of the queens so reared.

Speaking of the "jelly lump" at the base of the cell as indicating quality of the queen, I will say that there are other strong indications of the quality of the queen in a cell. When opening a hive and finding several queen-cells, just examine them and see if they are heavily waxed and thoroughly corrugated. This is a good indication of a fine queen within. When the young queens cut out of the cells, I notice that the good queens leave a large hole, and usually leave the cap hanging as if by a hinge, a sort of swinging door. I have been deceived many times in supposing a cell contained a queen, when, in fact, the queen had emerged and the cap flew back in place, and no indications that the cap had been removed. When a queen leaves a cell, and the outlet is small and ragged, the queen is worthless.

I never allow queens to hatch in the hives. I always remove the cells to nursery-cages. I do this to save time and bees. By having queens in cages they can be examined; if there is any defect in them (and there are many queens in a thousand that are defective), they are destroyed. Now, if defective queens are hatched in nuclei, much valuable time is lost to the queen-dealer, as it would require no more time to get a perfect queen fertilized than it does a worthless queen.

All queen-dealers have hundreds of testimonials in favor of their queens. Of course they publish them; but when a "kick" comes in we don't tell of that, do we, Mr. Doolittle?

I wish to speak of one testimonial that came in this very day. I mention it as Dr. Gallup says "we" can't rear queens that survive the second season. The writer says he "had a queen of me in 1899; she is now 3 years old, and seems more prolific, each year. It rained 25 days in June, and July was no better, yet she gave two good colonies and 25 pounds of honey, and the parent colony is overflowing with bees." I mailed this letter direct to Dr. Gallup. Now, such letters come in nearly every mail to all who rear queens, yet Dr. Gallup says our queens are worthless!

I know it makes no difference who rears queens, nor what method is used in rearing them, there will always be some trouble with queens sent out. I have sent thousands of queens to bee-keepers who write thus: "Send me a queen by return mail. I have a colony all run down that has been queenless 3, 4 or 5 weeks," as the case may be. Now what can a bee-keeper expect to do in that case? If the colony dies in the winter the queen-dealer catches it; this man tells his neighboring bee-keepers, "Such a dealer's queens are not worth anything. Put one in a hive last fall and she died in the winter." There is nothing fair about such a deal.

It is all right to introduce queens in such cases and take the chances of the colony living, but don't hold the queen-dealer responsible for the loss of the colony, if it should die before spring. It is the bee-keeper's fault, and not the queen's.

Hundreds of bee-keepers who purchase queens destroy their usefulness when they introduce the queen. A queen slightly stung (and many of the queens are), soon dies. Many of them lay a few eggs and then disappear, or are found dead in front of the hives; sometimes found in the hive and the bees building queen-cells; then they write the

dealer thus: "Queen received and introduced, but has not laid an egg," etc. In 90 percent of such cases the queen was all right but was ruined in introducing. I might go on and give hundreds of such cases.

Essex Co., Mass.

Our Bee-Keeping Sisters

Conducted by EMMA M. WILSON.

Salutatory.

DEAR SISTER BEE-KEEPERS:—

Mr. York is kindly giving us a department of our very own, in the American Bee Journal, in which we may freely give all our experiences, tell all our grievances, etc. It seems to me that there are enough of us to make this department very helpful, if we all do our part in trying to make it a success; and remember it depends upon ourselves whether it is a success or not.

It is not intended for large bee-keepers alone, but for all. No matter if you have only one colony, or may not have any as yet, but are interested in bees, and want to talk with some one else that is interested, too, please remember that this department is for you.

If there is any little item of information, anything that has helped you, and may be of benefit to some one else, even if you think it hardly worth mentioning, don't hesitate to send it in. It may help some one greatly. I sometimes think the little things are of much more value than we give them credit for. So much of our life is made up of little things. So let us hear from you all.

Marengo, Ill.

EMMA M. WILSON.

Bee-Dress for Women—Comments.

On page 317, Mrs. N. O. Penny suggests the wearing of bloomers in place of an underskirt; bloomers to be made of the best blue drill or denim. Also leggings made of the same material to be worn with low shoes. How many have tried them? How did you like them? Please report.

I have worn leggings made of heavy brown linen. They were as good as far as preventing stings was concerned, and cooler than shoes, but not as cool as low shoes without leggings; and for myself I prefer to take the stings and be a little cooler. I mean in the very warm weather during the honey harvest when bees are good-natured.

On page 345, Mrs. F. A. S. Snyder says:

"In advising woollen skirts we lose sight of the fact that the honey-bee has implements on the three little claws of its hind legs shaped like a hoe, a trowel, and a rake, and these delicate little implements catch on the wool and cause no end of unnecessary annoyance to the bees. I know if I wore woollen skirts in the apiary, the back, though 'the apron covers the front,' would be full of struggling, stinging little prisoners caught on the fuzzy material."

Mrs. Snyder evidently supposes that the back of the skirt is unprotected, whereas my aprons are made to cover the whole skirt—back as well as front. I have never had the least trouble with the bees stinging my woollen skirt.

Mrs. Snyder says she wears black cotton shirt-waists, and also says she rarely gets a sting. Now, I know if I wore black waists I should get many a sting, for if there is anything our bees seem to object to it is something black, if they are at all inclined to be cross. I have known at least a dozen cross bees at a time to attack the black head of my hat-pin, that being the only black object in sight. I could not see them on my own head, but it was very amusing to others to see them tumbling and sliding off the smooth surface trying to sting it.

If they are very cross or excited, anything black seems to enrage them, while they will seldom sting anything white.

Now, as to wearing gloves: I suspect each one must be governed by her own preference

in this matter. I certainly can work with much greater despatch with gloves, than without them. They protect my hands from stings, keep the bees from crawling up my sleeves—which I dislike quite as much as the stings; keep my hands and dress-sleeves clean. I have a pair of sleeves sewed to my gloves which, of course, are pulled over my dress-sleeves, and that one item of keeping my sleeves clean would count much with me. I never clip a queen with my gloves on, but as they are so easily slipped off and on, it is no trouble to slip them off when I want to do any work of that kind.

I decidedly prefer to wear gloves; but you have just as good a right to object decidedly to them; as I said, each one must be governed by her own preference in the matter.

Others may not object to the feeling of propolis on their fingers as I do. I have known persons who could not endure the least bit of honey on their fingers, but could have their fingers covered with propolis. That I never could have endured at all. You see we are not all made alike.

Smoker-Fuel.

Mr. Ralph D. Cleveland (page 620) thinks if I would try excelsior as a smoker-fuel I would abandon soaking rags, and hunting good "smoke-wood."

Well, Mr. Cleveland, I have tried it, and given it up because it did not last long enough; but perhaps I did not pack it down hard enough. Many thanks for the suggestion. I will try again, and give it a good, solid packing next time.

As to smoker-fuel, however, it is largely a matter of convenience. In this locality there are plenty of good chips handy; they make a good smoke, last well, and with a little saltpeter or a few live coals to start with, there is no trouble in lighting them, so they are likely to continue the favorite fuel for a time. Just so, others may find other things more convenient.

Apiary of Mrs. C. R. West.

We commenced the bee-business six years ago, and I was so enthusiastic that I thought the more colonies I had the more honey I would get. I was like some other so-called bee-people—I did not want one or two colonies. When I was at the business a little while it was no trouble for me to see I did not know so much. Two years ago I bought 26 colonies; they were good and strong, and made it pay me. I am a dear lover of the bee; I think it is such nice work, and then the little things teach such good lessons.

In the picture which I send is Mrs. Holoway and little son also. The little girls are Ruth and Mary McFarland. The man is my brother.

Our honey crop is short in Texas. In the spring we had every prospect of a good yield, but the hot, dry winds dried up the nectar, and also the bloom. I fed our bees for six weeks. Now cotton is blooming and they are storing honey. The cotton honey is pretty and white.

Last year they had a good honey exhibit at our convention, and this year only one man brought any, so we had to give him the blue ribbon. Oh, well, perhaps we will be more successful another year. I never give up. "'Tis try, try, try again."

I now have 35 colonies, and they are doing nicely. I

MRS. C. R. WEST AND APIARY, OF ELLIS CO., TEX.

live in hopes of a successful ending. Hope is a great anchor. Thank God for hope. "Faith, hope and charity, but the greatest of these is charity." But I am "stuck" on hope.

Ellis Co., Tex., July 21.

MRS. C. R. WEST.

Questions and Answers.

CONDUCTED BY

DR. C. C. MILLER, Marengo, Ill.

[The Questions may be mailed to the Bee Journal office, or to Dr. Miller direct, when he will answer them here. Please do not ask the Doctor to send answers by mail.—EDITOR.]

Beginning in Bee-Keeping.

I am an amateur, with absolutely no knowledge of the first principles of bee-keeping. I have no bees, hive, or friends that know, but an abundance of flowers. Will you kindly inform me how to begin? Where can I get supplies in this section of the country? CALIFORNIA.

ANSWER.—Well, now, that's refreshing, to find a man who knows that he doesn't know anything! The first thing is to get a good text-book, and as it is now late in the season, you will have plenty of time to become familiar with it before it is time to make a purchase next spring. Indeed, when you have been told to get a text-book you have been told about all you need to be told for the present, for the office of such a book is to answer a multitude of questions that will arise in your mind, besides a number of others that you would not have thought of. Before spring you will probably become so interested in the matter that you will want a bee-paper—unless you have made the mistake that so many make by getting a bee-paper before a text-book—and in the Journal you will find advertisements of those who have bees to sell, and you can then order from some one not too far off, so as to save enormous express charges. After you have fairly started in your text-book, your visits to this department will be specially welcome, and you need not hesitate to ask about anything that does not seem entirely clear in the text-book.

Queenlessness During Swarming-Time—Moths on Comb Honey—Wintering Bees.

1. What is the cause of bees getting queenless during swarming-time? I had one colony that cast a swarm about the middle of June, and not wishing for swarms I went through the hives and cut out all queen-cells, leaving one young queen in the hive, which was constantly singing from the time it hatched until she came fourth with another swarm, leaving the colony queenless, and no brood to rear. Two weeks afterwards I gave them a new queen which they accepted and everything was all right. What was the cause of the bees swarming out with that queen and leaving the mother colony queenless?

2. What is the cause of moth getting in the sections of comb honey? I keep them in a dark, dry, warm place? What can I do to kill them? I have about 400 sections of fine white honey, and I keep it in a closet close to the cook-stove, and some of it has small moth in it.

3. What is best to put over brood-frames to keep the bees dry in winter?

4. Will bees winter well in a tight shed closed all around except 14 inches. ILLINOIS.

ANSWERS.—1. It is not an uncommon thing for bees to swarm out with a virgin queen when she takes her wedding-flight, and whether they swarm out with her or not there is a chance that something may happen to the queen, such as being caught by a bird, and then, of course, the colony is hopelessly queenless. Once in a great while a colony is so foolish as to swarm out with a young queen in regular swarming style when there is no other queen or queen-cell left in the hive. I don't know why?

2. The probability is that the eggs of the moth were laid in sections while they were yet on the hive, and while you are keeping the sections in the best kind of a place, it is also a good place for the moth's eggs to hatch and develop. While they are still small it will be an easy mat-

ter to destroy them by fumigating with bisulphide of carbon or with sulphur.

3. It is largely a matter of convenience, depending upon what there is to be had most easily. Probably nothing is better than cork-dust. Dry leaves are also good, planer-shavings, chaff, rags, etc.

4. Some winter very successfully in that way, especially in localities as far south as yours, where the winters are not so severe as farther north.

Place to Winter Bees—Winter Temperature for Bees—Weight of Bees, Hive, Etc., for Winter.

I have a small room built up next to the roof of a double granary, enclosed with a 6-inch wall of chaff on top, bottom and all sides except south, which has one window. I wintered 5 colonies in this room last winter—all that I had—I am a beginner. Three of them came out sound and saucy, and the other two starved to death.

1. Do you think this is a good place to winter bees? or do they need more feed in such a place than in a cellar?

2. At what temperature should this room or cellar be kept to give the bees a chance to ripen and seal syrup given to them made of granulated sugar? Or will they ripen and seal it all in winter?

3. About what should a common 8-frame hive, bees and comb, weigh when it contains 25 pounds of honey? IOWA.

ANSWERS.—1. The probability is that a cellar would be better, at any rate the bees would consume less in a cellar.

2. The general opinion is that 45 degrees is the best temperature for a cellar. Warmer than that might favor ripening, but the bees would not do so well. Better not count on bees ripening syrup after the first of October. If you must feed too late for bees to ripen the syrup, give candy as directed in your text-book.

3. I don't know for sure, but think it would be about 45 pounds.

Worms Working on Honey—Keeping and Fumigating Honey.

1. I have about 100 pounds of comb honey in sections, and I notice here and there a section which has a few places where there are little grindings. It looks as if a worm is there, but I cannot see anything. Perhaps the black ants have done it, as there are still a few running around when I open the cupboard.

2. I have the honey upstairs in a cupboard, south side of the house. Where should it be kept?

3. Should honey be fumigated if to be kept until next year? What should I use? I have been thinking of using brimstone. Will this hurt the honey? PENN.

ANSWERS.—You are safe in laying the blame on worms rather than ants. The first intimation of their work on sections will be found on the edges where the comb joins the wood, a little heap of whitish powder, but the worm is so small it is not easily seen.

2. Upstairs is a good place if warm. A hot, dry place is the thing. Indeed, if kept in a very hot place through the summer, as in a garret next the roof, it will stand freezing in winter without injury.

3. It may or may not need fumigating. Depends upon whether the moth has laid any eggs in it. Brimstone will do, and will do no hurt if not used too strong. Bisulphide of carbon is more in favor than brimstone or sulphur nowadays.

Honey as a Health-Food is the name of a 16-page leaflet (3½x6 inches) which is designed to help increase the demand and sale of honey. The first part is devoted to a consideration of "Honey as Food," written by Dr. C. C. Miller. The last part contains "Honey-Cooking Recipes" and "Remedies Using Honey." It should be widely circulated by every one who has honey for sale. It is almost certain to make good customers for honey. We know, for we are using it ourselves.

PRICES, prepaid—Sample for 2 cts.; 10 for 10 cts.; 25 for 20 cts.; 50 for 35 cts.; 100 for 60 cts.; 250 for \$1.25; 500 for \$2.25; 1000 for \$4.00. If you wish your business card printed at the bottom of the front page, add 25 cts. to your order.

BEE-KEEPERS--ATTENTION.

Do not put your money into New Fangled Bee-Hives, but buy a plain, serviceable and well-made hive, such as the regular Dovetailed hive arranged for bee-way sections. Honey-producers of Colorado—one of the largest honey-producing sections in the world—use this style.

Thousands of Hives, Millions of Sections, ready for Prompt Shipment.

Going for the Doctor

through the storm and darkness while the suffering one at home is in danger, perhaps of death, is a terrible trip. Why not have a good, sure family remedy in the house? One that has proven a life saver in thousands of cases during the last forty years.

Watkins' Vegetable Anodyne Liniment.

Think what a world of terror and anxiety was saved this man.
DISPENSES WITH DOCTORS.

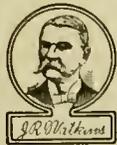

Middle Grove, Illinois, June 4, 1901.
We have used Watkins' Vegetable Anodyne Liniment in severe cases of flatulent colic; have employed veterinary surgeons before, but rely entirely on Watkins' Liniment now, for family use as well as for stock.

WALTER DIEMAN.
Watkins' Liniment is not only a great thing in cases of serious injury through accident, but is always helpful in cases of cold, Colic, Diarrhoea, Dysentery, Indigestion, Cuts, Burns, etc. It is equally good for man or beast. If by any chance we have no agent in your vicinity, write to us, and we will feel that you are supplied.

A TREAT FOR ALL.

Our new Cook Book and Home Doctor, containing a hundred pages of valuable information in cooking, gardening etc. is out for '02. We mail it free to anyone sending his name and address on a postal card. Write at once and address

What Yon Yonson Thinks

My ying, you better believe ven ay furst com to das country ay bean purty gread. Da boys, dom foller me roun, an von he say, "Git on to da Svede." Noder von feller he say, "Hey, Svede, drive under da shed!" Von boy he ask me if ay bean sure ma modder know ay vas vay from home." "Mine goodeness," ay say, "you boys vas make big misstake; ay don't got any home; ay bean look for yob."

So by an by ay hire for yob on section; dom pay me doller an quavter day, and ay ete me self. But ay don't lak very vell for to work an da section, so me hire for Ole Peterson to work on farm. He say he don't got very hard work, an ay only hav to milk 15 cows fore brekfus, so he pay me doller day an he ete me tre times a day cept Sunday, den he only ete me twice.

Von day ay vent to post-office an ay ask das office mans if he bean got any letter for me, and he yust stan an look at me an he say, "Vot bean your's name?" "Mine goodeness," ay say, "you tank ay bean fool? Vont da name be on da letter?" An he yust stan an laff for bout 15 minnit.

Ven das country bean first settled it bean yust plum full ma golden-rods, an all kines ma flowers, but now da mans dom bean plowed it up, an dom plant potatis an eorn an oats, an dat don't vas nutting for bees. An still dom mans tank dom can have hundreds ma svarms. Now, ven dom don't bean but few before, an dom don't plant nottings for da bees, dom vont dom to work all summer, Sunday an monday, an bord demselves, an make hole pile ma honny for da mans, yust like Pharaoh did ma Israel's childrens. He say dom got to make brick and dom got to make yust so much brick ven dom don't got any straw, som dom make before ven dom got plenty straw. Better take das bible down an read Eexodus 5th chapter, and den you vill fine out all about it. An if you vill read on you vill fine out how dom chilren go for 40 years to fine das Promis Lan, dom flow ma milk and honey. Ay tank da moste be lots ma flowers in das lan. Mebby it bean som sweet clover an catnip an phacelia an ross-berrys. Ay know it say it bean lots ma fruit, an ofull nice big frute vot dom spies bring back. It moste bean lots ma bees, cause ven dom svarm down even make das home in da big lion vat Samson killed, an Samson he say it don't bean nothing sweet like hunny. But ay don't kin fine dat dom blame dem little bees for to make da pears to blight, an da moste be good bees. Ay tank da bean lots about bees in da bible. Mebbe dom big bee-mans, some of dom, don't bean read all of it yet.

Da bees have bean give us for great blessing, and ve moste seen to it dat dom don't starve, an dat dom don't got any straw. Mr. Newman vot make das bee-book called "Bees and hunny," he say he don't cau understand how a yenerous-harted bee-keeper can go on an increas his bees an not make provide so dom don't starve. An he say if ve vill scatter bout tirty cent vort of seeds for each bee svarms ve can increas to 500 svarms an not be overstock. Mine goodeness, vat you tank of cas? Newman he don't bean von dem kine of fellers vot talk tru his had eder, you bet. Ay tank ven Yon Yonson git plenty all kines of honey-plants he yust goan to make Rambler's hunny crop per svarms, look lak bout five sents a vort of soap.

Now, if ve rais akers an akers ma corn for hogs an it pay, vy for it don't pay to raise somethings for dom bees vot work so hard? Ay got 42 head of hogs, nice vons, but, my ying, dom don't board domselves; dom youst ete all da time, an dom don't got sens nuff to work for nobody, and if I don't feed dom ragler dom youst stan aroun an make big squeal an fuss. Ay know dom big bee-mans dom say it don't goan to pay to plant any ting for bees alone, but ay tank dom make big misstake. Ay tank it don't bean fair for

Langstroth on... The Honey-Bee

Revised by Dadant—1900 Edition.

This is one of the standard books on bee-culture, and ought to be in the library of every bee-keeper. It is bound substantially in cloth, and contains over 500 pages, being revised by those large, practical bee-keepers, so well-known to all the readers of the American Bee Journal—Chas. Dadant & Son. Each subject is clearly and thoroly explained, so that by following the instructions of this book one cannot fail to be wonderfully helped on the way to success with bees.

The book we mail for \$1.25, or club it with the American Bee Journal for one year—both for \$1.75; or, we will mail it as a premium for sending us **THREE NEW** subscribers to the Bee Journal for one year, with \$3.00.

This is a splendid chance to get a grand bee-works for a very little money or work.

dom little bees to ride in hive-vagon all time, ven das nice hunnys vat dom make it bean fit to adorn any king's table. Ay bean look aroun' an ay don't fine it bean any bee-farmer vat plant his hole farm for da bees like dom do for da hogs, how kin dom tell ven dom never bean try it? It look like dom all bean fraid, au dom vant some von else to try it first. Now, ven ay ete a vatermelon ay don't svaller hole ting to vous. Mine goodness, no! But ay take little bite to see if it vas sveet, den a tak little bigger, an by an by it bean all ete up. So das vay moste ve du try vat bean best for our locality, den tak bigger bite; but if ve tak very big bite ve moste chaw fast.

Vell, if ve have nice vedder ay bean come over next week.

YON YONSON.

Pear-Blight Not Caused by Bees.

In regard to pear-blight, I can say that bees have nothing to do with it. If they have, they must have come some 10 or more miles to blight the trees here some years ago, and the trees where bees were, 12 miles from here, were full of fruit and no blight.

Ontario, Canada. THOS. ARCHER.

Craves a Warmer Climate.

Last year, about the same time of the year that you were at Denver this year, I made a trip into the mountains, and I also went up to Silver Plume, as well as up Pike's Peak, so I have been there, and know how to appreciate what you have to say about the grandeur of the mountains. I now think some of spending three months in California next winter (after New Year's) if nothing prevents. I do not like our cold and windy winters. It was all right when I was young, and for many years from 1857 onward I enjoyed hunting on the plains, even in the winter. But that good time has passed long ago. I am nearly 72 years old, and the fire of youth is vanishing, so that I begin to feel it. I crave for a warmer climate when the cold of winter is upon us.

Hall Co., Nebr., Oct. 24. WM. STOLLEY.

Little Surplus—Robber-Bees.

Bees here did store a little surplus honey late this fall. But there is not half the honey this year that there was last. It is nice, clear honey. The moths bother some. Neighbors' bees have robbed some, but mine did not rob or get robbed yet, that I know of. Some neighbors lost some colonies that were robbed.

Newton Co., Ind., Oct. 27.

No Surplus Honey.

This has been the poorest honey season I have had in 50 years' experience in bee-keeping. The bees started out fine in the spring, commenced to swarm about April 1, and quit on May 18. I was not expecting them to swarm, as the most of them had given up the swarming craze. I had 80 first swarms, but am doubling and trebling all of the colonies, and will have to feed them. No surplus honey from any of the colonies.

Christian Co., Ill., Oct. 27.

Large Queens and Hives.

I notice first and last there is considerable discussion in the Bee Journal about large, prolific queens. I want to say that from careful experience and observation in the queen-rearing business for 20 years I find the largest queens almost as objectionable as the small, dark queens. When compared with a medium-size, well-nourished queen that has a long, but good-sized pointed abdomen, these queens are the most prolific, the longest lived, will lay earlier in the spring, and their work-

A New Bee-Keeper's Song—

"Buckwheat Cakes and Honey"

Words by EUGENE SECOR.

Music by GEORGE W. YORK.

This song was written specially for the Buffalo convention, and was sung there. It is written for organ or piano, as have been all the songs written for bee-keepers. Every home should have a copy of it, as well as a copy of

"THE HUM OF THE BEES in the APPLE-TREE BLOOM"

Written by

EUGENE SECOR and DR. C. C. MILLER.

PRICES—Either song will be mailed for 10 cents (stamps or silver), or both for only 15 cents. Or, for \$1.00 *strictly in advance* payment of a year's subscription to the American Bee Journal, we will mail both of these songs free, if asked for.

GEORGE W. YORK & CO.

144 & 146 Erie St., CHICAGO, ILL.

apiary was large, and much swarming expected, I have usually noted those most likely to swarm.

Then in the afternoon, when the yard was quiet, and little or no swarming expected, I have anticipated their plans a little by artificially swarming them, and in this way avoided much annoyance, confusion, and demoralization of all the bees in the yard that a swarming-panic might create.

It is important that the bees should be gathering honey and secreting wax in order that their work of comb-building may be begun at once in the new hive, unless feeding is to be resorted to, in which case it is better to give the colony at least one liberal feed 24 hours before they are swarmed. The colony to be swarmed should be strong in bees and brood, and have a laying queen.—H. R. BOARDMAN.

Blacks are much more apt to swarm out than Italians. Carniolans build comb faster than the others, and build up quicker; or, at least, those in one of Cogshall's apiaries here do. The brood is to be put into a new hive and set facing away from the swarm. I stop the entrance with green grass; and by the time the grass wilts the colony is able to care for itself. In filling the hive with brood I put in ten full frames, the combs of honey or those with but little brood being put either on other colonies or extracted. This makes less increase and stronger colonies. Sometimes there will be brood from three different hives to make one.—HARRY HOWE.

M. A. Gill has practiced the plan for years, and among other things says:

This plan I consider the most sensible one for transferring from box-hives or crooked combs, only we are compelled to drive instead of shake, and the only plan by which we can successfully cope with foul brood.

If this plan is diligently followed through the honey season with all colonies that show even one cell of foul brood, we do not come up to winter with a lot of colonies that must be burned to prevent the spread of the disease. A colony that develops the disease in the fall after the honey season is past will live until the beginning of the next honey season in fair condition, when it can be shaken; hence, the great loss from foul brood is found only among careless bee-keepers.

In practicing this plan in out-apiaries I examine every six days, and shake every colony that has eggs in the cell-cups. Of course, this makes some swarms a little premature, say from four to six days before the swarm would emerge by the natural plan; and unfavorable weather conditions sometimes make you wish you hadn't; but it also makes the natural swarm wish they hadn't.

E. E. Atwater gives these points to be observed:

1. Shook swarms must be very strong.
2. A comb of brood will usually obviate danger of pollen in sections.
3. Supers must contain bait-combs, or, better, be taken from colonies well at work in the sections.
4. In the arid region, with its cool nights, brood from shook swarms must always be under the care of a large force of bees, to prevent loss by chilling.
5. Last, and of great importance, the shook swarm must be strengthened several times during the flow.

Walter S. Poulder disposes of the brood as follows:

I have always disposed of the remaining brood in two ways—by strengthening weak colonies and by tiering up over an excluder for extracting. I have tiered as high as five stories, and it seemed to me that such colonies contained a barrel of bees. In such cases I allowed only three or four combs of brood in the lower chamber, filling the remainder of the hive with empty combs or foundation in order that the queen might have plenty of room. As fast as the brood hatched in upper stories they filled the empty cells with honey, making the way possible for a large yield, and greatly improving the results from the hives from which the brood was taken.

Editor Root gives four important claims in favor of the plan, all of which look reason-

BARNES' FOOT POWER MACHINERY

Read what J. I. PARENT, of Charlton, N. Y., says: "We cut with one of your Combined Machines, last winter, 50 chaff hives with 7-in. cap, 100 honey racks, 500 brood-frames, 2,000 honey boxes, and a great deal of other work. This winter we have double the amount of bee-hives, etc., to make, and we expect to do it with this Saw. It will do all you say it will." Catalog and price-list free.

Address, W. F. & JOHN BARNES,
995 Ruby St., Rockford, Ill.

Please mention Bee Journal when writing

The Rural Californian

Tells all about Bees in California. The yields and Price of Honey; the Pasturage and Nectar-Producing Plants; the Bee-Ranches and how they are conducted. In fact the entire field is fully covered by an expert bee-man. Besides this the paper also tells you all about California Agriculture and Horticulture. \$1.00 per year; 6 months, 50 cents. Sample copies, 10 cents.

able, except that the third applies to natural swarms as well. His four points are these:

1. Swarming can be controlled at out-yards with small brood-chambers, when run for comb honey. This is of tremendous importance, if true.

2. A brushed swarm may be stronger and produce more comb honey than a natural one, because the former may have all the flying bees, and subsequently receive, at a second drive, the brood that is hatched from the parent colony. If reports may be believed, such a powerful force of bees in one brood-nest means a larger yield of comb honey.

3. It appears that starters are just as good as full sheets of foundation, under some conditions at least. If this is true, it will save buying some brood foundation. If a young queen is in the hive, and the supers are put on soon enough, it is asserted that worker-brood will be reared about as fast as the queen can take it. But suppose that drone-comb is built out instead of worker, no great harm results, it is argued; for such comb can be cut out and melted up, for every one knows that wax sells at a good price; and some there are who believe that wax and comb honey can be produced simultaneously, with profit and to advantage.

Yes, it has been urged in times past that, in a heavy honey-flow, bees will secrete wax *involuntarily*; that if the wax-scales are not used in comb-building they will be wasted. The inference is, that the brushed swarm with foundation starters can and does utilize this surplus wax. If this be true, the foundation bill can be cut down 75 percent, and, in addition, save wax-scales.

4. Another incidental result—that pointed out by Mr. Howe in this issue—is that foul brood can be kept under control: for the brushed-swarm plan has some of the principal features of the McEvoy treatment of curing this disease. I believe there may be something in this; for years ago, in our own yards, we cured something like 50 or 60 colonies of foul brood by merely shaking the bees on frames of foundation. Then the plan of brushing the swarms, or shaking them, will hold either foul brood or black brood in check; and perhaps cure it altogether in localities where the disease is raging.

CONVENTION NOTICE.

Chicago - Northwestern. — The executive committee of the Chicago-Northwestern Beekeepers' Association have planned to hold the best convention ever convened in Chicago. The date is Dec. 3d and 4th, Wednesday and Thursday. Five eminent bee-keepers have been invited, and are expected to attend. More definite announcement later. Watch for it. Reduced rates on account of the fat stock show, which is held Nov. 29th to Dec. 6th.

BEE=BOOKS

SENT POSTPAID BY

GEORGE W. YORK & CO.,

144 & 146 Erie St., - CHICAGO, ILL.

Bee-Keeper's Guide, or Manual of the Apiary, by Prof. A. J. Cook, of Pomona College, California. This book is not only instructive and helpful as a guide in bee-keeping, but is interesting and thoroughly practical and scientific. It contains a full delineation of the anatomy and physiology of bees. 544 pages. 295 illustrations. Bound in cloth. 1902 edition—19th thousand. Price, \$1.20.

Langstroth on the Honey-Bee, revised by Dadant.—This classic in bee-culture has been entirely re-written, and is fully illustrated. It treats of everything relating to bees and bee-keeping. No apiarian library is complete without this standard work by Rev. L. L. Langstroth—the Father of American Bee-Culture. It has 520 pages, bound in cloth. Price, \$1.25.

ABC of Bee-Culture, by A. I. Root.—A cyclopedia of 400 pages, describing everything pertaining to the care of the honey-bees. Contains 300 engravings. It was written especially for beginners. Bound in cloth. Price, \$1.20.

Scientific Queen-Rearing, as Practically Applied, by G. M. Doolittle.—A method by which the very best of queen-bees are reared in perfect accord with Nature's way. Bound in cloth and illustrated. Price, \$1.00; in leatherette binding, 60 cents.

Bees and Honey, or Management of an Apiary for Pleasure and Profit, by Thomas G. Newman.—It is nicely illustrated, contains 160 pages, bound in cloth. Price, in cloth, 50 cents; in paper, 30 cents.

Advanced Bee-Culture, Its Methods and Management, by W. Z. Hutchingson.—The author of this work is a practical and entertaining writer. You should read his book; 90 pages, bound in paper, and illustrated. Price, 50 cents.

Bee-Keeping for Beginners, by Dr. J. P. H. Brown, of Georgia.—A practical and condensed treatise on the honey-bee, giving the best modes of management in order to secure the most profit. 110 pages, bound in paper. Price, 50 cents.

Bee-Keeping for Profit, by Dr. G. L. Tinker.—Revised and enlarged. It details the author's "new system, or how to get the largest yields of comb or extracted honey." 80 pages, illustrated. Price, 25 cents.

Bienen-Kultur, by Thomas G. Newman.—This is a German translation of the principal portion of the book called "Bees and Honey." 100-page pamphlet. Price, 25 cents.

Apiary Register, by Thomas G. Newman.—Devotes two pages to a colony. Leather binding. Price, for 50 colonies, \$1.00.

Dr. Howard's Book on Foul-Brood.—Gives the McEvoy Treatment and reviews the experiments of others. Price, 25 cents.

Winter Problem in Bee-Keeping, by G. R. Pierce.—Result of 25 years' experience. Price, 30 cents.

Foul Brood Treatment, by Prof. F. R. Cheshire.—Its Cause and Prevention. 10 cts.

Foul Brood, by A. R. Kohnke.—Origin, Development and Cure. Price, 10 cents.

HONEY AND BEESWAX
MARKET QUOTATIONS.

CHICAGO, Oct. 9.—The advance noted in our last quotation has been maintained, and there is a very good demand for honey at the present time. No. 1 to fancy white comb brings 15@16c per pound, with the lower grades selling at from 2 and 3 cents less; this includes the light amber. Dark grades of amber sells at about 10@11c, and buckwheat 9@10c. Extracted is steady with white bringing 6@8c, according to color, flavor and quality; the amber brings from 6@7c; dark, 5@6c. Beeswax in good demand at 7c.
R. A. BURNETT & Co.

ALBANY, N. Y., Oct. 24.—The receipts of honey do not increase any, and there is a good, stiff demand at good prices. Ruling prices are 15c for white, and some extra fancy, 16c; buckwheat and dark, 13@14c. Extracted, dark, 6@7c; mixed, 6@7c; white, 7@7½c. Beeswax, 30c.
H. R. WRIGHT.

BOSTON, Oct. 20.—Our honey market remains firm, with good demand and fair stocks on hand. Honey is not coming forward as fast as usual, and the tendency of prices is steady. We quote our market as follows: Fancy white 1-pound sections in cartons, 16c; No. 1, 15c; No. 2, very light supply, 14c; glass-front sections generally one cent less than this. Extracted, light amber, 8c; amber, 7½c.
BLAKE, SCOTT & LEE.

KANSAS CITY, Oct. 20.—The receipts of comb and extracted honey are light, and demand steady at quotations: Fancy white comb, 14@15c; No. 1 white, 14@14½c; No. 2 white and amber, 13@13½c. White extracted, 7@7½c; amber, 6@6½c. Beeswax, 24@26c.
C. C. CLEMONS & Co.

CINCINNATI, Oct. 4.—The demand for extracted honey is good at the following prices: Southern and amber sells at 5½@6½c; better grades, 7@8c. Comb honey is scarce; fancy and No. 1 sells on arrival at 16@17c. Beeswax weak at 28c.
THE FRED W. MUTH CO.

NEW YORK, Oct. 10.—We are having a good demand for comb honey and receipts are quite plentiful. We quote fancy white at 15c, and some exceptionally fine lots will bring from 15½@16c; No. 1, white, 13@14c; amber, 12c.

Buckwheat is late arriving, and none has been on the market as yet to cut any figure. We expect large receipts next week, and it will sell at from 10@12c, according to quality and style of package.

Extracted in fairly good demand at 7½c for white, 6½c for light amber, and 5½@6c for amber. Southern in barrels at from 55@65c per gallon. Beeswax nominal at 28c.
HILDRETH & SEBELKEN.

CINCINNATI, Oct. 27.—The demand for comb honey is good and prices are a little better, as the supply does not meet the wants. Extra water-white fancy is selling as high as 16@17c; other grades less, according to quality. Extracted is very active and prices are a little better; amber, 5½@5¾c; alfalfa, 6½@7c; white clover, 7½c. Beeswax, 28c. C. H. W. WEBER.

SAN FRANCISCO, Oct. 15.—White comb honey, 12@12½c; amber, 8@10c; dark, 7@7½c. Extracted, white, 5½@6c; light amber, 5@5½c; amber, 5@5½c. Beeswax, good to choice, light, 27@29c; dark, 25@26c.

There are no heavy offerings of any description, either at this center or at producing points. Comb honey is in better spot supply, however, than extracted. Stocks of latter have been greatly reduced by recent shipments outward. Current values are being well maintained.

A Celluloid Queen-Button is a very pretty thing for a bee-keeper or honey-seller to wear on his coat-lapel. It often serves to introduce the subject of honey, and frequently leads to a sale.

NOTE.—One reader writes: "I have every reason to believe that it would be a very good idea for every bee-keeper to wear one [of the buttons] as it will cause people to ask

questions about the busy bee, and many a conversation thus started would wind up with the sale of more or less honey; at any rate it would give the bee-keeper a superior opportunity to enlighten many a person in regard to honey and bees."

The picture shown herewith is a reproduction of a motto queen-button that we are furnishing to bee-keepers. It has a pin on the underside to fasten it.

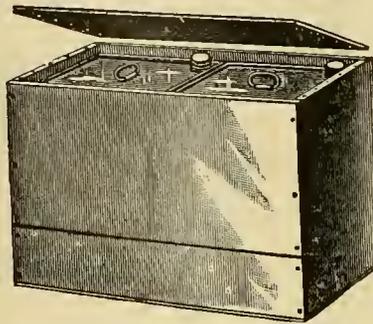

Price, by mail, 6 cents; two for 10 cents; or 6 for 25 cents. Send all orders to the office of the American Bee Journal.

BEST Extracted Honey For Sale

ALL IN 60-POUND TIN CANS.

Alfalfa Honey

This is the famous White Extracted Honey gathered in the great Alfalfa regions of the Central West. It is a splendid honey, and nearly everybody who cares to eat honey at all can't get enough of the Alfalfa extracted.

Basswood Honey

This is the well-known light-colored honey gathered from the rich, nectar-laden basswood blossoms. It has a stronger flavor than Alfalfa, and is preferred by those who like a distinct flavor in their honey.

Prices of Alfalfa or Basswood Honey:

A sample of either, by mail, 10 cents, to pay for package and postage. By freight—two 60-pound cans of Alfalfa, 9 cents per pound; 4 cans or more, 8½ cents a pound. Basswood Honey, ½ cent more per pound than Alfalfa prices. Cash must accompany each order. You can order half of each kind of honey, if you so desire. The cans are two in a box, and freight is not prepaid. Absolutely Pure Bees' Honey.

Order the Above Honey and then Sell It.

We would suggest that those bee-keepers who did not produce enough honey for their home demand this year, just order some of the above, and sell it. And others, who want to earn some money, can get this honey and work up a demand for it almost anywhere.

GEORGE W. YORK & CO., 144 & 146 Erie St., Chicago, Ill.

The Novelty Pocket-Knife.

Your Name and Address on one side—Three Bees on the other side.

(THIS CUT IS THE FULL SIZE OF THE KNIFE.)

Your Name on the Knife.—When ordering, be sure to say just what name and address you wish put on the Knife.

The Novelty Knife is indeed a novelty. The novelty lies in the handle. It is made beautifully of indestructible celluloid, which is as transparent as glass. Underneath the celluloid, on one side of the handle is placed the name and residence of the subscriber, and on the other side pictures of a Queen, Drone, and Worker, as shown here.

The Material entering into this celebrated knife is of the very best quality; the blades are hand-forged out of the very finest English razor-steel, and we warrant every blade. The bolsters are made of German silver, and will never rust or corrode. The rivets are hardened German silver wire; the linings are plate brass; the back springs of Sheffield spring-steel, and the finish of the handle as described above. It will last a last-time, with proper usage.

Why Own the Novelty Knife? In case a good knife is lost, the chances are the owner will never recover it; but if the "Novelty" is lost, having name and address of owner, the finder will return it; otherwise to try to destroy the name and address, would destroy the knife. If traveling, and you meet with a serious accident, and are so fortunate as to have one of the "Novelties," your POCKET-KNIFE will serve as an identifier; and in case of death, your relatives will at once be notified of the accident.

How appropriate this knife is for a present! What more lasting memento could a mother give to a son, a wife to a husband, a sister to a brother, or a lady to a gentleman, the knife having the name of the recipient on one side?

The accompanying cut gives a faint idea, but cannot fully convey an exact representation of this beautiful knife, as the "Novelty" must be seen to be appreciated.

How to Get this Valuable Knife.—We send it postpaid for \$1.25, or give it as a Premium to the one sending us THREE NEW SUBSCRIBERS to the Bee Journal (with \$3.00.) We will club the Novelty Knife and the Bee Journal for one year, both for \$1.90.

GEORGE W. YORK & CO.

Chicago, Ill.

Please allow about two weeks for your knife order to be filled.

* Editorial Comments. *

Keeping Combs of Pollen.—To preserve combs of pollen from one season to another, it has been recommended to dust well with powdered sugar the cells containing pollen as a protection against mold. In addition to this, some say sprinkle water over the sugar that is sifted on, treating only one side of the comb, then in a few days, after this side has become dry, treat the other side in the same way.

Generally, pollen may be left safely in care of the bees, especially if left near the middle of the brood-nest. But you may have combs of pollen outside the hives. If no honey be in the comb containing the pollen, don't put it in a damp place fitted to encourage mold, but, if you can do no better, leave it outdoors protected from mice and rain. Mold will hardly trouble it before severe freezing, and it will certainly not take any hurt during severe freezing weather, nor till well along in the spring. Then, before it gets warm enough for it to hurt, either by drying or molding, give it in care of the bees. They will turn it into brood.

Electing Officers at Conventions.—Mr. F. L. Thompson doesn't like the way officers of bee-keepers' associations are generally elected. In an article in the Rocky Mountain Bee Journal he gives the following as the usual form of proceeding :

"Mr. President, I nominate So-and-So for president," (or secretary or treasurer, as the case may be). No other nominations. "Mr. President, I move the secretary be instructed to cast the ballot of the association for So-and-So as president." Seconded and carried. So-and-So is then supposed to be the choice of the association.

Perhaps he is ; and perhaps he isn't.

This seems to result in electing usually the first man named, whether the best man for the place or not. Instead of this we should have the very best man available for the place, and there should be full opportunity to have each member suggest the man he thinks thus fitted. As to the means of accomplishing this, Mr. Thompson says :

There is only one way to do this, namely, by taking an informal ballot before the decisive one, and doing away with verbal nominations altogether. The informal ballot is the best kind of nomination, because it is a nomination by everybody who has ideas of what he wants. Verbal nominations are made only by a few, who may not come near covering the field. After an informal ballot, every one knows clearly what to choose between; after a verbal nomination he is often not conscious of much more than the temporary and adventitious prominence of those actually named. One may very readily, for the time being, even forget the existence of as efficient workers (or even more efficient ones) as those who happen to be named.

Entirely right, Mr. Thompson. The moment a name is mentioned on the floor of the convention, that moment the

personal element enters, and any one making a second nomination is likely to be considered more or less as antagonizing both the previous nominee and the man who nominated him. With the informal ballot all this is avoided. Then the formal ballot which follows is made intelligently.

It may be objected that balloting takes time. If there is to be a very short session, there may be some weight in this. But with one or more sessions of considerable duration, a good presiding officer will expedite matters so as to save a good deal more time than that lost in balloting. At any rate, if we want the best of anything, we must be willing to pay something for it.

Bee-keepers, perhaps, are not less informed on this subject than are other people. But, really, it was laughable to see how the election of officers was conducted at the Denver convention. We think it was the most poorly managed of anything we ever saw in that line. For instance, nominations of candidates was allowed first, and then what was called an "informal" ballot was taken! The informal ballot, as we understand it, is to take the place of public nominations. Then, afterward, the formal ballot is taken, which is to elect one from the persons nominated by the informal ballot.

We do not believe in public nominations for office, nor in nominating-committees. Neither method is fair. The informal ballot first is the best way, especially for important offices.

Hiving Swarms on Starters.—A practice that has been a good deal recommended is to hive a swarm on four or five frames furnished with narrow starters, and then when these frames are filled out to give the remaining frames filled with foundation. In *Gleanings in Bee-Culture* G. M. Doolittle gives a kink that is new, and it has a good look. When the five frames are given at the start, one or more of them are likely to have drone-comb started in them, and when once started it is likely to be continued to the bottom of the frame. So Mr. Doolittle fills the hive with frames at the start, and 36 to 48 hours later he takes out half of them, leaving those that have only worker-comb in them, and these will be filled out with worker-comb.

A Hive-Scraper.—R. D. Cleveland sends a pen sketch of a tool that he finds very useful as a hive-scraper. He says, "It is nothing but a common three-cornered scraper, but it 'everlastingly scrapes,' and with the angles and points to the head, you can scrape on all sides and into all corners with it." The tool is an excellent one, although by no means new, and a blacksmith can make one by fastening a handle into the center of one of the sections of the sickle of a reaper or mowing machine. For ordinary use in scraping hives nothing is better, although when it comes to the wholesale cleaning off the tops of brood-frames some who have tried both say they prefer a common hoe, well sharpened. It does the work as well, and much more rapidly.

Apiarian Ignorance in High Places may be productive of much mischief. Mr. David J. Ott, of Spottsylvania Co., Va., writes as follows:

EDITOR YORK:—It looks as if some people—especially those who hold public offices—can not tell the straight thing about bees, else they do not try to find out—I don't know which.

Our Commissioner of Agriculture has an article in the Richmond Dispatch, headed, "Pure Food Crusade." Of course, the most of this article is all right, but I don't think the part about bees will "hold water" very well.

Yours respectfully, DAVID J. OTT.

The clipping sent us reads thus:

SMALL CONFECTIONS.

"The children will buy cheap candy, and much of this is dangerous. It is adulterated with terra alba arsenic, sulphate of copper, and prussic acid, and is colored with aniline dyes.

"Licorice drops are often composed of sweepings of the candy factory. One plate of cheap strawberry ice-cream may contain as much fusel oil as five glasses of bad whiskey; it is a chemical product purely. Imitation leaves on fancy cakes are colored with Paris green. Maple sugar is glucose; honey is glucose. But glucose is harmless, and, therefore, to be passed over. It is said, by the way, that bee-keepers, besides furnishing paraffine combs for their bees, are feeding the insects on glucose to increase the amount of honey stored."

It is amazing that one holding so important a position should fail so utterly to inform himself as to the truth. The sweeping statement, "Honey is glucose," is likely to carry the impression that no pure honey is to be found. What, then, becomes of the tons of that delicious product stored by the bees each year?

"It is said, by the way, that bee-keepers, besides furnishing paraffine combs for their bees, are feeding the insects on glucose to increase the amount of honey stored." When a man assists in giving currency to a stupendous falsehood, he may screen himself behind the all-embracing "It is said," but the moral effect is much the same as if he makes the statement that to his certain knowledge the thing that "is said" is actual fact.

The great probability is that the gentleman in question has regard for the truth, but has suffered himself to be exceedingly careless. It is quite possible that he may do as some others in like position have done, inform himself fully upon the subject and then make the public statement that no such thing as paraffine combs are in existence, and even if they could be had that making a profit by getting the bees to store glucose in them is a thing out of the question.

* The Weekly Budget. *

NO MORE QUEEN ORDERS for delivery this fall can be taken at this office. All received after this time will be entered for mailing next May. We are receiving orders at 75 cents each for an Untested Italian queen; or for \$1.50 we will mail the Bee Journal a year and the queen; or if a paid-in-advance subscriber sends us \$1.00 and a new name for the Bee Journal a year, we will send a queen free as a premium to the paid-in-advance subscriber.

NOMINATIONS FOR DIRECTORS.—We have received the following on nominations for directors of the National Association:

EDITOR AMERICAN BEE JOURNAL:—

To fill the vacancies of the terms of the three directors in the National Bee-Keepers' Association, expiring Jan. 1,

I nominate G. W. Vanguundy, of Utah; Wm. A. Selser, of Pennsylvania; and Wm. McEvoy, of Ontario, Canada.

I believe these gentlemen are all practical bee-keepers, and interested in the welfare of the Association.

Yours very truly, EMERSON T. ABBOTT.

Homer H. Hyde, of Wilson Co., Tex., has this to say on the same subject:

MR. EDITOR:—As the time draws nigh for the election of some new directors for the National Bee-Keepers' Association, I wish to make a nomination and present a Texas claim for a member on the Board of Directors. Texas is the largest State in the Union, and, according to the last census, produces more honey yearly than any other State. The industry is rapidly gaining ground; many beginners are going into the business on a large scale, and there is a constant emigration of bee-keepers here from other States. Recently our Association secured an annual appropriation from the State Legislature, and we now have a well-equipped experiment apiary with a competent superintendent. Bees only are not being experimented with, but also different forage-plants; and, last but not least, there will be regular classes in bee-keeping at the A. & M. College of Texas, where the apiary is located. Not alone will our claims be apparent to Texas, but as well to the entire South, which, at present, is without representation on the Board of Directors. Our Association members are members of the National, and we feel we need recognition.

I, therefore, wish to nominate Mr. Udo Toepperwein as a candidate for director. HOMER H. HYDE.

MR. D. G. PARKER, of Brown Co., Kans., wrote thus Nov. 3: "It has been a poor honey-year, but the American Bee Journal is as good as ever." Thank you, Mr. Parker. And the prospects are that it will be *better than ever* the coming year. It will soon enter its 43d year. Surely, it has stood the test of time, and as to its value to bee-keepers—well, it seems to satisfy thousands of them. But thousands more will be able to testify to its merits when once they have made its acquaintance. It has no hobbies, except that of the best interests of its readers.

THE CHICAGO CONVENTION, to be held Wednesday and Thursday, Dec. 3 and 4, at the Briggs House, northeast corner of Randolph Street and Fifth Avenue, promises to be largely attended. Nearly every day we are hearing from bee-keepers who expect to be present. It can easily be the biggest and best bee-keepers' convention of the year. Everybody within a radius of 200 or 300 miles of Chicago wants to come here at least once a year, and the fall is just the time to come. The first session will begin at 10:30 a.m., on Dec. 3.

Honey as a Health-Food is the name of a 16-page leaflet (3½x6 inches) which is designed to help increase the demand and sale of honey. The first part is devoted to a consideration of "Honey as Food," written by Dr. C. C. Miller. The last part contains "Honey-Cooking Recipes" and "Remedies Using Honey." It should be widely circulated by every one who has honey for sale. It is almost certain to make good customers for honey. We know, for we are using it ourselves.

PRICES, prepaid—Sample for 2 cts.; 10 for 10 cts.; 25 for 20 cts.; 50 for 35 cts.; 100 for 60 cts.; 250 for \$1.25; 500 for \$2.25; 1000 for \$4.00. If you wish your business card printed at the bottom of the front page, add 25 cts. to your order.

Why Not Help a Little—both your neighbor bee-keepers and the old American Bee Journal—by sending to us the names and addresses of such as you may know do not now get this journal? We will be glad to send them sample copies, so that they may become acquainted with the paper, and subscribe for it, thus putting themselves in the line of success with bees. Perhaps you can get them to subscribe, send in their dollars, and secure for your trouble some of the premiums we are constantly offering as rewards for such effort.

The Premiums offered this week are well worth working for. Look at them.

Convention Proceedings.

THE DENVER CONVENTION.

Report of the Proceedings of the 33d Annual Convention of the National Bee-Keepers' Association, held in Denver, Col., on Wednesday, Thursday and Friday, Sept. 3, 4 and 5, 1902.

(Continued from page 71t.)

Pres. Hutchinson—There was a committee I failed to announce, which was to look after the question with the Government, with reference to co-operation, and so on. I will name the committee now: Messrs. J. U. Harris, R. I. Taylor, O. L. Hershiser, George W. York, and F. E. Brown.

Pres. Hutchinson then called on Mr. H. C. Morehouse, of Colorado, to present his paper, entitled: "Bee-Keeping Lessons that May be Learned from the Word 'Locality.'"

Mr. Morehouse—The topic assigned me by the Program Committee is one which I am sorry to say I do not know very much about.

Dr. Mason—We can tell better when you get through.

Mr. Morehouse—All right. The paper is as follows:

BEE-KEEPING LESSONS THAT MAY BE LEARNED FROM THE WORD 'LOCALITY.'

"Locality," in the sense in which we apply it to bee-keeping, means environment. The word "locality," as defined by Webster, means place, or geographical position. In bee-keeping we attach to it a much broader meaning, which comprehends not only geographical relations, but the influences of latitude, longitude, altitude, soil, meteorological conditions, and, in fact, everything that may be embraced in the term environment. According to our most learned observers of natural phenomena, environment is the controlling factor in the wide distribution of species of both animal and vegetable life, and the diverse racial characteristics of each. The same authorities also inform us that heredity has almost an equal potency, and that, together with environment, determines the destinies and accounts for the varied and peculiar characteristics of all the myriad forms that manifest life upon this planet. We learn from this that environment, or "locality," as we bee-keepers term it, is a mighty predestinating force in the world at large, and looking a little closer to our subject, I believe we will discover that it reigns with equal and inexorable power in that little corner of the universe that is comprehended in the world of apiculture.

It was not until recent years that locality was recognized as an important factor in bee-culture. Like all new ideas, this one, when first advanced, was greeted with derision. Now, there is a tendency toward the other extreme, and it is quite popular in the current bee-literature to solve the various puzzles of the bee-yard by broadly charging them to locality. Indeed, with some writers it has become the veritable philosopher's stone of apiculture.

I believe it is our neighbor Coggshall, over in New York, who, in enumerating the essentials of success in bee-keeping, places locality first of all. This is an estimate of its importance by one of the most extensive and successful bee-keepers in the world.

Locality, in the lexicon of apiculture, means not only the effect of environment upon the nature and habits of the bees themselves, but upon the honey-producing flora as well.

The first great lesson, then, to be learned in regard to locality is variation. There is a world-wide difference between New England and Colorado, and between Colorado and Texas, or Texas and California. Natural environments in these localities are very dissimilar, and the creatures of these environments are just as dissimilar as the environments themselves. A veteran bee-keeper from the verdant hills of old Vermont would make a flat failure were he to bring his apiary to Colorado and manage it the same as he has been accustomed to doing. The system of management that is suited to Southwestern Texas would not succeed at all in Southern California, or perhaps anywhere else but in Southwestern Texas. The same would be true

in the comparison of nearly all other localities, and, coming nearer home, I will venture to say that the management that gives the best results over on the Western Slope would not insure the same measure of success, without some modifications, on this side of the Rockies. It is not necessary, in this paper, to point out specifically any of these marked differences or variations.

To conclude this paper, I wish to emphasize as the paramount lesson to be learned from considering the word "locality," the importance of every bee-keeper becoming thoroughly familiar with his own immediate locality. To do this is the study and work of a lifetime, but, having acquired such a knowledge, even if to only a fair degree, one has at hand the elements of almost sure success in bee-keeping. You may write it down as an axiom that the man who does not understand his locality is not a bee-keeper in the Twentieth Century sense of the word.

I would amend Mr. Coggshall's statement of qualifications by placing *knowledge* of locality first. I know of some men who are making a good living from bee-culture in localities so poor that the majority of us would not think it worth while trying. They are succeeding because they understand their localities, and are taking every advantage possible. I also know of men in the best districts of Colorado who keep bees, but purchase all the honey that ever appears upon their tables. They pay no attention to locality, and very little to the bees themselves, and they will invariably tell you that bees are more trouble than they are worth—that they don't pay. Resolved down to its last analysis, success in bee-culture depends almost wholly upon the man, and the man will be successful just in proportion as he understands his locality and adapts his management to suit his peculiar needs. H. C. MOREHOUSE.

Pres. Hutchinson—The subject is before you for discussion.

Dr. Miller—I believe we are very unwise to tire ourselves out; the interims between the sessions are filled up with visiting, and that is more or less wearing, and when we take a long afternoon session we are unfit for the evening work. We have had a good deal this afternoon that was not regularly upon the program, so that we will not be able to go through the whole of the program, but I believe it would be very wise for us to defer until to-morrow, when nothing of that kind will come in, and I believe we can then easily dispose of all there is upon the program. It is now 20 minutes to 5, and I, therefore, move that we adjourn until this evening, at 7:30 o'clock.

Pres. Hutchinson put the motion, which had been seconded, and, on a vote having been taken, was declared carried, and the convention was adjourned until 7:30 p.m.

After the adjournment the members and their friends gathered on the steps of the eastern entrance to the State Capitol building, when Pres. Hutchinson took a group photograph.

SECOND DAY—EVENING SESSION.

At 7:30 p.m. Pres. Hutchinson called the convention to order, and after vocal selections by Miss Brown, of the Denver College of Music, Prof. C. P. Gillette, of Fort Collins, Colo., delivered his interesting lecture on "The Outside and Inside of a Honey-Bee," illustrated by the stereopticon.

During the course of the lecture many questions were asked by those present, which were very good-naturedly and patiently answered by Prof. Gillette. The convention then adjourned until Friday morning, at 9 o'clock.

THIRD DAY—MORNING SESSION.

Pres. Hutchinson called the convention to order at 9:45 o'clock, and the first thing he announced the committee on the matter of pear-blight: Messrs. F. E. Brown, Frank Benton, and M. A. Gill. He also appointed a committee on resolutions, viz.: Dr. C. C. Miller and James A. Green.

THE LOUISIANA PURCHASE EXPOSITION.

Dr. Mason—I have had some correspondence with Mr. Taylor, who represents the Agricultural and Horticultural interests for the Louisiana Purchase Exposition at St. Louis, or, rather, he has been corresponding with me. I am happy to state to you that Mr. Taylor has been able to get here, and he is with us this morning, and can speak to you himself. We are very glad to have him with us this morning, and he can tell us just what he wants, so much better than by writing.

Mr. Taylor—I should have enjoyed the next five minutes a great deal better to sit here and listen to one of these

warm scraps, and I thought you were getting up one for my benefit, so that as a stranger and sojourner I might see just how you do it; but I suppose that is one of the necessary adjuncts of being a bee-keeper, that you learn to push your stinger out once in awhile and stick it into somebody else. [Applause.] I think it is done good-naturedly; in fact, I never had a bee sting me but what I thought it was in fun, but sometimes it hurts just the same. I used to be quite a bee-keeper when I was young, and didn't know any better. My father was a nurseryman and horticulturist, and, incidentally, a bee-keeper in a small way, and whenever he got stung on the right elbow his left eye was always swelled shut. He was a Sunday-school superintendent, and it didn't look well to have him in that condition, so if we were doing anything with the bees on Saturday he let me do it; I could stay at home on Sunday and get fixed up. [Laughter.]

I am here to say something with regard to the Universal Exposition to be held in St. Louis in two years from now, and in which we want the co operation, as we are very sure we will have it, of this organization, which is so strong an institution among the bee-keepers.

I find about the first thing I have to do, in speaking with people about the Exposition, is to start a kindergarten for two or three minutes, and get down to first facts as to what we are going to have. An old friend down in Nebraska, where I used to live, wanted to know if we were hoping to have as large and successful and expensive an Exposition as they had in Buffalo. I said I hoped so, because we have got about ten times as much money to spend. They were about \$3,000,000 behind, and proportionately we would be \$30,000,000 in debt when we get through. I shall attempt to collect my salary on the first of every month, so that they won't owe much of that \$30,000,000 to me.

Here is one thing which will perhaps illustrate the scale on which that Exposition is being built. The department of agriculture, which comes within my charge, has for its reception under preparation a building the ground area of which will be nearly 25 acres; it will be the largest building ever built in the world at any Exposition for the reception of a single department. So far as I know, there have never been but two larger constructed; one of those was to contain two of the large and important departments in Chicago, the other was to contain the entire Exposition in Vienna, in Austria, in 1873. The agricultural building is much larger than the one in Chicago. The same is true of the building for horticultural, the same is true of practically every department; there are none of them housed in buildings smaller than those in Chicago, and a number of them in buildings from a little to a good deal larger. I speak of that not to disparage Chicago, because that was the most beautiful thing that has ever happened up to this time, and it would be preposterous for us to claim we are going to have a more beautiful Exposition than that. When we get through, and have gone on record, and you have all been there and seen it, if you are able to say we have had a larger and better Exposition scientifically, and from every point of view, we shall be happy; if that is not that case it will not be because we do not try.

As to what we are going to do for bees and bee-keeping: In this building of agriculture, covering 25 acres, will be brought together all of the agricultural and allied exhibits. By that I mean agricultural implements, dairy foods and their accessories, and those things which have, in some other Expositions, been put off in separate or lean-to buildings. This is all first floor; there are no gallery spaces; you will not be put upstairs nor down cellar, but on the first floor, where you will be just as well situated as the man who puts up a million dollar exhibit. If that does not bring out from you splendid installation and splendid material and sufficient quantities of it to make the best exhibit that has ever been shown in this country, I will leave it to you as honest men and women, whose fault will it be. It won't be ours. We wish to make the portion of the building assigned to apiculture precisely the sort of building that you want, and if there are any suggestions as to the way in which it should be allotted or done, or in the form in which you want those, so far as they are reasonable and consistent and fitting in accordance with those things which concern them, to that extent they will be accepted and used. I don't say that exactly the propositions that you bring can be incorporated exactly as they are brought up, but they shall have most respectful and careful attention, with the wish to make exactly what you want out of the portion of the building assigned to you for exhibits. The exact way in which the details of that will be handled I don't know, and I don't suppose that it is necessary to know.

I should be very glad, indeed, to have some expression from this organization, either directly or through its officials, the executive committee, president, secretary, or anybody else who is officially ordered by the Association to do it. I would be glad to have suggestions from them, and if any occur to any of you that are here, I would be glad to have them either at this time or through the proper channel in due time.

It is our business to house the exhibits, nothing else; we furnish the roof and the floor, and the air for you to breathe—we don't charge you for any of them—and the other things you supply yourself. There is no space charged for State or individual exhibits as there has been a many other Expositions; there will be no charge for the amount of floor-space which you need; you will have to put up your own installation, or if we put up special installation for honey and honey exhibits you will be expected to pay for your proportion of the construction, that is all. But so far as the building and floor and all that is concerned, it will be absolutely free. That means, if you come there and want a large amount of space I shall ask you very frankly how much money you have got, and how many people back of it to cover it. I will be down there in Missouri, and you have to show me. If you come and ask for a large space you will have to have a lot of honey, and a lot of money, and a lot of good people. If you ask for a modest amount, and have a modest amount of money, and have a modest amount of backing, and can keep it in that shape during the Exposition, you will get it. We are trying to handle it in a business way, but in a fair way, so that you will be satisfied to have come there.

I have spoken to the point, or have tried to, because, having gone through a number of Expositions, having given between five and six years now to this work, and nothing else, in Expositions held in Omaha, in Buffalo, and now in St. Louis, a continuous service entering upon its sixth year, I appreciate it is the facts you want to know. I shall leave it to the papers and literature to tell you the artistic side of things, and the other facts than those which relate to your own work.

We are laying our plans upon an enormous scale. We hope to have space enough for supplying a reasonable amount to every exhibitor who wants to come there with a good exhibit which he proposes to put up in first-class shape, and can take first-class care of all the way through; we don't want any other kind; and if there is any way to help we want to get their advice. We want an exhibit properly classified; we want everything done as scientifically and carefully as would be required in any of the departments at Washington or any university; we want things so placed they will be able to be found, and when you find them, so labeled you will know what they are. If you will pardon me for having spoken frankly to that particular point, and if you will believe me, we wish to do everything that we possibly can that it is consistent and possible for us to do, then I shall be very glad indeed to have met you. And I am glad, anyway.

Dr. Miller—May I be allowed to ask Mr. Taylor a question? I learn from good authority that your father was a Sunday-school superintendent, and from the pleasant flow of language I suspect that his son may have had some little practice in speaking pieces before the Sunday-school. There are some Sunday-school superintendents amongst the bee-keepers, and I believe I speak for a good many of them when I say we are interested to know what will be the final decision as to the opening of the Exposition upon the Sabbath day. Will you tell us what is the present expectation?

Mr. Taylor—Under the congressional law, which granted to the Exposition the \$5,000,000 of Government aid, the largest amount ever given to any Exposition, it is specifically provided that the Exposition shall not be opened on Sunday. I know of no possible way that the law should be evaded, if it was desired to evade it, or of any possible way in which it could be changed except through the office of the law itself, that is, through Congress. I have heard nothing from the officials of the Exposition except an expression of their intention to comply with the law. I am free to say for myself, I sincerely hope the Exposition will be closed on Sunday, not only from the moral side of it, but because all my life I have been able to get all the work I wanted on six days out of the week, and sometimes more, and I find for myself and my associates it is a great drag to have to trot around there on the seventh day. I don't like to do it, and I don't believe it pays from any point of view. That is my personal opinion and standing; but the legal question of it is such that I see no possible way, if the

Exposition desires doing so, which I don't think they do, that they could evade the law. The only possible way it could come about would be through a supplementary law passed through Congress.

Dr. Mason—I am glad to hear that expression. I had intended, as secretary, to notify Mr. Taylor of the action taken yesterday by which this whole matter was put in the hands of the Executive Committee. I did not have with me, at the time this matter was introduced, some things which I have, but I will introduce it now. It is this:

WHEREAS, There is to be held in the city of St. Louis, Mo., in 1904, an Exposition of the Arts and Sciences of the World, known as the Louisiana Purchase Exposition; and

WHEREAS, The said Exposition has the approval of the United States Government to the extent of an appropriation by Congress of \$6,500,000 for the Nation's participation therein; and

WHEREAS, The city of St. Louis is expending in the enterprise more than \$10,000,000, and the total appropriations by the various States of the American Union, and by foreign governments, now amount to over \$20,000,000; be it

Resolved, That the National Bee-Keepers' Association, in convention assembled at Denver, Colo., regards the Louisiana Purchase Exposition as an enterprise of national and international importance, which will be the highest possible expression of our advanced civilization, and the grandest and greatest Exposition in the history of the World's progress.

Resolved, That we cordially and heartily indorse the said Exposition, and pledge ourselves to give it earnest support, and that the National Bee-Keepers' Association desires to place itself on record as in favor of holding its annual convention in St. Louis in 1904, during the progress of the World's Fair.

Dr. Mason—I have been assured by Mr. Taylor that a place to meet in will be provided for us free, and we will have all the courtesies extended to us to which we are entitled. On consideration by you, I move the adoption of the resolution just presented.

R. L. Taylor—I second the motion.

The President put the motion, which, on a vote having been taken, was declared carried.

(Continued next week.)

Anti-Foul-Brood Legislation in California.

BY PROF. A. J. COOK.

I HAVE an interesting letter from Hon. J. M. Hambaugh, who is bee-inspector of one of our most important California bee-counties, that of San Diego. It goes without saying that Mr. Hambaugh would be alive to anything that interests the bee-inspector and so would be ready for criticism if our law is imperfect. He finds numerous imperfections, which tend greatly to impair his work. The work is also increased. As these are matters of general interest, I will comment upon the subject, as per request of Mr. Hambaugh, in the American Bee Journal.

BOX HIVES.

One would hardly suppose that any bees would be kept in box-hives in this advanced stage of the bee-keeping world. Yet it is a fact that there are many colonies in Southern California housed in these out-of-date receptacles. It goes without saying, that in an apiary affected with foul brood, these hives are a serious menace. The Inspector cannot know that the foul brood is present, and so the hive must either be destroyed, bees and all, giving the doubt the benefit, or else the bee-keeper must be compelled to transfer the bees to a movable-comb hive. Mr. Hambaugh suggests an amendment which shall oblige the bee-keeper to transfer such bees, or else submit to having all destroyed by the inspector. It seems to me this would be no hardship. If a bee-keeper has foul brood in his apiary, he is most interested that it shall be thoroughly extirpated. This would surely require none but movable-comb hives. For his own good, then, as well as that of his neighboring bee-keepers, he should proceed at once to transfer all bees into movable-comb hives.

Our law is also defective in that bees may be sold from an apiary to other apiaries in the same or in other counties. Of course, this is a serious obstacle in the way of curtailing the disease. Mr. Hambaugh would make it a serious of-

fense, subject to no mean fine, for any apiarist to sell bees that are diseased. In fact, no diseased colonies should ever be moved. In all such cases a certificate from the inspector should be made requisite to any such removal. Mr. Hambaugh thinks that in case an apiary has been treated for foul brood, no apiarist should be allowed to sell bees from such apiary until permitted to do so by a certificate from the inspector.

It is also thought desirable to give the inspector full power to act in case any bee-keeper offers resistance or obstructs said inspector in his duties. While the wise inspector will usually use tact and reason that will persuade the recalcitrant bee-keeper to submit to the destruction or the cure of the malady, as seems wisest, yet in case there is obstruction, the law should make it easy to require submission.

I wish also to call attention to the small pay that the inspector receives in California. This is disagreeable business, requires hard work, and takes the inspector away from home. It also often takes him from home just when his services are most needed in his own business. He cannot delegate this work, as he owes his appointment to the very fact of his own knowledge and ability. He must give it personal attention. In our State the law gives him only three dollars a day, as I understand it, and he must bear his own expenses. As he must of necessity keep a horse, the expense account will often be no small matter. California is surely as able as is Colorado to pay a reasonable price for such service. Colorado (see American Bee Journal, Sept. 25, Vol. 42, No. 39, page 615), allows four dollars per day and two dollars for each half day necessarily and actually employed, together with his actual and necessary expenses. It strikes me that this is none too much. Yet, if it is found that with the present law our supervisors are able to secure the service of suitable men, it is then a question whether we should pay any more.

ORGANIZATION.

Mr. Hambaugh asks how we can best secure desired action regarding the above suggestions. Here is a case where organization comes to the front and offers a great, strong, helping hand. Through our Farmers' Institutes in Southern California we have organized a large number of active Farmers' Clubs. These are wide-awake organizations and are fully alive to the importance of suitable legislation in all such matters. Those clubs all meet once a year in a delegate institute which we call the "Farmers' Clubs' Institute." The purpose of this meeting is to discuss all the great questions which concern the farmers. The clubs of each county are appointed a year beforehand to arrange for this meeting. It goes, then, without saying, that the program of this meeting will be one of unusual interest and importance. The next meeting will occur December 17 to 19, 1902, at Santa Ana. Our county of Los Angeles is given the subject of legislation. The different clubs of our county are working upon the framing of desirable laws, which, if approved by the institute as a whole, shall be passed on to the Legislature, which will meet in January. The recommendation of this Institute will go far toward securing the passage of the enactments. It would be a rash Legislature and a foolish governor who would think to antagonize so large a body of farmers regarding matters which were vital to their interests.

Our club in Claremont has in preparation a fertilizer law, which, owing to an incompetent governor, has failed at the last two sessions of the Legislature, though it was passed at both sessions. A bill is being prepared that will surely meet all the exigencies of the case. We have very little doubt but that it will be passed and signed by the governor at the next session of the Legislature. Our present governor failed of renomination largely because of his obstinacy in just such cases. We have great hopes that any such experience will never be repeated in our State.

I suggest to Mr. Hambaugh that he carefully prepare an amendment to our present law, or else, as in his judgment seems best, a substitute. It seems to me very unlike the present law of Colorado, referred to above. I suggest also that Mr. Hambaugh come to the meeting prepared, in a short, terse paper, to give the reasons for this action in such a forceful way that the Institute will be convinced and give the bill its full sanction. I have little doubt but that in this way the new amendment may be carried.

I also suggest that our State Association be called to meet on the 16th and 17th of the same month, either at Los Angeles or at Santa Ana, where the same matter may be presented by Mr. Hambaugh and be discussed by all the bee-keepers present, especially by the seven bee-inspectors,

that Mr. Hambaugh may get the benefit of their good judgment and experience, and that he may carry their sanction and approval with him as he presents the matter at the Institute.

We see, from the above, how important a matter it is, that all sections of our country become organized in just the way referred to. Most professions have a great vantage ground in such organizations. Thus the lawyers, doctors, railroad magnates, etc., can bring such force to bear upon any proposition that they are almost certain to gain their desires. I can but believe that the two most important things now before not only our farmers, but also before all working men, are organization and co-operation. Southern California is leading in both these directions. May all other parts of our country soon wheel into line, so that all our people who labor with their hands may be able to hold their own with those of all other classes of laborers.

