## THE AMERICAN BEE JOURNAL

PUBLISHED WEEKLY BY  
**GEORGE W. YORK & COMPANY**  
334 Dearborn Street, Chicago, Ill.

### IMPORTANT NOTICES.

THE SUBSCRIPTION PRICE of this Journal is \$1.00 a year, in the United States, Canada, and Mexico; all other countries in the Postal Union, 50 cents a year extra for postage. Sample copy free.

THE WRAPPER-LABEL DATE indicates the end of the month to which your subscription is paid. For instance, "dec'06" on your label shows that it is paid to the end of December, 1906.

SUBSCRIPTION RECEIPTS.—We do not send a receipt for money sent us to pay subscription, but change the date on your wrapper-label, which shows that the money has been received and credited.

Advertising Rate, per Aagate Line, 10c.

14 lines make one inch.  
Nothing less than 1/4 inch accepted.

Time Discounts.		Space Discounts.	
4 times.....	5 per cent	100 lines....	5 per cent
13 ".....	10 "	500 ".....	10 "
26 ".....	20 "	1000 ".....	20 "
52 ".....	30 "	2000 ".....	30 "

These rates are subject to either time or space discounts, at choice, but not both.

Reading Notices, 25 cents, count line, subject to the above discounts.

Goes to press Monday morning.

### National Bee-Keepers' Association Objects of the Association.

- 1st.—To promote the interests of its members.
- 2d.—To protect and defend its members in their lawful rights.
- 3d.—To enforce laws against the adulteration of honey.

Annual Membership Dues, \$1.00.

General Manager and Treasurer—  
N. E. FRANCE, Platteville, Wis.

If more convenient, Dues may be sent to the publishers of the American Bee Journal.

### Let Me Quote You My Direct Prices On Split Hickory Buggies

I am willing to take all chances on your not liking one of my Split Hickory vehicles. Every buggy I sell goes out on trial, subject to being returned, and refunding every cent of money, if not satisfactory. My FREE catalog of Split Hickory Buggies shows over 15 different styles of buggies, and a complete line of High-Grade Harness. I want you to have this book. No matter where you buy, you ought to read what I have to say about my direct method of selling at prices that are from 30% to 50% lower than you can buy a buggy of as high quality elsewhere. All my Split Hickory vehicles are guaranteed 2 years. The Buggy shown in this picture is my 1907 Split Hickory Special. I have an entire factory devoted to the making of this one job. Write today for catalog. A postcard—NOW—and you get it by return mail, with low prices on the best Buggies and Harness made. Address me personally.

Published Weekly at \$1.00 a Year, by George W. York & Co., 334 Dearborn Street.

GEORGE W. YORK, Editor

CHICAGO, ILL., JANUARY 3, 1907

Vol. XLVII—No. 1

**Effect of the Pure Food Law**

When we were in the honey-bottling business, a few years ago, we sold to a number of the wholesale grocers. Recently we received the following letter from one of them:

GEORGE W. YORK & Co.—  
Gentlemen:—The Pure Food Law enacted by Congress, taking effect Jan. 1, 1907, provides severe penalties for dealers who handle articles of food or drugs adulterated or misbranded.

In accordance with the provisions of the law, which exempts from prosecution those who procure a proper guaranty, we are requiring all from whom we purchase articles of food or drugs to execute a proper guaranty, and enclose herewith our regular form. It is essential that all blank spaces be properly filled in, and that the signature be in accordance with the directions on the form.

Please duly execute and return promptly to us. Very truly yours,  
Rockwood Bros. Co.

The "form" referred to in the above reads as follows:

**FOOD GUARANTY.**  
The undersigned,....., of....., State of....., United States of America, does hereby warrant and guarantee unto

Rockwood Bros. Co.,  
having principal office at Chicago, Ill., that any and all articles of food or drugs, as defined by the Act of Congress approved June 30, 1906, entitled

"An Act for preventing the manufacture, sale or transportation of adulterated or misbranded or poisonous or deleterious foods, drugs, medicines and liquors, and for regulating traffic therein, and for other purposes."

which the undersigned has sold since Oct. 1, 1906, or shall at any time hereafter prepare, manufacture for, sell or deliver to said

Rockwood Bros. Co.,  
will comply with all the provisions of said Act of Congress, and are not and shall not be

in any manner adulterated or misbranded within the meaning of said Act.

It is expressly understood that this shall be a continuing guaranty until notice of revocation be given in writing, and notice of acceptance of the guaranty is hereby waived.

Dated at.....this.....day of.....19....  
.....SEAL.  
.....SEAL.

1. Must be signed with full name of individual.
  2. If a firm, sign the firm name followed by name of partner executing document.
- If a corporation, must be signed by proper officer, and corporation seal attached.

It seems that wholesale grocers do not mean to take any chances in the matter of handling any adulterated or misbranded goods hereafter. They know the Pure Food Law has teeth in it that are sharp, and that the Law will be enforced to the letter.

A new day for pure honey is apparently dawning. We look for a greatly increased demand for it hereafter, and believe that the prices will soon be advancing. What beekeepers should do now is to let the people know the special food values of honey through the newspapers and magazines. To many, such information would be "news," indeed.

We are expecting, in the very near future—say 2 or 3 years—to see such a demand for honey that it will take every pound produced, within 6 months after the close of the honey harvest each year. Bee-keeping is not overdone. But general consumption of pure honey has been "underdone" for years, on account of adulteration and misbranding.

Let the National Pure Food Law have its chance, and then the producers of pure honey will have their chance, for which they have been waiting so long.

Love in the heart is better than honey in the mouth.—*Proverb.*

**Irish Bee Journal and Age of Queens**

Exception was taken in these columns to the teaching of the Irish Bee Journal in favor of "having every season, a young queen of the previous year's rearing, to head each colony," as that was understood to mean that the right thing would be to replace every queen when a year old; and it seemed an unsolvable puzzle to understand why the Irish Bee Journal should attempt to fortify its position by quoting authorities which plainly advocated that a queen was good for 2 years' work. The solution of the puzzle is now at hand. Our Irish contemporary says in the December number:

The question between us is, What is meant by "a queen of the previous year's rearing?" Let us see. Take the case of a queen born on May 1, 1906. On April 30, 1907, she will be a year old. Does Mr. Maguire teach that she must then be killed? By no means. Let us go farther. On Sept. 30, 1907, she will be 1 year and 5 months old. Must she then be killed? No. She is still "a queen of the previous year's rearing." On April 30, 1908, she will be 2 years old, but still "a queen of the previous year's rearing." Her year began not on Jan. 1, 1906, but on May 1, 1906. She is safe from the headsman, so far. Even if we allow that her year began on Jan. 1, 1906, 4 months before her birth, she will answer Mr. Maguire's requirements up to Dec. 31, 1907, when she will be 1 year and 8 months old. We, therefore, claim for our contributor that, at the very least, he is free of the charge of having taught that "each queen when it becomes a year old should be destroyed," and is, thus far, in strict agreement with the authorities.

It makes one the least bit dizzy to understand how a queen 2 years old can be a "queen of the previous year's rearing," for in this locality the phrase "a queen of the previous year's rearing" is generally equivalent to "a last year's queen;" and until the foregoing quotation appeared it never occurred to us that there was any question between us as to the meaning of the phrase.

This, however, is a very small matter, and it is a real pleasure to know that there is no greater difference between us than a different understanding of the meaning of a few words. Not knowing before this that there was any different understanding as to the meaning of words, of course no exception was taken in that direction. The Irish Bee Journal may charge us with thick-headedness in not understanding correctly the English language

but when it understands that we were honestly of the opinion that it was advocating that no queen should ever be allowed to live until 2 years old, it may possibly absolve us from the charge of hypercriticism in objecting to such advocacy. It is a thing to be desired to be in accord so far as possible with our bright contemporary.

## Shipping Comb Honey

We were recently requested to call and examine a shipment of about 160 cases of comb honey that was received from a Wyoming bee-keeper by a Chicago honey-dealer. It was fine alfalfa honey, put up in the usual 24-pound shipping-cases, and then two of the cases were fastened together by light strips at the corners, thus making each package between 50 and 60 pounds. That was all the preparation made to ship that honey perhaps 1500 miles.

Well, it arrived just as any experienced shipper of comb honey would expect—fully half of the combs broken out of the sections.

We do not find that particular shipper's name among the readers of the American Bee Journal, or he would have known better than to ship comb honey in the way he did. Doubtless he doesn't read any bee-paper. But he probably has lost enough on that one shipment of honey to pay his subscription to all the bee-papers in this country for the next 25 years.

We have so often published explicit directions for preparing comb honey for shipment that it would seem hardly necessary to tell it again, but we find that on account of the many new readers that are constantly being added to our list, it is well to repeat important directions that, if heeded, may mean the

saving of many dollars to a number of our readers.

After comb honey has been put in shipping-cases, the cases should be put into crates, or carriers, holding from 6 to 9 of the shipping-cases. But before putting the cases into a

the ends of the crate about 4 or 6 inches. These extensions will serve as handles for the train-men to carry the honey when loading and unloading it.

We have never known of any loss in shipping comb honey when prepared as we have

SUITABLE CRATE CONTAINING CASES OF COMB HONEY FOR SHIPMENT.

crate, there should be put in the bottom from 4 to 6 inches of straw or hay, to act as a cushion under the cases of honey.

Then after filling the crate with cases, put the cross boards on top, and also this sign, either printed or written in plain letters: COMB HONEY. HANDLE WITH CARE.

Near the upper sides of the crate should be nailed on pieces of boards about 4 inches wide, and long enough so as to extend out at

briefly outlined here. It seems too bad to lose heavily on a shipment of honey just because it was improperly prepared, especially when it is so simple and inexpensive to put it into the right shape for safe carrying either on cars or wagons.

The illustration herewith shows quite clearly how a crate of comb honey appears when ready for shipment either a long or a short distance on the railroad.

## Miscellaneous News - Items

Volume XLVII begins with this number of the American Bee Journal. The last volume (1906) contained the most and best bee-literature that has appeared in its columns in all its history. And there were in all 1060 larger pages than in any other bee-paper published to-day. All being well, this new volume promises to be even better than the last one. We hope that not only will all the present list of readers continue right along, but that each one may try to get some neighbor bee-keeper to become a subscriber. Remember, that neither the American Bee Journal nor its editor is connected in any way with any bee-supply business, so the Journal is entirely independent; and that it must depend upon receipts from subscriptions and advertising for support.

**Some San Antonio Pictures**, taken by Mr. Fred W. Muth, of Cincinnati, Ohio, appear on the first page. The upper one is a view of San Antonio, taken from Market Hall where the National convention was held. The lower picture represents 5 weary bee-keepers who were resting at the side of a clump of banana bushes. We only wish we could show the beautiful, broad, green leaves as they really appear. We had never seen bananas growing before, but there are plenty of them around San Antonio.

San Antonio is a Spanish-American city of some 70,000 population. It has many things of great historic interest. Several very ancient missions are located within a few miles, and The Alamo, right in the heart of the city, is a spot that few visitors fail to see. Within

its walls it was, during the war with Mexico, that less than 200 United States patriots held at bay some 4000 soldiers under Santa Ana, and although a mere handful in The Alamo, they slew about 1500 of Santa Ana's men before they were overcome and every one of their number killed.

Several of the Northern bee-keepers had their kodaks with them, and "took" many objects of interest in and around old San Antonio, which pictures will no doubt be greatly prized by their owners, as it was a trip and visit long to be remembered.

**An Announcement** has been received at this office of the marriage at Medina, Ohio, on Dec. 26, 1906, of Miss Carrie B. Root, youngest daughter of A. I. Root, and Mr. L. W. Boyden, manager of the A. I. Root Company's New York City branch office. This is the second "combination" of the kind, another daughter of A. I. Root having married Mr. A. L. Boyden, an older brother of "L. W.'s," some years ago. "A. L." is secretary of the A. I. Root Co.

Our sincerest congratulations are hereby extended to Mr. and Mrs. L. W. Boyden, and wishes for a long and happy voyage through life together.

## How Many Colonies to Become Well-to-Do?

BY C. P. DADANT.

On page 880, (1906), Mr. Doolittle asks, "How many colonies should we keep to become well-to-do?" and requests an answer from Dr. Miller, Hutchinson, myself, or others. On page 964, (1906), H. H. Moe reminds us of this question, and gives his views.

It is quite a long time since I "sparred" with Mr. Doolittle. I am not one of the "sparring" kind, unless I can see some gross error to redress, and the present subject is too indefinite to give any one a fair chance for discussion.

Perhaps the best thing I can do to answer the question is to cite my own experience. Mr. Moe says that each of us has what he calls a "prop" in addition to the bees, to keep us going. In the early '70's I had no such prop. It is true, we were rearing queens, and selling a few. But is not this legitimate bee-keeping? Must the bee-keeper sell only honey? Is not the sale of colonies or queens a legitimate part of bee-culture? For a number of years, I had nothing else. I can remember several seasons when we harvested from 40,000 to 50,000 pounds of honey. How many colonies did we keep? From 150 to 600. The manufacture and sale of comb foundation was just an accident—a result of conditions. We had bought a mill to make up our own wax, and it turned out that we could work our neighbors' wax and give them better satisfaction than any other, and so the business was built. But bee-keeping as a business was my principal occupation for some 15 years, and as I have already said, in the *American Bee Journal*, there was a time, when, if any one else had been entrusted with the care of any of our apiaries, I would have expected those bees to be entirely ruined. I got bravely over this notion quite a while ago.

How many colonies must we keep to become well-to-do? Why, it depends upon the apiarist, on the location, on the methods followed, on our greater or less ability to manage our affairs, etc. It takes a less number of colonies, when running for comb honey, than when producing extracted honey; but those colonies require more care. It takes less bees in a good locality than in a poor one, and yet the bee-keeper is more likely to keep many bees in a good locality than in a poor one. Locality is certainly a very important matter in securing a well-to-do occupation. In the alfalfa plains of Colorado, among the

mesquite brush of Texas, in the sage-covered hills of California, the bee-keeper will keep just as many colonies as he can care for, and will become well-to-do, if he exercises judgment. But how many colonies can he keep? That depends entirely upon his skill, his ambition, his wit, his health.

I have seen bee-keepers who would spend two hours in overhauling half a dozen colonies, and I have seen others who could tell you the condition of 25 hives in the same length of time. Yet the slow man might succeed as well as the quick man, if his needs were no greater than his speed. Let two men start in bee-keeping in this State. Let one of them be located among the corn-fields, the wheat and timothy fields, and let the other be in close proximity to a large dairy farm with a hundred acres of pasture in which clover abounds. Do you not see that the latter will have a much better opportunity, all other things being equal, to become well-to-do, than his less fortunate brother?

But take two men in similar locations. Let one of them watch his 100 colonies daily, supply their needs as soon as discovered, replace worthless queens, keep out worthless drones, attend to all details minutely; and let the other keep three times as many bees, and pay but little attention to them, and the latter is as likely as the former to succeed—probably more likely.

I think I have said enough to show that it is impossible to give a stated number of colonies of bees as either required or sufficient to render their owner well-to-do. So I throw the question back for Mr. Doolittle to answer, though I feel certain that his reply will be very similar to mine.

But should we encourage or discourage bee-culture? I do not think we have the choice. We are writing for bee-papers. The readers are keepers of bees, and they are entitled to know from those who endeavor to teach them, their very best thoughts, their most experienced recommendations. I have read complaints from people who think there are too many bee-keepers, and who would make it a crime for any one to encourage beginners. Those persons would make a failure in any avocation. If we were to believe them, there are too many doctors, too many lawyers, too many mechanics, too many farmers. But this is not true. There are not too many farmers as long as there is an acre of land that remains uncultivated. There are not too many bee-keepers as long as honey is wasting for want of harvesting bees. There are drawbacks, bad seasons, in every pursuit, but whether we are farming, or keeping bees,

let us try to follow the best methods, and be ready to take advantage of the bountiful harvest when it comes. We have just gone through a bad season, that is the time to make ready for good crops. After the years of famine come the years of plenty.

The question as I see it is not, How many colonies of bees shall we keep? but, How can we make the best success with the bees that we do keep?

Hamilton, Ill.

## Good Season—Methods of Making Increase

BY F. L. DAY.

The season of 1906 was a fairly good one in this locality in spite of the fact that basswood, which is usually our chief source of surplus, was almost a total failure. A late frost appeared to kill most of the buds so that only a few trees blossomed. White clover, on the other hand, was unusually abundant and yielded well.

My 28 colonies were increased to 43 full ones, besides 4 queen-rearing nuclei. I secured 2,600 pounds of honey, all but 80 pounds being extracted. For the nuclei, I used regular 10-frame hives with a partition in the middle, thus leaving room for 4 frames on one side and 5 on the other. My idea was to take one frame of brood with adhering bees and the queen from each of these nuclei and put in any colony where needed. This was the theory, but in practice I got only a very few laying queens from these nuclei during the whole season; but by placing choice queen-cells in West cell-protectors, with the spiral cage attached, and then hanging these between the frames of the 4 nuclei, I secured plenty of fine virgin queens. These were then introduced wherever needed, with fair success.

In making my increase of 15 colonies, I used both the nucleus and Alexander plans. From 5 colonies using the nucleus plan I secured 11 new colonies and 515 pounds of honey. Four colonies run by the Alexander plan gave me 4 new colonies and 475 pounds of honey. The nucleus plan gave me 220 per cent increase and 103 pounds of honey per colony. The Alexander plan gave only 100 per cent increase and 118 pounds of honey per colony.

The 4 queen-rearing nuclei were made from one of the 5 colonies used for increase. They would probably have produced enough honey if used for that purpose, to have made the 5 original colonies produce as high an average as the 4 worked on the Alexander plan. This makes the two plans about equal for honey-production, with the nucleus plan giving over double the increase that the Alexander plan did. Had we had our usual amount of basswood honey, the nucleus plan would have been far ahead in honey-production as well as increase, just as it was last year.

The Alexander plan undoubtedly has merit, but in this locality the lower story left on the old stand almost always becomes a most persistent swarmer, even though the upper story be removed 5 or 6 days after the preparations of the

colony. What we want to know about these matters is the truth without favor to any man's plan or hobby. Because one man's way is good for him in his own locality, it does not necessarily follow that every bee-keeper in all our broad land should be considered ignorant or stupid because he does not have so good success with the plan in question.

I notice that Dr. Miller's bees were cellared on Nov. 10; mine were put in on the 20th. Last year we both put them in the same day, that is, on Nov. 29. I am sorry he could not have had so good a crop in proportion to his large number of colonies as I did from my small number. I always enjoy his writings in the American Bee Journal and Gleanings, and hope they may be continued many years. I also have his book. I hope we may all have a prosperous season next year.

Detroit, Minn.

## Best Size of the Pound-Section

BY L. V. RICKETTS.

Having read with great interest the article by Mr. T. K. Massie, page 783 (1906), on the subject of "Best Size of Honey-Section," I will again attempt to write on the same subject. Mr. Massie and I, as well as some others, have for some time been advocating the use of a section large enough so that when fairly well filled with separated honey will weigh an average of 16 ounces. The one now in most general use—the  $4\frac{1}{4} \times 4\frac{1}{4} \times 1\frac{1}{8}$  bee-way section—weighs an average of only 14 2-3 ounces when filled as above stated.

Mr. Massie rather favors a plain section, to be used with some form of separator furnishing the bee-way. From the experience that I have had with both bee-way and plain sections, I prefer the former. The fence-separator costs more than the slotted wood, and as Mr. Massie says, "Some of them are very flimsily made, and do not last long."

However, it is results that we want, and in this case a heavier section of honey is the result that we are after, and it matters but little whether we use a bee-way or a plain section in obtaining it. The size, weight, and thickness of the comb in the sections are the main things to be considered.

After having very carefully considered the matter, I have concluded that a comb  $1\frac{3}{8}$  to  $1\frac{1}{2}$  inches thick is the best for section honey. With a bee-way section  $1\frac{7}{8}$  inches thick, used with slotted wood separators, we will get combs of the above thickness. As stated by me in previous articles, and as proven by experiments made during the season just past, I have come to the conclusion that the  $4\frac{1}{4} \times 4\frac{3}{8} \times 1\frac{7}{8}$  bee-way section (all things considered) is the best size of honey-section, and will come as near to giving us an average of 16 ounces of separated honey as we are likely to get

When writing on this subject of the weight of sections and selling honey by the piece or pound, page 633 (1906) among other things, Editor York says,

"Every little while, some one to whom the question is new appears on the scene with what he thinks is a satisfactory solution of the troublesome problem, and says, The whole thing is easy; just adopt that size of section which shall weigh an exact pound, and then it will make no difference whether the section is sold by the piece or pound." To this Mr. York says, "But when he attempts to produce a ton of honey with 2000 sections, each weighing an exact pound, he finds himself running against a snag." Our good Editor concludes by saying that the present object was only to show "that to find a section of such size that it shall always weigh an exact pound is one of the things that may be dreamed of, but never attained in actual practice." My only objection to the above is that it appears to convey the idea that those who are advocating the use of a section larger than the ones now in general use, are expecting to get a section in which the bees will always store an exact pound of honey. This, however, is not the case. Here are the facts:

The sections now in most general use, when fairly well filled with separated honey—sections that would grade No. 1, as to filling—do not average more than 14 2-3 ounces. Now the question is, Would it not be better for both the producer and consumer, if beekeepers in general would adopt a section which when filled as above would average about 16 ounces each, or 2000 such sections to weigh a ton, or a very few pounds more or less, instead of being 150 to 200 pounds short in weight, as is the case with the sections now in general use? There is no use to say it can't be done, for it can. The question is, Would it be best to make such a change? If best, then what size of section should we adopt?

After having very carefully considered the matter from many standpoints, I have come to the conclusion that there is no better size of section than the  $4\frac{1}{4} \times 4\frac{3}{8} \times 1\frac{7}{8}$  bee-way section; or for those who prefer a plain section and fence separator, the  $4\frac{1}{4} \times 4\frac{3}{8} \times 1\frac{1}{2}$  plain section will give the same results. Either of the last-named sizes of sections should give us a comb  $1\frac{3}{8}$  to  $1\frac{1}{2}$  inches thick, which, as before stated, is as near the right thickness for section honey as we could desire.

Pullman, Wash.

## First Things for the Bee-Keeping Novice

BY G. M. DOOLITTLE.

"I am a beginner in bee-keeping and have been persuaded to take the American Bee Journal, and in it I see that you sometimes answer questions if they are sent you. I wish you would tell us through the Journal's columns what you consider the prime thing a novice or a beginner in bee-keeping should know first. What is the main thing in bee-keeping necessary to know?"—CORRESPONDENT.

There are very many things in bee-keeping which are considered of first importance, and the novice should un-

derstand all of these, if he or she would be successful.

Perhaps the first thing that should be done by any beginner would be the reading of some one of the many good books on bee-keeping, such as "Langstroth on the Honey-Bee," Root's "A B C of Bee-Culture," Cook's "Bee-Keepers' Guide," Quinby's "Practical Bee-Keeping," etc. Having procured one of these books, carefully read it two or three times till the whole is as familiar to you as a nursery rhyme, from beginning to end, when you are ready to subscribe for, and read intelligently, one or more of the several good bee-papers published in America. Now, don't think that this is unnecessary to success, for it is necessary that you have some knowledge of the first principles of bee-keeping before you start out with the bees, if you are to take first rank as an apiarist.

Having gotten so far, I will tell you one of the many other things you will need to know, for on this hangs very much of that which will bring prosperity. In nearly all localities where bees can be kept there are certain plants and trees which give a yield of surplus honey at a certain time of year, while, aside from this, there is little more honey obtained by the bees than is needed to supply their daily wants. Some localities give a surplus at three stated periods, others at two, while the majority give only one such yield. Hence it must be apparent to even the novice, that if such a yield (or yields) pass by without any surplus, none can be obtained during the season. From this it will be seen that, in order to be a successful apiarist, a person must have a knowledge of his locality, and also know how to secure the laborers (bees) in the right time, so they can be on hand when the honey harvest is at its best. Failing to do this, there is little or no profit in apiculture, and my main reason for writing on this subject is that those who read may obtain the best results from their bees.

Practically, first, then, we must have a thorough knowledge of the first principles of bee-keeping; and, second, we have the location.

Here in Central New York our honey crop comes mainly from basswood, which blooms about July 3d to 12th, and lasts from 10 days to 3 weeks, according to the weather while it is in bloom. In other localities in this State white clover is the main crop, coming in bloom June 15th to 20th; and again in others, buckwheat, yielding nectar the last of August, while a few apiarists are blessed with a yield from all three. But as a larger part of those living in the Northern States have a yield of honey from basswood, I will speak of that as the harvest in illustrating what I wish to do. Bear in mind, however, that it devolves on the reader of this to ascertain by careful investigation just when and what is the source of nectar from which his surplus honey comes, so as to work accordingly.

After having determined from what and when we may expect our harvest of honey, the next step is to secure the bees in just the right time for that harvest. If you have a field of grain to cut, you hire the laborers just when the

grain is ripe, not before or afterwards. Everybody knows about this, yet in bee-keeping thousands pay no attention to this matter of securing laborers in time for the harvest, and then wonder why they secure only a meager return from their bees. Working thus, their bees, instead of becoming producers, far more often become consumers, as the tendency of bees, when left to themselves, is to produce the greatest amount of brood when the harvest is in its prime, rather than before it. Consequently, this greatest amount of brood emerges into bees just after the harvest has passed by, and thus have to be fed all through their lives from the supply of honey gathered by the few, while the many were in the brood form. I wish I could so emphasize this that it would "strike home" to every bee-keeper, be he novice or otherwise.

The queen is the mother of all the bees in a colony, she laying all the eggs producing them. Under the greatest stimulation she is capable of laying from 3,000 to 4,000 eggs a day, yet often she is laying only from 500 to 800 eggs daily at the time she should be doing her best. After the egg is laid it takes about 3 days for it to hatch into a larva. This larva is fed about 6 days, during which time it has grown to nearly fill the cell, when it is capped over and remains hid from view for nearly 12 days more, when it emerges a perfect bee. When every thing is in a normal condition, this bee works inside the hive for 16 days, doing such work as feeding the larvæ, building comb, evaporating nectar, etc., when it is ready to go out of the hive as a field-laborer; and at 45 days, during the working season, from the time of emerging, it dies of old age, and another generation takes its place.

From the above it will be seen that the egg must be laid at least 37 days before the honey harvest, in order that our bee has the opportunity of laboring in that harvest to the best advantage. Now, if the harvest is basswood, commencing to bloom, say July 7th, the egg for our laborer should be laid on or before June 1st.

But how shall we secure the laying of the eggs just when we want them? There are several ways of doing this, such as feeding the bees thin sweets when you wish the queen to lay more prolifically; giving young bees from other colonies that will feed the queen an extra amount of egg-producing food; spreading the brood, etc. But I will speak here only of the plan which I have used more lately to give a success greater than anything else which I have tried, taking everything into consideration. It is this:

About 40 to 45 days before the expected honey-harvest see that each colony has stores enough to make the bees feel very rich, so much so that there is no thought of any retrenchment; in fact, so that they can say "millions of honey at our house," and keep saying it all the time they are feeding it to the brood; when you will see that the queen will be fed so that the combs will be teeming with eggs as fast as the honey is removed from the cells to feed

the brood hatching from those eggs. A few days of cold or rain will not stop this brood-rearing, as it does when the colony is living from "hand to mouth," as is more often the case than otherwise, where no attention is paid to this

matter. As to where this feed should come from, it is easy to set aside full combs of sealed honey from the extracting supers the season before, instead of extracting from them.

Borodino, N. Y.

Conducted by EMMA M. WILSON, Marengo, Ill.

### Lady Bee-Keepers and Large Hives

On page 962, Mr. T. F. Bingham says: "I often wonder how the lady bee-keepers get along with the massive hives generally used." Just why he thus wonders he does not say; but it is probably fair to suppose that he has reference to the greater weight of such hives as compared with his own, and the feebler lifting powers of the sisters as compared with those of the sterner sex.

There is no question that it is a desirable thing to make the work of bee-keeping as light as consistent, and the matter that he suggests is well worth considering. Ought the sisters to have hives smaller than those in general use? At the outset comes the objection so strongly emphasized generally, that it is a bad thing to have odd-sized goods. But if all the sisters should use a hive of a particular pattern or style, would there not be enough of them to make it worth while for manufacturers to keep on hand a line of "Ladies' Hives," just as a line of "Ladies' Goods" may be found in the stores?

Suppose, however, that such a hive were agreed upon, and some sister wishing to enter the ranks of bee-keepers should desire to purchase a colony or two of bees with which to make a start, Of course she would want her bees in the kind of hive she expected to adopt; at least she would want the frame of the right size, and to have anything lighter than "the massive hives generally used" would require a smaller than the Langstroth frame; for to use less than 8 Langstroth frames in a hive is hardly a thing to be considered. Then to get her bees on "ladies' frames" she would be obliged to buy only of some sister, and sisters that keep bees are not always near at hand. Those near Mr. Bingham would, however, be specially favored. Again, if she would wish to sell, she could only sell to some sister, thus being handicapped whether she wants to start or stop.

But are we not told that the smaller hives are used because hives and not frames should be handled? Would it be any lighter work to handle a whole hive—even so small a hive as that of Mr. Bingham—than to handle the separate frames of Langstroth size?

On the first cover-page of the American Bee Journal for Nov. 22, is a very interesting picture of some of Mr. Bingham's hives. Would it be the lightest kind of work to lift down that 8th story? and wouldn't it be a rather precarious business to use a ladder to get to the top of pile?

All this talk, however, is more or less theoretical. Mr. Bingham's knowledge of small hives is obtained from actual practise, and if he can tell us just how bee-keeping for the sisters can be improved, we will gladly give him a place in our corner, with our most respectful attention. It is generally understood that he is much given to "smoking;" but there need be no fear that he would be so ungentlemanly as to smoke in the ladies' presence!

### A Plea for More Good Reading-Matter for the Home

A new year is just ahead of us—a new year christened "1907." A year? Possibly not all of it shall be ours, but what are we going to do with our allotment, be it all or only a portion of the next twelve months?

"Fill up each hour with what will last,  
Buy up the moments as they go;  
The life Above, when this is past,  
Is the ripe fruit of life below."

Now is the time when lots of thinking is done, but of what use are thoughts and sets of newly-formed resolutions unless put into action? Why the sadness always attendant upon the departing year? Is it because our censuring conscience convinces us of having lost a part of it, or at least of not grasping or making the most of the opportunities it offered?

Strange that this feeling is repeated with each passing of a year. The question just now under consideration is, How forcibly will it put in its appearance when the time shall have arrived for the retrospection of 1907?

The young year of 1907 brings to bee-keepers that which none of its predecessors brought—protection from adulteration and misbranding of their product, through the enforcement of the Pure Food Law. Most bee-keepers, while masticating their Thanksgiving

turkey (were they fortunate enough to be where that bird did not "roost" too high) gave thanks because of the enactment of this law; but now it is in order to return thanks that its enforcement has begun. And that the enforcement may not become *painfully real*, each honey-producer or shipper should thoroughly acquaint himself with the portion which affects the sale of our products. All bee-papers should make it a point to place it before their readers in a lucid, easy-to-be-remembered manner, as several have already done. And most certainly all bee-keepers should have the very best bee-literature.

As I gaze out on this wide, white world and its snow-hooded houses, the many shut-ins on account of the inclemency of the weather, pass in procession before my mind's eye, and I can but sympathetically wonder if all are supplied with entertainment in the way of good and helpful reading matter? The body will not more surely die from the want of bread—"the staff of life,"—than the mind will perish from want of proper nourishment.

Many who take pride in their ability to maintain a dining-table of ample proportions—daily loaded to the point of groaning, with not only the more common articles of food, but the luxuries as well—never dream that the keeping up of the reading table is of much greater importance. Custom should rule that a household without a reading table would be as much of an oddity as a household without a dining table; and that to be found upon the reading table from which the family are to be served should be, as to quality the choicest, and as to quantity, most liberal. Were such the case, we might expect the great army of wayfarers to die a natural death from want of fresh recruits. The memory of the family circle around the evening reading table has proved the beacon light that saved many a wanderer, not alone from home, but a wanderer from morality, and all that goes to make life worth living.

Stuffing the children with food for either the physical or mental being is poor policy—they most certainly should not wear glasses before teaching; but a preoccupation of the mind, by interesting and useful knowledge, to the crowding out of the objectionable and positively hurtful, is to be recommended. Time was when the training of children began, and gained considerable headway, at home; now, very generally, it seems not to begin until entering the school-room. After the parent finds he has lost control, or that he never had any, he rushes to the teacher and urges that the latter shall accomplish that which he himself has found impossible. Alas! how many times it is too late, and the youth is lost in the sea of his own selfishness and obstinacy. But how few of us, of mature years, cast adrift without any directory whatever, would be fortunate enough to keep within the line of safety or reach any haven of security?

The younger people are not the only ones to be considered in the maintenance of a reading table. How many self-sac-

rificing women rise by the break of day, or before, and cheerfully assume their daily duties which constitute a monotonous round, the variations being so slight as not to be perceptible, and keep everlastingly at it, the reading hour being the first, and only one, to offer rest in any degree? Statistics show that 75 to 80 per cent of insane women are farmers' wives? Their loss of reason is credited to monotony of life and isolation acting with crushing effect on their minds. Sociologists point to isolation as the active agent which drains our farms of young blood, and causes the constant gravitation of our boys and girls to the cities.

None will deny but that country life is far sweeter, attractive and independent than that of the cog-wheel workers of the crowded city. But its loss of advantage, more especially in winter, lies in its sameness and lack of that which brings new influences, fresh interests, and warm inspirations into the lives of the occupants of our farm homes. For want of the latter they prefer the cities' ceaseless grind, basement or tenement; accepting starvation wages; and being constantly lashed by the whip of comparison between their lot of pitiable self-denial and dependence, and that of the independently wealthy.

Older persons, especially women, suffer alike this sense of loneliness, but circumstances preventing any change of home, they quietly accept the situation as it exists, cultivating their powers of endurance until they lose their mental poise, or until physical death steps in to relieve them of their heavy burden. The lives of such teach us there is a possibility of being patient and contented to a fault.