Los Angeles Co., Calif.

Shading and Ventilating Bee-Hives.

Read at the Minnesota Bee-Keepers' Convention.

BY W. R. ANSELL.

IT is with great diffidence that I advance my ideas on shade and ventilation before this experienced gathering. My remarks will be few, will not be dogmatic, but may contain some novel suggestions on the value or inutility, of which I am perfectly open to conviction.

The title of my paper may seem ambitious, so let me at once assign its limits: "Shading the hive from the sun, and ventilating it in summer and cellar."

When on the subject of shade, I shall confine myself to two propositions: Do we want our bees shaded? and what is the best form of shade?

We do not want them shaded in the early spring nor in the late fall; we do not want them shaded during the early hours of the day, nor at any time when the weather is not very warm. Therefore the natural shade derived from trees or shrubs is not the best form of shade.

I fancy I hear some of my friends, who know the location of my apiary, say, "Sour grapes!" and I know how deliciously cool and comfortable their yards are to work in on a hot day. I do not underrate the value of personal comfort and artistic surroundings in the bee-yard, but I think better results can be obtained by placing our bees on an open plain than in the most beautiful Garden of Eden, if there are always to be apple-trees there.

I remember one apiary down in a dimly-shaded dell, where my friend considered he had an ideal location, because his swarms (he never clipped his queens) always hung about the trees, until he had leisure to hive them. His bees were late risers, judging by results.

We want our hives to be as warm during a honey-flow as is consistent without distressing the bees, so that the honey may ripen quickly.

For this reason I am of the opinion that a removable shade-board is the best device for us. Of the one I use myself, I present to you a few illustrations, showing its construction and manner of use, and I venture to recommend it to those who desire a cheap and effective article. It is, as you see, made of shingles nailed to a skeleton, gabled frame of lath. There is no waste in the use of either material, and 100 shade-boards will cost you only \$4.00, including a boy's time nailing them up. They are heavy enough to stay on the hive during an ordinary wind, and light enough not to do any damage if blown off in a gale.

They should be tilted toward the sun two or three times a day, and can be placed on the ground if a storm approaches. I can change the position of 100 in 5 or 6 minutes.

Ventilation of the hive during the honey-flow and during very hot weather must, I think, conduce to the comfort of the bees and ripening of the honey. For this purpose I have found nothing better than the much-practiced plan of placing a small piece of section at each corner under the cover. Perhaps a little thinner might be better, if the bees would not seal up the opening with propolis.

In the case of a newly-hived swarm, I have found it advisable to give even more ventilation than this for the first day; but for the second and third days to close the top down tight. Afterwards the hive may be ventilated as usual, if the bees have started work in the super.

My concluding suggestion will, I think, be a novel one. Considerable loss may sometimes be experienced, during the winter, through condensation on the under sides of the

covers, and consequent dripping on the cluster. Several devices are in vogue to obviate this, among others that of slightly raising the cover so as to allow the moisture to escape before condensation. This plan of ventilation may be all right in the case of a very strong colony, or of one which has a superabundance of stores. But I cannot help thinking the cover should be kept closed in most cases, so as to avoid waste of heat.

Last winter I experimented on 27 colonies in a cellar, by piling them against the wall at an angle of 45 degrees; my idea being that all condensation must of necessity fall down one of the inclined planes, and thus find an exit from the hive, without falling on the combs or cluster, and without the necessity of any top ventilation. Dead bees also fall, etc. I may mention that a couple of 2-inch slats of wood traverse the tops of each tier of hives; the hives above resting on these slats. Of course, the bottom-boards are removed.

Hennepin Co., Minn.

Rearing Long-Lived Queens and Bees.

BY HENRY ALLEY.

WHEN reading Dr. Gallup's article, on page 584, I couldn't help thinking he must have had more trouble in getting good queens than any other man in the bee-keeping line. Now, had everybody who purchased queens had the same trouble that the Doctor has had, where would the queen-breeders of the present day be? Does Dr. Gallup have an idea that one poor queen represents all the queens any dealer sends out? I wonder if Dr. Gallup always introduces his queens so that their fertility is not destroyed at the start? Hundreds of queens are ruined in the very act of introduction, and I really believe Dr. Gallup has spoiled many a good queen by his method of introducing. Many bee-keepers do this thing, and then put up a kick against the queen-dealer. Does any one suppose that where a queen-dealer presents Dr. Gallup with a queen that an inferior queen is sent him? Dr. Gallup says in his article (page 584) that he received two queens from some one in the month of August, and in the fall both colonies that the queens were introduced to dwindled down very low in numbers. Now, I believe those two queens were just as good as Dr. Gallup could rear, or they never would have been sent to him. The two queens which I sent Dr. Gallup were perfect in every way, yet he had the same bad luck with them as with all others. I believe the trouble is with the Doctor, and not with the queens.

I am sorry I did not get "on to" this queen-business earlier in the season. I tell you what I'll do, Doctor: You rear half a dozen queens as good as you know how, in 1903, and mail them direct to the A. I. Root Co. I'll do the same. If my queens don't turn out better than yours, I'll guarantee to go out of the bee-business.

Dr. Gallup says on page 585; "Mr. Doolittle and Mr. Alley comply with all the necessary conditions but one—their queens do fairly well the first year, and fail the second." Speaking for myself, I deny the statement, and if this were my paper I would deny it in as strong terms as the charge is made. Not one of the queens in 50 that I send out die the second year. One customer wrote me he had one of my queens that lived *six* years. I now have two queens in my yard that have gone through two years, and they are the strongest and heaviest colonies in the State of Massachusetts.

Dr. Gallup has made some most marvelous statements concerning queen-dealers. So far as I am concerned, I deny them all. The idea of judging a man's goods by one small sample! Just accept the challenge above, and that will settle the matter, whether the queens I send out die inside of one year or not. Dr. Gallup has made such terribly wrong statements that I begin to question his judgment on queen-bees. I really believe he destroys the vitality of the queens sent him when they are introduced.

The nonsensical talk about the "umbilical cord," "missing link," etc., is out of place. The meanest, half-starved, half-nourished queens I ever saw were the ones that appeared to be fixed up with what some people call the "umbilical cord."

Further on Dr. Gallup says, "Ridicule is not argument." Doctor, let me remind you that some of the statements you make are not argument.

Good queens, long-lived queens, and prolific queens, are reared under proper conditions. What are those conditions? The entire thing lies with the nurse-bees. No arrangement of cell-cups or eggs has the least to do with the

quality of the queens reared. When bees rear a queen, or queens, in colonies having a fertile, or, in fact, any queen, the nurse-bees will fill the base of the cell-cups with jelly, but not royal jelly. It is the same sort of food as is used in feeding worker-larvæ, consequently the queens so reared are of a very poor quality; they lack vitality and vigor, and are short-lived, unprolific, and worthless. In all my queen-rearing operations I have recognized all these important facts, and have prepared the royal food before eggs are given them.

Those queens reared in colonies having queens have the umbilical-cord attached as much as the naturally-reared queens, and so they have as large a lump of royal jelly at the bottom of the cell, as queens reared by any method. But such jelly is of an inferior quality; it was made up to nourish worker-bees, not queen-bees.

I never give bees eggs to rear a queen until they have been queenless several hours, and given time to prepare the royal food—a thing they are sure to do, and when eggs are given them this royal food can be found in the cell-cup within an hour after the eggs are given them. Won't some one who has the means at hand, analyze the two foods and report through the American Bee Journal?

I know of but one way to rear queens, outside of natural swarming, that I practice, and Dr. Gallup must practice it if he rears queens.

One other thing that Dr. Gallup has not mentioned as one of the causes of short-lived queens: The queen-dealer is too apt to allow a colony to rear a large number of queen-cells. If 100 cell-cups are given a colony of bees, they surely would build them out, and nurse up some sort of queen-bee-larvæ. But not one queen in the lot would be of the least value. Now, in Nature's way, how many queen-cells are usually found in a colony that has cast a swarm? Generally but eight queen-cells, sometimes a few more, but often a less number. Rear less queens per colony, and they will prove much better.

Dr. Gallup says he reared 36 queens that were all good, first-class queens. I have no doubt that is so. But hundreds of other bee-keepers have reared queens equally as good and by a similar, and by different methods. I have reared 50,000 queens equally as good; couldn't help rearing good queens. All I had to do was to do just as Dr. Gallup did—let Nature have her own way. But Dr. Gallup didn't send any of those queens by mail to Bob, Dick and Harry, all over the United States, and let them introduce them. Had he done so, no doubt he would have heard as much growling about them as he has done about other people's queens. Why don't you try it, Doctor, and see how it works? You would soon have troubles of your own.

I have come to the conclusion that we all rear queens by the same method as does Dr. Gallup. There is no other way to rear good queens. All queens reared in queenless colonies are reared by Nature's best plan. The troubles with the queens is not in the rearing, but in handling after they are reared.

Our Bee-Keeping Sisters

Conducted by EMMA M. WILSON.

Smoker-Fuel Again.

And, now, Mr. Hasty is objecting to my smoker-fuel. Well, you know there is nothing in the world as perverse as a woman (unless it is a man), and I am going to stay in the wilderness a while longer. He says:

"What in the world is the use of those of us that live in the country makeshifting along with anything else than the standard good fuel—rotten wood?"

Now, I say, "What in the world is the use of those of us that live in the country makeshifting along with" rotten wood when we have a good chip-pile right handy, and all we have to do is to pick up the chips and drop them in our smoker—no breaking or cutting necessary—we can pick out the right size to put in the smoker without any trouble at all? What more can we want? They last lots longer than rotten wood, and make a better smoke.

T. F. Bingham, of smoker fame, says that *sound, hard wood* is the best smoker-fuel, and he is good authority.

Rot in wood is slow combustion, and just so far as it

has rotted it is so much burned out, and will make that much less smoke. What we want is the best.

In getting chips for smoker-fuel I always pick out sound, hard wood chips. Rotten wood is all right to start with if you can't do better, but I can do better.

While you are tramping around hunting up your rotten wood to serve as kindling for your summer's work, Mr. Hasty, I will earn my 10 or 20 cents washing dishes, with which to buy my saltpeter, which will serve to light mine more than twice as long, and do a good deal better work, too. No, sir! I am not going to throw my saltpeter to the dogs yet.

Now, honestly, Mr. Hasty, have you ever tried saltpeter to light your smoker with? If not, just try it. Who knows but you may be living in the wilderness, too, some day? ☺

You can use wood soaked in saltpeter instead of cloth if you prefer. One is just as good as the other.

Cleaning Out Unfinished Sections.

Have you had the bees clean out all unfinished sections that have the least bit of honey in them, so that you can use them again next year? If not, better have them do it right away.

Let the bees rob them, although it is a little late for it. Then you will be sure they are thoroughly cleaned out.

Stack the supers up in a pile and leave an opening large enough for only one or two bees to pass at a time, then they will not tear or mar the combs. If you have enough of them to keep all the bees busy, you can spread them out as you please, and they will not tear the combs.

After they are cleaned out, pile up in the honey-room, and cover up mouse-tight. It is nice to inspect all supers as they are put away, to see if they are all right—no foundation down, or anything of the kind, then they are all ready for use next year.

Bees Cleaning Off Leaky Honey.

Did you ever have any leaking, dauby sections, some with honey streaked all over the comb, others all watery and sticky, making you feel as if you wanted to pitch the whole business out of your sight?

Well, just give them to the bees to clean up, and you will never recognize those sections after the bees have had them from 20 minutes to half an hour; but don't leave them on too long, or they may empty them. Just leave them long enough for them to clean up nicely.

I have tried it a number of times, and every time they have cleaned them up beautifully. Oh! it was such a relief to get back nice, dry sections in place of the sticky ones.

The Wax-Worm and Its Work.

There has been more or less said in the Bee Journal concerning the wax-worm and its destructive work. Please give a brief description of its manner of working; how it is gotten rid of when it makes its appearance; and a description of the worm itself. I think I have been troubled with it a little lately.

ILLINOIS.

ANSWER.—If there are any worms at work on your combs you may be sure they are wax-worms.

There are two species, one much smaller than the other. It is the larger one that does the most damage. If your colonies are strong the bees will take care of the worms for you, especially if the bees are Italians.

You will occasionally see little burrows under the capping of the brood. Pick a hole at one end of the burrow, then pick a hole at the other end, and follow along until you find the worm, and kill it.

But the greatest trouble with wax-worms is in brood-combs that are not in care of the bees. In the spring, as soon as the weather begins to be pretty warm, you may look out for them.

The eggs are laid by the bee-moth in the combs, and hatch out into tiny grubs or worms, and when full-grown are nearly an inch long, are not very much smaller around than a small quill, and are of a grayish, dirty-white color. It is while small and while growing that it puts in its work of destruction.

Examine your combs from time to time, and whenever you detect any cells filled with webs, or a series of little tunnels running across the combs from cell to cell, you may

be sure the worms are at work, and they must receive immediate attention, as their work is very rapid.

There are several different methods of getting rid of them. One of the best ways is to give the wormy combs to the bees to take care of. Or you may fumigate them with sulphur, or bisulphide of carbon. Or you may fill a small oil-can with gasoline, and wherever you suspect the presence of a worm fill the cell with gasoline. This is very effectual and an easy way.

If you use gasoline or bisulphide of carbon be careful not to use near a fire, as they are very inflammable.

Her Bees Held Their Own.

Bees have not done anything this season. Mine have held their own—only one super per colony. They have a full hive of honey and plenty of bees. I expect they will winter all right. Some of my neighbors say their bees have not even enough honey to carry them through the winter.

MRS. E. BURDICK.

Bernalillo Co., N. Mex., Oct. 10.

Questions and Answers.

CONDUCTED BY

DR. C. O. MILLER, Marengo, Ill.

(The Questions may be mailed to the Bee Journal office, or to Dr. Miller direct, when he will answer them here. Please do not ask the Doctor to send answers by mail.—EDITOR.)

Late Drones.

Last June I received a queen, and the colony in which I placed her did very well this season, but did not swarm. A short time ago I noticed there were still drones in the hive; thinking that perhaps they had lost their queen, I examined

them and found her there all right. Why are those drones kept at this time of year? I have never seen anything of the kind before.

MICHIGAN.

ANSWER.—I saw drones the last day of October this year at the entrance of one of my colonies concerning whose queen I have no anxiety. I think it is more common than usual this year to find late drones. The season has been such that bees have done some gathering every fine day, and so the bees have not felt keenly the lack of pasturage, and the lack of pasturage seems to be the principal thing that suggests the extermination of the drones.

Preparing Bees for Shipment.

1. What is the proper way to prepare bees to ship? and what is the cost per colony, say from here to California?

2. Would it be advisable to take 20 colonies from Iowa to California, as they will hardly sell for what they are worth here.

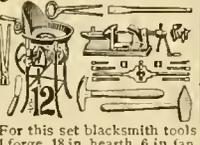

3. How would be the proper way to manage the entrance-guards during swarming season to prevent swarming?

IOWA.

ANSWERS.—1. Minutes of preparation varies according to the hive. Generally it is all right to fasten the cover and floor-board to the body of the hive by means of one or two cleats at each of the four corners of the hive, one end of the cleat being fastened to the floor-board and the other to the cover, and the middle of the cleat fastened to the hive. Abundant ventilation must be supplied by means of wire-cloth, one way being to have in place of the cover a rim an inch or two deep entirely covered over the top with wire-cloth. In this case of course the cover is omitted from its usual place. I do not know what it will cost to transport a colony of bees from Iowa to California, but you can learn from your freight or express agent.

2. I don't know, but I very much doubt the advisability. I'm not sure about your railroads, but I doubt whether you can send bees by freight without paying for a car-load, and the express charges are fearful.

3. They are simply to be left at the entrance, to be removed when a queen has been trapped or when drones are in them.

What Yon Yonson Thinks

Yon Yonson com from Sveden,
He havven lots to du,
He don't vas git so homesick,
He play das organ tu.

He vorken on das section,
He don't vas lak das boss,
So, Pat O'Rice, he don't speak twice,
He turn das Svede man off.

So he vork for Ole peterson,
He milk biss cows at nite,
He vork all day, and git big pay,
An don't vas bean git tite.

Vell, ay bean yust goin into das big lodg and vat bean called National Bee-Keepers' Assocation. Ay bean tank me for long time to join me selv in to das big yunyuns, but ay don't know it bean for any ting but dem big bee-keeper mans, but ven ay go to town you day ma som hunny, an ay ask das store mans vat he pay for nice hunny, an he look at him and he say, "Vell, das vas nice hunny, an ay kin pay you ateen cent a pound. Mine goodeness, ay yust purd neer to fall over! "Vat for you kin pay so much?" ay say. "Vell," he say, "dom bee-keeper mans vat be long to das yunyun dom git big law past so ve don't kin sell any more of das slop hunny's vat been in glas tumblers, vot got little bees come in it, an ven dom peoples begin to taste das regular bees hunny, den dome fine out dat it don't bean any hunny toll in dom glasses. An den dom reddy to pay big price for das regler bees hunny's; before dom tot every ting vat say hunny vas hunny."

My ying! ven ay begin to tank bout ay never giv dom fellers five cent an dom do me so much good to git big price for hunny. Mine goodeness, ay youst feel so small ay vas purdneer to fall tru a not-hole vat bean in das floor. For long time a go ay bean yoin me selv into Voodman, and dom ride me on das gote for bout two hours, but das yunyun it bean differat ting. Ay don't haf to ride das gote, an ay bean git benfit for long time ago. Ay sen Mr. New York von dollar, an ay tell him to yoin me into das big yunyuns vat do so much for Svede mans. Mr Huchinson he bean das president, an ay tank he bean glad to yoin dom peoples in das yunyuns. If you tak notis he bean vare viskers on da side, yust lak Mr. New York ven dom bean yoin dom peoples into das yunyuns. Dom make plenty big smile, an hy an by dom goan to come in so fast dom haf to vare side-boards to keep das smiles from running over

Now, ay tank all you bee-keepers vat don't belong to das yunyuns, you better git on bord das ban' vagen, for it goan to start up purty fast, an if you don't git into it purty soon mebbly you goan to git left. Yon Yonson he don't goan to hang on be hine eder, you bet. He goan to hole da whip, an ven dom come to big hill he goan to git off an push, an if all dom bee-keepers vat read das bee-paper vill yust push for about von dollar, on da start den, ay tank it soon bean goan hooping.

Now, dom yunyuns bean all reddy don gud for us, an ve mosta follow das golden rule. Das slop hunny mans dom got differnt rule. Dom say if dom bee-keepers don't du us ve goan to du you. Now, ve bean du dom fellers in Illenois, but in odder States dom bean du dom bee-keepers plenty bad. Ve musta have plenty spunk, and ve musta vork ma das law mans, and get some better laws, an das goan to tak monny. Course dom slop hunny mans dom goan to vork aganst us, but if ve all push plenty hard some tings goan to com luse, an ve will tak das slop hunny mans door an post an every ting an carry it up ou da hill, yust lak Samson du ma das phillistines, and den ve goan to play keep hous ma das fellers. An Yon Yonson he goan to spank das carpets an ven we have sweep das floor, den Dr. miller he goan to bring in big arm full of straw for carpets, an ven ve bean

Some Renewal Subscription Offers!

As the time is drawing near when a large majority of the readers of the American Bee Journal renew their subscriptions for another year, we thought it would be well to put before them in one place a few of our clubbing offers that they might like to take advantage of. We will number them, so that if you will order by number no mistake will likely be made at this end of the line. Here they are:

- No. 1— The Bee Journal a year and Prof. Cook's "Bee-Keeper's Guide," (book alone, \$1.20)..... **Both for \$1.75**
- No. 2— The Bee Journal a year and Dadant's "Langstroth on the Honey-Bee," (book alone, \$1.25)..... " 1.75
- No. 3— The Bee Journal a year and Doolittle's "Scientific Queen-Rearing," (cloth bound) (book alone, \$1.00).... " 1.60
- No. 4— The Bee Journal a year and Doolittle's "Scientific Queen-Rearing," (leatherette bound) (book alone, 60c) " 1.40
- No. 5— The Bee Journal a year and an Untested Italian Queen (to be mailed in May, 1903) (Queen alone, 75c). " 1.50
- No. 6— The Bee Journal a year and a "Novelty Pocket-Knife" with your name and address on it (knife alone, \$1.25) " 1.90
- No. 7— The Bee Journal a year and a "Wood Binder," for holding a year's numbers (binder alone, 20c)..... " 1.00
- No. 8— The Bee Journal a year and an "Emerson Binder," (stiff board) (binder alone, 60c)..... " 1.40
- No. 9— The Bee Journal a year and a Monette "Queen-Clipping Device," (device alone, 25c)..... " 1.10
- No. 10— The Bee Journal a year and Newman's "Bees and Honey," (cloth bound) (book alone, 75c)..... " 1.50
- No. 11— The Bee Journal a year and Newman's "Bees and Honey," (paper bound)..... " 1.20
- No. 12— The Bee Journal a year and a Corneil Smoker (\$1.00). " 1.80
- No. 13— The Bee Journal a year and a "Porter Bee-Escape" .. " 1.10
- No. 14— The Bee Journal a year and a No. 2 Bee-Veil (50 cent veil)..... " 1.30
- No. 15— The Bee Journal a year and a "Globe Bee-Veil" (\$1.00 veil)..... " 1.80
- No. 16— The Bee Journal a year and an Alley "Queen and Drone-Trap," (Trap alone, 65c)..... " 1.50

Of course all the above will be sent postpaid. We should be pleased to have all who can do so send in their orders at once, so as to cause less delay than there would be when so many renew their subscriptions at nearly the same time—from Dec. 15 to Jan. 15. We will try to do our part in filling your orders promptly.

This standard work on practical bee-keeping has just been thoroughly revised and brought down to date. About 100 pages and nearly 100 illustrations have been added, which makes it now a superb volume of 544 pages, with 295 fine illustrations. It is printed on clear white paper, and is bound in elegant brown cloth, gold-lettered.

Prof. Cook has been one of the leading contributors to the American Bee Journal for a quarter of a century. He is well known to bee-keepers everywhere. He is an authority on bees and related subjects. His book has had a large sale, which now bids fair to increase greatly.

In order that every reader of the American Bee Journal, who does not already possess a copy of Prof. Cook's work, may have it, we wish to make the following

FOUR LIBERAL OFFERS:

No. 1.—For \$1.75 we will mail the American Bee Journal one year and a copy of Prof. Cook's book.

No. 2.—Any one of our present subscribers whose subscription is now paid in advance, can have a copy of Prof. Cook's book mailed to him free as a premium for sending us two new subscribers to the American Bee Journal for a year (with \$2.00.)

No. 3.—Or, send one new subscriber for a year (at \$1.00) and 50 cents more (\$1.50 in all,) and we will mail to YOU a copy of the book and will send the American Bee Journal for one year to the new subscriber.

No. 4.—For \$1.00 we will send Prof. Cook's book by express or freight with other goods; or, if called for at our office, the price is \$1.00. But the post-paid price of the book alone is \$1.20.

Please remember that offers Nos. 2 and 3 of the above are made to those who are now subscribers to the American Bee Journal, and whose subscriptions are paid in advance. Offers Nos. 1 and 4 are made to any one who desires to take advantage of them.

Address all orders to the publishers,

YON YONSON.

Bees Did Fairly Well.

My bees have done fairly well this season. I got 2000 pounds of comb honey from 22 colonies, spring count, and increased to 38. They are in good shape for winter. This is getting to be a very fair place for bees, and they do as well here as anywhere.

F. H. MILLER.

Barton Co., Kans., Oct. 31.

He Appreciates this Journal.

The American Bee Journal is just the paper for any one keeping bees. I fail to see how any person can do without it and make a success keeping bees. I got my experience from it by putting what I read to practical use.

W. J. BROWN.

Skagit Co., Wash., Oct. 27.

Honey Crop Almost a Failure.

The honey crop was rather a failure in this locality. A bee-keeper in this neighborhood, having 450 colonies, had nothing to extract, although the bees have the hives heavy now, which insures at least good wintering. There is at present a good flow of honey from various fall flowers. In some places the ground is covered for acres with yellow flowers; it seems they belong to the sunflower family.

I extracted 360 pounds of honey from 8 colonies, and increased to 18; but I have to feed some of them.

OTTO SUELSNFUSS.

Bexar Co., Tex., Oct. 28.

Only a Fair Yield.

Although the weather the past summer was too chilly and wet I secured a little over 400 sections of honey from 11 colonies, and they were all sold to private families. They all came after the honey.

J. W. LEIB.

Franklin Co., Ohio, Nov. 4.

Building Comb to Separators.

I know from actual experience with hundreds of colonies, that the starter hasn't anything to do with building comb to the separator whatever, unless it breaks loose.

I have been wondering for some years past why so many bee-keepers advocate full sheets of comb foundation in sections, when, in this country, half and quarter sheets produce just as good results. I think that the advocating of full sheets of comb foundation is either advertising for the foundation, or else an ignorant statement of those making it. I think the same is true with fence separators. I have produced thousands and thousands of sections of comb honey, with plain separators, with sections partly filled with comb foundation, and very seldom have any attached to the separator. They have been as white as snow, and as straight as a board, so much so that I have taken premiums five or six times in succession, at the Northern State Fair, over any sections; the fence separators are no exception.

When I see a statement made that full sheets of comb foundation will do away with brace-comb, it makes me feel badly, not for those who make the statement, but for the poor beginners, who, like myself, seek a remedy for their troubles, and will invest heavily in the things recommended through the newspapers, only to be disappointed.

I am not able, however, to give a remedy to prevent the bees from attaching the combs to

the separators, but full sheets of comb foundation is not the remedy. The starter I have been using for the last eight years is a V-shaped piece, reaching nearly the entire length of the section at the top, and extending to within an inch of the bottom. It surprises me to see it advocated by old bee-keepers to put a bottom starter in the section in order to get the combs fastened. I do not use such a starter at all, and out of 100,000 sections of comb honey, I do not believe 100 sections were not fastened to the bottom solid.

A. C. F. BARTZ.

Chippewa Co., Wis., Nov. 3.

Wet Season—Carniolan Bees.

Strange things have occurred here in 1902. As I reported some time ago, we had a fine flow last spring, but we have had one of the driest, hottest summers ever known here. It seems strange to read what Northern bee-keepers say about cold, wet weather when we are burning and drying up.

The drouth lasted from May 31 to Aug. 30, when the rain came. Nearly everything was dried up, and most of the bees verging on starvation. I am glad to say, after the rain came, everything started anew, and the bees went to work rearing young brood like they do in the spring.

Some of the bees have four or five gallons of honey to the colony, and are still working. But we will soon have frost.

The most of my colonies have a fine lot of young bees to go through the winter.

I have read with interest all Dr. Gallup has said about rearing queens. I believe the Doctor is nearer right than some of our bee-men are willing to admit. I have tried to rear queens in weak colonies several times this year, but I failed nearly every time to get a good one. I do not see how it is that so many report failure with queens they buy; I have bought several, and they have all done very well except one. I must say a good word for the Carniolans; during the dry weather they kept rearing bees. When the honey-flow came they had plenty of bees to gather the honey, but the blacks were too weak to do much. If you want to build your bees up fast, just get one or two Carniolans and rear all the queens you want.

J. S. PATTON.

Hale Co., Ala., Oct. 31.

Asters.

I enclose two flowers on which the bees work so much—one with white flowers and the other with yellow and blue flowers. What are they?

F. J. GUNZEL.

Poinsett Co., Ark.

[Both are Asters: the one with white flowers is Aster-Belgii, commonly called white-weed; the other is Aster laevis. These are valuable honey-plants, and are among the latest flowers to attract bees.—C. L. WALTON.]

Results of a Wet Season.

I never saw as much wet weather as we have had this year; it has rained as often as every other day since last April, and has been quite cool.

I started in this spring with 11 colonies of bees, and increased to 22. I have taken off 1057 pounds of nice honey.

We had about 4 weeks of nice white clover bloom; the bees worked well on it, notwithstanding the wet weather. They are well provided for the winter with nice honey, and are in fine shape.

I am selling my No. 1 honey by the case for 14½ cents per pound, and the light weight for 2 sections for 25 cents, and my extracted at 12 cents a pound, with good sales. I have bought nearly a ton of honey of my brother bee-keepers, so I have honey to supply my customers.

Bees have done very well here in the Lake Champlain valley. I have reports from others only about two miles from here, and they say their bees are starving.

I have had orders for honey from Pennsylvania. I find that fair dealing and honest weight, and putting the honey up in cartons, with name and address on them, bring me

BEE-KEEPERS--ATTENTION.

Do not put your money into New Fangled Bee-Hives, but buy a plain, serviceable and well-made hive, such as the regular Dovetailed hive arranged for bee-way sections. Honey-producers of Colorado—one of the largest honey-producing sections in the world—use this style.

When Bees Build Queen-Cells Best.

On page 682, I see Mr. Hasty says I have taken a film or hide off his eyes. Oh, now, Mr. Hasty, don't be so hasty, for we have all the hides down here we want; better keep yours to distribute where they are needed more.

I am still making the statement credited to me at the convention, and, what is more, I thoroughly proved it the last year or so. I couldn't afford to be caught making an unorthodox statement. Yes, Mr. Hasty, it is true, as I have found in my experience, that a colony is in the best shape to build cells in from one to four hours (at most) after being made queenless and broodless. Just as soon as they begin to show that peculiar restlessness indicating their queenlessness, we are ready to give them the batch or batches of cells.

In transferring I use little or no royal jelly, and transfer very young larvae. They are then given in batches to the colonies as fast as they show they are queenless, and are at once received and well fed. True, the bees have not had time to secrete royal jelly, but has it not been proved that both workers and queens are fed on identically the same food for the first two or three days of their life? Therefore the bees will have ample time to secrete the more concentrated food by the time the larvae are old enough to take the richer food.

By giving the cells to the colonies early I get a much larger percent of accepted cells; and, what is more, a much better lot of cells. The quicker you can give bees the prepared cells after they show queenlessness the better it is all around. There are several hours saved, a better grade of queens, and no absconding of the bees. Sometimes, if bees are left queenless and broodless over night, they will abscond early the next morning, or unite with some other colony. I have found that blacks are worse at absconding than the pure Italians or their crosses. No, sir, Mr. Hasty, this is not a case of "sometimes," it is a case of "all times," that the bees give the best results if bees are given the prepared cups immediately after they show they realize their queenlessness.

Now, if any of the other so-called professionals want to have their say, or you want to remove some more "hide," pitch in.

Langstroth on... The Honey-Bee

Revised by Dadant—1900 Edition.

This is one of the standard books on bee-culture, and ought to be in the library of every bee-keeper. It is bound substantially in cloth, and contains over 500 pages, being revised by those large, practical bee-keepers, so well-known to all the readers of the American Bee Journal—Chas. Dadant & Son. Each subject is clearly and thoroly explained, so that by following the instructions of this book one cannot fail to be wonderfully helped on the way to success with bees.

The book we mail for \$1.25, or club it with the American Bee Journal for one year—both for \$1.75; or, we will mail it as a premium for sending us THREE NEW subscribers to the Bee Journal for one year, with \$3.00.

This is a splendid chance to get a grand bee-book for a very little money or work.

Bisulphide of Carbon—A Caution.

Some writers have told how they have had fire quite near this substance without its igniting. They'll repeat that thing just once too often some bright day when a draft of air brings the fumes toward the fire. It does not stop to burn—it goes off with a bang.—STENOG, in Gleanings in Bee-Culture.

Honey-Glands.

These are organs found in many flowers, and their office is to secrete the sweet saccharine juice and generate it in the nectareous sacs, where it is stored up until it is rifled by the bees on their foraging excursions. They differ in number in various kinds of flowers, from one to five or more, generally according to the arrangement of the flower-petals. Thus, in the Ranunculus family, with their five flower-leaves, there are five nectaries, corresponding with the five petals. In regular flowers, however, the base is different, and frequently but one exists. It is placed in different positions on different flowers, but always situated just where the bee can most easily approach and sip from it. If these glands differ in number and position, their shape and size are even more diverse. The raspberry flower has a regular circular honey-trough, and the bee sips all round it, taking some time to exhaust the supply. That bountiful bee-flower, the lime, has a boat-shaped structure, which, in certain seasons, is ever full to overflowing, and, perhaps, on no other plant does the insect load up so quickly, and with so little trouble and exertion. Hellebores, and many others, have little tubular honey-pots yielding their stores willingly. The buttercups have five small, circular glands, one on each petal. Though the flower is generally the seat of these receptacles for the nectareous secretion, other parts may be found at times to yield a flow, as in the case of beans and vetches, which secrete it by their stipules.—D. M. M., in the British Bee Journal.

Alfalfa Yielding Honey in the South.

By the way, speaking about alfalfa, I planted about one-fourth acre year before last for the bees. Last year it grew nicely and bloomed well, but the bees paid no attention to it. I decided to let it remain a year longer to test it thoroughly. This spring the bees worked on it well—so much so that the man who cut it (it was cut while in bloom), along toward the last, threatened to give up the job, as he said it was hard to tell which were in possession—he or the bees. So it is safe to say alfalfa has produced honey as far east as North Carolina.—"TAR HEEL," in Gleanings in Bee-Culture.

Worker-Comb Without Foundation.

G. M. Doolittle says in Gleanings in Bee-Culture that his favorite plan is to have combs built in a weak colony or nucleus.

He says: "If such a colony is deprived of all of its combs save one of honey and one of brood, and a frame having a starter in it is inserted between the two combs left in the hive, the bees will, ninety-nine times in a hundred, fill that frame with worker-comb, and said comb will be as perfect as one built from foundation under the most favorable circumstances. Taking advantage of this fact, I take frames of brood from the weaker colonies I have at the beginning of the honey-flow, those too weak to work in sections to advantage, and give this brood to the weaker of the stronger colonies, and set the weak colonies to building comb, as I have explained. You will note here that I really make a gain in this way as to surplus honey, for this brood, where placed, gives better results in section honey than it would have done had it been

left where it was with the weak colony, as it almost immediately puts the bees of the colony where given (into the sections) at work, while, had the brood remained in its own hive, these colonies would have been somewhat slow in starting in the sections."

CONVENTION NOTICE.

Chicago - Northwestern.—The executive committee of the Chicago-Northwestern Beekeepers' Association have planned to hold the best convention ever convened in Chicago. The date is Dec. 3d and 4th, Wednesday and Thursday. Five eminent bee-keepers have been invited, and are expected to attend. More definite announcement later. Watch for it. Reduced rates on account of the fat stock show, which is held Nov. 29th to Dec. 6th.

BEE=BOOKS

SENT POSTPAID BY

GEORGE W. YORK & CO.,

144 & 146 Erie St., - CHICAGO, ILL.

Bee-Keeper's Guide, or Manual of the Apiary, by Prof. A. J. Cook, of Pomona College, California. This book is not only instructive and helpful as a guide in bee-keeping, but is interesting and thoroughly practical and scientific. It contains a full delineation of the anatomy and physiology of bees. 544 pages. 295 illustrations. Bound in cloth. 1902 edition—19th thousand. Price, \$1.20.

Langstroth on the Honey-Bee, revised by Dadant.—This classic in bee-culture has been entirely re-written, and is fully illustrated. It treats of everything relating to bees and bee-keeping. No apiarian library is complete without this standard work by Rev. L. L. Langstroth—the Father of American Bee-Culture. It has 520 pages, bound in cloth. Price, \$1.25.

A B C of Bee-Culture, by A. I. Root.—A cyclopedic of 400 pages, describing everything pertaining to the care of the honey-bees. Contains 300 engravings. It was written especially for beginners. Bound in cloth. Price, \$1.20.

Scientific Queen-Bearing, as Practically Applied, by G. M. Doolittle.—A method by which the very best of queen-bees are reared in perfect accord with Nature's way. Bound in cloth and illustrated. Price, \$1.00; in leatherette binding, 60 cents.

Bees and Honey, or Management of an Apiary for Pleasure and Profit, by Thomas G. Newman.—It is nicely illustrated, contains 160 pages, bound in cloth. Price, in cloth, 50 cents; in paper, 30 cents.

Advanced Bee-Culture, Its Methods and Management, by W. Z. Hutchinson.—The author of this work is a practical and entertaining writer. You should read his book; 90 pages, bound in paper, and illustrated. Price, 50 cents.

Bee-Keeping for Beginners, by Dr. J. P. H. Brown, of Georgia.—A practical and condensed treatise on the honey-bee, giving the best modes of management in order to secure the most profit. 110 pages, bound in paper. Price, 50 cents.

Bee-Keeping for Profit, by Dr. G. L. Tinker.—Revised and enlarged. It details the author's "new system, or how to get the largest yields of comb or extracted honey." 80 pages, illustrated. Price, 25 cents.

Bienen-Kultur, by Thomas G. Newman.—This is a German translation of the principal portion of the book called "Bees and Honey." 100-page pamphlet. Price, 25 cents.

Apiary Register, by Thomas G. Newman.—Devotes two pages to a colony. Leather binding. Price, for 50 colonies, \$1.00.

Dr. Howard's Book on Foul-Brood.—Gives the McEvoy Treatment and reviews the experiments of others. Price, 25 cents.

Winter Problem in Bee-Keeping, by G. R. Pierce.—Result of 25 years' experience. Price, 30 cents.

Foul Brood Treatment, by Prof. F. R. Cheshire.—Its Cause and Prevention. 10 cts.

Foul Brood, by A. R. Kohnke.—Origin, Development and Cure. Price, 10 cents.

HONEY AND BEESWAX
MARKET QUOTATIONS.

CHICAGO, Nov. 7.—Prices remain steady, but the demand is small. We are not selling the quantity that we have done ordinarily at this season of the year. The advance in price has checked the trade, in addition to which retailers have got the impression that honey is going to be very scarce, and they are not pushing its sale. Fancy white comb brings 15¢@16c, with travel-stained from one to two cents per pound less; amber honey brings 12¢@13c, according to style and kind of package. There is very little call for the dark amber and buckwheat grades. Extracted white sells at 7¢@8c; dark and ambers, 6¢@7c; Southern is slow at about 5¢. Beeswax sells upon arrival at 30c per pound.
R. A. BURNETT & Co.

ALBANY, N. Y., Oct. 24.—The receipts of honey do not increase any, and there is a good, stiff demand at good prices. Kwing prices are 15c for white, and some extra fancy, 16c; buckwheat and dark, 13½¢@14c. Extracted, dark, 6½c; mixed, 6½¢@7c; white, 7¢@7½c. Beeswax, 30c.
H. R. WRIGHT.

BOSTON, Oct. 20.—Our honey market remains firm, with good demand and fair stocks on hand. Honey is not coming forward as fast as usual, and the tendency of prices is steady. We quote our market as follows: Fancy white 1-pound sections in cartons, 16c; No. 1, 15c; No. 2, very light supply, 14c; glass-front sections generally one cent less than this. Extracted, light amber, 8c; amber, 7½c.
BLAKE, SCOTT & LEE.

KANSAS CITY, Oct. 20.—The receipts of comb and extracted honey are light, and demand steady at quotations: Fancy white comb, 14½¢@15c; No. 1 white, 14¢@14½c; No. 2 white and amber, 13¢@13½c. White extracted, 7¢@7½c; amber, 6¢@6½c. Beeswax, 24¢@26c.
C. C. CLEMENS & Co.

CINCINNATI, Oct. 4.—The demand for extracted honey is good at the following prices: Southern and amber sells at 5½¢@6½c; better grades, 7¢@8c. Comb honey is scarce; fancy and No. 1 sells on arrival at 16¢@17c. Beeswax weak at 28c.
THE FRED W. MUTH CO.

NEW YORK, Oct. 10.—We are having a good demand for comb honey and receipts are quite plentiful. We quote fancy white at 15c, and some exceptionally fine lots will bring from 15½¢@16c; No. 1, white, 13¢@14c; amber, 12c.

Buckwheat is late arriving, and none has been on the market as yet to cut any figure. We expect large receipts next week, and it will sell at from 10¢@12c, according to quality and style of package.

Extracted in fairly good demand at 7½c for white, 6½c for light amber, and 5½¢@6c for amber. Southern in barrels at from 55¢@65c per gallon. Beeswax nominal at 28c.

HILDRETH & SEIGLEEN.

CINCINNATI, Oct. 27.—The demand for comb honey is good and prices are a little better, as the supply does not meet the wants. Extra water-white fancy is selling as high as 16¢@17c; other grades less, according to quality. Extracted is very active and prices are a little better; amber, 5½¢@5½c; alfalfa, 6½¢@7c; white clover, 7½c. Beeswax, 28c. C. H. W. WEBER.

SAN FRANCISCO, Oct. 15.—White comb honey, 12¢@12½c; amber, 8¢@10c; dark, 7¢@7½c. Extracted, white, 5½¢@6c; light amber, 5½¢@5½c; amber, 5¢@5½c. Beeswax, good to choice, light, 27¢@29c; dark, 25¢@26c.

There are no heavy offerings of any description, either at this center or at producing points. Comb honey is in better spot supply, however, than extracted. Stocks of latter have been greatly reduced by recent shipments outward. Current values are being well maintained.

Wanted—Extracted HONEY Mail sample, and state style of package and price delivered in Chicago.

1-lb Keystone ... Honey-Jars

These are clear flint glass jars holding just one pound, and the shape of a keystone. They are 7 1/8 inches high, and very pretty when filled with honey. The corks can be sunk a trifle below the top, and then fill in with beeswax, sealingwax or paraffin. We can furnish them in single gross lots, with corks, f.o.b. Chicago, at \$3.50; two gross, \$3.25 per gross; or five or more gross, at \$3.00 a gross. These are the cheapest glass one-pound jars we know anything about. We have only about 20 gross of them left. So speak quick if you want them. Address,

GEORGE W. YORK & CO.

EUGENE SECOR, General Manager and Treasurer, Forest City, Iowa.

MEMBERSHIP DUES, \$1.00 a year.

If more convenient, Dues may be sent to the office of the American Bee Journal, when they will be forwarded to Mr. Secor, who will mail individual receipts.

A Celluloid Queen-Button is a very pretty thing for a bee-keeper or honey-seller to wear on his coat-lapel. It often serves to introduce the subject of honey, and frequently leads to a sale.

NOTE.—One reader writes: "I have every reason to believe that it would be a very good idea for every bee-keeper to wear one of these buttons; as it will cause people to ask questions about the busy bee, and many a conversation thus started would wind up with the sale of more or less honey; at any rate it would give the bee-keeper a superior opportunity to enlighten many a person in regard to honey and bees."

The picture shown herewith is a reproduction of a motto queen-button that we are furnishing to bee-keepers. It has a pin on the underside to fasten it.

Price, by mail, 6 cents; two for 10 cents, or 6 for 25 cents. Send all orders to the office of the American Bee Journal.

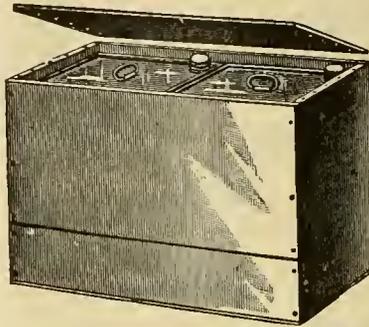

BEST Extracted Honey For Sale

ALL IN 60-POUND TIN CANS.

Alfalfa Honey

This is the famous White Extracted Honey gathered in the great Alfalfa regions of the Central West. It is a splendid honey, and nearly everybody who cares to eat honey at all can't get enough of the Alfalfa extracted.

Basswood Honey

This is the well-known light-colored honey gathered from the rich, nectar-laden basswood blossoms. It has a stronger flavor than Alfalfa, and is preferred by those who like a distinct flavor in their honey.

Prices of Alfalfa or Basswood Honey:

A sample of either, by mail, 10 cents, to pay for package and postage. By freight—two 60-pound cans of Alfalfa, 9 cents per pound; 4 cans or more, 8½ cents a pound. Basswood Honey, ½ cent more per pound than Alfalfa prices. Cash must accompany each order. You can order half of each kind of honey, if you so desire. The cans are two in a box, and freight is not prepaid. **Absolutely Pure Bees' Honey.**

Order the Above Honey and then Sell It.

We would suggest that those bee-keepers who did not produce enough honey for their home demand this year, just order some of the above, and sell it. And others, who want to earn some money, can get this honey and work up a demand for it almost anywhere.

GEORGE W. YORK & CO., 144 & 146 Erie St., Chicago, Ill.

The Novelty Pocket-Knife.

Your Name and Address on one side—Three Bees on the other side.

[THIS CUT IS THE FULL SIZE OF THE KNIFE.]

Your Name on the Knife.—When ordering, be sure to say just what name and address you wish put on the Knife.

The Novelty Knife is indeed a novelty. The novelty lies in the handle. It is made beautifully of indestructible celluloid, which is as transparent as glass. Underneath the celluloid, on one side of the handle is placed the name and residence of the subscriber, and on the other side pictures of a Queen, Drone, and Worker, as shown here.

The Material entering into this celebrated knife is of the very best quality; the blades are hand-forged out of the very finest English razor-steel, and we warrant every blade. The bolsters are made of German silver, and will never rust or corrode. The rivets are hardened German silver wire; the linings are plate brass; the back springs of Sheffield spring-steel, and the finish of the handle as described above. It will last a lifetime, with proper usage.

Why Own the Novelty Knife? In case a good knife is lost, the chances are the owner will never recover it; but if the "Novelty" is lost, having name and address of owner, the finder will return it; otherwise to try to destroy the name and address, would destroy the knife. If traveling, and you meet with a serious accident, and are so fortunate as to have one of the "Novelties," your POCKET-KNIFE will serve as an identifier; and in case of death, your relatives will at once be notified of the accident.

How appropriate this knife is for a present! What more lasting memento could a mother give to a son, a wife to a husband, a sister to a brother, or a lady to a gentleman, the knife having the name of the recipient on one side?

The accompanying cut gives a faint idea, but cannot fully convey an exact representation of this beautiful knife, as the "Novelty" must be seen to be appreciated.

How to Get this Valuable Knife.—We send it postpaid for \$1.25, or give it as a Premium to the one sending us THREE NEW SUBSCRIBERS to the Bee Journal (with \$3.00). We will club the Novelty Knife and the Bee Journal for one year, both for \$1.90.

GEORGE W. YORK & CO.

Chicago, Ill.

Please allow about two weeks for your knife order to be filled.

DEATH OF DR. A. B. MASON.

On Thursday, Nov. 13, we were shocked to receive the following letter, telling of the death of Dr. A. B. Mason, one of the oldest and most active bee-keepers in the United States, and for years Secretary of the National Bee-Keepers' Association:

TOLEDO, OHIO, Nov. 12, 1902.

MR. GEORGE W. YORK, Chicago, Ill.—

DEAR MR. YORK:—One week ago last Thursday, Father Mason met with a very serious accident. An explosion of natural gas occurred in the summer kitchen at his home, and he was badly burned about the head, face, and hands. From the first we were very anxious about his condition, knowing how difficult it is for one of his years to overcome the nervous shock of such an accident. For a few days he seemed to do nicely, but last Monday he began to fail, and died this morning at 7:55.

We knew that father would wish you to know the circumstances of his death, so I have taken the liberty of addressing this letter to you.

Very respectfully,
His daughter,
MRS. ELLIS E. MASON.

DR. A. B. MASON.

The foregoing sad notice came too late to permit of a biographical sketch appearing in this issue of the American Bee Journal, but next week we hope to be able to place before our readers an extended resume of Dr. Mason's life.

All will unite with us in extending sincerest sympathy to the bereaved family, in their untimely loss.

Uniting Colonies should have been done before this, but if you have unfortunately neglected it till now, you may as well take what comfort you can out of the thought that there is at least one advantage in late uniting—bees are not so much inclined to fight when it is too cool for them to fly. All you need to do is to put into one hive enough bees and enough honey, and there is not likely to be any fighting. It is better if the queen of the colony to be united has been killed a few days before uniting, but still you can leave that to the bees. Just take of the colony to be united the combs to which they are to be united, having first removed from this latter a sufficient number of combs for the purpose, making sure that you have enough

stores for the united colony. It is a good plan to do this removing a day or two in advance, brushing down upon the top-bars the few bees that may be on the removed frames, and it is also well to prepare in advance the bees to be united, by spreading the frames a little apart and moving them away from the side of the hive, so as to have the bees on as few combs as possible.

But don't count on doing this next fall, for it is better to do the work early and allow the bees plenty of time to arrange their brood-nest in the best possible manner. They can beat you all out at arranging a winter brood-nest.

Concrete Hive-Floors are spoken of considerably in the Australasian Bee-Keeper. They have the advantage of durability, and perhaps of economy. Their weight, of course, makes them objectionable, if they are to be moved.

Hive-Covers are having some discussion in the Australasian Bee-Keeper. Single board covers are in less repute there than here, because of the great heat, combs melting down under them. Preference is given to a cover having an air-space, as a gable cover, or a telescope cover, allowing some kind of a covering beneath, and the editor thinks protection should be given against the sun on the sides as well as the tops of the hives.

Alfalfa in the Future.—Some apprehension has been expressed as to the future of alfalfa, because of the tendency of ranchmen to cut it for hay before the time of bloom. M. A. Gill thinks this an idle scare. He says, in *Gleanings in Bee-Culture*, that intelligent cattle-feeders understand that the best results are to be obtained from hay cut when in full bloom, and earlier cutting is only made at a loss. H. D. Watson, the "alfalfa king," assured Editor Root that we need not be alarmed about the ranchers cutting their hay before it bloomed.

Don't Waste Pollen.—It is not an uncommon thing to see combs of pollen going to waste in the hands of those who are careful to save the smallest quantity of honey. Indeed, there are probably many who attach no money-value whatever to pollen. The bees, however, set a high value upon it. Without pollen, no brood-rearing. "But the bees gather more than they need, and there is no possible good to come from having a store of pollen in the hive when the bees can get plenty of it in the fields." Are you so sure of that? Do you know to a dead certainty that a colony which has a good store of pollen in its combs will bring in just as much pollen from the fields as it would with no pollen at all in the hive?

Probably few have made sufficiently careful observations to realize the great amount of pollen used by a colony of bees in the course of a year. During the great brood-rearing period, early in the season, a close observing will show that the store of pollen left over from the preceding

year becomes gradually less until the beginning of the harvest, when it becomes very low. Is it not barely possible that if the stock of pollen had been greater it would have allowed the gathering of just so much more honey? That is, if enough pollen were already in the hive, for use during harvest, the energies of the pollen-gatherers might be used entirely in gathering honey.

So if, in your preparations for winter, you have thrown out some frames well filled with pollen, see that they are carefully saved for the needs of the following spring. It is barely possible that in some places pollen is so very abundant that it is not worth saving. Testimony is needed as to this.

History of Shaken Swarms.—L. Stachelhausen, who is regarded as the pioneer in this country in shaking or brushing swarms, does not consider them as anything new. He says in *Gleanings in Bee-Culture* :

That we can take from a strong colony all the frames of brood except probably one or two, and give empty combs or starters in their place, was known long ago, and this is the same thing as a brushed swarm set on the old stand, and the same thing as the driven swarm forced from a straw-skep and known more than 100 years ago. Gravenhorst made a step in advance, advising a way by which the bees brushed or shaken from the combs could be set on a new place and would stay there, at least the greater part of them. This, too, is 20 or more years old. I myself, described this method in *The Apiculturist* in 1884, page 97.

* The Weekly Budget. *

PAY UP OR YOU CAN'T VOTE.—Any one knowing himself to be in arrears as a member of the National Bee Keepers' Association, and who desires to vote at the coming election (in December), should at once send his dues (\$1.00) to the General Manager, Eugene Secor, Forest City, Iowa. Voting blanks will be mailed early in December to every member whose dues have not lapsed.

Also, any bee-keepers who are not yet members, and would like to become such, will need to mail their dues to Mr. Secor right away, if they would like to vote at the election.

A General Manager for 1903, and three Directors to serve for four years, are to be elected.

The membership of the Association is now about 900. It should be at least 9000.

We understand that the General Manager's annual report is now ready for the printer, so it will likely be mailed promptly to the membership after Dec. 1. If not already paid, you would better send your dues (\$1.00) to Mr. Secor immediately—do it *now*, before you forget it.

MR. J. E. CRANE and Henry Robbins, of Addison Co., Vt., called on us on Nov. 7, when on their way home from a western trip, through Idaho, Colorado, and other States. Mr. Crane's honey crop, the past season, was upwards of 30,000 pounds of comb honey. He usually ships his honey to Chicago. Mr. Crane is one of the foremost bee-keepers of the whole East. Mr. Robbins is more of a farmer than bee-keeper.

S. F. NEWMAN, of Huron Co., Ohio, was killed on a railroad crossing by a passing train. Although not extensively known of late years, he was an intelligent and successful bee-keeper, and was noted as the man who wrote for the secular press the story of the making of artificial eggs.

The chemist was able to supply successfully everything to make an egg that hatched out a perfect chicken, only the chicken had no feathers, and efforts were being continued to find the proper chemicals to produce the feathers. It was a fine bit of work, and was written at the time when the canard about the manufacture of artificial comb honey was in its most flourishing condition, so as to help, by its absurdity, to show the absurdity of the artificial comb-honey lie. But the story was so well told, that, in spite of its absurdity, it had many believers.

MR. J. G. COREY, of Ventura Co., Calif., called on us last week. He had been on a trip to the Atlantic Coast. He reports scarcely any honey in his locality this year. There seemed to be abundance of bloom, but, practically, no nectar in it. In his early days in California he bought a small colony of bees for \$100. That season he increased it to six colonies, and then sold the six for \$600. Now fair colonies of bees can be had there for \$3.00 a colony, and with a pretty good hive, too. Quite a change in less than half a century.

THE APIARY OF G. G. FALL, of Strafford Co., N. H., appears on the first page. When sending the photograph he wrote thus:

I send a picture of my home apiary. I have another one situated in the White Mountains, about 60 miles away. I am a railroad man, and have kept bees for 20 years, more for pleasure than for profit.

I think the season of 1902 was the worst we have had during my experience with bees. Mt. Washington, which is 15 miles from my out-apiary, is now (July 5) quite white with snow, but I never saw more white clover, and the bees are doing nothing with it, as one day it rains and the next day the wind blows, and it is so cold they are unable to work. So the outlook for a honey crop is very poor.

A MAGAZINE 30 YEARS OLD.—The Christmas (December) number of the *Delineator* is also the 30th anniversary number. To do justice to this number, which, for beauty and utility, touches the highest mark, it would be necessary to print the entire list of contents. It is sufficient to state that in it the best modern writers and artists are generously represented. The book contains over 230 pages, with 34 full-page illustrations, of which 20 are in two or more colors. The magnitude of this December number, for which 728 tons of paper and six tons of ink have been used, may be understood from the fact that 92 presses, running 14 hours a day, have been required to print it; the binding alone of the edition of 915,000 copies, representing over 20,000,000 sections, which had to be gathered individually by human hands.

AN EXPLANATION ON THE DENVER REPORT.—We have received the following from Dr. Miller in reference to the report of the National convention which we are now publishing:

MR. EDITOR:—I desire a word of explanation with regard to the report of the Denver convention, as some who were not on the ground might not fully understand it. I refer to that part in the second column on page 694, where Dr. Mason, without addressing the President, turned to me and said, "That is pretty small, but you are a small man."

Mr. Harris, as appears on page 693, made a motion. After a little discussion Mr. Harris said, "We are all out of order at the present time, as the motion has not been stated." Still the discussion went on, and Mr. Booth rose to a point of order, and said, "I have not heard any question stated by the chair." Still the discussion went on, and Mr. Harris, again rising, said, "There is nothing for discussion, and I would like to talk on the motion when properly put by the chair." Seeing that the President evidently did not get Mr. Harris' point, I thought I could help straighten matters out, and arose and tried to make it clear to the President what it was that Mr. Harris wanted, using, I think, some words that do not appear in the report, and explaining further that the stenographer could read the motion, and then the President could state it. It was then that Dr. Mason said, "That is pretty small, but

you are a small man." It was not I, but Mr. Harris (who is not a "small man"), who was insisting on parliamentary rules, if insisting on parliamentary rules can be called "pretty small," and I was merely trying to call the attention of the President to what Mr. Harris wanted.

C. C. MILLER.

Convention Proceedings.

THE DENVER CONVENTION.

Report of the Proceedings of the 33d Annual Convention of the National Bee-Keepers' Association, held in Denver, Col., on Wednesday, Thursday and Friday, Sept. 3, 4 and 5, 1902.

(Continued from page 727)

Pres. Hutchinson then called upon E. R. Root to reply to the paper of Mr. Morehouse, on

"BEE-KEEPING LESSONS THAT MAY BE LEARNED FROM THE WORD 'LOCALITY.'"

E. R. Root—I read over the paper by Mr. Morehouse, but I have given the matter no further thought until just now. I don't know that I am prepared to give this matter a consecutive and careful reply, but I will try to take up some points he suggested.

If I remember correctly, he took up the matter in a general way, leaving me to take it up in a specific form, to suggest, if possible, how localities differ as to the mode of treatment of colonies in the United States.

If we take the locality known as the Rain-Belt, or that portion of the United States where rain falls, and they do not depend upon irrigation, starting, perhaps, southward of the Ohio River, northward taking from Minnesota to Maine, the New England States, and all that portion of the country including New York and Pennsylvania, we have a special mode of treatment for preparing colonies to bring them up to the condition whereby they may take in the white honey-flow that will commence anywhere from the first of June to the first of July, and lasting anywhere from four weeks to possibly two months. It seems to be necessary to make the treatments in the East of preparing colonies and getting them ready for the honey-flow that shall occur a little later, getting the largest force of bees possible to gather the honey-flow at that season of the year in June or July, as we do not over the other portions of the country.

Starting south in Texas, coming along through Arizona, up into California and back into Colorado, the mode of treatment has to be varied very considerably. Taking over that portion of the country out West, of which I speak, the seasons are longer, lasting anywhere from a few weeks to several months; the honey-flow is perhaps not so rapid as we have in the East, such as we get from basswood; it is slower, and the flow comes at such a time that the bees could readily take care of it. Take, for instance, in Texas, they have a number of unimportant honey-plants, such plants as are only useful for stimulating the bees for the honey-flow that comes on later; those plants are of such a nature that through a little honey-flow, slowly, brood-rearing progresses satisfactorily, no feeding necessary, as for us in the East; and the consequence is, when the heavy honey-flow comes on the bees are ready, and of the right age, to gather the flow that shall come. The most important flows in Texas, if I mistake not, are from mesquite, guajilla and catclaw. Those follow one after the other, so that the mode of treatment in Texas seems to be quite different from what it is in the Eastern States, and in the northern portion of our country.

Another peculiarity of locality is that which affects the swarming problem, and in lower Arizona, and some portions of California, it is not such a serious one as with us in the East; the swarming comes on earlier in the season, with the minor honey-plants, and it seems that the bees are not inclined to swarm when the heavy honey-flow comes on

later, and the bee-keepers are prepared to take care of the swarming when it does come, also the extracting, because they come at a time when there is not much work to do. Then, after the honey-flow comes on, the swarming ceases and the bees get down to hard work. That condition does not prevail in the East, only to a slight extent, when the heavy honey-flow comes on; that is, the bees may let up somewhat from swarming, but they do not cease entirely until the honey-flow stops. In Texas and Arizona, and some parts of California, the honey-flow comes on with such a rush, and continues for such a time, that the swarming stops almost entirely, or lets up enough so that it is not a difficult problem, and out-apiaries can be left to themselves. I see Mr. Scholl nods assent, so I am correct.

Then there is the question of disease. Bee-paralysis is much more virulent in the South, in some portions of California and the West than it is in the northern and central portions of the United States known as the Rain-Belt. When I speak of the Rain-Belt you will know exactly where I mean: Those States that I referred to in the East, north of the Ohio River and between the Atlantic Ocean and Mississippi River, and taking in perhaps Iowa, Minnesota and Wisconsin; in that portion the disease known as bee-paralysis never amounts to anything; we see, occasionally, colonies having that disease, where the bees are tremulous in their motions, some of them die off, but I never knew where it was very serious; it might amount to the killing of one colony.

When we go southward into the Southern States, especially Florida, we find bee-paralysis is a very serious disease; why, we don't know.

Then the question of foul brood and black brood seems to be somewhat a matter of locality. We find, so far, that black brood is confined mainly to the State of New York; I don't think there is very much in the West. I have known of one or two cases where it was in California, but I never knew of a case in Texas or Arizona; and, if I mistake not, there is very little or no foul brood in Texas. Am I correct in that?

Mr. Scholl—Yes.

Mr. Root—The conditions do not seem favorable for the propagation of that disease, but I advise my friends in Texas not to try the experiment.

Then the question of hives (the size of) depends largely upon locality. Large hives seem to be better in warm localities where the honey-flow continues for a considerable length of time.

Then the question as to whether comb honey or extracted honey is another factor; if extracted only, then the 10-frame Langstroth, or Jumbo, seems to be preferred; if comb honey, then the 8-frame Langstroth, or some similar small brood-nest would be used as in the East. In Texas and California comb honey can be produced over the 10-frame hive very satisfactorily, because that hive can be used for extracted or comb honey; it seems to prevail very largely, although there are marked exceptions to this rule.

There is another peculiarity that I noticed in Colorado from talking with a number of bee-keepers, and that is the matter of tiering-up. The question of tiering-up in the Rain-Belt is quite a complicated one. We don't know how long the honey-flow is going to last, or when the weather will change suddenly; that prevails over large portions of the United States; but in Colorado, if I understand it, you know just when your honey-flow is going to stop, or nearly so—when the mowing machines have gone over the field; you know when they will have about all the alfalfa cut, and you know when the honey-flow will stop. If I understand correctly, you tier-up in such a way that nearly all the sections will be completed at the end of that honey-flow, when the cutting of the alfalfa is through. The question of tiering-up in Colorado is quite peculiar.

Another peculiarity here is, you do not have to look out for the moth-worm or the moth-miller; I don't think that pest bothers at all in any of the localities except in the southern portions of the United States, among bee-keepers who are not possessed of the modern methods of handling bees, but it is somewhat a matter of surprise—was to me, certainly—to know that the moth-miller had not been known to exist here or do any harm whatever, even when the bees were handled by the old-fashioned method, and even when the box-hive with the black bees was used.

Then the question of wintering seems to vary a good deal in the United States. Take it on the Atlantic Coast and up as far as Massachusetts, a single-wall hive will do very well. In northern Minnesota, northern Michigan, in the northern States, and through the Rain-Belt, the cellar-wintering seems to prevail, because it gives better results

and less loss in wintering. But south of the Ohio River the chaff-hive is not used; even south of the lakes in our locality the chaff-hive and cellar-wintering are used about equally.

Then the question of buckwheat cuts considerable figure in the Rain-Belt. Take it in Ohio and most of the Eastern States, there is nothing we expect with any degree of certainty after the basswood flow; there may be a fall flow, but it is so exceptional we don't expect anything, and our intention is, so far as possible, to get done brood-rearing and keep the colony in as near a dormant condition as possible when wintering comes on, and then prepare for wintering.

In the State of New York there are vast fields of buckwheat, and shortly after the honey-flow of basswood and white clover then comes on the buckwheat, and there will be a flow for two or three weeks, or longer, perhaps, putting the bees in the best possible condition for wintering. So that even in the Rain-Belt we have conditions that vary considerably.

As I went over the country studying conditions that exist in various portions of the United States, I have said two or three times that the knowledge one bee-keeper might have in the East would avail him but little if he went to the West; it is true, one who is thoroughly experienced with bees can go West and carry on bee-keeping, as we know they do, and do it successfully, but I have known of cases where Eastern bee-keepers, who were successful, have gone West and failed just because they have gotten into ruts and couldn't possibly change their conditions; they thought they must continue stimulating by rearing brood, and so on, when that procedure would result almost in disaster when carried on to the same extent in the West.

Other conditions, which I noticed were a little peculiar in Arizona, and they are the matter of shade and the matter of entrances: that is, in Arizona, where it is so warm, when the temperature ranges up towards the hundreds, and perhaps more, they have these shades I speak of, and which were illustrated on the screen; they put their hives in such a way that the hives are protected from the sun. It is so very warm there that in Arizona I did not see a single hive out in the apiary exposed to the sun, and it seemed to me such shade as that would be very advantageous here in Colorado, in Central California, in Texas, and many localities where the sun beats down so hotly. The shades which I saw in Arizona were cheaply put up, made of common material, oftentimes over a rude, rough trellis, put up, perhaps, 20 or 30 feet wide, and perhaps 100 feet long, and so arranged that weeds or grass could be piled on top to make a shade, to protect it from the hot rays of the sun. I am convinced that that would be a great advantage in localities where the sun beats down very warmly, and it would better conditions all around.

As I said a moment ago, the greatest difficulty about one bee-keeper migrating to a new country is because he sticks to old ruts. If one wants to know about the conditions in the West he must study them thoroughly, and take the advice of those around him, and not follow the old methods of the old text-books that were prepared and written for bee-keeping as it exists in the Rain-Belt.

Pres. Hutchinson—I think Mr. Root has covered that subject very well, but if there is any one that would like to speak further he is privileged to discuss it.

A. Nelson—In reference to shade, I would like to say one word. In southeastern Utah we have a few colonies of bees. I have some which stand out under a row of trees, facing the east, and the sun shines on those trees, and at 12 o'clock those bees are in the shade the rest of the day. I also have bees right out in the open ground where the sun shines on them all day. The bees that are in the sun all day long are the stoniest colonies, and gather the most honey in our section of the country. The heat is not so strong there that we need to shade them. I don't know whether that would be the case here in Colorado or not, but that is the case in southeastern Utah. The sun seems to have a great effect on brood-rearing in the early spring, and, consequently, we get stronger colonies by having them out in the sunshine all day long.

Dr. Miller—What is the warmest weather you have.

Mr. Nelson—The warmest weather we ever have is 110 degrees.

Dr. Miller—In the shade?

Mr. Nelson—In the shade.

E. S. Lovesy—I am authorized by the Utah bee-keepers, and the Governor of our State, the Chamber of Commerce, and the citizens of Utah, to invite this Association next year to hold the convention on the shores of the great and only Salt Lake. Brethren, if you come along you won't

regret it; you will feel the way we do to-day. A gentleman that just sat down was somewhat undecided whether to come to this convention or not. Yesterday he said to me, "Why, Mr. Lovesy, I wouldn't have missed this convention for ten times the cost of the ticket." We wish to thank heartily the people of Colorado, and the bee-keepers of Colorado, for the generous way in which they have treated us. But, then, it is not to be wondered at; even the people from Illinois, Ohio and New York, when they get out into this mountain air, can't help but feel generous, whole-souled and big-hearted.

We produce some honey out in Utah, and we raise many other things. I brought a few things along here, and I wish the people to take them away. I brought a box weighing 75 pounds, and I had quite a job getting it here, and I don't want to take it back again. I need not boast to you about our honey-flow when I show you an article of that kind [exhibits a bottle of honey.] I have had reports from nearly all over the State, in the last three weeks, and while there are quite a number of places where they have not produced a great deal of honey, we have a number of reports that cover an average of 300 pounds per colony. When we get a flow of that kind, and honey like you see here, we have to have a big flow of honey to do it. You all know that bees always gather the best, and when you get a first-class quart of white honey it is always the best. I was thinking yesterday, when the subject of adulteration was up—and, do you know, it is a fact that we have to adulterate this honey to get rid of it? [Laughter.] A great many people declare up and down that it is sugar and water, when we present them with the very best quart of white alfalfa honey, and they say, "We don't want your sugar-honey." But if we put something dark-colored in, and give it a golden tinge, it is all right.

One gentleman, up in Idaho, wrote me last week, lamenting that he had left Utah and gone up there; he said, "Mr. Lovesy, the nights are too cold here, and we have too much wind, and Idaho will never be the country for a honey-flow that Utah is."

Nature, in her distribution of her treasures, made no mistake; the Saints made no mistake. The Mormons made no mistake, when they settled down in that country. We read and sing about the mountain sides covered over with Saints, milk, honey and wine. I wouldn't vouch for the former, and I am very pleased to say we do not have much of the latter, but when it comes to the milk and honey we have plenty. I remember a little story told when the Mormons were going to Utah. A man told Brigham Young he would give \$100 a piece for every ear of corn he could raise out in that country. "Why," he said, "a digger Indian can't live out there." Brethren, if you come out there next year we will show you what we are doing.

I thank you for your attention, and I hope you will come along and meet us next year, and if you do we will meet you the following season in St. Louis.

Dr. Mason—I had a letter from Mr. Lovesy, who is president of the Utah Bee-keepers' Association, expecting to introduce it at the proper time, but he has got the start of me, so I won't need to read it. I wanted to show him I was not negligent in the matter, and wanted to attend to it.

John Merkley—I want to say amen to what Mr. Lovesy has said. I will say, as one of the Utah bee-keepers, we will try and make you welcome. If you will come and see us I believe we can make it interesting for you.

J. Bolinger—In reference to keeping bees in the sunshine in Colorado, I have kept bees in Morgan County, 88 miles east of Denver, for 12 years, and I have never kept any in the shade except a colony or two, and I don't have my hive-covers painted either, and in 12 years I have never had any melt down. I really prefer to have my bees in the open sunshine, and not in the shade.

I. Williams—If we are going to take up a place of the next meeting I would like to have a word.

Pres. Hutchinson—This convention can't decide where the next place of meeting will be; the Executive Committee fixes the place. We might talk all day and we can't fix that here. When the time comes we will have to depend upon what rates we can get, and other things. All talk as to where the next meeting will be held would be useless.

(Continued next week.)

Honey-Dew in Colorado, the Rocky Mountain Bee Journal says, has never been seen until the present season; but this year, Sept. 19, the bees were fairly crazy over honey-dew on the willows.

Contributed Articles.

Where Shall the Bees Be Wintered?

BY G. M. DOOLITTLE.

QUESTION.—Where shall I winter my bees? Shall I put them in the cellar, wrap them up with tarred paper, or let them be as they are for winter? I have several colonies of bees for the first time in my life, and wish to know where and how it will be best to winter them. I take the American Bee Journal, and the reading of each number is a feast to us.

ANSWER.—As our questioner lives near latitude 41 degrees north, I will say that there is probably no better place for him to winter his bees than in a good, dry cellar; and if he has such a cellar I would advise him to put his bees in it for wintering. While this is not absolutely necessary for safe wintering, and not as necessary in our southern as in our northern localities, yet there will be a greater saving in honey to the apiarist, as well as better chances of successful wintering, even as far south as latitude 37-8 degrees, below, where bees seem to do fully as well when on their summer stands.

If the cellar of the questioner has a variable temperature it will not be as good for the bees as would be one in which the temperature could be kept as nearly at 45 degree as possible; yet if the temperature does not go above 50 degrees, nor go lower than 35, it will winter bees much better than to leave them on the summer stand unprotected. If the cellar is of more variable temperature than this, the bees would doubtless be better off out-of-doors.

To prepare the hives properly for wintering in the cellar they should be carefully carried in on some morning when it is a little cooler outside than the temperature which is required for the bees to fly, and never when the hives are frozen down to the bottom-boards or to the ground, if such can possibly be avoided. When the hives are thus frozen down, the jar and confusion which comes from prying them loose results in great irritation to the bees and causes them to consume so much honey that it often leads to unsuccessful wintering afterwards.