This condition of serfdom—for it's nothing else—would materially change, and matters adjust themselves, as it were, so that a broader and far more pleasant life—one that could be enjoyed—might yet be theirs, if they would only lend a hand to their emancipation.

Do they bring forward the claim that they are too old? Or do they offer as an excuse that they have been denied the advantages of schooling in their younger days? If the former is their cry, then they should read E. A. Daggett's article in November Bee-Keepers' Review, which closes with these sentiments:

"To keep off old age, and to remain young, we must keep in full strength and vigor our physical, mental and moral powers. Activity is life. I think it may be safely said that the foundation of youth lies within every one. To all, I say, keep young. If old age is stealing upon you, or has stolen upon you, shake it off. Through the activity of your functions bring back the elastic step, the deep and quickened thought, and the tenderest emotion. Gradually persevere, and success will attend your efforts. Effort and determination will work wonders, and here is the richest field for their labor, with the richest promise of the greatest rewards. Again I say, be young. Dress young, act young. Be young in heart, be young in sympathy, be young in sentiment—be young, be young."

If coupled with age they extend the plea of a lack of learning in extenuation of their apathy relative to a possible agreeable change for them, they should be referred to J. E. Crane's article in

December 1st Gleanings. One of his memories was of "a farmer who at the age of 70 took up the study of Latin and had the pleasure later of reading his old Latin authors." He cites the case of Owen Kildare, whose writings form books that have attracted much attention, yet he at 30 did not know his letters. He also tells us the story of the learned shoemaker who at 40 found himself in broken health, and consulted a specialist, with the result that outdoor life was recommended, with the study of botany thrown in as a diversion. In six weeks he was a well man; but so intense had his interest become in his studies, that he kept them up till he had exhausted all the text-books that would help him in this country. Then he sent to foreign countries and mastered foreign languages, in order to quench his thirst for botanical knowledge. Was not this to him an unexpected (and as agreeable as unexpected) break in a monotonous life?

Our bee-papers have many articles of like weight that should drive conviction home to the most reluctant mind. For more reasons than space permits me to recite, they should be on the reading table of every live bee-keeper.

Do you ask why I have written in behalf of the interests of women and children? My answer is, Because men-folks usually look out for themselves, and see to it that they have what reading matter they desire—more likely they expect women-folks to do the same. However, as wholesome reading matter has never been known to injure a man, he who considers himself a protector of his home should not lose sight of this particular obligation, but build up fortifications around his home with a liberal supply of interesting and beneficial reading matter.

When he goes forth these blustering winter mornings, fully equipped in the shape of snow-shoes, leggings, reefer, slicker and sou-wester, to meet and wrestle with the storm—which wrestling of itself gives him a warm glow and renewed vigor—let him not forget the weaker and thinner clad ones—who must remain prisoners for the day, at least, and sometimes many days—that they, with him, need diversion of some kind. These "weaker vessels," as men delight to style women, have been known as the mothers of the strongest of men—giants, as it were, in either physique and intellect, or both. Strange, is it not, that such strength could possibly come of such weakness? This happy lot, will, in the future, be that of some other mothers; then happy will be the man who can conscientiously share with her the honor.

Our homes constitute the bulwarks of the nation, and the farmer being a veritable Atlas to the world, our good, old fostering Uncle Sam saw, in the deserted New England farms, of not many years ago, sure signs of national declination, and went to work with characteristic vim to apply a remedy in the shape of Rural Free Delivery of mail. Now it is "up to" every patriotic rural citizen to make the most of his privileges.

(Mrs.) MARY E. NULL

### Value of a Note-Book in Bee-Keeping

A small tablet, or note-book, carried in the pocket daily is one of the most important things with me in doing my work. I prefer the small pencil tablets about 3x6 inches, costing about a cent a piece. From these the leaves are torn off as soon as the matter noted on them is of no more value. It is so much easier to "jot down" or make a memorandum of anything that may come up suddenly, but which would be forgotten afterward.

A wise practise, too, is to plan one's work. The day's work is planned the night before. When getting up the next morning a glance at the notes tells just what is to be done. Sometimes there are a great many little things that have to be attended to. These are all put down just as they come to my mind. In the evening I go over the list and mark all those to be attended to on the following day, and so on, day after day.

Just try such a plan, and see if it does not give more relaxation to an already overloaded brain. It also allows a person more free thought to devote to other important matters.

### Buying Bees in Box-Hives

The question is often asked, "Does it pay to buy box-hives of bees?" Yes, and no. If it is intended to continue to keep them in this style of hive, yes—in sections where the honey-crop is not a failure and they receive good attention, but this is hard to do, and often we sustain losses. And right here is where modern bee-keeping began, for it is a fact that bees will store honey in any sort of a hive if they are in a honey-gathering condition. In modern bee-keeping we can easily supply the needs of the bees, but in the old way it is nearly the reverse; besides, the honey is not in a marketable condition.

The beginner is not always successful in transferring his bees from old to modern hives. And right here is where many bee-keepers turn back. It pays modern bee-keepers to buy bees in box-hives, but they should examine each hive well, removing the top, also looking through the hive from the bottom, and noting the contents carefully. If the comb is old and black it will not yield so much wax as newer comb by the common rendering process. The amount of stores and the cluster of bees should be closely estimated. The writer buys about 100

colonies of bees in box-hives each season, and his experience is that a lot of valuable increase can be made with them early in the spring. If no increase is desired, they can be used to great advantage in building the apiary up to the best honey-gathering condition.

As soon as there is some honey coming in, in early spring, these old hives are split open with an ax, and if they contain any combs of brood straight enough to fill the frames, they are transferred, and the bees are used as seems best—either united with other colonies which may need strengthening, or enough of them united together to make booming colonies. As soon as the choice comb has been taken from the box-hive, and the bees disposed of, it is thrown to one side, and as soon as the bees clean out what honey it may contain, all the comb is removed, scraping all interior

### Report of the Ontario, Canada, Convention

REPORTED BY MORLEY PETTIT.

The Ontario Bee-Keepers' Association met in the York County Council Chambers, Toronto, Nov. 7, 8, 9, 1906. Pres. H. G. Sibbald occupied the chair. After the reading of the minutes of the last annual meeting, the President read his opening address. He regretted the failure of the honey crop for 1906, but congratulated the members on the advance in prices. On account of the increased population of the country, a large home market for honey should be found.

Announcement was made from the Department of Agriculture that the grant for suppression of foul brood is likely to be doubled, showing the increased interest taken in this by the Minister of Agriculture, Hon. Nelson Monteith, and Deputy Minister, C. C. James. This along with the change in regulation, taking the control of inspection entirely out of the hands of the

parts of the hive well and rendering into beeswax. An average of about 2 pounds per hive is obtained.

About the time the transferring is done there is abundance of pollen coming in, and soon the honey is turned into young bees; and by the time the main honey-flow comes on, the brood-nest is full of young bees, and the supers full of bees of the right age to gather honey, besides storing a large pile of fuel for winter.

J. J. WILDER.

Crisp Co., Ga.

This is a novel idea, throwing aside the box-hives with crooked combs and honey after the good, straight brood-combs have been taken from them, and letting the bees clean them up, and turning the honey into young bees for the honey-flow. In this way two purposes are accomplished, the other being that it saves the fussing with broken combs of honey from which the honey has to be pressed or strained. But is there not danger of starting robbing from the other bees in the apiary? It would be a good plan, perhaps, to remove the box-hives some distance from the apiary, as the danger of robbing is not so bad when the bees carry the stolen sweets from some distance away.

Another good idea is to sprinkle water over the broken hives, which has a tendency to extinguish the scent of open honey, and partly dilutes the honey, so much so that the bees engaged in the fracas are less liable to go at it in a helter-skelter manner.

Association, Mr. Sibbald considered moves in the right direction.

J. D. Evans spoke a few words welcoming the Association to the old historical hall, the York County Council Chambers.

R. H. Smith opened the discussion on the President's address. As one of the members at the first meeting of the Ontario Association in the old City Hall, Mr. Smith saw many advances among expert bee-keepers, but not so much among farmer bee-keepers, as there should be. He regretted the lack of interest shown by farmers in the local associations. The Executive had been working out some of the suggestions made by Mr. Pettit last year, by putting local associations in federation with the Ontario Association.

Mr. Smith regretted the light crop of honey—perhaps the lightest for 10 years; but the exhibit at the Fruit, Flower, and Honey Show was one of the best he has seen despite the light crop.

W. J. Brown suggested that in accord

# American Bee Journal

with the suggestions of Mr. Pettit in the Canadian Bee Journal last year, we stick close to the program so that members coming in can know what to expect at certain hours.

R. F. Holtermann, referring to the price of honey, thought that considering the price of everything else is up, bee-keepers could keep the price of honey up. Messrs. Brown, McEvoy and Sibbald, spoke on the matter of prices, and thanked the crop-report committee for the help they had been to the bee-keepers. Mr. Timbers considered it not necessary to export honey.

Mr. McEvoy would be in favor of exporting enough to keep the price up.

J. D. Evans sees that the lesson of the year of shortage to us is that in extra-good years we store the surplus for the poor years.

Mr. Holtermann—This report, that there is a combine, is more far-reaching than we think. We should assure people that the Crop Report Committee do not control prices. It merely advises members as to the price they can likely get.

Jno. Newton—Bee-keepers should be permitted to get together and agree on prices, as well as fruit-growers and others.

M. B. Holmes—It has always been my wish that this report be kept private, and should not find its way into public print. Take care that honey be kept A No. 1, as always.

G. A. Deadman agreed that the prices be kept private. The committee should always be cautious about setting the price too high, because bee-keepers sometimes keep honey till winter and sell at a lower price.

Mr. Couse, Secretary of the Committee, said the committee has not made a great mistake yet, though prices may vary slightly. This reporting is what is going on with reference to many other things—grain, seed, etc., and is quite legitimate and very helpful.

Mr. Chrysler suggested that the report of the Report Committee be sent to as many outside bee-keepers as possible, to influence them to keep prices right.

Mrs. Grosjean and W. A. Chrysler commended the work of the Report Committee, and moved a vote of thanks to them.

W. H. Kerby said it should reach smaller bee-keepers.

Mr. Holtermann—The only way to reach smaller bee-keepers is through the local associations.

Mr. Sibbald—The reason for publishing the crop report in the papers was that local bee-keepers, dealers and consumers should all understand the state of the crop.

Mr. Deadman—Too often bee-keepers charge a wholesaler the same price as the retailer, so the Committee should publish these prices.

## PRODUCTION OF COMB HONEY

The essential requisites for the production of comb honey are a good honey-flow, strong colonies of bees, convenient hives, and an apiarist who understands handling bees and hives so as to take advantage of the flow of nectar.

The first of these requisites is beyond our control, except that we should take care to locate our apiaries where there is usually an abundance of nectar-secreting plants and trees, such as clover, basswood, etc. In my location clover is the only source of surplus honey.

The strength of the colony of bees depends largely upon the care it gets after being taken from its winter quarters. A colony that has wintered well, and has a good queen and an ample supply of food, will usually be in good condition for the harvest when it comes.

The hive should be sufficiently large to contain a good supply of honey, and yet leave room for all the brood a good queen can produce. It should be easily enlarged or contracted as the occasion may require. The hive I use holds 8 Langstroth frames in the brood chamber, which is large enough for the greater part of the year. In the spring, when a colony is building up rapidly and needs more room, I enlarge the hive by adding a half-story super containing 8 frames, 5 inches in depth, being equal to 5 Langstroth frames, thus increasing the capacity of the brood-chamber to 13 frames.

When the harvest is at hand and the hive overflowing with bees, put on a super of sections. If the colony is in a 1½-story hive, remove the half story, making sure that the queen is in the lower brood-chamber, and put on a queen-excluder to keep her there. Put on the sections, and on top of them the half-story super that was on the hive in the first place. The entrance should be the full width of the hive, and about an inch wide during the harvest. After the bees are nicely started in the sections the super of shallow frames may be taken away and another super of sections put on in its place.

About this time the colony will be preparing to swarm. The swarming impulse is not the great misfortune that it is often represented to be. The choicest comb honey is usually produced by the colonies that have swarmed, either naturally or otherwise. But the swarming must be controlled, and I know of no better plan than the "shook" swarming. Shake the bees into a new hive containing 5 frames filled with wired foundation or starters, as you prefer (my preference is the wired foundation), and one frame of comb to catch the pollen. If that frame of comb contains a quantity of unsealed brood, no harm will be done. Put in enough dummies to fill out the hive. Set the new hive on the old stand with an empty hive-body below the brood chamber. This empty body will give the bees room to cluster in, and they are not likely to swarm out the next day, as they probably would do without it. It should be removed after the second or third day. In shaking the bees I prefer to shake all the bees and give the brood to some other colony to take care of. The sections should be taken from the old hive and placed on the new one.

Where shall we put the sections that we add to a hive that has one or more supers on? And how many supers should we have on a hive at one time? I have no fixed rule for putting on sections. It is largely a matter of judg-

ment, for what is all right in one case may be wrong in another. I usually put the second super on top of the first, leaving it there till I think it is safe to put it below without danger of the bees stopping work in the first one. The third super is put on top, with No. 1 next, and No. 2 below No. 1; and so on, crowding, if anything, the lower supers and keeping an empty one on top in reserve. It is there if needed, and if not needed it does no harm.

The sections and foundation we use are two important items in the production of comb honey. The plain or no-bee-way section with the fence separator is much superior to the old-style bee-way section and plain wood or tin separators. I have given both kinds a thorough trial and am decidedly in favor of the no-bee-way section.

The sections should be so placed in the super that there will be a fence separator between the outside rows of sections and the sides of the super, leaving a passage-way for the bees on each side, which results in the outside rows of sections being nearly, if not quite, as well filled as the middle ones, and in about the same time—sometimes sooner. I have taken off supers of sections where the only unfinished sections were in the center rows. Use full-sized sheets of extra-thin foundation in the sections. The thinnest foundation is the best and most economical to use. A section that is taller than it is wide is better than a square one. The tall sections sell more readily, and are preferred by dealers.

When removing the filled supers of honey from the hives, bee-escapes are very convenient, but it is not necessary to have an escape-board for each hive. A few puffs of smoke will drive most of the bees out of the super to be taken off, and then it should be quickly removed. Pile the supers up at the side of the apiary with an escape-board underneath, and in a few hours they will be free from bees. The honey should be stored in a warm, dry place, if possible. I use the cellar under my house for storing the honey, and keep it dry with a small stove burning natural gas, which is lighted more or less every day while the honey is there. If there is no unsealed pollen in the combs it will not be necessary to fumigate comb honey.

The Italian bees have not given as much satisfaction in comb-honey production as a cross between the Italian and the black bees, on account of the manner in which they seal the combs, that of the hybrids being much whiter.

At the close of the honey-flow enlarge the brood-chamber to its full capacity again. After having secured a crop of nice comb honey do not spoil it by slipshod methods of marketing. Put the honey in neat and clean cases holding a dozen sections each, having first thoroughly cleaned each section of propolis and carefully graded them. Time spent in this work is well and profitably spent.

U. H. BOWEN.

Niagara Falls, South, Ont.

"Can as good comb honey be produced above old comb as above new?"

Mr. Pettit—When there is a quick, sharp flow there is not much difference,

but when the flow is slower, or the sections are left on too long, the cappings are liable to be darkened by bits of dark colored wax being carried up from the old combs in the brood chamber. In this case of course the new combs are preferable.

"Why use dummies instead of the full number of frames, and why are fences better than plain separators?"

Mr. Pettit—The dummies fill the space at the outside of the brood nest, which would otherwise be filled with honey, and when it is desirable to have as many finished sections as possible, no room should be left for the storage of honey beside the brood.

"Are the sections over the dummies filled as well as over combs?"

Mr. Pettit—Quite as well. Fences are better than plain separators because they allow the bees more freedom of action in the super, and make them more contented. Three-sixteenth inch holes bored in the separators answer the purpose quite as well and do not give wash-board appearance.

"Why does not contraction of brood chamber induce swarming again?"

Mr. Pettit—It does when the flow is long, but by the time combs are built and brood reared, the swarming season is generally pretty well past.

"What strain of bees is considered best for comb honey production?"

Mr. Miller—Hybrids.

"Shall we winter bees inside or outdoors?"

Mr. Miller—Outside wintering in out-yards gives best results in spring. To keep the storm from driving in the entrance, tip the hive well forward.

"Have you had any experience wintering bees in a trench?"

Mr. Miller—None.

Mr. Whitesides—A number of years ago, I wintered 6 colonies that way quite well. The next winter I had them two deep in the trench, and the lower tier all died.

#### QUEENLESS COLONIES IN SPRING.

"Can colonies coming out of winter-quarters queenless be given a queen successfully?"

Mr. Miller—No. Not successfully.

Mr. Holterman—This *can* be done successfully by sending away for queens. It is *not* worth while to fuss with laying workers, but a good colony without a queen may be queened successfully.

Mr. Miller—Unite a strong colony with a weak one having a queen. We must consider all these questions from the standpoint of what expense will bring the greatest profit.

Mr. Holterman—You can introduce queens easily right after they come out of cellar.

In producing comb honey, use a queen-excluder over starters below the super if there are combs in the super instead of foundation.

Mr. Miller finds a gasoline engine very helpful in extracting. It saves more than a man's work. With that and a good uncapping machine he could almost "sit down."

Referring to the Alexander Method of building up weak colonies in spring, Morley Pettit said, "Put the weak col-

ony on a strong one with two queen-excluders between. Then in 2 or 3 weeks remove the strong colony to the vacant stand originally occupied by the weak one."

#### GOVERNMENT HELP FOR BEE-KEEPING.

The Hon. Nelson Monteith, in his address to the bee-keepers, stated that he came with the open mind that would enable him to learn from the discussions of the bee-men what can best be done in the way of legislation for this important industry. He believed that the value of honey as a food was not well enough known, and it might well be expected from the bee-men that they disseminate information along this line, and that there is also room for improvement in the article put on the market. This Province is growing rapidly in population, and an ever-growing market can be opened up if it is well looked after. With reference to the inspection of apiaries, the Department is anxious to do whatever is for the best interest of the bee-keepers, regardless of party influences. We recognize, said Mr. Monteith, that the season for inspection is so short that the work might be furthered by giving more attention to inspection, either by appointing more inspectors or by some other means we are not quite clear—districts for inspection, with an inspector resident in each. The Department would like the executive committee of the association to recommend the names of these inspectors, and would suggest that Mr. McEvoy be retained for inspector of his own division, and as referee in case of disputes in the others. Probably \$1,200 will be appropriated next year for the purpose of inspection. It was also suggested that the secretaryship of the association be located in the Department. This had been found to work well in the case of the other associations, and would, no doubt, be beneficial to the bee-keepers as well.

The president said he was glad to have Mr. Monteith at the convention and felt that the Department was making an effort to advance bee-keeping.

"We feel," he said, "that bee-keepers are utilizing a product that would otherwise be wasted, and that foul brood is a very serious menace. It means a \$2000 loss to one man alone in the last three years."

A letter was read from the Department proposing that the relationship between the association and the Department be strengthened. The Department would like the executive committee to suggest men for inspectors. They propose to divide the province into six districts for inspection, with one resident inspector in each. Mr. William McEvoy, as inspector in his own district and as a referee in case of disputes elsewhere. They would probably spend twelve hundred dollars on inspection next season.

It might also be wise, the letter continued, to have the secretaryship of the association located in the Department. This is done in reference to the other associations with profit.

The present secretary, Mr. Couse, expressed himself as being pleased with the new arrangement.

#### Letter from Deputy C. C. James

DEAR SIR:—Under instructions from the Minister, I beg to lay before you, for consideration by your Executive—and if thought advisable by your Executive, to lay before the members at your next convention—a proposition whereby we think the relationship of this Department with the Association may be materially improved, the usefulness of the Association extended, and the interests of the bee-keepers better served.

We have found that it has been to the mutual advantage of the Department and other associations to have the relationship strengthened and the work of inspection directed from the Department. You will recall that at the last session of the Legislature provision was made whereby more than one inspector might be appointed by the Minister, and the work of inspection directed from the Department. Owing to the lateness in the season when this bill became law, and also owing to the fact that your Association had already selected an inspector, it was felt advisable to continue your recommendation, and the work was begun somewhat late in the season.

We understand that the period of best inspection is somewhat short, and that, therefore, it might be advisable to divide the Province into six Districts, as follows:

1. Lennox and Addington, Frontenac and east.
2. Victoria, Peterboro, Northumberland, Durham, Prince Edward, Hastings.
3. York, Peel, Simcoe, Dufferin, Ontario.
4. Wellington, Waterloo, Perth, Huron, Bruce, Grey.
5. Norfolk, Brant, Oxford, Elgin, Kent, Essex, Lambton, Middlesex.
6. Wentworth, Lincoln, Welland, Hal-dimand.

We think that it would be practicable to secure a good man for each one of these districts. In making the selection, the Minister would naturally consult with the officers and Directors, as he would desire men who would be well informed and carry on the work with the approval of the society. We would suggest, however, that the services of Mr. McEvoy be retained, and that he be given section No. 6, providing he would be willing to continue. This section is in the vicinity of his own home, and he would be available for referring to him any points that might come up in connection with disputes in other districts. While we have in mind other bee-keepers for the other sections, it is not necessary to name them in this connection. It is the principles of the work and general lines of division that we submit to you for consideration.

This would necessitate a larger grant than we have at the present time. The Minister is inclined to think that next year a total appropriation of \$1,200 would be sufficient, as the inspectors would not have to travel so far from home, expenses would be lessened, and should be able to cover a much larger area than has been done under the old plan.

In the next place we have thought

# American Bee Journal

that, in order to carry out this work and keep in direct touch with the bee-keepers, it might be advisable to have the Secretary of the Association located in the Department. We are not anxious, in the Department, to monopolize any of the work or privileges of the Association, but if you think it would not interfere with the work of your Association in any way, but rather improve its working, to have the secretaryship here, we beg leave to say that that can be arranged. The Secretary of the Fruit-Growers' Association, Mr. P. W. Hodgetts, is an officer of this Department, and we understand that he would be willing to take the secretaryship of the Bee-Keepers' Association also. But that is a matter that we do not wish to force on you in any way, but submit for consideration. You may consider the question with the utmost freedom. Mr. Hodgetts is not seeking it, and we are not unduly urging it. We would hope to bring the work of the Association into closer relationship with other branches of work, more particularly the Farmers' Institutes, and it is just possible that some improvement might be made to the advantage of the Association and the Institutes. Please have this matter considered by your Executive. C. C. JAMES.

*Deputy Minister of Agriculture.*

Toronto, Ont., Oct. 31, 1906.

J. D. Evans—The bee-industry is not only for the honey and money, but the bees as fertilizers bring millions of dollars to the fruit-growers every year.

Mr. Sibbald approved the proposed plan.

Mr. Couse thought the Department could handle the secretaryship much better than any private individual.

Mr. McEvoy thought if he is to be referee in inspection, he should be allowed to choose the inspectors. He declared he would not act at all unless he could choose the other 5 inspectors.

Mr. Chrysler approved of the proposal.

Mr. Miller considered the propositions of untold worth to the Association.

W. J. Craig thought we should get together, and be unanimous.

Mr. Pettit—It might be wiser to leave the matter of appointing inspectors in the hands of the Department. We have had so much discussion and difference on appointing inspectors that it came as a relief that the matter of appointing was taken out of our hands.

Ed. Dickinson, Jr., agreed with this, that the Department might well retain the appointing.

Minister of Agriculture—The Department desires to be given a free hand, and we have endeavored to keep free from political appointments. It is from these organizations that we get the best advice. We hope you will settle your differences and agree on a line of policy.

Mr. McEvoy no doubt has the interests of bee-keepers at heart.

Mr. Couse was pleased to think of the secretaryship going into the Department, where the office machinery would greatly increase its efficiency.

Many expressed appreciation of Mr. McEvoy's superior knowledge of the cure of foul brood.

## WINTER REPOSITORIES.

Wm. Couse, Streetsville, made the keynote of his address on this subject "dryness." He argued from his experience from the "good old brimstone days" when every boy could smell brimstone in the fall for "three miles" and it spelled "honey" for him, to the present day of modern appliances. The first winter repository he remembered was a hollow pine log with a hole half way up for entrance and in this the bees invariably wintered because it kept them dry.

Dr. Thom and the Alpaughs were the first cellar winterers in his section (Centre Wellington). Their cellars sometimes had water on the floor but the atmosphere was dry and they wintered well. A little later Mr. Couse went to Beeton, where D. A. Jones wintered in sawdust houses. The loss here was always in the bottom rows where the bees were not kept dry as in the upper rows. Mr. Couse now winters about half in the cellar and half outside, and finds that they invariably winter better in the cellar and should not be taken out in spring till on towards the middle of April.

R. H. Smith said that old, black combs are warmer for wintering than new ones. He had bees winter well in a cellar where the floor was covered with water. The water seemed to purify the air. He thought the best temperature is 45 to 48 degrees above zero. The cellar is perhaps the best method of wintering bees in this country.

Mr. Holtermann—The only way to know the moisture of a cellar is to have a hygrometer to measure the moisture of the air.

O. L. Hershiser—It may or may not be true that water in a cellar constitutes a damp cellar. Mr. Couse has struck the keynote of successful wintering when he says it is dryness.

J. L. Byer—Wintering outside in an exposed manner is done at the expense of stores. A real strong colony with abundance of stores will winter in almost any shape outdoors.

Mr. Holtermann—It is more difficult to get bees into shape for outdoor wintering than for indoor wintering.

Mr. McEvoy—That might be.

A Member—I don't want winter brood-rearing before February. I can tell any time in winter when they are rearing brood. In that case they *must* stop the brood-rearing. Cool them off by taking off the cover, etc.

Mr. Miller said it is possible that a combination of conditions affects circumstances. He finds that it is not necessary to give upward ventilation.

Mr. Holtermann doubts the wisdom of sealed hive-covers in the cellar.

Mr. Brunne said the cellar should be on a slope. Dampness is necessary for wintering. Have the honey-board on top, but leave off the cover and bottom-board so the air can circulate through the whole hive.

(Continued next week.)

The "Old Reliable" as seen through New and Unreliable Glasses,  
By E. E. HASTY, Sta. B. Rural, Toledo, Ohio.

## ARE CLIMBING BEES A SIGN OF ROBBERING?

About the climbing of bees being a sign of robbing, Dr. Miller sticks to his t'other-way position like a good fellow. If the Question-Box wasn't dead beyond resurrection, I'd ask to have the thing submitted to the experts. If we could get an overwhelming majority against him maybe he'd down. And then, again, maybe he wouldn't. (And then, again, maybe I wouldn't get the majority.) About that time I might be saying, "Those experts are worse than a petit jury, anyhow." The question, mind you, is not whether it always means robbing, nor whether it usually means robbing, but, Is it robbing often enough that the apiarist ought to see about it promptly when it occurs? Page 985.

## POSITION OF FRAMES IN EXTRACTOR.

So the Canadians are figuring on putting combs into the extractor in

such a way as to capture the upward slant of the cells to help along the desired result. Evidently there is an item there that might be secured. But whether it is a valuable item, or an item so small that it is hardly worth bothering with, even my guessing prowess does not enable me to say. Decisive experiments not easy to hit on, either. And while you're at it, remember that gravity can also be made to help some by running the frames bottom upward. Page 983.

## BEES AND GRAPES.

John Kennedy thought hard of us all, and names me for one, because when he was deeply stirred up about something destroying his grapes, not one of us would say anything. He didn't realize what a dreadful worry-out and threshed-out subject "Bees and Grapes" has become. And I—well, I had an additional reason for "holding my whisk" in that my opin-

ions on the subject are a little heretical, and I am giving the brethren more heresy now than they are able to stand. Notwithstanding he "knows" it isn't the birds, I'll be just impolite enough to guess that it is. Let him look for very small and very sly birds, with needle-like bills, and a Satanic disposition to stab, stab, stab a multitude of grapes, taking only a minute drop from each. And if I am right, the only time in the day when they can be seen anywhere around the vines is just as day is dawning in the morning, when the grape owner isn't up yet. Mr. K. looked in the night with a lantern, and looked also through the day, but perhaps he didn't look closely enough just at the right time.

However, that's not the only theory open. His small bumble-bees may really be mason bees (so called from boring their nests in masonry where the mortar is not very hard), and mason bees are *likely enough* to have just as sharp mouth-parts as the carpenter bees have. I never observed mason bees when they were at the flowers, but the other fellows I have. The carpenter bee has a bill so sharp that he won't take pains to go inside flower-tubes, but just punches right through from the outside. Might, perhaps, serve grapes the same way. So I judge that the whole of these two "calabangs" of big bees (including several species) are possible enough culprits when grape mischief is being done. Page 980.

#### PUTTING A ROBBED COLONY OVER A STRONG ONE.

Sure! Robbers can't renew the same wickedness next day if you put the hive they are after over another and much stronger colony. Once in a while it may be desirable to do so, I guess. In general, putting a weak colony over a strong one doesn't seem to be winning popularity much; but this one item bids fair to be saved from the wreck. Page 983.

#### FAITH IN THE BEE-MAN.

A lesson to us all is that little girl on the face of No. 48. She is not one of the child bee-keepers, and she doesn't like to get stung. She simply believed what the bee-man told her, when he said the bees wouldn't hurt her. How good a thing is faith! (and how bad, sometimes, when the person at the far end is not worthy!)

#### THOSE NIGHT WATER-CARRYING BEES!

And J. Pawletta stirs us up again. He's the man whose bees carry water at night. Admits that at their daytime watering-place, 210 yards away, bees are not found at night. Sticks to his previous report. And still he finds it too tiresome ever to get around and say, squarely up and down, that he has ever seen a bee load up with water and start for home—sees 'em come and go at the hive-end of the performance. Page 968.

#### SPRING MOVING OF BEES.

And here is a very graceful and luminous sentence from Mrs. Null, on apiary moving: "Oh, but it's so natural to wait for spring, and join hands with Nature, and promenade all!" Page 965.

#### MR. BINGHAM'S STEP-LADDER HIVES.

Bingham thinks he's smart to show us, on the face of No. 47, hives tiered up till one needs a step-ladder to get the cover off. Mr. B., you never read the poem which says:

Not always people  
Clear up in the steeple.

No, I guess you never did.

## Pacific Coast Murmurings

#### CHICKENS IN THE APIARY.

The bee-periodicals from time to time have had something to say pro and con on the subject of chickens in the apiary. At our place the apiary and vegetable garden are on the opposite side of the fence from where the poultry is allowed to run, as none of the folks like the chickens to come near the house or roam through the garden. If poultry knew where to scratch without rooting up valuable seeds and plants, we would tolerate them in the garden; but how few chickens have "horse sense!" In a few minutes an old hen, which is a "lightning striker" with her "lower limbs," will do untold mischief to a bed of newly-planted seed or a bed of plants that we may have spent much time and considerable money in establishing. Too often do these old hens

This year I became, as it were, foster father to a pair of black chickens. How this came about I shall not here relate in detail, though suffice it to say that I took them under my "motherly" care when they were but a few hours old. I raised them in the way that a well-educated chicken should go. They are "cute" chickens now, though they are not yet fully grown. They were given privileges the other chickens were not allowed to enjoy. I early introduced them to the bugs and things that are to be found in an apiary. I would take them into the apiary, and by turning over a board or box would disclose a lot of worms or bugs. It was as good as a picnic to see how the little chicks would go for the insects. Sometimes I would find a moth, or the larva of a moth, inside a hive, and I would give the two-legged little pets a lesson in that sort of entomology. They did not seem to care for such study. "Gastronomy" was more to their liking, for they would devour the enemies of the bees quicker than one could say "Jack Robinson."

In time the little chicks made regular visits to the apiary in quest of insects. They soon got a brood of chickens that were just weaned to become regular bug-and-moth hunters among the bee-hives, too. In one part of the apiary were a few hives that I had not given any attention to, as my time among the bees for some years back has been far more limited than it was a decade and more of years ago. In this part of the apiary I found a few hives had become the prey of the abominable wax-moth. I closed the

A MOTH-RIDDEN HIVE BEING INSPECTED BY CHICKENS.

raise "old scratch," and a rank growth of nasty cuss-words, even, sometimes, in one religiously inclined. For this reason it may be believed that said old hens are in some way the instruments of the Evil One in the undoing of us humble mortals. But I am getting away from what I was going to say about chickens in the bee-yard.

hive until I secured my camera. Then I got things posed for a suitable view of the situation—"Chickens in the Apiary." What a world of endearment there is in the little picture I secured! One of my "black beauties" ran away, as a bee got tangled in the feathers about her ears. But a noble pullet, that learned to hunt about the

hives, took the truant's place and enjoyed a meal of "worms."

These "little birds" moved about so rapidly in their feasting on larvæ that I had a job to snap them in a position that just suited my "artistic" notions; in fact, I did not get them just as I wanted, after all. Anyway, it may be seen that the black bird is just picking a dainty tid-bit from off a Hoffman frame, and the larger chicken is about to strike out for a big fat larva on the top of one of said frames. Just before Black Bird No. 2 was skidoed by a bee, she flew up on the hive, and I was about to capture her "camerically" when she "lit out."

So much for these chickens. Does not the hive look wormy? It's a prize picture. But don't say anything about it!

#### ANTS—DO CHICKENS EAT THEM?

In my observations of the diet of chickens among the bee-hives, I noticed that ants and their larvæ were not on the former's bill of fare. I read somewhere that chickens were fond of ant-larvæ. Not so, my chickens. I suppose they were not the right kind of ants. I refer to the little black ant that is too often such an annoyance in the pantry

and about the hives. I have seen a hen with her little chicks thoroughly enjoy a feast of those ants that come out full-winged just after the first rainy day of the season. These are a sort of wood-ant, I believe, and are not "poluted" with the nasty taste and odor of the "house"-ant.

#### MOTHS VS. LANGSTROTH HIVES.

Referring again to the moth-infested hive, I want to record this fact, that of all hives I ever had anything to do with in a period extending over some 40 years, I never had a hive fall so easily a prey to the moths as the 8-frame Langstroth. Why is this? I don't know unless it is because the hive is too small, and for this location does not contain sufficient storage-room for food-supplies for the bees to subsist on. Then the division-board or follower is a bad thing, as behind it it can harbor the moth, and from there inroads are made upon the vitality of the colony. I think the time will come when the division-board feature of the hive will be abandoned. Then we shall have a different style frame, too. This is not intended as heretical; it's progress, I hope.

at opposite corners. I am going to do away with the division-board, and I was wondering if it would do any harm to drive the staples in a little further than usual, and make room for one or more frames where the division-board is. Would this narrow spacing—about  $\frac{1}{4}$  inch on the whole hive—make any difference? What would you do to make that  $1\frac{1}{4}$  inches big enough for a frame? or would you put one in at all?

ONTARIO.

ANSWER.—I hardly believe you will find any bad effect from squeezing together the frames so little. But I advise you to try it on a rather small scale for a year or two at first. There is considerable danger that you will count it too troublesome to get out the first frame if your frames are automatically spaced, and no more play than you propose. Even if you could do it well enough at first, propolis will accumulate, and you may find your frames wedged in so tightly as to make it a matter of too much difficulty to get out the first frame. It would take a good deal to get me to give up the convenience of having a dummy in each hive; for I take it for granted that you mean a dummy when you speak of a division-board. If they are really division-boards, that is, tight-fitting, then I'd cut them down to dummies, having a space of  $\frac{1}{2}$  inch or so at each end and underneath.

#### Feeding Bees in the Spring

1. As I fear that my bees will be a little light of stores in spring, would you advise feeding maple water reduced about half, so as to make it thicker? or do you think it would injure the bees?

2. As my bees will probably be light in spring, would you advise feeding in a wholesale way, or feed only a little at a time?

3. How soon would you advise feeding in spring? Do you think it is too soon to feed when the first pollen comes in?

MISSOURI.

ANSWERS.—1. Better not give such feed till bees are flying nearly every day.

2. About as well go it wholesale; bees feel encouraged to have a good lot of stores in sight. About the best way is to give them early in fall enough to last till the flowers will keep them busy the next year.

3. Feed in spring just as soon as you think there is any danger of starving. If they have enough to last through till flowers they'll not need feeding in most places. The places they will need it, even when there are stores in the hive, are those places where there is fine weather for them to fly every day, yet no flowers for them to work on. If such conditions last long enough, the queen will cease laying, and so you should feed every day, or every alternate day, to keep her laying.

#### Old Hives With Moth-Cocoons on Frames

I have bought a lot of old bee-hives that have been empty for 3 or 4 years. There are lots of moth-cocoons on the frames. Will these hives be suitable to put bees into the coming season, if thoroughly cleaned?

VERMONT.

ANSWER.—Yes, they will be all right so far as any danger from moths is concerned, for there is no life in the cocoons; although the frames may be somewhat gnawed by the larvæ of the moths.

**Our Wood Binder** (or Holder) is made to take all the copies of the American Bee Journal for a year. It is sent by mail for 20 cents. Full directions accompany. The Bee Journals can be inserted as soon as they are received, and thus preserved for future reference. Or we will send it with the American Bee Journal a year—both for \$1.10. Address the office of the American Bee Journal.

Send Questions either to the office of the American Bee Journal, or to  
Dr. C. C. MILLER, Marengo, Ill.

Dr. Miller does not answer Questions by mail.

#### Wiring or Splinting Foundation

Which is better to fasten brood-foundation, wire or splints?  
WISCONSIN.

ANSWER.—Just so far as the mere matter of fastening is concerned, the wire is better. Splints do not directly hold the foundation in the frame, although they stiffen it so there is little danger of its falling out. But splints have the great advantage that you can have the foundation built down to the bottom-bar with no danger of sagging or buckling—a difficult thing to accomplish with wiring.

#### Extreme Sensitiveness to Bee-Stings

A year ago last summer, whenever my wife went out to help with the bees, she would have an attack of sneezing and coughing; her eyes would run water, and she would breathe with difficulty. It acted a good deal like a severe case of hay-fever or asthma.

Last summer she came out one day to help me move a hive, when a bee stung her on the arm, through jacket and shirtwaist, so it was not a very severe sting. I told her to go to the house at once and put some turpentine on the spot stung. I came right along in, not a minute later, and found her nearly speechless, lips and tongue swollen, a fever all over as if she were burning up, and broken out in large water-blisters all over her body. She was nearly dying in a few minutes. After a while she became easier, but was sick about the rest of the day, and was not well again

for a couple of days after. So she did not dare to go out any more last season.

Now, is there any preventive, remedy, or cure? Do you think it will ever occur again? Will it be advisable for her to try it any more, that is, to go out into the bee-yard?

WISCONSIN.

ANSWER.—This is one of those very few cases of extreme sensitiveness styled "idiosyncrasies." It is quite possible that the results of the next sting would not be so severe; but the likelihood is that they would still be somewhat serious. Quite likely perseverance would in time secure to a great extent immunity; but whether it be worth while to pay the price for that immunity is a question. On general principles, the right thing for a person so peculiarly constituted is to keep away from the bees entirely; and only in case it should be of the highest importance to be able to assist at bee-work should an exception be made.

This, however, is only personal opinion; and in case any one can help out, such help will be gratefully received.

#### Staple-Spacing Frames

I am using hives which contain 10 Hoffman frames and a division-board, or, in other words, my hives are  $14\frac{1}{4}$  inches wide. Each frame takes up  $1\frac{3}{4}$  inches, so there is  $1\frac{1}{4}$ -inch space for the division-board. Now, I do not like the Hoffman frame so well as I thought I would, and am going to change to staple-spacing—one staple on each side of top-bar

## Reports and Experiences

### Poor Year for Bees

This year was a poor one for bees, for from 80 colonies, spring count, I got only 1500 pounds of honey. I think it was too wet. I put 100 colonies into the cellar Nov. 20, but I think a lot of them will starve before spring.

Cnas. J. MILLER.

Long Prairie, Minn., Dec. 10.

### Bees in the Rocks

In prospecting for gold on the Colorado River, in Nevada and Arizona, I carry water in cans, and sometimes 4 miles from the river bees cover the stopper so that I can not drink. They live in the rocks.

Searchlight, Nev. F. F. ROBINSON.

### Bees Carrying Pollen in November

Perhaps it would be of interest to you to know that bees were out at 7:30 this a.m., Nov. 19, 1906, and some of them carrying pollen. Temperature 62 degrees above zero.

North Scituate, Mass. W. A. CARTER.

### Bees Quiet in the Cellar

My bees are unusually quiet in the cellar. I have never had so few dead bees on the floor after so long a time—more than a month. There are very few on the floor.

We have 2 inches of snow and ice. It is fine wheeling and fair sleighing—not very cold, but not thawing.

Farwell, Mich., Dec. 18. T. F. BINGHAM.

### His Best Season in 1906

The season of 1906 was the best I ever knew. My bees commenced work in earnest about June 15, and continued to bring in honey until about Sept. 15. This is not a good locality for honey, there being no clover of any kind and but very little basswood, the principal sources being sumac, peas, and cotton.

I started in last spring with 44 colonies and increased to 54. I secured on an average 60 well-filled sections per colony, spring count. My best colony yielded 116 well-filled sections. My colonies in Danzenbaker hives yielded about 33% percent more honey than those in the 8-frame dovetailed hives. I have never been able heretofore to get more than 30 well-filled sections to the colony. I hope this locality will continue to improve as it did this season.

Success to the American Bee Journal.  
Danville, Ark., Nov. 19. J. H. McCARGO.

### Plain vs. Bee-Way Sections—Fastening Starters

I improve every opportunity to induce beekeepers to read the American Bee Journal, and learn how to make the bees keep them. While the past season was quite discouraging at times, on the whole it was quite satisfactory. My crop was 4000 pounds of extracted and 5065 pounds of section honey, or 5313 sections. One shipment of comb honey of 4502 sections weighed 4416 pounds net; near enough a pound to a section for all practical purposes. I have 18 unfinished sections left for bait. How is that for a finish-up?

There has been considerable discussion as to what size should constitute a 1-pound section, and I will say for the benefit of those concerned that these were about two-thirds 4 1/4 square plain, and one-third 4 1/4 square bee-way sections. In a dray-load, as they were hauled to the car for loading, a record was

kept of the kind of sections and their net weights, and here is the result: plain, 1124 sections, net weight 1032 pounds; bee-way, 792 sections, net weight 763 pounds. While the bee-way sections weighed slightly heavier, the difference is so slight it is not worth reckoning. In fact, almost if not quite sufficient extra wood is in the bee-way sections to make the difference. From the consumer's standpoint, it is about a "stand-off," and the producers are slightly ahead on the plain sections. First, 25 cents per thousand on first cost; second, less freight on sections. Then the casing costs less, and less freight on same, and hence less cartage if shipped by local freight.

Then scraping is quite an item, although this is offset somewhat in handling the sections into and taking out of the supers, at least it is with me.

As to the bees accepting them, I see no difference. They enter one as quickly as the other, and fill them out plump, one as well as the other.

I use the 10-frame hive with 9 frames and dummy, and like them better than the 8-frame, of which I have some 30 or 40 that I use when needed.

I use bottom-starters in every section, and have done so for 4 or 5 years. The last 3 years I have fastened the bottom-starters in sections as described at the St. Louis National convention, and later in Gleanings. The more I use the fastener the better I like it, and don't see how it can be improved upon, either for speed or quality of work. The machine or fastener described in Gleanings by Dr. M. A. Aulick, of Kentucky, is worked on a similar plan, but if he can place bottom and top starters in sections at the rate of 20 to 25 per minute, he can "move some." Try your speed on a hundred or more and report, will you, Dr. Aulick? Also, Dr. Miller his speed. And don't you forget to report, too, Doctor.

Hull, Iowa, Nov. 5. F. W. HALL.

### Bees in Good Condition for Winter

It has been raining a great deal here lately. We have also had a little ice, which is an uncommon thing in this part of the country. We are looking for a good honey season next year, of course, as we have had two failures in succession. Our bees are in much better condition for winter than we expected. I have just examined and found that they have plenty of honey.

DIXON C. GULLEY.  
San Antonio, Tex., Nov. 29.

### A Good Rainfall

This entire State has received a good rainfall up to the present time—over 2 1/4 inches having fallen hereabout, and a much heavier downpour in the North. I trust California beekeepers will be much benefited.

Los Angeles, Calif., Dec. 12. T. F. GRAY.

### MAKE GOOD MONEY

In Poultry business. Others do it. Why not you? Our big illustrated book, "Profitable Poultry," tells how to breed, hatch, feed, grow and market to make lots of money. Starts you on the road to success. Describes most wonderful Poultry Farm in the world—32 kinds of fowls. Gives lowest prices on fowls, eggs, Incubators, everything for Poultry. Mailed for 4 cents in postage. Berry's Poultry Farm, Box 72, Clarinda, Iowa.

Mention Bee Journal when writing.

## WANTED TO BUY AT TOP PRICES

WHITE CLOVER HONEY, both Comb and Extracted.

If you have any WRITE AT ONCE, saying how much you have, how it is put up, and your lowest price, and all about it, in first letter.

C. M. Scott & Co., Bee-Keepers' Supplies, Incubators, Brooders, Etc.

Catalog Free

### CONVENTION NOTICES.

**New Jersey.**—The New Jersey Bee-Keepers' Association will meet at the State House, Trenton, on Wednesday, Jan. 16, 1907, at 10:30 a.m. Addresses will be made by the President, also by Chas. Stewart, foul brood inspector, Summonsville, N. Y.; H. S. Ferry, J. H. M. Cook, and others. Much attention will be given to the Question-Box. All beekeepers, and especially ladies, are cordially invited to attend.  
W. W. CASE, Pres.  
G. N. WAUSE, Sec.

**Nebraska.**—The annual meeting of the Nebraska State Bee-Keepers' Association will be held in the Experiment Building at the State Farm, Lincoln, Nebr., Jan. 16, 1907. An interesting program on practical subjects has been prepared, and beekeepers will be benefited by attending.

LILLIAN E. TRESTER, Sec.

Lincoln, Nebr.

**Washington.**—The Washington State Bee-Keepers' Association will hold its 2d annual convention at the State Agricultural College, Pullman, Wash., Jan. 7, 8, 9, 1907. A good attendance is expected, and present indications point to an interesting and successful meeting. A number of prominent beekeepers will read papers which will be followed by discussions. For further information address the Secretary.

VIRGIL SIRES, Sec.

North Yakima, Wash.

**MAKE YOUR OWN CUT GREEN BONE**

It's a very easy, simple operation with a CROWN Bone Cutter. Green bone makes eggs, and stimulates the hen's productive organs. Cut bone fresh every day. The Crown does it quickly with no bother or mess. 25 years building cutters. Write for free catalog.

WILSON BROS., Box 618, EASTON, PA.

Mention Bee Journal when writing.

## THE TRAPPERS WORLD

Published Monthly by THE D. E. ALLYN PUBLISHING COMPANY

STAFF OF CONTRIBUTORS  
Our Subscribers, The Trappers, Hunters, Fur Collectors, Anglers, Guides, and Men of the Woods.

\$1.00 A YEAR. 10 CENTS A COPY.

Tells all about Trapping, Fur and Game Sections, Big Game Sections, Best Fur Buyers—everything in the interest of its readers. Subscribe now. One sample free.

## The Rietsche Press

Made of artificial stone. Practically indestructible, and giving entirely satisfactory results. Comb foundation made easily and quickly at less than half the cost of buying from the dealers. Price of Press for L. frame sheets, \$2.00. Other sizes, 25 cents extra. Price of the Press making the foundation directly on the wired frames, \$2.50, any size wanted.

ADRIAN GETAZ,

45Atf KNOXVILLE, TENN.

## PRACTICAL POULTRY BOOKS

### For Sale or Free as Premiums

(postpaid) for sending New Subscribers to the Weekly American Bee Journal; or we will club them with the Bee Journal, as follows:

For each NEW yearly subscriber to the American Bee Journal (at \$1.00) that is sent us by an already paid-in-advance subscriber, we will allow 25c to apply on any poultry book in the list; or, for \$1.10, we will mail to any one the Bee Journal a year and the last book mentioned in the list; for \$1 35 the Bee Journal and any one of the 50c books; or, for \$1.80 we will send the first book and the Bee Journal a year. Send all orders to the address as given below.

**SUCCESSFUL POULTRY KEEPING** Contains, we believe, more and better practical, reliable information on the subject of "Poultry for Profit" than any other book published. Gives the cream of established facts. Compiled by the editor of the RELIABLE POULTRY JOURNAL, who has given many years of careful study to the poultry business. 160 pages, nine by twelve inches, illustrated. Price \$1.00

**POULTRY HOUSES AND FIXTURES** Shows plans of all styles of low-cost, practical and labor-saving houses, designs for inside fixtures, such as nest boxes, drop boards, etc., also roosting coops and coops for young chicks, and all necessary appliances for the poultry yard. It is the most valuable and up-to-date book of the kind that has been placed before the poultry public. Used as a text book at Cornell University. 96 pages, nine by twelve, ill. Price 50c.

**ARTIFICIAL INCUBATING AND BROODING** Solves all problems of artificial incubating and brooding. Tells how to obtain strong-germed, fertile eggs, how to operate incubators and brooders, grow the greatest percentage of chickens, etc. Results gained from practical experience. 96 pages, nine by twelve inches, illustrated. Price 50c.

**THE CHICK BOOK** Tells how to obtain good hatches under different conditions, with hens and with incubators; how to feed and care for chicks of all ages, with hens and in brooders; how to feed for breeders and for broilers and roasters; how to build coops; gives complete instruction in all work connected with successful chicken growing. 80 pages, nine by twelve inches, illustrated. Price 50c.

**THE PLYMOUTH ROCKS** Barred, Buff and White. Make money and save years of useless breeding by adopting the rules of mating followed by the most successful Plymouth Rock breeders, with a chapter and chart on line breeding. Specialists describe clearly and concisely their methods of mating and breeding. Contains color plate of each variety. 110 pages, nine by twelve inches, illustrated. Price 50c.

**EGGS AND EGG FARMS** Is made up of articles from experienced and successful breeders, giving methods of housing, breeding, rearing and feeding to increase egg production. The lengthy chapters on pedigree breeding will be found invaluable to breeders of exhibition or utility fowls. 96 pages, nine by twelve inches, illustrated. Price 50c.

**THE LEGHORNS** The best illustrated standard of all varieties of the popular Leghorns. Mating schemes clearly described. You cannot afford to be without this valuable information. Color plate of S. C. White Leghorns. 78 pages, nine by twelve inches, illustrated. Price 50c.

**ASIATICS** A work on Brahmas, Cochins and Langshans. Contains "inside" information necessary to success, and impossible to secure elsewhere. Contains standard and ideal charts for all varieties. Color plates of Buff and Partridge Cochins. 100 pages, nine by twelve, ill. Price 50c.

**DUCKS AND GESE** Gives all details of hatching, rearing, fattening and marketing. Contains the actual labor-saving methods followed on the great duck ranges, and by farmers who make duck and geese growing profitable branches. 68 pages, nine by twelve, ill. Price 50c.

**TURKEYS** Every detail of the turkey business explained fully and clearly. It solves comprehensively the different branches of the market and standard-bred turkey industries. Written by the world's foremost turkey growers. Contains color plate of ideal Bronze turkeys. 84 pages, nine by twelve inches, illustrated. Price 50c.

**THE BANTAM FOWL** Mr. T. F. McGrew, judge and breeder, tells how to house, feed and grow Bantams, how to treat their diseases, how to select and fit the best for the shows. The most complete illustrated Bantam book published, 72 pages, nine by twelve inches. Price 50c.

**RELIABLE POULTRY REMEDIES** Points out the causes, describes symptoms and gives simple and tested remedies for all diseases. 84 pages, six by nine inches. Price 25c

## Engravings For Sale

We are accumulating quite a stock of engravings that have been used in the American Bee Journal. No doubt many of them could be used again by bee-keepers in their local newspapers, on their stationery, or in other ways. Also, if we can sell some of them it would help us to pay for others that we are constantly having made and using in our columns. If there is any of our engravings that any one would like to have, just let us know and we will quote a very low price, postpaid. Address,

**GEORGE W. YORK & CO.**

334 Dearborn Street,

CHICAGO, ILL.

"It is continuous advertising that impresses the public with the stability of a firm."

## Trade Notes. The A. I. Root Co., Medina, Ohio.

**Premium List.**—For the first time in many years we have been publishing a list of premiums offered for subscriptions to *Gleanings in Bee Culture* either six months trial, or new or renewal yearly subscriptions. We shall be pleased to send a copy of this premium list to any one who may have a little time to devote to securing subscriptions for us. With this are also listed our Clubbing offers which contain some very remarkable bargains. If you think of subscribing for *Gleanings*, and especially if there are others near you whom you can interest, you should have a copy of this premium list at once. We send it promptly on request.

**Book Circular.**—This is the season of the year when bee-keepers have time to read up on the subject of bee-keeping more than at any other time. If you haven't a copy of our book circular giving description of nearly every book published on *Bee Culture*, send for a copy of this at once.

**Old Books on Bee-Culture.**—There is a growing demand for old literature on *Bee Culture*, so much so that we have given considerable time during the past two or three years to looking into the matter. If you are interested in a single old volume or a large list of old books on *Bee Culture*, send us a statement to that effect so that we may enter your name on a list of those interested in these.

**Advertising Rates.**—We have some highly complimentary letters from subscribers who have used the advertising columns of *Gleanings in Bee Culture* during the past year. If you are interested in the sale of bees, queens, honey, or bee-keepers' supplies, and expect to advertise the same, you can not afford to fail to investigate our prices. If you can do so let us know about what amount you would be willing to expend in advertising, and your facilities for supplying the goods you advertise, and we will lay before you a definite proposition covering the proposed expenditure and a statement of what we think you might reasonably expect from it. If we do not think *Gleanings* is adapted to what you have to offer we will tell you so.

If you have a farm for sale, or want to locate in some other part of the country, or want help for your beeyard, or want to secure a position, *Gleanings* will undoubtedly be of value to you as it has been to hundreds of others.

**Dealers in Supplies.**—We are just now revising the list of names of dealers in bee-keepers' supplies, which we maintain whether they handle our goods or others. If you are handling bee-keepers' supplies either in a limited way or on a large scale, please send us

a postal card to that effect that we may have your name entered on this list with the correct present post-office address. Even if you buy none of our goods direct there may be some items in which you will be interested, and at least there will be no harm in having your name registered with us as a dealer in supplies.

**Observation Hives.**—There has been an increasing demand for observation hives for a number of purposes during the past few years. Bee-keepers have found in many places that an observation hive with bees placed in a store window is a good way to advertise their honey. Particulars regarding these have been published in various bee-journals from time to time. We shall be glad to quote you prices on any of our regular styles, or any special style, that you may want for this or any other purpose. Bee-keepers are learning that a better understanding of bees on the part of the public generally increases the interest in honey, and there is no better way to educate people regarding bees than by the use of a good observation hive.

**Early Order Discounts.**—For cash orders in January 3 percent. For cash orders in February, 2 percent. These are the discounts we offer for early cash orders. The discount is only for cash sent before the expiration of the month named, and is intended to apply to hives, sections, frames, foundation, extractors, smokers, shipping-cases, cartons, and other miscellaneous bee-keepers' supplies. It will not apply on the following articles exclusively; but where these form no more than about one-tenth of the whole order the early-order discount may be taken from the entire bill: Tinned wire, paint, Bingham smokers, Porter bee-escapes, glass and tin honey-packages, scales, bees and queens, bee books and papers, labels and other printed matter, bushel-boxes, seeds, and other specialties not listed in our general catalog.

**Weed Comb Foundation.**—The large sales of Weed Process Comb Foundation are a sufficient indication of its worth. There are, however, many bee-keepers that are not familiar with it, especially those in out-of-the-way places, who depend upon Foundation of their own or local make. If you have never used our Foundation and would like to see small samples of the four grades—medium brood, light brood, thin super, and extra-thin super—we shall be glad to send you samples on request, and at the same time will advise you, if desired, from what point nearest you you can secure our make of Foundation. We shall be glad to figure how many pounds you will need for a given number of frames or sections, and let you know the lowest cost

for our Foundation. The excellence and uniformity of its manufacture often make it require a great deal less than some inferior makes.

**Hoffman Frames.**—Considerable has been published in the various bee-journals during the past year on the use of the Hoffman or some other style of self-spacing frame as compared with the non-spacing frame. We have a leaflet giving the opinion of some of the leading users of these frames, and if you are in doubt as to the advisability of using these frames, we shall be glad to send you this leaflet on request. We will also send you a complete sample postpaid for 10 cents.

**Marbach Metal-Spaced Frames.**—For a full description of these frames we refer you to *Gleanings in Bee Culture* for January 1, 1906. These frames have been in use for about a year, and are very favorably regarded by those who prefer some metal instead of wood spacing for their frames. A sample of these frames will be sent for 10 cents, or a sample of the spacers only for 3 cents; or we will send a complete Hoffman frame and a set of spacers for 12 cents.

**Honey.**—We have at several of our offices large quantities of honey. If you are in need of either comb or extracted honey for your trade in excess of your own production, write us for prices, stating what you require.

**Breeding Queens.**—This is the season when orders should be sent us for breeding queens, if you have not already secured the same for the coming season's trade. As usual we have our Italian stock, Leather Colored or Three-Banded in breeding queens at \$5, \$7.50 and \$10 each. We can also select from our Medina yard a few queens at \$25 each. The number is limited, and we can not guarantee to furnish these beyond the certain number that we have now on hand in winter quarters.

**Bees of Other Races.**—While we do not breed other races here at Medina, we have most excellent facilities for furnishing high-grade stock of the following varieties: Carniolan, Caucasian, Banat, Cyprian and 5-banded Italian.

**Special.**—Send 10 cents (stamps or silver) for our 1907 Calendar, entitled, "Little Miss Mischief." Copyrighted in December, 1906, by T. Fred R6bbins. With it we will send your choice of the following books: "Habits of the Honey-Bee," "Bee-Keeping for Women," "Modern Queen-Rearing," or "How to Produce Extracted Honey."

(Entered at the Post-Office at Chicago as Second-Class Mail-Matter.)

Published Weekly at \$1.00 a Year, by George W. York & Co., 334 Dearborn Street.

GEORGE W. YORK, Editor

CHICAGO, ILL., JANUARY 10, 1907

Vol. XLVII—No. 2

## Editorial Notes and Comments

### Grand Future for Honey

Last week we had something to say about the effect of the National Pure Food Law on the demand for unadulterated food products. A few days after we wrote the matter referred to, we received a letter from one of the leading bee-keepers and apiarian writers of this country, who, in referring to the glucose manufacturers, said:

"I do not now see but what they will have to quit making glucose, if it is a fact that such mixtures, when properly labeled, will not sell. I tell you, Mr. York, I believe there is a grand future before the honey-business, and already we are beginning to see the effect of the new Pure Food Law. California honey has been adulterated very largely when it got to the East, you know. That can not be done any more now, and what is the result? Prices are going up very rapidly on that grade of honey. A report from California says that sage honey has now reached a level in price that it has not had for years. Advanced prices in honey are going to mean better days for all apiarian interests. Possibly I am over-enthusiastic, but there are so many things that go to show which way the wind is blowing, that I can not help but feel that I am right. Besides, I have been talking with experts on the subject, who express themselves even more hopeful than I do."

Not having written the above for publication, we omit the author's name, but we agree fully with him. As we said last week, we believe a new and brighter day is soon to dawn for the producer of pure honey for the market. Producers in other lines, also, feel that prices of pure food products will rule higher for some time to come. This certainly ought to result in greatly increased profits to those who produce such goods.

### Making A Bee-Paper Helpful to All

In the conduct of the American Bee Journal, the sincere desire is ever kept uppermost

to fill its columns with matter that shall be of most use to its subscribers. It is too much to hope that everything published shall always be exactly the thing best suited to every one of its readers, the needs of each one in so large a family greatly varying. Yet the hope is entertained that each and all shall find, if not in each number, yet in most numbers, enough real information throughout the year greatly to overbalance the small amount paid for each number—less than 2 cents. Indeed, many letters have been received saying that in a single number value had been received overbalancing the cost of the entire year. Occasionally a letter is received finding fault. Letters of both kinds are welcomed. The first kind serves as a stimulus, cheering on to more strenuous effort. The second kind, provided it be specific enough, points to a possible weak spot which may require strengthening.

So the two letters following, by the same writer in Ohio, are thankfully received. The second is in reply to a note sent from this office, the contents of which may be sufficiently understood from the reply:

### EDITOR AMERICAN BEE JOURNAL—

*Dear Sir:*—In the Journal of Dec. 6, is an article by C. W. Dayton, entitled, "Increase, or Prevention of Increase." When I saw the title it struck me as being to the point for beginners, but after reading it three times I could make nothing out of it. One thing I take your paper for is for what a beginner can learn, but thus far all articles have been only such as experts might comprehend, and solely for their amusement, none of them explaining how they perform the practical parts on which they write.

Take for instance the article on T-tin or T-super. As a fact, I never saw one, nor can I gain any idea what it is like by reading Armstrong's article. I must confess I fail to see how one is to get his dollar's worth out of it if all subjects are handled in like manner. I notice the same fault in all similar publica-

tions to yours. Such being the case, one better invest his dollar in good, reliable textbooks. I may continue to take the Journal, but with little satisfaction. It is my desire to learn, and I am willing to do so from any source. It is my desire to employ the most modern methods in bee-culture, and I am willing to pay my money for benefits. Now, Mr. York, reply to this as you see proper. I shall be glad to hear from you.

Yours truly, M. F. SOULE.

The second letter received from Mr. Soule is as follows:

### EDITOR AMERICAN BEE JOURNAL—

*Dear Sir:*—Yours of the 13th is duly to hand and noted. In replying I am going to insist that any article published in the Bee Journal should have its respective title, telling what the discussion is about, then beginners could also learn from such debates. Every subscriber has an interest in every subject within the Journal's covers. It will be just for me to admit you can't deal with beginners entirely. It is within my reach to refer you to other articles in the Journal, that are intelligible even to beginners; but the one referred to in my prior letter is but a jumble of words.

Allow me to inform you that I have "Langstroth" revised by Dadant, and "Bees and Honey," by Newman—the last you sent me quite lately. The first I have had over a year, and have used it much. It is not my purpose to be a kicker, nor a know-it-all. On the contrary, I am on the "mourners' bench" seeking light.

I wonder if Dr. Miller would explain the T-tin or T-super, or will I have to write him asking him to do so through the columns of the Bee Journal. Yours very truly,

M. F. SOULE.

While repeating the desire to profit by reference to faults or failings, it is only fair to the many who have helped by their contributions to make the American Bee Journal what it is, to take exception to the sweeping statement that "thus far all articles have been only such as experts might comprehend, and solely for their amusement." For a refutation of the first part, one need go no further than the second letter, in which is said: "It is within my reach to refer you to other articles that are intelligible even to beginners." As to the second charge, it may be that occasionally an article is written chiefly to exploit the writer, but unless it is believed that it contains matter of value to at least part of the readers of this periodical, the editorial prerogative is exercised, and the article is not published. There is a lot of the milk of human kindness in mankind in general, and

# American Bee Journal

bee-keepers have their full share of it; so when any one of them learns something that has been of value to him, immediately there arises in his mind the desire to share that knowledge with others.

Even supposing that most of the matter contained in these columns were of such nature as to be of interest only to those who have graduated from the ranks of beginners, would there be anything unjust in that? A little thought will suggest that beginners form only a small part of the clientele of any well-conducted bee-paper. The most part of bee-keepers who subscribe continue to be subscribers when they are no longer beginners, making the beginners always greatly in the minority. With this in view, perhaps our correspondent will admit not only that we "can't deal with beginners entirely," but that the larger body of advanced bee-keepers should be kept distinctly in view. Fortunately, things that are new to experienced bee-keepers are not always, perhaps not often, difficult of understanding for beginners.

The hint, however, should not be lost, and it will be well for all who write for bee-papers to keep in mind that if they write so clearly as to be understood by beginners, the extra clearness is not likely to be unwelcome to the more advanced.

It were "a consummation devoutly to be wished" that the title of every article should tell what the discussion is about, and no little effort is made to that end when the making of the title is left to the editor, as it generally is. That the effort is not entirely in vain is the opinion of at least one of the older readers, who lately wrote, "You have undoubted genius for getting up the right kind of headings." That "beginners could also learn" from articles with right headings is certainly true, but that their learning would depend to any great extent upon the headings, does not appear so very clear. Yet effort shall not cease to make headings in the future better than in the past, and any suggestions as to just how they can be improved will be thankfully received.

Whatever the lack as to information fitting each subscriber, there always remains the Question-Box open to him. Any question not already satisfactorily answered in the bee-book is ever welcomed. What more could be asked? The implied question of our correspondent as to whether Dr. Miller will answer a question that he has not been asked, nearly answers itself. In his department he is not writing essays, nor delivering lectures, but answering questions. How can he answer a question until it is asked? And would it not be a little hard on him besides furnishing answers to be obliged to guess at the questions as well?

It is our sincere desire that the American Bee Journal shall as nearly as possible meet the needs of our correspondent, and if he has not done so in the past, while thanking him for his interest in its columns, we earnestly advise him to make a full trial of the Question-Box; and if the information desired is not given in clear manner, he is at liberty to ask questions until he does get what he wants; always provided that the question be not of such character that Dr. Miller will be obliged to answer, "I don't know."

## Reading Now for Next Season

The long winter evenings are here again. What a grand time it is to read the bee-papers, and get ready to introduce improved methods in the conduct of the apiary next season.

There are perhaps many copies of the bee-papers that failed to receive more than hurried glances during the busy season last year. Why not get them together and go over them carefully now? Some bee-keepers think it doesn't pay to take a bee-paper. Of course it doesn't if it is not read thoroughly.

It is true that with many bee-keepers 1906 was the poorest honey season in many years. But it will not do to become discouraged. The good seasons will come again in the future just as they have in the past. The thing to do is to be ready in every way possible to take the fullest advantage of the big honey-flows when they come.

Competition in every line is too strenuous these days to win much success unless one

avails himself of all the possible short cuts in labor and management. And these are learned through reading what and how others are doing. Life is all too short to go by ox-team, or even horse and wagon to-day. We can not use the methods of our grandfathers if we would hope to get ahead these pushing, electric days in which we are living. We must not only read about the ways in which others have succeeded, but each must be quick to adopt, and also adapt, methods and plans in his own apiary that promise results.

Of course, all will want to do some experimenting, but there is no need of wasting time in going over things that others have proven to be failures, reports of which can be learned by reading the bee-papers and bee-books.

It may look as if we were saying all this in order to sell you something. It is not exactly that, but we want all our subscribers to get the most out of their bee-literature, which is really valuable if only rightly used.

**R. L. Taylor**, of Lapeer, Mich., has been re-elected chairman of the Board of Directors of the National Bee-Keepers' Association for 1907.

**A Cradle Song** has been received from Hon. Eugene Secor, of Forest City, Iowa, who wrote the beautiful words, and Robt. Chapman the music. It is a solo, and a very pretty one, suitable for either soprano or alto voice.

**Mr. M. M. Baldrige**, of St. Charles, Ill., one of the oldest bee-keepers in the United States, called on us recently. He is perhaps the best informed as regards the history of American bee-keeping of any bee-keeper living to-day. He knew those personally who helped at the beginning of things apicultural in this country.

**Connecticut Bee-Keepers** will introduce a Foul Brood Bill into the State Legislature before Feb. 1, 1907. J. Arthur Smith, Drawer 1325, Hartford, Conn., Secretary of the Connecticut Bee-Keepers' Association, would be pleased to receive names of bee-keepers throughout the State—not only readers of the bee-papers, but others as well. It will require the united efforts of the bee-keepers to secure the proposed law, which is needed to check and stamp out the disease of foul brood.

**"Canadian Beedom"** and **J. L. Byer** have formed a combination, as will be seen by referring to page 32. He takes the place recently vacated by Morley Pettit. Mr. Byer

is one of the leading honey-producers and apicultural writers beyond our northern border. He is a specialist bee-keeper—depends entirely upon honey-production for a living for himself and family. And he doesn't believe in "race suicide" either, for, by referring to the first page it will be seen he has almost a Rooseveltian family.