After getting them to the cellar the hives should be set on a bench a foot or more off the cellar bottom, and the hives raised by some means at least two inches off the bottom-board or bench. Failing to do this the hives will not be properly ventilated, and the result will be that the bees may become uneasy from lack of proper ventilation, which will cause them to consume more stores than is necessary to their existence, thereby needlessly using up the honey, and often leading to disease and death. If it is not convenient thus to place them, the hives may be turned bottom side up, if the frames are fastened in the hive, or box-hives are used, and a light, thin fabric of some cotton goods thrown over the mouth of the hive; still, the first is much preferred.

I also think it better that the cellar should be dark, or that part of it in which the bees are wintered. Some claim that bees will winter as well in a light cellar as a dark one, which may possibly be so if all the conditions for successful wintering are present; but as such conditions are usually not all present in many, if any, cellars, it is always best to be on the safe side; hence the advice to have the cellar dark.

If the cellar is lacking in many of the qualities which go to make a good cellar for wintering bees, then it may be best not to try it at all, in which case we must try the next best plan, and one which is quite suited to all latitudes south of 42 to 44 degrees, that is, wintering on the summer stands packed with chaff, leaves, fine hay or straw. While a chaff hive is the preferable thing, yet it is not supposable that all may have such hives, so we must fix the bees the best we can according to our environments.

If you do not have chaff-hives, go to your store and procure dry-goods boxes of suitable size, or otherwise make them, in which the hives can be set, and leave room all around for packing. A space of three or four inches is about the right amount to leave, for experience has proven that this is better than a larger or smaller amount. The bottom-board should be raised that distance above the bottom of the box, and after having packed under it, it should be secured there, and so as to touch the front side of the box

also, as the bees must pass over this to get outside of the box. Half an inch above the bottom-board a thinner board should be secured in the same way to both the hive and the box, immediately above the entrance to the hive, so as to keep the packing material from obstructing the passage of the bees, for this is now to become the entrance to the hive.

Having this fixed, and the hive thoroughly secured to its place, we now put in the packing, pressing it in quite tightly, so that as even a temperature as possible can be maintained inside of the hive, packing the material in as nearly alike on all sides as possible. When the top of the hive is reached, the honey-board, if one is used, should be removed, and two or three thicknesses of cotton cloth spread over the top to keep the packing from rattling down into the hive, and also that, in thus providing for ventilation, a direct draft shall not be allowed through the hive.

Having all fixed as above, fill in the packing to the depth of four inches all over the top of the other packing, as well as over the hive, keeping it as evenly distributed as possible, but allowing it to be more loose and open than at the sides. The box should be tall enough so as to come a few inches above the packing, so that the cover, which is now to be put on, shall not touch it. This last is very important, for, should the packing touch the cover to the box, it will absorb the moisture which condenses on the cover, to such an extent that all will become wet and moldy long before spring.

No matter whether it is chaff-hives, or boxes packed as above, there should always be a few inches of space above the chaff or packing so that the moisture arising from the bees may have a chance to pass off to the outside air with as little condensation as possible. Having your bees thus fixed, or in a good cellar, they will winter much better than if left to take their chances in unprotected hives.

Maeterlinck's "The Life of the Bee"—A Defense.

BY C. P. DADANT.

I CAN NOT pass, without a protest, the mention made by Mr. Albert Gale, in the Australasian Bee-Keeper, quoted in the American Bee Journal on page 547, of Maeterlinck's "The Life of the Bee" as a "comic book on bees." It is true that there are a few very unimportant incorrect statements made in the wonderful work of Maeterlinck. But this writer does not claim infallibility. He does not even claim to write a treatise for practical apiculture. I quote from his first page:

"It is not my intention to write a treatise on apiculture, or on practical bee-keeping. Excellent works of the kind abound in all civilized countries, and it were useless to attempt another. . . . Nor is this book to be a scientific monogram. . . . I wish to speak of the bees very simply, as one speaks of a subject one knows and loves, to those who know it not. . . ."

Maeterlinck has written a book that will remain, because it is a scientific subject put into prose. Any one who has read this book has become interested in the bee, whether he knew anything about bees before or not.

On the way home from the Denver convention, I met a gentleman from Chicago, traveling in the same sleeping-car I did, who was interested in entomology. He knew nothing about bees otherwise than as an entomologist; had dissected some bees, queens and drones, and had made some personal studies of their anatomy. When he found that I was a bee-lover, his first words were, "Have you read the 'Life of the Bee' by Maeterlinck? What a masterpiece it is. What a romance at the same time as a work of information!"

A few days ago, I met a lady teacher who had read the same work. She knew nothing about bees, had never owned a colony, but had become a lover of the bee through the inspiration given by this poetical prose.

We are all human, and therefore all liable to err. Mr. Albert Gale undoubtedly is not an exception to the common rule, but when one of our race writes something which can cause others to pass many pleasant hours, while reading the unfolding, in an attractive manner, of facts that are not in themselves enticing reading, a few slight errors may easily be pardoned, especially if the writer frankly dismisses all claim to technical knowledge.

Maeterlinck's work is beautiful, not "comic" or ludicrous, as the Australasian critic would make us believe. Let

me quote a page among the many, a gem among the gems, his admiration of the energy of the worker-bee:

"Why do they thus renounce sleep, the delights of honey and love the exquisite leisure enjoyed, for instance, by their winged brother, the butterfly? Why will they not live as he lives? It is not hunger that urges them on. Two or three flowers suffice for their nourishment, and in one hour they will visit two or three hundred, to collect a treasure whose sweetness they never will taste. Why all this toil and distress, and whence comes this mighty assurance? Is it so certain, then, that the new generation whereunto you offer your lives will merit the sacrifice; will be more beautiful, happier, will do something you have not done? Your aim is clear to us, clearer than our own; you desire to live, as long as the world itself, in those that come after; but what can the aim be of this great aim, what the mission of this existence eternally renewed?"

Perhaps Mr. Gale cannot see any literary beauty in such passages. Perhaps, when he reads of bees, he expects only to be told which is the best hive or the best manner of harvesting surplus. Perhaps, also, he has not read Maeterlinck very carefully, for he misquotes him. For instance, he quotes him as saying, "The nurse-bees feed nine or ten thousand eggs, the eighteen thousand larvae and the thirty-six thousand nymphs." Opening the book at the incriminated passage I read: "For this is the royal domain of the brood-cells, set apart for the queen and her acolytes; about 10,000 cells wherein the eggs repose, 15,000 to 16,000 chambers tenanted by larvae, 40,000 dwellings inhabited by white nymphs to whom thousands of nurses minister."

I read Maeterlinck in the original French when it was first published; I have since procured the English translation, and I have this to say to the readers of the American Bee Journal: If you wish a text-book on bee-culture, do not buy Maeterlinck's. If you wish a practical work giving cuts and descriptions of bee implements, you will find nothing of the kind in his "Life of the Bee."

Neither will you find in it anything ludicrous or comical. But if you wish to pass a few pleasant hours; if you can enjoy a little poetical prose, on a subject which is familiar to you, send for "The Life of the Bee." Any person, whether bee-keeper, banker, laborer, farmer, or school teacher, even if he were unable to know a bee from a hornet, can profitably and enjoyably read this book.

Hancock Co., Ill.

Our Bee-Keeping Sisters

Conducted by EMMA M. WILSON.

Suggestions for the Cool Months.

After the honey is sold, and the bees ready for winter, there naturally comes a little lull, and we have a chance to draw a long breath; but the winter months are not to be idle ones so far as the bees' interests are concerned. This is our chance to get ready for next year.

It is well to begin by taking an inventory of what we are likely to need—how many new hives, frames, bottom-boards, covers, sections, etc. In making an estimate, perhaps it is well to err on the side of having too much rather than too little.

In the very busy season we have no time for this kind of work, at least we don't want to take any time for it; we want this work out of the way while we have the leisure for it.

I know it is often said that a woman can not drive a nail, but bee-women know better than that, for many of them do their own carpenter work without any assistance, and do it well, too.

Besides making new, there is always some repairing of the stock on hand to be done. Now is the time to do it. There is boiled-down comfort in having everything ready for use.

CLEANING T TINS.

Do you use the T super? If so, have you your T tins all cleaned ready for next year? Don't forget that they can be cleaned with concentrated lye, so that they will look almost as good as new.

OVERHAUL THE SMOKER.

Give your smoker a good overhauling, and put it away in good shape for work when needed.

LATE FEEDING OF BEES.

Are you sure that your bees have plenty of stores for the winter, and that you have done everything you possibly can to insure their comfort and safety during their long nap? If you are so unfortunate as to have to feed your bees at this late hour, don't try to feed syrup, it is too late for that. If you do not have frames of honey to give them, then feed them candy.

READING BEE-LITERATURE IN WINTER.

How much of your time are you going to give to bee-literature this winter? Have you made any plans as to what you are going to read? Remember, if you are going to be a tip-top bee-keeper you must put your best effort into it. Get all the knowledge in regard to bees that you possibly can, and be ready to put it into practice when the right time comes.

"FAITHFULNESS" THE KEY-NOTE.

Don't get discouraged because you can't learn all about bees in a day. Possess your soul in patience, and keep pegging away. There is an old proverb that says, "Keeping everlastingly at it is sure to bring success." Be that as it may, be sure that *faithfulness* is the key-note to success in every department of work.

SAVING BITS OF WAX, COMB, ETC.

Now is a good time to get all the bits of wax and pieces of old comb, etc., together, and extract the wax from them. That is, unless you have been so energetic that you have it done already. If you have carefully saved all stray bits it may be a surprise to you to see the nice cake of golden wax you will have as the result of your labor.

Preparation for Whitening the Skin.

A very nice preparation for whitening the skin, is made of oatmeal, honey and lemon-juice. Mix oatmeal and honey together until you have a thick paste, then add enough lemon-juice to make the paste of the right consistency to spread on easily.

Advantages of a Deep Bottom-Board.

Are you using a deep or a shallow bottom-board? There are many advantages in having a deep bottom-board. Especially is this true in regard to wintering. It allows the bees to cluster below the frames; and what bee-keeper does not enjoy peeping into the hives and seeing a large cluster of contented bees hanging in plain sight, apparently saying all is well.

It gives them plenty of air, and there is no danger of the entrance being clogged with dead bees as with a shallow bottom-board. It is an easy matter to clean out all dead bees if you wish, the space (2 inches) being ample to allow their being raked out without disturbing the bees, unless they are clustered below the frames, in which case there is seldom any cleaning out necessary, for when you find a cluster so large as to extend down through the 2-inch space and rest on the bottom-board, you will generally—perhaps always—find that the bees themselves keep their floor swept up clean.

During the honey harvest 2 inches is too much space to allow under the brood-frames, for the bees will build down and fill it solid with honey and brood—a thing that is not desirable.

The bottom-board can be reversed, but that means a good deal of heavy lifting—a thing to be avoided as much as possible—so a false bottom-board can be slipped in under the brood-combs, leaving just the right space. It is taken out in the fall as soon as the bees quit storing, and left out until near the time for the next harvest.

Our Wood Binder (or Holder) is made to take all the copies of the American Bee Journal for a year. It is sent by mail for 20 cents. Full directions accompany. The Bee Journals can be inserted as soon as they are received, and thus preserved for future reference. Upon receipt of \$1.00 for your Bee Journal subscription a *full year in advance*, we will mail you a Wood Binder free—if you will mention it.

Questions and Answers.

CONDUCTED BY

DR. C. C. MILLER, Marengo, Ill.

[The Questions may be mailed to the Bee Journal office, or to Dr. Miller direct, when he will answer them here. Please do not ask the Doctor to send answers by mail.—EDITOR.]

Foul Brood.

1. How can one say for certain this is foul brood or chilled brood?
2. Is there a certain remedy for foul brood?
3. Can it be cured or not?
4. How do the bees carry foul brood from one hive to another? Is it in the honey, or is it transferred to other hives?
5. What would you advise one to do if he had 30 or more colonies that he was afraid had foul brood, and they were all the bees he had? I have 12 colonies that have had something the matter with them the past three years. I am afraid it is foul brood. Here it appears about the latter part of May and disappears during the latter part of August. Before and after that time the brood looks clean and nice, but when that appears it looks just as I see foul brood explained. The bees do not do so well as they would if that was not the case. What would you do in a case like this?

WISCONSIN.

ANSWERS.—1. The special feature of foul brood that distinguishes it from chilled brood is the odor and ropiness.

2 and 3. The McEvoy treatment has been effectual in a great many cases.

4. It is usually carried in the honey. A colony badly affected with foul brood is not able to protect itself against the robbing of other colonies, and the microbes are carried with the honey.

5. Make a business of informing yourself fully upon the whole subject. Study carefully all that is said in your text-book, and get Howard's foul-brood pamphlet. That will be much better than the information to be had in this department, for our good editor would be likely to shut down on me if I should attempt to take all the space necessary for subjects already treated in the text-books. It is possible your bees have foul brood in a mild form; and yet one would think greater headway would be made in three years.

Perhaps Bee-Paralysis—Wintering Bees—Eating Honey.

I have one colony of bees that I am puzzled with. In August and September, 1901, the bees began to die off very fast; even later on the bees, when in front of the hive dead, were swollen up and full, as if from confinement. I did not open the hive to see what was going on, and more than likely I could not have seen more than I could see outside. I thought to unite what would not die, but neglected to do it. When I came across that colony last spring I found a young queen, brood, and a goodly number of bees (strong), making the best showing of all, and they also proved the best. Now that same colony is dying off the same way. The reason I mention the young queen is because I always clip my old queens, and this was not clipped. This colony did not swarm in 1901 or 1902. It always goes with the rest of the best ones. Why is it that only the bees out of the one hive die off so early, and not any of the others that do but little better? This is what puzzles me. The colony is located at the same place. I do not meddle with bees any more than is necessary.

2. I winter my bees on the summer stands, where the sun shines on them. I have a rim under the hives 2¼ inches high, open the whole width of the hives, 16 inches, with wire screen 3 meshes to the inch. Is that too much opening for out-door wintering, and no packing? Bees have wintered best for me without protection; I only change the size of the entrance.

3. Don't you think every practical bee-keeper should pay his or her subscription to bee-papers in advance? Yes, sir; I will pay in advance, even though the subscriptions go up to \$5.00.

4. I eat honey on bread, pie and cake. I am often laughed at by my wife. What do you think about it? She

is good about cleaning sections, and hiving swarms when I am away.

PENNSYLVANIA.

ANSWERS.—1. I don't know what is the trouble. The swelling and dying looks like paralysis. In that case you ought to notice the bees standing about with their wings trembling, and with a more or less shiny appearance because of the disappearance of their plumage.

2. That seems pretty open, but the best proof of the pudding is the eating, and if you have had good success in any particular way it is not a bad plan to continue it.

3. You are quite right about the importance of subscribing for a bee-paper. I can hardly be called a beginner, and yet I dare not skip anything written by the rawest beginner, for there is always a possibility that he has struck upon something that I have not yet learned. It is no doubt true, also, that the larger the list of subscribers the better able the publisher is to make improvements that will be of value to the readers.

4. Your wife is quite right not to eat honey with pie and cake, at least not much of it, for the cake and pie spoil the honey; and people are learning that cake and pie are not nearly so good for the health as bread and honey. Still, it's a good deal a matter of taste how one eats honey. I drink more than I eat of it. First thing every morning I drink a bowl of hot water sweetened to taste with extracted honey. I think my folks find me less disagreeable to live with on account of the honey. Editor York eats an amount of honey that is surprising for one of his size.—[Prov. 24-13 says: "Eat thou honey because it is good." That's the reason we eat lots of it. It's good.—EDITOR.]

Young Queen Swarming—Shipping Bees—Bitter Honey

1. I have just read what "New York" says, on page 650, about his young queen swarming this year. During swarming-time, last spring, I took a frame of young brood and put it in an empty hive, moved a strong colony and put the hive with the young brood in place of the strong colony. They sealed up 8 or 10 young queens at once. When the young queens began to hatch they cast a nice swarm. In September this same queen led another swarm out. So you see this one was reared this year, and led out two swarms.

2. Did you ever know bees to swarm 3 months after the usual time to quit? They did this here this fall. The reason was, because there was a honey-flow of bitterweed.

3. In shipping bees you put the end of the frames toward the engine, don't you?

4. A keeps B's bees for half the honey and swarms. A decides to move, and take B's bees with him. Who ought to pay the freight, A, or B, or both?

5. In shipping bees in very cold weather would it do just to cover with wire-cloth? Would it not be too cold? If so, how would you fix them?

6. I am thinking of taking my bees to Texas. They are all in good hives, with nice combs. I could not sell them here for very much. Do you think it will pay me to take them.

7. When would be the best time to ship them, about Dec. 1, or in February?

8. I use a plain plank for a bottom-board. Would it do to nail the top and bottom boards on and close the entrance with wire-cloth, if I ship them in the winter?

9. I send you a sample of bitter honey. How do you think the bees will winter on it? We have never had to winter bees on it altogether before.

ALABAMA.

ANSWERS.—1. I am sorry there are so many exceptions to the rule, but glad to learn the truth about it. But I would not call the first swarm in your case an exception. It is just what would be expected as a general rule, that when several queens are reared in a colony, if conditions are favorable, a swarm will issue with the first virgin that emerges. Although it may not always have been explicitly stated so, the rule is that no *laying* queen will issue with a swarm if a queen has been reared in a colony during the same year. Your second case of swarming was an exception to this rule, but the first was not.

2. Yes, in some places this is more or less common. It is much the same as another season coming on, and such swarms are often called "buckwheat swarms," and a swarm of the same year may send out a swarm, called a virgin swarm. This makes your second case of swarming, previously mentioned, less of an exception than it otherwise would be.

3. Yes, the frames running parallel with the track on a railroad, and crosswise in a road wagon.

4. I suppose that moving was not contemplated in the first place, and being a matter entirely for A's benefit he should foot the bill.

5. I don't believe it would be too cold, yet if the entrances are as large as they ought to be for the best results, (mine are two inches deep), closing the entrances with wire-cloth would be enough in very cold weather.

6. As you have probably had little or no experience in shipping, very likely you might better sell at a low price and then buy again.

7. Likely February would be better than December. And yet, if you were sure of a flight immediately or shortly after the moving, December might be the better time.

8. If I understand you, the question is whether it would do to have one entire end of the hive open except the covering of wire. I think it would be all right.

9. What do I think of it? I think it's bitter, but not so bitter as I expected. I should have very little anxiety about bees wintering on it.

* The Afterthought. *

The "Old Reliable" seen through New and Unreliable Glasses.
By E. E. HASTY, Sta. B Rural, Toledo, O.

LAWS ON FOUL BROOD.

That is a good idea of the Colorado law concerning foul brood, to make the treatment conform to what is required by the State Association. Excellent way to keep a law up-to-date without the sad bother of getting additional legislation. In Wisconsin the treatment seems to be left for the inspector to direct. In some respects this would be still better, but the man is more liable to cherish dangerous whims about a dangerous disease than a State association would be. Wisconsin seems not to give the inspector power to destroy bees at first visit. Better not tie the inspector's hands that way. Page 615.

PAY OF FOUL-BROOD INSPECTORS.

Setting the county commissioners to fix the pay of foul-brood inspectors is a minor weak point in the Utah law—or would be for most of our States. They'd fix it very low, hoping nobody would serve. The commissioners are usually good men, but it would be exceptional for them to be anything else than densely ignorant about bees. They would naturally view inspection as a public expense little better than foolishness; and a campaign of education would have to be carried on, which would be (to somebody) expensive of time and patience. Better to obviate this by having the law itself fix the compensation. Page 616.

LAYING WORKERS AND DEAD BROOD.

Quite possibly right, is the first answer of Dr. Miller on page 617; but there is another thing to be thought of. If I am right, bees that have had laying workers for a long time do sometimes let their combs get filthy with dead brood, without their being any special disease in the hive. Merely discouraged and fitful in their efforts; now starting a considerable brood, now letting it all starve on their hands. The final kick-the-bucket of starvation may arrive after sealing, I think, and apparently often while in the very act of emerging from the cell. Long semi-starvation, either in the last stage of growth or a previous one, may suffice to cause this.

PROPOLIS ON THE FINGERS.

And so our British cousins want to handle frames without getting propolis on their fingers! I laugh. The desire is laudable enough, surely. But I suspect that the practical way to keep propolis off the fingers is to follow some other vocation. Propolis to the bee-man is like tar to the seaman on a sailing vessel. He has to get used to it, and the sooner the better. Page 628.

WINTERING OATS ON BEES.

We can't winter bees on oats; but it seems we can winter oats on the bees, with profit to the latter and no serious harm to the former. But, then, healthy bees with first-rate

stores hold a high record for wintering "any old way;" but with bad stores all the oats in Scotland can't save 'em. Page 629.

THE KNIFE IN QUEEN-CLIPPING.

"Ye Editor" left out the Hamlet from his editorial Hamlet on clipping the queen. The number of queen's legs which the scissors bereave of the foot, is about the most important consideration in the business; and to prevent needless maiming is about the weightiest reason for using the knife. Page 643.

FALL UNITING OF BEES.

To Mr. Doolittle's excellent and oft-repeated directions about fall uniting, I would add this: In a large apiary, with much uniting to be done, it is sometimes easy to use a hive foreign to all the colonies, and a full set of foreign combs of honey. Then run the bees in higglety pigglety, and their condition (from a bee's point of view) is that both nationality and home are completely gone, and fighting out of the question, because there seems to be absolutely nothing left to fight for—every bee a stranger in a strange land. Page 646.

The Buffalo Convention Report is issued in pamphlet form, size 6x8½ inches, 80 pages and cover. Besides a full report of the proceedings of the 32d convention of the National Bee-Keepers' Association, held in Buffalo, N. Y., Sept. 10, 11 and 12, 1901, it contains fine half-tone portraits of all the officers and directors of the Association; also the Constitution, a list of the membership up to the end of 1901, and the two latest bee-songs—"The Hum of the Bees in the Apple-Tree Bloom" and "Buckwheat Cakes and Honey." We believe it is the finest ever gotten out for the Association. Of course, all members of the Association receive a copy free, but there are thousands of our readers who are not yet members, but who should have this valuable Report. Better send for a copy, if you have not yet received one. Price, postpaid, 25 cents, or with the American Bee Journal one year—both for \$1.10. Send all orders to the office of the American Bee Journal. Better order soon, before all are gone.

Honey as a Health-Food is the name of a 16-page leaflet (3½x6 inches) which is designed to help increase the demand and sale of honey. The first part is devoted to a consideration of "Honey as Food," written by Dr. C. C. Miller. The last part contains "Honey-Cooking Recipes" and "Remedies Using Honey." It should be widely circulated by every one who has honey for sale. It is almost certain to make good customers for honey. We know, for we are using it ourselves.

PRICES, prepaid—Sample for 2 cts.; 10 for 10 cts.; 25 for 20 cts.; 50 for 35 cts.; 100 for 60 cts.; 250 for \$1.25; 500 for \$2.25; 1000 for \$4.00. If you wish your business card printed at the bottom of the front page, add 25 cts. to your order.

Why Not Help a Little—both your neighbor bee-keepers and the old American Bee Journal—by sending to us the names and addresses of such as you may know do not now get this journal? We will be glad to send them sample copies, so that they may become acquainted with the paper, and subscribe for it, thus putting themselves in the line of success with bees. Perhaps you can get them to subscribe, send in their dollars, and secure for your trouble some of the premiums we are constantly offering as rewards for such effort.

"The Hum of the Bees in the Apple-Tree Bloom" is the name of the finest bee-keeper's song—words by Hon. Eugene Secor and music by Dr. C. C. Miller. This is thought by some to be the best bee-song yet written by Mr. Secor and Dr. Miller. It is, indeed, a "hummer." We can furnish a single copy of it postpaid, for 10 cents, or 3 copies for 25 cents. Or, we will mail a half-dozen copies of it for sending us one new yearly subscription to the American Bee Journal at \$1.00.

The Premiums offered this week are well worth working for. Look at them.

My Neighbors Got No Honey.

My Golden Adel Colony gave me 125 pounds of honey; my others none, nor did my neighbors get any.—MRS. C. A. BALL, Vernon Center, N. Y.

The Adel queens are beautiful. One colony of them stored 110 finished sections.—W. B. Low, Cohoes, N. Y.

My Adel queen is 3 years old; grows more prolific each year. It rained all summer, but the Adel colony gave me two good swarms and 25 pounds of honey.—HUGH ORR, Port Huron, Ont., Canada.

My new book on Queen-Rearing will tell how such queens are reared. Work will contain 50 pages and 25 illustrations. Prospectus free.

What Yon Yonson Thinks

Doodle went to Yanka town,
He take along some hunny,
De price vas hi, he don't vas ery;
Now, he havven plenty hunny.

But he don't vas feel som very gud,
He know it don't vas rito,
For him to git das benefit
Ven dom yuyun as fite.

He tank himself vat he shal du,
He sen New York von dollar;
An now he feel so good he laff
A youst make grate big holler.

Ay vont to tell das Dr Miller if he don't vas trash his veet yet he better git some Svede mans to put good top on das straw stack, coz it bean so much raining. Ay tank ve bean plenty hungry for das nice straw das vinter. Ay tank he goan to gif us som of his finesta wheet in das merican bee-paper tu.

Ven dom bee-mans had big campmeetings in Denver, ay tank dom bean kin. of cool, an mebbly dom bean kine of discouragement. Mebbly it bean some gud ting if Yon Yonson poke up das fire little, and if Dr. Miller vill yust trow on big arm full of straw ay tank by an by ve goan to have purty big blazing, an den ve can cook dom fellers goos vat bean sell das slop hunnys in Denver.

Ven dom bean to big meetings in Denver, Dr Miller he clime up on big hi fens, an he look an he see ting vat dom call Propaganda, vat make dom peoples ete more hunnys. My ying, ay tank dat bean som gud ting. Ay vont to git tre or four of dem tings, coz ay expect to got lots of hunny nex year. Say, Mr New York, do you tank tre or four of das Propagandas vill fite if ay keep dom in da same field? Dan tank dom bean dangerous, an dom get loos? Ay tank you ought to hav lots ma dem tings in Chicago.

Now, da telephone vat ay got in de big room on da wall, he bean da best ting to sell hunny vat ay ever seen, an ay goan to tell you bout it after vile.

Now, ay bean sen for som clover quvens, an dom vas call right, but ay musta have some of das Propaganda tu; but if dom bean bad to fite ay tank ve better turn dem in da same field ma dem slop hunny mans, den de voel vill fly, you bet, an mebbly dom bean plenty sorry to put corn molasses in glas tumblers and put little bees comb in it an call it hunny.

Now, ven it bean som big vedding in das nabrehood ay yenerly hav sens nuf to stay home, if ay don't bean invited. Ven dom vant Yon Yonson to com dom sen awful nice card vat say some tings lak das:

"Ve be so happy to see Yon Yonson an vife to big vedding, an be shur an bring awful nice present." Coz den ve know ve bean in it, an ve goan to be dar rain or shine.

Now, don't you tank it bean som gud ting to sen every body big inviting to yoin demselves in to das yunyuns? Print nice card; on von side say vat das yunyuns bean for, vat it bean alreddy dun, and vat dom goan to do, an vat dom vont to do, an dat ve bean glad to hav dom yoin vid us so ve bean more able to du gud to us an dom too. Den on odder side of card say som dings lak das:

"Pleas look in close an you vill fine in das letter von dollar, for vich pleas yoin me into das N. B.-K. A. quvick."

An den sen dem cards to all dom mans vat make bee-papers, an dom kin sen ma deirs paper to all deirs subscribers. Don't you tank dat bean some gud ting? It bean so

"Bees in Colorado"

I still have several hundred copies of the souvenir with the above title. The bee-papers and a good many people without visible axes to grind have said it is a valuable and attractive thing. If you should like to have a copy, send me a silver dime or 5 two-cent stamps, and I will mail you a copy.

"BEES IN COLORADO" is the title of a 48-page and cover pamphlet gotten up to boom the Denver convention. Its author is D. W. Working, the alert secretary of the Colorado State Bee-Keepers' Association. It is beautifully illustrated, and printed on enameled paper. It is a credit to Mr. Working, and will be a great help in acquainting those outside of Colorado with the bee and honey characteristics and opportunities of that State.—American Bee Journal.

GENERAL ITEMS

Plenty of Stores for Winter.

I had 30 colonies of bees with queens in the spring. I averaged 16 gallons of extracted honey per colony. By dividing I have increased to 49 colonies. All have plenty of stores for winter, as I set aside honey gathered in August, and extracted the honey gathered later.

B. F. BARRUS.

Tooele Co., Utah, Nov. 4.

Wintering Bees in the Cellar.

As it is near the time when the bees in our cold climate will need to be fixed up in some suitable place for the winter, I will give you a little of my experience in the care of bees at this season of the year. I hope it will be of some use to some other novice or amateur.

In the fall of 1898 I bought 29 colonies, and

WHEN ACCIDENTS HAPPEN

and you never know just when that will be—it's very convenient to have at hand a good, reliable, dependable remedy, like

Watkins' Vegetable Anodyne Liniment.

A burn, a bruise, a frost-bite, a cut or a sprain, an attack of rheumatism, cholera morbus, cramps, diarrhoea, flux, sore throat, mumps or diphtheria do not admit of expediting. You want something to help you, and you want it right away. Why not, then, keep on hand a really reliable remedy, so as to have it by you when you need it?

Watkins' Liniment, for internal and external use, for man and beast, has been for 40 years the best standard household remedy known to medical science. It has peculiar penetrating qualities, and gets at the root of the trouble as does no other liniment.

Watkins' Vegetable Anodyne Liniment is sold by our traveling salesmen through the country. If our agent has not called on you, send us your name and address at once, and we will see that you are promptly supplied. Price \$1.00 and your money back if it isn't the best liniment you ever used.

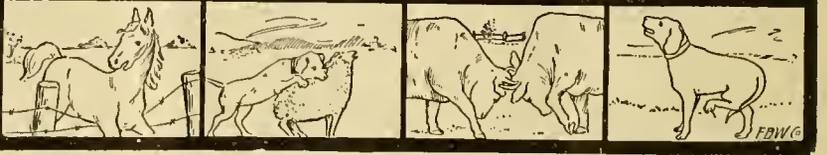

Watkins' Home Doctor and Cook Book free.

Gives home treatment for all common diseases of man and beast; contains numbers of valuable recipes, weather forecasts and an immense amount of interesting and useful information, for home and farm. Something for every member of the family, old or young. Send for copy free.

THE GREAT AND GROWING SEMI-MONTHLY

AGRICULTURIST

Minneapolis, Minnesota

Chicago, Illinois

OUR FRIENDS ON THE FARM

We want 100,000 circulation for **The Northwestern Agriculturist** and will pay you to aid us in getting it before **New Years, 1903**. That means 25,000 new subscriptions. Here is our offer (not good after January 1, 1903): **Send us 15 cents** in silver and promise to sign, address and mail three (3) postal cards for us, to farmers who, you know, ought to take such a standard farm paper, and we will send you **The Northwestern Agriculturist** a whole year. **Or send us 25 cents** in silver and agree to address five (5) such postal cards to farmers and we will send you **The Northwestern Agriculturist** for two years. Your subscription will begin as soon as you send us the names; we shall not wait until you have mailed the postal cards to your friends. We will furnish you the postal cards free by next mail after we receive your subscription. The cards will contain ready-printed message which you can sign as your personal recommendation to your friends, urging them to subscribe. That is all there is to our plan, but the secret is that we know that with your neighbor or friend, a recommendation from you, a farmer, to take **The Northwestern**

Agriculturist will usually result in our receiving the subscription. We want you first to read **The Northwestern Agriculturist** and be able sincerely to sign that recommendation. We shall authorize you to tell your friends that if they will enclose your postal card with their subscription before January 31, 1903, we will accept 30 cents silver and the postal card as full pay (regular price 50 cents) for the year's subscription, or we will accept 50 cents and one postal card as full pay (regular price \$1.00) for two years' subscription. Your postal card, therefore, will be worth to your friends either 20 cents or 50 cents, according to their choice. Only one such card, however, will be accepted from any one subscriber, and only when accompanied with the cash. We simply want you to aid us with your friendly influence to introduce the paper to your friends. If then they do not see fit to subscribe we will thank you just the same, and by doing us this favor you will get your own subscription for 1903 for fifteen (15) cents instead of fifty (50) cents, the regular price.

PRESENTS FOR YOU

If one such postal card signed by you comes to us with your friend's subscription before January 31st, 1903, we will send you a nice present. If two of your cards bring us resulting subscriptions we will send you a still costlier present, and if all of your postal cards bring us returns we will remember you proportionately. All of these presents will be mailed between February 1st and February 6th, 1903. This will be a special inducement for you to be careful to select persons who really ought to subscribe and then, if convenient, you can supplement the regular cards with any special personal urging you see fit, so that you will get your present and we will get the subscriptions. We have additional inducements for you if you can get more than the above mentioned number of subscribers for us. When you send in your 15 or 25 cents for your own subscription, we will write you details.

5000 MEN AND WOMEN ARE WANTED to represent **The Northwestern Agriculturist** in the Central States. We start you in business, pay liberally for work, protect your territory. Pleading, dignified and agreeable employment. Write us for particulars.

OUR EDITORIAL STAFF is made up of practical experienced Specialists in each department, who have actually demonstrated their knowledge and fitness for the position by having made a success in that line of work on their own farms. We employ no mere theorists, but only men and women of recognized ability.

WE GUARANTEE the integrity and honesty of all advertisements admitted to our columns. This means that if ever a subscriber is cheated by one of our advertisers we will pay the loss and then prosecute the advertiser. This paper is a vigorous defender of subscribers' interests. We have no mercy on fakes or frauds.

Northwestern Agriculturist, Room K19, Security Building, Chicago, Illinois

Please mention Bee Journal when writing

fixed a place in the cellar for them, by building a scaffold about five feet high under a part of the house, where there would be fire kept during the winter.

I placed the 29 colonies on this scaffold about the middle of November, with plenty of honey. The hives were dry, and I thought I had them fixed in good shape for wintering, as there would be a fire about three feet above them, and the cellar was arranged so I could ventilate it when I wished to.

The bees were quite noisy the latter part of the winter, and I took them out in March and found 15 colonies were dead. I saw why it was. I had left on the honey-board, which held the dampness in the hives, and the combs had molded.

I bought 11 colonies more and started in the spring of 1899 with 25 colonies; they increased during the summer by natural swarming to 40. I thought I would try the cellar again for wintering, and fixed a room in one corner, 10 by 12 feet, by putting up a board partition. This room was under a part of the house where there was no fire kept, and as I wanted to keep the room dark, I had no windows in it. I placed some sticks on the cellar bottom, about two inches thick, to set the hives on. I took off the honey-boards and put on supers with a piece of burlap in the bottoms, and then filled them with planer-shavings and dry corn cobs, about two-thirds of the former and one-third of the latter.

I put the bees into the cellar about the middle of November, one hive above the other, four tiers deep, with an arrangement for ventilating. They were quiet during the winter, and I took them out the first part of April, 1900—40 colonies, all of which were in fine condition. Since then I have kept my bees in the same room during the winter, and have packed them in the same way, with less than 2 percent loss. I lost only one colony that had honey enough to winter. They were in a box-hive, and I think had no queen. The others were late swarms that had but very little honey. I fed them in October by giving them supers partly filled with comb honey, but I did not uncup it, and when I packed them for winter, in November, I found they had not carried it below. Since then, when I have fed honey in the combs, I have uncapped it, and they lose no time in taking care of it.

My experience leads me to believe that if a cellar is kept as it should be, without decaying fruit or vegetables, it would not be necessary to ventilate it for bees. Keep them in a dark room, where they will not be disturbed, packed with something that will absorb the moisture they generate, and they will be all right. I think that dry, rotten wood in place of corn-cobs would be just as good, and may be better.

GEORGE BROWN.

Chickasaw Co., Iowa, Nov. 3.

Among the Oldest.

I am, I think, among the oldest apiarists. For 60 years I have never been without some colonies of bees, and now have only 73. The past season was a very bad one. C. ERB.

Clarke Co., Va., Nov. 8.

A Far Western Apiary.

This (Wahkiakum) county is about 25 miles from Cape Hancock, the most westerly point in the United States, and I think the most rainy, too. So you will know that it is not a good country for bee-keeping, yet I have 41 colonies and get some honey. A good many keep a few colonies of bees, but in a slovenly way. O. R. RICE.

Wahkiakum Co., Wash., Nov. 1.

A Peculiar Season.

This has been a very peculiar season in this locality. Bees have not done very much in the way of storing surplus honey. While there was plenty of white clover at the beginning of the season it was too wet most of the time for the bees to work. Some colonies

"What Happened to Ted"

BY ISABELLE HORTON.

This is a true story of the poor and unfortunate in city life. Miss Horton, the author, is a deaconess whose experiences among the city poverty stricken are both interesting and sad. This particular short story—60 pages, 5x6 3/4 inches, bound in paper cover—gives somewhat of an insight into a little of the hard lot of the poor. Price, postpaid, only 10 cents (stamps or silver.) Address,

ISABELLE HORTON,

227 EAST OHIO STREET, CHICAGO, ILL.

Please mention Bee Journal when writing Advertisers.

27 cents Cash paid for Beeswax.

This is a good time to send in your Beeswax. We are paying 27 cents a pound—CASH—for best yellow.

low, upon its receipt, or 29 cents in trade. Impure wax not taken at any price.

1-lb Keystone ... Honey-Jars

These are clear flint glass jars holding just one pound, and the shape of a keystone. They are $7\frac{1}{8}$ inches high, and very pretty when filled with honey. The corks can be sunk a trifle below the top, and then fill in with beeswax, sealingwax or paraffin. We can furnish them in single gross lots, with corks, f.o.b. Chicago, at \$3.50; two gross, \$3.25 per gross; or five or more gross, at \$3.00 a gross. These are the cheapest glass one-pound jars we know anything about. We have only about 20 gross of them left. So speak quick if you want them. Address,

GEORGE W. YORK & CO.

144 & 146 Erie St., - CHICAGO, ILL.

THANKSGIVING DAY EXCURSIONS

at rate of a fare and a third on all trains of the Nickel Plate Road, on Nov. 26 and 27, to points within 150 miles, and good returning to and including Nov. 28. Chicago Depot, Grand Central Station, Harrison St. and Fifth Ave. City Ticket Office, 111 Adams St. 'Phone Central 2057. 59-45A3t

stored about 30 pounds of comb honey, while others did not store any. I have had to feed several colonies to get them in shape for winter; but most of them seem to be in good condition.

E. N. EVERSON.

Jefferson Co., Ohio, Nov. 10.

A Good Season.

The honey season this year was a very good one. I got about three tons of comb honey from 100 colonies, and all are in good shape for winter.

HARRY H. BUCKMAN.

Bucks Co., Pa., Nov. 10.

Gathering Pollen Late.

I have not seen pollen come in as fast, and as much of it, as to-day, any time during the past summer. I cannot say where the gathering comes from. My bees have not done well this season.

C. J. ANDERSON.

Cook Co., Ill., Nov. 12.

When to Make Shaken Swarms.

Some are of the opinion that a colony should not be brushed or shaken before queen-cells are started. In the small Langstroth hives the starting of queen-cells will be a sign that the size of the hive (too small for the development of the colony) has caused the swarming impulse. My large hives give an unlimited space for development, and, consequently, in most years, no queen-cells are started at all; but the colonies are strong when the honey-flow commences. If I should wait for starting queen-cells I would not get any brushed swarms nor comb honey.—L. STACHELHAUSEN, in Gleanings in Bee-Culture.

Color of Italian Queens and Drones.

Replying to the question, "What is a pure Italian queen?" the editor of the Australasian Bee-Keeper replies in part:

The purity of a queen can not be told from the drones. Drones vary in color from all black to nearly all yellow, and yet the queen is pure. Drones from Italy-reared queens are mostly black, while American-bred queens produce drones with more yellow. Queens also vary in color from black to yellow. I have bred queens quite black from a queen imported from Italy, whose bees were undoubtedly pure, and the progeny of these black queens as nice, even-colored 3-banded bees as could be obtained. I am aware customers, especially novices, are frequently disappointed when they receive a dark queen from a breeder, hence the tendency to breed queens from light-colored mothers, though better honey-gatherers may be produced if a darker queen-mother were selected.

Phacelia.

This is the honey and forage plant that has so much said in its praise in the German bee-journals. It seems to be little known in this country, although it was introduced from this country into Europe. A letter from assistant agrostologist at Washington, Prof. Ball says:

So far as known there is no species of *Phacelia* which is known to have any forage value in this country, nor have I found a record of any species of this genus being used in Europe.

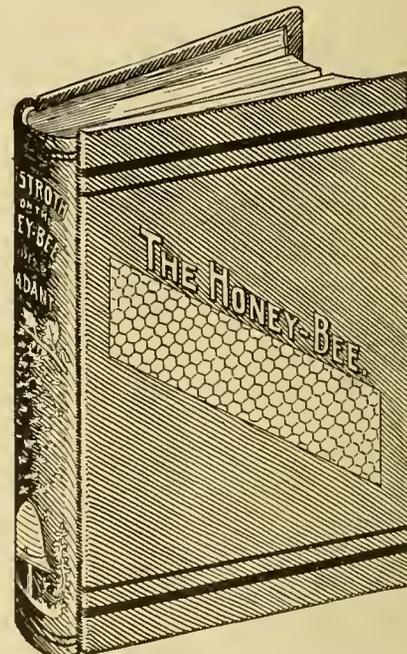

The following in Gleanings in Bee-Culture from Mr. Thos. Wm. Cowan is more encouraging:

I have just returned from British Columbia, and in looking through Gleanings I see that you have had some correspondence about

Langstroth on... The Honey-Bee

Revised by Dadant—1900 Edition.

This is one of the standard books on bee-culture, and ought to be in the library of every bee-keeper. It is bound substantially in cloth, and contains over 500 pages, being revised by those large, practical bee-keepers, so well-known to all the readers of the Ameri-

can Bee Journal—Chas. Dadant & Son. Each subject is clearly and thoroly explained, so that by following the instructions of this book one cannot fail to be wonderfully helped on the way to success with bees.

The book we mail for \$1.25, or club it with the American Bee Journal for one year—both for \$1.75; or, we will mail it as a premium for sending us THREE NEW subscribers to the Bee Journal for one year, with \$3.00.

This is a splendid chance to get a grand bee-book for a very little money or work.

phacelia. I see there is no reply to Dr. Miller's request for information as to the sort of phacelia obtained from California, and grown in Europe as a forage and nectar yielding plants nor has any one from California given any information in answer to your appeal on page 675.

I know thirteen species of phacelia in Western-Middle California, and there are probably several more in other parts of the State, as the genus comprises about fifty species of mostly hardy annual and perennial herbs. Several species are visited by bees; but the one grown in Europe, *phacelia tanacetifolia*, is literally covered with bees from morn till night. This species was introduced into Europe from California in 1832, and is called *tanacetifolia* (tansy-leaved) from the resemblance of its leaves to those of tansy. It is an annual with bluish pink flowers; racemes spike-formed, elongated, corymbose; height of plant, two feet. It is grown in Europe as a bee-plant for its nectar, and is the only one which produces an appreciable quantity of it. It certainly ought to grow in the North if treated as an annual. The phacelia of the florists in this country is quite different, if I may judge from plants raised from seeds purchased here. This is known to botanists as *Phacelia viscidula*, and by some florists it is called *Eutoca viscidula*, or *Eutoca viscosa*. The plant is about one foot high, and the flower is deep-blue with a lighter center. This is also a California plant, but I have never come across it in its wild state.

CONVENTION NOTICE.

Chicago - Northwestern.—The executive committee of the Chicago-Northwestern Beekeepers' Association have planned to hold the best convention ever convened in Chicago. The date is Dec. 3d and 4th, Wednesday and Thursday. Five eminent bee-keepers have been invited, and are expected to attend. More definite announcement later. Watch for it. Reduced rates on account of the fat stock show, which is held Nov. 29th to Dec. 6th.

BEE=BOOKS

SENT POSTPAID BY

GEORGE W. YORK & CO.,

144 & 146 Erie St., - CHICAGO, ILL.

Bee-Keeper's Guide, or Manual of the Apiary, by Prof. A. J. Cook, of Pomona College, California. This book is not only instructive and helpful as a guide in bee-keeping, but is interesting and thoroughly practical and scientific. It contains a full delineation of the anatomy and physiology of bees. 544 pages. 295 illustrations. Bound in cloth. 1902 edition.—19th thousand. Price, \$1.20.

Langstroth on the Honey-Bee, revised by Dadant.—This classic in bee-culture has been entirely re-written, and is fully illustrated. It treats of everything relating to bees and bee-keeping. No apian library is complete without this standard work by Rev. L. L. Langstroth—the Father of American Bee-Culture. It has 520 pages, bound in cloth. Price, \$1.25.

A B C of Bee-Culture, by A. I. Root.—A cyclopedic of 400 pages, describing everything pertaining to the care of the honey-bees. Contains 300 engravings. It was written especially for beginners. Bound in cloth. Price, \$1.20.

Scientific Queen-Rearing, as Practically Applied, by G. M. Doolittle.—A method by which the very best of queen-bees are reared in perfect accord with Nature's way. Bound in cloth and illustrated. Price, \$1.00; in leatherette binding, 60 cents.

Bees and Honey, or Management of an Apiary for Pleasure and Profit, by Thomas G. Newman.—It is nicely illustrated, contains 160 pages, bound in cloth. Price, in cloth, 50 cents; in paper, 30 cents.

Advanced Bee-Culture, Its Methods and Management, by W. Z. Hutchinson.—The author of this work is a practical and entertaining writer. You should read his book; 90 pages, bound in paper, and illustrated. Price, 50 cents.

Bee-Keeping for Beginners, by Dr. J. P. H. Brown, of Georgia.—A practical and condensed treatise on the honey-bee, giving the best modes of management in order to secure the most profit. 110 pages, bound in paper. Price, 50 cents.

Bee-Keeping for Profit, by Dr. G. L. Tinker.—Revised and enlarged. It details the author's "new system, or how to get the largest yields of comb or extracted honey." 80 pages, illustrated. Price, 25 cents.

Bienen-Kultur, by Thomas G. Newman.—This is a German translation of the principal portion of the book called "Bees and Honey." 100-page pamphlet. Price, 25 cents.

Apiary Register, by Thomas G. Newman.—Devotes two pages to a colony. Leather binding. Price, for 50 colonies, \$1.00.

Dr. Howard's Book on Foul-Brood.—Gives the McEvoy Treatment and reviews the experiments of others. Price, 25 cents.

Winter Problem in Bee-Keeping, by G. R. Pierce.—Result of 25 years' experience. Price, 30 cents.

Foul Brood Treatment, by Prof. F. R. Cheshire.—Its Cause and Prevention. 10 ets.

Foul Brood, by A. R. Kohnke.—Origin, Development and Cure. Price, 10 cents.

Please Mention Bee Journal when writing advertisers.

HONEY AND BEESWAX
MARKET QUOTATIONS.

CHICAGO, Nov. 7.—Prices remain steady, but the demand is small. We are not selling the quantity that we have done ordinarily at this season of the year. The advance in price has checked the trade, in addition to which retailers have got the impression that honey is going to be very scarce, and they are not pushing its sale. Fancy white comb brings 15@16c, with travel-stained from one to two cents per pound less; amber honey brings 12@13c, according to style and kind of package. There is very little call for the dark amber and buckwheat grade. Extracted white sells at 7@8c; dark and ambers, 6@7c; Southern is slow at about 5½c. Beeswax sells upon arrival at 30c per pound.

R. A. BURNETT & Co.

ALBANY, N. Y., Nov. 9.—Good demand for honey at former prices. Fancy white comb, 16c; A No. 1, 15@16c; No. 1, 15@15½c; buckwheat, 14@14½c. Extracted, light, 7@7½c; mixed, 6½@7c; buckwheat, 6½c. Beeswax, 30c.

H. R. WRIGHT.

BOSTON, Oct. 20.—Our honey market remains firm, with good demand and fair stocks on hand. Honey is not coming forward as fast as usual, and the tendency of prices is steady. We quote our market as follows: Fancy white 1-pound sections in cartons, 16c; No. 1, 15c; No. 2, very light supply, 14c; glass-front sections generally one cent less than this. Extracted, light amber, 8c; amber, 7½c.

BLAKE, SCOTT & LEE.

KANSAS CITY, Oct. 20.—The receipts of comb and extracted honey are light, and demand steady at quotations: Fancy white comb, 14½@15c; No. 1 white, 14@14½c; No. 2 white and amber, 13@13½c. White extracted, 7@7½c; amber, 6@6½c. Beeswax, 24@26c.

C. C. CLEMONS & Co.

CINCINNATI, Nov. 8.—There is a good demand for all grades of extracted honey, prices ranging as follows: Amber and Southern in barrels, 5½@6½c; clover and basswood, 7@8c. Fancy comb sells 16@17c. Beeswax, 27c.

THE FRED W. MUTH CO.

NEW YORK, Nov. 8.—Demand for comb honey is good and same finds ready sale at from 15@16c for fancy white, 14c for No. 1 white, 12@13c for No. 2 white, and 12@13c for buckwheat. Extracted in fair demand at 7½c for white, 6½c for light amber, and 6c for dark. Southern in barrels from 6@6½c per gallon. Beeswax quiet at from 27@28c.

HILDRETH & SGOELKEN.

CINCINNATI, Oct. 21.—The demand for comb honey is good and prices are a little better, as the supply does not meet the wants. Extra water-white fancy is selling as high as 16@17c; other grades less, according to quality. Extracted is very active and prices are a little better; amber, 5¼@5½c; alfalfa, 6½@7c; white clover, 7½c. Beeswax, 28c. C. H. W. WEBER.

SAN FRANCISCO, Oct. 15.—White comb honey, 12@12½c; amber, 8@10c; dark, 7@7½c. Extracted, white, 5½@6c; light amber, 5¼@5½c; amber, 5@5½c. Beeswax, good to choice, light, 27@29c; dark, 25@26c.

There are no heavy offerings of any description, either at this center or at producing points. Comb honey is in better spot supply, however, than extracted. Stocks of latter have been greatly reduced by recent shipments outward. Current values are being well maintained.

Tip-Top Glass Honey-Jars

The picture shown herewith represents the best one-pound jar for honey that we know of. It is made of the clearest flint glass, and when filled with honey, and a neat label attached, it makes as handsome a package as can be imagined. Its glass top sets on a flat rubber ring, and is held in place by a flat steel spring across the top as shown in the picture. It is practically air-tight, thus permitting no leak,

which is an important thing with honey-sellers.

We can furnish these jars, f.o.b. Chicago, at these prices: One gross, \$5.00; two gross, \$4.75 a gross; five or more gross \$4.50 per gross.

If you try them once you will likely use no other kind of top or sealing arrangement for honey jars.

GEORGE W. YORK & CO.

144 & 146 Erie Street, CHICAGO, ILL.

\$300,000,000.00 A YEAR

The classic in Bee-Culture—Price, \$1.25, by mail.

BEESWAX wanted at all times....

DADANT & SON, Hamilton, Hancock Co., Ill.

THE HERSHISER HONEY-JARS.

These jars were designed for use in the honey exhibit at the Pan-American Exposition, in Buffalo, and are very neat and attractive. They have cork-lined aluminum caps which seal them tight. If honey is sealed in these jars while hot there will be no annoyance from granulation.

For exhibition purposes and a fancy trade nothing on the market compares with these jars. Put up your honey in a neat, attractive package, and sell it at a good price.

The fact that the molds are constructed for making the jars by hand instead of by machine, and the addition of the aluminum caps, make the jars somewhat more expensive than the ordinary jars. They are made in four sizes square and three sizes round, as shown in the illustration. We can supply them either from Medina or from Philadelphia at the following prices:

1/4 pound Square Hershiser Jars, doz., 50c; \$5.40 per gross.
1/2 pound Square Hershiser Jars, doz., 55c; \$6.60 per gross.

1 pound Square Hershiser Jars,	- - - - -	Dozen, 80 cents; \$ 9.00 per gross
2 pound Square Hershiser Jars,	- - - - -	Dozen, \$1.00; 10.80 per gross
1/2 pound Round Hershiser Jars,	- - - - -	Dozen, 60 cents; \$ 6.60 per gross
1 pound Round Hershiser Jars,	- - - - -	Dozen, 75 cents; 8.40 per gross
2 pound Round Hershiser Jars,	- - - - -	Dozen, \$1.10; 12.00 per gross

These prices, although rather high in comparison with other jars, are as low as can be made on hand-made jars, and afford us a smaller margin of profit than other styles. Order a sample dozen of each size and be convinced.

THE A. I. ROOT CO., Medina, Ohio.

GEORGE W. YORK & CO. 144 & 146 Erie Street, CHICAGO ILL., are headquarters for ROOT'S BEE-KEEPERS' SUPPLIES IN CHICAGO. Send to them for their free Catalog.

THE AMERICAN BEE JOURNAL

PUBLISHED WEEKLY BY

GEORGE W. YORK & COMPANY
144 & 146 Erie St., Chicago, Ill.

Entered at the Post-Office at Chicago as Second-Class Mail-Matter.

EDITOR—George W. York.
DEPT. EDITORS.—Dr. C. C. Miller, E. E. Hasty,
□ Emma M. Wilson.
SPECIAL CORRESPONDENTS—G. M. Doolittle,
Prof. A. J. Cook, C. P. Dadant,
R. C. Aikin, F. Greiner, A. Getaz, and others.

IMPORTANT NOTICES.

The Subscription Price of this Journal is \$1.00 a year, in the United States, Canada, and Mexico; all other countries in the Postal Union, 50 cents a year extra for postage. Sample copy free.

The Wrapper-Label Date of this paper indicates the end of the month to which your subscription is paid. For instance, "dec01" on your label shows that it is paid to the end of December, 1901.

Subscription Receipts.—We do not send a receipt for money sent us to pay subscription, but change the date on your wrapper-label, which shows you that the money has been received and duly credited.

Advertising Rates will be given upon application.

The Novelty Pocket-Knife.

Your Name and Address on one side—Three Bees on the other side.

[THIS CUT IS THE FULL SIZE OF THE KNIFE.]

Your Name on the Knife.—When ordering, be sure to say just what name and address you wish put on the Knife.

The Novelty Knife is indeed a novelty. The novelty lies in the handle. It is made beautifully of indestructible celluloid, which is as transparent as glass. Underneath the celluloid, on one side of the handle is placed the name and residence of the subscriber, and on the other side pictures of a Queen, Drone, and Worker, as shown here.

The Material entering into this celebrated knife is of the very best quality; the blades are hand-forged out of the very finest English razor-steel, and we warrant every blade. The bolsters are made of German silver, and will never rust or corrode. The rivets are hardened German silver wire; the linings are plate brass; the back springs of Sheffield spring-steel, and the finish of the handle as described above. It will last a last-time, with proper usage.

Why Own the Novelty Knife? In case a good knife is lost, the chances are the owner will never recover it; but if the "Novelty" is lost, having name and address of owner, the finder will return it; otherwise to try to destroy the name and address, would destroy the knife. If traveling, and you meet with a serious accident, and are so fortunate as to have one of the "Novelties," your POCKET-KNIFE will serve as an identifier; and in case of death, your relatives will at once be notified of the accident.

How appropriate this knife is for a present! What more lasting memento could a mother give to a son, a wife to a husband, a sister to a brother, or a lady to a gentleman, the knife having the name of the recipient on one side?

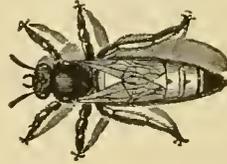

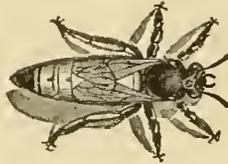

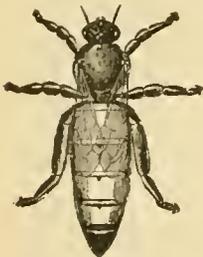

The accompanying cut gives a faint idea, but cannot fully convey an exact representation of this beautiful knife, as the "Novelty" must be seen to be appreciated.

How to Get this Valuable Knife.—We send it postpaid for \$1.25, or give it as a Premium to the one sending us THREE NEW SUBSCRIBERS to the Bee Journal (with \$3.99.) We will club the Novelty Knife and the Bee Journal for one year, both for \$1.90.

GEORGE W. YORK & CO.

Chicago, Ill.

Please allow about two weeks for your knife order to be filled.

An Italian Queen Free — IN MAY, 1903 —

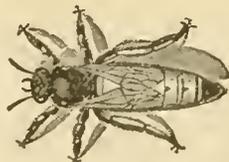

To Regular Paid-in-Advance Subscribers Only.

We wish to make a liberal offer to those of our regular readers whose subscriptions are paid in advance. It is this: We will send you FREE by mail, in May, 1903, an Untested Italian Queen for sending us \$1.00 and the name and address of a NEW subscriber to the American Bee Journal for a year. This is indeed a big premium, as the queen alone would cost you 75c.

We are booking orders for Queens now for next May delivery. Will you have one or more? This offer ought to bring in many orders. Our queens are reared by the best queen-breeders, and give satisfaction.

Address,

George W. York & Co., 144 East Erie St., Chicago, Ill.

IN AMERICA

BEE JOURNAL

42d YEAR.

CHICAGO, ILL., NOV. 27, 1902.

No. 48.

* Editorial Comments. *

The Date of the Ontario Convention, the reports of which are read with much interest by many on this side the line, was set for Dec. 2, 3 and 4. But Dec. 4 is the day to vote on the referendum over there, and the Canadian Bee Journal says:

The temperance cause (of which we are glad to say the majority of the members of the Ontario Bee-Keepers' Association are staunch supporters) requires every man at the polls that day. We must remember that it is not a political question, but a great moral issue that is at stake, the abolition of the drink-traffic. It may be, of course, that Ontario is not yet satisfied that she has sacrificed enough of her children to this demon of strong drink under the guise of "liberty," but there is a great opportunity now offered to have the "accursed" thing removed, and Christian men and women should make the most of it.

So the date of the Ontario convention has been changed to Dec. 16, 17 and 18, so that members may have a chance to vote on prohibition. Good for Kanuck bee-keepers. May they all help to win in the attempt to wipe out the worst foe of mankind.

Old vs. New Combs.—The discussion as to whether bees prefer comb foundation or new combs to those black with age seems to be a perennial one. It seems a little strange that a thing upon which observations can be so easily and so fully made should remain year after year in dispute. Can it be possible that there is such a difference in localities, or in bees, that one man shall find the oldest and blackest of combs preferred, while another shall find them used only as a last resort? While making plans as to the things upon which observations are to be made the coming year, let each one make a minute of this matter, and see if there can not be enough light thrown upon it to settle the question for all time.

Catnip.—Editor Hill, of the American Bee-Keeper, speaks thus of catnip:

"The big catnip balloon seems to have been pierced quite early in its vigorous flight by the snag of personal investigation. It is disappointing to be obliged to pursue old channels in quest of forage so very soon after having our catnip enthusiasm wrought to the extent of ecstatic anticipation; but it now appears that we shall have to come to it."

From which it may be inferred that Mr. Hill is not intending to plant a hundred acres in catnip, right away. But catnip is a good honey plant, just the same.

Smelter-Smoke and Bees.—At the National convention at Denver, mention was made of loss of bees in the vicinity of smelting works, especially the Salt Lake and Denver smelters, and, in the last Rocky Mountain Bee Jour-

nal, C. P. Dadant gives an account of the same thing in the Old World, it being claimed that in the gases set free to float away during the smelting of the ores, there is enough arsenic to poison the bees, analyses of the dead bees having shown traces of arsenic in them, as also in the honey and pollen. The fruit-trees are also injured so that they bear no fruit. May it not be possible that sufficient damage may be done without any arsenic in the case? In the coke regions of Pennsylvania trees are killed where there seems to be nothing but the smoke of the burning coal to injure them. At any rate, the moral is to keep away from such places, and to keep away a good distance, for the smelters kill bees at a range of five miles or more.

Wild Cucumber is quoted in the Bee-Keepers' Review as yielding honey abundantly until the vine is killed by frost. That is by no means the case in northern Illinois, if the plant be the same. It is a thing of great beauty, especially when in full bloom, but it ceases to bloom and dies down long before frost. It has not been noted as a honey-yielder, although proper credit may not have been given to it. Can any one tell what its value is in Illinois and adjoining regions? The illustration of the plant in the Review is from a photograph taken in Nebraska. Does it yield as abundantly in other parts of that State as in the region near Dr. Gandy?

The Double Hive, or what is called in England the Wells system—a hive with two compartments side by side, with a perforated separating wall, allowing the workers, but not the queen, to pass from one side to the other—has now been on trial for several years, and while some speak well of it, the testimony in general has not been such as to warrant its general adoption. One objection is, that when the colony on one side swarms, the colony on the other side is excited to swarming, whatever its condition may be. Another objection is, that when one side becomes queenless it is likely to remain so, the presence of a queen on the other side preventing the bees from feeling their queenlessness sufficiently to rear a new queen.

Anticipatory Swarming, by means of shaking or brushing, will be a boon to some who have run out-apidaries, and have keenly desired some way by which the necessity for keeping a watcher constantly at each apiary might be avoided. Of course, the depletion of a colony by taking away brood that would in a short time swell the host of gatherers is a thing not to be desired, but that is not so bad as losing the same amount of brood and a lot of bees besides in natural swarming.

The greatest gain, however, will probably be counted by most to consist in the fact that by shaking swarms the bee-keeper is made master of the situation, having the time of swarming come at his calling, and not at the whim of the bees. Add to this the advantage over foul brood obtained, and it will be seen that this system of management

is one of immense advance. Indeed, where foul brood prevails, nothing more need be desired, although elsewhere bee-keepers will still sigh for a plan that will leave a colony undisturbed in possession of all its brood and bees throughout the whole season.

Twelve-Frame Hives are having something of a boom in Canada. R. F. Holtermann speaks highly in favor of them in the Canadian Bee Journal, saying that the Bow Park Co., with which he is connected, are ordering 400 of them, and others are adopting them. A foot-note says:

Since Mr. Holtermann wrote the above he has returned from extracting buckwheat honey at an out-apiary of 81 colonies, and reports that while the bee-keepers in the vicinity secured practically no surplus buckwheat honey, his bees secured over 3000 pounds of surplus. This speaks well for the large hives.

* The Weekly Budget. *

THE CHICAGO-NORTHWESTERN CONVENTION—Wednesday and Thursday, Dec. 3 and 4—will be held in the Briggs House, Chicago, corner Randolph St. and Fifth Ave. It looks now as if it would be larger and better than the Denver convention was. Still, it may not be quite equal to it. But let all come who can do so. Low rates at that time on all railroads centering in Chicago, on account of the International Live Stock Exposition which is to be held here the same week. So there will be at least two "big shows" in Chicago at the same time. But this windy old city is big enough to have a number of shows going on all at once.

THE APIARY OF MR. N. NIELSON appears below. He has this to say of himself and his bee-keeping experience:

I moved to this place 24 years ago, and there had never been a plow or anything else here before I came. Every-

APIARY OF N. NIELSON, OF SAC CO., IOWA.

thing that is here I put here; it cost me \$10 an acre, and it would sell to-day for \$100 an acre, if it was for sale.

Eight years ago I had an attack of spinal meningitis, and have not been able to stand the heat of the sun since that time, so I have adopted the bee-business for the heat of the summer.

The season of 1901 was not a very good season for honey with us, as it was too dry. I had about 1400 pounds from 45 colonies: my extracted honey sold for 12½ cents a pound, and the comb for 15 to 18 cents a pound.

The picture was taken on a cold morning, as the photographer said he would not take the picture if there were any bees flying.

I have not had swarms this season so far (June 18) that I know of. I used to clip my queens, and intended to do so last spring, but I did not get at it in time. Losing my wife last fall left me with everything to look after, as she used to help considerably about the bees. There are five children and myself in the family.

My hives are facing the east. There is a small building in front of the bees used as an extracting-house; it is 14x16 feet. I have a solar wax-extractor on the east side of the door.

I think I have said all there is to be said of much interest, except to say the bees have paid me well so far.

N. NIELSON.

DENVER CONVENTION NOTES.—On page 677 we gave the last of our notes by the way, while on our Denver trip, describing Pike's Peak and Manitou. That trip was taken on Monday forenoon, Sept. 8. In the afternoon our party took a carriage drive through the Garden of the Gods, as it is called. This garden is filled with stone or rock images that one can imagine are gods, such as the ancients may have worshipped. In many instances, however, one's imagination must be very active and elastic in order to see all that the knowing driver explains. But it was a delightful drive of four or five hours. There were seven of our party on this drive, Mr. J. W. Lloyd, wife and daughter, having joined us, or, perhaps, we would better say, that our party of four joined them, as they had been in Manitou for a week or more before we arrived.

On Tuesday morning our party (increased to five by the addition of Miss Lloyd), started for South Cheyenne Canyon. Here was where we all mounted the snail-like burros, and wended our way up the trail of the Canyon. The picture on the first page shows how our party appeared that beautiful September morning.

We must confess that we are unable to do justice to a description of South Cheyenne Canyon, so we will make an extract from a publication which tells something of the beauties of the natural scenery that we were permitted to enjoy on that occasion:

CHEYENNE CANYON.

Oh, Cheyenne Canyon! in thy dim defiles,
Where glooms the light, as through cathedral aisles,
Where flash and fall bright waters, pure as air,
Where wild birds brood, wild blossoms bloom, and where
The winds sing anthems through the darkening trees,
A presence breathes the tenderest melodies.

—STANLEY WOOD.

A half hour's ride from Colorado Springs brings you to the entrance of the canyon. The road leads most of the way by the side of a beautiful stream thickly fringed with willows and cottonwoods. As the approach to the canyon is neared these give way to a sturdier growth of spruce and pine, while underneath is a dense thicket of scrub-oak, hemming in the road on all sides, and, in the summer months, completely shrouding the low foot-hills in their dark, green foliage.

The winding road, all the while closely following the curves of the stream, finally emerges from this labyrinth of trees and enters into the canyon proper, and here is unfolded to your view a panorama worthy of the artist's pencil or the painter's brush.

Before you is a great cleft in the granite mountain, as though some mighty hand had split and wedged it apart that one might enter and behold the wondrous works of Time within. To the right is a massive granite shaft tow-

ering almost to the sky. "Eagle Cliff" it is called, because our glorious American bird has chosen it as a fit place to build its home. Just before you is another giant, "Mount Cutler," equally grand and impressive, and clinging from its side, half way to its summit, and standing out in bold relief against the sky, are the "Vacant Chair" and the "Hindoo Baby," each curiously-suggestive rock formations.

But pass through the gate with me.

Before us are two tremendous cliffs "The Pillars of Hercules." They seem to stand squarely across the canyon, completely filling it and demanding a halt. The way seems barred, and the stranger is at a loss to know which way to go, but the brook has found a way, and so must we. Here is a most wonderful demonstration of the action of the water. For hundreds of feet the canyon at this point has been worn through the solid granite. On either side are perpendicular walls, nearly a thousand feet high, and at one place but 40 feet apart, barely giving room for the creek and roadway between them. Indeed, the whole space was originally occupied by the stream, which had to be crowded from its bed.

A short distance beyond the "Pillars of Hercules," on the left, is Observatory Point. This is one of the objective points of the burro brigades, which leaves the terminus of the electric car-line at the entrance of the canyon.

After proceeding through the ever-changing scenes in the canyon, we come to a place opposite Prospect Dome. This is a graceful, symmetrical pinnacle of granite, more than 300 feet in height. It stands alone in one of the side canyons like a watch-tower of the god of war, its base wrapped in a great cloak of dark, sombre evergreen. At this place the burro trail leaves the canyon and winds its way through a thickly wooded gulch to Point Lookout and the top of the Seven Falls, and from thence to Observatory Point, by whose base we have just come. The view from this point is unsurpassed. At our feet is the canyon with its mass of rended and shattered cliffs, and the stream, resembling a mere ribbon of light, entwined among the trees far beneath. Over and beyond the rugged walls, and just without the break of the foothills, lies Colorado Springs—an emerald checker-board midway in the picture. Far beyond are the great plains, rolling away like the waves of the ocean, to meet the sky. As we turn to the west the eye is dazzled with the unbroken grandeur of the mountains as they stretch away, tier upon tier, till they meet the blue horizon miles in the distance.

But let us return to the canyon. A short distance above Prospect Dome and we come to the foot of the Seven Falls, where Nature out-does herself in a grand display of mighty cliffs and rushing waters. Here the canyon proper ends in a colossal amphitheater, down one side of which plunges the foaming torrent in seven distinct leaps from a perpendicular height of 234 feet.

Until a few years ago our journey must have ended here, but modern enterprise has overcome the difficulty by the construction of a safe and easy stairway on the face of the wall to its top, so that now we may ascend and enjoy the beauties beyond.

Overlooking the falls, and towering far above them, is Far View Observatory, from the top of which a splendid view may be had of the falls and the canyon, and also through the entrance of the canyon out on to the plains for a hundred miles or more.

Just above the Seven Falls is the junction of the two branches of the stream. The west branch, formed by the melting snows of Mount Rosa, flows through Arapahoe Pass, itself a beautiful canyon, over logs and boulders, under mossy banks, giant rocks and waving bushes, past natural flower gardens, green meadows and thick forests, where bloom in wild charm and fragrance the columbine (the State flower), blue, white, and yellow; the tiger-lily, nursed and petted in the East; the primrose, flower of the night; lady-slippers, shooting-stars, buttercups, daisies and violets. Here, also, in their respective seasons, are wild raspberries, strawberries, thimbleberries, gooseberries, currants and cherries, and many other fruits and flowers which only attain their greatest beauty and charm in the wild and unkempt thickets where Nature plants and cultivates in her own inimitable way. Here, too, we may find ferns of many varieties, and some that are found in no other canyon in the vicinity.

We stroll up along the left or south branch of the stream for a quarter of a mile through a beautiful grove of aspens and majestic pines, and among great granite boulders, to the foot of Boulder Point, where we commence the ascent of Midnight Falls, one of the most beautiful in the

canyon. It is surrounded by alders, willows and birch and giant firs, pines and spruce, which, even at noon, almost exclude the sun's rays, and always make a cool and quiet retreat.

Just above the Midnight Falls, and along the west base of Boulder Point, are Granite Rapids, where, for 100 feet, the water rushes through a narrow trough in the solid flint-like granite cut by the ceaseless wearing of the never-tiring little brook, as it has, for ages, rushed downward to the greater leap below. A few more steps bring us to the Silvery Juanita Falls, where the water for 50 feet rolls and rushes over the cliffs, breaking into silvery spray and sparkling in the sunlight, plunging at last into a beautiful, crystal pool, clear as air, with a pebbly bottom, and surrounded by magnificent, stately balsams, firs and spruce. Here is the place to sit for hours, communing with the brook, forgetting all care, and even the world outside with its hurry and noise, uninterrupted unless by some squirrel or bird.

It is practically the universal verdict of visitors to South Cheyenne Canyon, that there is no place accessible to tourists, and of the same extent, which surpasses it in scenic attractions, and few that compare with it, not excepting the Yosemite Valley or the Alpine Gorges. The entire canyon, from the entrance to Juanita Falls—a distance of a mile and a half—presents a succession of the grandest views to be imagined; while the beautiful brook of crystal water, a flora unsurpassed in variety and beauty, and the finest falls in Colorado add to its surpassing attractions.