We believe Mr. Byer will prove a worthy successor to Mr. Pettit, as the conductor of "Canadian Beedom." We bespeak for him at least a cordial reception, and also a warm place at the thousands of cozy firesides where the American Bee Journal will introduce him this week.

**The Kretchmer Mfg. Co.**, of Council Bluffs, Iowa, has sent us one of the most unique calendars we have ever received. The flower-covered back-ground or card has fastened to it a half-section of a skep made out of tissue paper in partial imitation of honey-comb. Above the hive is a movable cover which can be raised and lowered, and on it is printed the business card of the firm sending it out. The whole is arranged to stand erect on shelf or table, and is a very attractive novelty.

**"Langstroth on the Honey-Bee"**—the well-known bee-book revised by the Dadants—has just passed into another edition. There have been some 75 pages added to it, and the whole work brought down to date in every respect. It is certainly a fine book, and should be read by every bee-keeper. It is really a classic. To become acquainted with the great Langstroth through the reading of his book is no small thing. Other bee-

books are good, but there is only one "Langstroth on the Honey-Bee." The latest revised edition will be sold at the same price as the one preceding, which is \$1.20, postpaid. We still have a few copies of the old edition on hand, which we will mail at 90 cents each, if preferred, so long as they last. We club the new edition of this book with the American Bee Journal for one year—both for \$2.00. So long as we have any copies left of the old edition, we will send it with the American Bee Journal one year—both for \$1.80.

Mr. C. P. Dadant, who alone has revised the new edition, is now starting on the revision of the French edition. We believe this book has been published in the Russian language, also, and perhaps in several others that we do not now recall.

Mr. Frank Benton, Apicultural Investigator for the Department of Agriculture, at Washington, D. C., made us a very pleasant call last week, when on his way back from a year-and-a-half trip through Europe and Asia in search of new honey-plants and improved races of bees. When Mr. Benton arrived again in Washington he had made a complete circle of the globe, making it the most extended tour of investigation in the interest of bee-keeping ever undertaken and carried to completion. Mr. Benton was looking and feeling well after his long journey. Doubtless the Department of Agriculture will publish the results of his trip in bulletin or other form, so that they may be of service to bee-keepers.

The San Antonio Convention Picture is a good one. It shows over 100 of those in attendance. We are mailing them, unmounted, for only 60 cents. They can be mounted by a local photographer for only 10 or 15 cents more. We will mail one of these pictures with the American Bee Journal one year—both for only \$1.40. Send all orders to the Bee Journal office.

Archie Newman, of St. Johns, Mich., sends us the following poem:

GATHERING ONLY THE SWEET.

Wandering one day in the clover,  
With eyes downcast to the ground,  
Under a large head o'er hanging,  
A little dead bee I found.

Long had she worked in the clover,  
Busily all the long day;  
On her return in the evening  
Death she had met in the way.

Dusted was she with the pollen,  
Full were her bags with the gold;  
But she now lay under the clover  
Stiffened with death and with cold.

Little Bee, thou hast done bravely,  
Altho' death on the way thou did'st meet;  
Yet all the day thou'st been busy  
And gathered only the sweet.

May we every day act as wisely,  
And every day duty so greet,  
That should death before night overtake us,  
We be gathering only the sweet.

MCDONALD H. BROWN.

I don't see how any one who keeps bees can get along without the American Bee Journal. It is so instructive. I have had many pleasant hours reading it.—MRS. KATE S. DEAN, of Wisconsin.

## Death of Dzierzon—Other Subjects

BY PROF. A. J. COOK.

Few men of this past generation, or any other, have done for bee-keeping what this great man, who has gone to his last resting-place, has done for us. It has been said that von Siebold, and Leuckart, did more than Dzierzon in establishing the doctrine of parthenogenesis. I do not think that this is true. It is easy for the microscopist to turn his instrument at any point to confirm or refute any theory, like this. It requires a master mind to discover the principle, or fact, as Dzierzon was the first to do. I regard this as the most—or one of the most—wonderful discoveries in biology. It cut across all experience and observation as to the origin of the individual in reproduction. Dzierzon was a very close and accurate observer, or he would never have made the discoveries that led to the generalization. After the observations, it was no mean accomplishment to formulate the theory. After the theory was announced, it was no great feat to look at the eggs and see if actual observation sustained the truth as stated in the theory.

### PARTHENOGENESIS.

What is this doctrine, that is so exceptional, that the great man discovered? Usually an egg will not develop until a sperm or male cell enters it and becomes incorporated with it. In case of bees, as Dzierzon discovered, the egg, if it is to develop into a drone or male bee, never receives a sperm cell; that is, it develops without fecundation. There are three cases in which such development will always occur. In case eggs are laid by a virgin, either queen or worker, they will develop, but only males will result. In case a queen becomes old, and all the sperm cells are used up, then she becomes a drone-layer, as no eggs after that will, or can, be fecundated, and yet they develop. Any queen, as she lays the eggs, may withhold the sperm, at will, and so only drone-eggs will be laid.

This, we see, is not only one of the most wonderful discoveries, but we see it has a very important bearing on the work and practice of bee-culture. No bee-keeper can claim to be abreast of the times, who does not understand this law of development among bees, and does not act upon it. This law is also called "Agamic Reproduction." It is not peculiar to bees, as wasps and ants follow the same law. With these, as

with bees, the males are the result of Agamic Reproduction. In a small water animal—the Rotifer—there are two kinds of eggs laid by the females, one of which is not impregnated, and those develop, and so here we have parthenogenesis. We also know that Aphids reproduce all summer long with no males at all, and so they also reproduce by Agamic Reproduction, or without males.

### PASTOR SCHONFELD.

Silesia, Germany, has also given the world another great bee-keeper, who has enriched our knowledge in this realm, as few others have. His work was principally confined to food and digestion, and here he did royal service. The function and anatomy of the chyle stomach was explained by him, and his views have been found to bear the test of fullest examination. We now know that the glands of the head furnish a ferment that digests the food-proteid food, and not the larval pabulum. This great man died at the ripe age of 85, while Dzierzon had reached the age of 95. I think both worked well towards the last. This is as we would have it.

### DIGESTION IN BEES.

We now know that bees secrete the ferment that acts on the nectar in the honey-stomach, from large head-glands, upper head-glands, and the still larger thoracic glands. The pollen is mostly proteid food, and is digested in the true stomach. The ferment that does this comes from the lower head-glands. Thus the food that is fed to the larvæ is digested in the true or chyle stomach. I do not think that any scientist has done more, if as much, to enlighten us on the matter of digestion in bees, as this great man who has just gone to his long home.

### RAINS IN CALIFORNIA.

As is well known, two things are requisite to secure a full honey crop in California. We must have enough rain, and we must have warm, genial weather. One year ago, we had ample rains, so that the fruit crop was fine, but the spring was very cold and damp, so that the honey crop was very meager indeed. This winter the rains are fine, coming in good abundance, and in fashion so that all is retained in the soil, and almost none runs off. We have now had nearly 3 inches. It looks now as if we shall have a good winter. We almost never have winds or cold in the spring so as to preclude honey-gathering, and we hope for a good season this year.

### THE TREE PROBLEM.

It is an interesting fact, that the

earth's surface is nearly  $\frac{3}{4}$  water. I think 70 per cent of the surface is ocean. We see that to secure abundant moisture, to give us the "early and the later rain," the seas must largely exceed the land. Nature was equally provident in her supply of forest growth. I do not know what proportion of the land was originally forest, but I think more even than  $\frac{3}{4}$ . We all know how valuable the forests are in our economy. What a wealth of lumber has come from our grand woodlands. We have felled them at an alarming rate, that we might turn them into gold. Many of the very rich men of our country, and of the world, have secured their riches from the forests, but only in their destruction. Do we appreciate the value of the forests as we should, in their better use of retaining the water as it comes in the rain? With the forests, the rain is largely retained and passes into the ground to keep it moist for plant-growth. When we cut them we destroy this agency for conserving the moisture, and make it certain that much more of the rain will run off, and so do no good, and often do great harm. There is no doubt that many lands have been converted into desert wastes by this ruthless destruction of the forests. Europe, wiser than we, has commenced tree-planting on a gigantic scale. She, also, by law prevents cutting of more of her forests. We must do the same, and must commence to replant, the sooner the better.

#### A CHANCE FOR BEE-KEEPERS.

We, as bee-keepers, should see to it that this work of tree-planting is carried on at once. We should see to it also that honey-trees are kept to the front. In Germany, the linden is one of the trees most planted. Let us work to have the basswood set out here in generous measure, in the East, and the honey and other locusts where they will grow and do well. The Tulip and Eucalyptus are well worth consideration.

Claremont, Calif.

## Home Hive-Making and at Factories

BY DR. G. BOHRER.

On pages 1015 and 1016 (1906) Mr. Latham calls attention to the length, width, depth, and space around the frames of hives; that it should be made very precise, as to uniformity—to all of which I fully agree. He also calls attention to the cover, I think, which (I will say with him), should be made as good as it is possible to make it.

But one other matter which I find quite important is the bottom-board, which should never be less than  $\frac{7}{8}$  of an inch thick, and should be well cleated at each end to prevent warping. I have some hives, made by a bee-supply factory, that have bottom-boards but little over  $\frac{1}{4}$  of an inch thick. They have 2 joints running crosswise. The result is that they shrink and let the bees pass out and in through these joints at will. Many hives with this kind of a bottom-board have been sold to bee-keep-

ers, and are but little better than no bottom-board at all. It is not at all safe either to move them from one apiary to another, a short distance, or to ship as freight or express by railroad, with such flimsy and almost worthless bottom-boards.

The object sought in making hives at home, and out of lumber selected from boxes, is, of course, to get them as cheap as possible. And though once in a great while a hive may be, and no doubt is, fairly well made, as to dimensions, workmanship, and material, the rule is, according to such observations as I have been able to make, that the home-made hives are poorly made, in workmanship, exactness in dimensions, and in fitting qualities of the comb-frames.

Forty years ago I made quite a number of my own hives, and while I succeeded quite well I could seldom hire a carpenter who would make them exact, except I was present to direct in detail just how each part was to be made. And while our factories, as a rule, make hives sufficiently uniform in each particular factory, the different factories make their hives too different. It is desirable, as a rule, to buy hives from but one factory to be used in the same apiary. Supers of different depths are made. Shallow frames also differ very much as to depth. All these differences should be done away with, as they cause more or less trouble where hives made in different factories are used in the same apiary.

In short, let our factories give us hives made of good, substantial material in every part of the hive, and cease trying to make something out of next to nothing; for, a thin and so, worthless bottom-board, a division-board of the same kind, and a leaking cover, are abominations that bee-keepers can not condemn in terms too pronounced.

Lyons, Kan.

## Experience with Bee-Sting Poison

BY WM. W. GREEN.

Having seen occasional references in the bee-papers to severe cases of poisoning from bee-stings, I thought perhaps my experience might be interesting. During the past 2 years I have received many stings that produced only the usual local swelling, but 4 times I have been affected very seriously. The last time I closed the hive at once, went into the house, got out my watch and clinical thermometer, and proceeded to take notes. Perhaps they will be of interest to some medical readers:

June 17, 1906, at 3:30 p. m., stung on neck near larynx by honey-bee. Received full charge.

One minute later, tingling of tongue, mouth, and throat.

Five minutes, tingling and burning of all mucous surfaces with swelling.

Ten minutes, face badly swollen, scalp tingling and hair erecting; eyes "full of sand" and almost closed; tears flowing freely; mouth, nose, and throat swollen internally, with choking sensation; face very red; temperature normal (98.6 degrees); pulse 96, and small.

Fifteen minutes, body very red all over, papillæ erected (goose-flesh) all over.

Twenty minutes, face swollen to bursting; applied cold wet cloths to face and lips; nasal passages closed; hands swollen, with intense itching; pulse 96, full and strong.

Thirty-five minutes, great pressure in head, throbbing of carotids and in ears; sensation of chilliness, but surface congestion not subsiding; temperature 97.7 degrees; pulse 80, small.

Forty minutes, swelling and redness of face beginning to subside, burning and itching of scalp very marked; headache; pulse 78; medium temperature, 97.8 degrees; drank a glass of water.

One hour, swelling of face and surface congestion subsiding; some chilliness; temperature 97.3 degrees; pulse 60, medium.

One and one-half hours, face still somewhat swollen, but surface congestion mostly subsided; tired, depressed feeling; temperature 98.0 degrees; pulse 62; drank a glass of water.

Two and a half hours, swelling of face almost gone, swelling of hands all gone, and hands cold; sensation of coldness predominant; temperature 98.0 degrees; pulse 62; took dose of whisky.

Four hours, ate small meal, the first since 9 a. m.; slight nausea afterwards.

Six hours, bad headache; face slightly flushed and swollen; slight eruption or rash on chest; *bee-odor* on skin very distinct. This was proved by three persons besides myself. Reminded some of us of formalin.

There was not much local swelling caused by the sting at any time, but the place was sore to the touch. My idea is that the whole charge was injected into a large blood-vessel, and carried all through the body at once.

On former occasions nausea was a more pronounced symptom, all the other symptoms subsiding for a time after vomiting, but returning again. The rash was also more marked.

Not being a "medico" I may have missed some points, but I at least did not complicate the symptoms by taking medicines, for my treatment is given in full above.

My apiary is not so large as it was once, as my experience is making me a little shy of the sharp-pointed bees. Chicago, Ill., Aug. 1906.

## Production of Honey on a Large Scale

BY G. W. MCGUIRE.

To make any calling in life a success requires both a theoretical and practical knowledge of the principles of the pursuit. And right here let's add one more word—SYSTEM. Every great movement of nature is conducted by a strict, divine system, which never errs. But in the frail systems of men we must keep culling out and adding new leaves to the adopted system of our pursuit, ever keeping an eye to the profit side, and everything to which there is no profit attached should be discarded. So in conducting a large business everything should be uniform and simple.

I believe it was M. A. Kelley who says in *Bee-Keepers' Review*, "Bee-keepers burdened with a world of fixtures, long for the simplicity of other days." But it is debated as to whether it even pays to paint hives or not. Yes, or even dress the lumber. I have some hives in my apiary in North Carolina that have been in service 20 years without paint, and I expect to use them many years yet. And tin rabbets—yes, we will cut this off our bill, and use the plain wood-bearing for frames; and the swarm-catchers and self-spaced frames we don't want. Paul says, "Let us lay aside every weight and the sin that doth so easily beset us, and run the race with patience."

So we will suppose you have cast aside these useless fixtures that must go to the rear with the honey specialist. And we will just step across the winter into the lovely spring, after the warm sun has caressed each bud and bloom, and the bees have awakened from their long repose.

Now we will go along in front of the rows of hives—how nice the bees fly. See this colony lugging in the big loads of pollen. We will not open the hive as that would do more damage than good, just now. See that colony! How scant their pollen-loads! It is short of stores. We give it enough reserve honey to last till fruit-bloom.

See that colony. How the bees run around the entrance, fly off a little and back! Let's look. Oh, plenty of stores, but queenless. We verily let this alone, as it never pays to fool with queenless bees at this season. We will hive our first swarm here.

So our first inventory is made largely by externals.

April passes by. May comes in with her gentle showers. We now can make a thorough examination of the bees as the fruit-trees are in full bloom. On all strong colonies we put an extracting story, as this advanced room tends to allay swarming. And now every week we make a brief examination, keeping advance room on all colonies. When a swarm issues, we hive it on the old stand, placing the parent colony in a new place to build up for the fall flow.

So time goes by; the harvest is past, and the summer is o'er. We rig up for extracting the summer crop. 'Tis quite a job from 425 colonies—our present number. We run a 4-frame Cowan reversible extractor, and a cart holding about 30 combs is used to bring in the honey. I don't see how Alexander ever "gets there" with his little, frail 9-frame carrier.

We want a common cotton-tulle veil, Coggshall brush, and heavy butcher knife to pry loose the frames; also a Bingham uncapping-knife. The honey, as it leaves the extractor, runs down to the cellar into a large tank holding over a ton. From this it is drawn off into cans, barrels, etc. The combs are again returned to the bees, and about October we do our fall extracting.

Now we take an inventory of each brood-nest, noting the amount of stores, and this number is marked on the cover. We estimate 28 pounds sufficient to carry each colony till spring.

Every colony that is short is fed till it has this amount. We feed in a 10-pound pail inverted over a pan, and set in an upper story upon the frames. We can feed 600 pounds of syrup in 30 minutes.

This is a glimpse of things in the

apiaries of Jas. McNeill, where I have been assisting.

The autumn winds carry a chill, and the leaves are taking on their rosy hues. Soon I return to the South to look after my interests there.

Hudson, N. Y., Oct. 1, 1906.

Conducted by LOUIS H. SCHOLL, New Braunsfels, Tex.

### Feeding Bees in Winter

Bees generally are apt to be in poor condition on account of the poor season the past year, hence it will pay every bee-keeper to look well ahead and feed if necessary. During a poor season much of the enthusiasm of the bee-keeper is lost, and his little workers suffer more or less neglect than when a paying crop is made. When the bees have gone through a poor season, they need close attention, and this given in time may mean money in the owner's pocket the following season, which may be a good one, while otherwise his bees may all have starved.

The wintering problem with us is mostly a question of stores, and if the colonies are found short of natural stores at this time, candy feeding should be resorted to at once. This is the safest thing to do, and the candy is easily prepared by liquefying granulated sugar with water and boiling it until it will harden if a little be dropped in cold water. This is then poured into large shallow pans and broken into pieces of suitable size, or into forms already the right size desired.

The cakes are laid over the brood-frames, directly over the cluster, 2 small sticks being placed under the cake to allow a passageway for the bees. An empty super can then be placed on and some covering material—a mat or old sacking—to retain the heat of the colony.

Full combs of honey from other or "rich" colonies are good, but I do not advise this to any great extent, on account of the many dangers of spreading diseases, especially if honey is obtained from some unknown source.

### Corn-Tassel Honey Again

EDITOR SCHOLL:—I have just received the *American Bee Journal* for Dec. 6, and note what you and others have to say about corn-tassels yielding honey. I also note the extract you make from an article written by me for the *Dallas News*, and can not resist the temptation to write further on the subject—not that I have had cause to change my

mind in regard to the various plants mentioned in the extract you made from the *News*, but you know it is said, "Smart men seldom change their minds, and a fool never." (I've not changed).

I am sure, yes, *very sure*, that bees get no honey from the corn-tassel blooms. Now note that I say from the tassel *bloom*, for it is a fact that in some of our very dry years that our corn, cane, etc., become infested with "plant-lice," which cause the corn to become covered with the so-called "honey-dew," and I have had bees store considerable honey from this source at various times in the past; but the tassel of the corn had nothing to do with the secretion of this so-called "honey-dew," for it was caused by the "plant-lice." And it would be an easy matter for any one to conclude at such times that bees were gathering honey fast from the corn-tassel blooms.

In the spring of 1886 (1886 and 1887 were the two extremely dry years in Texas) it was very dry, so much so that I was sure, after fruit-bloom, I would be compelled to feed my bees to prevent starvation. At the close of fruit-bloom the various oaks were in bloom, which the bees worked on vigorously for about 10 days, filling the hives almost full of pollen, but no honey, and the bees were almost at the point of starvation. In a few days, however, a change came. The bees were dropping at the entrances of their hives and roaring at night, that clearly showed a honey-flow season. I was puzzled at first to know what this flow was from, but a little investigation showed that a small green worm was gnawing and puncturing the small, tender leaves of the oaks, from which a sweet substance was oozing that the bees were eagerly lapping up and carrying to their hives; and this was as near a real honey-dew as I have ever seen. Strong colonies stored from 25 to 30 pounds of this dark honey, that had both the taste and smell of oak leaves.

Don't you see how easy it would have been for me, or any one that was not a close observer, to have thought this honey was gathered from the oak blooms?

It is easy to determine when bees are getting honey from any plant, by

doing as directed in the clipping from the Dallas News by me. See page 1003 (1906).

Rescue, Texas.

L. B. SMITH.

Your explanation is good. The same has happened to me, and one season bees were getting much honey (?) from blooming sorghum, but observation showed that the bees were not only working on the bloom, but at the base of the leaves and the upper part of the stem, as well. The cane-stalks were covered with lice, and the bees took home the honey dew.

At another time the bees were gath-

ering honey from the oaks, but an investigation showed that the real source was the "live-oak balls"—formed on the trees and caused by a gall insect—from which the "honey" was oozing in large quantities, and eagerly sought by the bees. The honey was dark brown and strong-flavored, unfit for human food, but came just at a time to be of much value in stimulating brood-rearing.

I have never thought the bees got honey, to any amount at least, from the tassels of the corn-plant, but I have gotten considerable corn-honey from the stalks after they had been cut off.

in May, 1901. When they swarmed I divided the bees and brood in the old brood-chamber, putting half into a new hive, and alternating each with frames of foundation. From the swarm I received 30 pounds of surplus honey.

In the spring of 1902 I had 3 colonies, which had given me so little trouble that I thought I could manage a couple more, so I purchased 2 strong colonies for \$15.00. When they started to cast out first, second, third and fourth swarms, I began to have some idea of what bee-keeping meant. Having double brood-chamber, 8-frame Langstroth hives, the swarms were large, and when 2 swarms issued at the same time I had enough to do to lift the double hives away and replace with new ones before the bees began to return, the queen being clipped. I had heard of 20 swarms issuing at the same time in large yards, but 2 at a time were enough for me just then. Those five colonies gave me 928 pounds of extracted honey, and increased to 16. At the end of the next season I had 35 colonies and 1400 pounds of honey from them. I had 30 colonies in the spring of 1904—5 having died in the cellar; they yielded about 2600 pounds.

In the spring of 1905 I had 33 colonies, when the weak ones were united with the strong ones; they stored 4700 pounds of honey and increased to 49 colonies. Last spring (1906), the number decreased to 40, 5 being queenless and 4 too weak to go alone. They yielded 1600 pounds of honey, and I have 39 colonies this fall.

As to stings, my first serious experience with stings nearly put me out of the business. It was when I had only 5 colonies. They seemed to be trying to make a record of 200 pounds per colony for that season, and when I attempted to take the honey off they resented my interference with their plans with such vigor that I left the hive open and ran to the house, saying to the folks when I got there, "There is no use talking about getting used to stings, I will never be able to stand such punishment as this. It is too much for me."

But I did not like to be beaten by the little bee so I fortified myself against another attack by covering my hands and wrists with long, heavy gloves, and succeeded in taking the honey off. Ever since that time I have worn gloves in handling my bees; even when clipping queens I used gloves with the fingertips cut off. I know that wearing gloves is not looked upon with favor by the professional bee-keepers, but when it comes to the question of gloves or defeat, wear gloves.

There are other things connected with the occupation that are not very agreeable—the stickiness of the honey in uncapping; extracting, weighing and pouring into cans, which has won for the male bee-keeper the title of "Lick Thumbs." This is one of the mildest miseries, so easily reduced to insignificance by the use of water as to be scarcely worth mentioning, only we are treating of bee-keeping as an occupation for women, and she who takes it up is sure to find that this feature certainly belongs to it.

She may expect, too, considerable

## Report of the Ontario, Canada, Convention

REPORTED BY MORLEY PETTIT.

[Continued from page 14]

### SMOKERS.

Mr. Miller never was accustomed to have any one use his smoker for him, so he makes a large smoker, the bellows 10½ inches long, with the barrel proportionately large. This is so he could use a large piece of wood, and so the use of the bellows would not make a flame. He holds the smoker between his knees when not in use, to avoid stooping to the ground.

Mr. McEvoy does not wear a veil, but smokes the bees so they won't sting.

Mr. Holtermann knows there is an art in smoking bees, yet it is wiser to wear a veil, and not smoke them so heavily.

Mr. Byer—It is better to smoke just enough, and not too much. The nozzle should be hinged on so it can not drop off.

Mr. Newton can easily tell by the sound of bees when and how much to smoke. As to a veil, he finds he can do more work in the same time by its use. He does not call for a large smoker, and likes the slip-over cover, not hinged.

Mr. Hershiser does not believe in being foolhardy about going without a veil, yet does not use it very much. He believes in using one when it is necessary, and not use too much smoke, because it will injure the flavor of the honey. He uses a large smoker because it does not need to be filled so often. He believes the latest Bingham smoker a good one, but has a weak point. It is not strongly enough connected with the bellows. Otherwise it is a good one.

Mr. Miller has a piece of light chain attached to the cover, and a hook on the barrel to fasten the nozzle on. To

keep the fire from falling out there is a narrow rim in the nozzle, and then wads the grass in behind this rim so it does not fall out.

R. Lowey does not like the hood that turns the smoke to one side. He likes a straight nozzle. He does not smoke bees much, and uses pine bark, second-growth.

Mr. Holtermann likes a narrow and longer barrel.

Mr. Bailey has an arrangement of the barrel of his smoker to hang it on the side of the hive. He uses green grass to keep the smoker cool.

Mr. Bruune has 110 hives and does not use a smoker at all during the honey-flow. He wears a veil and carefully handles the bees so as not to irritate them.

### BEE-KEEPING AS AN OCCUPATION FOR WOMEN

As a rule, to the woman who has had no practical experience with bees, if she thinks of the subject at all, bee-keeping stands for honey, large profits, studies in natural history, and stings, the latter probably being considered the surer and most objectionable adjunct of the business. But a few years' acquaintance with the bee-keepers' pets will teach her that stings are but insignificant incidents in the bee-keeper's life, that honey is not always sure, nor profits always large, but the study of the nature and habits of the bee can be depended upon at all seasons of the year to yield a fund of interest to any woman who engages in this occupation.

The story of my experience with bees is probably my best means of showing what bee-keeping may be as an occupation for women.

I started bee-keeping in 1900 with one colony, for which I had paid \$5.00. They did not swarm nor give any surplus honey during the summer, were weak the following spring, and gradually dwindled away till the hive was empty. I purchased another colony for \$6.00,

# American Bee Journal

hard work and heavy lifting, for in handling the 8-frame Langstroth—one of the smallest hives—there are many 60-pound lifts, and if she be incapable of lifting that amount, a woman is likely to be handicapped by her inability to move or carry a full hive or super, or 60-pound can of honey. It is well enough to depend upon outside help for big days, when carrying in supers of honey for extracting, or in weighing it and crating it for shipment, or conveying the bees to their winter quarters; but for the common, every-day work of the apiary, which requires much muscular exertion, the woman who aims to become an efficient bee-keeper can not afford to depend too much upon outside help.

Bee-keeping may be looked upon as a healthy occupation for women in comparison with many of the avocations to which she is called, wherein exercise, fresh air and sunshine are denied her. It is true, there will be times when the humidity of the air and the intense heat of the sun, aggravated by the exercise she is forced to take, through the excessive activity of the bees consequent upon the weather conditions, may lead her to exclaim, "Why was I ever born to be melted like this?" but these conditions usually last for only a few hours in a day, and not very frequently through the season, and there are so many rare, beautiful days to enjoy, during the honey harvest, that one forgets the discomforts of a few hot, damp, wily hours, in the pleasure of those when air, and sun, and bees, combine to make the bee-keeper's life worth living.

One very important part of the business is the melting of old combs. It is hard, sticky work to cut wired combs out of the frames and put them into the extractor. It is difficult for a woman to lift the lid, handle, screw and press off the extractor, without getting up on a chair, even though she be strong and tall; and this has to be done every time the extractor is filled with combs. The heat, steam and odor of hot wax, pollen, etc., make this one of the most objectionable features of bee-keeping; but as house-cleaning, with its dust, disorder, and discomfort, while in progress, proves such a delight to the house-keeper in its results, so comb-melting amply repays the bee-keeper by the improved sanitary condition of the hives; and from what we learn from conversations with experienced bee-keepers, items in the bee-papers, and deductions from papers read at conventions on the subject of healthy, disease-proof colonies, the renewal of clean, new foundation in the hive forms a very important factor in insuring healthy conditions in the apiary. And the possibility is that if woman, with her natural house-cleaning proclivities, should invade the realm of bee-keeping, this branch of business would be well attended to, and the problem of foul brood solved without any other formula.

There are many things in connection with bee-keeping that a woman can work at with great pleasure. Take that of opening up a few crates of bee-supplies and transforming the neatly-made and

precisely-fitted pieces into hive-bodies, bottom-boards and covers, frames with top, bottom and sides of white, clean wood that fit each other like a charm, and fit the hives just as perfectly. Then there are the folding of sections, the wiring of frames and imbedding wire in foundation, etc., all neat, clean, fascinating features of the business.

My advice to the woman who wishes to take up this work would be to spend a season with an experienced bee-keeper, if she has an opportunity, paying strict attention to every detail of the work. She would gain thereby much knowledge that if won by her own experience would cost her dearly. An instance in point of this:

I had been told to put an empty super under a large swarm, to give them room to cluster and prevent them from swarming out again. I only grasped the one idea—put the super under—and did not note that it should be taken away at a given time; the consequence was that that colony did not store as much honey in the supers; and in the fall, when I strove to take out what I supposed was an empty hive-body, I found a peck or perhaps a half-bushel of trouble accumulated there, in the shape of combs built toward all the points of the compass, young brood in all stages, hundreds of bees crushed between combs that had fallen when the hive was lifted off, and a possibility that the queen was killed in the general mix-up. To have seen this done promptly would have saved me time, trouble and expense.

In conclusion, this record shows that a woman may expect the little busy bee to gather honey for her at an average yearly rate of 81 pounds to the colony; that stings may be subject to her, with stickiness also; that hard work, heavy lifting, perspiration, and disagreeable odors must be borne with fortitude; that careful attention to detail is imperative; and that there are many things in bee-keeping that are calculated to make it an attractive and enjoyable, occupation for women. Miss TREVARROW.

Meadowville, Ont.

Mrs. Scott, daughter of Samuel Wood, one of the oldest members, thought that Miss Trevarrow's experience was very encouraging to women bee-keepers.

Mr. Hershiser—This paper shows what women can do in this line. They should be able to hire inexperienced help to do the heavy work.

Mr. Deadman—The lifting may be avoided by using Heddon hives, and a wagon to draw supers to the extracting room, and many other labor-saving devices.

Mr. Craig has visited Miss Trevarrow's apiary and found everything neat and in order.

Mr. Hershiser likes to have the heavy lifting.

R. W. Roach—Women will notice things going wrong in the yard before a man would do so.

## SUGAR BARRELS FOR HONEY.

"How would sugar barrels do for candied buckwheat honey?"

Mr. Timbers—If they would hold the honey till it is candied, they would be all right.

"How can we get 10 cents per pound for extracted honey?"

Always put out a good article.

Never offer buckwheat honey to a customer until he asks for it.

Mr. Hershiser—Well-ripened buckwheat honey is just as good as clover. The difference is a matter of taste.

Mr. Roach has learned to like buckwheat honey, and finds customers learn this, too.

Mr. Holtermann—It is important that buckwheat honey be well-ripened, and then people who are accustomed to it often prefer it to clover; and the more it is used the more they seem to like it.

Morley Pettit—When buckwheat honey is well granulated, it is more palatable than liquid.

Mr. Timbers—Next spring make the buckwheat honey all into bees, so it does not get mixed in with the white clover. Pure buckwheat honey is a better flavor than mixed, and the better flavor is obtained on the lighter soil.

Mr. Craig—Buckwheat is one of the honeys that won't stand re-liquefying. It injures the flavor.

Mr. Hershiser—You must go slow. Take 24 hours to liquefy a 60-pound can. As to value, I have found that buckwheat honey suits purposes of biscuit factories just as well as the white honey.

Mr. Timbers—It is all a question of locality. If we have more honey than we can retail, hold it over till the next year. Retail as much as possible. I retailed, in 1903, 3000 pounds from the house without soliciting a sale, and I live right in the country.

A. Laing condemned retailing at a wholesale price. It is not advisable to sell honey-dew at all for retail trade.

Mr. Holtermann and Secretary Kerby moved that where gross weight is put in a 10-pound and 5-pound pail, the label bear the word "gross weight." Carried.

Mr. Byer and Morley Pettit favored this idea.

Mr. Holtermann is in favor of legislation, but would not urge that.

Mr. Dickinson thought they should be compelled to put in net weight.

Mr. Hershiser puts net weight in 60-pound cans, but gross weight in smaller packages.

Mr. Timbers said we can not compel members to sell net weight when all other goods with which they have to compete are sold gross weight.

Laing and Byers—It is far easier to sell a package gross weight than to get pay for the package in any other way.

(Continued next week.)

**Honey as a Health-Food.**—This is a 16-page honey-pamphlet intended to help increase the demand for honey. The first part of it contains a short article on "Honey as Food," written by Dr. C. C. Miller. It tells where to keep honey, how to liquefy it, etc. The last part is devoted to "Honey-Cooking Recipes" and "Remedies Using Honey." It should be widely circulated by those selling honey. The more the people are educated on the value and uses of honey, the more honey they will buy.

Prices, prepaid—Sample copy for a 2-cent stamp; 50 copies for 70 cents; 100 for \$1.25; 250 for \$2.25; 500 for \$4.00; or 1000 for \$7.50. Your business card printed free at the bottom of front page on all orders for 100 or more copies. Send all orders to the office of the American Bee Journal.

Conducted by E. L. BYER, Markham, Ont.

## Introduction and Greeting

In stepping into the breach caused by Mr. Pettit's retirement from "Canadian Beedom," I feel that I am undertaking a somewhat difficult task. Be it remembered, Mr. Pettit is something over 6 feet in height, while "your humble servant" is—well, somewhat shorter, to say the least.

Somehow, I can not help but feel that our abilities and mental capacities are about in the same ratio of comparison as our physical stature. However, being by nature an optimist, I shall not worry over things that I am not responsible for, but shall endeavor to make the best of opportunities, and with this end in view, looking for the hearty co-operation of all, and especially of Canadian readers of the American Bee Journal, I shall try to make this department interesting and instructive.

While, as heretofore, our corner will be called "Canadian Beedom," the writer has intimated to Editor York that the privilege is reserved of "meddling" in "Yankee" affairs if occasion permits. As I purpose to abstain from doing anything of an extraditable nature, I do not anticipate much trouble along this line.

Permit me to wish all the readers of the American Bee Journal a Happy and very prosperous New Year.

Markham, Ont. J. L. BYER.

## Maintaining High Prices of Honey

Is it possible to maintain the present high prices of honey? Probably most readers of the American Bee Journal are aware that on this side of the "line" a very short crop of honey was harvested last season. As a result, prices of honey are unusually high—10 cents a pound wholesale for extracted being the common quotation all fall.

At the annual convention of the Ontario Bee-Keepers' Association, held in Toronto, in November, 1906, President Sibbald, in his address, thought that honey had advanced to where it ought always to stay. In his opinion, honey is a cheap and wholesome food at 12½ to 15 cents per pound, and at those prices it compares most favorably with other foods. The most of us are inclined to agree with Mr. Sibbald, but the question arises, How, in a good year, are we going to maintain present high prices?

In the discussion that followed President Sibbald's address, Mr. Holtermann thought it would be unwise to try to get present prices in years when we had a full crop. While I am, for obvious reasons, inclined to agree with Mr. Holtermann, yet in common with most bee-keepers, I suspect I would be *willing* to keep up the high prices, if it were possible to do so.

One thing seems certain, and that is, Canadian bee-keepers, for many years to come, should have no reason to sell at the low figures that have prevailed in some years. Our markets, right at our doors, have not been half worked in the past, and I think we would be safe in assuming that at least three times as much honey could be used in our own vicinity, as is the case at present, provided systematic methods were used to bring about this result.

With the tremendous influx of popu-

lation into the Provinces of Manitoba, Sackatchewan and Alberta, and with comparatively little attention being paid to apiculture as yet in these places, there can not help but be a great market there for years to come, for Ontario honey. At present everything is prosperous there, and experience has proven to me that if you send them the right article they do not "kick" about the price.

One great barrier to trade with the West at present, is the high freight-rate, but with two more transcontinental railroads in course of construction, possibly we may hope for some relief in that matter.

In connection with the matter of keeping up prices, the Crop Report Committee, working in conjunction with the Ontario Bee-Keepers' Association, is doing a grand work. When their report was sent out last September, some bee-keepers who happened to have a fair crop thought the news too good to be true, and I received letters asking questions something like this:

"Is the crop as short as reported by the committee? We came very near selling our crop the other day for 8 cents. Do you think there is a possibility of getting 10 cents, as advised in the committee report?"

As a result, if I am correct, I believe that every one of these enquirers received in the neighborhood of 10 cents, f.o.b., for their honey. Certainly co-operation paid these bee-keepers this year, and the lesson is not apt to be forgotten another season.

The "Old Reliable" as seen through New and Unreliable Glasses,  
By E. E. HASTY, Sta. B. Rural, Toledo, Ohio.

## DRONES FOR SERVICE.

That Irish editor makes me mad. Just as I was pluming myself on being, like Cassandra of old, the solitary prophet and witness to the truth, up he pops to remark that over in Britain my view (that when getting drones for service numbers don't count much) is common enough. So! Wish somebody would take the contract to furnish those common-enough fellows with tongues—tongues with a hung-in-the-middle arrangement. But as that editor is one that Digges in the opposite direction, maybe he thinks that one believer, and he a deaf-mute, would be, for the doctrine in question, common enough. Page 993.

## THE T-SUPER FIGHT.

Dr. Miller and Frank H. Drexel certainly make a good fight for the T-super on pages 995, 996, and 997. Then why don't I adopt it myself? Ah,

that's different! The double-deck section-holder arrangement is the kind for an old played-out like me, who never gets anything done. Also, I feel assured that in changing my system as a whole for the T-super system as a whole, I should greatly increase the number of my unfinished sections, now delightfully small. Also the job of cleaning the bottoms of those sections is going to forever bluff me off. Propolis is bad here, and my lazy sections have a habit of staying where they are put the entire season. You see, my locality is so poor a one that I am seldom driven to take anything off. More prompt taking would make the looks of my honey better, but the real quality not so good, with the quantity usually the same. And my old customers have learned to be satisfied with my honey without requiring it to be ghostly white. Some one has recently written that the double-deck section-holder, as A. I. Root originally in-

vented it, was no longer in use. It will stay in use as long as I keep bees, I reckon—unless I should change my strain of bees. Not every really good strain of bees likes to store honey so far away from the brood-nest when there is only a little coming in, anyway; but mine do it all right.

#### WATERING ANIMALS—BEES AND GRAPES.

Prof. Cook may help us in some things besides bees. In watering large animals it is oft quite a job to carry so much. And we may feel that they are drinking more than is good for them, and just making us needless work, and yet we don't think it's nice to deny them what water they want to drink. Let them have more *time* for the water to pass into their blood and the thirst will not persist until they have swallowed down all their great stomach can hold. Just now I am carrying water to 3 cows daily. They take 9 big buckets. Taking Prof. Cook's hint would be to give each cow one bucket, then do some other chores taking 5 minutes or so, then give each cow one more. Given in that way, perhaps 6 buckets would do better than 9, and be all they would take.

I note with surprise (but not at all with displeasure) that Prof. Cook wishes to avoid saying that bees *can not* puncture grapes; he rather suspects that they could if they got at it right. I believe as respectable a witness as John Pocklington, originator of the Pocklington grape, testified that he *saw* a bee puncture a grape—not only saw it, but watch in hand he timed it. I forget the time he named. Part of the time another bee was mounted on the shoulders of the first one helping to bear down. Well, what was this bee's method of operation? Suppose you wanted to perforate a base-ball with your thumb-nail. You would press hard and rub back and forth on exactly the same line. With long patience it could be done, I take it. Bees' mandibles are shaped much like thumb-nails. If I got Mr. Pocklington aright, his bee used one mandible and rubbed in just that way. Our safe defense, if we don't want to get cornered, is not that bees are incapable of perforating, but that they almost never learn how. See, I'm not "holding my whist" this time, when I can get behind Prof. Cook, out of sight. Shall I tell about the *other way* bees destroy sound grapes? I think I've seen a little of that—but have never seen the way just mentioned. It's to cluster on the bunch till they cover it all up out of sight—to get themselves into a boiling frame of mind, like they were balling a queen or trying to force a hole into a hive you had just shut them out of when they had been robbing it. I don't know which counts most, the heat they generate, or the joint power with which they pry the berries around; but the joint result is to start the berries from the stems, after which, of course, the rest is easy. Page 998.

I think a good deal of the American Bee Journal. When I sit down to read it I don't know when to stop.—MICHAEL McADAMIS, of Illinois.

Conducted by EMMA M. WILSON, Marengo, Ill.

#### A Sister in Charge in New Zealand

Miss Livesay has been placed in charge of the State Apiary of New Zealand, according to an article in *Gleanings*. She is a lady with English training, and "she hopes to popularize the industry among the farmers' wives and daughters. The supervisor, Mr. C. Sinton Hutchinson, is one of the best scientific bee-keepers in the country. The Langstroth hive is used, as is the case throughout the country, its general adoption being due to the efforts of Mr. Hopkins many years ago. American bee-literature, too, is read far more than English, which, indeed, is but rarely seen.

"The bees at the State Farm are hybrids, and nothing has been done yet to improve the strain; but next season Mr. Hopkins will import some of the best Italian queens. There will also be observatory hives and probably a library."

#### Not an Irish Sister—North Pole

The editor of the Irish Bee Journal says:

The American Bee Journal is called in the States the "Old Reliable," and is one of those ever-fresh, ever-welcome publications that no bee-man worth a dollar and a half can afford to do without. Of that attractive Journal, one of the most delightful departments is that of "Our Bee-Keeping Sisters."

Then, after some kind words about the head of this department, he continues:

Well, Miss Emma M. Wilson does us the honor of reading the Irish Bee Journal, and treats us very kindly in her department of the American Bee Journal. Our editorial on "Drivel," page 37, caught her attention, and, as with so many of us, the quotations we made amused her immensely. But how does she begin her article? "Woman's Life, a journal presumably published in Ireland," she says!

There you are again!

We have already so much to answer for in this country, a little more or less makes no difference. The article quoted was so unblushingly ridiculous that it must have emanated from one of the "writers for women's journals" here, and the publication itself must, of course, be Irish! If the sun, moon and stars, including the Milky Way and the Great Bear, were suddenly to drop into New York Harbor, the cry would immediately go up that an Irishman did it. It strikes us that we have here the secret of many national disasters and failures. Take, for example, the various North Pole exploration expeditions, of which America contributes her share, and each of which makes "a record," but with just as little hope of success. Why?

Because some one is constantly shifting the Pole farther north; and the explorers will have to set a dozen policemen on the chest of every Irishman in the Arctic regions before they can "discover the Pole!"

But, as a set off, let us assure Miss Wilson that the publication which has given good, healthy laughter to hundreds of us, has its home in London, where the apicultural knowledge of Europe is concentrated, and is no more Irish than are the Falls of Niagara. This, we feel sure, will be welcome information to the gifted lady who weekly delights us and all other readers of the American Bee Journal.

With this full explanation care will be taken in the future to keep in mind that a Woman's Life is not necessarily an *Irish Woman's Life* because mentioned in the Irish Bee Journal.

But is there not some mistake on the part of Editor Digges when he speaks of some one shifting the Pole farther north? Does he not know the Pole is lost, and that frantic efforts are being put forth to find it? Now how could any one shift it further north without first finding it? But if it had been found by any of "those Irish" that he speaks about as "always on the borderland of starvation," instead of shifting its place would they not have cut it up for firewood? In which case is it worth all this bother to try to find the stump?

Now, if Editor Digges wants to make sure that the Irish Bee Journal shall not be misquoted, the way is very easy: Just let him stop making its pages so bright that one is constantly tempted to quote from them.

#### Yellow Sweet Clover—Are There Several Kinds?

If I were sensitive about being called a "Sweet Clover Crank," I would certainly "let up" on writing about it, for a little while, at least.

I had a letter a short time ago from a valued friend of mine. He is a sweet clover expert, by the way, and few have done more to remove the prejudice against the beautiful "Melilotus alba."

He wanted to ask me about some sweet clover he had been growing. He said he bought 25 pounds of seed from a reliable firm (a bee-supply house), and sowed it on March 31. I will quote from his letter:

"The seed grew well, and on May 8 began to bloom. Soon there was a sea of yellow bloom everywhere that I had scattered the seed. This clover grew about 12 to 14 inches high, but—I never saw a single bee on this mass of sweet clover bloom. The plants of this

# American Bee Journal

clover appear to be dead now. What do you think of this yellow sweet clover? Do you believe it to be the genuine article?"

I wrote my friend that I did not know what he had gotten hold of unless what I have heard called "yellow blossomed alfalfa." "*Melilotus officinalis*" it certainly is not. That is a *biennial*, and does not bloom the same season it is sown. Besides that, it grows much higher than this plant described by my friend.

I spent an hour or two lately in looking up about "yellow sweet clover"—what others have said of it in years gone by. To me it was very interesting reading.

In the first number of the American Bee Journal for 1897, Mrs. Lambrigger, of Knox Co., Nebr., writes of "yellow sweet clover" with great enthusiasm, ranking it *far ahead of the white kind* for bees and for forage.

I got my first seed from Mrs. L. years ago, and I say that she did not overrate the merits of this clover. For myself, the longer I have it the more I appreciate it.

Mrs. L.'s article started M. M. Baldrige—a sweet clover expert in Illinois. He said:

"I don't believe the yellow sweet clover is a better variety than the white, but *there may be more than one kind*. I have seen the yellow growing in this city for years, but never saw many bees on it," etc.

I am really curious to know what Mr. Baldrige thinks of yellow sweet clover now.

John McArthur, of Ontario, another sweet clover expert, was also aroused. He said that in writing of "*Melilotus officinalis*," his experience dated back 17 years. Here is a quotation from his letter:

"I would say, emphatically, that the yellow is not equal to the white in many respects. It blooms at a time when we have an abundance of White Dutch and alsike clovers, and very few bees will then be seen upon it."

The letter is quite a lengthy one, and I don't feel at liberty to quote it all here, but there is something to which I must call attention, because it would seem to show that he has not my kind of yellow sweet clover—nor "*Melilotus officinalis*." He says:

"Examine the seed-pod and you will find that it contains from *one to three* seeds—different entirely from the white in this respect, which carries only a single seed in each pod."

"Gray's Manual of Botany," which, by the way, mentions the yellow melilot *first*, says the seed-pod is one and two seeded. I find this to be so with *both of them*. The pod has usually one seed, but occasionally *two*.

I took pains to examine the seed-pods minutely. In no case did I find *three* seeds.

The seed of the two varieties is almost identical in appearance, but that of the yellow is a little smaller. That was 9 years ago. It would be interesting to hear from Mr. McArthur again.

In this same volume of the American Bee Journal there was an account of a bee-keepers' convention in which Editor York read a letter from the late Mrs. L. Harrison, which is worth republication at the present time, when

there is renewed interest in yellow sweet clover.

Bee-keepers, I know there is great interest in it just now, or I would not be getting letters from *all over* in regard to it. Mrs. Harrison says:

"It blossoms a month earlier than the white, and is more profuse, looking like a yellow sea. It makes finer hay than the white, and is a greater favorite with the bees."

In the Bee Journal for 1900, there is a long, interesting article on yellow sweet clover, by John R. Schmidt, of Hamilton Co., Ohio. As to its time of blooming, he says:

"This year about the middle of May, which is at least *four weeks ahead of the white variety* of sweet clover."

Now, I have by no means made an exhaustive study, nor called all the witnesses, but I have given enough to show that the American Bee Journal

has done its part toward giving *light* on this subject. Bee-keepers, give us the facts, and don't let me do all the talking! I like to stir things up a bit, and then take a "back seat," and watch the fray!

(MRS.) A. L. AMOS.  
Custer Co., Nebr.

## Honey for the Hands

Until some one is bright enough to invent a machine to wash dishes, here is an item, taken from Vick's Magazine, that will always be timely for most of the sisters:

Rub the hands well with corn-meal and vinegar after washing dishes, etc.; it will then clean them; then put a few drops of honey in the palm, add a little water, and rub it well into the skin; it will make them soft and white. Do not use honey enough to make the hands sticky.

Send Questions either to the office of the American Bee Journal, or to  
DR. C. C. MILLER, Marengo, Ill.

Dr. Miller does not answer Questions by mail.

## Dummies in Place of Combs

What do you use for dummies in hives when taking out combs? TEXAS.

ANSWER.—Simply a pine board about 5-16 of an inch thick, with a top-bar. Formerly I had them about the same depth and length as the brood-frames, but it is easier handling them if they are an inch or so shorter; that is,  $\frac{1}{2}$  inch or so shorter at each end, and at the part of the hive where they are used the bees don't fill up the vacant space with burr-combs. I like shortened ends for top-bars of brood-frames, depending upon staples driven into the end-bars just under the top-bars to space the frames endwise, but that doesn't work well for dummies. The top-bar of a dummy should be nearly long enough to fill up the space; 1-16 of an inch being play enough. There is less danger of the dummy warping if it is cleated at each end, the cleat being fastened not on the side, but on the end, so that the thickness of the dummy is not increased at that part.

## Dampness in Hives

I have 12 colonies of bees under a shed, opened only to the east, or front. A while ago I made a case of heavy building-paper, put this around the hives and filled up the space between with shavings to protect the bees from cold, leaving the entrance open. In looking them over to-day I found a little ice on the alighting-board, and also a small icicle in the entrance of one of the hives, showing moisture inside. I would like to know if this will do any damage. If so, how can I help it? I have noticed on two of the alighting-boards a little honey. What is the cause of that? The hives all have flat covers.

VERMONT.

ANSWER.—It is nothing unusual in winter

time to see a little water trickling out of a hive-entrance, and of course when it is cold enough such water will freeze. In most cases no serious harm is done. The vapor from the bees, or the bees' breath, condenses, settles on the cold walls of the hive, and when there is enough of it it trickles down. There is, however, danger in two directions. If the moisture should settle over the bees, and then trickle down upon the cluster, harm would follow. To avoid this, see that there is plenty of packing on top. Another danger is that the ice may fill the entrance entirely and smother the bees. Keep occasional watch, and clean out the entrance. Too small an entrance may favor condensation of moisture. A strong colony may have an entrance equivalent to 3 or 4 square inches. The honey running out looks a little like too small an entrance, as the moisture probably settled on combs of unsealed honey, thinning it so it ran out of the cells.

## "Testing Swarms Before Hiving Them"

On page 931 (1906), C. W. Dayton gives an article with the above heading, that I have studied carefully, and it seems as if at least some of the views he holds are not in accord with generally received opinion. Which is right, the old view or the new? Kindly give your own view in detail.

ILLINOIS.

ANSWER.—Your question is a very broad one, as you do not say to what part of Mr. Dayton's paper you refer. There are some things in it that I am not sure whether I understand correctly; and without a full understanding it is not always safe to express an opinion. I feel very sure, however, that Mr. Dayton will be willing to correct any misapprehension on my part.

If I understand correctly his first paragraph, I think many experienced bee-keepers will be

# American Bee Journal

found who do not agree with him. He tells of "the dogs in Massachusetts, which, shorn of their tails, became a race of dogs which neglected to grow tails." I don't know whether that's meant for a joke or not, but unless meant in earnest it can hardly have any bearing on the case. I read within a week of a salve so wonderful that upon being applied to the stump of a dog's tail that had been cut off, the tail promptly grew on again. Then the salve was applied to the tail that had been cut off, and it promptly grew a dog onto the tail. These two dog-tail stories are alike in one respect; that is, that one is probably as reliable as the other.

Never mind the dogs; lets get back to the bees.

It is a matter of great importance to know whether it is true, as Mr. Dayton says in his first paragraph, "that the probability is that if the bees would not swarm they would breed only enough to keep the colony intact." For upon one's belief in that regard depends one's practise as to restraining or encouraging swarming. But if it be true that the result of no swarming would be colonies so small as to store only honey enough for their own use, as Mr. Dayton says, then one would naturally expect that where they come very close to no swarming they would come very close to such small colonies. If I am correct, about 95 per cent of the colonies of the Dadants do not swarm; if there has been a very material diminution in the size of the colonies, it seems to me that so candid a man as C. P. Dadant would have mentioned it. And if the general opinion is correct that a large hive is one of the most important factors in the prevention of swarming, is Mr. Dayton working in the right direction when he says (page 503), "My hives are abundant in size, early or late?"

I am not sure whether I understand just what he means when he says: "It appears reasonable to me that swarms and honey-gathering should go hand in hand." At any rate, my bumper yields have always been from the colonies that made no offer to swarm. I think it is the general belief that bees most given to swarming are not the best gatherers.

Mr. Dayton says, "It will not be proper to give this matter of breeding our bees entirely over to breeders." If by "breeders" he means the men that sell queens, Mr. Dayton has not a very large following in his belief. At least, whatever their belief, in their practise the great majority pay little or no attention to the matter of breeding their bees except to buy occasionally a queen of fresh blood. But the multitude is wrong, and Mr. Dayton is right, most emphatically right.

As to the remainder of his article, there are some things that I'm not sure I understand, and some things I am sure I don't believe. I don't understand how it can be a common thing for bees of a swarm to return to the old hive when the queen is not to their liking, and yet not to return when they have no queen at all. I don't understand what practise Mr. Dayton advises when he says, "The only swarms that it is advisable to hive in a new location are those where the bees all stay;" for I don't understand how he would tell about it without hiving. I don't believe that bees of a swarm do much returning, but I am ready to do so upon sufficient proof.

## Uncapped Sugar-Syrup Stores for Winter

I am wintering my bees in the cellar, and they seem to be doing all right now (Dec. 18). I gave them a thick syrup made of brown sugar. While the syrup was stored in the combs by the bees the latter part of September and first of October, they did not cap it. Is there any danger of its becoming so hard in the comb that they can not use it? and will there be enough moisture in it for them? or should I supply them water to drink? How could I best supply this water for them, if you think they may need it? I took the bees out of the cellar one day last week and they had a good flight.

I am reading two books now all the spare

time I have. One is "Langstroth on the Honey-Bee," and the other is "Manual of the Apiary," by Prof. Cook. I think they are excellent works. I also take great pleasure reading the "Old Reliable." I mean to study all I can along this line, and handle my bees as scientifically as I can. I love this kind of work.

IOWA.

ANSWER.—I don't believe there is great danger that the syrup will become too dry. The danger lies in another direction, especially as the syrup was unsealed. Granulated sugar is about the only sugar used for winter stores, and there is danger that before spring diarrhea may result from the brown sugar. If so, the only thing is to wait patiently for spring weather in which the bees can fly, hoping that it may come early. There is one thing, however, that I would try, although I'm not entirely sure it helps diarrhea. It is to warm up the cellar. A stove in the cellar is the best thing. Hot stones may do; bottles or jugs of hot water well corked. But no hot water uncorked. Don't use an oil-stove unless you can air out well, as the resulting fumes foul the air. Run up the temperature, if you can, to 50 or 60 degrees.

## Pacific Coast Murmurings

PERFUMES OF BEES, FLOWERS, AND WOMEN.

Some of the readers of the American Bee Journal may be opposed to there being any reference made in its columns about the aspirants for high political office. Under ordinary circumstances such should be the rule, but there are some persons who hold that such notice should be given. For a reason for such a view, they hold that these aspiring citizens are bee-keepers, every one of them. At first, I did not think that all the politicians of this broad and enlightened land could be apiarists. On expressing my disbelief, I was met with the reply, "Why, aren't they bee-keepers, for every one of them has a bee in his bonnet, and if that does not make a bee-keeper, well, what does?" Perhaps it does, but it is almost like straining at a gnat and swallowing a camel. Let's take it for granted that they are bee-keepers, and notice some of the more prominent ones—the ones who seek the highest office in the gift of our citizens.

William Jennings Bryan has already been noticed. He cropped up rather suddenly as a double-barrelled bee-keeper, inasmuch as he keeps the genuine article—the pets of all true apiarists—in his back yard, and this other sort (the politician's kind) is hived beneath his soft-felt hat. Well, that's good. I'm glad Billy Bryan likes bees and honey, and he's welcome to the bee in his bonnet. I do not pretend to be boosting him, or any of the other distinguished citizens (not even our good, strenuous [sic] President, Theodore Roosevelt), into high places.

There, I've named two bee-culturists, and here goes for another. He has the worst case of this kind of bee-fever that ever got loose in the United States. Whether the bee will ever hatch out a nestful of trouble like a queen-hornet does, I can not predict, and it is not my place here to intimate.

Like myself, he's a native Californian, but so many bad things have been said of him that I have not yet come to fancy him. As a trust-buster, he may appeal to the best side of true Americans. I am referring to William Randolph Hearst, the millionaire newspaper publisher.

Having named all the principal single bee-beepers in the United States, I trust there is no one who will say that I am unfair. Just watch me and see how I shall roast any of them that gives me a chance, if he goes "for-ninst" the interest of the bee and honey industry.

Speaking of Hearst a moment ago, reminds me that his knowledge of bees is very crude; in fact, the following editorial from his San Francisco Examiner of Oct. 2, displays an immense amount of ignorance. For instance, note the sub-head. Who ever heard of a drone-bee stinging any one, whether the latter was perfumed slightly or profusely? Mr. Hearst may have written this editorial, or it may have been done by some one of his writers. He has some excellent pencil-pushers, but it is quite evident none of them penned this rank editorial. I doubt very much if bees will, at all times, go for a scented person—one artificially perfumed. We have been told from infancy that bees do not like the odor of perspiration; that that of the negro and that of the horse are so obnoxious to the bee that the offending smells are attacked with formic acid, not as a neutralizer but as a killer. The fumes diluted (carbolic acid) is used as we use smoke to scare them into gorging themselves with honey, thereby making them good-natured.

I am not writing in defense of the perfumed woman, for I abominate the rank odor exhaled from some of these misguided creatures. A little perfume of a "genteel" variety may be excused. It may be said that the Creator gave charming odors to some of the fairest flowers, and that He would not hinder those others of his dainty flowers—fair femininity—from "laying on" themselves some of the odors He saw fit to bestow upon the lily and the rose.

Well, here is the editorial, without further comment. It's long, but it is worth reading:

### The Bee of Good Taste

DID YOU KNOW, FAIR LADY, THAT HE WILL STING ANYBODY USING PERFUMES?

The trusts, the earthquake, foreign riots and all the rest of the news shall not prevent our protesting occasionally against the dreadful *insistent* perfumes with which the women of to-day disfigure themselves. In public places suddenly an awful faintness comes over the crowd. There is a moment of horror, of gasping, and the dazed mind recognizes another one of those big or little, or yellow or black, or fat or thin women that wear the terrific perfumes.

We are glad to be informed, and to publish here, the fact that the self-respecting honey-bee—that knows everything about *real* perfume—*detests the artificial, hideous, high-smelling product with which women make themselves terrible.*

The intelligent, sane, moral bee likes good, clean flowers. And it likes good, clean human beings. You may go around its hive as much as you please while you are normal and self-

# American Bee Journal

respecting—if you don't bother the combs or the young ones.

But approach the bee-hive with any one of these terrific, high-smelling "odors" or perfumes attached to your person, and the self-respecting bees will pour out and sting you until you leave.

One of our readers informs us that experiment, often repeated, proves absolutely that the bee will not tolerate the insult to flowers, or to womanhood, implied in the wearing of the abnormal and offensive perfumes.

Women, be guided by the wisdom of the bee as you are inspired by that little animal's industry. Be your own selves. Be the natural flowers that Nature made you. Don't allow anybody to persuade you to make yourselves hideous with the perfumes that are a hundred times worse than the noise of a boiler-shop.

You wouldn't go around with a horrible, clanging, banging wash-boiler or beating drum to disturb the people. Then don't disturb them with "perfumes" more vicious and unforgivable than the savage tomtom. Be clean. Throw perfumery away.—*San Francisco Examiner.*

Please Mention Bee Journal when writing advertisers.

## CONVENTION NOTICES.

**Colorado.**—The 27th annual convention of the Colorado State Bee-Keepers' Association will be held at the Chamber of Commerce, Denver, on Tuesday and Wednesday, Jan. 22 and 23, 1907. The convention opens at 10 a.m., Tuesday morning. A good program is being arranged, and all bee-keepers should be present. This is Stock Show week in Denver, and a 1½ fare can be secured from all parts of the State.

Ft. Collins, Colo. G. J. TOMLIN, Sec.

**New Jersey.**—The New Jersey Bee-Keepers' Association will meet at the State House, Trenton, on Wednesday, Jan. 16, 1907, at 10:30 a.m. Addresses will be made by the President, also by Chas. Stewart, foul brood inspector, Sammonsville, N. Y.; H. S. Ferry, J. H. M. Cook, and others. Much attention will be given to the Question-Box. All bee-keepers, and especially ladies, are cordially invited to attend.

W. W. CASE, Pres.  
G. N. WAUSE, Sec.

**Nebraska.**—The annual meeting of the Nebraska State Bee-Keepers' Association will be held in the Experiment Building at the State Farm, Lincoln, Nebr., Jan. 16, 1907. An interesting program on practical subjects has been prepared, and bee-keepers will be benefited by attending.

LILLIAN E. TRESTER, Sec.  
Lincoln, Nebr.

**Our Wood Binder** (or Holder) is made to take all the copies of the American Bee Journal for a year. It is sent by mail for 20 cents. Full directions accompany. The Bee Journals can be inserted as soon as they are received, and thus preserved for future reference. Or we will send it with the American Bee Journal a year—both for \$1.10. Address the office of the American Bee Journal.

## BEE-BOOKS Sent postpaid by George W. York & Co. 334 Dearborn Street, CHICAGO, ILL.

**Advanced Bee-Culture.** Its Methods and Management, by W. Z. Hutchinson.—The author of this work is a practical and helpful writer. You should read his book; 330 pages; bound in cloth, and beautifully illustrated. Price, \$1.20.

**A B C of Bee-Culture,** by A. I. & E. R. Root.—A cyclopedia of over 500 pages, describing everything pertaining to the care of the honey-bees. Contains about 400 engravings. It was written especially for beginners. Bound in cloth. Price, \$1.20.

**Scientific Queen-Rearing,** as Practically Applied, by G. M. Doolittle.—A method by which the very best of queen-bees are reared in perfect accord with Nature's way. Bound in cloth and illustrated. Price, \$1.00; in leatherette binding, 75 cents.

**Bee-Keeper's Guide,** or Manual of the Apiary, by Prof. A. J. Cook, of Pomona College, California. This book is not only instructive and helpful as a guide in bee-keeping, but is interesting and thoroughly practical and scientific. It contains a full delineation of the anatomy and physiology of bees. 544 pages. 295 illustrations. Bound in cloth. 19th thousand. Price, \$1.20.

**Langstroth on the Honey-Bee,** revised by Dadant.—This classic in bee-culture has been entirely re-written, and is fully illustrated. It treats of everything relating to bees and bee-keeping. No apiarian library is complete without this standard work by Rev. L. L. Langstroth—the Father of American Bee-Culture. It has 520 pages, bound in cloth. Price, \$1.20.

**Honey as a Health Food.**—This is a 16-page honey-pamphlet intended to help increase the demand for honey. The first part of it contains a short article on "Honey as Food," written by Dr. C. C. Miller. It tells where to keep honey, how to liquefy it, etc. The last part is devoted to "Honey-Cooking Recipes" and "Remedies Using Honey." It should be widely circulated by those selling honey. The more the people are educated on the value and uses of honey the more honey they will buy. Prices: Sample copy for 2-cent stamp; 50 copies for 70 cents; 100 for \$1.25; 250 for \$2.25; 500 for \$4.00; or 1000 for \$7.50. Your business card printed free at the bottom of the front page on all orders for 100 or more copies.

**Forty Years Among the Bees,** by Dr. C. C. Miller.—This book contains 328 pages, is bound in handsome cloth, with gold letters and design; it is printed on best book-paper, and illustrated with 112 beautiful original half-tone pictures, taken by Dr. Miller himself. It is unique in this regard. The first few pages are devoted to an interesting biographical sketch of Dr. Miller, telling how he happened to get into bee-keeping. About 20 years ago he wrote a small book, called "A Year Among the Bees," but that little work has been out of print for a number of years. While some of the matter used in the former book is found in the new one, it all reads like a good new story of successful bee-keeping by one of the masters, and shows in minutest detail just how Dr. Miller does things with bees. Price, \$1.00.

**"The Honey-Money Stories."**—A 64-page-and-cover booklet, 5¼x8½ inches in size, printed on best quality paper. Many short, bright stories interspersed with facts and interesting items about honey and its use. The manufactured comb honey misrepresentation is contradicted in two items, each occupying a full page, but in different parts of the booklet. It has in all 33 fine illustrations, nearly all of them being of apiaries or apiarian scenes. It also contains 3 bee-songs, namely, "The Hum of the Bees in the Apple-Tree Bloom," "Buckwheat Cakes and Honey," and "The Bee-Keepers' Lullaby." This booklet should be placed in the hands of everybody not familiar with the food-value of honey, for its main object is to interest people in honey as a daily table article. Price, 25 cents, or 3 copies for 50 cents.

# Some Good Clubbing Offers

A good many subscriptions to the American Bee Journal should be renewed at once. We wish to call special attention to the clubbing offers below, which we are sure will commend themselves. **The American Bee Journal one year and your choice of one of the following:**

# ADVANCED BEE-CULTURE!

One of the most difficult tasks of my life is that of writing an advertisement of **ADVANCED BEE CULTURE**. Be as modest as I can, it still smacks of egotism—sounds like a parent praising his own child. If the book had been written by some other man, the writing of an advertisement would be comparatively easy. However, even at the risk of laying myself open to ridicule, of becoming a laughing-stock, I am going to *forget for once* that I am its author and publisher, and write as though of another's work.

When 18 years old I visited an apiary in swarming-time; saw bees hanging in great golden-brown clusters from the swaying boughs of the old apple-tree; saw the snowy white combs growing as by magic; saw the waxen cells filled with nectar, and inhaled that *sweetest* of all perfumes—the odor from a bee-hive in harvest time. I was filled through and through with enthusiasm. Here was a business that was most truly

## The Poetry of Life.

I was that day born a bee-keeper. There was no longer any doubt as to what should be my life occupation. I at once began buying bee books and journals, and visiting bee-keepers, and studying the business from every possible standpoint. It was six years later before I was able actually to engage in the business, but I then possessed as thorough a theoretical knowledge of bee-keeping as does a young physician of medicine when he begins to practise.

All this was 30 odd years ago; and, since then, I have

## Run the Whole Gamut

of bee-keeping, time and time again. I have practised all sorts of methods for artificial increase. I have battled with the difficulties of natural swarming; I have produced tons and tons of comb honey; have tried my hand at extracted-honey production; I have reared and sold thousands and thousands of queens; I have exhibited bees and honey for 15 consecutive years at from one to half a dozen State fairs. I have wintered bees in all sorts of ways, outdoors and in, in cellars and buried in clamps; I have attended nearly all of the conventions of a National character;

## Visited Hundreds Bee-Keepers

in their homes, scattered from ocean to ocean and from the lakes to the gulf. I have read all the books and journals; for nearly twenty years I have published the *Review*, enjoying the confidence and correspondence of bee-keepers scattered all over this country; in short, I have been a wide-awake, enthusiastic, practical, actual, work-a-day, bread-and-butter bee-keeper all of these years, making a living for myself, wife, and little ones, *out of bees*.

**ADVANCED BEE CULTURE** is the

## Ripened Fruit

of these years of varied experience; it is the crowning effort of my life. I look upon it as the best piece of work that I have ever done.

or, perhaps, ever *will* do. It is written from a bread-and-butter standpoint. It teaches how to make a living—yes, more than that,

## Make Money Out of Bees.

From all these sources I have mentioned, from my own experience, and that of the men with whom I have associated, I have described the most advanced, the *best* methods, of keeping bees for *profit*. I begin at the opening of the year, and go through the season, step by step, touching briefly but clearly and concisely, upon all of the most important points, showing their relationship one to the other, and how, joined together, they make a perfect whole. If I could have had this book twenty years ago, and followed its teachings, I might now have

## Been a Rich Man.

I say it fearlessly, because I *know that it is true*, that no practical bee-keeper can afford not to read it. The courage, enthusiasm, and inspiration alone will be worth more to him than the cost of the book, to say nothing of the more practical instructions. Many a man fails from a lack of these very useful qualities, and the perusal of **ADVANCED BEE CULTURE** will do much to help in this respect.