We do not think the foregoing description is very much overdrawn. It is truly an Eden of beauty, and some day, if ever we can get to Colorado Springs again, we want to repeat the trip to South Cheyenne Canyon, burro ride and all. But Mrs. York was the only one of the party that didn't enjoy the burro method of travelling. Next time she will ask to be excused, though, if we do say it, she looks "as fine as a peach," perched up on her burro.

By the way, the name of Mrs. York's burro was "Satan." He looks like him, doesn't he? But Mrs. York could hold him down all right, that is, if 150 pounds (pure-gold weight and value) could hold down a couple hundred pounds of "Satan."

THE MINNESOTA CONVENTION of bee-keepers will meet Wednesday and Thursday, Dec. 3 and 4, 1902, at Minneapolis, in Plymouth Church, corner Eighth St. and Nicollet Ave. Among the good things on the program are these:

Song—"The Honeysuckle and the Bee"—Miss Edith Dexter.

"Something of Benefit to Beginners in Bee-Keeping"—A. E. Hooker.

"Some of My Experience in Keeping Bees in Minnesota"—Wm. Cairncross.

"Disposing of Our Crop of Honey to the Best Advantage"—S. Lindersmith.

"Bees on a Poultry Farm"—Victor D. Caneday.

"Honey Exhibits"—Walter R. Ansell.

Address by Superintendent Gordon on the honey exhibit at the Minnesota State Fair.

"Bees on the Farm"—Mrs. D. C. Hazleton.

"Use and Abuse of the Honey-Bee"—Frank Yahne.

Address by G. L. Dingman, State Dairy and Food Commissioner.

The program says: "Please do not forget to buy your tickets for the Horticultural meeting, and take certificates for them to get reduced railroad rate."

Why Not Help a Little—both your neighbor bee-keepers and the old American Bee Journal—by sending to us the names and addresses of such as you may know do not now get this journal? We will be glad to send them sample copies, so that they may become acquainted with the paper, and subscribe for it, thus putting themselves in the line of success with bees. Perhaps you can get them to subscribe, send in their dollars, and secure for your trouble some of the premiums we are constantly offering as rewards for such effort.

Convention Proceedings.

THE DENVER CONVENTION.

Report of the Proceedings of the 33d Annual Convention of the National Bee-Keepers' Association, held in Denver, Col., on Wednesday, Thursday and Friday, Sept. 3, 4 and 5, 1902.

(Continued from page 742.)

Pres. Hutchinson next called on Mr. R. C. Aikin, of Colorado, to read his paper on

PUTTING UP EXTRACTED HONEY FOR THE RETAIL TRADE.

With many this is a burning question. For several years there has been a subdued and smoldering fire going, sometimes a good-sized smoke and considerable darkness, now and then enough light to let us see what the smoke was about. Well, I think there have been some of the brethren around poking the fire to make the blaze shoot up on high so that those at a distance could see, and I have a suspicion that that Irish mud-and-stone man from Toledo, Ohio, assisted by that other Irishman from Flint, Mich., has been putting up a job on me. Just think of it, after all the rumpus I have had with the Ohio Fowls and others, then, to cap the climax, ask me to treat this subject before this body of the wit and wisdom of the land, and me to prepare in advance what I have to say, and send a sample of the whole thing to that Chicago Irishman, so he could come prepared to lick me! But, brethren and sisters, I am still on the "ridge pole," and just as happy as an owl, and I will bet that I can fight just as long in this high altitude as all three of the other Irishmen. So up go my sleeves, and now watch the sparks fly.

You want to know how to put up extracted honey for retail, do you? Well, ask "Yorrick," he will tell you to find the "Root" of the matter in his catalog printed down at Medina, and when you have found that the price of one-pound glass jars is *almost* 4 cents each at New York, Philadelphia and Cincinnati, and even 4 cents each at Indianapolis, just send in an order and put your honey up in these. "Jones pays the freight" on these jars, and stands breakage; of course the supply dealer could not possibly do it!

You see that your honey is thoroughly liquid—if any granules, melt them; and as the wholesale price of extracted honey delivered in Chicago is 5 to 6 cents—call it 6—then deduct $\frac{3}{4}$ of a cent a pound for freights (that's the car-rate to Chicago), and another $\frac{3}{8}$ for cans in which to ship it, then a 5 percent commission, which is three-tenths of a cent, then allow two-tenths of a cent more for freights on the package (cans and boxes) and for postage, collections, etc., and you have just 4 cents left as the worth of your honey.

We mean that when honey delivered from Denver to Chicago brings 6 cents there in car-lots it is worth 4 cents at your honey-house. Put the 4-cent honey in the 4-cent jar, then add one cent for the freights you paid on the jar, and one cent more for your trouble in filling and boxing these jars ready for shipment, and you have a net price of 10 cents as the cost of your honey ready for the railroad—4 cents for honey and 6 cents for the other things.

Let me tell a little story. Once on a time there was a great hooting by one of the big owls down East, just to scare some of the other tribes out West. Well, I just thought I would try an experiment and see if high-priced, glass-packed honey in the lower altitudes was a myth or not, so I sent some honey into—well, away beyond Chicago—with instructions for the receiver, who was an honest man, to sell it, and after paying himself, and freights, etc., to send me the balance; and, sir, not one cent came back!

If you live near a big city, and have wealthy and stylish customers who do not care for price, so the honey looks nice through clear glass, and costs more than common people pay for it, pack it in glass every time, and stick on the price. I have figured it was worth at your honey-house in those jars 10 cents each. You are catering to the users of

luxuries, and as luxuries do not sell so well because the consumers of them have other luxuries of many kinds, and are a set of dyspeptics, and eat very lightly at best, and because luxuries are always uncertain of sale and subject to fluctuations, you ought to and must have a good commission to pay for insurance, taxes, and your own trouble and risks. You should add about 40 percent for *your* profits, another 40 for the retailer and others, and say 20 percent for the railroads and carriers. This will make the honey sell at 20 cents a pound and upward. This is for the small percent of the very wealthy who do not eat much honey, because they have so very many other good things.

If you have to sell to people like yourself, who have to work on from \$200 to \$600 salaries, and economize very closely to make ends meet, they can not and will not pay 15 cents for glass and things to get 5 cents worth of eating; and for that trade you must put up your honey so as to get it to them with the least possible expense for fancy wrappings; they want something to put to their ribs and to keep the babies from actual starvation. This is the big—let us spell that with capital B, I, and G—class of consumers. Put their honey into common lard-pails, wooden or pasteboard boxes, paper bags or some other cheap package that will get the goods there cheaply, yet neat and clean. If you want to sell lots of honey at retail, just cater to this trade, and you will enter a field that is as wide as the commercial world, few competitors, and a vast horde of hungry mouths. Do not go on trying to feed and stuff the wealthy who are already too full, but reach out to the middle and lower classes, who must, of necessity, look twice and think many times before buying a useless and expensive piece of glass-ware to get a little sweet.

Not one in a hundred have any use for the glass bottle after the honey is out of it. Some tell us these packages are valuable after the honey is out of them, but I tell you that very few of those who do and who *ought* to consume honey—such as the very wealthy in brown-stone fronts, and the laborers who have not a fruit-tree to their name—would or could use empty honey-jars, so that argument does not "go" where proper intelligence prevails.

Then, too, honey in glass is and must be fancy; it won't hold its place unless it is. It must be put up so that it will remain liquid and clear, which means an expensive bottling plant such as the ordinary bee-keeper can not have. Or, in lieu of this, the goods must not get beyond the immediate neighborhood of the producer or packer, for he must exchange or reliquefy when it candies or gets cloudy. The great producing districts are altogether too far from the consumer for this taking-back method, and even if close it is a very unsatisfactory and expensive plan, and can not prove practical with one producer in a hundred; for general results it is a mere makeshift.

I do not deny that there is a demand for fancy goods put up in fancystyle. Such have a place; but that such is practical for the average producer, and for the wholesale producer in the average locality, I do most emphatically deny. Give me 100,000 pounds of No. 1 extracted honey to pack in lard-pails before it has had time to candy the first time, and I will guarantee to sell it within a year and get better prices than can be had for the same honey in 5-gallon cans, and better prices than can be had for the same in glass, outside of the limited, fancy city trade. When I say better prices, remember that I do not mean that the gross price will be more, but I do mean that the producer will *net* more out of his crop. I also mean that the goods will reach a field that is neglected, and where it will do the most good to suffering humanity.

But some honeys will not candy freely and quickly, which is the misfortune of those who have such; it won't be long until many will be hunting methods by which to cause rapid and complete candying, which probably will not be a serious problem. We want the honey to candy quickly and solidly, be packed right into the retail package from the settling-tank, and the package to be the very cheapest that will successfully carry the goods to the consumer at a minimum of cost. At the present time lard-pails and paper-bags are the most feasible thing available until something better is invented. This may seem strange to many, but the proof is in the eating of the pudding, and I have partaken thereof. To get into the forefront of the battle is to be a target for the bullets of the enemy, but it is good for the cause. Every good thing has to run the gauntlet of criticism and meet with opposition, and the lard-pail-paper-bag-candied-honey scheme is, and will be no exception to the good, old rule.

In short, extract your honey into the big—yes BIG—honey-settling tank, from the tank draw into nothing more

expensive than tin, that which will candy into pails, and that which will not candy into sealing packages, and then put it into the hands of the retailer, and it is bound to sell. Every package must have printed instructions for liquefying, and the producer's or packer's guaranty; put out nothing of which you are ashamed or unwilling to back up.

Now, brethren, pile on a few more sticks to the burning; let us have a big fire, and warm up to the subject; hew to the line and make the chips fly. R. C. AIKIN.

Pres. Hutchinson—We have had a most excellent paper on a very practical subject, and of course it will give us something to discuss; but before we take up the general discussion we would like to hear from the gentleman who is on the program to respond—Mr. York.

Mr. York—I would like to have you keep one eye on this glass jar of liquid honey which I hold in my hand, and the other eye on me and on the paper while I read.

PUTTING UP EXTRACTED HONEY FOR THE RETAIL TRADE.

My good friend who has just preceded me seems to be "Aikin" to see a big fire and lots of smoke. If he'll just wait until he leaves this world (or, maybe before this hour passes,) he may see and feel more fire and hotness than he wants. But doesn't he know that so much fire might liquefy his granulated honey, that he has been trying to get you all to believe is the only form in which extracted honey should be put upon the market?

Then, the idea of calling three of us members *Irishmen*, when there isn't a drop of Irish blood or blarney in any of us—except it be *Dr. Mason!* And he hasn't any more than two drops! Why, a man that will publicly cast reflections upon fairly respectable people, and misjudge them, surely can not be in a proper frame of mind or brain to discuss this momentous subject before such a select audience as we have here to-day.

But my "Aikin" friend is not what I'm to talk about, even if he is an interesting subject, so I'll dismiss all further thought of him for a little while, and tackle his subject.

In the first place, I don't believe in starting out to feed all creation with honey. And almost making them a present of it, besides. What costs practically nothing is valued at just about as much as it costs. If all were to granulate their extracted honey and offer it at from 8 to 10 cents a pound, there wouldn't be more than a few grains per capita for all the Irishmen alone—that is, if you would call everybody an Irishman, as Mr. Aikin seems to do. And, the next thing, the price would be raised, because of the scarcity of the sweet article itself.

Honey is different from most other table articles. It is a necessary delicacy, not to be eaten as you do potatoes, soup, and corn-meal mush. A little of it at a meal—like butter—is all any reasonable person should want, unless he eats with a shovel, when, of course, he must have granulated honey. I will admit that such honey can be shoveled in faster than if it were in the liquid form.

But when I put extracted honey on the market I don't want to have to spend valuable time in telling people that it isn't sugar, or lard, or grained goose-grease. Every one knows, if he knows even a little bit, that all honey is in the liquid form when taken from the hive. Then why not pass it on to the crowd in its original, sparkling form, and not try to tell them how to liquefy it the first thing?

Again, honey is a tempting thing when it glistens through clear flint glass. What is 18 or 20 cents for a pound of such concentrated sweetness? Why, there are a good many people that will blow in 10 cents for a cigar and then blow it all out again in smoke. Two useless blows for a dime. And if the cigar blower is a big "blow" himself, you have three blows all in one, and all for 10 cents! Now, think of the pleasure and strength to be derived from the price of two such cigars invested in a pound of honey! Who would forego it if he only knew how good it is in the liquid form on bread, biscuit or flapjacks. And the people are learning every day that honey is a fine thing to eat—and not to be stored out of sight in tin, wood or paper-bags in the granulated form.

Now, perhaps, I have said enough on this part of the subject, so I will further consider the best packages to use for the retail trade.

I'm a defender of glass packages for the retail trade. As in a few other things connected with bee-keeping, localities differ, but in the majority of the retail stores glass jars holding $\frac{3}{4}$ or 1 pound each are the preferred sizes, retailing

at 15 and 20 cents respectively. In a country trade, when selling from house to house, the quart and pint Mason jars are best, or tin pails of various sizes. But it is utterly useless to talk of large glass or tin packages for the ordinary city retail trade to be handled by the grocers. And that is where the bulk of the surplus crop of the best extracted honey will eventually find the greatest demand—on the tables of the city people.

There is no need of bee-keepers trying to compete with cheap and adulterated table syrups or mixtures that are found in nearly every open market. What they should do is to produce only the finest honey, put it up in convenient packages for home consumption, and then go out after the people. I know men who are working on this plan, and their trade is constantly gaining in volume, and in satisfied customers.

We must remember that Mr. Aikin is a *producer*, and his little crop of honey, or what he handles, is scarcely a spoonful compared with the aggregate product of honey of the whole country. What he has said may do in *his locality*, and in *his hands*, but don't any of you ever go to any large city and try to put his methods into practice. If you do you will regret it. You can't succeed. Life is too short. You'll be gray-headed, or bald-headed, long before you can work up a paying trade.

Perhaps I have said enough for now, especially for a small man, and so far away from home. If I have helped to fan the blue blaze I trust there will be plenty to blaze away. It is one of the liveliest topics before this convention. The bulk of the honey put upon the market to-day is *extracted honey*. And I am glad of it. What you want to know is the best and most profitable way of getting it all on the tables of the people. You don't need to care whether the poorest people get it. You are not in the bee-business for your health alone. Some of you are making your living at bee-keeping, even if not a fortune besides. What you want to know is, how to realize the largest proceeds from the sweet product of your apiaries. But you can't all go into the retail honey-business. Such being the case, you should get in touch with those who are putting up honey for retailers, and see that they handle *your* honey. But you must produce a fine, thick, well-ripened article.

Well, I was going to stop before this. I will do so now. But be sure to make the fire that follows so fearfully hot that Mr. Aikin's granulated honey will be liquefied so that even "spoony" people can get it down without pick, shovel, and elbow-grease.

Now chip away, and see a glorious blaze!

GEORGE W. YORK.

Pres. Hutchinson—You have a burning subject, now fire away at it.

F. H. C. Krueger—I don't want to have anything to do with this fight—I just want to tell my experience, that is all. I have been in the bee-business for nearly 45 years; I have made it a point to produce nothing but extracted honey, and I never had any trouble in the world to sell it. I always had less honey than I could sell. My first experience was in Kentucky. Of course, the prices were magnificent; I sold my extracted honey by the barrel, wholesale, at 18 and 20 cents a pound.

Pres. Hutchinson—The question is, as to the best way of putting up honey for the retail trade. How did you put it up yourself for the retail trade?

Mr. Krueger—At that time what I didn't put up in barrels I put up in 2-pound glasses, which I shipped to consumers and grocerymen in the different cities, and the bulk I sold by the barrel. I came to Colorado, and when I extracted my honey first it was a drug on the market. Why? I put it up in pound glasses and 2-pound glasses, and carried it around in Denver. Of course, I sold it all, but it was a great deal of trouble to me. At the present time, as I put it up, the smallest amount I sell is a Mason jar—three pounds—the next is a half-gallon tin-pail, and the third is a gallon pail, and the fourth is 75 pounds in a big, round 5-gallon can. I fill it up with from 75 to 76 pounds, and I have no trouble in selling it. I want to say this, if people know that you give them a good article you will have no trouble to sell it.

First, when I went around and sold my honey in one and two pounds, it looked like clear and nice honey, just exactly like that looks, and the people said it looks too nice, it must be adulterated. I said to them, "I give you this; you can taste it, and if you afterwards think it is adulterated I will give you another one for a present." I never had to give one away; they always wanted some more. But that was too much trouble, so I put it up in half-gallons and

two-gallons. I have now in my possession letters showing that I could sell over 1500 pounds in Denver to my consumers. The only principle is to deal honestly with the people, and give them a good article, and then try to get as many consumers as you can. That is my experience, and I make the most money in that way. Although some of the bee-keepers here in Denver tell me, "Well, Mr. Krueger, you will have to produce comb honey," I never expect to do so; still, I would not say I may not have to do it by-and-by. I sell some to the grocery people here in Denver. I saw they had honey on the shelves which was adulterated, in nice, white-glass jars, and one of them told me, "I have lost every customer; they don't want to buy that stuff." I said, "Here is a 5-gallon can; put it up to suit yourself;" and to-day he tells me he has all his customers back.

I believe we should try to sell it in as large a pail as we can, and sell it to the grocermen and the home trade. I sold one company about 2500 pounds, and another company 2000 pounds.

Mr. Lovesy—I have introduced on our market a glass jar, but it is a quart jar; I call it a family package. When I commenced to introduce the package on the market in Salt Lake City people told me I couldn't sell it; they wanted those little jelly glasses, and if I had anything larger than that they wanted this size jar—quart Mason. I said I was going to put the quart jar on the market. It was the store-keepers who didn't want it, but I finally got it introduced, and now where I sell one dozen of the small I sell 30 dozen of the quart jars. I sell them for 27½ cents a jar, and they retail for 35 cents; they get more money for their money, they get 3 pounds of honey, and the jar for a nickel. The package helps to sell the honey; the jar is in demand all over the United States—the Mason quart jar—and the consequence is, sometimes I retail 1000 to 1200 pounds of honey by the dozen in Salt Lake City in the quart jar. I sell a few in small jars and a few in jelly glasses, but the quart jar is the package, and the one I sell the most of.

Mr. Cogshall—I will stand by Mr. Aikin in regard to selling honey. There is one thing I want to add to it which will help the everyday sale. In running over the honey wait till it begins to candy a little bit, and then run it; it will make the flavor much better, and granulate much finer.

L. F. Juno—I would like to know how Mr. Krueger gets 75 pounds in a 5-gallon can.

Mr. Krueger—That is all right; that is what it weighs. If you don't believe it come up and I will weigh one for you.

E. Davison—There is a great deal of agitation in regard to distributing our extracted honey, and there is a great deal of agitation in regard to the size and kind of packages which we use. We have two papers in our town, and I have an advertisement in each of them, something like this:

"Wanted.—Gallon syrup-pails in good condition, with lids to fit. We will take some half-gallons."

I pay 5 cents a piece for the gallon, and 3 cents for the half-gallon. There is a great deal of this common syrup used in our section of the country, and I don't find any trouble in getting all of the pails I want in good condition for 5 cents a gallon; and I put up my extracted honey in that shape. I furnish the grocery stores there with these gallon pails at 90 cents a piece, and the half gallons at 45 cents a piece. Where I retail to my customers I sell the gallon pails at \$1.00, and the half-gallons at 50 cents. These gallon syrup pails, as you probably all know, hold less than 12 pounds—probably a fraction over 11 pounds; I put these in the grocery-stores, and I find that the grocery-stores that are handling these in that way are building up a nice trade in extracted honey in that size packages. It is a matter of education. There are two or three grocery-stores in particular that have a good trade; people that want extracted honey go there for it; they know what kind of honey they get, and the kind of package; and nearly all that I sell is in gallon pails, and very few call for half-gallons.

Dr. Miller—The only extracted honey in which I deal is alfalfa honey, so far as the extracted part is concerned, and I prefer it in 5-gallon tin cans; I always dispose of all I get in that form. I buy just as often as I need it a 5-gallon can for use on my own table.

E. Davison—I would say I always put a label on these cans. I have 60-pound cans that I call my storage cans. If any one wishes a 60-pound can I have it. I sometimes sell 60-pound cans to the groceries, and they put it into the Mason jars to suit themselves.

The Sisters Department—Smoker-Fuel.

BY WM. M. WHITNEY.

MR. EDITOR:—I am so glad you have added that Queen-Bee-keeping department to the "Old Reliable." May it expand, and continue to expand, until—no, not till the drones are all crowded out, but until it shall occupy as many pages as the queen occupies frames of comb in the hive!

What a gay time these Queens can have all alone. It does not smack of perverseness to defend one's position with spirit and strenuousness, if logically done, unmixed with irritability. It ought to be one of the most interesting departments—be co-extensive with the life of bee-keeping and that of the Journal.

At times, one might feel like making the acquaintance of some one of those "queens," but my advice is: If you know when you are well off, you'll be careful how you introduce yourself. I don't want both of my eyes swollen shut with puncture from the poison-pointed pen of one of these analytical "queens." I'd fear to approach one of them, though protected with a Globe veil. No, no, I shall admire them at a distance.

Any old drone, who has the temerity to interfere, in the least degree, with the internal arrangement or management of this "hive," is to be pitied. One old fellow has essayed to do something of the kind already, and, from appearances, has been "gone for," with something worse than smoke from salted old rags. He looks as if he had been stung right on the end of his nose. No, no, I'll tell you: *Keep out of that enclosure*, or you'll have a tune hummed to you in "Rag-time," and you'll wish you'd done your buzzing and dancing out in the woodshed, or behind the barn.

Now, Mr. Editor, on this smoke question, allow me just a word—this is for the drones, understand, and for them alone.

Has any one ever tried decayed apple-tree wood? I've tried almost everything from hardwood to saltpetred rags, and nothing suits me so well, unless it be dry, decayed elm-roots. There is none of that black, liquid creosote, dripping all over everything, and making a nasty mess, as is produced by almost every other fuel used. It ignites quickly and, when packed closely, will keep, if the smoker is not in use, for half a day. But this may be another question of *locality*, as we find almost everything else in bee-keeping getting to be. Of course, this may be emphatically a question of locality, for you must be in the neighborhood of an old, decaying orchard to be able to secure the fuel; but I would go some distance to get it or elm root.

Now, remember I've said nothing about chips, nor have I a "chip on my shoulder." Walworth Co., Wis.

Various Methods of Rearing Good Queen-Bees

BY A. C. F. BARTZ.

IHAVE followed the discussion on queen-rearing with more than usual interest, because when such men as Dr. Gallup, Henry Alley, and Mr. Doolittle "take the floor," it becomes interesting to learn what the results may be. At one time during the dispute I had decided to keep still, and it would probably have been the best thing I could do, after all. But after seeing that the victory of the battle is leaning as much one way as the other, excepting the statement on page 596, together with that of Editors Root and Hutchinson taking a stand with Dr. Gallup, I feel encouraged to venture to give a little from my own experience in queen-rearing. And before I make any further statements I would like to have it understood that I do not rear queens for market; so what I intend to say in the following is not intended as free advertising.

Now, then, the statement has been made by Dr. Gallup that really good queens can be reared in strong colonies only, and from embryo queen-cells. Mr. Alley claims the best queen he ever owned was reared in a small nucleus, and advocates the nucleus method as the only right method for queen-rearing. Mr. Doolittle, who, I suppose, is as able

in the business as either Dr. Gallup or Mr. Alley, claims better results by the dipped-cup method; and either one boasted of his own success in producing the best queens; and their articles have a tendency to make us poor honey-producers believe that queens reared by their plans are the only ones good for anything.

I do not blame them for speaking a good word for their own business, but after trying the three different methods in question, I have found out that for the honey-producer the best and cheapest queens can be reared by the Gallup plan. I do not mean to say that every queen reared under the swarming or supersedure impulse is perfect. O, no! But I mean to say if the very best stock is used for the purpose, and an abundance of stores being on hand or supplied, the result will be a success. I will pay \$25.00 to any queen-breeder who can rear a better queen by either the Doolittle or the Alley plan (from either his or my stock, if he so desires) than I can, or the bees themselves, according to the Gallup or natural way. What is the use of talking or writing? The "proof of the pudding lies in the eating." After having bought dozens of queens from different breeders, together with hundreds of colonies of bees, and carefully noting the difference in the amount of honey they gather, I ought to know whereof I speak. And, which is the best queen? Now, I wish to say right here, that it is not color, or any other quality, excepting the amount of honey, and consequently the amount of money received, per colony. I have had colonies of bees gather 8 supers of 28 sections each in one season; and in 1898 I had 38 colonies average 100 pounds of comb honey to the colony, together with doubling their number in increase. How's that for naturally-reared queens?

Now I wish to give the beginner, and those not so much advanced as the professional queen-breeders, a simple method by which they can rear as good a queen as there is in the land. The method is as follows:

Rear a few queens under the swarming impulse—from eight to a dozen of the very best stock you have, marking in your diary or on the number-tag of each queen the number of the mother she was reared from. The following season test as to their honey-gathering qualities, and after having found which ones are the best and most uniform, rear from their mother the supply for your yard as follows:

Early in the spring, if the particular colony in question should for some cause or other not be very strong, make it so. Coax and crowd the colony to start swarming. When the queen-cells are begun in the colony, put a queen-excluding sheet under the entire hive. Now watch for the queen-cells to become ripe, and take out the ripe queen-cells as fast as they become ripe. I have taken as many as 50 queen-cells from a single colony by this plan. More queen-cells will be built if a brood-comb be cut in two lengthwise about half way. The brood-comb should be an old one—a black one if it can be had—as the bees do not like to build it down as they will a new one, but will start a lot of queen-cells on the lower edge. In this way you can keep on rearing queens as long as the colony insists on swarming, and good ones.

Never select a queen for breeding that has simply a large force of bees and 10 or 15 combs of brood, for that is no evidence of her being a good one. The only test that I know of is the amount of honey they have gathered, and if comb honey is desired the whiteness and the plumpness of their sections.

I have had large colonies in the spring like Mr. Doolittle wrote of years ago, that promised to outstrip everything, but proved worthless in the end as honey-gatherers. But the longevity of a queen is an important factor, and Dr. Gallup is right when he says it takes 2 years to test a queen. But for a breeder it takes 3 years; and if the queen should be dead before her daughters are tested, she would be of no use; but if the queens are reared rightly, they will nearly all live 3 years, a good many 4, and a very few five; at least such is my experience.

Of course, I allow my queens to lay to their full capacity, using 40 to 50 combs during the height of the season, and that may have something to do with shortening their lives. I am using the 10-frame Langstroth hive, and have to tier them up 4 and 5 stories high, and I wish now that I had a 12-frame hive, as 5 stories are too high for convenience, and 4 are not high enough to accommodate the most of my queens.

Chippewa Co., Wis.

The Premiums offered this week are well worth working for. Look at them.

Questions and Answers.

CONDUCTED BY

DR. C. C. MILLER, Marengo, Ill.

(The Questions may be mailed to the Bee Journal office, or to Dr. Miller direct, when he will answer them here. Please do not ask the Doctor to send answers by mail.—EDITOR.)

Wintering Bees in a Garret.

My kitchen is one-story, ceiled (not plastered) above. The garret is therefore warm. Would that be a good place in which to winter a few colonies, putting the hives against the wall and cutting a hole so they can fly at will? I have a weak colony (happened to be unfortunate). In this weak colony is a queen that I prize very highly. If I put this colony in the warm garret, with hive or brood-chamber space reduced, will she, or can she, be induced to rear brood there, this month or next? They have plenty of stores.

KENTUCKY.

ANSWERS.—I don't know enough to answer your question. It is barely possibly that bees would winter first-class shape in that garret, but it would be best to try it first on a small scale.

It will be difficult to get that colony to rear brood through November and December, and it would almost certainly be of no advantage if they should. The quieter they can be kept the better.

The Queen's Laying—Brood-Nest Covering for Winter—Langstroth Hive.

1. A queen deposits eggs in worker and drone cells. Does the location of the egg produce a male or female bee? or has the queen the capacity or ability to lay a drone-egg in a drone-cell, and a worker-egg in a worker-cell?

2. What is the best covering for the brood-nest in winter, a cloth or thin board?

3. A queen lays two eggs. One hatches a worker-bee, the other a drone. Now, the bees make a queen of the worker-egg, and she is fertilized by the drone—her brother. Will their stock be as good as if the queen and drone had come from different stock?

4. Are the Langstroth hive and frame as good as others?

KENTUCKY.

ANSWERS.—1. I don't know. Opinions are divided. Some think there is volition on the part of the queen, and some think there is some kind of mechanical compression or something of the sort that obliges the queen to lay in each cell the appropriate egg.

2. For outdoors it is generally believed that it is better to use the cloth so as to allow of upward ventilation. For the cellar it makes little or no difference if everything is open enough below.

3. The general answer will be "No."

4. That depends on what is meant by Langstroth hive and frame. One answer to the question is that there is no better, for every movable-frame hive is a Langstroth.

Cellar-Wintering—Robbing and the Robbed.

1. I have kept bees for 5 years, and I now have about 20 colonies. I winter them in the cellar, where the temperature is from 40 to 45 degrees. It is a good cellar to winter bees in, but this year I have 2 colonies that are very short of stores. How will it do to put a super on each of them with ten pounds of honey? This honey is stored in pound boxes.

2. How can I see that the bees are robbing? And how can I see when they are robbed?

MINNESOTA.

ANSWERS.—1. It will be all right if you are sure the bees will reach the honey. The danger is that that they will remain on the combs and starve with the honey out of reach above them. Indeed, they will be pretty sure to do so if they do not carry the honey down before being taken into the cellar. You might put the sections in frames, and then put the frames of sections in the hive close up to the bees. If eight of the sections will not go in a brood-frame, cut

away one or two sides from some of the sections until they will go in.

2. You cannot tell by appearances; indeed, it is seldom that you can tell from appearances that a colony is robbing. It merely looks like a colony working very busily. But if you see one colony working very busily when others seem idle, you may suspect that the busy colony is being robbed or is robbing some other colony. It is easier to tell the colony that is being robbed. If you find bees flying very busily at a hive, especially if you know that the colony is weak, and you know it is not a time when bees are storing rapidly, you may be tolerably sure mischief is going on. Catch and kill a bee coming out, and one going in. If it is a case of robbing, you will find the bee coming out filled with honey, and the one going in will be empty.

Producing Extracted Honey.

Kansas is not a great honey-State, and the past season has been a hard one on the bees—too cold and wet. I have kept bees for four years, and they have stored a little surplus every year. I have run for comb honey altogether, so far. I have at this time (Nov. 3) 28 colonies, having started in the spring with 19 colonies, good, bad and indifferent, and took off between 900 and 1000 sections. I get 12½ cents a piece for them.

1. I use the 8-frame hive, and think some of running part of my bees for extracted honey. Is that size large enough?

2. Will I have to wire all my combs?

3. Is there an extractor made that will give satisfaction with section honey?

I have taken the Bee Journal for two years, and read it with interest. While there are a good many things written that are hard for us beginners to understand, yet enough is written to help us on the right track; and then experience is the best teacher, anyway.

KANSAS.

ANSWERS.—1. It is quite possible you might be better pleased with a larger hive, but you can make the 8-frame very large by additional stories.

2. Combs were used for extracting before wired combs were heard of; but while combs are new great care must be used in extracting if they are not wired.

3. Probably any extractor can do the work of extracting sections by using in it wire-cloth pockets to hold the sections. But it is a fussy job, at best, to extract sections.

Queens Not Successfully Introduced.

I am not pleased with a queen that came late in August. I introduced her according to instructions on the cage, to a colony that had been queenless and without brood two or three weeks. After four or five days I examined, but failed to find the queen. The colony still remains queenless and without brood. Can you account for her non-acceptance?

UTAH.

ANSWER.—Hard to tell. None of the ordinary methods of introducing queens is infallible, and the safe introduction of queens is still an unsettled question. A plan may succeed ninety-nine times and fail the hundredth time, and yet no one can say why the hundredth time should be any different. It is barely possible that in spite of your not finding the queen she may still be present. Sometimes a queen will be in a hive a good many days before beginning to lay, and sometimes queens stop laying in September, and not very late in September, either. So the queen may be still there, waiting to lay next spring. The colony had been "queenless and without brood two or three weeks." Sometimes when queenless so long they become reconciled to their condition, and when a queen is offered they will have none of her. It is just possible that a young queen was reared in the hive, causing the death of the queen introduced, the young queen being afterwards lost on her wedding-tour.

Other guesses might be made, but I may as well own up first as last that I don't know why the queen was not successfully introduced.

Queenie Jeanette is the title of a pretty song in sheet music size, written by J. C. Wallenmeyer, a musical keeper. The regular price is 40 cents, but to close out the copies we have left, we will mail them at 20 cents each, as long as they last.

* The Afterthought. *

The "Old Reliable" seen through New and Unreliable Glasses.
By E. E. HASTY, Sta. B Rural, Toledo, O.

.6380, .6381, .6382, .6383.

The above, and the six numerals next in succession, stand for the different departments of apiculture, it seems. (Interjections from the boys.) Also, .63833 and .63834 stand for more minutely subdivided apicultural things. If we only go far enough we can find *ourselves*—instead of losing ourselves, as those who wander far are apt to do. Mayhap, about .63839876543210 will prove to be this here "Afterthought" of ours. "Amazin'!"

But, really, my mind has not had such a stirring up for quite awhile as it got by contemplating this simple scheme for putting absolutely everything into its own numbered pigeon-hole. I thank Mr. C. P. Dadant for bringing it to our attention. Both advantages and objections seem rather obvious. Very desirable that classification and subdivision should be the *best* possible, and an iron-clad rule to make just ten parts every time could rather seldom be exactly the best. Awkward to divide a clover leaf into ten parts, and simple to divide it into three. As a first division of all human thought, effort and knowledge, I should be for making nearer fifty items than ten.

Moreover, I think this can be done and will leave the advantages of the system intact. One foundation idea of the system seems to be that decimals can always be added to without affecting the value of previous figures. Adding two figures to simple five makes it five thousand, and we have to think of the great increase in value. That's an irrelevant idea in this use of figures, and it does not trouble so much on the other side of the decimal point. But putting the *first* division on the left of the decimal point does not bring in the difficult—and thereby we can have as many divisions as we want the first time. So doing we can leave some blanks (after the manner of numbering houses on a street) in which the world's future thought can have space to work without so completely abolishing our work. Let me illustrate my scheme, not having seen the other one.

A. Things pertaining in whole or in part to the soul of man.

- | | |
|------------------|---------------------|
| 1. Religion. | 4. Soul Philosophy. |
| 2. Evangelism. | 5. Music. |
| 3. Philanthropy. | |

Then five blanks left, and continuing—

B. Things most properly pertaining to the mind of man.

- | | |
|------------------------|------------------|
| 11. Mental Philosophy. | 16. Rhetoric. |
| 12. Languages. | 17. Mathematics. |
| 13. Literature. | 18. Astronomy. |
| 14. History. | 19. Geology. |
| 15. Logic. | 20. Cosmogony. |

And a big lot more. Then many blanks left, and continuing—

C. Things pertaining for the most part to the body of man.

- | | |
|-------------------|----------------------|
| 101. Medicine. | 106. Mining. |
| 102. Athletics. | 107. Engineering. |
| 103. Agriculture. | 108. Transportation. |
| 104. Hunting. | 109. Navigation. |
| 105. Fishing. | 110. Defense. |

And a lot more. Thus we get Apiculture as (103.8) instead of (.638).

Coming to our own corner, I suspect that those who look upon Apiculture mainly as a science will refuse to be pleased with any classification which satisfies those who consider it mainly as a means of getting a living—and vice versa.

I fear a similar trouble will go through pretty much the whole thing. Spiritually-inclined man will say that of *course* things pertaining to the soul must have the most prominent spread. Scientifically-inclined man will say that of course the sciences must have a raging lion's share of the whole view. Bread-and-butter man will want both spiritual and scientific things crowded into small and inconspicuous corners, that the general landscape may be filled with things "practical," as he would term it.

Also, so many things have a bearing on work-a-day affairs, too, that the pigeon-holing of the same thing in two places will be dreadful. Page 647.

SCRAPING SECTIONS OF HONEY.

Twelve hundred sections a pretty good day's work scraping honey with a knife. We should say so, Miss Wilson. Somebody, some time, will want to define a standard day's work at scraping honey. For the present we will let this be it. Possibly some of the brethren will call it nearer the "record" than the "standard," as it is one for each half minute of the ten-hour day.

And if your arrangements allow the bees to get at the section-bottoms, and if you are willing to sandpaper, then Miss Wilson's tightening-up frame, to facilitate sandpapering a whole super at once, is evidently very valuable.

As a matter of experience—with small crops—I scrape my sections a few at a time, and find myself looking forward to it as restful work instead of shuddering at it. I must confess, however, that it is dirty. Perhaps the grand key to this difference is the fact that bees can't get at my sections anywhere except on the edges. Page 647.

NURSE-BEES AND ADOPTED BROOD.

Not mentioned in print before—that's the kind of thing readers cry for. This time it is the alleged fact that nurse-bees will stay a little more faithfully with recently adopted brood than with their own. This when making nuclei. Unexpected. Both "Ohio" and Dr. Miller agree that it is so. Here's my guess: Want-to-be nurses and the bees below crowd them off and will not let them, because they are not needed. Having just got a longed-for job they naturally incline to stick to it. Page 650.

BUCKEYE—ROBBER-BEES—VIRGIN QUEENS—SWEET CLOVER—HEARTSEASE.

Buckeye is abundant here, and much visited in bloom-time; but I never saw or heard of any ill from it. Have my eyes been dull? or has California a more poisonous species than ours? or is Mr. Brown mistaken? Page 651.

Spoil the welcome of quiet robbers by scenting them with something sprayed on them. Shouldn't wonder if that would work sometimes. Page 652.

Interesting experience of Dr. W. A. Johnson. Very young virgins will very often supersede old queens by merely running them in as soon as they emerge. Page 653.

Aha! Sweet clover has (in Mississippi) learned to grow in competition with weeds and grasses, without requiring the grinding of wheels or trampling of stock. And this within the last two years. Page 655.

Have often wondered why our abundant heartsease should be of so little value to us when it is so often mentioned as important. Another case of longitude. Like alfalfa it leaves its honey when it comes this side the Mississippi. Page 659.

Honey as a Health-Food is the name of a 16-page leaflet (3½x6 inches) which is designed to help increase the demand and sale of honey. The first part is devoted to a consideration of "Honey as Food," written by Dr. C. C. Miller. The last part contains "Honey-Cooking Recipes" and "Remedies Using Honey." It should be widely circulated by every one who has honey for sale. It is almost certain to make good customers for honey. We know, for we are using it ourselves.

PRICES, prepaid—Sample for 2 cts.; 10 for 10 cts.; 25 for 20 cts.; 50 for 35 cts.; 100 for 60 cts.; 250 for \$1.25; 500 for \$2.25; 1000 for \$4.00. If you wish your business card printed at the bottom of the front page, add 25 cts. to your order.

"The Hum of the Bees in the Apple-Tree Bloom" is the name of the finest bee-keeper's song—words by Hon. Eugene Secor and music by Dr. C. C. Miller. This is thought by some to be the best bee-song yet written by Mr. Secor and Dr. Miller. It is, indeed, a "hummer." We can furnish a single copy of it postpaid, for 10 cents, or 3 copies for 25 cents. Or, we will mail a half-dozen copies of it for sending us one new yearly subscription to the American Bee Journal at \$1.00.

Please send us Names of Bee-Keepers who do not now get the American Bee Journal, and we will send them sample copies. Then you can very likely afterward get them subscriptions, for which work we offer valuable premiums in nearly every number of this journal. You can aid much by sending in the names and addresses when writing us on other matters.

Our Bee-Keeping Sisters

Conducted by EMMA M. WILSON, Marengo, Ill.

Late Strawberries.

November 12 I picked nearly two quarts of large, ripe strawberries, and we had strawberry short-cake for dinner. Isn't that doing pretty well for McHenry Co., Ill.?

When to Put Bees into the Cellar.

When shall I put my bees into the cellar? This is my first year of bee-keeping, and I want to put them in at just the right time, but I don't know what the right time is.

BEGINNER.

ANSWER.—Just as long as the weather is pleasant, and there is a chance of your bees having a flight occasionally, they are better out-of-doors.

In regions where it is cold enough to make cellar-wintering desirable, it is well to leave the bees out until settled cold weather comes. It is very difficult to tell just when is the right time to put them in. The temperature may go down to zero, and if it is early in the season, and there is a reasonable chance for their having a good flight later, better leave them out. On the other hand, if it is the middle of November, and the bees have had a good flight within a day or two, and it comes a cold snap, better not take many chances. That last good flight just before they go in is what we want to make sure of, and we may reasonably expect settled cold weather soon after the middle of November. If possible, it is best to put them in the very day after they have had a good flight.

Put it down as a fixed rule that it is always the right time to put bees in just after they have had their last flight; but the trouble is to know which is going to be their last flight.

Sweetening Up Sour Honey.

Four kegs of last year's fine, white honey have soured. Will heating up sweeten it? If not, what will? They are a mild case of it? A prescription for use will greatly oblige.

NEW YORK.

ANSWER.—Being a mild case, heating up may do some good, but great care would be required in not heating too much, as the flavor would be spoiled. Slow and long heating is best, setting on the reservoir of the cook-stove, or some place where it would heat very slowly, during several days.

It might be a good thing to skim or pour off the top, as that is probably the worst, and treat separately.

Perhaps the best way would be to let it candy, then drain, and the thin part will all drain off, and after heating what is left you will no doubt have some very good honey. The thin part which is drained off you can use for vinegar. If too bad to candy and drain, the whole of it might be used for vinegar. Or, as it is a mild case, the whole of it might be used for cooking purposes, always supposing you can dispose of it to some baker who uses a good deal.

A Silver-Spoon Swarm.

There has been no need for us to invoke Jupiter Pluvius, for rain we had in plenty, and not only rain, but sometimes thunder and lightnings too genuine to be mistaken for Salmoneus driving his chariot over his brazen bridge and throwing down lighted torches. During these manifestations of Jupiter, the bees necessarily stayed at home, and as we learn from Indiana papers, the heavy rains, and the limited supply of white clover caused by last summer's drouth, have both combined to make the honey crop short this year in Indiana.

As regards my own bees, I have but one colony, for never having kept bees until this year, I thought it best to confine my experiences to a single hive, until profiting by what lessons I learn, I can perhaps one day realize my vision of a long bee-bench occupied with colonies, whose homes fairly overflowing with their luxurious sweetness, might

well rival the palace of Madame Tartine and her family, that is described in such appetizing verse in La Mere L'Oie.

One remembers the old adage—

"A swarm in May
Is worth a load of hay;
A swarm in June
Is worth a silver spoon;
But the swarm of July
Isn't worth a fly."

My own belongs to the silver-spoon class, so I could not expect much, if, indeed, anything, in the way of surplus honey. No, not a drop of honey by way of tribute, or to pay for a silver spoon, was ever taken upstairs, but downstairs investigation shows that they have collected sufficient food for their winter provision.

Then, besides, my colony was occasionally visited by small bands of robber-bees. I do not know what Hippolyta was doing during the sieges, but I know that her Amazons fought bravely, and were victorious. I had an anti-robbing entrance made according to Cheshire's device, and it proved the most effectual of all my plans to aid the bees. Bold, indeed, must be that bandit bee or wax-moth which would thread that narrow and crooked passage! Alert, indeed, are the sentinels stationed at those corners to meet the daring foe!

Therefore, taking into consideration the disadvantages resulting from a late swarm, robbers, wet weather, and the cornucopia not overflowing, the owner of this colony has no cause to be dissatisfied if the bees failed to bring her a silver spoon; and, if on account of empty supers, the commercial honey-king sits in the parlor without money, let us hope, at least, that the blessed queen-bee is in the kitchen eating bread and honey from out of numberless silver spoons brimful and running over!

One can build hives in the air as well as castles, so I have visions of hives and honey, of prime swarms and after-swarms, of flowers and of bees. But so have we all visions of summers to come, when the visible delights of flower and bee will make us say with Zonas the Sardinian:

"Ye nimble honey-making bees, the flowers are in their prime;
Come, now, and taste the little buds of sweetly breathing thyme;
Of tender poppies all so fair, or bits of raisin sweet,
Or down that decks the apple-tribe, or fragrant violet;
Come, nibble on—your vessels store with honey while you can,
In order that the hive-protecting, bee-preserving Pan
May have a tasting for himself, and that the hand so rude
That cuts away the comb, may leave yourselves some little food."

KATE V. AUSTIN.

Wayne Co., Ind., Sept. N.

What Yon Yonson Thinks

Well, Peter Peterson he com over das dinner time, an das veder bean awful fine an varu, an dom bees dom bean flying som hunding for somdings eider sweet or green. Bees Wanted on Shares.

HAVE YOU IDLE CAPITAL?

We are owners of 1000 colonies of bees, and want 1000 more to run on shares. We have the best location in the best part of Texas, and will give as references H. W. Wiseman & Co., Bankers, Paul Neubauer, P.M., or any responsible business firm of Floresville or Hutto, Texas. We have the best assistants we can procure, and have been in the business since 1893. We have heavy fall rains, and next year will be a big one for honey. If you have as many as 250 colonies of bees, ship them to us, pay the cost of location, and supply us the necessary equipment for honey production, and we will give them all the necessary attention, and give you one-half the honey. Bees must be all in either 8 or 10 frame Dovetailed or Langstroth hives. Let us explain to you more fully; therefore, we solicit your correspondence.

advocating the name of a jounced swarm; or before Von Yonson Gallups up the Alley, Bent-on expressing himself in his Swedorgen-Limbergerburg excruciatingly funny expressions, I must retire from the platform of argument, and "go back and sit down" among the small fry, and fold my arms over my palpitating heart, while big men, with big capacities and big ideas, harangue and argue over the momentous question whether the swarm is brish, brash, or brushed; shick, shack, or shaken; jim, jammed or jounced.

Now, I thank you for your forbearance with my nonsense, and will say with the patriarchs of old, "Let er go; let 'em have it."

I will now crawl back into my little cell, until disturbed again. SHAKER.

BEST Extracted Honey For Sale

ALL IN 60-POUND TIN CANS.

Alfalfa Honey

This is the famous White Extracted Honey gathered in the great Alfalfa regions of the Central West. It is a splendid honey, and nearly everybody who cares to eat honey at all can't get enough of the Alfalfa extracted.

Basswood Honey

This is the well-known light-colored honey gathered from the rich, nectar-laden basswood blossoms. It has a stronger flavor than Alfalfa, and is preferred by those who like a distinct flavor in their honey.

Write for Quantity Prices by Freight, if Interested.

A sample of either, by mail, 10 cents, to pay for package and postage.

Order the Above Honey and then Sell It.

We would suggest that those bee-keepers who did not produce enough honey for their home demand this year, just order some of the above, and sell it. And others, who want to earn some money, can get this honey and work up a demand for it almost anywhere.

GEORGE W. YORK & CO., 144 & 146 Erie St., Chicago, Ill.

reared in queenless colonies are reared by Nature's best plan," etc. I do not write to oppose Mr. Alley or any one else, but I do want to say that whenever I rear queens in queenless colonies I get the poorest queens, and I consider those colonies *forced* to rear queens and far from Nature's way of rearing them. Nature makes arrangements for young queens before the old queen departs (except in case of accident). When Nature has not been thwarted by man, but rightly assisted, good queens are the results, with a fertile queen at liberty and laying in the hive.

I wonder if my article on page 268 (1900) was the start of this commotion on rearing long-lived bees. Dr. Gallup is on the line for the production of the best queens, yet he admits he does not know all. Again, on page 519, Mr. Alley says: "I have found by actual experiments that a colony of bees will not rear good queens while there is a fertile queen present. I don't want anyone to tell me it can be done, for I assert that it cannot be done by any person," etc. Well, well, I might assert it can be done *by the bees*, but not by "any person." I have demonstrated this to be the only way I can depend on getting good queens, and when conditions are right, in perfect harmony with Nature.

Lucas Co., Iowa. GEO. W. RIKER.

Had to Feed All Summer.

I have 40 colonies of bees, and I had to feed them all summer; it was so cold and rainy that the bees could not get much chance to work. I took off 1800 pounds of fine basswood honey, all in one-pound boxes.

Lycoming Co., Pa. T. S. APKER.

CONVENTION NOTICE.

Chicago - Northwestern. — The executive committee of the Chicago-Northwestern Beekeepers' Association have planned to hold the best convention ever convened in Chicago. HONEY AND BEESWAX MARKET QUOTATIONS.

CHICAGO, Nov. 19.—A slow, steady market may be said of conditions now prevailing in Chicago. The volume of sales are small, and the receipts are correspondingly so. 15@16c is obtained for best lots of white comb in a jobbing way, while for selections a little more is asked; amber grades, 10@15c, according to flavor, style, etc. Extracted, white, 7@8c; amber, 6@7c. Beeswax, 30c on arrival.

R. A. BURNETT & Co.

ALBANY, N. Y., Nov. 9.—Good demand for honey at former prices. Fancy white comb, 16c; A No. 1, 15@16c; No. 1, 15@15½c; buckwheat, 14@14½c. Extracted, light, 7@7½c; mixed, 6½@7c; buckwheat, 6½c. Beeswax, 30c.

H. R. WRIGHT.

BOSTON, Oct. 20.—Our honey market remains firm, with good demand and fair stocks on hand. Honey is not coming forward as fast as usual, and the tendency of prices is steady. We quote our market as follows: Fancy white 1-pound sections in cartons, 16c; No. 1, 15c; No. 2, very light supply, 14c; glass-front sections generally one cent less than this. Extracted, light amber, 8c; amber, 7½c.

BLAKE, SCOTT & LEE.

KANSAS CITY, Nov. 22.—We quote fancy white comb honey, per case 24 sections, \$3.50; No. 1 white, per case 24 sections, \$3.40; No. 2 white and amber, per case of 24 sections, \$3.25. Extracted, white, per pound, 7½c; amber, 6½c. Beeswax, 27@30c.

Our market has changed quotations of comb honey from pound to the case.

C. C. CLEMONS & Co.

CINCINNATI, Nov. 8.—There is a good demand for all grades of extracted honey, prices ranging as follows: Amber and Southern in barrels, 5½@6½c; clover and basswood, 7@8c. Fancy comb sells 16@17c. Beeswax, 27c.

THE FRED W. MUTH CO.

NEW YORK, Nov. 8.—Demand for comb honey is good and same finds ready sale at from 15@16c for fancy white, 14c for No. 1 white, 12@13c for No. 2 white, and 12@13c for buckwheat. Extracted in fair demand at 7½c for white, 6½c for light amber, and 6c for dark. Southern in barrels from 60@65c per gallon. Beeswax quiet at from 27@28c.

HILDRETH & SEBELKEN.

CINCINNATI, Nov. 18.—The demand for comb honey is good and prices are a little better, as the supply does not meet the wants. Extra water-white fancy is selling as high as 16 cents; other grades less, according to quality. Extracted is very active and prices are a little better; amber, 5½@5¾c; alfalfa, 6½@7½c; white clover, 7½@8c. Beeswax, 28c.

C. H. W. WEBER.

SAN FRANCISCO, Nov. 12.—White comb honey, 10½@11 cents; amber, 9@10c; dark, 5@—c. Extracted, white, 6@6½c; light amber, 4¾@5½c; amber, 3½@4c. Beeswax, good to choice, light, 26@27c; strictly fancy light, 29@—.

White is reported scarce; light amber honey in fair supply. The bulk of California produced honey is sold for Eastern shipment in carload lots from producing point at bottom price. Small lots of choice honey that can be used in local trade bring more. Quotations here given are current prices to producer, f.o.b. shipping point, on Eastern basis for extracted and California basis for comb.

BEE-KEEPERS,

Save Money by Buying

Hives, Sections, Brood Frames, Extractors, Smokers, AND EVERYTHING ELSE YOU NEED, OF

THE W. T. FALCONER MFG. CO.,
Jamestown, N. Y.

Our goods are guaranteed of superior quality in every way. Send for our large illustrated catalog, and copy of

THE AMERICAN BEE-KEEPER,

a monthly for all bee-keepers; 50c a year. (Now in 12th year. H. E. HILL, Editor.)

W. M. GERRISH, E. Nottingham, N. H., carries a full line of our goods at catalog prices. Order of him and save freight.

Please mention Bee Journal when writing

Tip-Top Glass Honey-Jars

The picture shown herewith represents the best one-pound jar for honey that we know of. It is made of the clearest flint glass, and when filled with honey, and a neat label attached, it makes as handsome a package as can be imagined. Its glass top sets on a flat rubber ring, and is held in place by a flat steel spring across the top as shown in the picture. It is practically air-tight, thus permitting no leak,

which is an important thing with honey-sellers.

We can furnish these jars, f.o.b. Chicago, at these prices: One gross, \$5.00; two gross, \$4.75 a gross; five or more gross \$4.50 per gross.

If you try them once you will likely use no other kind of top or sealing arrangement for honey jars.

GEORGE W. YORK & CO.

144 & 146 Erie Street, CHICAGO, ILL.

\$300,000,000.00 A YEAR

and you may have part of it if you work for us. Uncle Sam's poultry product pays that sum. Send 10c for samples and particulars. We furnish capital to start you in business. **Draper Publishing Co., Chicago, Ill.**

DADANT & SON,
Hamilton, Hancock Co., Ill.

THE HERSHISER HONEY-JARS.

These jars were designed for use in the honey exhibit at the Pau-American Exposition, in Buffalo, and are very neat and attractive. They have cork-lined aluminum caps which seal them tight. If honey is sealed in these jars while hot there will be no annoyance from granulation.

For exhibition purposes and a fancy trade nothing on the market compares with these jars. Put up your honey in a neat, attractive package, and sell it at a good price.

The fact that the molds are constructed for making the jars by hand instead of by machine, and the addition of the aluminum caps, make the jars somewhat more expensive than the ordinary jars. They are made in four sizes square and three sizes round, as shown in the illustration. We can supply them either from Medina or from Philadelphia at the following prices:

1/4 pound Square Hershiser Jars, doz., 50c; \$5.40 per gross.	1/4 pound Square Hershiser Jars, doz., 55c; \$6.00 per gross.
1 pound Square Hershiser Jars, Dozen, 80 cents; \$ 9.00 per gross	Dozen, \$1.00; 10.80 per gross
1/2 pound Square Hershiser Jars, Dozen, 60 cents; \$ 6.60 per gross	Dozen, 75 cents; \$ 8.40 per gross
1 pound Round Hershiser Jars, Dozen, \$1.10; 12.00 per gross	

These prices, although rather high in comparison with other jars, are as low as can be made on hand-made jars, and afford us a smaller margin of profit than other styles. Order a sample dozen of each size and be convinced.

EUGENE SECOR, General Manager and Treasurer, Forest City, Iowa.

MEMBERSHIP DUES, \$1.00 a year.

If more convenient, Dues may be sent to the office of the American Bee Journal, when they will be forwarded to Mr. Secor, who will mail individual receipts.

A Celluloid Queen-Button is a very pretty thing for a bee-keeper or honey-seller to wear on his coat-lapel. It often serves to introduce the subject of honey, and frequently leads to a sale.

NOTE.—One reader writes: "I have every reason to believe that it would be a very good idea for every bee-keeper to wear one [of the buttons] as it will cause people to ask

questions about the busy bee, and many a conversation thus started would wind up with the sale of more or less honey; at any rate it would give the bee-keeper a superior opportunity to enlighten many a person in regard to honey and bees."

The picture shown herewith is a reproduction of a motto queen-button that we are furnishing to bee-keepers. It has a pin on the underside to fasten it.

Price, by mail, 6 cents; two for 10 cents, or 6 for 25 cents. Send all orders to the office of the American Bee Journal.

Forty Years Among the Bees

By DR. C. C. MILLER.

DR. C. C. MILLER.

The above is the title, and name of the author, of a new bee-book which will be ready some time in January, 1903, as it is now in the hands of the printers. It is a book that every bee-keeper in the world that can read English will want to own and read. It will contain over 300 pages, be bound in handsome cloth, printed on good book-paper, and illustrated with over 100 beautiful original half-tone pictures, taken by Dr. Miller himself. The book will show in detail how Dr. Miller does things with bees.

The first few pages of the new book are devoted to an interesting biographical sketch of Dr. Miller, which finally tells how he happened to get into bee-keeping. Seventeen years ago he wrote a small book, called, "A Year Among the Bees," but that little work has been out of print for a number of years. While some of the matter used in the former book is found in the new one, it all reads like a good new story of successful bee-keeping by one of the masters.

How to Get a copy of Dr. Miller's "Forty Years Among the Bees."

The price of this new book is \$1.00, post-paid; or, if taken with the WEEKLY American Bee Journal for one year, BOTH will be sent for \$1.75.

Or, any present regular subscriber to the American Bee Journal whose subscription is paid in advance, can have a copy of Dr. Miller's new book *free as a premium* for sending us **Two New Subscribers** to the Bee Journal for one year with \$2.00. This is a magnificent offer. Better send in the new subscriptions before Jan. 1, so they can begin with the new year. Or, if sent at once, we will throw in the rest of this year's numbers of the Bee Journal free to the new subscribers.

* Editorial Comments. *

Non-Swarming Bees.—Few things have advanced so rapidly in general favor as forced swarming by shaking or brushing. A good many seem to regard it as the Ultima Thule, resting content to seek nothing further. Others, while yielding no whit in their appreciation of the value of forced swarming, will still continue to attach importance to the encouragement of non-swarmling tendencies in bees, or rather to the repression of swarming tendencies. In a paper at the Denver convention, W. L. Porter said that in running out-apiarles one of the two important things to be considered was "that a stock of bees may be carefully bred which is not predisposed to swarm."

It is entirely possible that forced swarming itself will tend in the direction of breeding out the swarming tendency, but there should be no let-up in the selection of the best stock in breeding, and one of the characteristics of best stock should continue to be considered freedom from a tendency to excessive swarming. Forced swarming is a long step in advance over natural swarming, but it is well that there are those who do not consider it the final good.

Must Bee-Cellars Be Dark?—The general teaching has been that absolute darkness was a matter of first importance. A few, however, have testified that at times the full light of day might be allowed to shine into the cellar without harmful results. The Canadian Bee Journal gives the testimony of quite a number to this effect, some holding that up to February darkness is not essential, but that later it is important.

The truth probably is, that the matter is entirely dependent upon conditions, the time having nothing to do with it only as the change of time brings a change of conditions. Note a colony of bees upon its stand in the apiary. When a day comes so cool that the thermometer does not rise above 45 degrees, the bees do not offer to stir out of the hive all day long, even though the bright sun shines directly into the entrance. Why should they any more fly out at the same temperature in the cellar?

There are two answers to the question. First, the quality of the air. Outdoors it is always pure, in the cellar not always. Second, the overloaded condition of the bees' intestines. Outdoors the bees have had frequent opportunities for flight; not so in the cellar. Let the bees be confined to their hives when outdoors a sufficient length of time to have their intestines loaded, and they will fly out at a much lower temperature than if they had had a flight the previous day.

But why discuss the question? Why not keep on the safe side and keep the cellar always dark? Just because it is quite possible, if not probable, that the safer side may be

to let light into the cellar when conditions allow. Darkness continued is not a good thing for the health of man or beast, and it may not be for bee. When bees are first put into the cellar, it often happens that for days the cellar may be left open day and night without the bees flying out, and so long as the temperature does not run down below 45 degrees, and the bees show no disposition to fly out, it is pretty sure that the light and the fresh air will do good and not harm. Let a little watch be kept, and if the bees begin to fly out in the bright sunshine, then close the cellar, only to open it again as soon as darkness comes on to keep them in, or rather, when the brightness of the day begins to fade in the afternoon.

Especially is it important to open up the cellar when warm spells come in winter or early spring. The warm, light air outside will not force itself by its weight through the crevices of the cellar-wall as will colder air, so at such a time the air of the cellar becomes foul. Open it in daytime, and the bees will rush out of the hives. But open it when darkness falls, and let it remain through the night, so that the cellar may be filled with fresh, pure air, and the bees will remain quietly in the hives for some time after it becomes light in the morning. As soon as the bees begin to fly out close up the cellar, only to open it again in the evening if it is warm enough.

Instead of continuous darkness, the desideratum may be light whenever it will be endured, and fresh air which will be endured at all times.

Knife vs. Scissors for Clipping Queens.—Our genial afterthinker suggests on page 746 that some leaving-out-Hamlet business had been going on at page 643, his idea being that the chief objection to the use of scissors was the danger of cutting off a queen's leg. It had not occurred to us that there was any serious danger in that direction, and a note from one of the veterans who has clipped hundreds of queens—yes, probably thousands—shows that "there are others" who have never thought of any special danger from leg-clipping. Here is what Dr. Miller says:

"Has not our friend who takes the forethought to prepare us so delightful a feast in the way of afterthought, struck a new thing when he suggests that the principal objection to clipping with scissors is the danger of maiming the queen? I think Mr. Doolittle has been the leading advocate of the knife, and if he has ever suggested that maiming was likely to occur with scissors, he has certainly not made it the prominent objection. I'm not sure that I ever saw the objection raised before. I think there would be no excuse except extreme carelessness for taking off a queen's leg with the scissors. I have been clipping for a great many years, and I think in all that time I took off a leg for just one queen. That merely proves that I am not as careful as I should be, for there is never any need to make the cut until the scissors and legs are in such a relative position that there is no possible danger. Neither would it be such a terrible thing to take off a leg. I have had quite a number of queens that were born minus a leg, which, nevertheless, did excellent work."

The danger of making five-legged queens having now been brought prominently to the front, it may be left to

Messrs. Hasty, Doolittle, and Miller to fight out the case on its merits, suggesting that each bee-keeper be allowed to try a few thousand queens each way, and then pursue the plan that gave him the smallest number of amputations.

“Two Defects of Bee-Literature” is the caption of a thoughtful article in the Progressive Bee-Keeper, written by F. L. Thompson. One of the defects is the lack in bee-papers of an index sufficiently full and of a character to allow the reader easily to find that for which he is seeking. The other is the lack of a digest of the things of value to be found in other bee-papers. Mr. Thompson gives pretty full instruction as to how this should be done, and, indeed, does this so well that one is led to think, “Well, Mr. Thompson is just the man to do this work,” when Mr. Thompson dashes all hope in that direction by saying:

“I should not care to undertake it unless I were an editor myself, for the pay would be sure to be inadequate; and if I were an editor myself, I would not care to hire it done, for then it would be almost certain to be done inadequately.”

But excellent editorial work is done on our dailies and other periodicals by editors who are employed to do special editorial work, and if a man were employed to edit a department giving a digest of matters contained in other papers, why would he not be the editor of that department?

The task, however, that Mr. Thompson sets for the one undertaking such a compilation is a difficult one. He says:

“Absolutely everything that is of any value to bee-keepers at large must be included, and fairly set forth whether the compiler thinks it of any value or not; he must, for the time being, see things from everybody’s point of view.”

He must include everything of value, whether he thinks it of value or not. How is he to know it is of value, if he does not think it of value? How can he “see things from everybody’s point of view?” A hard task, indeed.

* The Weekly Budget. *

MR. F. A. SNELL, of Carroll Co., Ill., gave us a brief call when in Chicago, last week. Mr. Snell is one of the oldest readers of the American Bee Journal, having begun in 1866, and is still at it. And he seems to be as much interested as ever, too.

JOHN M. RANKIN resigned his position as foul brood inspector of Michigan, to accept a more lucrative position in a sugar-factory. It is a great pity that a young man of such fine ability should be lost to the interests of bee-keeping. Very likely, however, he may be found drifting backward again.

MR. FRANK B. WHITE, our capable advertising manager, we notice is on the program of the Minnesota State Horticultural Meeting, which meets Dec. 2, 3, 4 and 5, in Plymouth Church, corner 8th and Nicollet Aves., Minneapolis. Mr. White’s subject is, “Practical Advertising for the Fruit-Grower.” He will give his hearers something good. He always does.

MR. D. W. WORKING, of Denver, Colo., who did so much toward making the last National convention a success, spent a few days in Chicago recently. It is a pleasure to know Mr. W. But you can’t get acquainted with him all at once. It takes time, and several times, at that. We regretted that he could not be here at the Chicago-Northwest-

ern convention this week. He was secretary of the Colorado State Bee-Keepers’ Association for nearly two years, his term of office expiring last September.

ILLINOIS STATE ASSOCIATION.—The officers elected at the 12th annual meeting of the Illinois State Bee-Keepers’ Association, held at Springfield, Nov. 18 and 19, are as follows:

President, J. Q. Smith. Vice-Presidents: 1st, Miss L. C. Kennedy; 2d, S. N. Black; 3d, S. T. Crim; 4th, Geo. Poindexter; 5th, P. J. England. Secretary, Jas. A. Stone, Route 4, Springfield. Treasurer, Chas. Becker.

Secretary Stone reports the usual attendance and good time.

Biographical.

DR. A. B. MASON.

Nov. 20 we announced the sad news of the death of Dr. A. B. Mason by an explosion of natural gas that had escaped from the stove in the kitchen, whither he had gone, on Oct. 30, with a lighted lamp. The burns and shock to his nervous system resulted in his death on Nov. 12, and he was buried on Nov. 14.

We had known Dr. Mason for nearly 20 years, and quite intimately for over 10 years. While the writer was for two years President of the National Bee-Keepers’ Association Dr. Mason was Secretary, and we planned the two annual programs together without a ripple. And when we were elected as his successor at Denver, in September, he referred very kindly to our work together in those other years.

Dr. Mason was born in Erie Co., N. Y., in 1833, and was raised on a farm. When 17 years old he taught school, and then attended Beloit College, Wis., for several terms. He then began the study of medicine, and attended lectures at the University of Michigan in 1857 and 1858. But the practice of medicine was not to his taste, and having studied it in connection with medicine, he adopted dentistry as his profession, and continued to practice it throughout his whole life.

In 1862 he moved to Waterloo, Iowa, and was president of the Northern Iowa Dental Association for two years.

Dr. Mason was prominently active in religious work. He united with the Baptist church when 18 years of age, and was active in filling different offices in the church. At one time he was a church clerk, a trustee, and clerk of the board of trustees, besides being a Sunday-school superintendent. In Sunday-school work he was prominent, his activity extending to neighboring counties.

He was pronounced in his temperance principles and efforts, and held tobacco in much the same contempt as alcoholic liquor. His temperance creed extended to the use of tea and coffee, and neither he nor his children used either.

His interest in bee-keeping began in 1869, at which time a brother left in his care two colonies of bees till convenient to move them. Increase of interest and increase in number of colonies continued until in 1873 he made his bees an important source of revenue, severe attacks of rheumatism making close confinement to office-work objectionable.

He was well known as prominent in apicultural matters in Ohio, to which State he moved in 1874, locating in the vicinity of Toledo. In 1882 his apiary was infected with

foul brood, but he succeeded in curing it so effectually that there was no return of the disease.

He was the leading spirit in securing prominence for apiculture at the Tri-State Fair which was held yearly at Toledo, and was the efficient superintendent of that department. He was also superintendent of the Apiarian Department of the Ohio Centennial Exposition, which took place at Columbus in 1888.

For four years he was secretary of the Buckeye Union Poultry Association, although, perhaps, not generally known among bee-keepers as a poultry fancier.

In 1887 he was elected president of the National Bee-Keepers' Association (known by another name at that time), to which office he was re-elected the following year. For the past seven years he has been secretary of the same body and occupied that position at the time of his death, his term expiring with the end of this year.

Dr. Mason was a man of fine appearance and commanding presence, and was always a conspicuous figure at the National conventions, his jovial manner always adding interest to the meetings.

We feel a personal loss in the death of Dr. Mason, and we are sure the old American Bee Journal also has one less admiring friend. But they are fast passing to the Other Shore. Only a few more years, and we who now remain will be called to join "the great majority" who are constantly assembling there. Until then we can only fill the years with patient toiling, each doing his duty, and thus perfecting such characters as shall be worthy an eternal existence beyond the tomb.

Convention Proceedings.

THE DENVER CONVENTION.

Report of the Proceedings of the 33d Annual Convention of the National Bee-Keepers' Association, held in Denver, Col., on Wednesday, Thursday and Friday, Sept. 3, 4 and 5, 1902.

(Continued from page 760.)

Mr. Hawley—On the question of this package, in my locality, it is quite different from that in the East, I think. I have sold it in 60-pound cans, because a great deal of our honey goes by carload lots, and goes to a foreign market, such as Chicago and Cincinnati, but when it comes down to the retail trade I must say that the price of the glass jar and the price of the tin convinces me that the paper package is the coming package for honey to reach the homes of the people, on account of its cheapness, and on account of the handling. I have quite a number of paper packages, and I use at the present time what we call an oyster-pail—a handy package; it is a very nice package. Mr. Aikin has gone a little further than I have in experience, but in my locality and market one firm alone ordered 4500 pounds of honey, and they placed it in the tin pails, but they said to me, "Last year you gave us about five dozen odd, handy packages, and we want to have it that way. We are convinced by the way they went off, and the way people came back after them and called for them again, that that is the only package."

Now, as to the 60-pound cans; probably I have in the last five years marketed 90,000 to 95,000 pounds of honey. If I put that in those paper packages, or paper oyster-pails, or 5-pound pails, I would not have had it all sold to-day. Consequently, I think we have to study our conditions, and if we are going to ship, the great amount of our honey has got to go in 60 pound cans.

M. A. Gill—Mr. Aikin very conclusively and concisely

covered the question, showing that he was doing the best for his location, showing that it is a matter of locality, the same as in production. Mr. York has done the same thing, and I want again to say it shows that it is a matter of location. Every bee-keeper we have heard say something says he can't produce what he can sell. Then, isn't it time to drop this question and talk a little about production, so that we can get up to that point?

Mr. Abbott—I have had a little experience here, and I want to touch on Mr. Aikin's paper; it said that it required an expensive plant to put up bottled honey. I think my kitchen stove cost me, second-hand, about \$10, and I don't know how much the wife paid for the other paraphernalia we had around there. I wouldn't undertake to tell how many thousand pounds of honey I have put in bottles, and that is all the expensive machinery I have ever had. If you think you can't bottle it without expensive machinery, it is all a mistake.

Some men think they can't start in business without a lot of money; they invest about \$18 in an office-desk, and start out, and in a week or two the sheriff has his sign on the door. We don't have to have expensive machinery to do business. The fellow that has all the machinery to sell would like to make you believe you have to have it. I sell apiarian supplies, and all the foundation that is put in the sections in my office is put in with a screw-driver. I sell foundation, first-class color. The fellow that comes in says, "Let me see you operate these machines." I say, "I can't; I don't know how." He wants the machine, and there it is, and I can put in foundation faster, with the help I have, with a screw-driver than I can in any other way. It doesn't always require expensive machinery to do things.

Now, on the other hand, when you go out before the public with an article there is another question that comes into consideration; the question of cheapness must not cut too much of a figure. I got to thinking about it, and about such packages of honey as I saw this morning put up in papers, and I just imagined about 150,000 men who have to go out to the suburbs on the cars, and each of the men with four or five of those bologna-sausage packages in his pocket. I just thought what a time they would have, how they would run, how they would sweat, and what various things they would do and say! The truth of the matter is, a package like that in a city, or in any large market, is not a practical thing; you couldn't get it home without it running all over your buggy on a hot day. If the mercury was down 30 below zero, and you handled it carefully, it might be all right; but carry it in your hand, or in your pocket, and in a little while it is simply all over the paper. A man would rather pay 25 cents and have it in a can than get it for 5 cents in a paper sack and have it smeared all over creation; he would be just like that fellow that sat down with his girl to tell her something sweet, and had trouble. There would be more people who would pay for the fancy package, if the fancy package appeals to them. The idea that because a man is poor he must have something cheap is all a mistake. I don't care how poor a man is, he must have a good package if he wants it, and the people who work for \$1.50 a day will buy that honey as Mr. York puts it up just as quickly as they will buy it in a paper bag; in fact, they will buy it quicker in our country, after they carry it home and have the experience I have told you about. The price doesn't cut any figure. Extracted honey has retailed at 25 cents a pound in St. Joseph for 20 years, and the price has not been changed, and the people buy it; they come into my office and say, "I bought honey so and so," and they are laboring people. I know what they paid for it, because the price is put on the package before it goes out. They have paid 15 cents for a half pound of honey for 20 years, and they are paying it to-day, and they will go on paying it; as long as E. T. Abbott's head is above the sod, and his name is on a bottle of honey, it will never be sold any cheaper than that in St. Joseph; and that can be done in any city in this country if you have a salesman—an energetic man—to sell it.

J. B. Adams—I think the last speaker lets his imagination run considerably sticky. I have had considerable experience with the bologna-sausage package for the first time this year. I can put up all the honey I can get in bologna-sausage packages and sell it at a good figure, satisfactory to me, satisfactory to the man who eats it, and he doesn't have to pay for the glass that he throws away; and I have never had a complaint about them sticking in their pockets going home; it is always delivered in good order, and gives perfect satisfaction.

Mr. Aikin—I am up on the ridge-pole yet. I always thought that there was something wrong with some of the

eastern cities, and I am glad that our friend from down on the Big Muddy has given us just the information that we wanted; he has told us how intensely hot it is, and it is getting hotter and hotter down there. Surely, that is the place to liquefy honey; I turn to my friend from Chicago, and my friend from St. Joe, who are in such a hot place already that they can't carry a package of granulated honey in a paper-bag without it running all over. How will it be when they put one of those glass things in their pocket, and when that fellow that you hear and read about so much begins to get after them, and they get to sailing around the corner, and whack it against something hard, I guess it will be running all over, too. They forget it takes in the neighborhood of 150 degrees to liquify honey, and it doesn't get so hot in this country, nor it doesn't get so hot in many of the towns and cities where I send my honey.

I want to tell you what I did last year. I packed in lard-pails over 20,000 pounds of extracted honey, let it candy slightly, and I want to tell you that now, and for about six months, I have not been able to supply my customers; my own town is without honey; my customers in towns and cities all around the country are without honey; I have reached out into a field, as I indicated in my paper, which is as wide as the commercial world, and because there is nobody in the field. I notice that my friend from Fort Collins, and another from Longmont, and a good many others, are beginning to fall in line; the people from that hot country have been talking to me and admiring those paper-bags. I went back a bit ago to find a sample bag without honey in it. I brought in several, but I don't know what has become of them; I guess they have gone off to Chicago or St. Joe, and the next thing you will hear about them putting up honey there in that shape.

Now, this is a practical question, it is a question everyone of you is interested in. I know just as well as you know that when you produce extracted honey—I am talking to producers—and put it up in 5-gallon cans, and undertake to sell that honey and get living prices out of it, you can't do it. You may sell a limited amount to your store-keeper, and he will lay the can up on his desk or on a box or something, and he will unscrew the top and run out a little and spill a lot of it, and you will sell him two or three times; after that how much will you sell him? Just what he can sell in the original package, because he will not retail it if he has to draw it out from the can, and it is only a little while till it has candied. A few days ago there was a German came into my honey-house, and he had gotten some honey I had melted a few days before, but when he came back for the second lot that honey was candying, and when I took out some of it and showed him, he said, "No, no; I don't want that; you put flour in that; you mix flour in it." And another one said, "You mix lard in it." Just a little bit of talk, and a little bit of persuasion, showed them that it was honey; they took it and went home, and came back and bought again.

In my own town, in my own market, the retailers, the grocerymen, do not want honey in liquid shape; they want it candied, and they want it in a package; they can just hand it out, and there is just so much profit on each package. There is no leakage; and this honey, when it is candied solid (speaking of the honey I produce, and the honey others produce in this country), is hard, and if you put it in a paper-bag you could stick it in your pocket and go around the corner just as fast as you want to, and it won't leak; it will leave the surface of the honey, where the paper touches it, smoother than would be the skin of a sausage; that is how it comes out. It is a fact, if I would send my honey down to that Irishman who publishes the American Bee Journal in Chicago, he would pay me a price that would net me about four cents a pound. Isn't that about right?

Mr. York—I'd pay you more than that.

Mr. Aikin—Just now you will; and the same if I send it to the other city. This man in St. Joe wouldn't do a bit better. Yet, I have been selling my honey in lard-pails and paper-bags, and almost anything that will hold it, and getting from one to three cents a pound more than they will get me for the same product.

Now, producers, each one of you wants to follow my advice, and do not pay any attention to what that man told you, but put up your honey in the package that will get you the most money, and get it to the consumers in the shape that will be the easiest for them to carry home at the least expense.

As to this package here (Mr. York's), I didn't say one word in my paper against putting it up in this shape for any trade that demands it in that way. There is a place for it; there are people who will pay more for that because

it looks nice, and because there is not one, perhaps, out of this whole audience could pay the same price for it. Some people glory in paying more for a thing than the thing costs—than you and I can pay for it—but there is a great horde of people all over this country, east, west, north and south, that do not know what honey is. Mr. York told you about it; he said our honey would hardly make a single grain to each one of the population of this country.

Mr. York—For the Irishmen, you mean.

Mr. Aikin—The Irishmen. There is a vast amount of people in this country who want honey so that they can use it, but if you put it up in this shape they couldn't buy it. Why? In the first place, their salary won't allow them to do it; and they will turn around on the other side of the counter here, and there is a bag of granulated sugar; they will take home 25 cents worth of granulated sugar, and they will put a little water in it, put it on their cakes and eat it, and your honey and glasses will stand on the shelves. That is true in the towns and cities all over our country. There is a vast population that will use the goods if it is at a price that they can consume it; and I have put goods of my own packing in lard-pails, and candied, into the city of Omaha and sold it there, and I am selling honey to-day, or would be if I had it (I am sorry to say I can't do it this year), I could sell it anywhere between here and the Mississippi River; and my customers are writing me almost daily to know when I am going to send them some more of that honey. And so it goes.

The market is before you, if you will only take advantage of it; but you can't sell to those people in 5-gallon cans or barrels, because you can't get to them except at a price five times what sugar will cost them, and then it becomes decidedly a luxury, and sells just as I have indicated in my paper.

J. A. Green—Like Mr. Aikin, I am on the ridge-pole, but Mr. Aikin appears to have gotten off on one side, and I am on both sides. I have sold honey extensively, and I have observed the market, and I can tell you that there is a market where it would be useless to attempt to sell honey in any other than such a package as that on the desk there (Mr. York's); such a package as that is attractive, and it is small, and people will buy it for those reasons when you couldn't induce them to look at candied honey in a tin-pail or a paper-bag. That jar is useful after the honey is taken out, and many people will take account of that, and they will pay more for it on that account.

Now, I have sold a great deal of honey in pails, and I have experimented somewhat with it in paper, and undoubtedly in some places there is a demand for it. Mr. Aikin has told us that there is, and it is undoubtedly true, and I just want to emphasize a little more what Mr. Cogshall has told, and what Mr. Aikin has said in regard to Mr. Abbott. If you produce a good article of extracted honey, you can get it candied so dry and hard that you could wrap it up like a bar of soap, or anything of the kind, and carry it home without any danger of it ever melting or breaking; you get a good, ripe article of extracted honey, and when you think it is beginning to granulate then stir it up well and run it through the honey-gate while it is in that condition; let it go as far as it will go so that it will run well, then run it into your packages, and it will be hard, and white, and dry. I know this, because at one time I experimented extensively with a view to putting it up as confectionery, as caramels, and I found the only objection to doing that was the need of some machinery to do it cheaply enough. I could put it up and it would be just as hard as caramel in the candy-store.

REVISING THE CONSTITUTION.

Mr. Abbott—I would like to make an amendment. Before I make it I will read a section of the Constitution: "This Constitution may be amended by a majority vote of all members voting, providing notice of the said amendment has been given at the previous meeting." It does not require any discussion or anything of that kind. I desire to give notice now that Article IV, Section 1, will be amended, or an amendment to it will be offered as follows: "And no member of the Board shall hold any other office in the Association, and no State shall have more than one Director; in all cases when the vote shows that more than one Director from any State has been elected, the one who receives the highest number of votes shall be declared the Director for said State, and the vacancy shall be filled by the Board selecting the one who receives the next highest number of votes who lives in a State not represented on the Board at that time." Article V, Section 8, will be amended so as to read as follows—the last clause: "For any cause

they may deem sufficient, and fill any vacancy which may occur." Article VII, on Vacancies, will be amended as follows: "Any officer who wishes to resign shall present that matter to the Executive Committee for their action." This is not a matter for discussion. I propose to offer these to be presented to the members of the National Association at the next election, in December.

Pres. Hutchinson—I see there is a very fine exhibit in the alcove, and some of us Western or Eastern people have been asked to pass our opinion upon it after dinner. Messrs. Root, Hutchinson, Dadant, Hershiser, and Mrs. Booth are the committee.

Dr. Miller—This matter that has been presented by Mr. Abbott is an important one, and I believe good will come from it, but it is necessary for us to have time to think it over, and that is one reason why it is given to-day. The electing of one or more members of the Board of Directors from one State is, in general, an objectionable thing, they should be over the whole country. Here comes, however, what might be objectionable also in that. The representation should be somewhat in accordance with the numbers. If a State has a very large number of members, and another State has almost no members, there would seem to be an element of unfairness in allowing one Director to have such a very small representation; and if there is no other way of getting at it, I would give notice that an amendment would be offered, "That no State shall have a Director unless such State shall have 50 members of the Association within its bounds." I have not had time to think about it, only it would seem to me fairness would require something of that kind.

Dr. Mason—I could give a little idea by stating how many States have 50 members and over.

Dr. Miller—Mr. Abbott says to take that as part of his notice.

Dr. Mason—California, 136; Illinois, 124; New York, 146; Wisconsin, 88; Colorado, 51; there is no other one that has 50.

Mr. Abbott—I am perfectly willing to put that in. There has not been a change suggested but what I am willing to embody in my notice, and I don't know but what I will embody a good deal more.

Dr. Miller—After Dr. Mason's statement I should judge 25 would be a better number than 50.

Mr. Marks—I wish to say in regard to Dr. Miller's motion, that you are limiting the number of Directors to a State to one. As far as the State of New York is concerned, I might say that that is a reflection upon us; we have had the largest number of members in this organization ever since it was started. There is no time since it was organized, since I have been able to get hold of the list of members, but what we have had from one-fifth to one-sixth of the members in this Association, and since it was organized we never had a Director in this organization up to two years ago, and now some of you are finding fault because we have got, you say, more than we are entitled to. Perhaps we have; I won't deny that perhaps we are not entitled to any, but when you strike at a State that has had from one-fifth to one-sixth of its members, and which up to two years ago never had a Director in the Association, you are hitting a pretty hard blow. You are limiting the number to 25. Let them go out and get other members; it is members that make this organization. Come in here with your 50 members, and you are entitled to a Director. You can get them. It is members we want; it is members that are going to make this organization. If you want to increase the membership of this Association you have to get some inducement to do it; don't let a man come in here and be a Director of this Association for life with perhaps a dozen members in his State.

Dr. Miller—I believe that I have, perhaps as early as any one, made some objection in this direction, and it has certainly not been with any thought of striking at New York. Now, to come right down to it, the thing has stood a little in this way: The Directors have been elected year after year, and whoever has been in when the election comes—there have been no nominations, and they have a kind of a life tenure of office. I have been a Director—not ever since I was born—but ever since the Association was born, and unless I die I don't see any other way of getting out of the thing as yet. There are two of us in Illinois, and when I have any objection to it I am striking just as much at Illinois as at New York; and there are two in one family in Ohio. Those things, in some way, I would like to see arranged so that we could have some kind of an understanding, and not have the thing run on with the appearance of being in the ring. It looks like that to outsiders,

that we have got there, and the thing is fixed so that we can stay there, and you can't help yourself. Unless you get some other rigging on, I am going to stay a Director as long as I live.

Mr. Taylor—Mr. Abbott gives notice of an amendment, that no State shall have more than one Director, and I suggest that he add, "And that no Director shall hold the office for more than two terms consecutively."

Mr. Abbott—I will take that.

Mr. York—I think Mr. Marks is wrong in saying that his State had no representation until two years ago. If I remember correctly, Mr. Doolittle had always been on the Board of the National Bee-Keepers' Union, which was merged into this Association. Another thing, the whole South has no Director whatever. If we put this limit of 25 members, they will get a hustle on and come in. Another thing, you can't have more than 12 Directors, so there might be 20 States that would have 50 members each, but they couldn't all have Directors, only 12 of them. I think we ought to do something for the South; we have no Director there.

Mr. Taylor—It seems to me, in this discussion, we are doing the work that must be done a year hence. We have notice of these amendments, and the form in which they go in to-day does not bind the Association to adopt them; if it adopts them in the form in which they now stand, amendments can be made, and they can be disposed of in a way that the Association sees fit at the next annual meeting. The necessity for this notice, and the importance of it, is that it gives all the members of the Association notice of the subject-matter that is to come up and be amended in the Constitution, and every member has a year in which to consider it and he can come—

Mr. Abbott—It is only till the coming December.

Mr. Taylor—I supposed it was at the annual meeting.

Pres. Hutchinson—No, it is at the next election, in December.

Mr. Taylor—Then it is very important that these should be gotten in form.

Mr. Harris—To cover this ground I move that a committee of five be appointed by the chair to take this matter up, look into it most thoroughly, and report at the next annual convention for their adoption or rejection.

Mr. Darby—I second that.

J. P. Ivy—I hope the motion will not prevail.

Mr. Abbott—I simply say that I do not waive my rights. I have given the notice, and I can't have it put off for a year. This amendment is going to be sent to the membership in December, no question about that. I am waiting, but you can't make any motion to cut that off because—

Mr. Ivy—I hope this motion will not prevail; if it does it practically does away with the whole Constitution. The Constitution says that any member has a right to propose an amendment at any of the annual meetings, and it is the duty of the person proposing that amendment to reduce it to writing and hand it to the Secretary, and there is no need of us discussing this proposition. If Mr. Abbott has an amendment he wishes to place in the Constitution, it is his privilege; if I, being a member from Arizona, have an amendment I wish to submit, it is my privilege to do so. There is only a small handful of the members of this Association here to-day that are permitted to vote upon this, and I contend, under our Constitution as it was adopted originally, it was intended to submit these amendments to the whole of the voters of this Association, not to the members who are present, and I hope the amendment will not prevail, and that Mr. Abbott will reduce his amendment to writing and hand it to the secretary and let it be submitted to the voters of the National Bee-Keepers' Association.

A. C. Van Golder—I move we adjourn.

Dr. Mason—I second the motion.

C. P. Dadant—This matter should be put before the members right away—put the amendments before them so that our members may read and judge of this. We are not going to decide this; the members must decide it, and we must try and be peaceable, and be kind to one another, and bring the matter forward in a way that will be intelligible to everybody.

Mr. Harris—With the consent of my seconder, I would like to add this, to be harmonious, that a committee be appointed by the chair to look into this matter, and see what it is going to do in regard to our Constitution and By-Laws, report this afternoon, and then let the discussion come up. That is only fair and right, that they may go into the question in the proper way.

Mr. Taylor—I don't understand how it can be proper for a committee to act upon these notices. A member has

the right to give notice of any amendment he sees fit to propose, and it would not be his notice if a committee changed it; if the committee has an amendment to propose, and gives notice of it, that is another thing—

Mr. Van Golder—I rise to a point of order.

Pres. Hutchinson—The question is, Shall we adjourn?

Pres. Hutchinson then put the motion to adjourn, which, on a vote having been taken, was declared carried, and the convention adjourned until 1:30 p.m.

(Continued next week.)

Brushed Swarms—Locality—Bee-Keeping Made Easy.

BY F. GREINER.

THE brushing or shaking off of bees to place colonies in the condition of a young swarm is being more and more recognized as *the method* to handle the bees in out-apiaries. The idea of the original inventor (Gravenhorst, of Germany) was to make the strong colonies as strong as possible at the expense of the weaker ones, and when they had arrived at the danger-line (swarming-point), then to shake the bees off their combs and let them build combs in an empty hive. The brood-combs gained were utilized to bring the next strongest to the same state of populousness, and then shake these off and put them into empty hives. This was continued to the end, or till the season came to an end, or the yard had been gone over.

The conditions must have been different with Gravenhorst than they are with us. We don't find it advisable to "brush" bees till the honey season is at hand; then we would like to shake or brush all colonies if they were all good and strong. It may be necessary to hold back some of our best or most populous colonies, either by taking a frame of brood from them occasionally and substituting empty comb, or by giving more combs by enlarging the brood-nest. A colony brushed or shaken off in May cannot be expected to be in the best condition for storing by June 20. The colony shaken off on the last-named date will be in excellent condition for work then.

Our object is not the rearing of the bees, but to produce honey, and our management much be in accordance therewith. He who can so manage as to exchange all surplus bees, grown during the season, for honey, and come out with the same number of colonies he started out with, has solved the problem best. Many are the inventors who hit on the plan of shaking swarms simultaneously, or without any previous knowledge—it is to their credit; but Gravenhorst undoubtedly was the first who made it known to the world.

In practicing the method locality plays an important part, as it does in many other manipulations. The shaken-off bees *absconding* is, for instance, unknown to some, whilst with others precautionary measures have to be taken or else 20 percent of the brushed colonies leave the bee-keeper. There is really too much at stake to run any chances. One single swarm held from going to the woods will pay in honey for all the entrance-guards needed in a large apiary, or pay for the trouble of keeping a brood-comb in each prepared hive for a few days. The brood-comb, or rather comb of brood, does not always hold the bees from absconding in my own locality, and the entrance-guard has failed once with me. This, however, does not hinder me from applying these means. It is the best we can do, as far as I know.

In some localities a hive full of brushed-off brood-combs may be set up on a new stand—the hatching bees will take care of things. I learn this from the writings of others, for I have never tested it myself, not being of that venturesome nature. I prefer to make a sure thing of it, by placing one or more sets of brushed combs upon some colony, leaving them there from 6 to 9 days. Then they can be separated without the slightest risk of losing brood or starting a case of robbing. If the weather is very warm, and there is not much open brood in a hive, it may do to leave things to the emerging bees.

I believe more disagreements and disputes arise among

bee-keepers on account of differences in localities than from any other one cause. This is more apparent the more I see of different localities and the bee-keepers residing therein.

When I was with Mr. W. F. Marks two weeks ago, I viewed his section honey with a great deal of—well, I could almost say, envy. Although it was produced in section-holders minus tops, the sections were free from propolis and stain. My own honey is principally stored in wide frames which protect the section on all four sides, but it could not compare with Mr. Marks'. There is no use in talking, a super that does not protect the sections all around is of no good here; it is all right with Mr. Marks.

BEE-KEEPING MADE EASY.

At the Chicago Bee-Keepers' Convention last winter one good friend gave his management of bees. It consisted, in short, of giving plenty of room—two extra 10-frame brood-chambers full of comb added below the hive containing the bees. It prevented all swarming.

Another friend remarked that he had just learned how he could go a-fishing.

If there are any lazy bee-keepers anywhere, or some others that would rather go a-fishing than work in the beeyard, let them heed what Dr. Gandy said in *Gleanings* a short time ago. In substance it is: "Invest \$60.00 in catnip and sweet clover seed, and sow it around your neighborhood. The bee-pasture will be so much improved, that colonies will store 400 pounds of honey. Dr. Gandy also controls the honey market, so that he obtains 15 cents per pound for any kind of honey he produces."

Now the lazy bee-keeper must "get on to" this scheme; then keep 15 colonies of bees only, because the proceeds from them will be enough to furnish him with all the necessities of life. It should certainly not take more than one day's work each week to attend to these 15 colonies, and he would have five days for fishing and one day for rest. Don't you see what an easy time the bee-keeper could have? Fifteen colonies of bees, each producing 400 pounds of honey would give a total of 6000 pounds. Sold at 15 cents per pound—proceeds, \$900.

I would like to be in it.

Prolific Queen-Bees and Large Hives.

Read at the Minnesota State Bee-Keepers' Convention,

BY W. J. STAHMANN.

MUCH attention has been paid by queen-breeders to color and beauty of queens, and too little to the prolificness, comb-building and honey-gathering capacity of their progeny. When a practical bee-man wishes to improve his bees he does not as a rule look for beauty, but he does want to know something about their ability to yield dollars and cents.

Breeders of live stock have some wonderful improvements in their stock by careful breeding. Why should not bee-keepers do the same? It is certainly as easy, if not easier. I do not wish to give the impression that I think bee-keepers have not made much advancement along this line, they certainly have, and especially in color. But I do want to mention two very important points that I believe have been neglected, viz.: Prolificness of queens, and comb-building qualities of their progeny.

We cannot very well have a prolific queen without a large hive—the two, as a rule, go together. My experience is that a queen reared and allowed to lay eggs for the space of a week or more in a small hive, or having a small amount of bees, will seldom make a prolific queen, regardless of the stock she comes from.

Hence two things are essential in rearing prolific queens—a strong colony, and a large hive when she is about to begin laying. I also find that a prolific queen is injured by putting her in a hive too small for her capacity, or by confining her through a honey-flow. A prolific queen that has her brood-nest reduced to 4 or 5 combs through a honey season will seldom be the egg-layer that she was, and I am inclined to believe that where large hives are used and care is taken, when the young queens are about to lay, that they have a strong force of bees. In several generations the egg-laying capacity of queens can be increased, and on the other hand if kept in small hives the tendency is to degenerate and lessen the capacity of a prolific strain of queens.

Years ago I used quite a number of 8-frame hives—at one time I had 150 of them—and I also used the 10-frame

hive quite extensively. I noticed all along, year after year, that I got considerably more honey from the 10-frame hives, so I decided to try a 12-frame hive. I transferred six 8-frame colonies into the 12-frame hives, one having a young queen just starting to lay, and quite strong in bees; this was in the early part of the season, and that season all the bees bred unusually heavy, and it was also an unusually good season for honey.

The hive having the young queen filled all 12-frames with brood, leaving scarcely any honey in the brood-nest, and kept it full until fall, while the other five had only from 6 to 10 frames full of brood. This is when I first began to notice or believe that egg-laying capacity of a queen was made when she was young.

The next season I put in use about 100 11-frame hives, the frames having no bottom-bar, which for brood have a greater capacity than a 12-frame hive having bottom-bars.

I took particular pains to see what difference, if any, there was in queens from the 8-frame hives, and young queens that started laying in the large hive, and I was convinced that there was a vast difference in most cases, and since then, in rearing queens, if I neglect to give a queen the required amount of bees in time—that is, when she is about to begin laying—I find, as a rule, such queens inferior as to laying eggs.

I wish to speak about comb-building. Nine years ago I bought 10 colonies, and in this lot I found a strain of bees that would not fasten the comb in the sections at the bottom or sides, and as I had lost nearly all my bees the winter before, and was practicing natural swarming, I reared several queens and found their progeny did the same kind of work. I bring out this to show the inherent tendencies in bees.

There are bees that fasten the combs on all four sides of a section—fasten it before the comb is half finished; that makes comb honey that can be shipped with safety. This I consider a very important point in a good strain of bees, and one that should receive more attention than it has.

Our Bee-Keeping Sisters

Conducted by EMMA M. WILSON, Marengo, Ill.

Bee-Literature to Begin With.

What literature in books or pamphlets would be best for a person to read who thought of venturing in a very small way in the bee-business? My husband and myself are thinking strongly of doing a little in the line of bee-keeping next spring. We are both inexperienced in that line of work, and would be thankful for advice as to what and where we can find such information as we may need.

NEBRASKA.

ANSWER.—The first thing for you to do is to get a good text-book on bee-keeping and study thoroughly. The "A B C of Bee-Culture," Prof. Cook's "Bee-Keeper's Guide," and Dadant's Langstroth are all good, and the instruction that you would get from any of these books is reliable. Either of them can be obtained at the office of the American Bee Journal.

You can hardly begin too soon being a regular reader of the American Bee Journal—an excellent journal for beginners, as well as for those the most advanced. If you do much at bees you will probably want to subscribe for one or more of the other bee-papers later on.

Beginning Bee-Keeping—Bee-Veils—Gloves—Miller Feeders.

Three years ago this winter I first became interested in bee-keeping from reading an article on the subject in a farm paper. I bought a copy of "A B C of Bee-Culture," also subscribed for the American Bee Journal and Gleanings in Bee-Culture, and these I studied diligently all winter.

In the spring I bought my first colony of bees; in fact, the first one that I had ever seen. I have continued to study the subject, also to talk with all the experienced bee-keepers that I chanced to meet, and have received much help from them. I have bought a few new colonies each

fall since I had my first one, and now I have about 40 to put into the cellar this winter. I work for both extracted and comb honey, selling the former at 15 cents, and the latter at 20 cents a pound. The rows of white hives in our side yard are a good advertisement to the many who drive by, and this fall I could not supply the demand that I had for "some good, pure honey."

It seems strange that so few women are interested in bee-keeping, but I suppose it is largely because their attention is not called to it. Judging from my own experience there is no comparison in the amount of work between caring for a large flock of poultry and managing a moderate-sized apiary; and I certainly think the bees yield the largest profit for the time, labor, and capital invested.

1. Can Miss Wilson tell me why white veils are not worn instead of black ones?

2. Also, what kind of gloves does she use?

3. How is it possible to fix the Miller feeders so they will not leak even after the seams have been well paraffined? The two that I bought this fall from a bee-supply house were too long for a dovetailed super, and had to be shortened before they would go in at all.

Have any of the sisters used the Danz. hives for comb honey? I just commenced using them the past season, and like them very much.

I use a small force-pump to spray the bees in swarming-time, and in that way I can nearly always prevent them from going up very high, or out of my reach.

I hope we shall hear from many of our bee-keeping sisters in our new department. MRS. W. S. W. Minnesota.

ANSWERS.—1. White veils are very hard on the eyes. Black being the absence of all color, it is the nearest looking through nothing that we can have. I never realized what a difference it would make until one day I forgot my veil when going to the out-apiary, and wore one made of white mosquito-bar all day. I assure you I was glad to get back to a black veil again.

In very warm weather the black veil will sometimes crock. It is a good plan to put a piece of white on the bottom edge of your veil, and use a white rubber cord in place of the black.

2. I use a light-weight buckskin, and like them very much. The more they are worn and washed the better they are so far. I suppose there is a limit to their wearing capacity, and some day they will wear out for good, in which case I hope to get another pair just like them. This is the first pair of buckskin gloves that I have had, and I have worn them a little over two years, and they are not worn out yet.

3. Try thick, white paint and let it dry well before using.

A Cheap Wax-Extractor.

And a good one, too. Take an old dripping-pan—or a new one; split open one corner, and your extractor is made. Put in it the scraps, pieces of combs, cappings, or whatever you have to extract. Better not put in too much at a time. Set the dripping-pan in the oven of the cook-stove, with the slit corner projecting out; the oven-door, of course, being open. Put a little stone or something under the end that is the farthest in the oven, so as to raise it half an inch, or an inch.

Slowly the wax will melt, and as it melts it will trickle towards the split corner, which is lowest. It will not do, of course, to have it fall on the floor, so you must have something standing on the floor for it to drip into. The result will be about as nice wax as you get from the sun extractor, which means it will be very fine.

The sun extractor is less trouble, and takes less time, but the dripping-pan extractor will work at a time of the year when the sun extractor is taking a vacation, and when, perhaps, you have more time to fuss with it.

Mice in the Bee-Cellar.

If you winter your bees in the cellar one of the first things to look after is the mice. While the bees are in a dormant condition, a mouse can do a great deal of damage. A mouse in a hive means holes in your nice combs, which will be filled by the bees with drone-comb next summer, unless you are very careful about it; honey eaten up, and possibly the bees themselves gobbled up.

It is easier to keep out than to get them out after they are once in.

A very good plan is to barricade them out of the hives

before the bees stop flying, with heavy wire-cloth having about three meshes to the inch, but don't use wire-cloth so fine that the bees can not get through it.

If you don't use the wire-cloth you must see to it that the mice are gotten rid of in some way, unless you are so fortunate as not to have any mice, which would be better yet. Peristent trapping will accomplish much. You can do very good work poisoning them, providing you are faithful about it, and see that fresh poison is put down every so often, and if they don't like one kind try another.

Strychnine is good. Cut a slice of cheese about a quarter of an inch thick, sprinkle it lightly with strychnine, and cut it up into little cubes. Put in a saucer, or on a bit of card-board, in a place convenient for the mice.

It requires some time and patience, but it pays.

Honey-Cookies.

One cup of honey, 1 cup sugar, 1 large cup of lard, $\frac{3}{4}$ cup of sour cream, 1 egg, 2 teaspoonfuls of soda, 1 teaspoonful of cinnamon, $\frac{1}{2}$ nutmeg, a very little cloves, 2 tablespoonfuls of melted chocolate.

If the cream is very good do not use so much lard. Part sour-milk and part cream will do if you do not happen to have enough cream, and the sour-milk used alone will give good results, but, of course, the amount of lard used must be increased accordingly.

Mix until you think they are about right, and then bake one for a sample. If not stiff enough, add a little more flour.

For frosting, take two cups of sugar; add just enough water to dissolve the sugar; add a small pinch of cream of tartar; boil until it will thread when you pinch a little between your thumb and finger. Take off and let cool a little. Stir briskly until it creams, and add about a tablespoonful of melted chocolate, stirring it in well. This recipe is original, has been thoroughly tested for years, and we think it excellent.

The Afterthought.

The "Old Reliable" seen through New and Unreliable Glasses.
By E. E. HASTY, Sta. B Rural, Toledo, O.

MANAGING A LAYING-WORKER COLONY.

Getting something out of nothing—well, half mankind, and more than half womankind, are sure they can do it, and must aye keep on trying. But its getting something out of less than nothing, I suspect, to get something of value out of a colony with laying workers. Can't say I admire the method of W. Hickox, page 659. Like pretty much all methods that will work at all it disturbs and bothers a good colony—adds something to less than nothing and rejoices to find the result something. Also it looks to my eyes like a promising way to rear a poor queen—which same is an apicultural asset that may, or not, be less than nothing in value.

REV. W. F. CLARKE AND DR. A. B. MASON.

Some men are overvalued and some are undervalued by their cotemporaries. W. F. Clarke has seemed to me to be a man we have for long years very much undervalued. Not sure but we have gone further and measurably frozen him out of print so far as apiculture is concerned. What personal qualities (if any) may have helped on this I am not competent to say, never having met him. I can sincerely feel his loss now he is gone, and it is fitting that I should lay a wreath on his coffin. Farewell to a fellow-worker; farewell to a friend of the exact truth; farewell to a man who saw and saw correctly, a great deal in this world that needed mending, and who deeply desired that it should be mended. Earth can ill spare such, they are so few. Page 660.

Of course I would have a chaplet for Dr. Mason, the all-around good man. His foes were the foes of all civilization and righteousness—and scarce a man besides them it would seem. "How blest the righteous when he dies!" We don't have to hunt with lanterns and optical instruments to find something good to say of him just for once. Page 739.

BEEES AND PEAR-BLIGHT.

Makes me squirm—"Prof. Waite has proved beyond any question"—(Here's a small boy who never gets so badly floored that he cannot ask a question.) But our best science sharp, Prof. Cook, says it's proved that bees are the "chief agents" in spreading pear-blight. Sorry. Another fact in this matter is more pleasant reading to us. Notwithstanding bees scatter more pear-blight germs than all other culprits, the other culprits scatter so many that abolishing bees is not practically of much use, if any. When all the forest is dry and coals are flung, whether it's a million or a hundred matters but little.

A man seven miles high, eh? And the pear-blight microbe is such a little fellow that he is the antitype of that. Now do you realize he is? If he was as big as a man, a man to correspond would have to be seven miles high. To say that his length is one ten-thousandth of an inch sounds unimpressive to some minds.

Diluted carbolic acid to dip tools in when cutting away blighted twigs.

BORDEAUX MIXTURE—BEEES IN GROUND-HOLES.

And the famed Bordeaux mixture is, Lime 4 pounds, Copper sulphate 4 pounds, Water 46 gallons.

Prof. Cook wants to know if others have known bees to take possession of holes in the ground. Can't respond on exactly that, but I once put several colonies into holes in the ground as an anti-swarmer experiment. Failure. From a big hole in the ground they swarm allee same. Page 664.

Questions and Answers.

CONDUCTED BY

DR. C. C. MILLER, *Marengo, Ill.*

(The Questions may be mailed to the Bee Journal office, or to Dr. Miller direct, when he will answer them here. Please do not ask the Doctor to send answers by mail.—EDITOR.)

Uniting Weak Colonies of Bees.

1. Would it be advisable to unite a weak colony with a weak robbed colony, rather than to unite the robbed colony with another weak colony?
2. At what time in the day should uniting be done?
3. Can it be done with perfect success by use of smoke alone?

COLORADO.

ANSWERS.—1. I suppose the question is whether, when uniting two weak colonies, one of which has been robbed, it is better to unite them on the stand of one that has been robbed, or on the stand of the other. Having been robbed once, there is danger that the same colony would be robbed again on the same stand, even if reinforced by another weak colony; so it may be better to bring the robbing colony to the hive of the unmolested colony.

2. The time of day is not an important matter, but sometimes it is better to unite toward evening, so that foreign bees may not try to rob, and thus start bad feeling in the community. Yet a cool morning, when no bees are flying, is a good time.

3. No, not at all times.

Wintering in a Bee-House—Wax-Worms.

1. I keep my bees in a winter bee-house, with ventilator for occasional use. It is large enough for 60 hives?

I store my bees, 40 colonies, in pyramid shape on winter bottom-boards, which have an opening of four inches wide along the center and the length of the hive. The natural heat of 40 colonies during moderately cold weather in the winter is from 40 to 42 degrees. During extra-cold nights I fire up the stove in outer room, and let the heat go into this bee-room until it runs up to 45 or 48 degrees. Would it be necessary during the winter to put water in the bee-room for moisture? If so, to what extent?

My bee-house is built of 2 by 6 (2 by 8 would be better) with 2 by 8 joist under the floor (under floor, sides and the top to the peak of the roof filled with sawdust.) Sides are

papered and sided, inside drop-siding and coat of plaster, with $\frac{1}{4}$ inch space.

2. A few days ago I came across one dozen sections half filled in July. I was going to put them in a super to give it back to the bees. When I uncapped them with a table-fork, I found in all of them large spots where the fork went in without any resistance (mushy), and when I turned a section around, as much as a teaspoonful of honey fell out. I put it in the garden and let the bees help themselves. Could this be caused by wax-worms? But where did they come from, as nothing in any shape has entered my yard for a long number of years?

MINNESOTA.

ANSWERS.—1. It is probably not necessary.

2. An apiary without a wax-worm is about as hard to find as a garden without a weed. Even if you have not seen one for years, it is still possible that they are there, only constantly kept down by the bees, and these sections, in which eggs had been laid, when left unprotected by bees were proper ground for the growth of the worms. If that isn't the proper answer to the conundrum, I don't know what it is.

Bisulphide of Carbon for Fumigating Honey.

1. I read that honey is fumigated with bisulphide of carbon. How do you use it?

2. Suppose I have 150 pounds of honey to fumigate, where am I to put it?

3. How much will it take for that amount?

4. Am I to put it in a saucer and set fire to it, or not?

5. I do not know a thing about it. Is it a poison?

6. Where can I buy it?

7. How long is it to be under fumigation?

8. If I fumigate it in the fall, where am I to put it? It does not freeze here all winter like it does in your State, so the frost will not keep the worms out of honey.

OREGON.

ANSWERS.—1. It is used in any way that will allow the fumes that evaporate from it to be confined long enough to kill.

2. Put it in a saucer over the pile of honey, having the honey enclosed so the fumes will remain with it.

3. Probably two tablespoonfuls will be enough.

4. No, unless you want the top of your head blown off. Just pour it in a saucer and cover up as quickly as possible; it will evaporate fast enough without lighting.

5. The danger is in its explosiveness, and the greatest care must be taken to have no fire or light near it.

6. Your druggist ought to be able to get it for you.

7. Half a day would probably answer, and several days would do no harm.

8. After the honey is thoroughly fumigated, boxing and pasting with paper, as you suggest, would be all right; but even if you do not have severe freezing I have some doubt whether bee-moths lay eggs in winter where you live, and, if not, the honey would be safe until they do lay again.

Trouble in Introducing a Queen—Wintering.

1. I received a premium queen in fine condition. After getting home that evening I removed the queen in my strongest colony, and in 48 hours after I placed the new one in the hive, as per directions. In two days I examined them to see if they had released her, but they had not; they did not seem to work on the candy. I looked again the next day, and still she was not released. I then went through the hive and cut out all queen-cells I could find, two in number. I then released her, and let her run down between the brood-combs, where they instantly balled her. I gave them a good smoking, but it did no good, so I took out one of the frames, and found a large ball on the bottom of the hive. Upon removing it I found the dead queen, and the bees very vindictive.

Can you tell me why they did not release her by eating out the candy? Did I introduce her too soon, *i. e.*, by placing the cage over the brood-nest?

I introduced the queen I removed to a queenless colony, and shut them up. So after they would not accept, and killed the new queen, I placed the queenless colony over them and they were all right. I want to say, while I was trying to get them to accept the new queen, they were fearfully cross—stung everything that came near them.

2. I have 9 colonies in two-story hives, and the upper story is empty, or nearly so. Should I remove the upper

story? Will it be too cold for the bees, or should I remove the upper story and place the cover right over the brood-nest? Will they need protection of any kind in this damp climate? It rains almost constantly from the first of November to the first of March.

WASHINGTON.

ANSWERS.—1. There is always some risk about introducing queens by any ordinary plans, and with any amount of care a queen may be killed. Yet care makes a difference. The time when a queen is released, if the bees do not release her themselves, and the temper they are in, are matters of consequence. If the bees are very busy storing, the chances are favorable. If nothing is doing, and robbers are trying to crowd into every crack, the bees are likely to be on the offensive, ready to attack viciously any intruder, worker or queen. At such times it is better to free the queen in the evening, when there is no danger of annoyance from robbers.

But it is generally better to let the bees free the queen. It is not easy to say just why your bees did not do so. If the queen is too far from the cluster, the bees will not free her so promptly. The best place is right in the brood-nest, but a shipping-cage does not lend itself easily to this, as does the Miller introducing-cage. It was not the best thing to let the queen out of the cage when the bees were cross. Partly opening the entrance to the cage, and putting it nearer the brood-nest, even separating the frames so as to put the cage between them, would have been a good thing.

2. Better remove the upper story, or else put a burlap cloth over the lower story before putting the upper story over.

Fumigating with Bisulphide of Carbon.

I had a pile of hives about 7 feet high, containing frames. On the top of the frames I placed a cloth, about half covering the frames, then saturated it with bisulphide of carbon. In looking through a glass at the bottom I saw a few bees and a couple of flies drop dead, so I supposed I had given enough to kill the worms. But the next day I found live worms scattered from top to bottom. So you see it was not a success with me. The few bees that were killed, and also the flies, got in while I was piling up the cases.

OREGON.

ANSWER.—You do not say whether you covered the top of the pile, so that the fumes could not escape. If not, the bees and flies which came closely in contact with the cloth might be killed, while the worms farther away would be little affected. In any case, a worm is protected greatly by its web, making it harder to kill than a fly or bee left unprotected. A stronger dose might have finished the worms.

Oily Sugar for Feeding Bees.

I have about 100 pounds of soft white sugar that I let just a little oil slop on it. Could I use the sugar to feed my bees next spring? One can hardly taste the oil in the sugar.

PENNSYLVANIA.

ANSWER.—Unless the sugar is so strongly flavored with oil that the bees refuse to take it, it will probably be all right.

Honey as a Health-Food is the name of a 16-page leaflet (3½ x 6 inches) which is designed to help increase the demand and sale of honey. The first part is devoted to a consideration of "Honey as Food," written by Dr. C. C. Miller. The last part contains "Honey-Cooking Recipes" and "Remedies Using Honey." It should be widely circulated by every one who has honey for sale. It is almost certain to make good customers for honey. We know, for we are using it ourselves.

PRICES, prepaid—Sample 2 cts.; 10 for 10 cts.; 25 for 20 cts.; 50 for 35 cts.; 100 for 60 cts.; 250 for \$1.25; 500 for \$2.25; 1000 for \$4.00. If you wish your business card printed at the bottom of the front page, add 25 cts. to your order.

Please send us Names of Bee-Keepers who do not now get the American Bee Journal, and we will send them sample copies. Then you can very likely afterward get them subscriptions, for which work we offer valuable premiums in nearly every number of this journal. You can aid much by sending in the names and addresses when writing us on other matters.

Bees Wanted on Shares.

HAVE YOU IDLE CAPITAL?

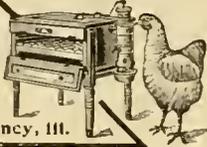

We are owners of 1000 colonies of bees, and want 1000 more to run on shares. We have the best location in the best part of Texas, and will give as references H. W. Wiseman & Co., Bankers, Paul Neubauer, P.M., or any responsible business firm of Floresville or Hutto, Texas. We have the best assistants we can procure, and have been in the business since 1893. We have heavy fall rains, and next year will be a big one for honey. If you have as many as 250 colonies of bees, ship them to us, pay the cost of location, and supply us the necessary equipment for honey production, and we will give them all the necessary attention, and give you one-half the honey. Bees must be all in either 8 or 10 frame Dovetailed or Langstroth hives. Let us explain to you more fully; therefore, we solicit your correspondence.

What Yon Yonson Thinks

Vell, Peter Peterson he don't bean com over since dom bees bean bite him so bad. An ay vos purdneer to forgit dat he say he goan to git even. But das morning he com over before brekfus, an he seems awful hurry, and kine excited, an he say, "Ole Peterson got awful sick horse, an vont Yon Yonson to com over an bean hors docker." "Iss he very sick?" Ay say, "Mine goodness, he bean siek plenty bad," he say. "He bean so sick he don't kin hardly live from von end to de odder," he say.

Vell, it don't bean very far so I go ma Peter, and he show me da hors, but he don't seems to be very siek, so ay ask Peter vat he tank bean da matter. "Vell," Peter say, "ay don't know, but every ting vat he ete it seems lak it go rite to his stumaiik."

An den Peter he mak plenty big laff. My ying, Peter bean plenty gud feller, but he git kine of funny som time. Ven he furst com over hedon't got sens nuf to tell big lie po das vay, but he bean awful quick to ketch on from dom Yankees.

Vell, bout two years ago Yon Yonson git kine of crazy streak on rural telephones. He talk to all das nabors to git dom to join vid him to put up telephone line, but, mine goodness, dom don't vas interested. So ay git nodder von Svede feller to help, coz ven Yon Yonson tak notion, you better believe he stick to his yob; so odder feller com over horsbak, an ay git on old Yim, an ve go an se all das nabors. An vile Yon Yonson mak awful big talking, an explain to dem til dom purdneer to fall over, odder feller he git dom to sine paper vat say dom have to go an cut an set 16 poles apiece, an den ve goan to furnish all da vire an dom glas marbles, an put it on da poles, an furnish an put in plenty awful good telephone for each von of dem. Den if dom all bean satisfied dom hav to pay us \$25 each von of dom, an den dom boss an own hole ting, an dom kin mak big talking and hav plenty big time.

Den ve hire feller vat dun all da work, an ven it bean all dun da line bean purdneer 12 miles long, an git 17 fones. Den ay go roun ven dome use dom bout two weeks, an ay say if dom don't bean satisfied ve tak dom fones out, an dom don't have to pay; but, my ying, dom say dom don't vill hav him fone ketch out for \$100, so dom pay das money; an dom have big lection, an dom lect Yon Yonson to big, fat office, cause he work for nutting and he ete himself; but, my goodness, he hav to buy new cap and plow shoes to be in stile.

But purty soon all dom peoples in das country git crazy, an vont telephone, so now ve got dom all over das country, an ve got \$100 svehbord in town, and ve pay \$2.00 per year sveh service each, and den ve talk all over das country for 50 or 60 miles, an even in big cities, an it don't cost von cent but \$2.00 per year at our home sveh, coz ve all give free exchange, and ve can now talk ma over 7000 phones free any time; dom country lines have 15 to 20 fones on von line, and sometimes ay tak das fiddle down an de girls play de organ, an maw an all of us sing and mak big music, an dom kin hear for plenty long distance. It bean nodder von feller on da line, som got von of dom sausage mills vat dom call phonograph, an ven evening com ve say, "Hello, Smit!" and den he turn das mill luse an youst grin out all da latest songs an finest music vot you never burd. My goodness, das telephone it bean da finest ting vat ay never seen. You better believe dom tramps and thieves don't dare to play hob in das country for ve ketch dom on da telephone quivker as nutting. An if dom smart proples vat live in big cities don't vetch out, dom goan to be vay behine da times.

Vell, you know ay bean had som catnip hunny das year, an von day da woman come to visit, an maw she give her box nice hunny, an nex morning ven ve youst git up somebody ring one long an three short rings, dat mean Yon Yonson, so maw say hello, an dom woman up da line bout 5 miles she say, "You can't bet vat ve goan to have for brekfus. Ve goan to

The Family Friend

An old and true friend that will help you in times of distress. When racked with pain you would give anything for relief. In the hour when the little child, too young to make its wants known, lies suffering, its little face drawn with agony; in the hour when the good wife, worn and tired, needs an arm to lean on; at all such times, when the calling of a doctor means a dangerous delay, besides great suffering and a heavy bill, there is nothing else so good as a bottle of

WATKINS' Vegetable Anodyne Liniment.

We receive numberless letters like these:

SAVED THE CHILDREN.

CLARA CITY, Minn., June 14, 1901.
We had five children sick with diphtheria last winter and carried them all through in one week without any doctor. Watkins' Vegetable Anodyne Liniment should be used at once as soon as any symptoms appear. We mixed two teaspoonfuls of Watkins' Liniment with two of vinegar and one of salt. Gave some of the mixture once an hour, also rubbed the Liniment on outside of neck.

HORSES WOULD HAVE DIED.

SHIPSHEWANA, Ind., June 18, 1901.
I have used Watkins' Vegetable Anodyne Liniment for nine years and find it the best remedy for colic in horses I ever knew. I saved two horses with it that would have died. Cannot speak highly enough of it.

The best thing made for Cholera Morbus, diarrhea, flux, rheumatism, cuts, cramps, strains, burns, colic, mumps, sore throat, diphtheria, frosted limbs, etc. For horses and cattle it cures sprains, cuts, scratches, bruises, swoony, colic, etc. Of course when you read this advertisement you may not feel the need, but the need of it may arise at any moment of the day or night, and then its worth can not be counted in dollars and cents. Order it the next time our agent calls, or if we have no agent in your county, send us your name and address at once, and we will see that you are supplied.

FREE! FREE! FREE!

We send out a beautiful 100 page illustrated Home Doctor and Cook Book absolutely free, and want to place your name on our mailing list. It is the cleverest and most complete thing of its kind ever issued. Write for one to-day.

Wanted a Man. We want one good, open-eyed, young man in each neighborhood who has a little ambition, and an inclination to get on in the world, to write to us. We are in a position to start him in a good paying business of his own. We have lots of young fellows, "boys" you might call them, who are making a nice thing selling Watkins' Remedies.

The J. R. Watkins Medical Co.
10 Liberty Street,
Winona, Minnesota, U. S. A.

each of these, first placing a piece of burlap over the frames of the hive so as to cover all but about an inch or an inch and a half at the end of the hive. The bees will remove the honey from the super to the brood-chamber in the day-time and go back to the brood-chamber for the night. Before putting on the burlap the bees, or many of them, would stay in the super all of the time. With the burlap on they remove the uncapped honey in a short time; then I remove all cleaned out sections, and with the uncapping knife uncap the rest. The honey in these soon goes below. Putting on supers and uncapping honey is generally done late in the afternoon, or early in the morning.

I will relate how I get the cappings from extracting combs cleaned up after they are tolerably well drained. Instead of washing them I put them in shallow boxes with expansive bottoms, or in large tin pans, and set where the bees can have free access to them. Soon there is a rolling and tumbling of bees in the boxes and pans, and the cappings look as if they had become living and moving masses. The bees go clear through them, except that now and then there will be found a sticky mass at the bottom which they cannot easily penetrate. These masses are loosened up late in the evening or early in the morning before the bees are astir, and by the end of the second day the picnic is over, and I have lots of cappings as dry as cornmeal.

Decatur Co., Iowa. EDWIN BEVINS.

Next Year—Honey-Boards—Unfinished Sections and Extracting-Combs.

White clover was still blooming a little on Oct. 25, and bees were carrying in pollen of a dark red color. Just where this pollen came from I do not know.

I have a portion of my apiary in chaff-hives, all packed with leaves on the top of the frames; the balance are in simplicity or dove-tailed hives, and are to be left on the summer stands. The hives are well supplied with honey, with the exception of 3 or 4, which were late swarms.

Next year promises to be the best white clover season that has been known in this locality, as there is a heavy growth of it everywhere, and if nothing happens to it—well, I am going to get ready for a big crop, anyhow, by having plenty of surplus arrangements for my hives.

I made an improvement in honey-boards the past season by putting an 8x10 glass in the center of the board, so that the inside of the super could be examined without disturbing the bees. The board is the same size as the hive, and need not be removed until the super is filled. Just try them and see.

All of my extracting-combs and unfinished sections were placed in the upper story of the hives of the latest swarms along in September, so the honey could be removed by the bees, thereby accomplishing two objects, that of supplying the bees with more stores for winter, and getting all the unsealed honey from the combs ready for the next year. The unsealed honey often sours or candies in the comb, making them almost unfit for use the following season. Usually the bees will carry the honey down, if you drop a little down among the bees and get them started.

J. M. YOUNG.
Cass Co., Nebr., Nov. 12.

The Carniolan-Italian Cross.

In response to a call for information concerning the Carniolan-Italian cross of bees, I will say that I have in one of my apiaries, side by side, 5 colonies in 10-frame hives, representatives of their respective strains, each having characteristics of its strain, and I could not say which I prefer.

First in the row is the Buckeye 3-banded long-tongue, every bee alike; their superiors do not exist. Next, imported Carniolan, just ended her third season; next the Muth strain golden Italian; then two Carniolan-Italians.

It was exceedingly interesting to study closely the nature of each during the last

three seasons. Early last spring the first three mentioned started off with the Carniolan the strongest, the 3-banders second, and golden third. For a time neither of them seemed to increase, owing to the unfavorable spring. Then all at once the Carniolan began to increase rapidly—just seemed to boom; it was not long until I gave the other two each a frame of brood and bees from them to start them a-going, because it was getting late if I expected honey. One could see the improvement in the two very quickly.

The latter part of May I noticed queen-cells in the Carniolan colony, and, knowing their willingness to swarm, I quickly changed their minds by making two nuclei, when it was time for mating, placed entrance-guards in front of all hives except the 3-banders, and I now have two true-to-name of the Carniolan-Italian cross. Their bees resemble the 3-banders, though somewhat darker, and bands narrower, with characteristics of Carniolans, gentle to the extreme, boil over when you open the hive; and breeders, never had better. It was no time until these two nuclei were as strong as any in the lot. The only objection that prevents them becoming popular in the hands of novices and apiarists having many colonies, is their swarming propensity; however, I must say I give them close attention, and seem to catch them in the nick of time, as they never swarmed for me.

In the fall of 1901 I presented a friend of mine with one of the fine Carniolans, because he was "taken" with their gentleness; but last August he did away with them, "Because," he said, "that colony swarmed only seven times in less than three months;" so it seems I averted their swarming impulse, and my friend failed to understand.

The Carniolan-Italians will always have my closest attention. I find they winter better, and breed up better in the spring. I helped strengthen weaker colonies with frames of brood and bees from them.

My other strains have good qualifications which these bees do not possess.

I often thought if I could combine only the good qualifications of these different strains I would have a race that might be christened "Eureka" bees. FRED W. MUTH, Hamilton Co., Ohio.

CONVENTION NOTICE.

California.—The California State Bee-Keepers' Association will hold its annual convention at the Chamber of Commerce, Los Angeles, Dec. 16, 17, 18, 1902, opening Dec. 16, at 1:30 p. m. The convention is called in December to give opportunity to ask for additional legislation. A good program is expected, and a cordial invitation extended to all who are interested.

HONEY AND BEESWAX MARKET QUOTATIONS.

CHICAGO, Nov. 19.—A slow, steady market may be said of conditions now prevailing in Chicago. The volume of sales are small, and the receipts are correspondingly so. 15@16c in obtained for best lots of white comb in a jobbing way, while for selections a little more is asked; amber grades, 10@15c, according to flavor, style, etc. Extracted, white, 7@8c; amber, 6@7c. Beeswax, 30c on arrival. R. A. BURNETT & Co.

ALBANY, N. Y., Nov. 22.—Honey market is still in strong position with ready demand for all receipts at good prices. Fancy white comb, 16c; A No. 1, 15c; No. 2 and mixed, 14@15c; buckwheat, 14@14 1/2c. Extracted, buckwheat scarce at 6 1/2@7 1/2c; light grades more plenty at 6 1/2@7c. Beeswax, 29@30c. H. R. WRIGHT.

BOSTON, Oct. 20.—Our honey market remains firm, with good demand and fair stocks on hand. Honey is not coming forward as fast as usual, and the tendency of prices is steady. We quote our market as follows: Fancy white 1-pound sections in cartons, 16c; No. 1, 15c; No. 2, very light supply, 14c; glass-front sections generally one cent less than this. Extracted, light amber, 8c; amber, 7 1/2c. BLAKE, SCOTT & LEE.

KANSAS CITY, Nov. 22.—We quote fancy white comb honey, per case 24 sections, \$3.50; No. 1 white, per case 24 sections, \$3.40; No. 2 white and amber, per case of 24 sections, \$3.25. Extracted, white, per pound, 7 1/2c; amber, 6 1/2c. Beeswax, 27@30c.

Our market has changed quotations of comb honey from pound to the case. C. C. CLEMONS & Co.

CINCINNATI, Nov. 8.—There is a good demand for all grades of extracted honey, prices ranging as follows: Amber and Southern in barrels, 5 1/2@6 1/2c; clover and basswood, 7@8c. Fancy comb sells 16@17c. Beeswax, 27c. THE FRED W. MUTH CO.

NEW YORK, Nov. 8.—Demand for comb honey is good and same finds ready sale at from 15@16c for fancy white, 14c for No. 1 white, 12@13c for No. 2 white, and 12@13c for buckwheat. Extracted in fair demand at 7 1/2c for white, 6 1/2c for light amber, and 6c for dark. Southern in barrels from 60@65c per gallon. Beeswax quiet at from 27@28c. HILDRETH & SGOBLEEN.

CINCINNATI, Nov. 18.—The demand for comb honey is good and prices are a little better, as the supply does not meet the wants. Extra water-white fancy is selling as high as 16 cents; other grades less, according to quality. Extracted is very active and prices are a little better; amber, 5 1/2@5 3/4c; alfalfa, 6 1/2@7 1/2 cents; white clover, 7 1/2@8c. Beeswax, 28c. C. H. W. WEBER.

SAN FRANCISCO, Nov. 12.—White comb honey, 10 1/2@11 cents; amber, 9@10c; dark, 5@—c. Extracted, white, 6@6 1/2c; light amber, 4 1/2@5 1/2c; amber, 3 1/2@4c. Beeswax, good to choice, light, 26@27c; strictly fancy light, 29@—.

White is reported scarce; light amber honey in fair supply. The bulk of California produced honey is sold for Eastern shipment in carload lots from producing point at bottom price. Small lots of choice honey that can be used in local trade bring more. Quotations here given are current prices to producer, f.o.b. shipping point, on Eastern basis for extracted and California basis for comb.

Tip-Top Glass Honey-Jars

The picture shown herewith represents the best one-pound jar for honey that we know of. It is made of the clearest flint glass, and when filled with honey, and a neat label attached, it makes as handsome a package as can be imagined. Its glass top sets on a flat rubber ring, and is held in place by a flat steel spring across the top as shown in the picture. It is practically air-tight, thus permitting no leak,

which is an important thing with honey-sellers.

We can furnish these jars, f.o.b. Chicago, at these prices: One gross, \$5.00; two gross, \$4.77 a gross; five or more gross \$4.50 per gross

If you try them once you will likely use no other kind of top or sealing arrangement for honey jars.

THE HERSHISER HONEY-JARS.

These jars were designed for use in the honey exhibit at the Pan-American Exposition, in Buffalo, and are very neat and attractive. They have cork-lined aluminum caps which seal them tight. If honey is sealed in these jars while hot there will be no annoyance from granulation.

For exhibition purposes and a fancy trade nothing on the market compares with these jars. Put up your honey in a neat, attractive package, and sell it at a good price.

The fact that the molds are constructed for making the jars by hand instead of by machine, and the addition of the aluminum caps, make the jars somewhat more expensive than the ordinary jars. They are made in four sizes square and three sizes round, as shown in the illustration. We can supply them either from Medina or from Philadelphia at the following prices:

1/4 pound Square Hershiser Jars, doz., 50c; \$5.40 per gross.
1/2 pound Square Hershiser Jars, doz., 55c; \$6.00 per gross.

1 pound Square Hershiser Jars,	- - - - -	Dozen, 80 cents; \$ 9.00 per gross
2 pound Square Hershiser Jars,	- - - - -	Dozen, \$1.00; 10.80 per gross
1/2 pound Round Hershiser Jars,	- - - - -	Dozen, 60 cents; \$ 6.60 per gross
1 pound Round Hershiser Jars,	- - - - -	Dozen, 75 cents; 8.40 per gross
2 pound Round Hershiser Jars,	- - - - -	Dozen, \$1.10; 12.00 per gross

These prices, although rather high in comparison with other jars, are as low as can be made on hand-made jars, and afford us a smaller margin of profit than other styles. Order a sample dozen of each size and be convinced.

THE A. I. ROOT CO., Medina, Ohio.

A Celluloid Queen-Button is a very pretty thing for a bee-keeper or honey-seller to wear on his coat-lapel. It often serves to introduce the subject of honey, and frequently leads to a sale.

NOTE.—One reader writes: "I have every reason to believe that it would be a very good idea for every bee-keeper to wear one of the buttons; as it will cause people to ask questions about the busy bee, and many a conversation thus started would wind up with the sale of more or less honey; at any rate it would give the bee-keeper a superior opportunity to enlighten many a person in regard to honey and bees."

The picture shown herewith is a reproduction of a motto queen-button that we are furnishing to bee-keepers. It has a pin on the underside to fasten it.

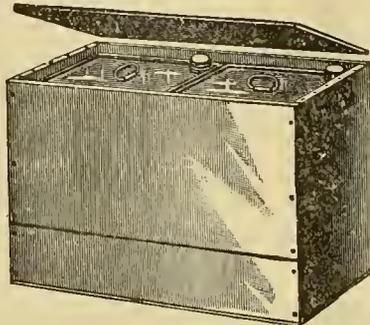

Price, by mail, 6 cents; two for 10 cents, or 6 for 25 cents. Send all orders to the office of the American Bee Journal.

BEST Extracted Honey For Sale

ALL IN 60-POUND TIN CANS.

Alfalfa Honey

This is the famous White Extracted Honey gathered in the great Alfalfa regions of the Central West. It is a splendid honey, and nearly everybody who cares to eat honey at all can't get enough of the Alfalfa extracted.

Basswood Honey

This is the well-known light-colored honey gathered from the rich, nectar-laden basswood blossoms. It has a stronger flavor than Alfalfa, and is preferred by those who like a distinct flavor in their honey.

Write for Quantity Prices by Freight, if interested.

A sample of either, by mail, 10 cents, to pay for package and postage.

Order the Above Honey and then Sell It.

We would suggest that those bee-keepers who did not produce enough honey for their home demand this year, just order some of the above, and sell it. And others, who want to earn some money, can get this honey and work up a demand for it almost anywhere.

GEORGE W. YORK & CO., 144 & 146 E. Erie St., Chicago, Ill.

The Novelty Pocket-Knife.

Your Name and Address on one side—Three Bees on the other side.

[THIS CUT IS THE FULL SIZE OF THE KNIFE.]

Your Name on the Knife.—When ordering, be sure to say just what name and address you wish put on the Knife.

The Novelty Knife is indeed a novelty. The novelty lies in the handle. It is made beautifully of indestructible celluloid, which is as transparent as glass. Underneath the celluloid, on one side of the handle is placed the name and residence of the subscriber, and on the other side pictures of a Queen, Drone, and Worker, as shown here.

The Material entering into this celebrated knife is of the very best quality; the blades are hand-forged out of the very finest English razor-steel, and we warrant every blade. The bolsters are made of German silver, and will never rust or corrode. The rivets are hardened German silver wire; the linings are plate brass; the back springs of Sheffield spring-steel, and the finish of the handle as described above. It will last a last-time, with proper usage.

Why Own the Novelty Knife? In case a good knife is lost, the chances are the owner will never recover it; but if the "Novelty" is lost, having name and address of owner, the finder will return it; otherwise to try to destroy the name and address, would destroy the knife. If traveling, and you meet with a serious accident, and are so fortunate as to have one of the "Novelties," your POCKET-KNIFE will serve as an identifier; and in case of death, your relatives will at once be notified of the accident.

How appropriate this knife is for a present! What more lasting memento could a mother give to a son, a wife to a husband, a sister to a brother, or a lady to a gentleman, the knife having the name of the recipient on one side?

The accompanying cut gives a faint idea, but cannot fully convey an exact representation of this beautiful knife, as the "Novelty" must be seen to be appreciated.

How to Get this Valuable Knife.—We send it postpaid for \$1.25, or give it as a Premium to the one sending us THREE NEW SUBSCRIBERS to the Bee Journal (with \$3.00.) We will club the Novelty Knife and the Bee Journal for one year, both for \$1.90.

GEORGE W. YORK & CO.

No. 50.

* Editorial Comments. *

The Bacillus of Foul Brood.—That excellent apicultural journal, *Le Rucher Belge*, has published an article of exceeding interest, being a report of investigations made at the laboratory of the Institute of Pathology and Bacteriology of the University of Liege, in Belgium. The report is made by Dr. Ul. Lambotte, who, at the instance of the Society of Apiculture, made the most searching investigations, and announces that instead of the microbe of foul brood being a specific bacillus to be found nowhere in Nature except in cases of foul brood, it is one of the common microbes to be found everywhere, the bacillus *alvei* being identical with the well-known *bacillus mesentericus vulgaris*.

This announcement will be received with surprise—indeed, by many, with incredulity. But there seems little chance for any mistake in the matter. Microbes of the foul brood were obtained from many and widely different localities, and comparisons were carefully made with bacillus *mesentericus*, as also were searching tests, and all led to the one conclusion.

For the present it may suffice to withhold comment, further than to say that under the assumption that the two microbes are identical, every effort should be made to preserve our colonies in clean and healthy condition so that they may be able successfully to resist the attacks of the enemy everywhere lying in wait, and await investigations on this side the water, especially looking toward Prof. Harrison over in Canada, and Dr. Howard, in Texas.

Late Introduction of Queens has been recommended, but perhaps no one has given the matter just as G. M. Doolittle gives it in the *Progressive Bee-Keeper*. He says:

There is one thing I have learned of late which I have never seen in print, which is, that it is almost the easiest thing imaginable to introduce a queen in the late fall after all the brood has emerged from the combs. Simply take the old queen out, then wait a couple or three days, during which time the colony will find out that they are hopelessly queenless, and being in this condition, and not having even any sealed brood, they will take kindly to any queen even if she is dropped right in amongst the bees.

So, if you know that any colony has a poor queen in August, and you have not supplied them with another till October, it can be done during that month more easily than at any other time. Therefore, do not put off this matter till another spring, when it will be hard work to get a queen, and hard to introduce her.

What is a Tested Queen?—Not long ago, at a bee-convention, a committee was appointed to report an answer to this question. The appointment of such a committee will bring a smile to the faces of some who know that for

years it has been understood that a tested queen is one whose worker progeny shows three yellow bands.

But a thing that "has been" may not be the best. At least not for all time. When Italians were first introduced into this country, their superiority over the common stock was considered so great that any admixture of Italian blood was an acknowledged gain, and the easiest way to tell whether a queen was of pure Italian stock was to see whether her worker progeny were uniformly provided with the three yellow bands. It was worth much to have such a test, and great good has come thereby. But in these days of golden Italians and 5-bandeders the possession of three yellow bands is not the clear proof that it once was of pure Italian stock. Moreover, now that pure Italian blood has become so common, the mere fact that one has Italian workers uniformly 3-banded is not sufficient. Uniformity as to bands is by no means indicative of uniformity of character. While possessing the desired number of bands, a colony may be the best storer in the world, and it may be one of the poorest.

So the set of bee-keepers who raised anew the question, "What is a tested queen?" are merely taking the lead in trying to decide a question that is likely to be a very live question. It is not the purpose here to discuss the question, but this much may be ventured, that the tested queen of the future will not, as the tested queen of the past, be one which has been laying only three weeks.

The Inversion System—turning the brood-frames upside down once in so often for the sake of having the bees destroy the queen-cells—was at one time looked to as a hopeful method of overcoming the swarming evil; but nothing has been heard of it for some time. Now, however, "Dilston" says in the *Australasian Bee-Keeper* that the system "is carried on successfully year after year by one, if not more, of our Australian bee-keepers." N. E. Loane also says in the same journal:

"Whatever sort of hive is used in the home apiary (I prefer the "Langstroth"), those in the out-apiaries should permit of inversion, and have a divisible brood-chamber, as, with such, swarming troubles can be greatly minimized."

The question is, whether "Dilston," in saying the system "is carried on successfully," merely means that "swarming troubles are greatly minimized."

Here comes something later on in the same journal by the editor, which gives a clear exposition of the system in full:

"Inverting the hive will not prevent swarming nor will it check swarming, but inverting the hive at the right time gives the bee-keeper entire control of swarming, if he visits his bees every eight days. Inverting has no effect on the hive unless queen-cells are present. Say you visit your bees, you find one colony preparing to swarm in three days, several others with queen-cells so far advanced as to swarm in four, five or six days, you don't want to be all those days in the apiary, simply invert those hives. Now consider what you have done. All colonies showing indication of swarming have their queen-cells turned the wrong way up. The bees destroy them and start fresh cells. You have

now so many colonies starting cells on the one day, which means they will all be ready to swarm on the one day. In eight days' time you may find others preparing to swarm; you now invert them, but those hives inverted on last visit are not again inverted, but artificially swarmed. You could invert a second time, or even a third time, but with what result? Frequently the bees in disgust either sulk or swarm, leaving advanced queen-cells. Inversion gives the bee-keeper control of swarming, it does not prevent or check it except for a few days, unless the honey-flow is at its close; it may then check it altogether."

* The Weekly Budget. *

MR. C. P. DADANT has resigned as a director of the National Bee-Keepers' Association, and Mr. C. A. Hatch, of Richland Co., Wis., has been appointed to fill the vacancy. A good selection, but all will regret the resignation of Mr. Dadant.

SOMNAMBULIST, the "delightful dreamer" of the Progressive Bee-Keeper, has this to say of one of our department editors:

"Miss Emma Wilson, Dr. C. C. Miller's right hand (wo) man, is still with us, and long may she be. Her articles in the American Bee Journal are inspiring to the faint-hearted, and are of great practical value to all."

The question now is, whether there is any sinister meaning in that partially obscured "wo" pronounced by Sommy. His established character for geniality, however, warrants the belief that his digestion is so good that he never has "bad dreams," so nothing but good must be read into what he says.

THE ELECTION OF DIRECTORS—three of them—takes place this month, for the National Association. The following inquiry has come in:

MR. EDITOR:—As I understand it, three directors are to be elected to fill the places of three of the directors of the National whose time expires, and I have seen some names put in nomination, but have not seen the names given of the directors whose time expires. Will you kindly give their names, as a good many of us may not keep track of such things closely enough to know the order in which they were elected.

INQUIRER.

The three whose terms expire with this year are: Thomas G. Newman, of California; G. M. Doolittle and W. F. Marks, both of New York.

Those who have been nominated for directors are these: Wm. A. Selser, of Pennsylvania; Udo Toepperwein, of Texas; G. W. Vangundy, of Utah; and Wm. McEvoy, of Canada.

THE CHICAGO-NORTHWESTERN BEE-KEEPERS' ASSOCIATION met in convention last week as announced. The attendance and interest were splendid throughout the two days. Among those from other States who were there are these: Dr. Miller, E. T. Abbott, N. E. France, R. B. Leahy, W. Z. Hutchinson, Dr. Nussle, Huber H. Root, J. E. Armstrong, N. Young, W. J. Pickard and wife, Frank Wilcox; and Morley Pettit, of Canada.

The officers were re-elected as follows: President, George W. York; Vice-President, Mrs. N. L. Stow; and Secretary-Treasurer, Herman F. Moore.

We had a full shorthand report taken, which will appear in the American Bee Journal in due time. It will be worth many dollars to those who will be fortunate enough to read it.

Convention Proceedings.

THE DENVER CONVENTION.

Report of the Proceedings of the 33d Annual Convention of the National Bee-Keepers' Association, held in Denver, Col., on Wednesday, Thursday and Friday, Sept. 3, 4 and 5, 1902.

(Continued from page 776.)

Pres. Hutchinson—The next thing on the program is the paper by Mr. C. A. Hatch, of Wisconsin. Mr. Hatch is not here, so the secretary, Dr. Mason, will read it.

Dr. Mason then read the paper, which is as follows:

REPORTING THE HONEY CROP; WHEN AND HOW IT SHOULD BE DONE.

Statistics can be used for two purposes—one to give general information as to a business or calling, for the purpose of educating the public and thereby increasing or showing up the importance of the calling or business; the second use of statistics is for commercial purposes only, and need not be as elaborate and exhaustive as the former, and, therefore, is less expensive to obtain. The first would require a complete and extensive report from each bee-keeper as to the number of colonies kept, and the amount of honey and wax produced; while, for the second, the honey alone would be sufficient to furnish all data needed.

WHEN STATISTICS SHOULD BE COLLECTED.

While there are many localities that get the larger part of their surplus in dark or amber honey, we have noticed that while this later, or fall crop, of dark grades may be abundant, it cuts only a small figure in influencing the honey market, its price being graded from the price of white honey at the time; but if white grades are in excess of the demand, the dark is sure to feel the depressing effect. While this may not always be true, for practical purposes we think it is, and, therefore, assume it as a fact.

In looking over the field from Maine to California, we find that most, if not all, the white honey of this country is produced during June and July. Therefore, if we have a report for the two months we will have the white honey crop report.