One more point: A dozen years ago I took up photography as a hobby, as a pastime. I have studied it just as you have studied bee-keeping. I have read journals and books on the subjects, attended the conventions, etc. I have lugged a large camera along with me all over the United States and Canada, and used it with loving care. **ADVANCED BEE CULTURE** contains the

## Gems of this Collection

of all these years—a collection that is simply unapproachable in the line of apiculture.

The book is beautifully printed with clear, large type, on heavy enameled paper. It is bound in cloth of a bluish drab, and the front cover embellished with a green vine of clover, a

## Bee of Gold

sipping nectar from the snowy-white blossoms of the clover. Taken all in all, it is a beautiful book.

If the advertising that I have done in the past has not convinced you that you need the book, then the fault is in the *advertising*; and, for this once, I have cut loose and said just what I think of the book—I may never do it again.

Price of the book, \$1.20, or the *REVIEW* one year and the book for only \$2.00.

## Special Offer.

Just at present I am offering all of the back numbers of this year free to all who send \$1.00 for 1907. In other words, you can get the *Review* for 1906 and 1907, and this book for only \$2.00! I know of no way in which you can get so much helpful, practical, valuable apicultural information for so little money.

## Langstroth on the \*\*\* Honey-Bee

Revised by Dadant—Latest Edition.

This is one of the standard books on bee-culture, and ought to be in the library of every bee-keeper. It is bound substantially in cloth, and contains over 500 pages, being revised by those large, practical bee-keepers, so well-known to all the readers of the *American Bee Journal*—Chas. Dadant & Son. Each subject is clearly and thoroughly explained, so that by following the in-

structions of this book one cannot fail to be wonderfully helped on the way to success with bees.

The book we mail for \$1.20, or club it with the *American Bee Journal* for one year—both for \$2.00; or, we will mail it as a premium for sending us **THREE NEW** subscribers to the *Bee Journal* for one year, with \$3.00.

This is a splendid chance to get a grand bee-book for a very little money or work.

# Make More Money on Fruit Crops

Everyone who grows fruit, whether a large commercial grower, or one who has only a few fruit trees, a berry patch or a garden, should be interested in knowing how to get the most profit from his crops.

## THE FRUIT-GROWER

ST. JOSEPH, MISSOURI

is the only magazine in America which is devoted exclusively to the interest of those who grow fruit. It is handsomely illustrated, and contains from 38 to 56 pages each month. It tells all about fruit of all kinds—and nothing but fruit—how to market, how to pack, cultivate, spray, prune, how to MAKE MORE MONEY from your crops. Sample copy sent free. Regular price is a dollar a year, and each subscriber is entitled to a choice of any one of our series of ten Brother Jonathan Fruit Books—the best in existence.

### Three Months Free

We are so confident The Fruit-Grower will please you that we will send it to you three months absolutely free. If, after three months, you like the paper, we will make you a special offer for twelve months more. If you don't like it, notify us and we will take your name off the list. The three months will cost you nothing. We offer cash prizes for new subscribers—write for particulars. Write your name and address in blanks below; mail to The Fruit-Grower Co., Box 15, St. Joseph, Mo.

I accept your FREE three months' trial offer. At end of three months I will either pay for a year's subscription or notify you to stop paper. In either event there is to be NO charge for the three months' trial.

# American Bee Journal Novelty Pocket-Knife Gold Fountain Pen

All for \$3.00

(This cut is the full size of the Knife.)

## NOVELTY POCKET-KNIFE

(Name and Address on one side—Three Bees on the other side.)

Your Name on the Knife.—When ordering, be sure to say just what name and address you wish put on the Knife.

The Novelty Knife is indeed a novelty. The novelty lies in the handle. It is made beautifully of indestructible celluloid, which is as transparent as glass. Underneath the celluloid, on one side of the handle is placed the name and residence of the owner, and on the other side pictures of a Queen, Drone, and Worker, as shown here.

The Material entering into this celebrated knife is of the very best quality; the blades are hand-forged out of the very finest English razor-steel, and we warrant every blade. It will last a life-time, with proper usage.

Why Own the Novelty Knife?—In case a good knife is lost, the chances are the owner will never recover it; but if the "Novelty" is lost, having name and address of owner, the finder will return it. If traveling, and you meet with a serious accident, and are so fortunate as to have one of the "Novelties," your POCKET-KNIFE will serve as an identifier; and, in case of death, your relatives will at once be notified of the accident.

How to Get this Valuable Knife.—We send it postpaid for \$1.25, or club the Novelty Knife and the American Bee Journal for one year—both for \$2.00. (Allow two weeks for Knife order to be filled.)

## SOLID GOLD FOUNTAIN PEN

Finally we have found a good Fountain Pen that is reasonable in price. The manufacturers of this pen say that if you pay more than \$1.25 for other fountain pens, it's for the name.

This pen is absolutely guaranteed to work perfectly, and give satisfaction. The Gold Nibs are 14 kt., pointed with selected Iridium. The Holders are Para Rubber, handsomely finished. The simple feeder gives a uniform flow of ink. Each pen is packed in a neat box, with directions and Filler.

Worker

Queen

Drone

We mail this Gold Fountain Pen for only \$1.25, or for \$2.00 we will mail it and the weekly American Bee Journal for a whole year.

Sample copy of the American Bee Journal free; trial trip of three months (13 copies) for 20c; regular yearly price, \$1.00. Address all orders to

Will be found in

The

**American Bee - Keeper  
for 1907**

It is profusely illustrated and enlarged, and contains only articles of the most practical as well as scientific nature. A special corps of the best writers has been engaged. The editors are Harry E. Hill and Arthur C. Miller, than whom there are no more practical or experienced bee-keepers in this country. We have published the American Bee-Keeper continually and regularly since 1890.

Regular subscription price, 50 cents a year. One year to new subscribers, 35 cents; three years for \$1.00.

Send for sample copy and our new illustrated price-list of **BEE-SUPPLIES OF ALL KINDS.**

Guaranteed highest quality at lowest price. Address,

**THE W. T. FALCONER MFG. CO.**  
JAMESTOWN, N. Y.

[Established 25 years.]

**Honey and  
Beeswax**

CHICAGO, Dec. 7.—There is the usual dullness in the honey-trade at this date owing to most of the retailers having stocked up sufficiently to carry them over the holidays; but the stocks in the hands of the trade generally are below the normal; hence prices are firm at 15@16c for No. 1 to fancy white comb, with off grades at 1@2c less; amber grades dull at 10@12c. Extracted white, firm at 8c for clover and basswood; ambers, 6½@7½c per pound. Beeswax, 30c.  
R. A. BURNETT & CO.

KANSAS CITY, Dec. 28.—The demand for comb honey is only fair with market well supplied; market is almost bare of extracted, however, and the demand very good. We quote: Fancy white comb, 24-section cases, \$3.25; No. 1, \$3.00; Extracted, white, per pound, 7½@8c; amber, 7@7½c. Beeswax, per pound, 25 cents.  
C. C. CLEMONS & CO.

CINCINNATI, Nov. 8.—The market on comb honey seems to be a little quiet; No. 1 sells wholesale for 14½c; retail by the case, 16c. Extracted firm; light amber in barrels, 6c; in cans, 7c; white clover, 8½c. Beeswax, 30c.  
C. H. W. WEBER.

PHILADELPHIA, Nov. 8.—While the supply of comb honey is equal to the demand, large quantities of comb honey having arrived in the market in the last few days, the price still remains high. The outlook, however, is that when the season advances and the bee-keepers ship more of their crop to the market, the prices will be a little weaker. We quote: Fancy white comb honey, 16@18c; No. 1, 14@15c; amber, 11@13c. Fancy white extracted, 7½@8½c; light amber, 6½@7c.  
We are producers of honey and do not handle on commission. WM. A. SELSER.

NEW YORK, Dec. 3.—Comb honey is in good demand, and No. 1 and fancy white stock seems to be pretty well exhausted. Buckwheat is in sufficient supply, also off grades of white, to meet all demands, but there is no overstock as yet. We quote fancy white at 15c; No. 1 at 13@14c; No. 2 at 12c; buckwheat and amber at 11c per pound, according to quality and style of package. Extracted is firm at unchanged prices. California white sage, 8c; light amber, at 7@6½c; buckwheat, 6@6½c. Beeswax steady at 30c.

**C. H. W. WEBER** CINCINNATI  
... OHIO ...

Office and Salesrooms, 2146-48 Central Ave. Warehouses, Freeman and Central Aves.

DENVER, Oct. 20.—All desirable lots of white comb honey in double-tier cases have now been shipped out of this State, leaving only a few cars of single-tier cases. The quality of this year's crop was fine, better than for several seasons. We quote our local market as follows: Strictly No. 1 white, per case of 24 sections, \$3; ordinary No. 1 and off grade, \$2.50 to \$2.75. Extracted, white, 6¼@7¼c. Beeswax, 24c for average yellow delivered here.  
THE COLO. HONEY-PRODUCERS' ASSN.

CINCINNATI, Dec. 7.—The honey market is in a healthy condition, particularly extracted honey, the demand being better than one year ago. This is probably due to the excitement among those holders who are trying to inflate the prices. We quote amber extracted honey in barrels at 6@7c, according to the quality. Fancy table honey in barrels and 60-lb. cans at 8@9c. The demand for comb honey has decreased, somewhat, owing to the season of the year when the sale of that article suffers. Our prices of fancy white comb honey, in a wholesale way, is 15@16c. Choice yellow beeswax, 30c, delivered here.  
THE FRED W. MUTH CO.

INDIANAPOLIS, Jan. 3.—comb honey is not plentiful, but demand is slack. Fancy white comb brings 16@17c; No. 1 white, 14c; amber, 12@13c. Best grades of extracted honey bring 8@9c; amber, 6@7c. Good average beeswax sells here at \$33 per 100 pounds.  
WALTER S. POWDER.

TOLEDO, Nov. 30.—The market on comb honey remains about the same as last quotations, but has been coming in much more freely, as bee-keepers seem to be very anxious to get rid of their stock. Fancy brings in a retail way 16c; extra fancy, 17c; No. 1, 15c; buckwheat, 15c. Extracted white clover in barrels brings 7@7½c; cans the same. Beeswax, 26@28c.

## The Bee-Hive Clock

A \$4.00 CLOCK FOR \$2.50 ... With the  
American Bee Journal 1 Year—  
Both for Only \$3.00

We have originated and had made specially for our readers, a bronzed-metal Clock, called "The Bee-Hive Clock." It is 10¼ inches wide at the base, 9¾ inches high, and deep enough at the base to stand firmly on a mantel or elsewhere. It is a beautiful piece of work, and would be both ornamental and very useful in any house, and particularly in a bee-keeper's home.

The Clock part itself is warranted for 3 years to keep good time. So it is no plaything, but a beautiful and needful article for everyday use.

Clocks like "The Bee-Hive Clock" usually sell in the stores at from \$4.00 to \$5.00 each, but having them made for us in quantities enable us to offer them at \$2.50 each by express, or with the American Bee Journal a year—both for only \$3.00. Either Clock or Journal would make an ideal gift.

### How to get "The Bee-Hive Clock" FREE

Send us 5 New Subscribers to the Weekly American Bee Journal for one year, at \$1.00 each, and we will send you this beautiful "Bee-Hive Clock" FREE (excepting express charges). Or, send us 4 New Subscribers (at \$1.00 each) and 50 cents—\$4.50 in all. Or, 3 New Subscribers (at \$1.00 each) and \$1.00—\$4.00 in all. Or, 2 New Subscribers (at \$1.00 each) and \$1.50—\$3.50 in all.

Only \$2.50, f.o.b. Chicago, by Express.  
Weight, with packing, about 4 pounds.

### What Dr. Miller Thinks of the Bee-Hive Clock

Busily ticking away, in the room where I am sitting, stands a genuine bee-keeper's clock (please understand that the word "genuine" belongs to the clock and not to the bee-keeper) or, as the legend upon the clock has it, "The Bee-Hive Clock." I don't know

whether the idea of getting up such a clock was conceived in the brain of the Editor of the American Bee Journal, or whether he got it elsewhere, but the wonder is that such a thing was not thought of long before.

Setting aside all idea of its association with the business of a bee-keeper, there is a peculiar appropriateness in having the minutes and the hours "told off" in a case representing the home of the busy little workers. The glance at the clock, with its ceaseless tick, tick, tick, can not fail to remind one that the flying moments must be improved now or be forever lost, and that suggestion is reinforced by the thought of the never ceasing activity of the little denizens of the hive, always busy, busy, busy, working from morn till night and from night till morn, working unselfishly for the generations to come, and literally dying in the harness.

Let us be thankful that the form of the old-fashioned straw hive or skep was adopted, and not that of any modern affair, patented or unpatented. The latter smacks of commercialism, but the former of solid comfort, for no other form of hive has ever been devised that contributes so fully to the comfort and welfare of a colony of bees as does the old-fashioned straw-hive. It appeals, too, to one's artistic sense as can no angular affair of more modern times. As an emblem of industry, artists have always used—probably always will use—the old straw skep.

Thanks, Mr. Editor, for furnishing us a time-keeper so appropriate for all, and especially for bee-keepers.  
C. C. MILLER.

"It is continuous advertising that impresses the public with the stability of a firm."

## Trade Notes. The A. I. Root Co., Medina, Ohio.

### Photographic Competition

We are pleased to announce another series of prizes for the best photographs submitted to us, as described below, in two series, American and Foreign, under the following conditions:

**FIRST.**—The competition opens January 15th, and closes October 1st, 1907. All photographs intended for this competition must be in our hands by the last-named date.

**SECOND.**—Competition for these prizes is limited to bee-keepers or some member of the family. Entries may be made for as many different classes as may be desired.

**THIRD.**—A photograph entered in one class can not be entered in any other class.

**FOURTH.**—Each photograph should be marked on the back with the name and full address of the sender, and the class in which it is entered. This is important.

**FIFTH.**—In judging the photographs, the general appearance, neatness, etc., of the apiary, or exhibit, or yard, will be taken into consideration. Photos may be sent unmounted. We rather prefer them this way, and in a solio or reddish-brown if possible. However, send such as you can get most easily.

**SIXTH.**—With each of the photographs submitted we would like a brief statement of the conditions under which the apiary was photographed or honey produced, or similar information regarding the photograph. This should be limited to about one hundred words.

**SEVENTH.**—All photographs and correspondence regarding the same should be addressed to Advertising Department, GLEANINGS IN BEE CULTURE, Medina, Ohio.

**EIGHTH.**—We reserve the right to limit the number of awards or withhold any award if no photo worthy is entered in the class.

#### AMERICAN COMPETITION (Including Canada and Mexico)

AND

#### FOREIGN COMPETITION

The following are the classes in which entries may be made:

**CLASS A.**—Photographs of any apiary in village, town, or city.

**CLASS B.**—View of an apiary not exceeding six hives in town or city.

**CLASS C.**—Apiary in town or country of not less than six hives or more than fifty hives.

**CLASS D.**—Apiary in town or country of fifty hives or more.

**CLASS E.**—Photograph of comb honey produced by a single colony of bees; not less than ten sections, and this preferably in plain sections.

**CLASS F.**—Photograph of a bee-keeper's home, showing some view of the apiary if possible. The apiary need not be prominent in the picture, however.

**CLASS G.**—Photographs of a crop of honey from any number of colonies, six or more.

**CLASS H.**—Photographs of any apian exhibit of bees, supplies, or honey taken at fairs or shows of any kind.

**CLASS I.**—Photographs of any work in the bee-yard, such as hiving swarms, extracting, or any other operations with the hive.

**CLASS J.**—Photographs of any other subject relating to bee-keeping not classified above.

	Value, Postpaid
<b>FIRST.</b> —One leather-bound "A B C of Bee Culture," 1907 English edition, or cloth-bound French or German.....	\$2.00
<b>SECOND.</b> —One-half leather "A B C of Bee Culture," 1907 English edition....	1.75
<b>THIRD.</b> —One "How to Keep Bees" and any two Swarthmore books.....	1.50
<b>FOURTH.</b> —One full cloth-bound "A B C of Bee Culture," 1907 English edition....	1.20
<b>FIFTH.</b> —One "How to Keep Bees," by Anna Botsford Comstock.....	1.10
<b>SIXTH.</b> —No. 1 bee-veil, all silk.....	.80
<b>SEVENTH.</b> —No. 2 bee-veil, silk face.....	.50
<b>EIGHTH.</b> —One illustrated book, "Bee Culture in Foreign Countries".....	.50
<b>NINTH.</b> —One Bee Model, Queen.....	.50
<b>TENTH.</b> —One Bee Model, Drone.....	.50

Ten prizes are offered for each class: Ten for Class A, Class B, Class C, Class D, etc.—one hundred prizes for American contest, and one hundred prizes for the Foreign contest; two hundred in all if that number of entries are received, the prizes offered being identical for each class for the American competition and for the Foreign.

If the winner of any certain prize already has the prize offered, we will, on request from him, furnish a selection of other items from our catalogs, of equal value.

### Danzenbaker Prizes

It is to be regretted that so many bee-keepers are satisfied to produce year after year a very ordinary grade of honey as regards its appearance, when by a little more care, and having more suitable fixtures, and by taking the honey from the hive at just the right time, a much larger percentage of "fancy," or "extra fancy" honey could be produced, which would sell at a much higher price. The experience of honey-merchants generally is that there is no difficulty in disposing of large stocks of fancy or extra fancy, even when the market is dull. It is the inferior grades that suffer most at these times. We believe, too, that bee-keepers would be very much better satisfied with their season's work if their best efforts were made to produce a really fine product. To increase further the interest in extra fancy honey, the following prizes are offered for honey produced in Danzenbaker hives during the year 1907, under the following conditions:

**FIRST.**—As above stated, the honey must be produced in a Danzenbaker hive, either the present style or any Danzenbaker hive that has been put out within the last few years. These hives may be had of any dealer in beekeepers' supplies in any part of the country.

**SECOND.**—For Classes 1 and 2 we require a shipment of approximately the amount stated, to be made by the bee-keeper direct to us at Medina. After the prizes have been awarded the honey entered for competition in Class 1 or 2 will be held subject to the instructions of the producer. We will sell it at 5 percent commission, or we will ship it to

any point direct by freight or express. There being good honey markets in our immediate vicinity, such as Columbus, Cincinnati, Cleveland, Buffalo, and Pittsburg, it can be disposed of without difficulty at good market prices, and the shipper will not have to lose a good market by shipping it here. Neither the honey awarded a prize nor that which obtained no prize is to be our property, but will be sold subject to the instructions of the producer who sends it to us. We are interested in inspecting it to award the prizes.

**THIRD.**—For all honey submitted for prizes we must have a definite statement from the producer regarding the conditions under which it was produced, whether a light or heavy flow of honey, how the colony was handled, how many colonies in the yard, from what source produced, etc.

**FOURTH.**—For Classes 3, 4, and 5, we must, in addition to the above report, have the signature of two witnesses, certifying to the correctness of the report. If the party who sends us the report for the competition is well known to us we shall not require these witnesses. References may be given instead of the signature of witnesses if desired. All parties intending to compete for these prizes should send for blanks which we will furnish, on which the report may be made out.

**FIFTH.**—It will be noticed in the last three classes, three to five inclusive, that it is not at all necessary to send us the honey—all we require is a report.

**SIXTH.**—We reserve the right to limit the number of awards in each class, or to make no awards in a class if there are no satisfactory entries for the same.

**SEVENTH.**—No contestant will be awarded more than one prize in each class, but may make two entries if desired—one in Class 1 or 2, and another in Class 3, 4, or 5.

The classifications for the prizes are as follows:

**CLASS 1.**—For best shipment of 200 lbs. of comb honey in Danzenbaker sections.

**CLASS 2.**—For best case of comb honey in Danzenbaker sections.

**CLASS 3.**—For best report of yield from single colony in Danzenbaker hive.

**CLASS 4.**—For best report of yield from five colonies in Danzenbaker hives.

**CLASS 5.**—For best report of general results from use of Danzenbaker hive.

For each class there will be ten prizes as follows:

<b>FIRST.</b>	—\$10.00.
<b>SECOND.</b>	—\$7.00.
<b>THIRD.</b>	—\$5.00.
<b>FOURTH.</b>	—\$2.00.
<b>FIFTH TO TENTH.</b>	—\$1.00 each.

This is the time to decide to enter this competition. No matter where you live, whether in the United States or elsewhere, you can certainly find one class in which you can make an entry; and as there are ten prizes in each class, we believe that no one will be greatly disappointed in the results unless it is ourselves, and we hope that we shall not be, but see a large number of entries. Even if you fail to get a prize, you will doubtless have increased the value of your own product by your efforts to produce some big results or an extra quality of honey.

(Entered at the Post-Office at Chicago as Second-Class Mail-Matter.)

## Editorial Notes and Comments

### Ordering Government Publications

We have received the following relating to the ordering of publications issued by the Government at Washington, D. C.:

A mistaken idea seems to have gained currency among those making application for Government publications, namely: that the authors of publications should be addressed personally, whereas all requests for such publications as are distributed free by the Department of Agriculture should be addressed to the Honorable Secretary of Agriculture; or, in case of special publications, to the chief of the bureau under whose direction the publication was prepared. Those apicultural bulletins which may be distributed free can be obtained by addressing letters: *Bureau of Entomology*, adding the words *Apiculture* and also *United States Department of Agriculture*. Publications to which a price has been attached should be obtained directly from the Superintendent of Documents, Government Printing office, Washington, D. C.

FRANK BENTON.

### Educating Consumers on Honey

We have often urged our readers to write something on honey and its value as a food, for their local newspapers. Quite a number have done so, and have sent us copies after publication. Dr. F. D. Clum, of Columbia Co., N. Y., has done something in this line, and wrote us as follows concerning it, under date of Jan. 4, 1907:

EDITOR YORK:—It may interest you to learn that the largest and most successful apiarist in this county is Mr. James McNeill. He owns nearly 500 colonies of bees, nearly 200 of which he has in an out-apiary on my land.

In supplying the local trade with honey it was found that the great majority of people knew so little about it that they raised "a great hue and cry" about the honey being impure, because it granulated from effects of cold. To counteract this, I wrote a few simple facts regarding honey, which the editor

of our leading county paper gladly published, free of charge, in both his daily and weekly edition. I think if the bee-keepers throughout the United States would publish similar communications in the local papers, it would greatly increase the sale and use of honey.

I enclose herewith the article referred to.

Yours very truly, F. D. CLUM, M. D.

As what Dr. Clum has written is among the best productions of its kind that we have seen, we reproduce it here in full, so that all may have a clear idea of the kind of honey-information that should be placed before the people if we would have them use more honey. Here is what Dr. Clum wrote, and had published in the Hudson, N. Y., Gazette:

#### INTERESTING FACTS OF HONEY.

The production of honey in this county and State is on the increase, and under modern methods has developed into a large business, during the last few years, and yet the general public know but little more about honey than the fact that it is made by bees, and is good to eat. They think "honey is honey"—all just alike—but this is a mistake.

How many people know that honey has as many flavors as the flowers from which it comes? or that honey may be as colorless as water, or as dark as black molasses? Honey should never be kept in a cellar, and yet the average housekeeper is apt to keep it there. The majority of people call all liquid honey "strained honey," while there is no such thing on the market to-day. The old-time "strained honey" was obtained by crushing the comb, bees, pollen and honey together, then straining the mixture through a cheesecloth. This wasteful, disagreeable method is not practised to-day by any up-to-date bee-keeper who produces honey for market. Like the old straw-skep, it has long since been abandoned.

The liquid honey on the market to-day is called "extracted honey." It is a much finer and better article than the strained honey of our grandfathers. Extracted honey is taken from the comb by centrifugal force without destroying or injuring the comb. Many people prefer to buy honey in the comb

because it looks pretty, but the pure extracted honey is really the most wholesome and nutritious. The comb, when melted, is called beeswax, and it not only has no nutritious value as food, but is indigestible.

All liquid honey, if strictly pure, will sooner or later become cloudy, granulated and thickened, and if it becomes solid this is one of the best proofs of its purity; and yet, the great majority of the public are not aware of the fact, and think because the honey looks "sugary" that it is adulterated. It is a very serious matter to produce or sell adulterated honey, and those who condemn a man's honey as spurious, usually do not know what they are talking about; they are not familiar with honey.

Those who buy extracted honey in a candied or solidified state may rest assured that they are getting a strictly pure article. Sugar syrup or glucose, while it may thicken from effects of cold, will not become solid like pure honey.

Honey, both comb and extracted, should be kept in a dry room as near summer temperature as possible. The mercury should not fall below 65 degrees Fabr. if it is desired to keep the honey in perfect condition; but honey that is granulated and has become thick and solid from the effects of cold, can easily be made liquid again by placing the vessel containing it in warm water and slowly heating it over a fire. Some people heat and liquefy a small quantity of honey in this way whenever they desire to use it, and if care is taken that the water does not boil, the honey thus liquefied has the same delicate flavor as when first removed from the hive.

Certain flavors do not suit all tastes, and it is possible to find honey that has an unpleasant taste to certain people; and then, again, comb honey may acquire a disagreeable flavor by being kept in a damp, musty cellar, and be called spurious when strictly pure. The Government has three honey and bee inspectors in the State of New York, and if any one in this State purchases honey which he thinks impure, let him make a complaint, and if it is a just one, the producer and seller of the impure honey will find that under the new pure food law there are heavy penalties to pay, or imprisonment.

Many hundred years before sugar was known, honey was the chief sweet used by the people, and it would be greatly to the health of the present generation if honey could be restored to its former place as a common article of diet, as it is the most wholesome and delicious of all sweets, and contains the most delicate of all flavors—that of the flowers from which the nectar is taken.

F. D. CLUM, M. D.

Perhaps some may say, "O I can't write anything as good as that!" Well, then try to have Dr. Clum's article reprinted in your local newspaper. Start by saying, Dr. F. D.

# American Bee Journal

Clum, one of New York State's physicians, writes as follows in the Hudson, N. Y., Gazette: Then let his article follow.

All bee-keepers need to "get busy" in this way, and help not only themselves, but those who would be benefited in their health by eating honey as a daily food.

## Starting New Bee-Papers

Occasionally we have remarked in these columns that we thought it was very unwise to start any more new bee-papers. At the same time we could easily see that some people imagined we spoke because of a jealous feeling on our part—as if the American Bee Journal feared any more competition. The fact was, we knew exactly what we were talking about, having had a good many years' experience in the bee-paper publishing line, and the "other fellows" were talking or thinking "through their hats."

To show that we are not alone in our views

concerning this matter, we quote from an editorial in the December Bee-Keepers' Review, written by W. Z. Hutchinson, who also knows what he is saying when he puts himself on record in the following:

The plain fact is that the field of apicultural journalism is now pretty well covered, and a new journal, to succeed, should need to be *different* from the others, have an editor of most decided ability, and "barrels" of money. It is true I started the Review 20 years ago, with neither the money nor the experience, and made a success of it; but there were a number of peculiar factors in the case that I won't take space to discuss. I'll say this, however, if I should sell the Review now for \$5000, I would not, with that amount of capital, and my 20 years of experience, think of such a thing as starting another journal. . . . The same amount of money, time and energy, put into straight honey-production, would bring a much larger profit.

The occasion of the above utterance by Mr. Hutchinson, was the announcement that the Rural Bee-Keeper (published for about 2 years by W. H. Putnam, of Wisconsin) had recently been transferred to the American Bee-Keeper.

Von Hruschka and the Honey-Extractor are thus mentioned in a "Stray Straw" in Gleanings in Bee Culture:

Major von Hruschka, the inventor of the honey-extractor, born in Moravia, was an officer of the Austrian army at Legnano, Italy. His leisure was occupied with bee-keeping, and one day he sent his little boy to the house with a comb of honey on a plate in a hand-basket. The boy whirled it about to get rid of robber-bees. The lower side of the comb was emptied, and the honey-extractor was born. After the peace of 1866, von Hruschka left the army, lived a while at Dolo, and then at Venice, where he ran a big hotel. This swamped him financially, and in May, 1888, he died a poor man, forgotten by most bee-keepers.

This little tribute is to awaken in the minds of the younger members of the fraternity a feeling of warm regard for one to whom we owe so much.

Mr. J. L. Patterson, one of the "Bee Journal Family," had one of the most interesting exhibits at the Fair, held in Augusta, Ga., the past fall. He is one of the most enthusiastic and up-to-date apiarists of the Savannah valley, and had in his exhibits some very fine honey in the comb, as well as extracted honey and beeswax. He was awarded two first prizes for these exhibits, which carried with them a purse of \$20. The honey was of the best and finest ever seen in that locality, and was the occasion for much favorable comment during the week. So a local newspaper reported.

Mr. J. T. Hillery, of Columbus, Ohio, when renewing his subscription to the American Bee Journal for 1907, enclosed these two stanzas:

Enclosed you will find a dollar—  
My renewal for "A. B. J.;"  
"I can not bear to lose" it,  
For it cheers the lonely way.

And when we have a poor season  
Like Nineteen-Hundred-and-Six,  
The "A. B. J." encourages us  
To press on and put in "best licks."  
J. T. HILLERY.

**The Apiary of Fred Hoffman.**—When sending the photograph of his apiary, which is shown on the first page, Mr. Hoffman wrote thus:

I enclose a snapshot of a corner of my "beeorchard." This is my third year, and I have 20 colonies. We have a good country for bees, as there is a great deal of white clover. The hardest part is to winter bees here. I had them up-stairs one winter, and also have a small bee-house outside. I could not see any difference in their wintering.

I have had many useful hints from the American Bee Journal. FRED HOFFMAN.

**Amerikanische Bienenzucht,** by Hans Buschbauer, is a bee-keeper's handbook of 138 pages, which is just what our German friends will want. It is fully illustrated, and neatly bound in cloth. Price, postpaid, \$1.00; or with the American Bee Journal one year—both for \$1.75. Address all orders to this office.

**San Antonio Photograph.**—We have some of the San Antonio convention photographs, showing over 100 of those present at the National convention. We are sending them out in mailing-tubes at 60 cents each, postpaid. Send orders to the office of the American Bee Journal.

## Miscellaneous News-Items

### Bee-Keeping in Germany and Spain.

—C. B. Chevalier, of Maryland, sends the following clipping taken from the Philadelphia Press for Nov. 7, 1906:

Germany has 1,910,000 colonies of bees, which furnish 20,000 tons of honey in a year; while Spain comes second as a producer of honey among European countries, with 1,690,000 colonies and 19,000 tons of honey.

**A Misapprehension.**—We find the following in a recent issue of the American Bee-Keeper:

"The editor of the American Bee Journal refers to the American Bee-Keeper as 'a somewhat obscure publication!'"

No such reference was made in these columns, Mr. Hill. The reference was to a document of the United States House of Representatives, which is so obscure that very few probably know of its existence. It is to be hoped that the American Bee-Keeper has a much larger circulation, and that it is more carefully read than will be the document referred to.

**The Minnesota Bee-Keepers,** it seems, divided into two organizations at their meeting early in December, 1906. We have received the following concerning the matter:

The inevitable has happened, and the Minnesota Bee-Keepers' Association, which has had an existence for 18 years, has been divided, and the old members have formed a new society, which will be called "The Minnesota State Bee-Keepers' Society."

The old constitution, under which we have been working for years, did not take into ac-

count the ambitions of individuals, and therefore, did not guard against any such who wished to dominate the Association.

At the opening of our meeting, Dec. 5, an element which for 3 years has been trying to turn the Association into commercial channels, got control of the meeting, and a resolution was then passed to admit proxy voting, and the deed was done. The old officers and members withdrew in a body, and formed a new society; and while we do not have the old name, we do have most of the old members, and we will have peace in the future.

The Minnesota State Bee-Keepers' Society was organized Dec. 6, 1906. It is affiliated with the Minnesota State Horticultural Association, and voted to join the National Bee-Keepers' Association in a body. Its objects are the promotion of scientific bee-keeping and such legislation as may be of benefit to the bee-keepers of Minnesota. It has 30 charter members, and every prospect of building up into a strong and useful society.

The officers elected for the coming year are: L. D. Leonard, President; Scott LaMont, 1st Vice-President; J. M. Doudna, 2d Vice-President; Rev. Chas. D. Blaker, Minneapolis, Sta. F, Secretary; Mrs. Helen G. Acklin, Rev. J. Kimball, and J. E. Stryker, Executive Committee; and Mrs. W. S. Wingate, Treasurer. L. D. LEONARD.

**The Apiary of John Stevens,** of England, is shown on the first page this week. It was taken from a souvenir postal card. When sending it, Dec. 3, 1906, Mr. Stevens wrote as follows:

I am sending a photograph of my home apiary, for many recent improvements in which I have to thank the American Bee Journal.

The past season was very fair in this locality, my own "take" being the best I have had in the last 6 or 7 years.

JOHN STEVENS.

### Drones' Flight—Building Drone-Cells

BY DR. C. C. MILLER.

When a man puts up as good a fight as does the Afterthinker on page 950 (1906), it's hard for me to repress a feeling of sympathy, and certainly there is more or less an inclination to capitulate to the enemy. But, as the enemy says, "cause a pretty important one," and I musn't weakly give way to sentiment. So here's at you again, O mine enemy, the Afterthinker!

"Neither swiftness nor numbers avail; and the queen does not lead off with any great swiftness." I think that statement has the merit of originality. So far as I remember, others have held the opposite view. But if you know you're right and they are wrong, Mr. Hasty, your word goes a long ways with me. Only I'd kind of like to know how you know.

"The drone that wins is *the one that gets ready first.*" That's a new one, too. Not so very unlikely, though; for the one that's first ready is likely to start first. Let us accept, then, that speed doesn't count, nor numbers; only being ready first. Remains for you to satisfy the court, Mr. Hasty, that an only son will be ready sooner than any one of a large family of brothers. "Among plains-cattle the bull that can conquer in fight wins." Sure; but then you know that if that same bull be stall-fed he'll not conquer in fight. Doesn't pampering tend to loginess rather than promptness in readiness?

Without stopping to inquire how the answer might affect either or both sides, it might not be irrelevant right here to inquire whether in reality there is any shortage of rations on account of the large number of male members in the family; in other words, at the time when drones are likely to be in demand, have you any proof, Mr. Hasty, that there is not ready for each and every drone all and more than he is willing to eat?