WHO SHOULD MAKE THE REPORT.

Facts are what are wanted, and there is no one who can furnish these facts as well as the bee-men themselves; and where there is an organization it should be done through the local society to the National, the secretary of the National giving out a summary each month, or oftener, to all the bee-papers, showing tons of product this year and previous years at that date. This need not be a report from every bee-keeper, only an aggregate of the crop for a certain locality, say Colorado, for instance, 200 tons for June; last year's crop 175 tons; Wisconsin, 150 tons for June; last year, 200 tons. This kind of report, stating kind, extracted or comb, is all the buyer or seller need know; and we take it that their interests are mutual, about knowing the facts as to a crop.

STATISTICS MUST BE COMPARATIVE.

To know that the crop this year is so many tons amounts to but little when it is not also known how much the same territory produced last and previous years. The crop last year might have been 100 tons, and the demand 120 tons, consequently good prices. The crop this year might be 130 tons, and demand the same, and low prices are sure to follow unless a new use can be found to increase the demand. As a rule, lowering the price increases the demand, but not always. Some markets will take only so much, no matter what the price, and to lower prices for such a market is only to lessen profits.

THE EXPENSE OF REPORTS.

The ones benefited ought to, in justice, pay the expense; but that, perhaps, would be hard to adjust; so, according to present light, the larger or National association

should pay the bill. This society has most of the larger producers as members, and they could report for small producers and other large producers who are not members. Three postal cards sent to each reporter would cover the cost, except condensing and arranging. To avoid confusion, each correspondent should understand what territory he is reporting for, and not do as the editor of one of our bee-journals does, assign a man to a county, even if it is as large as an ordinary State. Mr. York please note this last item.
C. A. HATCH.

Pres. Hutchinson—The man who was chosen to respond is a man who can probably tell us something from actual experience. I will call on Mr. Frank Rauchfuss.

RESPONSE OF MR. RAUCHFUSS.

Frank Rauchfuss—Our brother bee-keeper from Wisconsin says that statistics can be used for two purposes: First, for general information about the business; second, to give the necessary information for commercial purposes. For the sake of brevity I will confine my remarks to the latter, as this is of the most importance to those engaged in the business, and also the dealer in honey.

It is of great value to the bee-keepers to know at the earliest possible date what the honey crop of the country will be; what sections are likely to have an available surplus, and what sections are short, and, therefore, may furnish a market for the surplus of other localities.

As matters have stood so far, the bee-keeper has had a decided disadvantage, because there was no way for him of securing the desired information, except what he could find out from the fragmentary reports published in the newspapers.

On the other hand, the merchant dealing in honey, by reason of his keeping in close touch with his shippers and others, is generally well-informed about crop conditions when the time comes around for marketing the crop, and he naturally makes the best possible use of it. It behooves the producer of any commodity to be as well informed as possible about the supply and demand of his products, and he should not be afraid to spend some money in securing this information, as it is wisely invested.

The first reports of the commencement of the season should state how the bees wintered, and their condition at the time of making such report, and whether there are more bees in the locality than the previous season. A little later the prospects for a crop should be reported. When the honey-flow commences reports should be made semi-monthly, giving conditions of flow, quantity of honey taken off, comb or extracted, white or amber, and if sales have been made, to give quantity sold and price obtained.

If it were a fact that all the honey-producing sections of the United States were supplied with well organized County and State bee keepers' associations, then I would strongly recommend that all county associations should report at certain intervals to their State associations, and the State association report as often to the National. These reports should then be published in the official organ of the National association promptly. But as long as there are many States in this Union that do not even have a State association, this course can not be pursued, and we have to look for some other way.

It is probable that the United States Department of Agriculture could be interested in the matter, and induced to undertake this work; crop reports gathered by the government are, as a rule, reliable, if they could be secured promptly. However, if there is no hope to secure it through these channels, it seems that the National Bee-Keepers' Association might be able to start the ball rolling, by gathering at first reports of the principal honey-producing sections of the United States, and if this attempt proves to be successful, branch out until every honey-producing State in the Union is included.

As Mr. Hatch says, this should be borne by the persons receiving such information; if the National association does the work, these reports will go to all the members, and the Association bear the expense. Whether this is feasible at the present membership fee, a trial only will show; but that good, reliable and prompt reports will be appreciated by all progressive bee-keepers is quite certain.

Now, if it is of any value, I will make a few remarks regarding our experiment of gathering crop reports last year.

We, last year, sent about 400 postal cards to bee-keepers that we knew were interested in this work. It seems the effort was not very much appreciated, as there were only about 46 to 48 replies. These people paid in 50 cents at the commencement of the making of the reports with this un-

derstanding: "This season the Honey Producers' Association has decided to take up the work with some modifications suggested by experience, such as, that questions will be sent out to be answered before May 20, June 15, July 1 and 15, Aug. 1 and 15, Sept. 1 and 15, and Oct. 1, respectively. A copy is enclosed, and you are requested to answer at once those asked for May 20; details from the reports received will be compiled and sent to all bee-keepers shortly after each of the dates mentioned." (Reads copy of letter sent out.)

Now, these reports were received all through the season, and as the season progressed, and the work of the bee-keeper was more pressing, we found they were getting less and less all the time, but we were fortunate in retaining sufficient people in each locality to make the reports of considerable value to every Western bee-keeper, and there is no doubt they have been largely instrumental in obtaining better prices for honey not only in Colorado, but also all the honey-producing sections of the West. I spoke to a gentleman from northern Colorado last night, and he says he is quite sure that these reports which he had obtained at a cost of 50 cents, had benefited him to the extent of at least \$30.

F. E. Brown—We can see by these papers and discussions how it is possible to get reports from our members, where we are organized in the local societies, but the thing that interests me is, How can I get the reports from you of other societies? In California the buyers who control the honey of central California for sale, will come to me and say that Arizona has stacks and car-loads of honey, and they are offering it on the market at such and such prices; they will tell us that in southern California they have tons and tons, and, as it was reported last year, they had anything from 500 to 1000 car-loads to be put on that market. These reports were used to influence the market. The thing you want, and I want, is to know exactly what is reported all over, and the question is, How shall we accomplish that object? How can these reports that come in be communicated to me, and how can my report be communicated to you, that we may all know?

J. C. Carnahan—I don't know who originated the idea that Mr. Rauchfuss spoke to us about a minute ago, but I do know this, that if we had followed the instructions of Mr. Rauchfuss, it would certainly have been worth \$100 to me this year in the marketing of my honey crop. I think if it was followed right through the whole country, it would be a good idea—each one in the State reporting to the headquarters of the State, and then the headquarters of the State reporting to the National, so that each bee-keeper in the National might know the condition of the honey supply in all parts; he would know when to sell, and what price to ask for his honey; and I think it is a grand idea, and everybody, not only in Colorado, but in the whole country, would profit by the idea that was gotten up in that pamphlet by Mr. Rauchfuss; it is a good one.

Herman Rauchfuss—I believe this convention helps a great deal towards accomplishing just what we have been talking about; we just have to get acquainted with each other. Mr. Brown said he had written to Colorado trying to get some information, and he couldn't get it. We never were able to make any connection with the California bee-keepers. We come together here, and we come to these meetings, and the better we get acquainted the sooner we will accomplish our objects. After we have accomplished them we will certainly get a better price for our honey than we have been getting up to this time. We have had this in Colorado, and the same works all over the country. In fact, I believe the time will come when we will not have local organizations—we will have a National organization all over the country, and this one here, and in California, and in other States, will be nothing but branches.

W. L. Porter—It seems to me that this is a field that the National association might do a great deal of good in. We know by the experience of last year how the reports in the different newspapers of the country exaggerated the amount of honey that was to be sold; those in the East, and parties who wished to buy honey, did it for a purpose—to lower the price of honey when it was offered for sale, and then, afterwards, they expected the price of honey would rise, and they would profit by it. Now, if we had data from the National association so that we could go to the press and say the National association says so and so, we would have something that would have weight; and if the National association would do something in that line there is no doubt but what we would all benefit by it.

Mr. York—In the last paragraph of Mr. Hatch's paper,

he refers to me, and wishes me to "make a note of it:" he seems to intimate that I assign a reporter to each county of the United States. I do nothing of the kind; I do not try to get reports, either, for all the counties. I don't know what he refers to when he says I assign a man to a county.

(Continued next week.)

Report of the Northern Illinois Convention.

The Northern Illinois Bee-Keepers' Association held its convention in Freeport on Oct. 21 and 22, 1902. The meeting was opened with a fair attendance, considering the short crop of honey. Pres. N. A. Kluck delivered an address, referring to the peculiar season for bees, outlining the work for the season, and urging harmony and regard for the opinions of each other.

There were reported 781 colonies, spring count, and 909 colonies in the fall. Pounds of comb honey produced in 1902, 8560; extracted, 4639—or an average of a little less than 17 pounds per colony.

It was generally admitted that the past season had been one of the strangest known for many years. Nearly every one reported having to feed the bees all through the month of June, and very few took any surplus honey before the middle of August. The excessive rains all summer caused white clover to bloom in August and September, giving some honey late, which is very unusual. All reported bees in good condition for winter.

Mr. Arthur Stanley, a queen-breeder, showed some fine queens, also his method of making queen-cups, putting royal jelly in them, and transferring larvæ to cups. He also showed his queen-cell protectors. He has applied for a patent on them.

Among the questions discussed were:

"Which is the best size for a hive?" The most prefer the 10-frame.

"Would there be any advantage in having two queens in one hive?" The most of the members thought not, but Mr. Lee thought it would be an advantage.

"How do you prepare your bees for wintering in the cellar?" Mr. Hitt takes off the honey-boards and puts three thicknesses of burlap over the bees; a number of others use burlap and like it better than the honey-board. J. W. Johnson takes off the bottom-boards and puts on a wire-screen with strips to make a larger space between the screen and the lower part of the brood-frames.

"Is the fence separator and tall section a success?" Many of those who had used them like them, as they thought a nicer article of honey could be produced with them.

The election of officers resulted as follows: President, N. A. Kluck; Vice-President, O. Taylor; Secretary and Treasurer, B. Kennedy.

The next annual meeting will be held in Rockford, Ill., in October, 1903. B. KENNEDY, Sec.

Winnebago Co., Ill.

Contributed Articles.

Something About Carniolan and Italian Bees.

BY G. M. DOOLITTLE.

"I am a beginner in bee-keeping, and have been taking the American Bee Journal for a short time. I have been very much interested in your answers to questions during this year, as you make things so plain. I have only the black bees, but I see by reading that there are bees called Carniolan, and others called Italians. Will you please be so kind as to tell us, through the American Bee Journal, something about these bees, so that I may know something of them.

"CORRESPONDENT."

ANSWER.—In reply will say that, with the editor's permission, I will do the best I can in this matter.

If I am right, Carniolan bees are natives of Carniola, and were imported mainly into this country through Mr. Frank Benton, when he was in Germany. There seems to be a difference of opinion regarding these bees, some extolling them very highly as comb-builders and honey-gatherers, while others have no words of favor for them. Some

years ago I obtained a Carniolan queen, and, from careful experiments, comparisons, and close observations, it seemed to me that they were very nearly allied to the black bees I had years ago, when I first entered the ranks of bee-keepers. As there were several traits about them which I did not like, I got rid of them. The two main dislikes were that they would not go at brood-rearing to make a business of it till the honey harvest came on, when they would boom their brood at a tremendous "pace," and begin to swarm, and keep at it all through the honey harvest, which resulted in the consuming of nearly or quite all of the honey gathered through the harvest in rearing bees, which, later on, would consume all there was left in the hive before winter came, so that they gave little or no surplus, and were universally short of stores for winter, I having to supply them their winter stores from other colonies.

Later on I was led to think that those first tried might not have been the genuine article, so I procured some queens from two others who advertised the "Simon pure." But these last proved to be little, if any, different from the first. I kept these two years, but as I always had to feed them for winter, with no results in surplus honey as compared with the other colonies in the apiary, I again pinched the heads of all of these queens and installed others in their places. There may be localities in the country where the seasons and honey-flow are different, where they would do well, but I cannot help thinking that where there is only one regular honey-flow, and that lasting only three or four weeks, as a rule, these Carniolan bees are about the poorest of any for such a locality.

The Italian bee belongs to one of the yellow varieties, to which also belong the Cyprian and Syrian. The Italians are very quiet and gentle, while the other two varieties named are comparatively cross and vindictive, especially the Cyprians. Italians were imported from Italy into this country as early as 1860, so that they have had a longer experience in the United States than any other bee except the blacks.

Nearly all agree in placing the Italian bee at the head of all others, both as to ease of manipulation and honey-gathering qualities. As comb-builders they are not quite as good as the German bees, or what are commonly called black bees, which our correspondent says he has. Neither do they use so much wax in capping their surplus honey, which gives the surplus product a little inferior appearance, or what is commonly termed a "watery look." They cling very tenaciously to their combs, while the black bees often stampee and fall off their combs when the same are being manipulated. This tendency in the Italian bee makes the handling of the combs very pleasant, unless we wish to get the bees off for extracting honey, or for other purposes, when it is much more work to rid the combs of bees.

However, the main point of superiority of the Italian bee is its honey-gathering qualities, and its booming the brood in just the right time so as to have the maximum amount of bees on the stage of action just when the honey harvest is at its best. If there is any honey to be had they are away to the fields after it, and will toil incessantly all day for a very little, while the black bees often seem to think this little is not of enough account worth looking after.

In times of a good honey-yield there is not much difference between the working qualities of the two races of bees—the Italian and the German—except that the Italians are more likely to have a larger force ready for the honey-flow than the others; and, then, in connection with this, they will reduce their brood during the honey-flow so that we do not have so many useless consumers after the flow is over, to eat up what should be the winter stores. Then, in addition to this, they toil, as I said, for the littles, so that often, after the main harvest is past, they will hold "their own," even if they do not add to it, while the blacks are showing a decrease in their stores right along.

This is as I find it in this locality; but I realize that in a locality where there is a continuous flow of nectar for three or four months, a bee that is likely to breed steadily right straight along—one which did not slack up during the honey-flow—might prove to better advantage during the latter part of the season.

Therefore it is well for each to look for the bees best suited to his own special location, and after once having found such bees, I should hold to them the same as I do to the Italians for Central New York.

Onondaga Co., N. Y.

The Premiums offered this week are well worth working for. Look at them.

Report for the Season of 1902.

BY WM. STOLLEY.

THE season of 1902 proved to be abnormal in every respect, in this section of the country, as far as bee-keeping is concerned. It was a cold and exceedingly wet summer, with but very short intervals of seasonable weather, propitious for the gathering of nectar by the bees.

My bees had wintered well (in an open shed) as usual, and after selling and uniting some colonies for the sake of reducing the number wintered, I commenced the season with 28 run for extracted honey, and 3 colonies in Heddon hives for comb honey. While in former years the month of June always was the month when judicious feeding was indispensable to prevent a serious set-back in brood-rearing, this year the month of June gave me quite a little surplus in the supers from dandelions, for the first time.

This honey-producer (dandelion) made its appearance here some ten years ago, and, gaining ground continually, now is quite a factor in the keeping of bees, and the product of the apiary. This season I had colonies which gave me 20 pounds of surplus dandelion honey in June.

Another abnormal feature that presented itself the past season, was the excessive swarming, such as I never experienced in all the 23 years that I have been keeping bees, notwithstanding the very cold and wet weather we had. From the 28 colonies run for extracted honey, in large hives, I had 14 to swarm, while in previous years, five swarms from the same number was the most I got. All those farmers hereabout, who keep bees, were even much more subjected to this excessive swarming than I was.

I have a number of suitable boxes for squirrels, fixed 40 to 50 feet high up in the trees in my park, and the inmates of three of them were driven out by stray swarms from other parts of the neighborhood, and one large stray swarm went into one of my roof-hives on June 15, from which I took, on Aug. 4, 42 sections of nicely finished comb honey.

From the 28 colonies (spring count) run for extracted honey, I got on an average 108 pounds per colony, or 3013 pounds of nice, white honey, and 48 pounds of light-colored was from cappings.

The season this year practically ended about August 15, while in former years up to 1898, the 15th of August was about the time when the fall honey-flow of native bloom began; and I have had as much as 2000 pounds of dark and rank honey, obtained after that date. This state of things is changed altogether now.

But since the year 1897, I have had no dark honey, owing I think, to the increase of alfalfa and sweet clover, which blooms, it seems, are more attractive for the bees to gather from, than the wild bloom.

I increased from 28 colonies to 40 in my hives run for extracted honey, and from 3 in Heddon hives to 5; so that I now have 45 colonies, all in good condition, and packed for winter. But I propose to reduce this number next spring again, to from 25 to 30 colonies, this number being all I care to keep.

I learn that in some sections (in Michigan, for instance) locations which used to be first-class as to honey production, have become gradually poor locations, while here in Nebraska, along streams, the product of the apiary has, by proper management, been greatly enhanced, and the prospects for the future are promising still better results. The bees have found a permanent home in what was termed "the American desert" but 20 or 30 years ago.

The "white man's fly," the Indians used to call the bees, when I (now 41 years ago, in the winter of 1860 to 1862) took 3 colonies of black bees, on a common farm wagon from Omaha to Grand Island—a distance of 153 miles, and it took a 5 days' journey to land the bees in Grand Island, over a road anything else but smooth. But those 3 colonies of bees carried all right, and for 3 years I kept those bees. They never swarmed; I never got a pound of surplus—they simply lived. They were in a box, with immovable frames, of the size of the American frame—about 12 inches square—and had 8 frames. Subsequently I broke into one of them to investigate, and an old practical bee-keeper, of Germany, who was anxious to buy them, bought them and kept them for years, without getting anything out of them.

Those bees kept their own, but never sent out a swarm, as far as known. But in the summer of 1880, I once more tried my hand at bee-keeping as "a side-show," and I have been quite successful ever since. My location has improved from year to year, since I got sweet clover and alfalfa started in every direction, and of late the dandelion

and white and red clover promiae to supplement and still more improve my location for the keeping of bees. Now my bees are my much-loved pets, and will remain so, I suppose, to the end of my life. Hall Co., Nebr., Oct. 22.

Methods of Making Artificial Swarms.

BY WM. M. WHITNEY.

I READ with much interest the account of the various methods of producing artificial swarms of bees, as given in late numbers of *Gleanings in Bee-Culture*, but I am surprised that the idea of *forced, brushed, or shaken* swarms should be considered a new thing.

Of course, my personal knowledge of the subject dates back but seven years, the beginning of my bee-keeping. From what I find in the works on bee-keeping, with which I am familiar, I had thought that the practice of the several methods, not excepting the *brushed* or *shaken*, to have been well understood for many years. Perhaps my reading has not been extensive enough, or that I have taken too much for granted to form correct conclusions. I have experimented with all the methods described, but have ordinarily adopted substantially the one recommended by Dadant's Langstroth.

To illustrate: Suppose one wanted only a moderate number of colonies. Take two colonies that are preparing to swarm; for convenience designate them No. 1 and No. 10. Bring the hive with the frame of foundation or comb that is to contain the new colony, say, to No. 1; shake or brush the bees from the combs of No. 1 in front of new hive on No. 1's stand, being careful not to injure the queen, which I usually find and put her into the hive; also being careful to brush the bees from any frame having queen-cells which it might be desirable to save instead of shaking, as by so doing there would be danger of destroying the embryo queen. Then remove hive No. 1 and place upon stand No. 10, removing No. 10 to a new place; find the frame in No. 10 containing the queen, and hang in a frame-box, or set to one side in some safe place until the work in this hive has been completed. Take the frames of bees from the hive and shake in front of the new hive on No. 1's stand, until at least one-half the bees have been removed. Cut out all queen-cells and replace the frame with the queen, and the work is done. Enough bees will return to the old stand occupied by No. 1 to keep the brood warm, and enough will return from the new colony to supply the deficiency.

If No. 1 is to be re-queened, cut out all queen-cells, or in two or three days a swarm might issue. In time of rapid honey-flow surplus-cases might be put on all of the hives immediately. In fact, with prolific queens this would be necessary in case of No. 1 and No. 10, to prevent swarming.

Another method of making artificial swarms, and which has been quite successful with me, is as follows, viz.:

Early in the season, say during fruit-bloom, select a strong colony for division, and place an empty hive on a stand beside it. Remove at least one-half the bees, frames and all, with the queen, to a new hive. (I include the queen because the bees are more likely to remain if she is with them.) Separate the frames of brood in each hive, and fill in with frames of comb or foundation. Close the hives, and the work is done, re-queening in a few hours the queenless colony.

If one seems weaker than the other, change places with the hives, and everything works well, and no quarreling. I have obtained very good results in surplus honey from both colonies thus treated. Of course, if queen-cells were found, and it were desirable to rear a queen in the queenless colony, all cells excepting one or two of the best ones might be removed; but so early in the season there would seem very little danger of swarming if left alone.

It seems to me, however, not advisable to make division on the eve of a honey-flow, especially to leave a queenless colony to rear a queen from the egg unless it were to be reinforced frequently with brood from other colonies. But unless the very best judgment were used in this method of strengthening weak colonies, the production of surplus honey would be very seriously affected. Divided colonies, or forced swarms, sometimes operate like a two-edged sword. In the hands of an inexperienced person it cuts both ways, resulting in loss of surplus and destruction of what otherwise would have been a very good colony. The safe practice for such person is to wait until the swarming instinct develops.

Walworth Co., Wis.

Our Bee-Keeping Sisters

Conducted by EMMA M. WILSON, Marengo, Ill.

Value of Stored-Up Bee-Information.

Don't forget that while the bees can't store any now, that you can.

You can store your mind. If you have read your bee-book from cover to cover, don't think that is all that is necessary. Don't be satisfied with reading; study it. After you have studied it a dozen times you will still find that there are a whole lot of things that you don't know about bees.

Possibly you may not be satisfied with one text-book, and you surely need a bee-paper. You may save a good deal more than the price of a book or a bee-paper in one season if you get the contents into your head; but remember you won't have time to run and consult a bee-book when the critical time comes to apply your knowledge, and you must have it in your head ready for use.

How many blunders it would have saved bee-keepers 40 years ago if they could have had the books we have now; but the books weren't made then.

Some think there's no need to get bee-books unless they have 50 or 100 colonies. That's a mistake; yes, a big mistake. You need the bee-books, even if you have only one colony.

Using Honey in Cooking and Candies.

How many of the bee-keeping sisters are using honey in their cooking? It is more wholesome than sugar, and cookies, etc., made with honey keep fresh much longer. In fact, I think they are improved with age.

Candy made of honey is much better for children than that made of sugar, and children will have more or less candy. Why not make your own candy? Then you know what they are getting. Honey caramels are delicious, and easily made. They are nice for children with colds and coughs, and they never have to be coaxed to take such medicine.

Can't we do more to increase the use of honey by using it ourselves, and inducing our neighbors and friends to use it, too? Just send them a sample of our product once in a while, when we have extra-good luck. I often think the saloon-keepers are much wiser than we are. They know how to create a taste for their goods, and succeed in selling them, too, in spite of all the misery and woe that follow in their wake.

Uniting Weak Colonies in the Fall.

The season of 1902 being so poor, on account of a late spring and wet and cold weather, half of my bees did nothing at all. I took off eight supers that had nothing in them. I got only \$12.60 worth of honey. I sold it for 15 and 20 cents a section. When I took off the supers, the last of September and the first of October, they all seemed to have enough stores to last them. The weather the latter part of October and the most of November has been very nice, and the bees have flown quite freely almost every day. The latter part of November was too cold and windy. When I examined the bees lately I found I would have to do a good deal of feeding, so when it was a nice day and they were flying pretty freely I went to work doubling them up. I have united eight colonies; that is, I have put so many in with so many more. I had three colonies that seemed to have plenty of winter stores.

I have been very successful in doubling up, no fighting at all. I paid no attention to the queens—thought they could do that themselves. I had the hives in pairs, and I overhauled them to see that there were no worms, then I took out the frames in the one that had no honey, or not much, then took the full ones out of the other one, bees and all, and put it in the other hive, and so on until I got the one full; when I had taken all out, then I brushed the bees off the corners and set them to one side; the hive-body would be thick with bees. I would then set it on top of the other one, then brush the bees down and give them a few puffs of smoke to drive them down among the other bees. Then I took the bottom-board and brushed them in the

same way, and left the body on top, and put in all the frames that had any honey in them that was capped. I uncapped it, then put on the cover and stopped the entrance of the top body, so that no other bees could get in, then gave them a few puffs of smoke at the entrance to drive them up to the upper part. So you see by the time I was through with them they were pretty well mixed up; either that, or the honey took all the fight out of them—at least, they showed no signs of fighting.

I was taken sick after swarming was over, so the bees were neglected, the worms got in three, but did not destroy any. I put the bees in with others. I think I must tell you how I did with the worst one; perhaps it may be of benefit to some other sister under like circumstances:

I took the hive—bees and all—off the bottom-board and set it up on end a little way from the bottom-board, with the bottom facing where it set. Then I took another body and set it in the place where that one had been, and put in two frames of comb (three would have been better); the two hardly held the bees. When I had the cover on I commenced to puff the smoke in the one that had the worms in, and kept it up until I drove them all out of that one, so they went into the one I had put in its place. The combs were empty, but I poured a little syrup in one side, so they all went in very nicely.

In the morning I stopped the entrance and carried the hive to another one, as it had none by it, and brushed the bees in front of the other and drove them in with smoke, and there was no trouble with them. All three that had the worms in them I put in with others.

If this will help some other sister it will be worth all the trouble of writing it.

I have received so much benefit from the Bee Journal that what success I have had has come from information gathered from reading it.

SARAH J. GRIFFITH.

Cumberland Co., N. J., Nov. 22.

A Kind Notice of "Our Sisters."

The Rocky Mountain Bee Journal kindly noticed our department as follows:

"A commendable bit of enterprise on the part of the American Bee Journal, is the addition of a ladies' department. This ought to increase the popularity of the 'Old Reliable' with the fair sex."

Honey as a Health-Food.

The Chicago Daily News gives in its "Health and Beauty" department this item about the use of honey:

"If people would use more honey and less butter on their bread it would be better for their health, especially for children and invalids—at least such as suffer from defective or weak digestive power. Honey is a partly-digested form of sugar, and thus relieves the stomach from the task of changing cane-sugar to grape-sugar, which must be done with other forms of sugar before they can be absorbed into the system. Many resort to honey when they want a remedy for coughs and sore throats, but why not use as a preventive?"

There is nothing particularly new in this, but the Daily News has a large circulation, and that "Health and Beauty" department is read by nearly every woman wherever it goes; and the Daily News is doing a big thing in printing that item. It is going to help a good bit to increase the use of honey.

"The Hum of the Bees in the Apple-Tree Bloom" is the name of the finest bee-keeper's song—words by Hon. Eugene Secor and music by Dr. C. C. Miller. This is thought by some to be the best bee-song yet written by Mr. Secor and Dr. Miller. It is, indeed, a "hummer." We can furnish a single copy of it postpaid, for 10 cents, or 3 copies for 25 cents. Or, we will mail a half-dozen copies of it for sending us one new yearly subscription to the American Bee Journal at \$1.00.

Queenie Jeanette is the title of a pretty song in sheet music size, written by J. C. Wallenmeyer, a musical bee-keeper. The regular price is 40 cents, but to close out the copies we have left, we will mail them at 20 cents each, as long as they last.

Questions and Answers.

CONDUCTED BY

DR. O. O. MILLER, *Mnrengo, Ill.*

[The Questions may be mailed to the Bee Journal office, or to Dr. Miller direct, when he will answer them here. Please do not ask the Doctor to send answers by mail.—EDITOR.]

Prevention of Swarming.

I see a good deal about brushed swarms, and piling up the brood several stories high. I have not tried that plan, but have practiced putting nearly all the brood over an excluder at intervals of about 3 weeks, which, on the whole, was very successful in preventing swarming; but the difficulty was that I was obliged (or thought so) to look over all the frames so put up, 8 or 10 days after, in order to cut out any queen-cells that were started, which of course, took up much time.

1. Is it necessary to do that?
2. If they were not cut out what would be the consequence?
3. If a virgin queen managed to squeeze through, I have had laying queens, in two cases, pass backward and forward through separators. Would it not result in swarming or the death of the old queen? BRITISH COLUMBIA.

ANSWERS.—1. I don't know. I hardly think so.
2. I don't know that, either. I think there would be queen-cells started in some cases, and these might be destroyed before maturing, and in some cases be allowed to mature. Just what would happen if a virgin queen should be in the upper story with a laying queen below I don't know, and I wish some one who has had experience would tell us. In some cases she would likely be killed, possibly in all.

3. In the first place, I do not believe (although there is a bare possibility I may be mistaken) that a virgin can get through a queen-excluder that she cannot get through after she gets to laying. The thorax of a virgin, I think, is just as large before laying as after, and it is the thorax that hinders going through. Let a perforation be large enough to allow the passage of the thorax, and I am pretty sure any queen will have no trouble in getting her abdomen through, no matter how heavy with eggs. I admit that a virgin will make more desperate efforts to go through than a laying queen, and that a virgin will squeeze through if she possibly can, while a laying queen in most cases will not try so hard. But let the perforation be small enough so that a laying queen *cannot* squeeze through, and she cannot squeeze through the same aperture when a virgin. Suppose, however, the perforations are large enough for a virgin to squeeze through. She would in most cases be killed—I've had that happen always in the early part of the harvest. Toward the last of the harvest, if the queen should be old, the young might supersede her. It is possible swarming might occur, but my guess would be no swarming. But I don't know, and will be glad to learn from those who have had experience.

Unfinished Sections—Placing Bees Near a Sidewalk.

1. I had quite a number of unfinished sections at the end of the season. Part of them I put on the hives, and the rest I fed back at the entrance, but the weather was too cold and the honey was not carried into the sections but was stored below. Nearly all that was not capped in the sections was carried below. Can I keep these partly-filled sections to use next season? If so, how should they be kept?

2. I live in a small village on the north side of a street running east and west. In front of my lot, six feet outside of the fence, is a row of hard-maple trees, the sidewalk being between the trees and the fence. If I should put my bees in the shade of these trees, say one rod inside of the fence, with the entrances of the hive turned to the north, do you think they would bother people going along the sidewalk? IOWA.

ANSWERS.—1. There are some who say a section left with some honey in it may be used the following season, but I think the majority would agree with me that no section

should be used next year that has even the smallest particle of honey left in it from this year. It must be cleaned out *clean*, and that by the bees. I would rather melt up a section than to use it next year if the bees have not cleaned it out this year. It is just possible that next year the bees may clean them out sufficiently if they are put where the bees can rob them—say in a pile with an entrance large enough for one bee at a time, water being sprinkled into the cells to dissolve the grains, or the sections being previously kept in a damp cellar, so that the bees would leave no granules.

2. Probably not, especially if the trees come down pretty low and are pretty close, while it is all open on the north side. It might be a good deal better, however, to have a tolerably close fence five or six feet high to prevent the flight of bees in wrong direction.

Preventing Honey-Granulation.

My honey is of very fine quality, but candies so quickly and hard I cannot obtain sale for it. Will heating prevent candying? If so, what amount of heat can I employ without injuring the quality of the honey? It is pure apple-blossom honey, and of exquisite flavor. CALIFORNIA.

ANSWER.—It is difficult to answer. Some honey candies more quickly than others, no matter what is done. Heating will not prevent candying again, unless it be sealed up as in canning fruit. It is possible that allowing it to be very thoroughly ripened before extracting would make a difference. Keeping it in a hot place, say in the neighborhood of 100 degrees for a good many days after extracting, might also help. If you heat it don't heat beyond 160 degrees; better still if not heated beyond 130.

The Buffalo Convention Report is issued in pamphlet form, size 6x8½ inches, 80 pages and cover. Besides a full report of the proceedings of the 32d convention of the National Bee-Keepers' Association, held in Buffalo, N. Y., Sept. 10, 11 and 12, 1901, it contains fine half-tone portraits of all the officers and directors of the Association; also the Constitution, a list of the membership up to the end of 1901, and the two latest bee-songs—"The Hum of the Bees in the Apple-Tree Bloom" and "Buckwheat Cakes and Honey." We believe it is the finest ever gotten out for the Association. Of course, all members of the Association receive a copy free, but there are thousands of our readers who are not yet members, but who should have this valuable Report. Better send for a copy, if you have not yet received one. Price, postpaid, 25 cents, or with the American Bee Journal one year—both for \$1.10. Send all orders to the office of the American Bee Journal. Better order soon, before all are gone.

Honey as a Health-Food is the name of a 16-page leaflet (3½x6 inches) which is designed to help increase the demand and sale of honey. The first part is devoted to a consideration of "Honey as Food," written by Dr. C. C. Miller. The last part contains "Honey-Cooking Recipes" and "Remedies Using Honey." It should be widely circulated by every one who has honey for sale. It is almost certain to make good customers for honey. We know, for we are using it ourselves.

PRICES, prepaid—Sample for 2 cts.; 10 for 10 cts.; 25 for 20 cts.; 50 for 35 cts.; 100 for 60 cts.; 250 for \$1.25; 500 for \$2.25; 1000 for \$4.00. If you wish your business card printed at the bottom of the front page, add 25 cts. to your order.

Our Wood Binder (or Holder) is made to take all the copies of the American Bee Journal for a year. It is sent by mail for 20 cents. Full directions accompany. The Bee Journals can be inserted as soon as they are received, and thus preserved for future reference. Upon receipt of \$1.00 for your Bee Journal subscription a full year in advance, we will mail you a Wood Binder free—if you will mention it.

Please send us Names of Bee-Keepers who do not now get the American Bee Journal, and we will send them sample copies. Then you can very likely afterward get them subscriptions, for which work we offer valuable premiums in nearly every number of this journal. You can aid much by sending in the names and addresses when writing us on other matters.

REVERSIBLE WALL MAP

—OF THE—

UNITED STATES AND WORLD,

WITH SPECIAL INSET MAPS OF

China, Cuba, Porto Rico, The Philippines, Hawaii, and Alaska,

Especially prepared to meet the demand for a first-class map that will give a quick, general idea of location of events the world over, and particularly to the United States and our territorial possessions. **Very useful in every Home and Office.**

66 x 46 INCHES IN SIZE.

ELEVEN BEAUTIFUL COLORS.

Best and Most Necessary Map Ever Issued.

No Home or Business House should be without it.

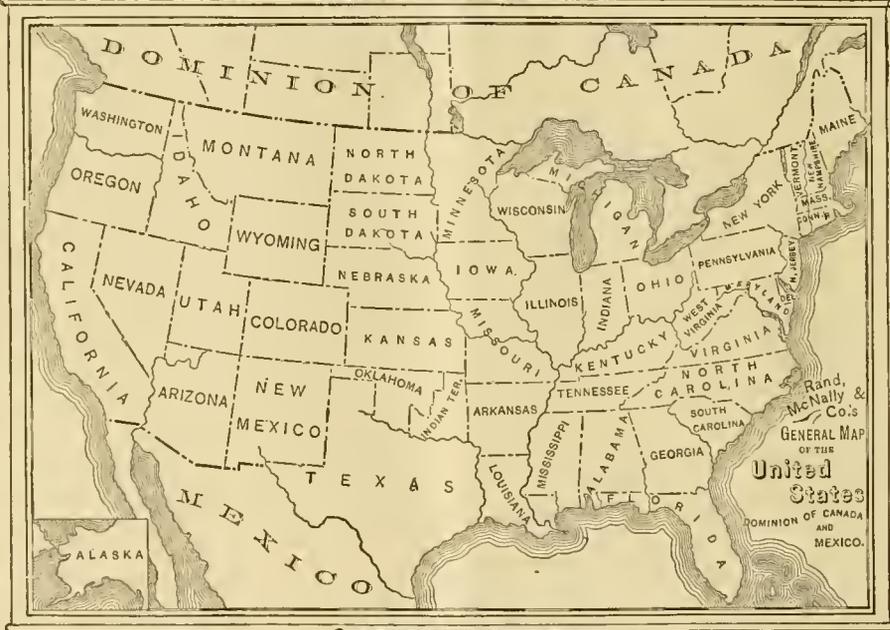

The Plates

are works of art. The engraving is plain, bold, and decisive. The color work is elegantly contrasted, but not gaudy.

Perfection and Artistic Elegance

a salient feature of this map not approached by any similar publication.

A Marginal Index

is one of the invaluable features.

It gives an alphabetical list of countries, their location on map, style of government, population, area, products, minerals, imports, exports, etc.

It has been pronounced a **Photograph of the World**

The 1900 Census of the largest American Cities is given.

One side shows a grand map of our great country, with **counties**, railroads, towns, rivers, etc., correctly located. The other side shows an equally good map of the world. Statistics on the population, cities, capitals, rivers, mountains, products, business, etc., a veritable photograph of the UNITED STATES AND WORLD.

The map is printed on heavy map paper and is mounted on sticks ready to hang. Edges are bound with tape.

1901 EDITION.—Every reader should consult it every day. The plates show all the new railroad lines and extensions, county changes, etc. Especial attention is given to the topography of the country; all the principal rivers and lakes, mountain ranges and peaks are plainly indicated. The leading cities and towns are shown, special attention being given to those along lines of railroads. The Canadian section of the map gives the provinces of Ontario, Manitoba, and British Columbia, with nearly all of Quebec and New Brunswick, the county divisions being clearly marked. The Southern portion of the map includes the Northern States of the Republic of Mexico, and the Bahama Islands.

On the reverse side is the Library Map of the World. The largest and most accurate map on Mercator's Projection ever produced. The political divisions are correctly defined and beautifully outlined in colors. The ocean currents are clearly shown and named. Ocean steamship lines with distances between important ports are given. A marginal index of letters and figures enables one easily to locate every country in the world. A series of short articles in alphabetical order is printed around the border of this map in large, clear type, containing valuable information concerning agricultural, mining, and manufacturing statistics, also the value of imports and exports in dollars. The area, population, form of government, and chief executive of every country in the world is given up to date, also the names of the capitals and their population. **The Inset Maps** are elegantly engraved and printed in colors. They are placed in convenient positions around the United States map, and will be invaluable to every person desiring a plain understanding of our possessions. An inset map of China on the World side of map adds to its value.

Two maps on one sheet, all for only \$1.50, sent by mail or prepaid express; or we will forward it free as a premium for sending us **Three New Subscribers** at \$1.00 each; or for \$2.00 we will send the Map and the American Bee Journal for one year. Address,

GEORGE W. YORK & CO.,
144 & 146 Erie Street, CHICAGO, ILL.

FREE Christmas Dinners For 10,000 Chicago's POOR will be supplied by **The Salvation Army**. You are invited to contribute either cash or provisions Address **CHICAGO Headquarters 84 Adams St. Dexter Bldg.**

FROM MANY FIELDS

Moving Bees.

On page 745, Alabama asks: "In shipping bees in very cold weather, would it do just to cover with wire-cloth? Would it not be too cold?"

I shipped 29 colonies last April from Iowa to Minnesota, over 200 miles, and perhaps my experience will help him.

I covered the top of the hive with wire-cloth, fastened up the entrance and fastened the hive to the bottom-board with strips of lath. I put the hives in the end of the car, tying them up with pieces of seantling between them, filling the rest of the car with buggy, cutter, household goods, etc.

The weather was cool, as there was snow still on the ground, though at that time of year it would not be "very cold." The bees were in the car four days. When I took them out they were so warm they were just tumbling over each other in their anxiety to get out, and were all right.

I think that as far south as Alabama and Texas there will be no danger of the bees being too cold with all the ventilation possible to give them.

My bees stored scarcely any surplus honey the past season. It was so cold and wet the middle of June, that they had but little honey in their hives. They swarmed some, and most of them have honey enough to keep them through the winter. During the white clover bloom they did quite well, but basswood bloom did not yield much honey.

J. RIDLEY.

Wright Co., Minn., Nov. 21.

Common Everlasting.

I send under separate cover a plant which please name in the American Bee Journal.

E. A. DONEY.

Scott Co., Iowa, Nov. 16.

[The plant is called the Common Everlasting, because of its persistency in blooming throughout the fall until cold weather freezes it out. It belongs to the Composite family, and no doubt is a fairly good honey-producer. —C. L. WALTON.]

Smoker-Fuel—Wintering Bees.

If you would have first-class, high-toned, way-up, crackerjack smoker-fuel, take cedar-bark, tie it in bundles the proper size for your smoker, and cut it off the right length. Try it once. Some of our Colorado people make use of cylinders made from old tin cans, that will just slip into the smoker, and when one has burned out replace it with a fresh cartridge. Very convenient. Have a lot of such prepared at leisure hours, and you will be contented and happy ever after, so long as they last.

That article on "Shade" on page 728, is all right, according to my experience, and the item on "Wintering Under Snow," page 734, is all right too. I have tried and proved it in New England, also Iowa; but the beautiful snow is not plentiful in southern Colorado. Some of our people use earth instead, with a super half filled with chaff.

JAMES H. WING.

Prowers Co., Colo., Nov. 14.

A Beginner's Experience.

I am a beginner in the bee-business. I started last fall by buying 8 colonies in box-hives. One melted down before I got it home, and later I found they were all short of stores. I fed them dry sugar in the winter, and sugar syrup in the spring. One colony deserted its hive in April and united, of its own accord, with a colony in a cracker-box. One colony

December Eggs—With the cold snap of December the egg-supply usually drops off; not altogether, however, from the actual cold as from change in the feeding ration of the hens. At this time more than ever poultry needs a liberal supply of animal food to take the place of the insects and worms which the hens get on the range in summer-time. The Stratton Mfg. Co., of Erie, Pa., have just issued a very attractive book entitled, "More Money From Your Hens." It goes into the question of winter feeding very thoroughly, and describes in detail the Dandy Bone Cutter, a well built, substantial machine for reducing green bone to poultry food. The manufacturers make a very strong claim of excellence for the Dandy, and sell every machine with a warrantee to take it back and refund every cent paid for it should it prove unsatisfactory in any way after the purchaser gives it a fair trial. We know that every reader of the American Bee Journal will be interested in the Dandy Catalog. It is mailed free. Send for it, and mention this journal when writing.

was destroyed by the bee-moth, and one did not build up in time to swarm or store any surplus. The other four did fairly well. I got 163 sections of honey, which I sold at 15 cents, and hived 12 new swarms, including 3 strays that I picked up. I find one of the new colonies is queenless, so this leaves me 16 colonies to put into the cellar, and I believe all are in good condition.

It was very wet and cold the past season—no work in the sections until July. My bees were very cross the first part of the season, and tried to rob each other a great deal; even the new colonies went at it. I expected to transfer the box-hive colonies, but gave it up on account of the robbing. I will try the job next spring. **J. J. VAN WEY, Winneshiek Co., Iowa, Nov. 19.**

Wet and Cold Season.

As I am about through extracting my crop I will report. I had one swarm the past season. It was so wet and cold until August that by that time they gave up the idea or notion. I have 8 colonies, and took 400 pounds of honey, fall flow, but of nice color and good flavor. The bees have plenty to winter on.

I can not do without the "Old Reliable." **A. J. FREEMAN, Neosho Co., Kans., Nov. 19.**

Bee-Keeping in the Southwest—Cleome and Foul Brood.

There are over 90 bee-keepers in Uvalde Co., Tex., and about one-half of these make a specialty of the business. Apiaries average about 100 colonies each.

On account of the drouth this has been the worst year for bee-keepers in the history of the county. Not one apiary in 10 has yielded any surplus, and many have required feeding.

The leading honey-plants of this region are a small tree called cat-claw, a shrub called waubea, and another called white-

An Italian Queen Free

— IN MAY, 1903 —

To Regular Paid-in-Advance Subscribers Only.

We wish to make a liberal offer to those of our regular readers whose subscriptions are paid in advance. It is this: We will send you **FREE** by mail, in May, 1903, an Untested Italian Queen for sending us \$1.00 and the name and address of a **NEW** subscriber to the American Bee Journal for a year. This is indeed a big premium, as the queen alone would cost you 75c.

We are booking orders for Queens now for next May delivery. Will you have one or more? This offer ought to bring in many orders. Our queens are reared by the best queen-breeders, and give satisfaction.

Address,
George W. York & Co., 144 East Erie St., Chicago, Ill.

SWEET CLOVER

And Several Other Clover Seeds.

We have made arrangements so that we can furnish Seed of several of the Clovers by freight or express, at the following prices, cash with the order:

brush. A plant adapted to the semi-arid region of the Lower Austral Zone, which would yield both nectar and chicken-feed, could be cultivated by the bee-keepers here with great advantage. Would cleome answer the purpose?

Foul brood made its first appearance in Texas this year, and many of us expect trouble next spring. Has any one, except Mr. Creighton, tested the rosemary cure? Would it be safe to give combs a formaldehyde bath in December, and place bees on them in February following?

I think the National Bee-Keepers' Association should bring suit for libel against the Virginia Commissioner of Agriculture. (See page 724.) One who repeats a falsehood damaging to another can not screen himself from legal consequences by prefacing his statement with, "It is said." Lying about bee-keepers will continue as long as notoriety-hunters and sensation-mongers think they can kick the bee-keepers with impunity. When they learn that bee-keepers are as good fighters as are the bees themselves, this lying will stop. The statement referred to by Mr. Ott was apparently made in the interest of the glucose manufacturers, whose product reaches the market in the form of cheap syrups which compete with honey. The commissioner does not mention these syrups, while we can not believe that he is ignorant of their composition.

J. F. GARATT.

Uvalde Co., Tex., Nov. 19.

Honey Crop a Failure—Feeding Bees.

The past season, in this section, has been an entire failure honeyward. Back from the coast 30 to 60 miles, I hear of from half to three-fourths of a crop, but next to the coast it is from a "very little" to nothing at all. Our rains were over two months late, and quit more than a month early. No rain in April, and that is the month that rains make us honey. The first rain came Jan. 24, and stopped a little after the first of March.

I came in for an extra shortage, through a brush-fire which swept off several square miles of my best bee-pasturage. Black and white sage, wild buckwheat, sumac, stick'em brush, manzanita so dense and large as to form a complete barrier against stock—all cleaned off clean as a street. Only by the greatest exertion did I save bees, honey-house, and everything connected with the business.

All this made feeding quite necessary, and the question was how to do so the cheapest and easiest. I think I solved the question in a way that, to me at least, seemed the most simple and easy of any way I have seen.

I went to the tin-shop and bought sheets of IX tin 20x28 inches, and on the tinners' square shears cut them each into six pieces of equal size (I paid 12 1/2 cents each for the sheets), turned up an edge 3/8 inches wide and folded the corners around. This gave me a shallow pan 3/8 inches deep, and about 8 inches square. Then I took old fruit-cans and either cut out the top or put them on the stove and melted them off. These I distributed around where I wanted to feed, and in the evening, after the bees had practically ceased to fly, I went around with a bucket of syrup, and dipping up a can full of the syrup placed the pan over it bottom up, and turned the whole thing over quickly and placed it on top of the frames, inside of an empty hive, and covered it up, the whole operation taking less than one-half minute, and I was done before the bees were fairly aware of being disturbed, and my hybrids are prompt and vicious in resenting an intrusion. I did not

BINGHAM'S PATENT Smokers

25Atf T. F. BINGHAM, Farwell, Mich.
Please mention Bee Journal when writing

the largest queen-bee going, and I have blacks that work on red clover, and, as to swarming, they only need watching about two weeks every spring, and then they quit swarming and settle right down to business, and will stand considerable crowding after that without swarming, which is a big advantage in getting filled-out sections.

Some time ago experience in feeding sugar syrup was asked about. I went over the ground pretty thoroughly, in nearly every respect, several years ago, and could tell of many different experiences, but a few of the successful ones will do for this time.

Two years ago I bought several colonies of bees in the valley, in box-hives, and packed them into the mountains on horses, and among the lot were two hives that were all to pieces, so I drove out the bees into boxes and carried only the bees in them. Then I run the bees into new hives with full sheets of foundation, and fed each of them \$1.00 worth of dry granulated sugar mixed with an equal quantity of water (this was the first week in September); well, they drew out about four combs each, and ripened and sealed it, wintered on it better than the others did on honey and pollen, and filled three supers each the next season, and it was not necessary for them to take any cleansing flight during the winter, as all the excrement was a little dry powder on the bottom-board. Can any one beat that for sugar-feeding?

As to feeders, there are only two kinds I would have. One is the inverted fruit-jar for outdoor feeding, the other an inverted jelly-glass with the lid full of holes for inside the hive; and my reason for liking the jelly-glass better than the pepper-box is because it is a sight feeder, and all that is necessary to do to ascertain whether it is empty or not is to raise the cover and look in.

It is worse than useless to undertake to feed after winter sets in, as I have never been successful in a single attempt to save a colony where I had to feed during the winter with anything but sealed stores in the comb.

GEORGE B. WHITCOMB.

Linn Co., Oreg., Nov. 14.

CONVENTION NOTICE.

California.—The California State Bee-Keepers' Association will hold its annual convention at the Chamber of Commerce, Los Angeles, Dec. 16, 17, 18, 1902, opening Dec. 16, at 1:30 p.m. The convention is called in December to give opportunity to ask for additional legislation. A good program is expected, and a cordial invitation extended to all who are interested.

In the Interest of the Whole People.—One of the wonders of the present age to all persons unacquainted with the true conditions is the rapid growth and development of the modern mail-order house. If only the proposition could be better understood it would occasion no wonder. The object sought to be attained is so commendable and so worthy that it has met with the entire approval of the public.

That is so because the mail-order house sells everything anybody could possibly want, giving the largest possible selection and at prices which mean a saving to any purchaser. We must admit to some surprise, however, at the very rapid growth of our advertising patrons, the Marvin Smith Company, of Chicago. This is evidenced by their large new catalog of 433 pages and cover, and contains literally thousands of cuts, diagrams and illustrations of the goods carried by this young but large, enterprising and reliable house.

Our readers will remember the Marvin Smith Company as having been the largest exclusive farm implement house in the country. Their well-known reliability and responsibility in this direction induced their many friends and patrons to write them from all sections of the country, sending in orders for goods which they did not carry. It was this constant demand which induced them to add departments of hardware, tools, builders' supplies, builders' hardware, gentlemen's clothing, all kinds of hosiery, all kinds of underwear, gloves and mittens, cook-stoves, ranges and heaters, sewing machines, tin and enamel ware of all kinds, lanterns, household supplies, trunks, valises, etc. By all means send to these people for their latest catalog if you have not already done so. The book is almost certain to save you money on every article which you wish to buy. Please mention the American Bee Journal when writing to them.

HONEY AND BEESWAX MARKET QUOTATIONS.

CHICAGO, Nov. 19.—A slow, steady market may be said of conditions now prevailing in Chicago. The volume of sales are small, and the receipts are correspondingly so. 15@16c is obtained for best lots of white comb in a jobbing way, while for selections a little more is asked; amber grades, 10@15c, according to flavor, style, etc. Extracted, white, 7@8c; amber, 6@7c. Beeswax, 30c on arrival.

R. A. BURNETT & Co.

ALBANY, N. Y., Nov. 22.—Honey market is still in strong position with ready demand for all receipts at good prices. Fancy white comb, 16c; A No. 1, 15c; No. 2 and mixed, 14½@15c; buckwheat, 14@14½c. Extracted, buckwheat scarce at 6½@7½c; light grades more plenty at 6½@7c. Beeswax, 29@30c. H. R. WRIGHT.

BOSTON, Oct. 20.—Our honey market remains firm, with good demand and fair stocks on hand. Honey is not coming forward as fast as usual, and the tendency of prices is steady. We quote our market as follows: Fancy white 1-pound sections in cartons, 16c; No. 1, 15c; No. 2, very light supply, 14c; glass-front sections generally one cent less than this. Extracted, light amber, 8c; amber, 7½c.

BLAKE, SCOTT & LEE.

KANSAS CITY, Dec. 6.—We quote fancy white comb honey, per case 24 sections, \$3.50; No. 1 white, per case 24 sections, \$3.40; No. 2 white and amber, per case of 24 sections, \$3.25. Extracted, white, per pound, 7c; amber, 6c. Beeswax, 27@30c.

Our market has changed quotations of comb honey from pound to the case.

C. C. CLEMONS & Co.

CINCINNATI, Dec. 8.—The demand for honey, both extracted and comb, has eased off somewhat the past few weeks, however the prices rule steady, as follows: Extracted, amber, in barrels, 6@7c; white clover, 8@9c. Comb honey, fancy, 16@17c; amber, 11@12c. Beeswax, 27@30c. THE FRED W. MUTH CO.

NEW YORK, Nov. 8.—Demand for comb honey is good and same finds ready sale at from 15@16c for fancy white, 14c for No. 1 white, 12@13c for No. 2 white, and 12@13c for buckwheat. Extracted in fair demand at 7½c for white, 6½c for light amber, and 6c for dark. Southern in barrels from 60@65c per gallon. Beeswax quiet at from 27@28c. HILDRETH & SEIGLEEN.

CINCINNATI, Nov. 18.—The demand for comb honey is good and prices are a little better, as the supply does not meet the wants. Extra water-white fancy is selling as high as 16 cents; other grades less, according to quality. Extracted is very active and prices are a little better; amber, 5½@5¾c; alfalfa, 6½@7¼c; white clover, 7½@8c. Beeswax, 28c.

C. H. W. WEBER.

SAN FRANCISCO, Nov. 12.—White comb honey, 10½@11 cents; amber, 9@10c; dark, 5@—c. Extracted, white, 6@6½c; light amber, 4¾@5½c; amber, 3½@4c. Beeswax, good to choice, light, 26@27c; strictly fancy light, 29@—.

White is reported scarce; light amber honey in fair supply. The bulk of California produced honey is sold for Eastern shipment in carload lots from producing point at bottom price. Small lots of choice honey that can be used in local trade bring more. Quotations here given are current prices to producer, f.o.b. shipping point, on Eastern basis for extracted and California basis for comb.

Tip-Top Glass Honey-Jars

The picture shown herewith represents the best one-pound jar for honey that we know of. It is made of the clearest flint glass, and when filled with honey, and a neat label attached, it makes as handsome a package as can be imagined. Its glass top sets on a flat rubber ring, and is held in place by a flat steel spring across the top as shown in the picture. It is practically air-tight, thus permitting no leak,

which is an important thing with honey-sellers.

We can furnish these jars, f.o.b. Chicago, at these prices: One gross, \$5.00; two gross, \$4.75 a gross; five or more gross \$4.50 per gross.

If you try them once you will likely use no other kind of top or sealing arrangement for honey jars.

DADANT & SON, Hamilton, Hancock Co., Ill.

THE HERSHISER HONEY-JARS.

These jars were designed for use in the honey exhibit at the Pan-American Exposition, in Buffalo, and are very neat and attractive. They have cork-lined aluminum caps which seal them tight. If honey is sealed in these jars while hot there will be no annoyance from granulation.

For exhibition purposes and a fancy trade nothing on the market compares with these jars. Put up your honey in a neat, attractive package, and sell it at a good price.

The fact that the molds are constructed for making the jars by hand instead of by machine, and the addition of the aluminum caps, make the jars somewhat more expensive than the ordinary jars. They are made in four sizes square and three sizes round, as shown in the illustration. We can supply them either from Medina or from Philadelphia at the following prices:

- 1/4 pound Square Hershiser Jars, doz., 50c; \$5.40 per gross.
- 1/2 pound Square Hershiser Jars, doz., 55c; \$6.00 per gross.
- 1 pound Square Hershiser Jars, Dozen, 80 cents; \$ 9.00 per gross
- 2 pound Square Hershiser Jars, Dozen, \$1.00; 10.80 per gross
- Dozen, 60 cents; \$ 6.60 per gross
- 1 pound Round Hershiser Jars, Dozen, 75 cents; 8.40 per gross
- 2 pound Round Hershiser Jars, Dozen, \$1.10; 12.00 per gross

These prices, although rather high in comparison with other jars, are as low as can be made on hand-made jars, and afford us a smaller margin of profit than other styles. Order a sample dozen of each size and be convinced.

EUGENE SECOR, General Manager and Treasurer, Forest City, Iowa.

MEMBERSHIP DUES, \$1.00 a year.

If more convenient, Dues may be sent to the office of the American Bee Journal, when they will be forwarded to Mr. Secor, who will mail individual receipts.

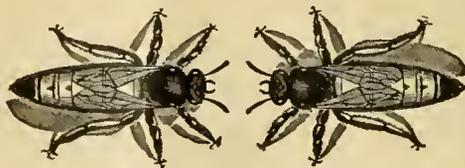

A Celluloid Queen-Button is a very pretty thing for a bee-keeper or honey-seller to wear on his coat-lapel. It often serves to introduce the subject of honey, and frequently leads to a sale.

NOTE.—One reader writes: "I have every reason to believe that it would be a very good idea for every bee-keeper to wear one [of the buttons] as it will cause people to ask questions about the busy bee, and many a conversation thus started would wind up with the sale of more or less honey; at any rate it would give the bee-keeper a superior opportunity to enlighten many a person in regard to honey and bees."

The picture shown herewith is a reproduction of a motto queen-button that we are furnishing to bee-keepers. It has a pin on the underside to fasten it.

Price, by mail, 6 cents; two for 10 cents, or 6 for 25 cents. Send all orders to the office of the American Bee Journal.

Forty Years Among the Bees

By DR. C. C. MILLER.

DR. C. C. MILLER.

The above is the title, and name of the author, of a new bee-book which will be ready some time in January, 1903, as it is now in the hands of the printers. It is a book that every bee-keeper in the world that can read English will want to own and read. It will contain over 300 pages, be bound in handsome cloth, printed on good book-paper, and illustrated with over 100 beautiful original half-tone pictures, taken by Dr. Miller himself. The book will show in detail how Dr. Miller does things with bees.

The first few pages of the new book are devoted to an interesting biographical sketch of Dr. Miller, which finally tells how he happened to get into bee-keeping. Seventeen years ago he wrote a small book, called, "A Year Among the Bees," but that little work has been out of print for a number of years. While some of the matter used in the former book is found in the new one, it all reads like a good new story of successful bee-keeping by one of the masters.

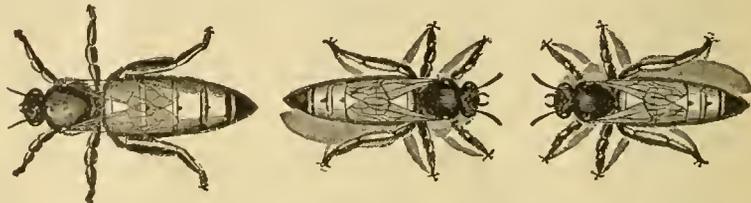

How to Get a copy of Dr. Miller's "Forty Years Among the Bees."

The price of this new book is \$1.00, post-paid; or, if taken with the WEEKLY American Bee Journal for one year, BOTH will be sent for \$1.75.

Or, any present regular subscriber to the American Bee Journal whose subscription is paid in advance, can have a copy of Dr. Miller's new book *free as a premium* for sending us **Two New Subscribers** to the Bee Journal for one year with \$2.00. This is a magnificent offer. Better send in the new subscriptions before Jan. 1, so they can begin with the new year. Or, if sent at once, we will throw in the rest of this year's numbers of the Bee Journal free to the new subscribers.

* Editorial Comments. *

When to Put Bees into the Cellar.—Those who winter bees outdoors hardly realize how grateful they should be for being free from one source of anxiety that always confronts the man who cellars his bees. Just about now there will be some puzzling over the vexatious question as to whether the bees shall go in as they are, or wait for another flight. For some reason they have been left out till they have had quite a nip of frost, and have not flown for a number of days. Every day they continue out makes them less fit to be taken in. But there is a chance that in a few days there will come a day warm enough for them to fly. On the other hand, there is a chance that no day before spring will be warm enough for a flight, and the poor cellarer is on the rack to know which way to decide. Be thankful if you can winter your bees outdoors.

A Bright Trick With Forced Swarms was given at the Chicago Convention by J. C. Wheeler, who, it seems, has been making such swarms for a number of years. Some say that all the bees should be shaken or brushed from the combs, so that the whole force of bees may be left on the old stand; and others reply that if the brood be placed on the new stand without any bees there may be a great loss from robbing, starving, or chilling. Well, Mr. Wheeler succeeds in leaving all the bees with the swarm and yet avoiding danger to the brood after the following fashion:

All the bees are shaken or brushed off, and the hive of beeless brood is set on the old stand, the forced swarm near by. The field-bees will return to the old stand, and the brood will be well cared for. In a day or two the forced swarm is put on the old stand, and the hive of brood removed to a new stand some distance away. All the old bees will be sure to go to the old stand, and enough young bees will have emerged to care for the brood, thus leaving all the bees with the swarm, and yet running no risk with the brood.

Brushing Bees from Combs.—In a very interesting report of a visit to that veteran, O. O. Poppleton, Editor Hill, of the American Bee-Keeper, gives Mr. Poppleton's plan of getting ahead of the dodgers when clearing the extracting combs of bees:

After dislodging the greater part of the adhering bees by shaking, the frame is rested upon the other frames, while Mr. P. at the right, and his assistant at the left, each provided with strong feathers, quickly brush the bees into the hive. By thus brushing both sides at the same time, there is little chance for dodging from side to side, and it is readily cleared, and passes to the hand of the assistant, who places it in the carrier while another is withdrawn and treated as before.

Eggs for Drones and Workers.—In the British Bee Journal is copied without note or comment an article by Sir Edward Arnold, in which, speaking of rearing a queen, he says:

Simply they build a special cell, shaped like the wicker basket that is used when pool is played at the billiard-table, and thither they conduct her Majesty. There does she enter, "high and composedly," like Queen Elizabeth, at Hatfield. In that cell she deposits one of the 2000 eggs which it is her daily duty to lay, and no microscope can detect the slightest difference between that egg and the others which will turn into workers or drones. But the bees place in her cell certain special foods, and lock up its gates with certain solemn observances, after which, in 16 days, lo! there is a new queen, who shall lead a swarm or govern in the old one.

If Sir Edwin had said that no microscope can detect a difference between an egg intended for a queen and one intended for a worker, it would have been all right. But when he puts in the lot eggs intended for drones, and then says no microscope can detect any difference, it shows that he has not made microscopical examinations with sufficient care, for in an egg intended for a queen or a worker will be found one or more spermatozoa, while nothing of the kind will be found in an egg that will produce a drone.

Is Sweet Clover Good for Pasture?—Some report that cattle and horses will not touch it, others that they will eat it greedily. Both are no doubt correct; at least those who say cattle will not touch it are so far correct that cattle unacquainted with it must learn to like it. But that argument might apply to corn as a feed for stock, for it is said that cattle which grow up without ever having had a taste of Indian corn must learn to like it. Look at the cultivated taste of a cow for "slops." The family bossy will eat a mixture of dishwater and almost anything else, while a cow that has never had anything besides green feed or grain will sniff at it in disdain.

An editorial in the Bee-Keepers' Review has this upon the subject:

Sweet clover as a pasture has been condemned by some people, but down in Lenawee County, Mich., I recently saw a striking illustration of the manner in which stock will eat it down. Mr. C. A. Huff, of that county, seeded down 12 acres to sweet clover. By the way, he secured an excellent catch by sowing the seed in the spring with oats. One portion of the field was fenced off and rented to a neighbor, who put in plenty of stock, and they kept it chopped down close. Mr. Huff put in only a small amount of stock, not enough to keep the clover down, and it grew as high as a man's head nearly all over his part of the field.

Here comes a note from Dr. Miller bearing in the same direction:

"At one time one or both of the Dadants said that sweet clover would not be allowed to grow if cattle were allowed access to it when young. I don't know that I ever said so out loud, but I thought that was putting the case a little strong. For the unkindness of that thought toward such reliable men I have been personally punished. Last year I turned my horses into a field which contained a patch of sweet clover some rods in extent. It was luxurious in its second year's growth. I wanted it to re-seed the

ground, but those horses kept it eaten down so closely that scarcely a seed was allowed to mature, and whatever seed may have fallen and started into growth this year, not a thing has been allowed to continue in growth, and the place is now bare of sweet clover. Last year was an exceedingly dry season and the pasturage a little short, or the case might not have been so bad. This year has been as wet as last was dry, and the horses have had more pasture than they could manage, so another field with a good start of sweet clover has been cropped by the horses in moderation."

Balled Queens in Swarms, says G. M. Doolittle in *Gleanings in Bee-Culture*, are sometimes responsible for the bees deserting the hive and returning to their old homes, just as they would do if the queen had not accompanied them. The remedy he gives is to find and smoke the ball to make the bees release the queen, when a general hum of content will announce that all is well. In exceptional cases the queen will again be balled in a few minutes, when the smoking must be promptly repeated or the hive will be deserted.

Baby Bees—Too Funny for Anything.—Occasionally one meets with information about bees good enough to find a place in a comic almanac, albeit the medium may be very far from a comic almanac in character. The following sent us by Mr. H. W. Cornelison, of Wisconsin, and taken from that very excellent periodical, the *Sunday-School Advocate*, has been received at this office:

A BABY BEE.

The honey-bee, like every other created thing, whether beast, bird, insect, or plant, was once a baby. In the spring the empty combs, made just the right size for baby bees to grow in, are carefully looked over and made clean by the bees that were born the year before, and in these cells they lay some tiny eggs. In a few days each egg becomes a little white worm. It has a large mouth like a baby bird, and is very hungry. It is fed very often with bee-bread from the mouth of a nurse-bee. In a little while it has filled the cell with its soft, white body. Then it no longer needs food. The old nurse looks at it and seems to say, "Poor little dear, you are sleepy!" and she tucks a coverlet, which has been used before, all over the top of the cell, and goes to look after her other babies. She comes back to listen once in a while to see if it is all right, and she hears a little sound. It is the baby bee weaving for itself a blanket of the finest silken threads, for it must be wrapped up for a long nap. It is now a chrysalis, and while it is taking a long rest its preparation for life is going on quietly and beautifully. The same divine hand that formed the baby boy or girl forms the baby bee, and does it just as wisely and perfectly.

In about three weeks from the time the egg was placed in the cell, if you lift the cover and look carefully into the top of their house, you will see the top of the cell, or a little waxen coverlet, break gently. Then a tiny face peeps through the opening. It looks wondering and innocent as young birds and animals do. Then it puts two hands on the broken rim of the cell and lifts itself out.—ELIZABETH GRINNELL.

Comment is unnecessary. If "Elizabeth" should get a text-book on bees and look into a bee-hive, she might be better fitted to give instruction to Sunday-school scholars, but she can do vastly better work at writing funny things for the bee-papers by remaining in her present state of mind.

"The Hum of the Bees in the Apple-Tree Bloom" is the name of the finest bee-keeper's song—words by Hon. Eugene Secor and music by Dr. C. C. Miller. This is thought by some to be the best bee-song yet written by Mr. Secor and Dr. Miller. It is, indeed, a "hummer." We can furnish a single copy of it postpaid, for 10 cents, or 3 copies for 25 cents. Or, we will mail a half-dozen copies of it for sending us *one new* yearly subscription to the American Bee Journal at \$1.00.

* The Weekly Budget. *

THE CHICAGO-NORTHWESTERN CONVENTION had a gratifying attendance, especially of those outside of Illinois, and yet quite a number were absent who possibly might have been present if they had realized in advance what was to be the character of the meeting. Bearing directly upon the matter comes the following letter from one who was present:

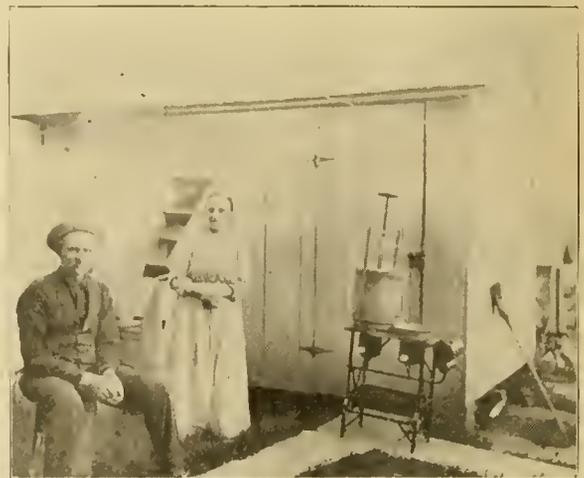

"MR. EDITOR:—I wish I could say something to some of my brother bee-keepers within easy reach of Chicago, to awaken in them a sense of the privilege they are missing by failing to attend the meetings of the Chicago-Northwestern. It was a wide-awake convention. The time was not filled up with long, prosy papers, but the question-box, for the most part, furnished material for live discussion. Bright bits of information sparkled out here and there, some of them from men who would never have given them in the columns of a bee-paper, nor in any other way than by the stimulating influence of personal contact with other men of experience in convention assembled.

"Possibly the plan of having a convention with little or nothing prepared in advance by way of program might not be a success with a sleepy presiding officer, but with the right man in the chair there will be brought out an interchange of opinions such as can not be secured in any other way. Written papers can be read at our leisure at home in the columns of the bee-papers without the expense of traveling miles from home, long speeches are likely to bore all but those who are making them, but face-to-face discussions are the things for a live convention. The personal meeting and interchange of opinion between two bee-keepers is interesting and profitable in nearly every case, and when, by set agreement, the number of such persons meeting runs up into the scores, embracing in their number thoughtful men of large experience, it is hard for any one to attend without carrying away a considerable fund of useful information. Add to this the social feature, the hand-grasp of old and new friends, and those who have never attended a live bee-keepers' convention little know the treat in store for them if they attend the next meeting of the Chicago-Northwestern."

MR. JAMES H. FISHER, when sending the pictures shown on this and the next page, wrote us as follows:

I have been sitting on the fence and watching the bee-keepers in this vicinity for about six years, and now I am about ready to come down and start for myself. I have experimented for six years. I have 9 colonies in good shape.

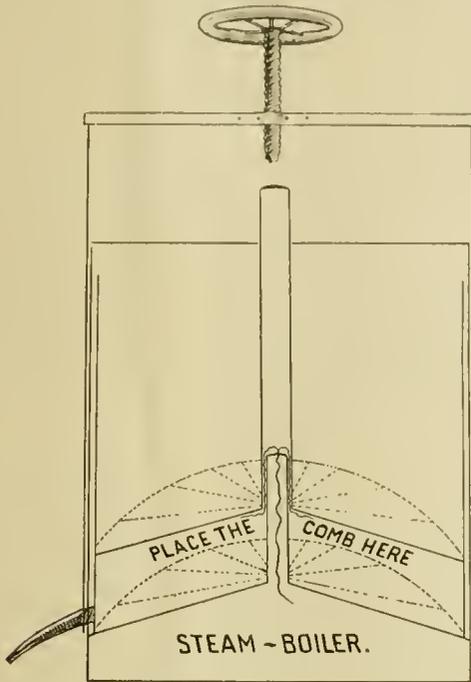

I will send a picture of my apiary and Mr. Beitel's,

Mr. and Mrs. Fisher, and the Wax-Extractor at work.

combined ; also a picture of my wax-extractor in operation, showing my wife and myself.

This extractor is an improvement over the Swiss. It has a cone-shaped bottom so as to make it strong to resist the screw ; a cone-shaped plunger to work freely so as to

Outline of Mr. Fisher's Wax-Extractor.

follow down the combs as they melt, and keep the steam in contact with same. It is guided at the top lid so it has to stay straight. The steam comes up the small pipe from the boiler into the larger one in the plunger, then down, and carries the wax out to the screen ; from there it goes to the outlet pipe to a dish or pan to receive it. Too much pressure must not be put on the screw, for the more pressure you put on it the higher the steam pressure. The steam will carry the wax out to the periphery of the machine, and there will not be any left in the refuse. It works to perfection, as the smile on the faces tell.

Northampton Co., Pa.

JAMES H. FISHER.

THE DEATH OF A. I. ROOT'S MOTHER is announced in *Gleanings in Bee-Culture*. She died full of good works and full of years, having lived another score of years beyond the "three score years and ten."

MR. R. D. CLEVELAND'S observation hive with bees appears on the first page. He has this to say about it :

I send herewith a photograph of one of my hives which, perhaps from its singularity, your readers may find more interesting than one of my whole apiary. As you will see, it is an observation hive which I made myself, and have placed on a bracket shelf attached to the sill of the sitting-room window.

I took a comb of brood with two queen-cells and all the bees and put in the observatory, and they went to work as if they had always lived there. The queens hatched in about a week, but we never saw but one of them. A few days after we saw "H. R. H." return from her bridal trip, and since we have watched all the various stages of house-keeping and rearing "children." I also added a four-section super, but the honey-flow was so scanty that they would not go up. I tried a section of uncapped honey for bait, and they took it all right, but left an empty comb. I intend to try again next year, and hope to get them to work in the super.

I am sure if bee-keepers knew how easy an observation hive is to make and manage, and how interesting and instructive it would be to themselves and friends, no apiary would be without one.

RALPH D. CLEVELAND.

Convention Proceedings.

THE DENVER CONVENTION.

Report of the Proceedings of the 33d Annual Convention of the National Bee-Keepers' Association, held in Denver, Col., on Wednesday, Thursday and Friday, Sept. 3, 4 and 5, 1902.

(Continued from page 790.)

THIRD DAY—AFTERNOON SESSION.

At 2 o'clock Pres. Hutchinson called the convention to order, and requested Mr. W. L. Porter, of Colorado, to read his paper on "Managing Out-Apiaries for Comb Honey."

Mr. Porter—As the topic assigned is on producing comb honey in out-apiaries, and as that is about the same as producing comb honey at home, therefore the paper will cover a kind of synopsis on organizing an out-apiary and running it.

MANAGING OUT-APIARIES FOR COMB HONEY.

The out-apiary is an invention of the specialist, that is, of the bee-keeper who devotes his whole time to bee-culture, depending on it for his income. In a country where the honey-producing plants are scattered, he finds it necessary to keep more bees than one location will furnish flowers for. In order that he may have a full crop he seeks a new and more favorable location.

In an out-apiary three things must be considered: 1st, Location. 2d, Stock of bees. 3d, Method of manipulation.

In seeking a location it is important that the bee-keeper should keep in mind three important facts, viz.:

1st. There must be an abundance of honey-producing plants.

2d. This must not be already stocked by other bee-keepers.

3d. A favorable place to set the hives must be found. The land should slope gently to the south, with shade ; on the north and west protection from the wind.

After a suitable location has been found it should be stocked with bees which have been bred with special reference to hardiness, to insure good wintering ; strong wing-power, for long flights and to resist the wind. They should have energy and good comb-building qualities. There should be colonies enough in a place to make it an object to spend a whole day in one yard to furnish work for the bee-keeper and his assistants. The hives should number from 100 to 150. It is necessary to have a bee-and-mouse-proof building large enough to hold supplies for a year's crop of honey and increase.

In winter the bee-keeper should make visits from time

Messrs. Fisher and Beitel in their Apiary.

to time to prevent robbing weak or queenless colonies, especially those weak or dead from foul brood. In spring the out-yards need watching for colonies which may need feeding, and later all need stimulative feeding that they may be in full strength for the honey-flow. Before plants or trees bloom wheat-flour may be fed to be used in place of pollen, and the honey in the hive may be unsealed, and, where necessary, combs of honey given them.

A very important problem which presents itself is the control of swarming. Many methods are used by different bee-keepers. Some make a practice of clipping the queen's wings, and allow natural swarming. Others dequeen the hives entirely. Whatever method is employed, two things may be profitably considered: 1st, That shaded colonies having plenty of storage-room are less apt to swarm than those under opposite conditions. 2d. That a stock of bees may be carefully bred which is not predisposed to swarm.

At the home of the bee-keeper there should be a commodious workshop, well lighted and heated for winter work. Here all hives and supers should be prepared and sections filled with foundation. As fast as these are ready they should be moved to the buildings at the out-yards. Thus, everything is made ready for the rush of the season. As fast as the honey is finished it should be taken off the hives and stored in a warm, dry room. There the sections should be cleaned, the honey carefully graded and crated. The earlier this is done the better prepared the bee-keeper is to meet the demand for early comb honey at high prices.

Managing out-apiaries for comb honey is not easy work. It is continuous work the whole year. It has some disadvantages over having all one's bees at a home yard. Much valuable time is lost each day on the road to and from the yards. But there are great advantages. In one locality, from one or another cause, the bees may dwindle badly, or the flowers may fail, then if the bees are all there a complete loss results. At another yard, perhaps at a short distance, conditions may differ so that there is a full crop and some profit is realized. Different parts of the country vary so that in one State it may be advisable to concentrate the stock; at another to scatter it widely. Each bee-keeper must study and adapt himself to the conditions of his own environment. There is one principle that applies to all localities: To get good results in comb honey it is absolutely necessary to have all hives full of bees at the time of the honey-flow.

W. L. PORTER.

Mr. Gill, who was to have responded to Mr. Porter's paper, not being present, and being engaged on a committee, the President stated they would proceed with the discussion of the paper without waiting for the response.

R. D. Williams—I have four out-apiaries, and I have never any use for a honey-house. When the honey is ready to take off I go with a wagon and haul it home; I think it is cheaper than to build a honey-house, and I don't think it is necessary; if a person is careful in taking the honey off he will have no trouble. Cover it up well, and you can get away with it all right.

R. A. Wilson—What is the best plan for handling the swarming question in out-apiaries?

Mr. Brown—In our locality [California] our out-apiaries are usually managed by dividing. We go through perhaps once in ten days and divide all colonies that have any indications of swarming; and about two or three times over is sufficient.

W. P. Collins—Do you take the brood-frames and remove them from the hives you expect are going to swarm?

Mr. Brown—Yes.

Mr. Collins—What do you put back?

Mr. Brown—Empty combs.

Mr. Collins—That you had brood in the previous year?

Mr. Brown—Yes; take them from the extracting super.

W. L. Hawley—I understand this is for comb honey. I have two out-yards that I run for extracting, and the swarming does not trouble me very much; but if I run it for comb honey it would fail entirely. I think the system of removing or dividing is all right for extracting, but when it comes to comb honey, it is a question.

Mr. Collins—I have seen hives prepared that way for comb honey, and I have taken five frames out of an 8-frame hive, and, in eight days after, I have seen a swarm cast. It is a very doubtful question whether we can produce comb honey in that way. My plan is to have two hives for one colony, and shift my colony, and fix the honey hive so that the hatching bees for the next 21 days pass continually through into the new hive; and it is not once in a hundred times that a swarm will issue.

S. Francis—I have had a little experience in managing

some out-apiaries, and we have practiced the shaking-out plan; we have the colonies all in good shape, and they are about ready to swarm, and we have the stands arranged in pairs. We take the queen from one and shake all the bees from the other, and then make one colony of the two; we take the one we took the queen from and put it on another stand, and put the new stand on the one we took the queen from, and in that way we get all the working force into one colony.

Mr. Ivy—I would like to ask those people who recommend that plan if that does not interfere with the bees storing comb honey? Do they continue as well after the manipulation as they did before?

Mr. Collins—As far as I am concerned I followed out the plan from which I suppose it has hindered a little the storing of honey. Where I have allowed the hatching bees to pass out through the hives which I shift the colony onto, I have been unable to see any difference. The plan Mr. Porter has spoken of is the one I follow where I want an increase. If I don't want it I attach the old hive to the new one so that every bee, in order to reach the field, must pass through the new one, so that when the worker returns he will return and stay in the new one.

I never had any die, and it is the handiest way, by far, because it saves a second shaking.

Mr. Hutchinson—Mr. Gill, of Colorado, is now here, and will respond to Mr. Porter's paper.

MANAGING OUT-APIARIES FOR COMB HONEY.

When W. L. Porter has told you what he knows about running out-apiaries for comb honey, there is nothing left for me to say. But I will attempt to make a few comments and add a few suggestions.

What Mr. Porter has said about locating of apiaries and about certain strains of bees, is terse, and to the point, and any one will find it profitable to follow his advice.

In locating an apiary I like to have it convenient to drive to, and have at least one approachable side where I can drive to and from with my loads without being in an exposed place with my team.

If I had everything just as I want it, I would prefer to have only one shop and honey-house. I would have a good shed at each out-apiary, under which to set supplies temporarily that were not in use. I like a good wagon adapted to the business, a Daisy wheelbarrow, and a large wagon-sheet. All supplies would be hauled from the central location to the out-apiaries, and all honey loaded right from the hives onto the wagon and taken to the central location, where it would be cleaned and cased ready for market.

With regard to the kind of hives and fixtures, and as to some particular strain of bees or some particular mode of management, I would say, follow no fad beyond the practical point. There is a limit as to how far we shall carry out the minor details in the management of out-apiaries that is certainly found between the practical and fussy plans for such work.

In the running of several out-apiaries for comb honey there is a constant demand upon our energy, and while what Mr. Porter says about valuable time being lost in traveling from one apiary to another is true, we find that there is rest in the variation, and that the changed scenes and conditions help to keep the work from sameness and drudgery.

Again, much depends upon being prepared, and if you are running a number of out-apiaries, and haven't faith in your business, and faith in the promise of a seed-time and harvest enough to prepare for a crop during the winter and early spring, you do not deserve a crop, and, in fact, can not secure one.

At the close of the season finish your work just before the bees finish theirs. Don't leave on a part of the supers perhaps all winter, but remove them, and take good care of all drawn combs, as they are valuable next season.

August and September is the time to put bees in condition for next year's crop.

In conclusion I would say, don't let this season's work lap onto next year's work, but put your bees in good condition, clean up all your honey, both comb and extracted, and sell it. Save and make all the wax from combs that accumulate.

If you are going to be a honey-producer, produce some, and when you get it produced sell it to some one who likes to dabble with pints and pounds, and turn your attention towards producing some more.

M. A. GILL.

Pres. Hutchinson—In order that some one may pass upon the exhibits, I would ask the Vice-President to take the chair so that I may get the committee to work.

Vice-Pres. Harris—Is there any discussion upon this response read by Mr. Gill?

J. Merkley—Mention is made in the paper about the Daisy wheelbarrow. We are using what I call the daisy wheelbarrow; the handles run straight to the wheelbarrow, and are hinged at the top, and there is a spring under the top that rests on a top-bar running down to these handles. That will explain the construction of the machine. We have tried the Daisy wheelbarrow and several other kinds, and this is far ahead of anything we have used. It is simple to make—a thing you can make yourself if you so desire.

Mr. Ivy—I would like to ask Mr. Gill, who recommended saving all drawn combs, whether he would use those combs the following season for the purpose of putting up comb honey, and, if so, can he have stored a first grade of honey in those combs?

Mr. Gill—I don't say I can put up a first grade of honey, but I can put up honey that will sell this year.

Vice-Pres. Harris—If there is no further discussion I will appoint Messrs. Gill and Rauffuss to escort to the front Miss Ellen Grenfell, Colorado's lady superintendent of schools, whom I have the pleasure of introducing to you. She is one of the best educators, and one of the most brilliant women that the State of Colorado has ever had in the position.

ADDRESS OF MISS GRENFELL.

After that very flattering introduction I feel as if I would like to go to the back part of the room again. I came up here not as one understanding the scientific matters regarding bees and honey, but simply as a person, who, being very fond of honey indeed, was naturally attracted by any gathering which tends to increase the production of honey in Colorado and the United States. As a school teacher, and one engaged in school work for about 20 years, I have every reason in the world to speak highly of bees. I don't know what the educational people would do if they did not have the little busy bee to hold up as an example to the rising generation as to how their work should be pursued; there certainly is not a creature after which the young people have been requested to pattern their ways as much as that little creature known as the bee.

We feel very much honored—we in Denver and in Colorado—to have you meet here from all parts of the United States.

I came to Colorado so many years ago that I don't believe there were half a dozen hives or colonies in this State; I came when there was no railroad in the State; and I know that for some time they were very unsuccessful indeed in keeping bees here and producing honey; and I remember when honey was a dollar a pound right here in Colorado, and to a child who was fond of honey that was a serious matter; and I personally have a feeling of deep gratitude to those pioneers in bee-culture who persisted in spite of repeated failures, and finally have placed Colorado among the leading honey-producing States, that is, in proportion to the amount of farming land we have, and to the amount of agricultural facilities we have in this State.

We hope you have had a pleasant visit here. We have all appreciated your visit, and we hope that you have mixed the sweet in with the work of your gatherings. I have read with much interest the account of your meetings in the papers, and I realize how much it means to have an intelligent body of people gathered together and paying attention to these details of the work. Years ago it would have been thought perhaps a strange thing that people would travel from all parts of the United States—and I notice delegates even from Canada—to consider such a thing as producing honey and bee-keeping, and yet here you are; it shows that you have dignified the business, that you are bound to make of it truly a scientific thing, and that means that there will be great improvement, because when a body of earnest people put themselves to work to understand thoroughly the conditions and to improve them, it means that the whole business is going to be elevated, and that better results will be derived than otherwise could have been the case. The great things that have been accomplished in this world have not been by hit or miss work among individuals, it has been by the steady, continued, persistent, systematic effort of the people all over the country who are engaged in that particular line.

Now, I have taken too much of your time, you have so many valuable things to discuss; but I thank you very much for giving me this opportunity to meet you, and I am looking forward with much pleasure to the discussion to be brought up here this afternoon. (Applause.)

(Continued next week.)

Rearing Long-Lived Queens and Bees.

BY C. P. DADANT.

I HAVE read with interest the numerous articles and valuable discussions on the above subject, in the American Bee Journal, for the past five months. Dr. Gallup's renewed mention of our name prompts me to present my views on the matter.

I want to tell the reader that perhaps he does not know Dr. Gallup as well as I do. My acquaintance with him dates back to 1867. I was then 16 years of age, and, though a novice, I was much interested in bees, for my father was already beginning to succeed with them on a comparatively large scale. Gallup's articles were among the first I read. He became noted at once for his practical methods, his pithy arguments, and the forcible way in which he expresses himself. At that time the contributors of the American Bee Journal were very few, and Gallup is one of the few remaining. I have kept the entire file of the American Bee Journal since the beginning. It was then, as it is now, the open field for discussion, free to all who kept within the limits of good-nature. Its first editor, Samuel Wagner, set the example, so well followed by his different successors, of refraining from influencing the deductions of the readers by any criticisms of the ideas advanced, unless evidently improper or incorrect. It is a pleasure to go back to those files, bound by my father in a simple way, and with leaves yellow from age, and see how many of the so-called new ideas that are presented now were talked over at that time by our elders. "*Nil sub sole novum*," says the proverb—"Nothing new under the sun," and many of the new things are only old things renovated, or presented under different conditions.

The "umbilical cord." This new presentation by Gallup and Doolittle would explain to me a thing at which I have often wondered. I have often asked myself whether the larva ate anything after it had begun to stretch in the cell. The food is at the bottom, the larva stretches with its head outward, therefore the food is behind it. Does it cease to eat as soon as it stretches in the cell at full length, or does it turn about once in a while, or does it absorb food through its skin, or is there a feeding canal—an umbilical cord—as Gallup says very properly, to help it to feed itself until it needs nothing more? I have looked through our scientific works in vain for the umbilical cord. Cheshire, Cowan, Cook, all say that the bowel of the larva is closed so that it cannot pass any dejections; they assert that most of the food is taken through the mouth, or perhaps through the pores of the abdomen. Cheshire states plainly that the larva turns about in the cell to throw up its stomach-lining, and lap up its remaining food previous to metamorphosis. I quote:

"The imprisoned larva, having a little more than enough room for turning, must be freed of these objectionable residua, but Nature is equal to the difficulty, accomplishing all in a manner commanding our admiration. In a word, the larva turns its head upon its stomach, and pushes the former toward the base of the cell until its position is reversed, the tail being outwards, and, thus placed, it laps up all residue of food, especially from its old clothes (the previous moultings) previously referred to, until they are dried and practically occupy no space. It now throws up its stomach and bowels, with all their contents, and without detaching them from its outer skin, which is moulted as before, but, in this instance, to be depressed against the cell so as to form for it an interior lining.... It now turns its head and resumes its old position...."—Cheshire Vol. I, page 21.

The above is concerning the worker-bee. Of the queen he says:

"The skin and bowel are indeed cast as by the worker, but they are not spread out on the cell-wall. The bowel, relatively small, and containing little waste product, is thrown against the side of the cell, just below the mass of royal jelly; and here the skin of the body is placed also, where both can always be found, by opening a queen-cell, on the third day after sealing." Here he adds: "During the earlier part of the changes, the developing insect ad-

heres, by the dorsum, to the wet royal jelly, and probably continues to take nourishment through a part of the skin." (Page 243). Here he touches the point for which we are looking, but says nothing of an umbilical cord.

I do not happen to have Prof. Cook's latest edition, I think I loaned it to some one, but one of his former editions is at hand and he says: "They [the larvæ] have a mouth with soft lips and weak jaws, yet it is doubtful if all or much of their food is taken in at this opening. There is some reason to believe that the honey-bees especially, like many maggots, absorb much of their food through the body-walls."

Cowan, while repeating the same thing, or about the same, on the intestine being blind and passing no dejections, adds that the larva absorbs the food "by the mouth, and likewise by that portion of the body floating in it."

If there is an umbilical cord—and there is one if Gallup and Doolittle have not mistaken something else for it—it is time that our scientists found it. This would not be the first time that practical men had compelled a discovery by pointing to it. The soft nature of the grub or larva renders the study of its physiology rather difficult, and that is perhaps why this has not been brought to light. But if there is an umbilical cord, it surely exists in all the bees, and is only larger or smaller, sooner or later destroyed in each one of the insects. Thus of course the best queens would show it best. I appeal to Prof. Cook, Prof. Benton, Prof. Gillette, Mr. Cowan, and all our other microscopists, to investigate this subject, and let us know what they find. Our text-books must not ignore this if there is anything in it.

Now as to the practical part of the arguments.

There was a time when we reared queens for sale on a large scale. The Italian bees were then scarce in America, and the queens were in demand to supersede the black or common race. We never attempted to rear queens in any large quantity under the swarming impulse. Our queens were reared by removing the queens from a large colony, usually the strongest in the yard. When the cells were mature they were removed and placed in nuclei in which they hatched and became fertile. These nuclei were made with two or three frames of brood and enough bees to keep it warm. Some of the best queens that we ever had were reared in this way. It would be a waste of time for any one to tell me that our bees were inferior, for I know better. The crops that we harvested were the evidence. If the rearing of the queens in this manner had been an injury, we should have had an inferior race to the common bee whose queens were all, or nearly all, reared by the swarming impulse in box-hives of all sizes. But our Italians were ahead of the blacks in every instance. A little later, we know that a great many queens were reared that were inferior, all through the country. I ascribe this fully as much to the in-and-in breeding resorted to, owing to the desire for yellow bees, as to breeding in diminutive hives. The Italians were yellow, and every one wanted yellow bees. The yellower they were the purer they were thought to be. Thus quality was set aside for color. I believe my father was the first to talk about leather-colored bees. These were better. Why? Not because of their color, but because they were bred in reference to their producing quality, and not in reference to color.

Dr. Gallup speaks of queens living 6 years, and occupying 36 combs. Such queens are exceptions. I never saw one. We used to clip the wings of our queens, and know that the average is 3 or 4 years. Unless a queen's wing is clipped it is next to impossible to assert that it is the same one, from year to year. Dr. Gallup may say that we had no such queens as he describes, because we did not rear them under the swarming impulse. But he will surely acknowledge that when one has had bees for nearly 40 years, one has seen queens reared in the natural way by the bees under the swarming impulse. It was the queens that had the strongest colonies which we clipped, because we feared to lose them.

Now as to longevity of workers. I feel that I am in very good company when I am with Dr. Miller on any point. Dr. Miller often says, "I don't know," but that gives him so much more strength when he says "I know." I hold, and think that he will back me in it, that there is not a queen in existence whose bees live from the first of May to the first of September. I say this because I have in years gone superseded many queens of the common variety with Italian queens—of course, had all been reared in the natural way—and I make bold to say that not a single bee will remain on the first of September from eggs laid in April. But if the queen is changed in August there will be many bees still left on the first of April. I believe that nine-tenths

of the bee-keepers who have tried it will agree with me. This gives plain evidence that the main cause of short life is in the wearing out of the wings and the accidents, storms, rains, enemies of all kinds, etc. When there is plenty of honey in the field the life is short and the queen must be prolific to keep up the numbers; but when there is nothing in the fields, and the bees stay at home, they have much more chances of long life. The bees of a queenless colony will live longer, because they become apathetic and stay at home.

I am very free to acknowledge that Gallup is right when he says that if we want long-lived queens we must rear them in propitious conditions, and not have her stunted and stunted by cold or want of food. I am also very free to say that the Doolittle method is the very best that has yet been devised, to my knowledge, for queen-rearing. This is known not only here, but on the continent where Doolittle's name will be fully as famous by this discovery as by all of his numerous writings. If Gallup is properly named, since he gallops ahead in spite of his 82 years, and shows us the path, I must say that Doolittle has been given the wrong appellation, and should be called "Domuch." But, gentlemen, I cannot agree to condemn all queens that are reared by other means, if they are reared with plenty of food, and plenty of warmth, in a colony that is not suffering.

Gallup says, on page 680: "Mr. Dadant, Mr. Hetherington and Mr. Quinby, all successful bee-keepers, use large hives, but they do not use hives four times as large as a 10-frame Langstroth hive." Beg pardon, but my father, who was always trying something new, did try hives with 24 Quinby frames, and found them *too large*. He had some 25 or 30 of these. Then he concluded that perhaps what the queen wanted was a large sheet of comb, so as to lay eggs uninterruptedly for twenty-four hours or more without having to pass on to another, and he had us build hives with frames 18x18 inches—a small barn. They were entire failures. No, Dr. Gallup, we are as much as any one the champions of large hives, but the man who expects any queen, no matter what she is, to fill more than 13 or 14 Langstroth frames full of brood and keep them full at one time, will find that he has to hunt for a very great exception. Exceptions do not make rules, but confirm them.

I beg to be excused for writing such a lengthy article. This is not my practice, but I wanted to view the matter from all sides. I will sum up by saying that in my opinion we must rear our queens in good, healthy colonies, of good, prolific stock, not breed too much from just one strain, try to rear queens and drones from different mothers, and look to prolificness rather than color in our selections. I cannot see any other way than to breed from those colonies that have given the best results. It is after honey that we are, and the best queens will come from those colonies that have produced the best crops. Hancock Co., Ill.

Our Bee-Keeping Sisters

Conducted by EMMA M. WILSON, Marengo, Ill.

Our Sisters in England.

"One of our most prominent bee-keepers a year or two ago wrote an article on our hobby as an occupation for the gentler sex, and at the time I felt perturbed, as I dreaded that a great and mighty Amazonian host might join the ranks and oust all of us who are mere men. The lapse of time, perhaps, or the discovery that affairs have undergone no serious revolution, have soothed my nerves and enables me now to view the matter with perfect equanimity, and I feel no perturbation of spirit even when reading over the list of new experts on page 381. Thirty-six ladies have obtained the much coveted certificate, as against twenty-five gentlemen. That must mean that the cult is extending and finding special favor amongst women, or that those going forward give more attention to preparation for the oral and written part, as well as the manipulation of hives, so as to be better fitted for passing the examination with credit. I understand they are apt pupils, and, as might be expected of their sex, readier to respond fully and promptly to the questions of the examiner. They are tactful and full of resource in manipulation, and their smart and active, yet

neat and gentle, movements tell in their favor in capturing queens and handling frames. Even in regard to the heavier and more trying calls on their strength and endurance, I remember one of the examiners once wrote words of praise and commendation."—D. M. M., in the British Bee Journal.

This shows that the women of England are pushing to the front, for 36 women against 26 men obtained certificates. That speaks well for the women. Also that the journals are willing to accord to the weaker sex their full rights and privileges.

Bee-Dress for Women—Smoker-Fuel, Etc.

On page 713, the statement is made, that bees will sting anything black more readily than any other color. Miss Wilson says:

"If there is anything our bees seem to object to, it is something black. I have known at least a dozen cross bees at a time to attack the black head of my hatpin, that being the only black object in sight."

Does Miss Wilson not wear a veil? Does not that cover at least 3 inches of the hat, making the rim black, besides wearing it over the face? If bees have such an antipathy to black, why is the black net unanimously adopted for protection by all bee-keepers? and why do not the bees sting the veil? Our veils would be attacked and covered with bees all the time, if they had such a keen appreciation of the difference of the color. Indeed, I have many times forgotten and looked over a whole hive with my black veil thrown up, entirely covering my hat, and not experienced a sting.

No, bees do not wait to see what colored shirt-waist you have on, but they scent what odors are objectionable, and if you have been doing light housework, or have been about a domestic pet, such as a dog, or a horse, their sense of exquisite odors are so acute they recognize it as a foreign odor, and sting immediately. I make it a rule never to wear my bee-dress outside of the yard. I disrobe on returning and leaving the yard. No, the grand secret of no stings is a perfectly clean garment, starched is best, and if worn only in the yard it will attain a peculiar sweet odor from the ozone of the hives, which, whether black, green, yellow or any other color, our little pets will delight in and never sting. Of course, there are a few mad bees that will sting any way, and when I have a colony that is cross I handle them very firmly, not nervously (a good bee-keeper ought not to have nerves); I give them a reasonable quantity of smoke, and talk to them; they learn in time to know my voice; and, right here, I want to say, with all due deference to the statement that bees cannot hear, I say bees can hear. I don't think they have ears, but that sound reverberates almost with electric rapidity" though their little bodies, and is the same to them as hearing is to us, one cannot doubt. You cannot walk past a hive without attracting their immediate attention; and just fire off a gun in or near the apiary, and see what an uproar it will cause at each and every hive. Tap on the hive, and how instantaneous is the result. I cannot see how any bee-keeper can say that bees cannot hear.

I left my apiary for a month; they wrote me the bees were robbing, and on my return I was worried. I entered the yard without veil or gloves; I went up to one very strong colony and spoke to them, and they all came running out, tumbling over each other. I thought I would get badly stung, but instead they just fluttered their little wings and returned to their hive without attempting to sting me, as much as to say, "You are here; we are all right now." Three other persons witnessed this extraordinary discernment of sound, and remarked it.

However, to resume: I smoke a cross colony three times, with an interval of, say 10 minutes between, and usually after three times smoking, I can open the hive and handle the bees with no further trouble.

Now as to the wearing of gloves. I think no bee-keeper ought to handle bees without them, because the hand naturally perspires, and this is exceedingly objectionable to the bees. I always wear a pair of kid gloves that come well up on the wrists, with the finger-tips cut off, so that I can feel when I lift the frame if there are any bees under my fingers, because if I squeeze and hurt them, they will sting, and the gloves are no protection then, because the stings penetrate, so one is better protected with the finger-tips of the gloves cut off. Take an old pair of kid gloves, with no holes in them, rub beeswax well into them, back and front, place them in a warm oven until the wax has thoroughly permeated the kid, and you have an ideal covering for the

hands, and our little pets will alight on the gloves, crawl over them, and never sting, because the scent is agreeable to them. I have written this before, for the sake of humanity to the bees, and comfort to ourselves. I wish every bee-keeper would adopt this method of wearing waxed gloves, as it also prevents the perspiration from saturating the gloves.

And now, with regard to fuel for the smoker. I have tried everything for 15 years. I find chips from the wood-pile make the fire too hot, and sparks fly out of the top. I find rotten wood too hot, and also sparks and cinders fall out of the top. I find excelsior burns out too quickly. I use old sack, cut in pieces, say 4 or 5 inches square. I dip one corner of the piece in coal-oil, and light up the smoker; as soon as it is about $\frac{1}{2}$ burnt out, I put in 2 or 3 pieces more, thus creating a smouldering fire which if renewed say every $\frac{1}{2}$ hour or 1 $\frac{1}{2}$ hours, according to how rapidly it is blowed, I get a good volume of smoke, with no spark or cinders to annoy the bees or cause danger of fire. Saltpeter I have never used, but if it caused the sack to burn more quickly, it would not answer my purpose. In this way I have kept rags smouldering for 3 hours, and while I go to lunch and back.

I bought a Bingham smoker 10 years ago and am still using it. I had to have a new funnel made, but the body is as good as ever, and the tin is not burned out yet.

I started bee-keeping with D. A. Jones, of Canada, and the dress I wore then, I think, can never be excelled for coolness and comfort. My dress was grass-linen, with blouse waist, ruffles at the neck, and buttoned at the wrist, and an elastic run into the blouse at the waist, fitting tight over an ordinary gored skirt with a deep hem, a pair of bloomers of grass-linen, with elastics and a ruffle, fitting over my boot tops—thin kid boots, not laced too tight; a white hat, with a strip of Victoria lawn hemmed at each side, and made long enough to tie with bow and ends, which could be removed, and laundered and replaced each week with a clean tie.

I have been reading with much interest the different methods of queen-rearing, and although I have only reared queens for my own apiary, I wish to say, that D. A. Jones had all his \$10.00 queens fertilized in those little hives, which I believe Mr. Alley is now using. I think Mr. Jones and Mr. Frank Benton were the first to use them, the latter for shipping from Italy, and many a beautiful leather-colored queen, with her 3 black dots, have I seen liberated out of said little hives. The small hive is no new idea—Mr. Jones had hundreds of them. This winter I will write an article on his method of fertilizing queens on the Islands of the Georgian Bay, of which there are 27,000.

Maybe Miss Wilson had a little sister who had inadvertently handled that hatpin with sticky hands, or else the bees mistook it for the center of a flower; certainly the odor was objectionable if they were stinging it.

Sonoma Co., Calif.

MRS. F. S. A. SNYDER.

Yes, you are right, the veil I wear is black; and mine is sewed under the brim of my hat. I had for the moment forgotten it, but the veil is not nearly so black as the head of the hatpin or black cloth, as only the thread is black, the larger part of the veil being open-work or holes.

We don't all think alike about wearing gloves. While you and I prefer to wear them, the larger majority of bee-keepers could not be induced to wear them, as very few men wear them, I believe.

Your fuel is excellent. Mr. Cogshall uses gunny-sacks for fuel. He rolls them up, I believe, in a roll, ties them at intervals with a string, and then with an ax chops them up the right length to go into the smoker. I am surprised that you are bothered with sparks and cinders from the chips. We are not troubled in that way.

Those small nucleus hives have been in use a long time. I don't know how long Mr. Alley has used them, but Adam Grimm used them many years ago, probably before Messrs. Jones and Benton started on their bee-keeping careers.

Why Not Help a Little—both your neighbor bee-keepers and the old American Bee Journal—by sending to us the names and addresses of such as you may know do not now get this journal? We will be glad to send them sample copies, so that they may become acquainted with the paper, and subscribe for it, thus putting themselves in the line of success with bees. Perhaps you can get them to subscribe, send in their dollars, and secure for your trouble some of the premiums we are constantly offering as rewards for such effort. □ ■ □

Questions and Answers.

CONDUCTED BY

DR. C. O. MILLER, Marengo, Ill.

(The Questions may be mailed to the Bee Journal office, or to Dr. Miller direct, when he will answer them here. Please do not ask the Doctor to send answers by mail.—EDITOR.)

Growing the Basswood for Bees.

1. When is the best time and the best way to plant basswood seed?
2. What will be the best time of the year to transplant basswood trees?
3. How old is the basswood before it blooms?
4. Will it pay to plant 2 or 3 acres with basswood for the bees to work on? WISCONSIN.

ANSWERS.—1. Raising basswood from seed is, I think, generally considered a troublesome thing, and I have never seen any account of any one making a great success at it. A row of about 25 trees runs from my house to the public road, and every spring a number of seedlings spring up, but never live to the next year. This year I saw hundreds of them when they were two or three inches high, and I've just been out to look over the ground and I cannot find a single plant. What becomes of them is a mystery to me. Judging from the freedom with which these have sprung up, I should say it best to plant in the fall, covering the seed from a fourth to half an inch.

2. In Wisconsin I should transplant in the spring.
3. I don't know. Perhaps ten years. Plants that shoot up from the stump of a tree that has been cut down will bloom in less time than those starting from seed.
4. With low priced land it might pay well.

Filling Combs with Honey.

Is there any demand for a feasible method of filling honey or syrup into combs? ILLINOIS.

ANSWER.—Probably not. At one time it was more or less common to fill syrup into combs with which to feed bees, and some excellent plans for that purpose were devised, but such improvements have been made in bee-feeders that it is somewhat doubtful that any one would care to fill syrup in combs.

Swarms Crawling Out After Hiving—Management for Extracted Honey.

1. I have 40 colonies of bees, and last summer when they were swarming almost every young swarm would come out over the new hive one, two and three times before I could get them to stay. What was the cause of this? How can it be stopped?
2. Which is the best way to handle bees for extracted honey, to let them swarm naturally, and then let the young colonies store section honey, or build colonies, say about one colony from two old ones, or divide them in half, or shake them off the combs in a new hive? This year I let them swarm, and extracted from the old ones, and put sections on the new colonies. I got 80 pounds of extracted honey, per colony, in spite of all the cold, wet weather. WISCONSIN.

ANSWERS.—1. It is quite possible that the new hives were too warm, because too close. If that was the trouble, the way to prevent it would be to give more abundant ventilation. When the swarm is first hived, see that the hive is shaded in some way, raise the hive from the bottom-board an inch or so by blocks, and for a day or two raise the cover or shove it partly off, so that there may be a free circulation of air through the hive. It is a good thing in any case to take these precautions with newly-hived swarms.

2. It is a hard thing to say what is best for each individual. The plan which has already proved so successful in your hands may be best for you, although you can only be sure about it by giving both plans a trial under the same conditions. That will not be a very hard thing for you to do,

Bee-House for Winter—Text-Book on Bees.

1. I am new in the bee-business, and have 7 colonies. I want some advice about my bee-house. It is 7x16 feet, paper on two sides, shiplap over that on the inside. There are two windows on top. Is that a good place to winter bees in this State?

2. What does a text-book cost? Is that the right name for it? WASHINGTON.

ANSWERS.—1. Such a house so constructed that the bees can fly freely whenever the day is warm enough, will very likely give good results in the State of Washington. My judgment in the case, however, is not worth nearly so much as that of some one who has had personal experience somewhere near you.

2. On page 815 of this journal you will find prices given of such text-books on bee-keeping, as "Bee-Keeper's Guide," "Langstroth on the Honey-Bee," "A B C of Bee-Culture," and others. By all means, secure one or more of them.

Large Hive for Extracted Honey.

Can a hive 8 feet square, for one or more colonies of bees, be made profitable for extracting honey? If so, how should it be built? Any suggestions you may make will be greatly appreciated. IOWA.

ANSWER.—I never heard of such a hive, and I doubt the advisability of building a hive equaling in capacity thirty or more ordinary hives. The only suggestion I have to offer is, "Better not try it."

* The Afterthought. *

The "Old Reliable" seen through New and Unreliable Glasses.
By E. E. HASTY, Sta. B Rural, Toledo, O.

PREVENTION OF SWARMING.

C. P. Dadant handles the prevention of swarming in a masterly manner. If there is a spot where I might rub in a little it is this. Mere *space alone* counts very little as a repressive. It must be *comb space*, and not only that, but *comb-space*, abundant *comb-space*, convenient to the center of the brood-nest. Even this, unless they have had it for a good, long while, may not suffice.

I think that perfect wintering the winter before helps on repressive measures greatly. That is, colonies which have come up rapidly from mere remnants swarm much worse than those which have been strong all the while. Page 665.

GOOD QUEENS AND BETTER ONES.

And Yon Yonson, getting one too many systems into his head (if not two too many) thinks to rear queens the size of horses by rearing them in the barn—whence he could ride them on the Gallup down the Alley. His conclusion that all good queens are good, but better ones may be a little better, is an unanswerable conclusion. On that basis our warring breeders ought to be able to make peace. Page 690.

THIS DO, AND THY BEES SHALL LIVE.

First, plenty of good food; second, plenty of bees; third, good shelter. Yes, sir, Mr. Dadant, this do and thy bees shall live. Page 679.

MOVING BEES.

On page 685, I think Wm. M. Whitney's experience in moving bees worth remembering, the outcome being so different from what one would expect. No precaution at all, and yet everything came out all right—no going back, no quarreling. He doesn't say, in regard to one of the moving troubles, whether he looked right sharp or not to see. Sometimes part of the hives get a great deal more than their share of the bees, with other hives correspondingly depleted. My guess is that it was being shut up quite awhile, under circumstances tending to make them kind o' mad, that helped them to forget so well. It's quite a distance, 130 rods; so they were bundled off quite a journey as captives. It might have been different had it been 130 feet instead of

130 rods; and especially it might have been different had they been working strongly right straight along on some source of supply.

CLEARING UP HONEY-DAUBED SECTIONS.

Perhaps we are most of us too fond of killing two birds with one stone. Might kill ten singly while getting the two in line. As to the plan on page 685 to clean up daubed sections, and incidentally feed in the open a needy colony, I'll guess the latter bird will get away. Should have a little more hope if the whole hive of sections could be set over the needy colony for a few minutes, then carry all away and treat as described. I think a strange body of bees on plundering bent at times show some disposition to protect their plunder. Defending an entrance is largely the work of a particular and small number of bees, I believe; and I opine that these cannot readily be made to leave home and do service elsewhere. A beginner will say to me; Why not leave the sections on the needy colony when you've got them there once? To make bees clean up comb placed over them, and carry down the honey, is one of the provoking things of apiculture—more frequently failure than success.

CALL "SHOOK SWARMS" SIMPLY "SHOOKS."

As for the bad grammar of the term "shook swarm," it helps some to leave the word "swarm" off, and say simply a shook, or a lot of shooks. But I hear some of the boys saying, That suggestion isn't worth "shucks"—grammar may be better, but the sound of the thing is worse. Page 691.

RED-TAPE AND RULES.

How wonderful is red-tape! A national association and a government department are engaged in the same good work, yet the latter must not directly recognize or help

the former. Rules. Very true that rules are oft necessary things; but may we not have a rule or two too many sometimes? When rules forbid that which is desirable, and we see undesirable things getting done in spite of all rules, we grumble. Wonder what sort of red-tape will be woven for use in the millennium! Page 693.

EXCHANGING EXTRA-PROLIFIC QUEENS.

The experiment of Dr. Hamlin and Dr. Gallup, exchanging extra-prolific queens, although somewhat costly, was a valuable experiment. Of eight such queens sent a long journey for test purposes all proved unprolific afterwards. Still, I guess that a week or two of just the right preparation will enable such a queen to go without much damage. Page 695.

QUEENS TO SUIT HIVE-CAPACITY.

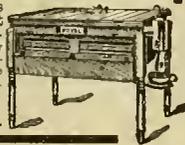

"If bees will rear a queen to suit the capacity of the hive where will the limit be found?" I echo this parting shot of E. F. Atwater, pages 696; but it is not (not on my part) with any desire to fling a hostile argument. I should not wonder if there was something in the alleged correspondence of queen and brood-chamber; but whether that something is a large something or a small one, I wonder and doubt. Willing it should be either way. Also willing to find out that any good little queen can be boomed to the point of seeming a superior and larger breed.

Queenie Jeanette is the title of a pretty song in sheet music size, written by J. C. Wallenmeyer, a musical bee-keeper. The regular price is 40 cents, but to close out the copies we have left, we will mail them at 20 cents each, as long as they last.

30 Days Free Trial

The Royal Incubator

is so good and works so well that we don't ask you to buy it before you try it. Entirely automatic; certain in results. May we send you one on trial? Catalogue free.

ROYAL INCUBATOR COMPANY, Dep. 78, Ites Moines, Ia.

FROM MANY FIELDS

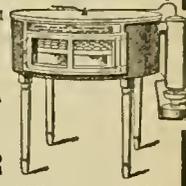

It is Helpful to Him.

The American Bee Journal has been very helpful to me, as I am yet a novice in bee-keeping. I prize it very highly for its instruction in bee-keeping, and also for its high moral and religious tone when occasion offers for such influence. STEPHEN DAVENPORT. Albany Co., N. Y., Dec. 1.

Counting Chicks Before Hatching

Is not safe unless you have an

IOWA ROUND INCUBATOR

R. C. Bauerminster, Norwood, Minn., got 493 chicks from 503 eggs. He followed directions, the machine did the work, because it was built on right principles and by good workmen. The IOWA has fiber-board case, does not shrink, swell, warp or crack. Regulation and ventilation perfect. Our free book gives more testimonials and full particulars. Everything about incubation free. IOWA INCUBATOR COMPANY, BOX 198, DES MOINES, IOWA

IT IS A FACT

That our line of Bee-Keepers' Supplies are some of the best goods in the world, and that our system of dealing with our trade is not excelled by anybody. Plenty of testimony from satisfied customers proves these things. Write and get our suggestions, our catalog and our discounts for winter-time orders—ALL FREE.

But Little Honey Gathered.

The bees gathered some nectar about three weeks in July, and that is all they gathered the past summer, not one section of dark honey this year. Nearly all the bees will have to be fed this winter, or starve, and perhaps both. J. V. B. HERRICK. Hennepin Co., Minn., Dec. 1.

Please mention Bee Journal when writing.

SPRAYING

Our line of sprayers and appliances fits every man's needs. Hand, Knapsack, Bucket, Field, Barrel, and Power sprayers twenty styles. Best nozzles made, attachments, formulas etc. Select the useful and reliable. Catalog free.

THE DEMING CO., Salem, Ohio. Western agents, Henton & Hubbell, Chicago, Ill.

Short Season in Manitoba.

The season is so short here that colonies have to be very strong early in the spring in order to get lots of honey.

I have a very poor place to winter my bees. I tried four different ways of wintering in the cellar last winter. I had four even-sized colonies. One died in January, and another was very weak in the spring, and dwindled to nothing. The other two wintered in perfect order, and were strong in bees. I got 82 pounds of comb honey from one colony, the other I kept for increase, and I got 6 colonies, making me 8 to winter this year. Manitoba, Canada, Dec. 4. A. GILBERT.

"Bees in Colorado"

I still have several hundred copies of the souvenir with the above title. The bee-papers and a good many people without visible axes to grind have said it is a valuable and attractive thing. If you should like to have a copy, send me a silver dime or 5 two-cent stamps, and I will mail you a copy.

"BEES IN COLORADO" is the title of a 48-page and cover pamphlet gotten up to boom the Denver convention. Its author is D. W. Working, the alert secretary of the Colorado State Bee-Keepers' Association. It is beautifully illustrated, and printed on enameled paper. It is a credit to Mr. Working, and will be a great help in acquainting those outside of Colorado with the bee and honey characteristics and opportunities of that State.—American Bee Journal.

D. W. WORKING, Box 432, Denver, Colo.

FOR SALE.

7000 lbs. Extracted Basswood Honey, stored in basswood barrels and kits. Large barrels each holding 330 lbs. net; 1/2 barrels, 180 lbs.; kits, 33 1/2 lbs. Prices—74c per pound in barrels, and 8c in kits, f.o.b. cars at Viola. Cash must accompany order. Sample by mail, 10c. Address, 41A131 N. L. HENTHORN, box 83, Viola, Wis.

Wild Swarms—Ginseng.

On page 762, "Utah" says he has had trouble with queens this summer. The bees have acted very queerly around here. Some colonies are queenless, and some have a good many drones at this time (Nov. 30), but still have good queens. I put my bees into winter quarters last night.

Last fall I got a swarm from the woods, and asked you about their stores. You said they were short of stores. Right, as usual.

Don't Pay Double.

We'll sell you a better hatcher for the money than any other incubator concern on earth. New improved regulator, that can't get out of order. Big book—200 illustrations free.

WHITE COMB HONEY WANTED.

Please write us, stating source gathered from, quantity, and price delivered here. It must be put up in no-drip cases. Address,

GEORGE W. YORK & CO.,
144 & 146 E. Erie Street, CHICAGO, ILL.

But they hung on until I put them out, then gave them two combs of honey from a dead colony; the queen is the best one I ever had. I got 90 sections from the young colony; then I split the old one into three parts, leaving one with four frames; one of the two-frame ones built up to 70 pounds; none of my hives weigh less than 45 pounds. This fall I am trying three more wild swarms, hived on dry comb. October 16 I fed syrup.

I see one correspondent advises putting an 8x10 glass in the honey-board. It is very good for warm weather, but as soon as it gets cold it draws moisture. I have a glass hive, but change boards in cold weather.

How long does it take ginseng to mature from seed? F. DURANT.

Winnebago Co., Wis.

[Will some one who knows please answer the ginseng question?—EDITOR.]

Worst Season in 30 Years.

I began the season with 68 colonies. I got two pounds of honey, and decreased to 60 colonies, with prospect of a good many more. This certainly has been the worst season for 30 years. R. R. STOKESBERRY.

Vermilion Co., Ind., Nov. 27.

Sweet Clover for Hay.

I put my bees into the cellar Nov. 26, 150 colonies in good shape. They had a good flight Nov. 21.

The bees worked on sweet clover from July 1 to Nov. 12. What do you want of a plant that will last longer than that? Sweet clover makes good hay in this locality.

Sauk Co., Wis., Dec. 1. H. H. PORTER.

A Good Foul Brood Law.

I am glad to say that the State of California has now a good foul brood law which is enforced to the letter, and I hope it will tend to free us in time to come from the most dreaded disease—foul brood; and that every State in the Union will do likewise, to banish for good this fatal calamity.

We have had this month about 1 1/4 inches of rain as a beginning, and prospects are good for more. GUSTAV VOSS.

Riverside Co., Calif., Nov. 29.

Feeding Bees for Winter Stores.

Since arriving home from the Denver Convention I have had a pretty hard problem to face, that of feeding my bees for winter stores. In place of their gathering a surplus they were dragging out their brood to keep from starving. Some colonies had as much as a good quart of brood dragged out, and scarcely any open honey in the hive.

Cold and rain prevented their getting out after anything. All supers with a small amount of honey in them were removed to the honey-house, following up with a pail of sugar syrup, dashing a dipper full over the tops of the frames, repeating this in about 20 minutes. This was sufficient to tide them over for two days, when we had warm sunshine again.

An examination was made of each colony, and only a very small percent of them were found with sufficient stores, and the next problem was, How shall I go about it to feed them?

Several ways were tried, but I found them too slow for 97 colonies needing enough stores for winter.

Despite the advices from the veterans, I decided to try them "wholesale," and use the watering trough, which is 12x12 inches by 14 feet long, with 6-inch fencing nailed together flatwise, with a 3/4-inch cleat between them for a float. Putting it in a warm, sheltered place I next arranged two 14-foot boards one above the other, and above the trough, with one end elevated about 16 inches. Sticks of stovewood were placed between them (the boards) to give bee-space. Two 5-gallon kegs with faucets in, completed the feeder, except

It Means Something
to the world that there is one old family remedy that is believed in by endless thousands of humanity after 40 years' trial.

WATKINS' Vegetable Anodyne LINIMENT

It means that here is a remedy that makes you feel certain of the lives of your dear ones in cases of accident or sudden sickness. It means many dollars saved to you that would otherwise go to the doctor or veterinary. In all cases of cholera morbus, diarrhoea, flux, rheumatism, cuts, cramps, strains, burns, mumps, sore throat, diphtheria, etc., it is a God-send.

Worth Its Weight in Gold.
Red Lake, Minn., June 5, 1901.
One time last summer I got very sick with cholera and thought sure we would have to send for the doctor, but after taking 3 doses of Watkins' Vegetable Anodyne Liniment I felt as well as ever. Since then I use it every day and find it the best family medicine in the market to-day; it is worth its weight in gold. JOSEPH DUCHARME.
Thousands of good people have written in the same vein.

FOR ANIMALS it cures colic, diarrhoea, sprains, cuts, scratches, bruises, swellings, etc.

Don't wait until you are down sick, or injured by some bad accident, but be sure to get a bottle from our agent when he calls. If no agent in your county, write us at once and we will see that you are supplied. Price \$1.

FREE! FREE! FREE!
We send our instructive 100-page finely illustrated Home Doctor and Cook Book to every inquirer free. It is a very valuable and interesting work for farm and home, containing weather forecasts, fine cooking recipes, etc. We send it free whether you are ready to buy now or not.

that lath were nailed on the boards 1 inches from each edge, and a 4-inch strip of sacking was laid down the center part of the boards to form more drinking-room.

The feed at first was one-third sugar, but later they were reversed, with a tablespoon of tartaric acid for 20 pounds of sugar. The feed was placed in the kegs, and a stream of syrup sufficient to allow it to run off some at the opposite end into the trough. I have fed them 1500 pounds of sugar made into syrup, and a few colonies will need more, which I am feeding individually.

I think they have sufficient to winter on, but I want to know it, so I can better enjoy the winter. A "whole lot is just about right," is good advice.

As a whole, I have no regrets having fed them as I did. The main thing is to give them plenty of drinking space, that they may not crowd one another into the feed. I found when mine were working at their best, the two 14-foot boards and the trough with fencing float was hardly sufficient space.

Syrup made 2 parts of sugar to one of water, would be carried away at the rate of about 125 pounds of sugar to the hour. I used the wash-boller on the gasoline stove to make the syrup, and fed it as warm as they would take it.

Before I commenced feeding all were examined and marked on the front of the hive, its condition as to stores and other conditions. Two drone-layers and one laying-worker colony were found, and their honey distributed to equalize with, so far as they went.

Before feeding the last 500 pounds they were again examined, and equalized by the exchange of frames. I have some 1500 partly filled sections which I will give them as soon as I take them from the cellar.

The weather during October was warm and pleasant, with but few exceptions. The bees have worked some on sweet and white clover, and dandelions, which are still blooming quite freely.

F. W. HALL.

Sioux Co., Iowa, Oct. 25.

Bees and Pear-Blight.

The editor of Gleanings in Bee-Culture comments quite fully upon the able article of Prof. Cook, published in this journal on page 664, quoting freely therefrom, assenting in general to the views expressed by the Professor. The following extract from the editorial, however, takes a little different view, and is worthy of careful perusal:

The question naturally arises, then, "If the local bee-keepers of Hanford and other infected districts can not by any procedure abate the nuisance, what is there to be done?" If the pear-blight would come anyhow without the bees, if it would spread from tree to tree by the agency of other insects, although not nearly so numerous, what possible good can come from persecuting the bee-keeper? Even if it be admitted that the bees themselves are almost the sole means for the transmission of the disease, then there is the stubborn fact that there are many colonies of bees in the rocks and caves that are what would be called in law *ferre nature*, or animals out of the jurisdiction of man, and, therefore, man can not be held responsible for the deprivations that they may commit.

Prof. Cook, in the first quotation above given, suggests or points out a reason why young nursery stock that has never bloomed should be blighted. The virus found in the semi-liquid resinous secretion, he says, would be visited by the bees, and, therefore, the bees would help spread the disease. Right here, it seems to me, we lack proof. I carefully questioned the bee-keepers and pearmen in the vicinity; and so far as I can remember no one was prepared to say that bees were ever found on these young shoots—that

1-lb Keystone ... Honey-Jars

These are clear flint glass jars holding just one pound, and the shape of a keystone. They are 7 1/4 inches high, and very pretty when filled with honey. The corks can be sunk a trifle below the top, and then fill in with beeswax, sealingwax or paraffin. We can furnish them in single gross lots, with corks, f.o.b. Chicago, at \$3.50; two gross, \$3.25 per gross; or five or more gross, at \$3.00 a gross. These are the cheapest glass one-pound jars we know anything about. We have only about 20 gross of them left. So speak quick if you want them. Address,

The Novelty Pocket-Knife.

Your Name and Address on one side—Three Bees on the other side.

[THIS CUT IS THE FULL SIZE OF THE KNIFE.]

Your Name on the Knife.—When ordering, be sure to say just what name and address you wish put on the Knife.

The Novelty Knife is indeed a novelty. The novelty lies in the handle. It is made beautifully of indestructible celluloid, which is as transparent as glass. Underneath the celluloid, on one side of the handle is placed the name and residence of the subscriber, and on the other side pictures of a Queen, Drone, and Worker, as shown here.

The Material entering into this celebrated knife is of the very best quality; the blades are hand-forged out of the very finest English razor-steel, and we warrant every blade. The bolsters are made of German silver, and will never rust or corrode. The rivets are hardened German silver wire; the linings are plate brass; the back springs of Sheffield spring-steel, and the finish of the handle as described above. It will last a last-time, with proper usage.

Why Own the Novelty Knife? In case a good knife is lost, the chances are the owner will never recover it; but if the "Novelty" is lost, having name and address of owner, the finder will return it; otherwise to try to destroy the name and address, would destroy the knife. If traveling, and you meet with a serious accident, and are so fortunate as to have one of the "Novelties," your POCKET-KNIFE will serve as an identifier; and in case of death, your relatives will at once be notified of the accident.

How appropriate this knife is for a present! What more lasting memento could a mother give to a son, a wife to a husband, a sister to a brother, or a lady to a gentleman, the knife having the name of the recipient on one side?

The accompanying cut gives a faint idea, but cannot fully convey an exact representation of this beautiful knife, as the "Novelty" must be seen to be appreciated.

How to Get this Valuable Knife.—We send it postpaid for \$1.25, or give it as a Premium to the one sending us THREE NEW SUBSCRIBERS to the Bee Journal (with \$3.00.) We will club the Novelty Knife and the Bee Journal for one year, both for \$1.90.

GEORGE W. YORK & CO.

Chicago, Ill.

Please allow about two weeks for your knife order to be filled.

they never saw them; in fact, except when the trees were in bloom. It was admitted, however, that ants and other insects would crawl all over them. For that reason I can not think that the bees are proven guilty as charged by Prof. Cook. If it be true that other insects spread the blight on young nursery stock, it only goes to prove Prof. Cook's other statement, that the removal of the bees controlled by man would not abate the nuisance. If bees do not visit the small trees, and such young stock is blighted just as badly as the old trees, it goes to show very clearly that the same agency that scatters the disease on young trees (insects, not bees) can and does scatter it on the old trees.

Safe and Rapid Increase of Colonies.

Prevention, rather than securing increase, is the thing chiefly desired nowadays, but there probably will never come a time when it will not be desirable to be informed as to the best plans for increase. The following discussion on the subject is given in the Canadian Bee Journal:

"Is there any safe way to increase faster than by natural swarming? If so, what is it?"

Mr. Sibbald—I think the best way is to keep the brood-chamber intact as long as you can keep all the bees in one family; keep them all working together and you get far better results than to let them swarm; and at the same time you can take out one frame of hatching brood, put it in a hive; give them a queen-cell, and you will soon have a colony started there; you can add another one, and so on, and at the end of the season you can equalize them. You can increase almost as much as you like in the season and it costs you nothing scarcely. You have kept your bees all working, and your colony all together, and you have the full force all gathering surplus honey on that one stand while the other one is growing up. The brood we take out in the middle of the season would not be hatched and old enough to be in the field by the end of the season, unless we have a fall flow.

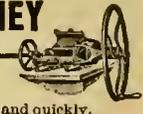

Mr. Frith—When I was burned out with foul brood and lost all my bees, and I was anxious to build up very rapidly, I bought a colony in the spring and I had 12 in the fall, and I did it just upon the same principle as Mr. Sibbald suggests.

Mr. McEvoy—I wish to indorse what Mr. Sibbald said. In selecting this brood I like

The Cyphers Incubator Company, of Buffalo, N. Y., suffered a loss by fire Saturday night, Dec. 6. While this fire caused some loss, it was not specially severe, nor will it cause any interruption in filling their orders promptly. The fire destroyed one warehouse only (a frame structure); it did not touch to any extent whatever the main factory or offices, nor the main stock-room, which is located inside of a large brick building. A considerable stock of panels for incubators was stored in the warehouse that burned, also a quantity of clover products and materials for mixing poultry foods, all of which were totally destroyed, but in the main factory building, which comprises 60,000 square feet of space, they still have ample materials for filling orders promptly, besides plenty of lumber in their yards, none of which was reached by the fire. The frame warehouse and contents were insured, hence the net loss will not be severe. We are glad to know that the Cyphers Company will not miss filling a single order promptly and satisfactorily on account of this fire loss. Send to them for their free catalog, and please mention having seen their advertisement in the American Bee Journal.

to bring the frame above the queen-excluder. Every bee-keeper knows as well as I do that nine days after the eggs are laid, if you take a frame of brood out and examine it you will find sometimes there are quite a few of the young that are not fed as well as they might be. That can be prevented by selecting a comb out of the brood-chamber that is nearly all full of larvae that is not capped, and take that to start the nucleus. On and after that Mr. Sibbald and I will go together.

Mr. Sibbald—I would do that, only the two or three days you have that brood up there they will carry up any amount of pollen and store it in the next comb to it.

Mr. McEvoy—That would depend somewhat on the locality.

BEE=BOOKS

SENT POSTPAID BY

GEORGE W. YORK & CO.,

144 & 146 Erie St., - CHICAGO, ILL.

Bee-Keeper's Guide, or Manual of the Apiary, by Prof. A. J. Cook, of Pomona College, California. This book is not only instructive and helpful as a guide in bee-keeping, but is interesting and thoroughly practical and scientific. It contains a full delineation of the anatomy and physiology of bees. 544 pages. 295 illustrations. Bound in cloth. 1902 edition—19th thousand. Price, \$1.20.

Langstroth on the Honey-Bee, revised by Dadant.—This classic in bee-culture has been entirely re-written, and is fully illustrated. It treats of everything relating to bees and bee-keeping. No apiarian library is complete without this standard work by Rev. L. L. Langstroth—the Father of American Bee-Culture. It has 520 pages, bound in cloth. Price, \$1.25.

A B C of Bee-Culture, by A. I. Root.—A cyclopedia of 400 pages, describing everything pertaining to the care of the honey-bees. Contains 300 engravings. It was written especially for beginners. Bound in cloth. Price, \$1.20.

Scientific Queen-Rearing, as Practically Applied, by G. M. Doolittle.—A method by which the very best of queen-bees are reared in perfect accord with Nature's way. Bound in cloth and illustrated. Price, \$1.00; in leatherette binding, 60 cents.

Bees and Honey, or Management of an Apiary for Pleasure and Profit, by Thomas G. Newman.—It is nicely illustrated, contains 160 pages, bound in cloth. Price, in cloth, 50 cents; in paper, 30 cents.

Advanced Bee-Culture, Its Methods and Management, by W. Z. Hutehinson.—The author of this work is a practical and entertaining writer. You should read his book; 90 pages, bound in paper, and illustrated. Price, 50 cents.

Bee-Keeping for Beginners, by Dr. J. P. H. Brown, of Georgia.—A practical and condensed treatise on the honey-bee, giving the best modes of management in order to secure the most profit. 110 pages, bound in paper. Price, 50 cents.

Bee-Keeping for Profit, by Dr. G. L. Tiaker.—Revised and enlarged. It details the author's "new system, or how to get the largest yields of comb or extracted honey." 80 pages, illustrated. Price, 25 cents.

Bienen-Kultur, by Thomas G. Newman.—This is a German translation of the principal portion of the book called "Bees and Honey." 100-page pamphlet. Price, 25 cents.

Apiary Register, by Thomas G. Newman.—Devotes two pages to a colony. Leather binding. Price, for 50 colonies, \$1.00.

Dr. Howard's Book on Foul-Brood.—Gives the McEvoy Treatment and reviews the experiments of others. Price, 25 cents.

Winter Problem in Bee-Keeping, by G. R. Pierce.—Result of 25 years' experience. Price, 30 cents.

Foul Brood Treatment, by Prof. F. R. Cheshire.—Its Cause and Prevention. 10 cts.

Foul Brood, by A. R. Kohake.—Origin, Development and Cure. Price, 10 cents.

DAIRYMEN ARE DELIGHTED to meet those who work for us. Cow keepers always have money. We start you in business. You make large profits. Easy work. We furnish capital. Send 10 cents for full line of samples and particulars. **DRAPER PUBLISHING CO., Chicago, Ills.**

Please Mention Bee Journal when writing advertisers.

HONEY AND BEESWAX

MARKET QUOTATIONS.

CHICAGO, Dec. 8.—There is no special change in the honey market, prices remain as last quoted and the volume of sales are not large. The weather is such as usually prevails at this season of the year, and the cold may induce people to buy more freely. Best lots of fancy white comb honey brings 16c per pound; No. 1 to choice, 15c; off grades, 2c to 5c less, and not much demand for them. Extracted, 7c for white; amber, 6c for 7c; Southern, 5c for 6c. Beeswax, 30c. **R. A. BURNETT & CO.**

ALBANY, N. Y., Nov. 22.—Honey market is still in strong position with ready demand for all receipts at good prices. Fancy white comb, 16c; A No. 1, 15c; No. 2 and mixed, 14c for 15c; buckwheat, 14c for 14c. Extracted, buckwheat scarce at 6c for 7c; light grades more plenty at 6c for 7c. Beeswax, 29c for 30c. **H. R. WRIGHT.**

BOSTON, Oct. 20.—Our honey market remains firm, with good demand and fair stocks on hand. Honey is not coming forward as fast as usual, and the tendency of prices is steady. We quote our market as follows: Fancy white 1-pound sections in cartons, 16c; No. 1, 15c; No. 2, very light supply, 14c; glass-front sections generally one cent less than this. Extracted, light amber, 8c; amber, 7c.

BLAKE, SCOTT & LEE.

KANSAS CITY, Dec. 6.—We quote fancy white comb honey, per case 24 sections, \$3.50; No. 1 white, per case 24 sections, \$3.40; No. 2 white and amber, per case of 24 sections, \$3.25. Extracted, white, per pound, 7c; amber, 6c. Beeswax, 27c for 30c.

Our market has changed quotations of comb honey from pound to the case.

C. C. CLEMONS & CO.

CINCINNATI, Dec. 8.—The demand for honey, both extracted and comb, has eased off somewhat the past few weeks, however the prices rule steady, as follows: Extracted, amber, in barrels, 6c for 7c; white clover, 8c for 9c. Comb honey, fancy, 16c for 17c; amber, 11c for 12c. Beeswax, 29c for 30c. **THE FRED W. MUTH CO.**

NEW YORK, Dec. 8.—Demand for comb honey not quite as brisk, owing, we presume, to the fact that prices have been ruling higher. Supply, however, is moderate, and there is no other stock on the market.

Prices remain unchanged; fancy white, 15c, with exceptionally fancy at 16c; No. 1, 14c; No. 2, 12c for 13c; buckwheat and amber, 11c for 13c. Extracted, white, 7c; light amber, 6c for 7c; dark, 5c for 6c. Beeswax in fair demand at 28c for 29c.

HILDRETH & SGOELKEN.

CINCINNATI, Dec. 12.—The comb honey market is a little quiet, almost everybody is filled up. As there is hardly any new supply coming in, there is no change in prices, namely: Fancy water-white, 16c; off grades less. The market for extracted white clover shows a slight advance. Fancy white clover brings 8c for 9c; alfalfa water-white, 6c for 7c; but amber, if anything, has weakened. 1 quote same, in barrels, 5c for 5c. Beeswax, 27c for 28c.

C. H. W. WEBER.

SAN FRANCISCO, Nov. 12.—White comb honey, 10c for 11c; amber, 9c for 10c; dark, 5c for 6c. Extracted, white, 6c for 6c; light amber, 4c for 5c; amber, 3c for 4c. Beeswax, good to choice, light, 26c for 27c; strictly fancy light, 29c for 30c.

White is reported scarce; light amber honey in fair supply. The bulk of California produced honey is sold for Eastern shipment in carload lots from producing point at bottom price. Small lots of choice honey that can be used in local trade bring more. Quotations here given are current prices to producer, f.o.b. shipping point, on Eastern basis for extracted and California basis for comb.

Wanted Comb and Extracted Honey!

BEE-KEEPERS,

Save Money by Buying

Hives, Sections, Brood Frames, Extractors, Smokers, AND EVERYTHING ELSE YOU NEED, OF

THE W. T. FALCONER MFG. CO., Jamestown, N. Y.

Our goods are guaranteed of superior quality in every way. Send for our large illustrated catalog, and copy of

THE AMERICAN BEE-KEEPER,

a monthly for all bee-keepers; 50c a year. (Now in 12th year. H. E. HILL, Editor.)

W. M. GERRISH, E. Nottingham, N. H., carries a full line of our goods at catalog prices. Order of him and save freight.

Please mention Bee Journal when writing.

\$300,000,000.00 A YEAR and you may have part of it if you work for us. Uncle Sam's poultry product pays that sum. Send 10c for samples and particulars. We furnish capital to start you in business. Draper Publishing Co., Chicago, Ill.

Tip-Top Glass Honey-Jars

The picture shown herewith represents the best one-pound jar for honey that we know of. It is made of the clearest flint glass, and when filled with honey, and a neat label attached, it makes as handsome a package as can be imagined. Its glass top sets on a flat rubber ring, and is held in place by a flat steel spring across the top as shown in the picture. It is practically air-tight, thus permitting no leak,

which is an important thing with honey-sellers.

We can furnish these jars, f.o.b. Chicago, at these prices: One gross, \$5.00; two gross, \$4.77 a gross; five or more gross \$4.50 per gross.

If you try them once you will likely use no other kind of top or sealing arrangement for honey jars.

GEORGE W. YORK & CO. 144 & 146 Erie Street, CHICAGO, ILL.

If you want the Bee-Book

That covers the whole Apicultural Field more completely than any other published, send \$1.20 to

BOYS WE WANT WORKERS

Boys, Girls, old and young alike, make money working for us. We furnish capital to start you in business. Send us 10c stamps or silver for full instructions and a line of samples to work with. DRAPER PUBLISHING CO., Chicago, Ill.

25th Year **Dadant's Foundation** 25th Year

We guarantee Satisfaction. What more can anybody do? BEAUTY, PURITY, FIRMNESS, No SAOINGO, No LOSS. PATENT WEED-PROCESS SHEETING.

Why does it sell so well? Because it has always given better satisfaction than any other. Because in 24 years there have not been any complaints, but thousands of compliments.

Send name for our Catalog, Samples of Foundation and Veil Material. We sell the best Veils, cotton or silk.

Bee-Keepers' Supplies OF ALL KINDS *****

Very fine pure-bred BARRED PLYMOUTH ROCK Chickens and Eggs for sale at very low prices.

Langstroth on the Honey-Bee—Revised, The classic in Bee-Culture—Price, \$1.25, by mail.

BEEWAX wanted at all times.....

DADANT & SON, Hamilton, Hancock Co., Ill.

The Holidays Are Almost Here,

And you are doubtless undecided as to what to get your friends for Christmas.

Why not get.....

The "Post" Fountain Pen

The very best in the market; regular price, \$3.00, and not obtainable under this price anywhere. The Six Cardinal points Peculiar to the "Post":

Self-Filling, Self-Cleaning, Simplicity, Durability, Reliability, No Leaking.

Given Absolutely Free

For two new subscriptions to Gleanings and your own renewal with \$3.00; or for one new subscription and your own renewal with \$2.50; or your own subscription will be advanced 2 years, and the Pen furnished for \$2.50.

In each case all arrears, if any, must be paid in addition, the above offers being for subscriptions fully in advance only. We believe we can say truthfully, without fear of contradiction, that no fountain pen ever put upon the market ever received in so short a time so many unsolicited testimonials from such distinguished men as the POST. The above drawing shows its construction. To fill the POST, all you have to do is to dip the nib into the ink-bottle, draw out the plunger, and the pen is ready for use. Compare this with unscrewing the ordinary style, and refilling with a glass filler that you can not always find when wanted. The self-cleaning feature of the Post, as illustrated, will also commend itself. With most pens specially prepared ink must be used or they are soon of no use, because they become so gummed up and it is well nigh impossible to clean them. With the POST you simply dip the nib in water, draw the plunger back and forth like a syringe or squirt-gun, and in less than five seconds it is clean and free for a perfect flow of any ink that may be handy. We will send, on request, a few of the many testimonials from noted men in various callings who have written merited words of praise for this most valuable invention. We can not offer the pen for sale for less than \$3.00; but by special arrangement we are enabled to offer it free as a premium with Gleanings in any of the following combinations: All arrears, if any, must first be paid at \$1.00 a year. Then for \$3.00 we will send Gleanings for one year, to two new names; for one year to yourself, and send you the pen free. For \$2.50 we will send you the pen and Gleanings for one year, and to one new subscriber a year; for \$2.50 we will send the pen and Gleanings for two years. If you have ever been disappointed with a fountain pen we assure you that you will not be with this one.

AMERICAN BEE JOURNAL

GEORGE W. YORK,
Editor.

CHICAGO, ILL., DEC. 25, 1902.

FORTY-SECOND YEAR
No. 52.

WEEKLY

APIARY OF E. H. STEWART, OF ONTARIO, CANADA.

THE AMERICAN BEE JOURNAL

PUBLISHED WEEKLY BY

GEORGE W. YORK & COMPANY
144 & 146 Erie St., Chicago, Ill.

Entered at the Post-Office at Chicago as Second-Class Mail-Matter.

EDITOR—George W. York.
DEPT. EDITORS.—Dr. C. C. Miller, E. E. Hasty,
Emma M. Wilson.
SPECIAL CORRESPONDENTS—G. M. Doolittle,
Prof. A. J. Cook, C. P. Dadant,
R. C. Aikin, F. Greiner, A. Getaz, and others.

IMPORTANT NOTICES.

The Subscription Price of this Journal is \$1.00 a year, in the United States, Canada, and Mexico; all other countries in the Postal Union, 50 cents a year extra for postage. Sample copy free.

The Wrapper-Label Date of this paper indicates the end of the month to which your subscription is paid. For instance, "dec01" on your label shows that it is paid to the end of December, 1901.

Subscription Receipts.—We do not send a receipt for money sent us to pay subscription, but change the date on your wrapper-label, which shows you that the money has been received and duly credited.

Advertising Rates will be given upon application.

The National Bee-Keepers' Association.

OBJECTS:

To promote and protect the interests of its members.

To prevent the adulteration of honey.
To prosecute dishonest honey-dealers.

EUGENE SECOR, General Manager and Treasurer, Forest City, Iowa.

MEMBERSHIP DUES, \$1.00 a year.

If more convenient, Dues may be sent to the office of the American Bee Journal, when they will be forwarded to Mr. Secor, who will mail individual receipts.

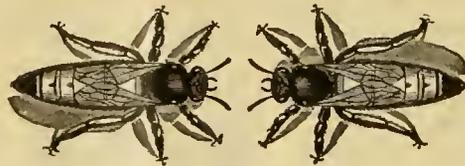

A Celluloid Queen-Button is a very pretty thing for a bee-keeper or honey-seller to wear on his coat-lapel. It often serves to introduce the subject of honey, and frequently leads to a sale.

NOTE.—One reader writes: "I have every reason to believe that it would be a very good idea for every bee-keeper to wear one [of the buttons] as it will cause people to ask questions about the busy bee, and many a conversation thus started would wind up with the sale of more or less honey; at any rate it would give the bee-keeper a superior opportunity to enlighten many a person in regard to honey and bees."