"Now, Dr. Miller and his nice little square of comb," etc. Who said anything about "square" of comb? Did you never hear of patching comb by cutting out circular pieces with a cake-cutter? Pray, where, in that case, would be your corners for your drone-cells, Mr. Hasty? But I'll be on the square, and admit that I've put in more square than round patches; indeed, I've put in a big lot of the square ones. Then you ask: "How on earth is he going to prevent one drone-cell on each corner of his sliced work?" and before I have time to gather breath to tell how to prevent it, you run right on with 4 drone-cells

on each side and get a Gideon's band of 320 in a yard. Cool of you, isn't it? What made you stop with the corners? Why didn't you, while you were at it, just as well assume that there would be a whole row of drone-cells clear around the patch?

Before I answer your question as to prevention, suppose I ask *you* a few questions: Did you ever put in a square patch of worker-comb in place of drone-comb? And did the bees decorate the corners with 8 drone-cells? Were there 4? Did you ever see one? Did you ever hear of one?

While the stenographer is taking down your answer to those questions, I'll answer your question as to what I did to prevent drone-cells when patching. I never did anything. I just put in the patches, and the bees did the rest. And although I put in lots of patches, I do not remember to have seen one single drone-cell as corner-work. And I feel pretty sure that if there had been one I should have noticed it; and just as sure that I would have remembered it. A sealed drone-cell among worker-cells is somewhat conspicuous. Now, it would be just like you to ask why the bees didn't build any drone-cells in those corners; but I'm not obliged to answer that question. Maybe they didn't have room; maybe they're not in the habit of putting in a single odd cell; I don't know; the important thing is that they don't—at least not "in this locality."

You say, Mr. Hasty: "Slicing patches of drone-cells is not very difficult; but getting all the scattered single ones is desperately difficult \* \* \* \*". The work is disagreeable as well as long." That makes me wish very much I could look through some of your hives: I'm sure you'd allow me for that length of time if I came under a flag of truce. For it would be something in the line of a curiosity for me to see single drone-cells scattered about through a hive. I can stretch my imagination far enough to suppose that a colony with a mania for producing drones, if it had all its combs filled with worker-bees, might, in its desperation, try to get a cell or two wherever there was a chance; but I never yet saw a case in which there was any such scattering. You know that G. M. Doolittle advises an inch or two square of drone-comb left in one comb, saying, if I remember rightly, that that will satisfy the bees so they will build no more. And then if you come and look through my hives—I'll let you come without the flag of truce—I'll show you comb after comb, nearly all of my combs, where you'll not find a cell, even with your "specs" on. But some combs have patches in spite of me: holes have in some way got in, and have been filled

with drone-comb, and I've been too negligent to patch them. But a patch or two in each hive is all you're likely to find, with none in the other combs.

I've turned somersaults in my lifetime before this, and it is among the possibilities that the time may come when instead of discouraging drones of poor stock I shall believe in allowing a lot of drones in all but best colonies, and limiting the number in the best; but I'll wait to hear from you again, Mr. Hasty, before embracing that doctrine.

### Fumigating Foul-Broody Combs with Formaldehyde

BY DAVID J. WEST.

On page 884 (1906), the question was asked, "Has fumigation of brood-combs exposed in a tight room ever been tried on foul-broody combs with formaldehyde?" One answer was "Yes, and as a rule not successful." Another answer was, "It will never be a success in an apiary." We have used formaldehyde on foul-broody combs with good success, and have cured many sets of combs of the disease, and, without doubt, now have a hundred colonies on combs that were once affected with foul or black brood.

We have several ways of treating foul brood, but when we wish to use the combs again, we shake the bees into a clean hive on starters for 3 to 5 days, then take out the starters and put in foundation, which will usually free the bees of the disease.

To free the combs of the disease, we stack them 3 or 4 hives high, on a colony that is slightly diseased—so as not to carry the disease farther—with a queen-excluder on to keep the queen in her own hive, and use the combs that season for extracting combs. This saves the good brood, and makes a strong colony, which will clean the combs of the bad brood and fill them with honey. The combs are extracted as often as needed, and, after the harvest are left to be cleaned out by the bees.

Then we place the combs in an airtight box, which holds about 100 combs, and fumigate them from 20 to 40 minutes with water and formaldehyde mixed in equal parts. About one quart of formaldehyde and water is placed in a galvanized kerosene-can, and the gas or steam is led through the spout and a small rubber hose into the box of combs. The kerosene-can is heated by a 2-wick oil-stove, which sends out a lot of steam, and two such arrangements are used at the same time in fumigating the one box of combs. After fumigating the box of combs, the box is left airtight for about 24 hours. Then the combs are taken out and well aired, and put away to use the next season to catch swarms on, or to use for anything we wish.

This way does not always prove a success, but usually does if care enough is taken to give the combs a good fumigating, and the combs are not too awfully bad with disease.

I ought to know something about doctoring foul brood, as we have had foul brood in our county for 8 years. And

my father is a New York State Inspector of bee-diseases, etc. And we have 532 colonies of bees, fall count, which gave us over 10 tons of comb honey this year, which went to market in October. Middleburg, N. Y.

## Native Bee-Keeping in East Africa

BY F. GREINER.

Sauberlich, a missionary, who has been among the negro people of Africa for 18 years, tells in "Die Biene" what he has observed during these years in regard to bee-keeping. The following is an extract:

The African bee is very light in color and slightly smaller than the Italian, and the brown or German bee. As to the stinging propensity, it is about on a par with the latter.

The kind of apiculture I am about to describe is probably nearly as old as the hills. The son learns from the father, and nothing new is added. As in other parts of the world, hollow trees are favorite places for bees to build their combs. The trees being large, and the timber hard, it required much time and expenditure of labor to obtain the sweet, particularly as the negro's tools are very inferior, consisting only of a small ax tied to the helve with a piece of rhinoceros skin.

Although the negro does not economize in time, yet he must have come to the conclusion that it would be an advantage to furnish the bees such hives as would make it easier for him to secure his harvest. Advanced apiculture, therefore, consists in putting out decoy hives, and robbing them when they have become inhabited and are filled.

The manner of making hives is very laborious and the process slow. A saw being unknown, all the cutting is done with the aforesaid ax, and another tool similar to a carpenter's adz, but smaller. The latter is used in hollowing out log-gums, and is made in similar fashion as the ax, tied to the handle by means of rhinoceros or hippopotamus skin.

Soft-wood timbers are naturally preferred by the natives for hive-purposes. The logs are cut in 3-foot lengths, then peeled, and eventually excavated or hollowed out. It requires several days' work to hollow out one hive. At first this work is done roughly, and when in this condition the log-gums are transported to the village. Here they are finished up and made very smooth, inside as well as outside. The cover and bottom are fastened on with wooden pins. It is a most tedious process to work the "boards" out of logs, with the tools described.

A hole about 2 inches square is cut into each hive for an entrance near the center of it, and then it is ready to be put in some tree, often many miles from home. Each hive bears the mark of the owner, and this may be seen from a distance. It is usually recognized by the natives as evidences of ownership. Some of these "bee-keepers" own as many as 200 such hives, of which, however, seldom more than half are occupied by bees.

Two methods are practised to fasten the hives up in the trees. Some prefer to hang them up by means of ropes; others select a favorable spot on two stout limbs, then pin the hive to the tree.

In the putting up of these hives care is taken so to fasten them that neither wind nor quadruped animals can upset them. A certain four-footed animal, the size of a ground-hog, or larger, is very eager for honey and wax, and is apt to visit these hives. As expert climbers it is an easy matter to reach them. They will then upset them if they can, and help themselves to the broken comb, then on the ground. The natives seldom place more than 2 or 3 hives in one tree, generally only one. This work is done in September or October.

Towards the end of October the rainy season commences, and soon the ground is covered with grasses and flowers. The honey season is at hand. Usually the rain occurs at night. There is neither cold nor winds, and the bees work 12 hours uninterruptedly, day after day. After the beginning of this honey season we can see swarms of bees going over our heads every day. Occasionally the attempt is made to hive a swarm, but only about one in 20 will stay. It is difficult to say why this is so.

With the beginning of January the real honey harvest commences; it lasts till July, and immense quantities of honey are stored by the bees. The natives never "tackle" a bee-hive till after sun-down. A bee-hat is unknown among them; it would be useless, anyway, as the face is only a very small part of the vulnerable portion of their bodies. When robbing the hives a torch-light is used, and a large portion of the bees are naturally burned. In consequence many a colony is thus totally ruined. The majority of hives are lowered to the ground by means of ropes before robbing them, and put up again afterward.

When the more distant hives are to be (mal) treated, caravans of from 10 to 20 men and women start out and are many days on their way. The combs are mashed down and put up in barrels and bags, consequently the honey contains many impurities, dead bees, etc. The barrels are of wood, covered and bottomed with buffalo skin. The bags are made of goat-skins, which have seen long use as bedding previously. Receptacles for honey are never washed. It would be contrary to the common uses.

Much of the honey is made up into wine, or which the native is very fond. The men who climb the trees to obtain the honey from the hives are often well under the influence of this honey-wine, when doing the work, and it is no rare occurrence that some of them, on this account, have serious accidents happen to them by way of falling, breaking their limbs, etc.—Information from Deutsche Bienenzucht.

## Best Size of Honey-Sections

BY R. E. MERRILL.

I have read with great pleasure the articles by Mr. T. K. Massie, page 783 (1906) and L. V. Ricketts on page 8

(1907), on the subject of best size for honey-sections. I would like to see a sample of a section for comb honey that will actually hold 2 pounds, with separator or fence, but would prefer one plain, for, from the experience I have had with sections, I prefer the former. The fence separators cost more than the slotted wood, and as Mr. Massie says, "Some of them are very flimsily made and do not last long." However, it is rather difficult to say which section I would prefer, for we have always used the 2-bee-way sections, and I have considered the matter very much.

I have concluded that a comb thick enough and large enough to weigh 2 pounds instead of one pound would be much better, either in the plain or bee-way section. All considered, I think it would be the best size of honey-section, and as coming as near the average as can be. Instead of 16 ounces, have 32 ounces as near the average as possible, although it is rather difficult for me or any bee-keepers in this country or any other country to select a section, (or a weight for a section), to be the exact number of ounces the same all the way through a crop. Of course, it would be different, if we bee-keepers could govern so as to make things suit us, but as we can not, and haven't the power to confine the bees to a certain size section, we will have to be satisfied fully with what they do for us.

The sections we are now using are the  $4\frac{1}{4} \times 4\frac{1}{4} \times 1\frac{1}{8}$ , bee-way sections, and weigh an average of only 14.2-3 ounces when filled as stated. Now the question is, Would it not be better for both the producer and the consumer, if bee-keepers in general would adopt a section which, when filled as mentioned, would average 32 ounces, or 2 pounds each, or 1,000 sections to weigh a ton, or a very few pounds more or less, instead of being 150 or 250 pounds over. Short weight is not an advantage to the bee-keeper with the sections now in general use, or the sections we are using, as above mentioned. We have to give about 120 sections for 100 pounds of honey by weight. The question is, Would it be best to make such a change? and if best, then what size of section should we adopt?

Having very carefully considered the matter from my standpoint, I have come to the conclusion that there is no better size of sections than one that would hold as nearly 2 pounds as possible, or 1 ounce over. For me, I would think it would be very advisable, less work and less expense to the bee-keeper in general, if we could adopt a section of this kind. Of course we would all have to make some changes in our supply line, such as supers and shipping-cases, but, as far as I am concerned, I think I would save big money in the end. As for supers, I suppose they would have to be a little higher, hold less sections, contain more honey, or double the amount of honey; and we would have to change our shipping-cases to fit the new style of section, or a section, when fully completed, weighing 2 pounds.

I think all bee-keepers should consider the matter as to the expense of producing comb honey in 2-pound sections, instead of 1-pound.

## Bee-Stories—Report for 1906

BY WM. STOLLEY.

I send a clipping from a St. Louis daily paper, and the translation into English also. Here it is:

### BEES IN A FUNERAL PROCESSION.

Des Moines, Iowa, Nov. 13.—Bees at Wall Lake, Iowa, have shown that they are capable of being attached to their keeper, when Oliver J. Seer died, in a very remarkable way. Seer was a bee-keeper and habitually worked among his bees with bare hands and unprotected face. His bees followed him wherever he went on his premises and into his workshop, without attempting to sting him. In winter, when winter stores gave out, Seer fed them with sugar syrup and rye-meal, and covered them with woolen blankets to keep them warm. On the day when Seer was buried, his bees swarmed about and around the hearse and thousands of them followed the hearse to the graveyard. Several colonies swarmed out of their hives and were found on trees in the graveyard near the grave of Seer, their former owner.—*Westliche Post*.

Now, what next? Here it is:

The foregoing seems hardly to be taken as truth, but I can pen another story about my own bees, that is—every word of it—as true as the above, and I think, proves beyond a reasonable doubt, that bees, even if they are not of the superior Red Clover "strain" are possessed of not only keen discrimination, but they morally entertain lofty notions, and by their actions prove that they hate liars.

Among the many people who visit my place, and quite often take a look at my well-kept apiary in the summer season, it sometimes happens that a newspaper reporter is among these visitors. And strange as it seems to be, my bees seem to know *at once* when one of them is about. Yes, it is a joy to see the bees go for these fellows.

We know that bees are prompted a good deal in their action by their sense of smell, and that explains probably that they recognize the reporter at once as soon as he has entered the bee-yard. I am somewhat inclined to think that it is the *liar's smell* that enables the bees to hit the right man. My bees at once swarm about the head and right hand of a reporter, and I have seen one of these chaps with a light, sandy mustache, where the bees covered it in a big cluster so that it appeared as a big black Russian beard. The bees were evidently all scrambling for a chance to put their stingers into that fellow's tongue. His right hand was just bristling with stingers, and for two weeks he could not write and report absolute nonsense to his newspaper; but after he got over it, so I learned, he went on lying as usual.

### REPORT FOR THE SEASON OF 1906.

When my report reaches you in Chicago, I hope that you, Mr. Editor, have returned to your sanctum all right, with sound limbs, invigorated and refreshed in spirit, and that you and your bee-keeping traveling-companions, have en-

joyed your trip South, relished the various Mexican spicy dishes, and were prudent enough to avoid drinking the "cistern waters" to appease your thirst, naturally created by these highly-seasoned meals. I refrain from suggesting other drinks instead as very wholesome, for fear that that might hurt my reputation, but I am sure that I know something more safe and palatable to take. However, if you did drink cistern water, while down in Texas, I hope you escaped carrying home malaria fever and tape-worms. I am very well acquainted with Southern life, and I am free to say, "I like it."

I very much regret that unavoidable circumstances prevented my going, as much as I would have liked to be with you and participate. Well, soon "the Old Reliable" will divulge, I suppose, and tell us about all that was going on down there in San Antonio, and, no doubt, it will be interesting reading for us who had to stay at home. Many will enjoy reading it when zero weather rules supreme, and the snow-storms sweep over this Northern section of our great country.

My report for the last passed season of 1906 will be short and to the point. After selling 5 colonies for \$40 last spring, I had but 27 colonies left. These I increased by the nucleus plan to 42 fine colonies, rearing at the same time 31 first-class young queens.

I took 2710 pounds of honey, of which 235 pounds were in sections from 3 colonies. The rest was all extracted. My best colony gave me 153 pounds of extracted surplus, and the queen of this colony was hatched June 10, 1902. I do believe in "long-lived stock," and I never kill a "real good queen" as long as she fills her hive with bees, from early spring and late into fall. I would much rather have a queenless colony in the spring, once in a while, than to make a rule to kill all queens when they are but 2 or 3 years old. My queens must show decline and weakness, *i. e.*, approaching barrenness, before I pinch their heads off.

I also got 42 pounds of fine bright-colored wax from cappings.

We had but 20 inches of rain the past season, while we had all of 40 inches in 1905.

Last spring (1906) I bought 25 pounds of what was to be yellow sweet clover seed, and sowed it on March 31. The seed grew well, and I had the very unexpected pleasure to see it begin to bloom on June 8, only 69 or 70 days after I scattered the seed. Soon all was a mass of yellow bloom, but—not a single bee ever visited this strange "yellow sweet clover bloom." According to what I knew of the yellow variety of sweet clover, it would *not* bloom the first year, but would, like *Melilotus alba* (white sweet clover), bloom the second year and then die, root and branch.

I have had some correspondence with my highly-respected lady friend, Mrs. A. L. Amos, who is known to have grown yellow sweet clover for years, and this lady wrote to me: "Seed of sweet clover sown in March *never* blooms until the following season, and then not so early as that bloomed for you." Mrs. Amos very kindly sent me quite a package of

the genuine sweet clover seed, which I have sown this day, but I do not expect any bloom of it until the middle of the month of June, 1908. I suppose that the firm from whom I got seed had been imposed upon by some one, who sold this seed to them, and passed it off as "yellow sweet clover seed," and I hope that they will look the matter up.

The seed sent me most certainly was not yellow sweet clover seed, and since bees seem not to take to it *at all*, and the plants appear to be dead now, the \$3.05 that the seed cost me, is a dead loss, unless it is made good to me. I never saw any kind of seed grow as readily, and bloom so willingly and profusely, and the plant, after blooming, die so speedily, as this new-fangled "yellow sweet clover seed." It looks and smells all right, but, after all, it is not all right.

Certain Red Clover queens are reported as a "very extraordinary, superior strain of bees." Now, if there is also a strain of "Yellow Sweet Clover Queens" whose workers understand how to get nectar out of this new-fangled yellow sweet clover, I would like to get a queen of that very remarkable strain, provided, however, such a queen is guaranteed to produce worker-bees that will store honey obtained from this new-fangled yellow sweet clover, and will not cost more than \$100 for one queen!

I wonder if we ever will find out what kind of stuff that yellow sweet clover seed was, anyhow.

Grand Island, Neb., Nov. 15, 1906.

## Hive-Lifting Devices—Super-Protection

BY GRANT STANLEY.

Quite a considerable space in the September 1st issue of *Gleanings in Bee-Culture* is devoted to hive-lifting devices, of which several illustrations are presented. The bee-industry has grown to such proportions that an invention of this kind is a necessity in the apiary. It is certainly hard work to lift 3 or 4 partly filled supers of honey, and place them on the ground, in order to examine the brood-chamber, and if many colonies are to be thus gone over the work becomes burdensome. It matters little if we can do this kind of work or not; if we can have an invention that will do it so much easier it surely enables us to do more work, and in business of every description men are endeavoring to invent methods by which the maximum result can be obtained with a minimum of labor.

But while we are thinking about hive-lifting devices, we should have one possessing as many practical features as possible. We not only want an invention to be used in hive-lifting and removing supers, but it should be so constructed that the supers of honey can be wheeled right to the honey-house when removed from the hives, and empty supers wheeled out. We also need this invention in wheeling our bees to the cellar in wintering, and to wheel them out again in the spring. If for any reason the bee-keeper desires to move colonies from one part of the apiary to the

other, placing nuclei in various parts of the apiary, wheeling out winter-cases in preparing bees for wintering on the summer stands, and wheeling them away again in spring, or where the bee-keeper depends upon natural swarming for his increase, and hives the swarms where they cluster, the swarms can then be wheeled to the stands prepared in advance and placed on them with very little labor.

The wheels should be sufficiently large so that it will run fairly easy with a number of heavy supers of honey, and should be wide enough so that it will not upset if the ground is not perfectly level. Whether the bee-keeper uses such a device or not, it will be found a great convenience in many instances to have the apiary graded.

### BETTER SUPER-PROTECTION.

In one feature, in comb-honey production, at least, it can be said locality plays no part, as I believe it will be found in all localities, and that is, the rows of center sections in the super will be sealed over much sooner than the two outside rows. In fact, in many instances, it is a hard matter to get the bees to seal over these outside rows, and as a result of this kind of experience for a number of years, I have spent considerable thought in trying to find the cause, and at the same time solve a way to prevent it.

Here is another thing: When there are 2 or 3 supers of sections on the hive at the same time in course of completion, the outside rows in the lower supers would be sealed over as well as those in the center. Now why is this? In removing a super of filled sections the past season by the use of a bee-escape board, I let this board remain on top of the super under the one removed until the next examination, and, though this was only a few days later, to my surprise I also found this super all filled and sealed over ready to come off, and even the outside rows being sealed. I believe this was due, largely, to the bees sealing this board down solid, barring out the light and currents of air, as no other colonies made such rapid gains at storing. I am of the opinion the reason bees will seal the outside rows in the under supers, and not do it on top, or under the roof, is because it is further away from the light and currents of cool night air.

It should be remembered that bees can gather and store honey when it is too cool to work at comb-building or sealing, and for this reason (for I believe this is the chief cause), we should provide much better protection to the top of the hive in order to retain the warmth. There is entirely too much warm air going out, and cool air coming in, and as most comb-building is done during the night, this is also when the supers are the coolest if no protection is provided. For this very reason many bee-keepers use a telescope cover, as by the use of a deep cover of this kind the heat can not escape nearly so rapidly. During the storing season is also when brood-rearing is the heaviest, and on cool nights the bees will leave the supers and go down below in

order to prevent a possible loss to the brood, if the matter of warmth has not been attended to.

I believe we will secure better results by giving much better super-protection during the honey harvest,

than by ventilating at the top of the hive. The entrance is the proper place to ventilate. It must be a faulty hive that must be ventilated at the top in our Northern latitudes.

Nisbet, Pa.

Conducted by EMMA M. WILSON, Marengo, Ill.

### Keeping Bees and Poultry

DEAR MISS WILSON:—I wonder if the sisters all want to "talk back" every week when the American Bee Journal arrives, as much as does the "Mistress of Clovernook." Also, if they promise themselves that they will, and then—don't.

About every week since you "called me down" on my emergency-cell business written for Poultry Husbandry, I've tried to find the leisure to "have it out with you;" but, alas, by now all the brilliant things I have been concocting and treasuring up to rout you with completely, would at this late hour prove but flat, uninteresting stuff to read. So Father Time draws the sting and dulls the venom.

Really, though, it is very hard for amateurs to write correctly on bees; to express exactly so as to convey what they mean to our readers.

I've been tasked with a lack of interest in my bees as compared with my poultry, because I so seldom write concerning this very important branch of Clovernook. I tell them that I'm "scart" to; that bee men and women are very quick to "catch on" to our inaccuracy and bring us up standing, while I can reel off miles of poultry-lore in blissful security. It seems to make no difference what I or anyone else says—all is silently accepted. Those who know may smile, but do not correct the error, and those who don't know, will, ultimately, at a costly price.

That is one reason why I'm especially fond and proud of the bee-keeping fraternity. There is a largeness of scope and a scientific pride that is above mere mercenary consideration, and a broad truthfulness is demanded and exacted.

Now after all this bouquet throwing, let us have another whack at "Bees and Poultry," as discussed in our own corner on Dec. 6, 1906.

I'm not so sure as I was then, or 4 years ago, that the two industries work well together, and can be conducted so that the bees do not suffer. At that time, I was sure that certain persons who advocated bees as a specialty were wrong. It now seems to me that while a limited number of fowls and of colonies work all right, as a side-issue—for

pin-money—where a living is to be made from the two, it is hard to give the bees a fair show. And this for the reason that poultry is so clamorous for attention, and the neglect shows up so quickly and fatally in results, and the routine of care so constant and every day and three times a day (the bee-work being sandwiched in between whiles). It is quite likely on the days favorable for opening up the hives, that some imperative demand of the fowls must be met. So time slips by, and when our honey crop is in, we wonder why it is so light, and are chagrined at the inroads made by moths, and at other mischief which shows up.

It works somewhat after the fashion of a good and a bad child. The bad one absorbs three times the care of the good one, and the needs of the good one and its rights are too often sacrificed. I don't think any one can exaggerate the "cursedness" that there is in a chicken, nor the arduousness of the work entailed in caring for them under certain conditions, nor the slowness of the return for labor and money expended. On the other hand, where "chicken nature" is intelligently studied, the occupation is fairly remunerative, and fairly easy, and fairly pleasant. But as compared with bees, it is not in it! I think Sister Williams hits the nail on the head when she says, "If I should do the work that is most agreeable, I would take bees, every time, and believe they can be made to pay quite as well, if not better than chickens."

My experience is that, given the right locality and conditions for pasturage, and the proper care, a good living can be made with bees alone, providing the local market is not hurt or glutted by precipitating the crop on it at once, and by inferior grade of honey.

I have run bees and poultry for 12 years, and not a single season has drawn to its close but I've felt guilty of neglect to my bees, and have promised myself that it was the last time. And I've tried to plan the work so as to do justice to them, but have never succeeded. The past fall I decided to give up the White Wyandotte branch of Clovernook's business, in favor of the bees, and have farmed out 22 of our White Holland turkeys; so that next

year we have practically only ducks and bees to care for, in live stock, and the fruit and writing. So again I feel hopeful of unhurried, happy hours with my bees next year. We have recently not had nearly so large a crop of honey as in seasons past. I think that the young apple-trees have grown so as to shade our bee-yard too much, and that the felling of the basswoods and other varieties in our neighborhood, tend to lighten the crop. Also that perhaps our yard needs requeening. It may be "run down," as they are native bees with a cross of Italians about 20 years ago.

I know that 4 miles from us bees do fine. There is a splendid range of sweet clover and a large field of alfalfa and grain and buckwheat. The small apiaries scattered through that section do well. They run for comb honey and produce more pounds of it per colony than do mine in extracted. They are the native bees, are never requeened, and are given very little attention. This is a new experience for Clovernook, as, until recently, we produced away ahead the heaviest crops of any apiary in northern New York, and near-by apiaries in Canada. We usually run some 80 colonies, but this year they have dwindled to 58. From these we produced only about 500 pounds of white and 800 pounds of dark honey. From the same number of colonies, or a half-dozen more, in former times, we harvested between 4 and 5 tons. With so nice an outfit as Clovernook's, we can not afford to lose our record and our good income, and must get to work

in the spring, and bring our yard up to its former high standard.

I will take this opportunity to wish one and all—sisters and brothers—a Happy New Year, and to hope that those of us who have had a good 1906 will succeed in having a still better 1907; and that our misfortunes may hold for us "a precious jewel" in experience, by which we may mount next year into the sunshine of prosperity.

FRANCES E. WHEELER.

Clinton Co., N. Y., Dec. 12, 1906.

It comes as a sort of disappointment that the thief, Procrastination, should have prevented you from routing completely the enemy, for one can fancy that it would be rather an agreeable sensation to be routed by so pleasant a router. That's one of the nice things about bee-keepers—however fierce the combat over this or that plan or principle, the combatants become only the closer friends.

It is perhaps well that you did not tell us in advance that there was any question whether bees and White Wyandottes could both hold the field, for the sisters would have been in unpleasant suspense lest the larger birds should win the day.

It is doubtful that the shade of the apple-trees lessens your crops. Loss of basswood may, and very likely fresh blood would be a good thing. But aside from all that there are variations in the seasons that one can not account for, and next season may be one of your best. Get at least one new queen, and then hope.

tributed throughout the entire State of Texas.

#### BUSH HONEY-SUCKLE.

*Lonicera fragrantissima*, Lindl. Bush Honey-suckle. Family *Cuprifoliaceae*. Honey-suckle family. A shrubby vine, cultivated, with yellowish-white flowers, blooming in January. Honey-yield extremely early and also pollen. Much visited by bees and valuable to stimulate the bees if the weather is favorable. Throughout Texas.

#### TRIPLE-LEAVED BARBERRY.

*Barberis trifoliata*, Moric. Triple-leaved Barberry. Family *Berberidaceae*. Barberry family.

An evergreen shrub with yellow wood, growing 4 to 6 feet high, and often forming large thickets. The leaves are cut into 3's, and these are lobed with 3 to 5 spines. The flowers are yellow, and are borne in clusters close to the stems. The berries, about as large as peas, and red in color, are the fruit. These are sweet and acid when ripe, and can be eaten. The fruit is much used for preserves, jellies, and for barberry wine. "Agberites" is the common Mexican name for this shrub. It is found mostly on gravelly slopes and foot-hills, from the Gulf Coast to the Limpia Mountains, according to Coulter. It yields honey and pollen in abundance, and is the best of our early bloomers for brood-rearing, blooming from the latter part of January into February.

### From Ireland—Reading Bee-Papers

The editor of the Irish Bee Journal has sent me several marked copies of his paper, calling attention to several abstracts (?) which he has made from the American Bee Journal. This is much appreciated, and we understand his good meaning. We shall use our "honest opinion" and investigate the matter of "keeping bees by reading one or more bee-journals," etc., and report as soon as the results have been obtained. Yes, 'tis true it makes a difference whether "a bee-journal is filled up with stuff suitable for a dime novel," and also whether such journals are "paid for, or gotten for nothing, free of charge." My "honest opinion" is that bees can be kept better by reading one or more good bee-papers than without them, whether you pay for them or get them for nothing.

**Honey as a Health-Food.**—This is a 16-page honey-pamphlet intended to help increase the demand for honey. The first part of it contains a short article on "Honey as Food," written by Dr. C. C. Miller. It tells where to keep honey, how to liquefy it, etc. The last part is devoted to "Honey-Cooking Recipes" and "Remedies Using Honey." It should be widely circulated by those selling honey. The more the people are educated on the value and uses of honey, the more honey they will buy.

Prices, prepaid—Sample copy for a 2-cent stamp; 50 copies for 70 cents; 100 for \$1.25; 250 for \$2.25; 500 for \$4.00; or 1000 for \$7.50. Your business card printed free at the bottom of front page on all orders for 100 or more copies. Send all orders to the office of the American Bee Journal.

Conducted by LOUIS H. SCHOLL, New Braunsfels, Tex.

### January Texas Honey-Plants

It is of much value for every bee-keeper to know his honey-plants, when they bloom, and their value to his bees. Here in Texas we have some plants blooming practically the whole year, that are of some value to the bee-keeper. Even in the month of December, the mistletoe—about which everybody knows—comes into bloom. It is of value for its pollen. This is soon followed by others in January, and by many more as the season advances.

My collections contain specimens of most of our important honey-plants, and of these I have made a card catalog from which I will each month give the names of the plants blooming at that time, together with their distribution in the State, as far as is possible, and their value as honey or pollen yielders. I should be glad to hear from others about the honey-plants of their respec-

tive localities, not only in this but in other Southern States.

#### AMERICAN MISTLETOE.

*Phoradendron flavescens* (Pursh) Nutt. American Mistletoe. Family *Loranthaceae*. Mistletoe Family. This is a shrubby, evergreen, parasitic plant on branches of trees, such as the elms, oaks, mesquite, bois de Arc, and others. It has jointed and much-branched stems, thick and firm green leaves. The flowers are small and greenish yellow. The fruit is a small, white, viscid berry. It grows in bunches or clusters, and is somewhat odd and pretty in appearance, hence much used for decorative purposes, especially during the Christmas holidays.

Mistletoe is the first source of the season, beginning to bloom in December and into January, yielding an abundance of bright yellow pollen and honey, which makes it valuable for early brood-rearing. It is widely dis-

## Report of the Ontario, Canada, Convention

REPORTED BY MORLEY PETTIT.

[Continued from page 31]

### STIMULATIVE FEEDING—REPORTS.

I would advise anyone who can not stay right with his bees to let stimulative feeding alone, and to bruise capped honey whenever the weather is favorable, and when you can stay right with the bees and see that started larvæ is kept fed.

Mr. Pettit—You might have combs uncapped inside, and take them along to the yard. This saves the wax of the cappings, and saves keeping the hive open while you bruise the cappings.

The Director's Report, Secretary's Report, and Treasurer's Report showed a successful year for the Association. The Transportation Committee's Report showed that some points had been gained from the Railroad Commission, principally the reduction of the minimum car-load of honey from 20,000 to 12,000 pounds. Beeswax has been changed from first-class to fourth-class rating.

Mr. Grainger, representative to Toronto Exhibition, reporting, urging beekeepers to take more interest in the Exhibition as it offers a great opportunity to educate the public on the food-value of honey. He showed a plan for the new building which will stand where the old main building stood. It is proposed to have windows at the rear, so that the light can shine through the honey. There will be many improvements to make the best building we have had to exhibit honey in.

There was more discussion on the Alexander method of strengthening weak colonies. Some considered it a help, and others thought it a disadvantage.

### FALL MANAGEMENT OF BEES

Fall management consists of preparing our bees for winter, for spring, for next season, and in many ways it is laying the foundation for future success.

The work of the fall season may be lessened to a great extent by the system of managing during the summer season. About the middle of September make an examination of each colony, find out its condition in regard to its strength of bees and quantities of stores, as well as to know it has a good laying queen and is in a healthy condition. If sufficient bees to cover 5 Langstroth frames are found it will be safe to put such colonies into winter quarters; if less than this amount of bees it will be better

to unite with another weak one and have a good colony.

To do this, remove about half of the lightest combs from colonies to be united and, sometime afterwards, on a cool evening, put 2 weak ones together by placing the combs of one with adhering bees alternately between the combs of another. Remove one queen if one is inferior to the other, otherwise the bees settle it amongst themselves. Be careful not to get too strong colonies in this way, as they do not, as a rule, winter as well as medium ones.

All colonies going into winter quarters should have a laying queen, and colonies that have been queenless a short time may be given a laying queen by some safe plan of introduction.

If the colony has been queenless since the swarming season it will be useless to spend time and feed on them, as the bees are too old and will die during the winter.

The most important part of the fall season's work is to provide each colony with sufficient good stores to carry them through until they gather feed next season. If we could supply them with about 25 pounds of good clover honey, well ripened and capped, there would be little danger of winter losses. We must have some reliable way of determining the amount of honey each colony contains, as found when on scales, allowing so much for the hive, combs, etc.; but I consider this unreliable, as there may be a difference of 10 pounds in the make-up of different colonies—a difference in the material of the hive, amount of brood, pollen, etc., in the combs. I consider an examination of the combs the best way of weighing stores, and if honey to the amount of 5 or 6 Langstroth frames is found, it will be sufficient. A colony with less than this amount should be given well-capped combs to make up the shortage, removing empty combs, and crowding the bees on as few combs as the food-supply and quantity of bees will allow, putting in division-boards or dummies; this keeps the cluster more compact, and in a body during cold snaps in winter.