The picture shown herewith is a reproduction of a motto queen-button that we are furnishing to bee-keepers. It has a pin on the underside to fasten it.

Price, by mail, 6 cents; two for 10 cents; or 6 for 25 cents. Send all orders to the office of the American Bee Journal.

Forty Years Among the Bees

By DR. C. C. MILLER.

DR. C. C. MILLER.

The above is the title, and name of the author, of a new bee-book which will be ready some time in January, 1903, as it is now in the hands of the printers. It is a book that every bee-keeper in the world that can read English will want to own and read. It will contain over 300 pages, be bound in handsome cloth, printed on good book-paper, and illustrated with over 100 beautiful original half-tone pictures, taken by Dr. Miller himself. The book will show in detail how Dr. Miller does things with bees.

The first few pages of the new book are devoted to an interesting biographical sketch of Dr. Miller, which finally tells how he happened to get into bee-keeping. Seventeen years ago he wrote a small book, called, "A Year Among the Bees," but that little work has been out of print for a number of years. While some of the matter used in the former book is found in the new one, it all reads like a good new story of successful bee-keeping by one of the masters.

How to Get a copy of Dr. Miller's "Forty Years Among the Bees."

The price of this new book is \$1.00, post-paid; or, if taken with the WEEKLY American Bee Journal for one year, BOTH will be sent for \$1.75.

Or, any present regular subscriber to the American Bee Journal whose subscription is paid in advance, can have a copy of Dr. Miller's new book *free as a premium* for sending us **Two New Subscribers** to the Bee Journal for one year with \$2.00. This is a magnificent offer. Better send in the new subscriptions before Jan. 1, so they can begin with the new year. Or, if sent at once, we will throw in the rest of this year's numbers of the Bee Journal free to the new subscribers.

GEORGE W. YORK & CO.,

BEE JOURNAL

42d YEAR.

CHICAGO, ILL., DEC. 25, 1902.

No. 52.

* Editorial Comments. *

A Merry Christmas we wish to all the readers of the American Bee Journal, and many of them ere they shall be called to leave this world.

The Index to Volume XLII appear in this number. We trust it may prove of value to all who have preserved each week's copy as it has come.

By the way, if any subscriber finds he has failed to receive any copy that is due him, we will be glad to send it again if we are asked for it, and if we still have any of them on hand. Better ask at once if any missing copies are wanted.

Forced Swarms—Questions About Them.—There seems quite a general agreement that in at least most localities the anticipation of natural by forced swarms is a boon, but there is not entire agreement as to the minutiae. Indeed, it is quite possible that there can be no general agreement, because difference of localities, seasons, or conditions make an entire agreement as to the details of management impossible. Among the questions to be settled are the following:

Shall forced swarms be made before or after queen-cells are started? Shall a frame of brood be left with the forced swarm, or shall it be left with neither brood nor honey? If brood is left, how long shall it be left, or shall it be left permanently? What is best to give the forced swarm, drawn combs, frames filled with foundation, large starters, small starters, or what? Is there more or less likelihood of forced than of natural swarms deserting? And that may be only a small part of the questions arising in actual practice, and to which answers will be expected from those who have had experience.

Bottled Honey Growing in Popularity.—Editor Root has the following paragraph in a recent number of Gleanings in Bee-Culture, on the growing subject of putting up and selling honey in bottles:

"If you, my dear reader, happen to live in a locality where there is no bottled honey except that which comes from some packing-house, unknown or of doubtful reputation, just try putting out some neat bottled goods of your own, bearing your own label, and see what a nice trade you will have. Your own good reputation, with a personal explanation from yourself, will make the goods move off like hot-cakes. But you must make one trip around among the consumers, explaining that it is your honey; how you put it up, and that you guarantee it to be absolutely pure."

But we do not advise putting up honey in glass bottles or jars to be sold by the bee-keeper direct to the consumer. Such should only be sold to consumers through the grocery trade. There is many a town or small city where a live, wide-awake bee-keeper could do well if he would keep

the grocery trade well supplied with pure honey in glass jars holding $\frac{3}{4}$ or one pound each. He could first dispose of his own crop of honey, and then afterwards buy honey, so long as he got it from a dealer who would guarantee its purity.

But some one may say, "Honey is too high in price now. I can't afford to buy and sell again." And yet you were the chap that was kicking a while ago, because honey was selling too cheap. Yes, and you wanted to organize a honey exchange so as to boost up the price of honey! Oh, you had your own crop of honey to sell then, did you? Ah, we see.

But when honey, like any thing else, is higher in price in the market, you must ask *more*, when you sell it. Of course, some people will object to paying a cent or two more on a pound, but such are very few indeed. A few words of explanation usually satisfies them, if you are a truthful and honest man. If you are any other kind, you hadn't better try to sell honey, or anything else, for that matter.

Amending the National Constitution—Mr. Geo. W. Brodbeck, one of the leading bee-keepers of California, wrote us as follows, Dec. 8:

The American Bee Journal of Dec. 4th is just at hand. I note in the report of the Denver Convention several propositions to amend the Constitution of the National Bee-Keepers' Association. I, too, fully recognize the existing defects, but until the Constitution is amended so as to permit time for full and free discussion, pro and con, in our bee-papers, I desire to enter my protest against any action by vote presentation without due notice. We who reside in the North, South, East and West, and are not so fortunate as to be present at these annual sessions, desire to be heard. I believe in the recognition of the rights of every individual member present or absent, and no other method will ever incite a hearty co-operation of the membership at large. I firmly believe there are great possibilities in store for this organization in its proper and consistent management.

Los Angeles Co., Calif.

GEO. W. BRODBECK.

There is considerable in what Mr. Brodbeck says, but it is too late now to help any this time, we fear. Still, the proposed changes are not serious, and if adopted the Association could still go forward and be as successful as it is now. We are willing to trust to the majority in this as well as in other matters affecting the welfare of the Association.

Benefits of Co-Operation.—In discussing this matter in the Bee-Keepers' Review, E. A. Daggitt claims that the farmers produce wealth but fail to get their proper share of it, the lion's share being absorbed by those who distribute the product of the farmer, while he gets only what others are willing he should have. He gives the following striking illustration:

In this part of the New Jersey peach section we have raised and shipped millions of baskets of peaches, yet most of the growers have been left poor. Why is this? Let us see. Baskets have cost from $2\frac{1}{2}$ cts. to $4\frac{1}{2}$ cts. each. When the most peaches were shipped the prices ranged from 3 to $3\frac{1}{2}$ cts. Freight was 9 cts. a basket; cartage 4 cts.; commis-

sion 10 percent. On a 50-cent basket the cost would be from 21 cts. to 21½ cts. per basket, about double what it should have been, leaving to the growers 28½ to 29 cts. per basket—less than cost of production.

The larger part of the peaches have been sold for less than 50 cts. per basket—many away below that price. In some instances a bill of costs has been rendered. We have had returns of 8 cts. per basket, net. When peaches have sold at wholesale for 25 and 30 cts. per basket, I have known them to retail at 10 to 15 cts. per quart. One season when we were getting from about 50 to 75 cts. per basket for the best grade of peaches, a friend told me that he had seen good peaches offered for sale on Staten Island for \$3.00 per basket. Another season there was only a moderate crop of peaches here, and the crop was a small one generally throughout the country, yet, when the "run" of the Reeve's favorite variety came, there was a "glut"; and when the "run" of late Crawfords came on there was a worse "glut." So the manipulators said, but, in reality, there was no glut at all. The manipulators of prices were only fixing things to suit themselves, but to the injury of the growers.

I then saw what was the trouble, the great trouble, with farming. If there is manipulation of prices with one product, then there must be the same with all products, if it is worth while. It is just the same with honey, without a question.

* The Weekly Budget. *

MR. MORLEY PETTIT, of Ontario, Canada, was one of the very prominent young men at the recent Chicago-Northwestern convention. His impression of that meeting is expressed as follows in a letter we received from him Dec. 12:

DEAR MR. YORK:—The convention fully repaid me for coming, although it was 400 miles. Not only were the discussions pleasant and profitable, but the meeting with men whom I have known for years through bee-literature added materially to my enjoyment of the convention. It is so much better to know flesh-and-blood men than paper men. While you are shaking hands your little differences of opinion fade away into the vague regions of "locality."
Fraternally yours, MORLEY PETTIT.

TO FOREIGN SUBSCRIBERS.—Occasionally it seems necessary for us to say, for the information of foreign bee-keepers, that none of our special offers found anywhere apply to them. They apply only where domestic postage rates are in force. Neither do we export queen-bees. But we mail bee-books at regular rates where the book postage is the same as in the United States. Whenever we get a foreign remittance on a combination offer of the Bee Journal and something else, we simply apply it all on the subscription to the Bee Journal, as in that way the subscriber gets full value for his money.

Please remember, foreign readers, that our special clubbing or combination offers do not apply to you. They could not, as all know that there is extra postage to those countries, so we intend our special offers for those countries only to which our pound postage rate applies.

DR. MILLER OF ALL STATES.—We have received this from Dr. C. C. Miller, of Marengo, McHenry Co., Illinois.

MR. EDITOR:—On page 788, I see my name mentioned among those present from other States at the Chicago convention. This is to give you notice that I still reside in McHenry county, and that said county has not yet been moved out of the State of Illinois—indeed, it has not yet been jacked up on wheels for that purpose.
C. C. MILLER.

When first reading the above, we wondered how we were going to get out of the dilemma we had gotten our-

selves and also the good Doctor into. An easy exit immediately suggested itself to us. Doesn't Dr. Miller belong to all the States? Of course he does. He lives (apiculturally and "bee-literaturely") all over the United States as well as in the rest of the world. We know he eats and sleeps in Illinois, but that is a very small part of his real life.

Now, haven't we gotten out of the difficulty fairly well? Of course Dr. Miller didn't have to get out of any scrape. Physically he's still in McHenry County, Illinois. In every other way he's everywhere where bee-keeping and bee-keepers exist. And when his new book—"Forty Years Among the Bees"—is out, he will very soon thereafter be more scattered than ever, for every (bee)body will want to read about him and his life work.

LATER.—A day or two after writing the foregoing we received this from Mr. Abbott.

DEAR MR. YORK:—I notice your editorial about those present at the Northwestern from other States, among them Dr. Miller is named. What county does he hail from, anyway? I guess you are correct, he is big enough to belong to the United States, and good enough for any State.

Fraternally yours, E. T. ABBOTT.

It will be noticed this agrees with the explanation we had already written. So it might have been a bigger mistake.

TEXAS HONEY.—Louis H. Scholl says in the Progressive Bee-Keeper, that southwest Texas alone will use, during the coming season, not less than 20 car-loads of tin cans to be filled with honey for strictly family use.

MR. E. J. ROOT, 90 West Broadway, New York, N. Y., is a correspondent of the London Grocer and other journals. Well, what of it? Who cares if he is? There's this of it: He is a brother to W. P. Root, the "Stenog" of Gleanings in Bee-Culture, has a warm side toward bee-keepers, and is in a position to get before a large class of readers, whom the bee-papers never reach, information about honey that may do us a whole lot of good. Witness the following clipping from the London Grocer:

"Honey is a valuable and wholesome article of food, which is not so much seen on our breakfast tables—and on our readers' counters—as it ought to be; but it will probably be taken up commercially one of these days. A Colonial Office report on Malta, mentions that honey is one of the products of that British island. In the northwest portion, overlying the upper coralline limestone, are uncultivated lands suitable for the growth of the wild thyme. A firm at Birchircara cultivate the bee on a rational and commercial basis, and the honey produced is of the first quality. The output could be increased were it not for the destruction of the thyme, which is, when dry, collected for fuel."

Honey as a Health-Food is the name of a 16-page leaflet (3½ x 6 inches) which is designed to help increase the demand and sale of honey. The first part is devoted to a consideration of "Honey as Food," written by Dr. C. C. Miller. The last part contains "Honey-Cooking Recipes" and "Remedies Using Honey." It should be widely circulated by every one who has honey for sale. It is almost certain to make good customers for honey. We know, for we are using it ourselves.

PRICES, prepaid—Sample for 2 cts.; 10 for 10 cts.; 25 for 20 cts.; 50 for 35 cts.; 100 for 65 cts.; 250 for \$1.50; 500 for \$2.75; 1000 for \$5.00. If you wish your business card printed at the bottom of the front page, add 25 cts. to your order.

Please send us Names of Bee-Keepers who do not now get the American Bee Journal, and we will send them sample copies. Then you can very likely afterward get them subscriptions, for which work we offer valuable premiums in nearly every number of this journal. You can aid much by sending in the names and addresses when writing us on other matters.

Convention Proceedings.

THE DENVER CONVENTION.

Report of the Proceedings of the 33d Annual Convention of the National Bee-Keepers' Association, held in Denver, Col., on Wednesday, Thursday and Friday, Sept. 3, 4 and 5, 1902.

(Continued from page 807.)

REPORT ON THE PEAR-BLIGHT QUESTION.

M. A. Gill, on behalf of the committee, presented the report on the pear-blight question, as follows:

WHEREAS, The National Bee-Keepers' Association assembled in Denver, Sept. 5, 1902; and

WHEREAS, The Central California Bee-Keepers' Association has submitted for our consideration a preamble and resolution embodying the "pear-blight-bee" question, asking for advice and protection, providing there is further trouble. Therefore, be it

Resolved, That we grant unto them the request embodied in their resolution heretofore submitted.

M. A. GILL,
F. E. BROWN, } Com.
FRANK BENTON.

R. H. Rhodes moved, and it was seconded by J. P. Ivy, that the report be accepted. The chairman put the motion, which, on a vote having been taken, was declared carried.

F. E. Brown—In accepting the report of the committee that does not adopt the resolution submitted by the committee, does it?

Vice-Pres. Harris—No, sir. What is your pleasure with regard to adopting the report of the committee?

Mr. Brown—I move that we adopt the report of the committee.

J. B. Adams—I second the motion.

The chairman put the motion, which, on a vote having been taken, was declared carried.

REMOVING SUPERS OF HONEY.

QUES.—"Will Mr. Coggs shall show or tell us how to kick off supers?"

Mr. Coggs shall—Always get the bees subdued before you do any kicking.

Dr. Mason—How do you subdue them?

Mr. Coggs shall—With smoke. The jar is no more when you kick it off than when you pry it off with a chisel.

Dr. Mason—Do you kick it off with your toe or heel?

Mr. Coggs shall—I do it with my heel, usually. If it is necessary, use your toe.

CONSIGNING HONEY TO COMMISSION MERCHANTS.

QUES.—"Is it advisable for the bee-keeper to consign his honey to the commission merchant?"

Mr. Hershiser—On that question I desire to read a little correspondence, and I will be just as brief as possible. [Mr. Hershiser read correspondence passing between a shipper and commission merchants by the name of Batterson & Co.]

Batterson, the commission merchant, in this case knew just when the honey referred to in this correspondence would arrive; it was shipped immediately after the shipper received instructions. He offered to sell his honey so that it would net 4½ cents per pound; the shipper afterwards let him down to 4 cents net. He promised the shipper he would not sell it for less than his limit, unless he got the advice and consent of the shipper. It was necessary for the shipper afterwards to place the matter in the hands of his attorney, J being his attorney. I took the honey out of the hands of the commission merchant, and ordered that no more of it be sold. Then I asked for a statement of the honey that had been sold, and he rendered such statement showing that out of 204 cases there were 203 to be delivered to me, he having sold one case.

It was not very long after that till I found out, as a matter of fact, that a ton of it had been placed in the hands of another commission merchant in Buffalo, and that part

of it had been sent to Cleveland to some other alleged good commission men who knew all about honey! These men had said it was adulterated; and when I got his statement it amounted to this, among other things: The freight came in \$305.25; then a matter of car service, \$5; cartage, \$5.40; storage, 12.24; insurance, \$5; and interest, \$4.25. In the first instance the cartage was about \$10.40, but I showed him that the prevailing price for cartage was only about half that, so he cut that about in two. In the first instance the storage was \$18.24, and I cut that down to \$12.24; I could get no reduction on the item of insurance; and I got 80 cents off the item of interest, \$4.25, on the ground that part of the honey he had sold to another man, and there was a little rebate on that amounting to 80 cents. He suggested that was a very small matter, and I told him it was just as small for him to take it as it was for me to take it, and he suggested we cut it in two. With reference to the item of car service, I contended it was owing to his negligence the car was not unloaded, and by inquiry at the freight-office I found he had increased that by one dollar, one dollar of the car service having been charged up on a car-load of potatoes.

In order to get possession of this honey, it was either necessary to settle with him on these expense charges he had made, or else replevin the honey. To replevin it would have meant three bonds, and would require, besides that, bonds for security for cost on the ground that the plaintiff lived outside of the State. So it would have cost, perhaps, \$150 or \$200 in sheriff's fees, and fees for the bonding companies, and so on, before he could have got in possession of this honey, so it was necessary for me to settle and let him bleed this man out of \$60 in addition to his attorney's fees.

After this I demanded that he make this amount good on this car-load of honey on the price he had agreed to net him, and if he didn't do it that I, as an officer of this Association, would deem it my duty to lay the matter before them, which I am now doing. So if any of you want to ship honey to any like Batterson, and you lose your honey, don't blame the Association or anybody that has given you this information. I don't desire any practice of this kind; I am an attorney, and anxious to earn fees, but I don't want to earn fees of this kind; I would rather earn them in some manner that is not bleeding people out of their money.

I think it would be a good thing for this Association to take up matters of this kind so that commission merchants in various parts of the country will realize that it does not make any difference whether the shipper resides within three or three thousand miles of this place; that he has no more protection in cheating a man out of his money, or honey, if he lives three thousand miles away than he has if he lives three miles away.

I simply give you these facts, and you may do with them as you please.

Vice-Pres. Harris—I will take up the question of the committee on the proper marketing of honey, to look after the common interests of the whole country. I will name on that committee, Messrs. F. Rauchfuss, of Colorado; F. E. Brown, of California; Dr. A. B. Mason, of Ohio; W. Z. Hutchinson, of Michigan; and O. L. Hershiser, of New York.

Vice-Pres. Harris then left the chair, and Pres. Hutchinson resumed it.

EFFECT OF COMB ON THE COLOR OF EXTRACTED HONEY.

QUES.—"Does the color of the comb, from which honey is extracted, have any effect on the color of honey?"

Dr. Miller—I should like to hear from any who have had personal experience that would help to decide positively that question one way or the other. I may say in general terms that it has been claimed that the old combs did have that effect upon the color of the honey, and some, who say they have produced extra-white honey, say they have done it by taking it from virgin combs. Mrs. Harrison, for one, claims that there is some reason for believing that comb of a very dark color should have an effect upon the honey for this reason: I think nearly all of you know that when you have taken some very old, black comb that has been filled with water, no matter how, if that has stood for some time, and you take it and shake out the water, it looks almost as black as ink. I think I can appeal to the majority of you as to that. If water will take the black color out of the comb, then the water which is in honey one might naturally suppose would also take the color out. I think the argument is plenty strong in that direction, and yet if any one has had positive proof about it, it will be worth more than theory.

Mr. Dadant—On this question there are two points to be considered, if you wish to know whether it has a great or small effect on honey. There is the possibility that the color of the comb has a very slight effect on the color of honey, but if any one says that the color of the comb has a great effect on the color of honey, I will dissent altogether. We used to save all our old comb, all the broken combs, to put into the frame; we used to import in small boxes combs 6x4; we thought so much of the comb that we saved it and put them one above the other, 16 pieces for one frame; we used those for extracting, and we have produced as white honey as anybody else. There might be a very slight difference in the shade, we do not know whether that is due to the comb or due to other causes, but we do know we can produce a very white honey in very dark combs. There is one color which gets into the comb that I think has more influence than the dark color, and that is the yellow color of the blossoms. Sometimes the combs are turned yellow in a very few days; I believe that color can get into the honey, but usually the honey we harvest at that time is of the same shade, so that it can have no influence over it.

J. A. Huebner—In regard to this question of honey-coloring, I want to say that I had an experience of that kind last year. Last fall I extracted some honey out of dark comb, and it was almost water-white, and then two weeks later these combs were filled up again, and I was absent from home, and this honey was not extracted until the next May, 1902, and that honey which stood in the comb over winter got darker, which I have every reason to believe was color taken from the dark comb.

W. P. Collins—That honey which stood over might have been darker, and even the white honey might get dark.

Mr. Dadant—There is one thing I might state. If the dark comb is likely to give any color I think it will give it the first time. We have extracting-combs from which we have extracted every year for 30 years, and they are better to-day because they are heavier.

Dr. Mason—Dark combs?

Mr. Dadant—Certainly. Before foundation was invented we used to save the pieces of our combs and put them in the supers. Those dark combs, after you extract from them three or four times, do you hold they still color the honey? Suppose there is color the first time, it is not likely that the color will be dissolved in the first extracting, and that for 15 years they will be as good as new combs? It looks to me unreasonable to think we can make old combs white by having them color the honey. There may be a very slight difference, but you must be sure that that difference is not caused by some other things, such as you mentioned here when you get two bottles of honey side by side and say they are two grades of honey. Some of you, I understand, say when there is no water in the soil the honey is darker, although it is from the same blossom. Don't charge the dark comb with the coloring of the honey unless you are positive that that has done it. I believe you can only say it has done it in perhaps the first instance, that is, the time when it has just been used for brood, and afterwards used for honey, and then this color is likely to become loosened and absorbed by the honey.

Mr. Gill—In my judgment I am satisfied that the honey Mr. Huebner speaks of was darker when it was gathered than the other honey was.

Dr. Mason—I can understand this whole question. It all depends upon the locality. You have had that before you to-day. Now, then, you may argue all you have a mind to. You can see those two bottles now, the honey in one bottle is light honey, and that same honey was put in the same combs ten days before I came here and left till I came away, and that is the same honey, and those combs have been used for extracting for the last four years. It all depends upon locality, not on the combs.

J. A. Green—I would like to ask Dr. Mason how he is sure that is exactly the same honey in those two bottles?

Dr. Mason—I know in this way, because I took some of this honey and put into the dark combs myself just to test it, because this question has been asked so many times. That is the same honey, precisely; it was in there seven or eight days perhaps, and I took it out just for the purpose of bringing it here.

Mr. Green—Did you give it back to the bees after that?

Dr. Mason—No, sir; the bees had nothing to do with it since I got it, of course not.

Mr. Green—I ask that because it is so easy for the bee-keeper to be mistaken in that respect. The first honey that I extracted this year was very light in color, about a white, and a few days later, and from the same source, and from

the same comb, much darker. Like Mr. Dadant, I have old combs.

Dr. Mason—The question is, Will the color of the comb make any difference in the color of the honey?

Mr. Green—I have a large number of old combs, and I agree with Mr. Dadant that for the first extracting there will be a slight tinge given to the honey, but after that there certainly can not be, or at least very little. I have these old combs, thousands of them, some of them 25 years in use; to all appearances they are just as black as ever, and I get just as light honey from those combs as from new combs.

J. B. Adams—One year I had a good chance to test that. I had white combs. I had read in the journals considerable about the combs coloring honey, but I didn't want the bees to be idle, so I used black combs, and I got just as white honey from those black combs as can be produced anywhere. It didn't make a particle of difference; there was no more shade to the honey than there was to any water-white honey.

R. D. Williams—I use in my upper stories half-drawn combs, and I have full sheets of foundation; the full sheets of foundation are white, while the others are very often very black, and I notice there is no difference at all in the honey.

Mr. Dadant—I was called upon to give an opinion on this subject, and I think it would be well for me to add that in regard to the color of honey we must never be too sure on that point. We have had honey from the same blossoms in three or four different yards, and there was so much difference in color that while we could sell the honey from one yard we could not from the other; the difference in shade was quite perceptible, so that the person buying would not accept the honey from one yard in place of that from another, and yet the blossoms were the same. What caused it, I am unable to tell. I believe if you can at any time get very white honey from very dark comb, that will settle the question. I, perhaps, have seen that, but I have not paid any particular attention to it.

W. L. Hawley—For the last eight years there is one thing that I have borne in mind. I have noticed one particular thing: Take a frame and put it into the super, leave that till the last, and throw that out while there is a light flow of white honey, and you will see a difference; but the next time you go around and perform the same operation you will see no difference whatever; from that time on, as long as you use those combs for extracting, there is no difference whatever between the old comb and the white comb; but the first time you remove it out from below, or use it for extracting, is where the difference comes, and that is the only time you can see any difference in the use of the comb.

Dr. Mason—This thing probably depends upon locality, for the gentleman is absolutely wrong so far as my locality is concerned. I tell you, the comb that colored this honey has been used for extracting purposes for five years, and has been extracted from a good many times, you can not be right. Locality makes a difference.

Mr. Green—Was there no brood reared in that comb during those five years?

Dr. Mason—No, sir.

Mr. Brown—Speaking about locality and color of honey, in receiving honey I received it from central California and different locations, and on the south is Tulare Lake; it is a shallow body of water, and the ground being sandy the water runs under it, and alfalfa is grown upon its borders, the roots run down directly into the water; the honey that is produced in that locality is darker; but a little further away where it is dryer the honey is whiter; when you come up to where it is very dry, and no moisture, our honey is white; and when you show me white alfalfa honey I will tell you the condition of the ground on which it is grown, every time; but whether that holds good with reference to other honey, I can't say.

(Continued next week.)

Why Not Help a Little—both your neighbor bee-keepers and the old American Bee Journal—by sending to us the names and addresses of such as you may know do not now get this journal? We will be glad to send them sample copies, so that they may become acquainted with the paper, and subscribe for it, thus putting themselves in the line of success with bees. Perhaps you can get them to subscribe, send in their dollars, and secure for your trouble some of the premiums we are constantly offering as rewards for such effort.

THE HIVE PROBLEM.

What Size is Best, Eight or Ten Frame?

BY R. C. AIKIN.

I KNOW this is an old and worn subject, but I do not consider it settled, by any means. This question, like very many others pertaining to the honey industry, is not thoroughly understood; we are constantly learning by experience and in other ways.

I will not say that any particular size of hive is what we need, but I want to tell some things I have found in my experience, and give the reader my conclusions. And, beginning right now, when the bees are starting into winter, let us trace them along through the year, and, as an illustration consider a colony that has been on 6 brood-combs through the summer. If run for comb honey, the probabilities are that there will be some pretty solid packing of the brood-combs with honey, but whether they are well filled or not depends on several conditions. Notice that I say it depends on conditions, and in discussing this question I will do it from the standpoint of the apiarist producing conditions, or meeting them so as to modify the effects following.

A colony on 6 combs through the summer, and for comb honey, if they had the 6 combs well filled with brood when the flow began, and if the flow came on abruptly and the weather hot or favorable to super-work, the nectar being plentiful and the colony strong enough to start work in the sections and keep it going, and if (note these ifs), the flow suddenly stopped, and if the queen was laying vigorously at the time and kept the combs full of brood and they were so when the flow stopped; and if that flow stopped near the end of summer when the season for breeding was about over, then you have a colony with many young bees and in prime shape for winter, so far as number and age go, but with not stores enough to last till spring, or, if they do last till spring, there will be a poor condition in the spring, if not actual starvation.

But (now don't laugh at the string of buts and ifs), if you will just put right on top of that strong colony at the close of the season, another 6 brood-combs *solid full of honey*, then you have a colony that is in almost ideal condition for winter; and not only for winter, but for building up nicely in the spring. Remember that we are discussing the hive question, and that it is understood that the stock and queen is O. K. A poor queen would be bad in the best hive.

A man ought always to be able to give a reason for the faith that is within him, so I would better tell you why I consider the colony just described as being in prime condition. They have plenty of bees of all ages. It is the commonest kind of knowledge to bee-men, that old bees would not live through the winter and into the spring when and until there is sufficient young bees hatching to take their places. And we all know that one bee, all by itself, can stand but little cold until chilled, and in like manner proportionately a small cluster will chill quicker than a large one; hence, to start the colony into winter with a big force of young, vigorous bees means that they can stand much cold, and when the time comes to begin breeding they can supply the necessary heat. We all know these things.

And we know that those bees will naturally cluster on the original empty combs—they will be practically empty by cold weather because the brood hatched out in meantime, and having the solid combs above them they will consume of it, following *up* as the honey is used, and when spring comes the colony is found in the *top* of the hive. All this time the stores have been closed to the bees—it was easy for them to feed, whether warm or cold.

There, I heard some one say that I must take away that lower hive of empty combs as soon as the bees are out of it, else they would waste a great lot of heat trying to keep it warm, using too much honey to get the heat, wearing out stores and bees both. Well, now, don't you worry one minute about that problem, it is not a fact at all. Don't you see that there is not one hive in 100 that fits the colony in

the spring—no, not one in a thousand, except where the apiarist keeps contracting the hive as his colony grows smaller; every colony under normal conditions in cold climates becomes too small for its hives in the early spring. If it is a fact that the hive is always larger than the colony in spring—and it is a fact—don't you see that all the talk about having a small hive so the bees can keep it warm is foolish?

Notice that I said this sample colony we are speaking of was on 6-frames to start with. They will not warm the entire hive, no colony outside in winter ever keeps its *hive* warmed. They do, however, if the cluster is large, keep themselves and the comb they cover, warm, and in a large measure keep the *upper* part of the hive somewhat warm, particularly right above the cluster. It is common in very cold weather for the colony to warm a spot immediately above the cluster so as to melt the snow from the cover, yet at the same time there is ice (frost) on all sides and below them. It is the melting of this frost and ice, and its precipitation upon the cluster, wetting and chilling them, that kills many a colony in winter. This leads me to say here that every colony should have some means of getting rid of this moisture, and the way to do it is either to have the hive top so warm that it will not condense on it, or have it so arranged that the moisture-laden air can pass off. A good, large cluster will usually take care of the heating question if kept *dry*, but they cannot get rid of the accumulations of frost and ice.

Here in Colorado we have a very dry air, and it is a fact that bees will winter successfully in old boxes or hives that are open both top and bottom, with almost unlimited upward ventilation. The whole secret of it is that the free ventilation carries off the moisture, keeping the bees and combs dry; there is no sour, thin honey and no chilled bees. I have both chaff and single-walled hives, and the bees winter fully as well, if not a little better, in the single-walled ones, and breed up as quickly and early in the spring as in the chaff-hives. I have thought that the chaff-hive colonies were slower, and I know they show more wet, moldy combs.

In late spring and early summer when a colony has become strong enough to fill the brood-chamber and keep it warm, I think possibly the chaff is some help by keeping the colony a little more even, and it is a fact that the packed hive will not be troubled with robber-bees so much as the single-walled. To average the question, I would not give a cent more for chaff hives than for single-walled, for this or a similar climate. Really, I am a little skeptical about the value of the chaff hives anywhere, but don't any one discard them or change because of my skepticism regarding them, in moist climates. Do this, however: Try some big hives, and so manage to have some rousing big colonies in these big hives to winter alongside of your little-hive colonies, and compare the wintering and the results after the next honey-flow; but you may have to contract *during the flow*.

Following out some of this reasoning—and it is based on experience—I conclude that there is no better shape for a hive than about 12 inches square, and 20 to 30 inches high, so far as successful wintering, and building-up after the winter is over. The reason is plain: If they start into winter with many bees they live through with a good start of bees in the spring to mature the first brood; and in wintering they have such a good store of honey above them that they have but to follow it up, and eat as they go, and in the spring they are close to the top, and but a small space about them to warm. It makes no difference if there is a bushel of comb beneath the cluster, or if those combs be full of honey—if full of honey they will be opened, and all honey next to the entrance carried up, and this carrying up of honey encourages breeding. The colony will not, and does not, need to warm what is below them.

But there is some reasons why we do not want a hive of the proportions of 12 inches square, no matter how high, and we will go further into the subject in the next article.

(To be continued.)

Growing Alfalfa for Honey in Illinois.

BY J. E. JOHNSON.

AS I consider honey-plants the foundation of successful bee-keeping, I have been investigating and experimenting on the same for some time. This is the plan I have formed for the coming season in regard to alfalfa:

I have an uncle living near Hutchinson, Kans., who has

raised alfalfa successfully for many years without irrigating. He has found that alfalfa is able to resist drouth better than many other crops, and gets three cuttings nearly every year. I also find that alfalfa is raised in many parts of the West, without irrigation. I have also seen one little patch near here which stands the winter well, but does not seem to flourish as it should. Something seems to be lacking, which is no doubt the bacteria spoken of in Bulletin No. 76 of the Illinois Experiment Station. It is on high land, not very rich.

I have talked with my neighbors, many of whom are cattle-raisers, and all agree that alfalfa would be a fine thing here if we could grow it successfully. All seem anxious to try it, and I have agreed to furnish them 1 to 5 pounds of seed each at 25 cents per pound. I shall also try a patch myself. I shall send to my uncle for infected soil from a successful alfalfa field, and furnish some free to my neighbors so as to enable them to get their soil inoculated with the necessary bacteria. If I manage this plan properly, I see no reason why I should not be able, in time, to find myself surrounded by alfalfa fields, as my neighbors are as eager to try the experiment as I am to have them, as it would be a great advantage to stock-raisers. Any one in Illinois, or the Eastern States, could try this matter for himself with but little expense; but he must persevere if he wishes to succeed, as in other enterprises.

I think the reason alfalfa has not been thoroughly tested in the East is because we can raise many other forage crops successfully. This they cannot do in the far West, and therefore they have persevered because of necessity, and have succeeded. No doubt any field of alfalfa would finally develop this same bacteria, or germs, in time, but by inoculating the soil from other fields we can hasten the matter very much. On my own patch I shall sow infected soil, and use either manure or commercial fertilizer.

Now as to the honey: Alfalfa is a species of clover, and very closely related to sweet clover, and I have always found that sweet clover produces honey in dry weather, if not too cool, but will sometimes fail in extreme wet weather, and that is also more or less the nature of all clovers. Alfalfa has roots that penetrate the earth deeper than any other clover; so, judging from other clovers, it ought to produce as well, or better, than in the West.

From both observation and what I can learn by correspondence, I shall follow these directions: Sow on ground well drained, not on low, wet soil. The soil should be clean from weed-seeds, and be made very rich, but avoid any very strawy manure.

If I do not get a good catch the first year I will sow again on the same ground, and furnish seed for neighbors to sow again, if not successful the first time. Even a small amount of infected soil scattered over the patch would no doubt give good results in time, if the ground is made very rich.

* The Afterthought. *

The "Old Reliable" seen through New and Unreliable Glasses.
By E. E. HASTY, Sta. B Rural, Toledo, O.

UNITING A LAYING-WORKER COLONY WITH A NUCLEUS.

If I understand correctly Mr. Baldwins' way of getting something out of a laying-worker colony, it is simply to unite it with a nucleus. Yes, that plan seems to be calculated to save whatever of value there is to save. On the other side of the balance-sheet is the risk of getting a queen killed; and, in fact, the existence of her little colony is put at stake also. Six trials and success every time is a good showing, surely. Page 699.

NAMES FOR VARIOUS FORMS OF HONEY.

Perhaps it would be nice if we could adopt Mr. Cary's three terms—"section honey," "comb honey," and "extracted honey"—as per page 700, but practically it is not possible. "Comb honey" has been so long used, and so often used, as an alternate term for section honey that if we start in to use it for something else we shall for years have a large share of our hearers and readers misunderstanding us. The term "chunk honey" has the merit that it goes right to the spot, and it is not to be misunderstood;

but confessedly it doesn't sound altogether alluring. Those who produce the article are entitled to have a name that doesn't insult their product, if they can discover and introduce such a name. I believe the terms "bulk comb" and "bulk honey" have been used to some extent. Those terms rather convey the idea of large quantity. What's wanted is a term that will fit a pound or a thousand pounds equally well.

SUCCESS WITH ALFALFA DEPENDS ON SOIL.

"It beats the bugs!" Now it's not soil, nor climate, nor irrigation, nor longitude, that forbids the growing of alfalfa in our Central States, but lack of the proper microscopic bug in the soil. And you can introduce him by taking a ton of the soil he inhabits and applying it to an acre—and then all will be lovely. And it's not Mark Twain, nor a newspaper columnist, nor your humble servant, that says this, but the Illinois Experimental Station. Page 709.

EXPERIMENTS WITH PEAR-BLIGHT.

False reports of important experiments—

"What turpitude of art
Can fitly barb the dart—"

which is needed to transfix them? Where shall we be if that sort of thing is tolerated and allowed to spread? According to page 709, the facts about pear-tree screened under netting were that there was *less* blight than outside—reported free from blight—but no more pears than outside—reported full burden of fruit. That is, the netting was some defense against blight, either by keeping off insects or otherwise, but also hinders fertilization enough to about even the thing up, so far as fruit is concerned. I do not understand that it was any paid scientist in State or National employ that made the false reports.

"OUR SISTERS."

"Our Bee-Keeping Sisters," eh? Well, they do say that "right smart" of bee-men are bachelors; and I venture the timid conjecture that now and then one has had a—somebody—offer to be a "sister" to him before. Page 713.

STYLES OF QUEENS—AND QUEEN-REARING.

Abbott L. Swinson's paper, page 716, gets in some live ideas. Two styles of shape in laying queens, the beautifully tapering kind, and the less tapering kind. Former the best, but latter often decidedly the largest. I think lack of taper and extra size in a queen are occasionally symptoms of disease. If so, we should not expect diseased queens to be as good as healthy ones; but, apart from this, quite possibly Mr. S. is on track of an interesting and valuable fact.

To remove a queen-larva which swims in a very abundant supply of food and put in a much younger one, is a promising experiment. I feel interested in his experience, that the resulting queen is extra large, but not valuable. A calf two days old is best on the milk of a cow only two days in milk, rather than on the milk of one a month progressed in milking; and something analogous to this may affect the above experiment just a little.

MOVING BEES ON A HAND-SLED.

Fifty miles travel with a hand-sled is what George Hodges had if we accept the text on page 717. Must send him to try for the North Pole. Text doubtless has some mistake in it—200 rods too long for a field, except on the plains.

Our Wood Binder (or Holder) is made to take all the copies of the American Bee Journal for a year. It is sent by mail for 20 cents. Full directions accompany. The Bee Journals can be inserted as soon as they are received, and thus preserved for future reference. Upon receipt of \$1.00 for your Bee Journal subscription a *full year in advance*, we will mail you a Wood Binder free—if you will mention it.

"**The Hum of the Bees** in the Apple-Tree Bloom" is the name of the finest bee-keeper's song—words by Hon. Eugene Secor and music by Dr. C. C. Miller. This is thought by some to be the best bee-song yet written by Mr. Secor and Dr. Miller. It is, indeed, a "hummer." We can furnish a single copy of it postpaid, for 10 cents, or 3 copies for 25 cents. Or, we will mail a half-dozen copies of it for sending us *one new* yearly subscription to the American Bee Journal at \$1.00.

Index to Volume XLII.

SUBJECTS.

Abnormal swarming..... 131
 Acorns and queen-cells..... 105
 Adding supers above..... 62
 Adulteration of honey..... 189, 345
 Advice to beginners..... 217
 Against liquor and tobacco..... 511
 Age of larvae for queen-rearing..... 80
 Age of queens..... 621
 Age of workers..... 583, 691
 Allials..... 47, 333, 409, 595, 707, 734, 739, 823, 824
 American queens in Australia..... 397
 Amount of brood in a Langstroth frame..... 217
 Amount of brood in large hives..... 583
 Answering comb-honey flies..... 333
 Ants..... 3, 9, 184, 212, 216, 633
 Ants and bees..... 9
 Ants and wet locations..... 184
 Apiculture as a business..... 69, 107, 282
 Apis dorsata..... 139, 136, 217
 Artificial swarms—methods of making..... 791
 Associations and conventions..... 533, 691
 Association seal..... 623

Baby bees—too funny for anything..... 804
 Bacillus of foul brood..... 747
 Back numbers—read up..... 67
 Bacteria and their relation to disease..... 804
 Balled queens in swarms..... 203
 Basswood..... 35, 147, 170
 Basswood and wax-worms..... 147
 Basswood tea..... 410
 Bee and honey statistics..... 185, 281
 Bee as a lawyer..... 21
 Bee books and their readers..... 140, 195, 229, 345, 675, 744
 Bee-bread flavor..... 149
 Bee-cells..... 121, 196, 297, 391
 Bee-dress for women..... 344, 713, 809
 Bee-dysentery—cure for..... 3
 Bee-fever..... 38, 77
 Bee-keepers..... 522
 Bee-houses and house-apicultures..... 185, 281, 503
 Bee-keeping as a business..... 136
 Bee-keeping as a department of study..... 547
 Bee-keeping a specialty..... 274
 Bee-keeping for invalid ladies..... 278
 Bee-keeping for women..... 55, 150, 197, 234, 279, 300, 343, 392, 437, 567, 598

BEE-KEEPING IN—
 Brazil..... 438
 Chile..... 1-7
 Oklahoma..... 60
 Russia..... 122
 Sandwich Islands..... 49
 Southern States..... 110
 United States..... 211
 Yakima Valley..... 155

Bee-louse..... 579
 Bee-paralysis..... 107, 378, 427, 457, 506, 633, 745
 Bees and ants..... 110
 Bees and bacteria..... 664
 Bees and fruit..... 73, 101, 168, 181, 277, 633
 Bees and grapes..... 1-4
 Bees and honey in Michigan..... 60
 Bees and pear-blight..... 23, 709, 813
 Bees can hear..... 142
 Bees coming out of hive at night..... 232
 Bees darker when hungry..... 631
 Bees don't hear..... 313
 Bees flying in winter..... 10
 Bees good work..... 21
 Bees hanging out..... 71
 Bees in box-hives..... 10
 Bees in hot countries..... 35
 Bees in law..... 11, 21, 23, 108, 552, 599, 615
 Bees in spring..... 408
 Bees killing each other off..... 425
 Bees not carrying pollen..... 335
 Bees starving in winter..... 341
 Bee-sting remedies..... 75, 218, 269, 332, 436, 457, 499
 Bee-trees..... 92
 Bee-veils..... 362

BEESWAX—
 Clarifying..... 10
 Cleaning with sulphuric acid..... 11, 698
 Colors of..... 58

Beginners in bee-keeping..... 394
 Benefits derived from attending conventions..... 455

BIOGRAPHICAL—
 Cinte, Oscar..... 199
 Dadant, Chas..... 564
 La Barre..... 5
 Mason, Dr. A. B..... 772

Bisulphide of carbon..... 99, 168, 390, 457, 470, 554, 734
 Bitter honey..... 745
 Bitterweed honey..... 457, 619
 Black and white bees..... 2-9
 Black brood..... 108
 Black bees vs. other races..... 468
 Bleaching combs..... 52, 310
 Bleaching honey..... 1-11
 Blight—the spread of..... 664
 Bottled honey..... 819
 Bottom-boards..... 139, 214, 325, 739, 744
 Box-hives..... 579
 Brasswood..... 582
 Breathing air from a paper-bag full..... 183
 Breeding queens and bees..... 9, 26, 105, 117
 Brittoning bees..... 194
 British standard frame..... 211
 Brushed swarms..... 605, 637, 717, 740, 750
 Brushing bees from combs..... 803
 Buckwheat..... 107, 108
 Buckwheat honey..... 184
 Building up colonies..... 180
 Building brood-combs..... 409
 Bumble-bees..... 28
 Burr-combs..... 456
 Buying bees..... 197, 313

Can bees hear?..... 42, 217, 239
 Canded honey..... 49, 70
 Cane vs. beet sugar..... 212
 Capping queen-cells early..... 51
 Carbolium..... 35, 110, 184
 Caring for old brood-combs..... 417
 Carniolan bees..... 71, 391
 Cathip..... 508, 755
 Cases vs. cells for bees..... 414
 Cellar temperature..... 71
 Cellar wintering..... 79, 803
 Changing brood..... 3
 Changing hives..... 297
 Choosing a location..... 71
 City of Rochester vs. Tain..... 23
 Classifying knowledge—condensed method..... 617
 Cleaning glass for shipping-cases..... 292
 Cleaning off leaky honey..... 729
 Cleaning T. ins..... 744
 Cleaning unfinished sections..... 685
 Cleaning up combs..... 651
 Closing the queen's wings..... 180, 317, 405, 443, 6-4
 Closed-end brood-frames..... 184
 Cockroaches..... 3-4
 Cold..... 58
 Cold-water paint..... 20, 122
 Color of honey affected by comb..... 71, 618
 Comb foundation..... 202
 Comb foundation for swarms..... 85, 113
 Comb honey by case or weight..... 19, 24, 87, 101, 120, 166, 230, 260..... 262
 Comb-honey production..... 85, 153, 180, 259, 297, 311, 313, 343, 358, 363, 375, 424, 456, 491, 571, 579, 582, 667, 681, 691..... 805
 Comb-honey slander..... 51, 84, 243, 325, 563
 Comb vs. extracted honey..... 563
 Commercial queens..... 583
 Commission men..... 23, 67, 85, 821
 Competition of Cuban honey..... 500
 Consumption of stores..... 163
 Conveniences..... 87

CONVENTION REPORTS—
 California..... 67, 102
 Chicago..... 133, 235, 260, 276, 292, 308, 325, 341, 377, 378, 384, 404..... 421
 Colorado..... 117, 133, 470
 Michigan..... 163, 140
 Minnesota..... 613
 National..... 7, 22, 101, 629, 645, 661, 678, 693, 706, 725, 741, 758, 788, 805..... 821
 New York..... 439
 Northeastern Wisconsin..... 669
 Northern Illinois..... 730
 Ontario..... 39, 53, 71, 85, 148
 Parma (Idaho)..... 125
 Texas..... 277, 549, 566, 581, 596
 Utah..... 341
 Vermont..... 181
 Wisconsin..... 99, 196

Co-operation of bee-keepers..... 248, 327, 819
 Co-operative union..... 116
 Corn—boney from..... 35
 Cough mixture..... 708
 Cross bees..... 394
 CS2..... 390
 Cuban honey..... 236
 Cucumber—wild..... 755
 Curious ways of climate..... 58
 Cutting out drone-comb..... 3-7
 Cyprian bees..... 63, 316

Danger in cell-cup plan..... 318
 Danzenbaker hives..... 74
 Danzenbaker vs. Langstroth hives..... 74
 Dark-colored wax and foundation..... 505
 Dark color for hives..... 218
 Dead bees..... 10, 74
 Dead cells..... 458

DEATH NOTICES—
 Clarke, Rev. W. F..... 680
 Dadant, Chas..... 467
 Mason, Dr. A. B..... 739

Dealing with misrepresentations..... 91
 Deep end of frames for wintering..... 260
 Determining sex..... 653
 Difference in locality..... 237, 344
 Disinfecting foul-broody hives..... 4
 Dividing colonies..... 41, 169, 377, 506, 621
 Do bees hear?..... 62, 447
 Dog..... 27
 Drowning out brood..... 282
 Don't crowd the bees..... 307
 Don't discourage the farmer..... 51
 Don't neglect the bees..... 278
 Don't put honey in the cellar..... 515
 Doolittle's best season..... 58
 Do rubber-bees sting?..... 115, 359
 Dragging out brood..... 473
 Drones in the super..... 602
 Drone-killing and no swarming..... 329
 Drone-traps..... 650
 Drones..... 3, 9, 10, 249, 282, 371, 611

 Shading and ventilating bee-hives.....728, 824
 Shaking bees from the combs.....185
 Shallow frames vs. standard in extracting.....180
 Shipping bees.....32, 731, 745
 Shipping smoke and bees.....103, 219, 404, 711, 828
 Shipping honey.....163, 173, 388, 807
 Shooting birds.....104
 Size of bees.....264, 356
 Size of cells.....622
 Size of honey-cans.....275
 Skin-whitening preparation.....744
 Smelter smoke and bees.....755
 Smoker-fuel.....85, 620, 713, 729, 760, 795, 809
 Sour honey—sweetening.....763, 829
 Specialist bee-keepers.....218, 666
 Specific gravity of honey.....72
 Spraying fruit-trees.....67, 67, 94, 147, 266, 269, 505
 Spraying to thin fruit.....436
 Spray with bell-bore.....320
 Spreading brood.....247
 Spring dwindling.....250
 Spring feeding.....218, 232
 Spring killing of drones.....407
 Starting in bee-keeping.....90
 Starting queen-cells.....51, 398
 Stinger and feeding.....41, 115, 153, 227, 266, 282, 334, 621
 Stingless bees.....115, 184
 Sting of the queen.....35
 Stings for rheumatism.....435
 Storing in the supers.....632
 Strong vs. weak colonies.....83
 Sugar for bees.....289
 Sugar trap.....659
 Sulphur smoke and black brood.....291
 Super foundation in brood-chamber.....132
 Superseding queens.....360, 425, 441, 494, 499, 667
 Swarm-catcher.....252
 Swarming.....74, 89, 92, 94, 131, 147, 217, 227, 249, 329, 335, 381, 394, 409, 411, 419, 442, 458, 473, 482, 501, 506, 568, 602, 745, 825, 810, 825, 810
 Swarms leaving after being hived.....755
 Swarthmore system of nucleus management.....810
 Sweet clover.....26, 35, 123, 138, 196, 211, 228, 244, 248, 355, 394, 424, 429, 488, 586, 675, 803.....812
 Sweet-clover honey.....297, 309
 Temperature.....375
 Temperature proper for keeping hives.....347
 Ten-frame vs. eight-frame hives.....129, 139
 Tent-canvas.....103
 Tested queen—What is a.....787
 Testing tongue-length of bees.....199
 Text-book on bees.....83, 810
 Testing supers.....339, 340
 Tongue-length and supers.....322
 Tongue-length vs. hustle.....294
 Tongue-reach.....71, 199, 212
 Tools for bee-keepers.....222
 Too much honey in spring.....218
 Tooth-wash—honey.....3
 Transferring.....41, 74, 152, 201, 214, 217, 218, 232, 293, 292, 346, 362, 435, 438, 115, 131, 147, 157
 "Truth about honey".....35, 51, 89, 88, 115, 131, 147, 157
 T supers.....139, 169, 601
 Two queens with a swarm.....501

Uncaping machine.....70
 Unfinished sections.....9, 685, 729
 Uniformity of hives and fixtures.....439
 Uniting colonies.....62, 267, 521, 537, 646, 659, 739, 792
 Uniting nuclei.....586
 Uniting weak colonies in the fall.....792
 Unrecognized heroism.....59
 Uniting queens.....483
 Using honey in cooking and candies.....294, 483
 Use of smoke.....409, 505
 Use of the queen's sting.....409, 505
 Utter vs. Utter case.....22

Value of good queens.....264
 Value of honey as a food.....551
 Value of old combs.....307
 Value of stored-up bee-information.....792
 Ventilating hives.....792
 Ventilation of bee-cellars.....163, 199, 211
 Vetch as a honey-producer.....476
 Vetch not a good honey-plant.....9
 Virgin queens uniting with a swarm.....458
 V-shaped top-bar—originator of.....5

Wasps and bees compared.....3
 Watering bees.....99
 Watermelons for bees.....687
 Wax-extractors.....153, 163, 330, 805
 Waxing barrels.....681
 Wax-presses.....163, 181, 686
 Wax-production.....535, 579
 Wax-worms.....633, 714, 729
 Wax-worms and basswood.....211, 248
 Weather for handling bees.....307
 What determines sex.....502
 Whipping up the queen.....291
 White clover—large.....179, 515
 White-eyed drones.....489, 601
 Wild swarms.....811
 Wintering a nucleus in an observatory hive.....217
 Wintering bees.....37, 70, 74, 75, 85, 94, 121, 164, 170, 215, 232, 284, 344, 350, 550, 619, 629, 649, 667, 679, 714, 743, 745, 761.....763
 Winter stores.....42
 Wiring comb foundation by electricity.....427
 Wiring frames.....153, 614
 Wooden comb-guide (triangular).....374
 Worker-comb without foundation.....73
 Working for wax and honey.....100

Yellow box-honey.....227
 Yellow-pine hives.....233
 Yellow sweet clover.....189, 248, 494, 505
 Young queens.....378, 419, 822

1-lb Keystone ... Honey-Jars

These are clear flint glass jars holding just one pound, and the shape of a keystone. They are 7 1/8 inches high, and very pretty when filled with honey. The corks can be sunk a trifle below the top, and then fill in with beeswax, sealingwax or paraffin. We can furnish them in single gross lots, with corks, f.o.b. Chicago, at \$3.50; two gross, \$3.25 per gross; or five or more gross, at \$3.00 a gross. These are the cheapest glass one-pound jars we know anything about. We have only about 20 gross of them left. So speak quick if you want them. Address,

FROM MANY FIELDS

Filling Shipping-Cases.

Having read Mr. Doolittle's article on "Filling Shipping-Cases with Sections," on page 711, and noticing the trouble he had with putting in the sections, as the paper tray was usually torn, I decided to let him know that he could do away with his tin, by a much easier method, which I discovered at the filling of my second shipping-case.

When putting in the second last section, push it against the wall of the case and then the last one next to it, or fill up all around the wall first, and at last in the center. I think Mr. Doolittle will find this method much more convenient and easier, if he will try it.
Clinton Co., Ill. J. D. HOLDENER.

Results of the Past Season.

I have 85 colonies. The honey season for 1902 was poor. I took 3500 pound sections of honey in August. September has always been our best month, but this year we did not get a section after August.

ALFRED E. SMITH.
Posey Co., Ind., Dec. 2.

Young Queens Swarming.

My first swarm came out May 21, and was put in a hive filled with old comb, and the same queen had a swarm out the last of June, and left 15 pounds of honey in sections.

The colony that swarmed May 21 cast a swarm August 3; that was a very large swarm, as large as any I ever saw, and I have kept bees the past 30 years. This young queen must have laid the eggs of this swarm that was hived August 3; and November 22 it was killing off the drones.

All three new colonies have enough to winter on. They are Italian bees and are in movable-comb hives.
Cheshire Co., N. H., Dec. 3. C. HODGKINS.

A Shade-Board for Hives.

On page 728, W. R. Ansell describes, before the Minnesota Bee-Keepers' Convention, a shade-board made of laths and shingles.

Would it be possible to have his method of shading described a little more particularly? It might also be practical to insert the illustrations which Mr. Ansell presented at the convention.

I believe that many bee-keepers are interested in a practical shade-board, and would appreciate it if this shading-board were fully described.

I am just preparing my bees for wintering, and find I have 87 colonies in good condition. Bees have not gathered much honey this year, and I never have seen bees as mean and angry as they were this year. I suppose the changeable cold weather was the cause of it.

I like the American Bee Journal very much, and have received a great deal of valuable information from it.
St. Louis Co., Mo., Dec. 2. R. A. HOLEKAMP.

[A picture of Mr. Ansell's shade-board was sent us, but it was not the right kind to make an engraving. If he will send us a good one, with full description, we will be glad to publish all.—EDITOR.]

Keeping Bees on Shares.

From the comical aspect, this little branch of the great apicultural waters does not glide away to a haven of peace and rest; but in reality there is no better or cheaper way for the beginner to get a start in bees, and, in many cases, may be the best way for the apiarist who is overstocked with bees, to manage his surplus colonies. Else out-apiaris

must be started, which means a great expense, and calls for almost ceaseless attention.

In letting bees out on shares, one is then free to turn his attention to other matters, and all that is made is clear gain. While one has the whole production of an out-apiary, after the expenses are taken out, the profit is more than apt to fall below what it would have been if the bees had been out on shares of half.

I have kept bees on shares, and have let them out on shares; in fact, I still have 8 colonies that I am keeping in this way, and have over 200 colonies out on shares, scattered about among a number of farmers, and covering a range of 300 miles, in two States. Yet I have never had the slightest misunderstanding with any with whom I had dealings in this respect.

It was necessity which forced me to adopt this method of disposing of my surplus colonies at first; but I am now free to place my bees in out-apiaries and tend them myself, and I do not care to.

In order to avoid any misunderstanding, the whole agreement is put in writing, and provision made for every detail, however trifling. Then, as soon as the honey season is over, a division of stock is usually made, and each party takes his chances of wintering. The old colonies, of course, are not divided, but remain the property of the one who let them out in the spring for a share of what they may produce in swarms and honey.

The man who has nothing to do but attend his out-apiaries can sometimes make these quite profitable; but for one who has other matters to claim a good share of his attention, it may be best to let his surplus colonies out on shares.

L. E. KERR.

Saline Co., Ark.

Sweetening Sour Honey.

On page 763 is a query in regard to sweetening sour honey. I have had some experience along that line, and will give my method of treatment. Last fall I had four tons of sour honey, it was thoroughly candied before it commenced to sour, and some of it was fermented so badly that the cans bulged and had to be replaced with others. I procured a galvanized-iron tank capable of holding ten 60-pound cans. I sawed strips of board, placing them on the bottom of the tank. I then filled the tank with water, until 3/4 of the can was submerged, built a fire under the tank, and in about 5 hours the first lot was thoroughly heated and ready to be taken out and poured into a large honey-tank. I continued to treat each lot the same until it was all finished, then let it stand 4 or 5 days, and when thoroughly cool skimmed off what foam had risen, and I had as good a grade of honey as before it soured, and I think the color had improved. In heating, the honey had a tendency to run out of the can; to obviate that it will be necessary to draw a little from each as it melts. An old pop or squirt gun answers for that purpose. Whatever is drawn off must be thoroughly heated before being added to the tank. I had a separate vessel to heat that in.

W. W. VARNER.

Ventura Co., Calif.

A Broken Silence—Rearing-Queens.

Except for Dr. Gallup's startling discovery, as told on page 408, I should not think of disclosing the remarkable facts which are to follow. But when the "cat is out of the bag" why seek to keep secret longer that which so mightily concerns the rearing of queens full of years?

It was early in my bee-keeping career that I first noticed the umbilical cord (scientific name, pupaskinna castoffica) of the queen-bee. I attached great importance to that attachment, and immediately placed an attachment on my discovery. What I recovered and discovered is as follows:

I reasoned that the royal jelly is so thick and tough that the poor queen, in the short time at her disposal, could only get a little benefit from the food through the umbilical cord—pupaskinna castoffica. If I could substitute a thin and vitalizing fluid I could, per-

haps, work wonders. After much thought I proceeded as follows:

On June 2, 3:05 p.m., I transferred 500 freshly laid eggs from ten of my best queens to cell-cups previously prepared. These 500 cups were given to 100 strong, queenless colonies, five to each. On June 16, 4:07 p.m., at which hour the pupaskinna castoffica is wont to appear, I carefully removed the 500 nymphs (royal) from these cradles and laid them in a row on a downy strip of cotton-batting. After much scrutiny I selected the fairest of the 500 and most carefully set her to one side. With a hypodermic syringe I now took the *lives* of the 499 remaining princesses, carefully drawing each out through the pupaskinna castoffica (umbilical cord—E. Gallup). With considerable skill I now injected through the pupaskinna castoffica of the selected nymph these *lives* at the rate of 15 per minute until I had injected 299. The remaining 200 were reserved for a most delicate operation.

By the aid of the X-rays (yes, I knew all about the X-ray at the time, but refrained from giving my discovery to an incredulous world), I now injected 100 of the remaining *lives* into each ovary of my princess—destined to be a queen full of years.

It required the utmost skill to insert the syringe under the third abdominal ring and into the delicate ovary. Had it not been for the fact that the subject had been given 299 *lives* through the pupaskinna castoffica I fear that I should have failed here.

The royal subject was now put into a cell and given to a nucleus in a glass-hive so I could watch what followed. I tell you true, I watched there 55 hours and 10 minutes. The queen first began to show vitality at the end of the 31st hour, by emitting piping that caused the glass of the hive to shiver. At the close of the 32nd hour she came forth, an ordinary queen except for her exceeding activity.

In less than four hours she showed signs of anxiety to take her marriage-flight. My task was not yet done.

I had the day before prepared 1000 lusty drones from the best stock in my yards. The task of dissecting out the male elements of each was a tremendous one, but I succeeded in getting at least three grains of the rich fluid. This fructificative fluid was injected into the retaining-sac of the queen. Here again the excessive vitality of the subject was called upon, not to mention the elasticity of the retaining-sac. The queen laid her first egg three hours and ten minutes from the moment the syringe ceased its work.

Such a queen! A brief mention of what she did in her 10th year will show her worth. I kept her in her 10th year with a colony of her three-year-old workers. I kept no other queens except two in my log-gums and one in a straw skep. This queen laid all the eggs for my 20 regular colonies. She would fill 10 frames in 24 hours. I simply set in empty frames as I took out full ones to give to the other colonies.

Space will not allow me to tell much about the wonderful work of the mammoth 20 colonies. I will merely state that the workers never die of old age. They all meet death through violent causes. (I might digress to

THE GLORY OF HEALTH.

What is more pleasing to the eye than an athletic, clear skinned, deep chested man, ready to toil or play, with the free, easy grace of perfect health? The kind of man that goes singing about his work, because he feels that way.

WATKINS'

VEGETABLE ANODYNE LINIMENT

will not make a lazy man muscular, but it will keep the body in such perfect condition that the food you eat, the work you do, will all help to build up a big, strong body. It is the cold in the chest, followed by a troublesome cough that breaks down so many strong bodies. A dose of Watkins' Liniment will stop it all before the harm has been done. **No running for Doctor, no paying big doctor bills.** Use internally or externally for Colds, Coughs, Colic, Diarrhoea, Dysentery, Cholera Morbus, Indigestion, Cuts, Burns, Bruises, for man or beast.

Watkins' Liniment is good for so many diseases because of the large number of valuable ingredients, each of which does its own work, and does not interfere with the others. Let our agent leave a bottle at the house. If there is no agent in your neighborhood, write to us, and we will see that you are supplied.

A Valuable Gift.

We have a beautiful Cook Book and Home Doctor that we send free to all. It is full of valuable recipes and good wholesome advice. Everyone is surprised that we can afford to send out such a complete and beautiful book free. Write to—

day. Send your name and address on a postal card.

Extracted Honey For Sale

ALL IN 60-POUND TIN CANS.

Alfalfa Honey

This is the famous White Extracted Honey gathered in the great Alfalfa regions of the Central West. It is a splendid honey, and nearly everybody who cares to eat honey at all can't get enough of the Alfalfa extracted.

Basswood Honey

This is the well-known light-colored honey gathered from the rich, nectar-laden basswood blossoms. It has a stronger flavor than Alfalfa, and is preferred by those who like a distinct flavor in their honey.

Write for Quantity Prices by Freight, if Interested.

A sample of either, by mail, 10 cents, to pay for package and postage.

Order the Above Honey and then Sell It.

We would suggest that those bee-keepers who did not produce enough honey for their home demand this year, just order some of the above, and sell it. And others, who want to earn some money, can get this honey and work up a demand for it almost anywhere.

GEORGE W. YORK & CO., 144 & 146 E. Erie St., Chicago, Ill.

the extent of saying that I once saw a spider cut one of these bees. That spider was immediately so filled with vitality that she went on a stampede; and it is a fact that spiders could not stay in the vicinity of these hives.) Some of the colonies occupied 3000 sections at one time. I had to give an entrance the whole breadth of the hive-bottom.

Though the queen was endowed with such amazing vitality her claws would wear out as fast as those of an ordinary queen, and at the end of the sixth year she experienced difficulty in clinging to the combs. I experimented a long time before I discovered a way to help her. Finally I replaced her six feet with those of a young queen, cementing them on with royal jelly. The task was done so easily and well that the royal circulation was scarcely interrupted. I now practice giving her a new set of feet and new antennae every second year, believing that it pays to do so. Hoping to hear more from Dr. Gallup and the unbilical cord (pupaskinna castofoica), Yours truly, **BARON M. LIEAWFUL.**

SWEET CLOVER

And Several Other Clover Seeds.

We have made arrangements so that we can furnish Seed of several of the Clovers by freight or express, at the following prices, cash with the order:

	5lb	10lb	25lb	50lb
Sweet Clover (white).....	\$.75	\$1.40	\$3.25	\$6.00
Sweet Clover (yellow).....	.90	1.70	4.00	7.50
Alsike Clover	1.00	1.80	4.25	8.00
White Clover	1.20	2.30	5.50	10.50
Alfalfa Clover80	1.40	3.25	6.00

Prices subject to market changes. Single pound 5 cents more than the 5-pound rate, and 10 cents extra for postage and sack.

Add 25 cents to your order, for cartage. If wanted by freight, or 10 cents per pound if wanted by mail.

"Bees in Colorado"

I still have several hundred copies of the souvenir with the above title. The bee-papers and a good many people without visible axes to grind have said it is a valuable and attractive thing. If you should like to have a copy, send me a silver dime or 5 two-cent stamps, and I will mail you a copy.

"BEES IN COLORADO" is the title of a 48-page and cover pamphlet gotten up to boom the Denver convention. Its author is D. W. Working, the alert secretary of the Colorado State Bee-Keepers' Association. It is beautifully illustrated, and printed on enameled paper. It is a credit to Mr. Working, and will be a great help in acquainting those outside of Colorado with the bee and honey characteristics and opportunities of that State.—American Bee Journal.

HONEY AND BEESWAX MARKET QUOTATIONS.

CHICAGO, Dec. 8.—There is no special change in the honey market, prices remain as last quoted and the volume of sales are not large. The weather is such as usually prevails at this season of the year, and the cold may induce people to buy more freely. Best lots of fancy white comb honey brings 16c per pound; No. 1 to choice, 15c; off grades, 2c to 5c less, and not much demand for them. Extracted, 7½¢ for white; amber, 6½¢; Southern, 5½¢@6c. Beeswax, 30c.
R. A. BURNETT & CO.

ALBANY, N. Y., Nov. 22.—Honey market is still in strong position with ready demand for all receipts at good prices. Fancy white comb, 16c; A No. 1, 15c; No. 2 and mixed, 14½¢@15c; buckwheat, 14¢@14½c. Extracted, buckwheat scarce at 6½¢@7½c; light grades more plenty at 6½¢@7c. Beeswax, 29¢@30c.
H. R. WRIGHT.

BOSTON, Oct. 20.—Our honey market remains firm, with good demand and fair stocks on hand. Honey is not coming forward as fast as usual, and the tendency of prices is steady. We quote our market as follows: Fancy white 1-pound sections in cartons, 16c; No. 1, 15c; No. 2, very light supply, 14c; glass-front sections generally one cent less than this. Extracted, light amber, 8c; amber, 7½c.
BLAKE, SCOTT & LEE.

KANSAS CITY, Dec. 6.—We quote fancy white comb honey, per case 24 sections, \$3.50; No. 1 white, per case 24 sections, \$3.40; No. 2 white and amber, per case of 24 sections, \$3.25. Extracted, white, per pound, 7c; amber, 6c. Beeswax, 27¢@30c.

Our market has changed quotations of comb honey from pound to the case.
C. C. CLEMONS & CO.

CINCINNATI, Dec. 8.—The demand for honey, both extracted and comb, has eased off somewhat the past few weeks, however the prices rule steady, as follows: Extracted, amber, in barrels, 6½¢; white clover, 8¢@9c. Comb honey, fancy, 16¢@17c; amber, 11¢@12c. Beeswax, 29¢@30c.
THE FRED W. MUTH CO.

NEW YORK, Dec. 8.—Demand for comb honey not quite as brisk, owing, we presume, to the fact that prices have been ruling higher. Supply, however, is moderate, and there is no other stock on the market. Prices remain unchanged; fancy white, 15c., with exceptionally fancy at 16c; No. 1, 14c; No. 2, 12¢@13c; buckwheat and amber, 11¢@13c. Extracted, white, 7½c; light amber, 6½¢@7c; dark, 5½¢@6c. Beeswax in fair demand at 28¢@29c.
HILDRETH & SEIBELKEN.

CINCINNATI, Dec. 12.—The comb honey market is a little quiet, almost everybody is filled up. As there is hardly any new supply coming in, there is no change in prices, namely: Fancy water-white, 16c; off grades less. The market for extracted white clover shows a slight advance. Fancy white clover brings 8½¢@9c; alfalfa water-white, 6½¢@7½c; but amber, if anything, has weakened. I quote same, in barrels, 5½¢@5½c. Beeswax, 27¢@28c.
C. H. W. WEBER.

SAN FRANCISCO, Nov. 12.—White comb honey, 10½¢@11c; amber, 9¢@10c; dark, 5¢—c. Extracted, white, 6¢@6½c; light amber, 4½¢@5½c; amber, 3½¢@4c. Beeswax, good to choice, light, 26¢@27c; strictly fancy light, 29¢—.

White is reported scarce; light amber honey in fair supply. The bulk of California produced honey is sold for Eastern shipment in carload lots from producing point at bottom price. Small lots of choice honey that can be used in local trade bring more. Quotations here given are current prices to producer, f.o.b. shipping point, on Eastern basis for extracted and California basis for comb.

Tip-Top Glass Honey-Jars

The picture shown herewith represents the best one-pound jar for honey that we know of. It is made of the clearest flint glass, and when filled with honey, and a neat label attached, it makes as handsome a package as can be imagined. Its glass top sets on a flat rubber ring, and is held in place by a flat steel spring across the top as shown in the picture. It is practically air-tight, thus permitting no leak,

which is an important thing with honey-sellers.

We can furnish these jars, f.o.b. Chicago, at these prices: One gross, \$5.00; two gross, \$4.77 a gross; five or more gross \$4.50 per gross.

If you try them once you will likely use no other kind of top or sealing arrangement for honey jars.

DADANT & SON,
Hamilton, Hancock Co., Ill.

The Holidays Are Almost Here,

And you are doubtless undecided as to what to get your friends for Christmas.

Why not get.....

The "Post" Fountain Pen

The very best in the market; regular price, \$3.00, and not obtainable under this price anywhere. The Six Cardinal points Peculiar to the "Post":

Self-Filling, Self-Cleaning, Simplicity, Durability, Reliability, No Leaking.

Given Absolutely Free

For two new subscriptions to Gleanings and your own renewal with \$3.00; or for one new subscription and your own renewal with \$2.50; or your own subscription will be advanced 2 years, and the Pen furnished for \$2.50.

In each case all arrears, if any, must be paid in addition, the above offers being for subscriptions fully in advance only. We believe we can say truthfully, without fear of contradiction, that no fountain pen ever put upon the market ever received in so short a time so many unsolicited testimonials from such distinguished men as the POST. The above drawing shows its construction. To fill the POST, all you have to do is to dip the nib into the ink-bottle, draw out the plunger, and the pen is ready for use. Compare this with unscrewing the ordinary style, and refilling with a glass filler that you can not always find when wanted. The self-cleaning feature of the Post, as illustrated, will also commend itself. With most pens specially prepared ink must be used or they are soon of no use, because they become so gummed up and it is well nigh impossible to clean them. With the POST you simply dip the nib in water, draw the plunger back and forth like a syringe or squirt-gun, and in less than five seconds it is clean and free for a perfect flow of any ink that may be handy. We will send, on request, a few of the many testimonials from noted men in various callings who have written merited words of praise for this most valuable invention. We can not offer it free as a premium with Gleanings by special arrangement we are enabled to offer it free as a premium with Gleanings in any of the following combinations: All arrears, if any, must first be paid at \$1.00 a year. Then for \$3.00 we will send Gleanings for one year, to two new names; for one year to yourself, and send you the pen free. For \$2.50 we will send you the pen and Gleanings for one year, and to one new subscriber a year; for \$2.50 we will send the pen and Gleanings for two years. If you have ever been disappointed with a fountain pen we assure you that you will not be with this one.