If colonies are short, and combs of honey are not at hand, liquid feed may be given after first contracting the space for storing, as in the other case. As a rule, pure sugar syrup is fed, made from best granulated sugar; it may be given in any kind of feeder if fed early in the season. A handy feeder may be made to go into an extracting super made 1 inch smaller than the inside of the super; it may be made of undressed lumber, waxed at the corners, and made of different depths, to hold just enough for any colony, and a few strips or blocks of wood for floats put in.

Place the feeder on the tops of the frames, and if the weather is cool, feed the syrup warm, contract the entrance, and feed during the middle of the day. The syrup, I think, gives best results when made of a consistency of 3 parts sugar to 2 of water. Sometimes a little honey is added to prevent granulating, but I never practised doing it. Our syrup is made with steam, and it gives good satisfaction. A ½-inch steam-pipe is run down into a barrel or honey-storing tank; put in 2½ pails of sugar and 1 of water, until the tank is nearly full, then turn on the steam, which will warm the water and agitate the sugar; with a little stirring the sugar is soon dissolved, and the syrup can be drawn off at the bottom.

In conclusion I wish to say that what I have just given you on this question is solely for the preparation of bees for outdoor wintering. Not having any experience in wintering otherwise, I cannot say that it would answer for preparation for indoor wintering.

DENNIS NOLAN.

Mr. McEvoy—The middle of September is too late in the season to look for queen condition.

Mr. Holtermann—September is too late to know whether the colonies are queenless.

Mr. Hershiser—You can not tell by examining the combs for the amount of stores. You must weigh the hives to get the best results.

Mr. McEvoy—There should be plenty of pollen. Be sure there is plenty of honey or syrup, and it should be capped.

Mr. Newton—I should just try the weight.

Mr. Sibbald—After weighing several, then you can have learned to tell the weight without weighing.

Mr. Deadman—The strength of the syrup depends upon the time of year you feed. As to weighing, allow half-pound for one frame of bees.

Mr. Pettit—The neatest way to weigh hives is with a spring balance and arrangement to hook around the hive. Then as soon as the hive clears the stand, the weight is seen at a glance.

Mr. Couse—You can not feed back honey, as it will granulate in the comb.

Mr. Grainger—Save the combs and place them back.

Mr. Holtermann—You should be careful about feeding back honey, with reference to danger of spreading foul brood.

Mr. Nolan—You should not feed too late, because the bees can not ripen it nor cap it. I would rather feed good combs of capped clover honey than any other way.

Mr. Timbers—Will they not ripen it after the middle of October?

Mr. Hershiser—Isn't syrup not capped just as good as what is capped?

Mr. Bruune—You can feed in the cellar at any time. Simply take tin dishes and slip them under the cluster. Make a syrup half water and half sugar. It is best, though, to have the feeding done by October 1st.

J. D. Evans does not think it matters if the syrup is not capped. He likes to feed late, so the bees will not use it

up before winter. If you have the right kind of cellar, that is, dry enough, you can feed in the cellar at any time.

Alex Taylor had a similar experience. Mr. Sibbald—It pays to make a good syrup 2 to 1, and boil it. You can't

feed enough thin syrup in a short time for winter. You must give it to them thick. It is safer to follow along good lines that you have tested, than to leave them.

(Continued next week.)

Three or 4 supers were taken possession of for nests; the combs were all cut out, and the paper from the wall carried in by the peck, and mixed up with grass, feathers, and other litter.

A person would not think it possible that 4 such small creatures could work such destruction in so short a time; and while I felt somewhat annoyed at the damage done, yet I confess that it was with a feeling of pity that I dislodged them from their snug quarters. I was made to think of the passage in Proverbs, referring to "things that are little upon the earth, but are exceeding wise"—feeling sure that our mischief-loving little squirrel would not be misplaced if classed among the number.

Conducted by E. L. BYER, Markham, Ont.

### Wintering On Solid Sealed Combs of Honey

Readers of the American Bee Journal will possibly remember that only a few months ago the writer had a friendly "mix up" with Dr. Miller and Mr. C. P. Dadant on the above subject. As an evidence of proof that Mr. McEvoy (an earnest champion of the system) is not at all afraid of risking everything by following the plan, I submit the following from a private letter just to hand:

"I have the bees in every one of my colonies crowded up with division-boards. Each colony has from 4 to 6 combs, all of which were sealed from top to bottom in September." As Mr. McEvoy has somewhere in the neighborhood of 300 colonies, any one who has an idea of a wholesale death loss, would better write to him in May or June next, sending their sympathy, and at the same time convince him of "the error of his ways."

### Those "Mouse-and-Honey" Experiments

Those experiments recorded by Mr. Hasty (page 1036—1906) are quite interesting. At the risk of exposing my ignorance, I must confess that although I have many a time known mice to eat honey, yet previous to Mr. Hasty giving his ideas on the matter I never suspected that they recognized honey as "drink" rather than "meat."

More than once I have left piles of extracting combs at an out-yard where the honey-house was anything but mouse-proof. While I always like to know that mice are pretty scarce around the place, yet we can never be positive but that some may put in an appearance. To settle this matter, I always set aside two or three combs with honey in, close to the piles of super combs. On my next visit, if the combs with honey in were not touched, there was no need of looking at the empty combs—there were no mice present. If the honey was eaten any, sometimes traps were set as recommended by Mr. Hasty; but instead of putting a dish with water in for drinking purposes, we would substitute a

dish of meal with a percentage of arsenic mixed in.

I remember on one occasion I called at the honey-house in question and found that the mice had been levying a pretty heavy toll on my "test" combs, and I also recall the fact that although quite early in the fall there was considerable snow on the ground, and unmistakable evidence that the offending mice had come from the outside of the building through the snow.

It seems strange that these mice did not quench their thirst with the moist snow instead of gouging into the combs of honey, especially as the snow was not more than a foot or more away—some of it actually being on the floor, having sifted in through a crack in the wall. However, mice may be like quite a few people—prefer to have their drinks well sweetened.

While there is no question that mice are a nuisance, yet with ordinary precautions there is no need of much actual loss from that source. While I have some 5000 extracting combs scattered around, some of them, as I have intimated, in places not mouse-proof, yet I do not believe that I have lost two dozen combs by mice since I have been keeping bees. My worst experience was with the common red squirrels—an experience lasting and decisive. Lasting, because it cost me about \$25; and decisive in so far that all the culprits were shot inside of 24 hours after I learned of the damage; and also because I mentally decided never to take chances again with a red squirrel, if he were within a quarter of a mile of the combs at an out-yard.

The mischief was all done inside of 2 weeks in November, 1905. Everything was all right when I left the yard after packing up for winter. When I called again in 2 weeks, what a change! During my absence, 4 squirrels had "moved in" and taken possession, and proceeded to fix up things for winter according to a squirrel's idea of comfort. The farmer on whose place the bees are, had built the honey-house and had finished the building by papering inside with heavy building paper. Not one square foot of this paper was left entire! At least a dozen holes were chewed through the walls and roof for convenience of entering.

### How the Bees are Wintering

To-day, at 9 a.m., the temperature was 48 degrees. The sun is shining, and bees wintered outside are likely to get a flight. Mine are all in the cellar, the temperature of which in the middle runs about 46 degrees, and I think they are in excellent shape.

R. F. HOLTERMANN.

Brantford, Ont., Dec. 31, 1906.

I hope expectations were realized. I am sorry to say here in York county, although fine in the early morning on the day in question, later—about 10 a.m.—the sky became clouded over, and the bees (and bee-keepers) were disappointed.

My bees are all outdoors, and they have not had a flight since Oct. 25. If they could have but one flight any time now, personally I would rather that were the last till some time in the latter part of March. Barring that one flight, things may not turn out any too well. But time will tell the tale.

### Honey from Alfalfa in Ontario

Can we expect anything from alfalfa here in Ontario? From the Farmers' Advocate I clip the following:

"At the annual conference of the Victorian Apiarists' Association, Melbourne, Australia, Dr. Cherry, Director of Agriculture, in an address, said he thought he might, perhaps, get bee-keepers to act as propagandists in the culture of lucern. He believed that if alfalfa [lucern] were more generally grown the bees would gather more honey. Honey produced by the legumes is of the best quality. This family of plants produce in their tissues abundant nitrogen—the element which enters into the composition of protein. From analysis of samples of pollen submitted to him, he had found in the case of pollen from cultivated plants of alfalfa as much as 27 percent of protein; eucalyptus showed 20 percent, and weeds 10 percent. Pollen, with a high percentage of protein, is said to be necessary for the rearing of strong brood, and if Dr. Cherry's claims are well founded, Canadian bee-keepers should become enthusiasts in extending the area of this invaluable agricultural plant."

While alfalfa has, aside from its value as a honey-producer, enough claims to warrant it being grown on every farm, yet I very much doubt if Canadian apiarists have much to hope for from this source.

As to its possibilities in Alberta and other Western localities, under or about to come under irrigation, I know

nothing; but as to Ontario and Quebec, I have heard of only one instance where bees have been reported as working on alfalfa. This report came from Mr. Adams, of Brantford; and while Mr. Adams is a reliable source of information, yet it is a question in my mind if he finds the same thing to happen *very often* in his locality.

For 10 years we had about an acre of alfalfa within a few rods of the home apiary, and while it was in all stages of bloom through the season (being cut from time to time for green feed), yet I don't remember ever seeing a bee on the blossoms, even when there was a total drouth of honey, and the alfalfa was in the height of bloom.

making a change; so we will applaud instead of scold. By the way, however, the man who has a department in a journal of world-wide circulation, has no right to say, "I am a dry tree" so far as opportunities to do good are concerned. Christian preaching not so scarce as Christian writing—Christian writing to the extent of earnest watchfulness to get in a word for the right whenever an opportunity occurs. I'll take a dose of that myself right now. Here's advice to him as he goes: Don't follow the new and awfully prevalent style of preaching humanitarianism to the extent of forgetting that man has a soul. Man has a soul that dreadfully needs discovering and cultivating—never so badly as now. Don't agonize much to mend biblical or theological broken eggs. There are still some valuable eggs left that are not broken. Hatch 'em. Page 1031.

The "Old Reliable" as seen through New and Unreliable Glasses,  
By E. E. HASTY, Sta. B. Rural, Toledo, Ohio.

PROF. WILEY AND PURE FOOD LAW.

Yes, as we have much that's ill to remember of Prof. Wiley, we might in justice remember that he was very prominent in the fight for the Pure Food Law, which, after many defeats, finally won out. Page 1029.

#### REQUIREMENTS FOR SWARMING.

I feel like driving a "coach and six" right through C. W. Dayton's three requirements for swarming. These were old queen, populous colony, and honey-flow. One may have the youngest kind of a queen, only a few hours old, a colony not nearly populous enough to do good work, and decided dearth of nectar in the flowers; and yet with a swamy strain of bees, and a swamy location, and the cell building half of a recently divided colony, there may be a natural swarm. When bees get the swarming fever furiously, and are compelled to wait because they have no queen out yet, the fact that the honey-flow has ceased and famine times have begun, is not always sufficient to halt them. Influences in that direction, but not always sufficiently. Page 999.

#### METHODS OF FOUL BROOD TREATMENT.

And the world will move. We had become settled that shaking bees onto clean foundation or starters (repeatedly, if necessary) was the way to cure foul brood. Now we learn that both in California and in Texas curative methods are being abandoned in favor of total destruction. And we also (wrathfully) read of the inspector who gets his pocket instrument well loaded with the virus of foul brood in one apiary and plants the same in the next apiary which happens to be clean. Page 1000.

#### SEAL FOR GUARANTEED HONEY.

Then hurrah for the brother that can invent the most convenient seal for guaranteed honey! But it must be thoroughly rascal-proof, else a less convenient kind that is proof would be greatly preferable. Right at this point the oft-recurring need of reliequifying may be bothersome. Who'll give us a seal that will hang tight to its duty while the package is being reliequified? Page 1004.

#### VALUABLE QUALITY OF CAUCASIAN BEES.

Frank Rauchfuss certainly puts in a valuable additional quality for the

Caucasian bees. Virgins stand 30 days caging without companions. Not altogether clear whether immersed in bees or away from the bees. Surprising any way. Yet virgins of *Homo sapiens* consent to 30 years' caging, and seem to like it! But there must be a well-chosen companion. Page 1013.

#### HOW TO SHAKE BEES OFF FRAMES.

Mr. McMurdo is "a man after my own heart" when he takes a shot at the "patent" ways of holding and shaking frames which have been published. And he's O. K. when he tells you to let the projections alone and grip well down on the end-bars. The way to shake bees off is to shake—shake good and hard—shake like Marco Bozzaris wanted his men to strike. And, eke, put some brains in the performance, and learn for yourself a practical movement that works. Quickness counts more than elephantine force apparently; and peculiarities of motion count for something. But none of your holding the end-bar between first and second fingers like it was a lead-pencil. Page 1016.

#### BEES AFTER MEAL IN RED-PEPPER, PERHAPS.

Sister Wilson, that red-pepper was badly adulterated with meal, I reckon, 60 percent or so. The bees went for the meal and succeeded in ignoring the fiery stuff mixed with it. Very remarkable, and worth some study, that they should be able to ignore red-pepper for the sake of the meal. Still it may turn out that bees like red-pepper, for its own sake; and that would be more remarkable still. Babies in hives where cayenne takes the place of pollen would never need any of Perry Davis' Pain-Killer. Page 1018.

#### A GOOD-BYE AND SOME ADVICE TO MORLEY PETTIT.

And so we must say good-bye to Morley Pettit. Well, parting is a more tolerable kind of sorrow when our brothers do not "pull a tombstone over their heads" when they go. Wanting to do more for the good of man is certainly a noble reason for

Send Questions either to the office of the American Bee Journal, or DR. C. C. MILLER, Marengo, Ill. (Dr. Miller does not answer Questions by mail.)

#### Getting Candied Honey Out of Combs

I left the top supers on full of honey last fall, so that the bees would not starve, and from the way it looks it will last all next summer. How do you get the bees to work the candied honey over so as to get it out without destroying the comb? UTAH.

ANSWER.—I don't know any very good way. Perhaps you may do it in this way: Uncap any that are sealed, and sprinkle all the surfaces with a fine spray of water. If you have nothing better, you can use a whisk broom to sprinkle the water. As fast as the bees clean it up dry, sprinkle again till the honey is all out. They will do it more surely and more rapidly if you set the honey away from the hives, instead of letting each colony keep its own super. But in that case you must allow a passage so small that only one bee at a time can enter the super, or else the bees will tear the combs to pieces. Of course, if neighbors' bees are plenty, and close by, they may get more than your bees.

#### Wintering Bees on Cakes of Sugar

I had 2 colonies of bees that were almost entirely out of stores for the winter. So on Thanksgiving Day I put a cake of sugar on top of the frames of each of them, just above the cluster of the bees. To one I gave a cake made of granulated white sugar and the other of brown sugar. Each cake was made by boiling 5 pounds of sugar with a pint of water until it would grain so as to form a cake by putting it in a shallow tin pan and letting it cool. Now what I want to know is, How long do you think that sugar will last

those bees? They are wintering out-doors. I thought, perhaps, it would be necessary to give another cake some time this month, provided the bees were still alive.

I have been reading the American Bee Journal for some time, and notice that you occasionally answer a few questions, and maybe you might help me out of my uncertainty, and at the same time save those 2 colonies of bees. One of the colonies contains a Caucasian queen that I am very anxious to have some fun with next summer. I understand that Caucasian bees can sting if they want to, but seldom seem to have the desire. I think that kind of bees would suit me exactly, for I never did enjoy being stung, any more than some people "enjoy poor health."

If I am successful in getting the information I am asking for, I may come again some time.

Your answers to questions in the American Bee Journal I consider the best thing for beginners.

NORTHERN ILLINOIS.

ANSWER.—For some time after Thanksgiving Day the bees are likely to consume less than at any other time; yet the amount they consume varies greatly. Two colonies, side by side, apparently alike, will consume different quantities. Five pounds of sugar made into syrup (equivalent to about 7 pounds of honey) may last a colony in the cellar clear through till time to be taken out in spring, and it may not last till February. At any rate, you will be on quite safe ground if you renew the supply before Feb. 1. Outdoors, better see to it a week or two sooner. You will understand, of course, that no harm can come from being a little too early, while a little too late may do a good deal of harm.

Please report how the colonies come out. I should not expect the brown sugar to do as well as the granulated.

### Treatment for Bee-Paralysis

What is the best way to cure bee-paralysis without spreading it, and without burning the hives? Will washing the hives with strong salt water help it, when the bees and honey are out of them, and the hives have not been used for a month or two, or all winter? I have used sulphur on the alighting-board for some time, but it did not help it.

IOWA.

ANSWER.—I didn't suppose that bee-paralysis would be very bad so far north as Iowa. I don't believe salt water would do any good, and probably there would be no danger in using the hives over again. Many cures have been offered, but it seems none have stood the test unless it be sulphur, and some have no faith in that. Possibly you did not have the sulphur as deep at the entrance as those who have had success in that way. But Mr. O. O. Poppleton, who is the most prominent advocate of the sulphur cure, does not use it at the entrance, but powders it on the bees and combs. If the disease acts with you as it has with me, it will disappear of itself without any worry on your part; but down South it is a terrible scourge.

### Preventing Honey-Granulation by Heating

1. What is the best way to heat white honey that is to be sold in glass jars? and to what degree must it be heated so that it will not granulate?

2. How should I heat buckwheat honey before it granulates so that it will look clear, and not granulate when put in glass jars? I tried to heat buckwheat honey before it granulated last fall, and I could not do anything with it. If I got it a little too hot, it would look cloudy or muddy; and if I did not get it hot enough it would granulate after being put into the glass jars.

NEW YORK.

ANSWER.—Whether the honey be light or dark, it should not be heated to more than 160 degrees, and it will be better not to go

above 130, allowing it a long time to melt the grains. Those who melt it on a large scale have special apparatus for that purpose. If you do not care to melt more than 50 or 100 pounds at a time, you can do that with utensils you are likely to have on hand, using a kitchen range or cook-stove. Don't set the vessel containing the honey directly on the stove, but set it in another vessel containing water, having a thin board or something else for the honey-vessel to rest on, so the inner vessel will not come directly in contact with the bottom of the outer vessel. If the water in this outside vessel is never allowed to come to the boil, there is not much danger that the honey will be heated too much, but it is well to have it on the back part of the stove to make the melting slower. No matter how you melt it, it will granulate again unless it is sealed up. I have never tried it, but it is said that if it be sealed at 160 degrees it will not granulate again.

### Painting Hives

1. Can I paint my hives containing bees at any time of the year? And if so, at what time? I thought maybe I could paint the hives during winter, but having chaff-packed hives I would not have any chance, for during winter it would be impossible for paint to dry outdoors.

2. What paint is best for chaff-packed hives?

MICHIGAN.

ANSWERS.—1. You can paint your hives any time of the year when it would do to paint a house. Of course, as you suggest, it will not do to paint in freezing cold weather, but as soon as thawing weather comes it will be all right. Your chief desire, no doubt, is to know whether you can paint the hives at a time when bees are active. Yes, you can do it even when they are in their busiest season. The only thing to look out for is that the bees don't stick in the paint before it dries. If it is made rather thin there is little danger. If you paint a hive in the evening, as soon as the bees stop flying, using a little drier in the paint, by morning no bee will stick in it. Of course, it will be well to be rather gentle in painting, for if you should pound on the hive too hard with the brush, it would rouse the curiosity of the bees to investigate.

2. Any good outdoor paint, white lead probably being as good as any.

### Northern Indian Territory for Bee-Keeping

1. Is the northern part of Indian Territory a good place for bees?

2. Would you advise me to go there to keep bees, and make it pay?

ILLINOIS.

ANSWER.—Although I have an impression that it is a fairly good bee-region, yet I have no positive knowledge about it, and wouldn't dare to advise in the case. Possibly some one else may tell us about it.

### Why Did the Bees Die?

Some time in March, during a warm spell, I noticed a colony of my bees acting as if they were short of supplies. On examination, I found them entirely out, fed them rather thin syrup warm, and about a week after feeding them there came a very cold spell, about 4 degrees above zero. After it became warm again I found a number of dead bees on the alighting-board. On looking into the hive I found them all dead. The syrup was in the cells of 3 frames. During this warm spell I thought I would try stimulative feeding, so began with 3 colonies, 2 rather weak ones and one good, strong one. In a few days after feeding thin warm syrup, another cold spell came not so cold as the other (about 20 degrees above), and the bees did not come out for a week. When it warmed up again I found the strong colony nearly all dead, and

the 2 weak ones doing nicely, and they did as well as any I had during the summer. I would like to know the cause of the dying. They were all in dovetailed hives.

MISSOURI.

ANSWER.—Your letter partly answers itself, and if I read correctly between the lines, your question is rather to confirm your own opinion than to seek light upon a question on which you are entirely ignorant. The bees being filled with a lot of water (of course in the syrup), were in no condition to withstand the cold, and succumbed. Granted that it was fed warm, it wouldn't stay warm, and the evaporation was of course a cooling process. "But why was it that the 2 weak colonies thrived under the same treatment that killed the strong one?" Now, look here, don't try to get me in a corner and expose my ignorance. Your experience in dealing with human ailments has told you that what will kill one man doesn't kill another, and no one can tell just why. But seeing it's you, I'll make at least a guess in the case. The strong colony was thoroughly active, and thoroughly loaded up; and the weak ones were more inclined to be sluggish, and a smaller proportion of their bees worked on the syrup, and when those that carried down the syrup shared their loads with the others, none were discommoded.

The moral is, that while stimulative feeding may do good, it may do harm; and after many years' experience I feel that it is a pretty safe thing to let alone. Of course, it's the right thing to feed rather than to let a colony starve; and the thing to learn is to have plenty of stores in the hive to last through. It takes a long time to learn that, especially with small hives.

### Wintering Bees Outdoors, But Enclosed With Wire Frame-Work

I winter my bees on the south side of a building in a place built on for that purpose, packed in straw, and they trouble me by flying out on warm days and alight on the snow and die. Of late I have made a frame-work of wire-netting which gives them a chance to come out, but they can not fly away now. Is it as well to have them so, or would it be better to let them fly?

MAINE.

ANSWER.—Whatever you do, don't try to keep the bees in by force. The only kind of wire-cloth that should close the winter entrance of a hive is the coarse kind having about 3 meshes to the inch. That will bar the mice, but will allow the bees a free passage. The trouble is that if you use wire-cloth that will fasten the bees in, then any bee that wants to get out will stir up others and get the whole hive in such commotion as to do quite a bit of harm. You can darken the entrance to keep out the light. But after they have been in for some time there may come a warm day when you want them to fly, but don't want them to drop down into the soft snow to die. You can tramp down the snow so it will be hard for some distance in front of the entrance. You might also throw hay, straw, old carpet, etc., on the ground. It is only fair to say that you are not to count as a total loss all the bees that come out and drop down. More or less of the bees are getting old through the winter and dying off, and it is just as well, or better, that they come out to die. If you should put into winter quarters a colony of 50,000 bees, and 25,000 of them should live through to begin work next spring, you may feel well satisfied. In other words, you needn't worry yourself sick if half the bees die between now and fruit-bloom.

The Chicago-Northwestern Convention Photograph was taken Dec. 6, 1906, which was very good indeed. Price, post-paid, in mailing tube, 60 cents. Send orders to the office of the American Bee Journal, and we will see that the pictures are mailed.

# American Bee Journal

## Reports and Experiences

### Bees Did Fairly Well

My bees did middling well the past season. Some did very well, while others did nothing more than fill the brood-chamber, but not one section. I have taken the American Bee Journal for over 20 years. We sell our honey around the place at 13 cents a section, or 2 for 25 cents. If less than one pound, it goes for 10 or 8 cents. Others we use ourselves or for feeding to the bees. The colonies are all heavy with winter stores.

GEORGE HODGES.

Belmont, N. Y., Dec. 29, 1906.

### Last Season a Total Failure

I have kept bees (usually about 100 colonies) for about 30 years, and the past season is the first absolute, total failure I have ever had. I have now only 52 colonies.

Gilson, Ill., Jan. 8.

C. W. McKOWN.

### Poor Season, But Living in Hopes

I had 64 colonies in the spring of 1906, and got 734 pounds of extracted honey, and 1065 pounds of comb honey. This honey was fair to good, but very little of it was choice or fancy. I sold nearly all of it to my home trade at 10½ cents a pound for extracted, and from 14 to 16 cents a pound for comb honey. I have now 90 colonies in good condition, and, like almost all other bee-keepers, live in hopes.

Campbellsport, Wis.

THEO. REHORST.

### Season Short and Dry

The honey season was short in our part of Missouri. My 12 colonies averaged 40 pounds each. The Italians did better, for I took off as high as 3 supers of honey from each of them. I had one swarm. It was too dry for honey here last summer.

Milan, Mo., Dec. 20, 1906.

C. E. BAKER.

### From "a 3-Year Old"

The first of January marks the close of my third year as a subscriber to the American Bee Journal. I am owner of a small apiary, and have on hand about 600 pounds of honey for the season's work. I find the Journal very helpful in my work.

Linden, Iowa.

J. KRAPP.

### Secured a Good Yield of Honey

I live at the foot of the Adirondacks, or the Spur—not very good for a bee-keeper, but I manage to get quite a bit of honey. The past season was very fair here. With 26 colonies, spring count, I increased up to 39, and have 2350 pounds of honey—1400 comb and the rest extracted; besides, we have honey every day for our own use.

My bees are very heavy in stores for winter. I have them in the cellar in a room by themselves. Our honey is clover, basswood, buckwheat, and heartsease for fall. I make my own hives, bodies, covers, and bottom-boards. I use the Hoffman frame and the 4½x4½ sections. No trouble to sell all the honey I had, and had to buy more. I have had to contend with black brood. It was hard to get it cured to stay cured, on account of the box-hive farmers and carelessness of the farmer bee-keepers; that class of bee-keepers in this part of our town are now out of bees, and it will be a good thing for those that are bee-keepers. I could not teach them. They cared for only enough honey for their own use—only poor stuff at that, with bee-bread and larvae all mashed together. They would not

take a bee-paper, claiming it was useless to go to the expense of frame-hives, and they knew all about it—more than any paper could tell them! They are "wild" now, when they see me taking super after super from a hive, and call me a wizard. I love the bees; love to watch them and care for them, and to attend to all their little wants—and large ones, too.

E. M. LAWRENCE.

Mayfield, N. Y., Dec. 12, 1906.

### Home Demand for Honey

I got about 2800 pounds of honey the past season. I am getting quite a good home demand. I shipped 500 pounds, but am afraid I will run short at home now.

HUGO ZACHGO.

Danforth, Ill., Dec. 7, 1906.

### Poorest Season for Surplus

My bees were all in winter quarters in good shape, Nov. 20. I think the past season was the poorest for surplus honey that I ever saw. Some of my best colonies filled one super, while others had to be fed. I work for comb honey, as a rule.

Success to "Old Reliable."

JOHN CLINE.

Darlington, Wis., Dec. 31, 1906.

## CONVENTION NOTICES.

**Minnesota.**—The Fillmore County Bee-keepers' Association will meet in the Court House at Preston, Minn., on Friday and Saturday, Jan. 25 and 26, 1907.  
Canton, Minn. P. B. RAMER, Sec.

**Vermont.**—The 32d annual convention of the Vermont Bee-keepers' Association will be held in the parlors of the Addison House, Middlebury, Vt., Jan. 24, 1907.  
Shoreham, Vt. W. G. LARRABEE, Sec.

**Colorado.**—The 27th annual session of the Colorado State Bee-keepers' Association will be held in the Chamber of Commerce Building, Denver, Colo., Jan. 22 and 23, 1907. The State Horticultural Association, the State Forestry Association, the Dry Farmers' Congress, the American National Stock Growers' Association, and the Colorado Cattle and Horse Growers' Association, will all hold their annual sessions in Denver during the same week. Besides this there will be the greatest live stock show held in Denver ever west of Chicago. The railroads have made a fare of one and one-third for the round-trip for this week, which should assure us a large attendance. A section-putting-up contest will be a feature of our meeting.

G. J. TOMLIN, Sec.

FRANK RAUCHFUSS, Vice-Pres.

**Wisconsin.**—The annual meeting of the Wisconsin State Bee-keepers' Association will be held in the Court House, at Madison, Wednesday and Thursday, Feb. 6 and 7, 1907. Reduced rates on all railroads, but if you cannot obtain them, ask your agent for full fare receipt. By courtesy of Mr. Bacon, of the G. B. Lewis Co., arrangement has been made to have a stenographer in attendance, to take a verbatim report of the entire proceedings, which will be published for the benefit of members and interested bee-keepers. This feature will make this the most interesting convention ever held by the society. The Question-Box will be the main feature, and we want every bee-keeper who has one or more questions of interest to mail them to the Secretary prior to the convention, that they may be properly arranged. Questions may be handed the Secretary at the convention, but mail them prior if possible. We also want a good honey display, so bring your choice samples of honey or anything of interest. Pres. France will speak on the Inspector's Convention in Texas, and Diseases of Bees. Every person may become a member, for one year, by the payment of \$1.00,

which will also make him a member of the National Bee-keepers' Association, which alone costs \$1.00; and every member of the National, not a member of the State, should pay his dues to the State Secretary, and for the same money, become a member of both. Ladies may become members by the payment of 50 cents for National dues. Kindly make remittance for membership dues before the meeting, to the undersigned.

Augusta, Wis.

GUS DITTMER, Sec.

C. B. LEVINS CO. - DADANT & SONS' GOODS

While the Present Stock of these BEE-HIVE CLOCKS lasts, we will sell them at only **\$2.00 each**, by express; or \$2.50 for the Clock and the Weekly American Bee Journal one year. **Better order at once**, before all are gone.

## The Bee-Hive Clock **A \$4.00 CLOCK FOR \$2.50 ... With the American Bee Journal 1 Year— Both for Only \$3.00**

We have originated and had made specially for our readers, a bronzed-metal Clock, called "The Bee-Hive Clock." It is 10 1/4 inches wide at the base, 9 3/4 inches high, and deep enough at the base to stand firmly on a mantel or elsewhere. It is a beautiful piece of work, and would be both ornamental and very useful in any house, and particularly in a bee-keeper's home.

The Clock part itself is warranted for 3 years to keep good time. So it is no plaything, but a beautiful and needful article for everyday use.

Clocks like "The Bee-Hive Clock" usually sell in the stores at from \$4.00 to \$5.00 each, but having them made for us in quantities enables us to offer them at \$2.50 each by express, or with the American Bee Journal a year—both for only \$3.00. Either Clock or Journal would make an ideal gift.

### How to get "The Bee-Hive Clock" **FREE**

Send us **5 New Subscribers** to the Weekly American Bee Journal for one year, at \$1.00 each, and we will send you this beautiful "Bee-Hive Clock" **FREE** (excepting express charges). Or, send us **4 New Subscribers** (at \$1.00 each) and 50 cents—\$4.50 in all. Or, **3 New Subscribers** (at \$1.00 each) and \$1.00—\$4.00 in all. Or, **2 New Subscribers** (at \$1.00 each) and \$1.50—\$3.50 in all.

Only \$2.50. f.o.b. Chicago, by Express.  
Weight, with packing, about 4 pounds.

### What Dr. Miller Thinks of the Bee-Hive Clock

Busily ticking away, in the room where I am sitting, stands a genuine bee-keeper's clock (please understand that the word "genuine" belongs to the clock and not to the bee-keeper) or, as the legend upon the clock has it, "The Bee-Hive Clock." I don't know

whether the idea of getting up such a clock was conceived in the brain of the Editor of the American Bee Journal, or whether he got it elsewhere, but the wonder is that such a thing was not thought of long before.

Setting aside all idea of its association with the business of a bee-keeper, there is a peculiar appropriateness in having the minutes and the hours "told off" in a case representing the home of the busy little workers. The glance at the clock, with its ceaseless tick, tick, tick, can not fail to remind one that the flying moments must be improved now or be forever lost, and that suggestion is reinforced by the thought of the never ceasing activity of the little denizens of the hive, always busy, busy, busy, working from morn till night and from night till morn, working unselfishly for the generations to come, and literally dying in the harness.

Let us be thankful that the form of the old-fashioned straw hive or skep was adopted, and not that of any modern affair, patented or unpatented. The latter smacks of commercialism, but the former of solid comfort, for no other form of hive has ever been devised that contributes so fully to the comfort and welfare of a colony of bees as does the old-fashioned straw-hive. It appeals, too, to one's artistic sense as can no angular affair of more modern times. As an emblem of industry, artists have always used—probably always will use—the old straw skep.

Thanks, Mr. Editor, for furnishing us a time-keeper so appropriate for all, and especially for bee-keepers. **C. C. MILLER.**

Address all orders to **GEORGE W. YORK & CO., 334 Dearborn St., CHICAGO, ILL.**

## Langstroth on the \*\*\* Honey-Bee

Revised by Dadant—Latest Edition.

This is one of the standard books on bee-culture, and ought to be in the library of every bee-keeper. It is bound substantially in cloth, and contains over 500 pages, being revised by those large, practical bee-keepers, so well-known to all the readers of the American Bee Journal—Chas. Dadant & Son. Each subject is clearly and thoroughly explained, so that by following the in-

structions of this book one cannot fail to be wonderfully helped on the way to success with bees.

The book we mail for \$1.20, or club it with the American Bee Journal for one year—both for \$2.00; or, we will mail it as a premium for sending us **THREE NEW** subscribers to the Bee Journal for one year, with \$3.00.

This is a splendid chance to get a grand bee-work for a very little money or work.

Guaranteed highest quality at lowest price. Address,

**THE W. T. FALCONER MFG. CO.**  
JAMESTOWN, N. Y.

(Established 25 years)

**Honey and  
Beeswax**

**CHICAGO, Dec. 7.**—There is the usual dullness in the honey-trade at this date owing to most of the retailers having stocked up sufficiently to carry them over the holidays; but the stocks in the hands of the trade generally are below the normal; hence prices are firm at 15¢@16¢ for No. 1 to fancy white comb, with off grades at 1¢@2¢ less; amber grades dull at 10¢@12¢. Extracted white, firm at 8¢ for clover and basswood; ambers, 6½¢@7½¢ per pound. Beeswax, 30¢.  
R. A. BURNETT & Co.

**KANSAS CITY, Dec. 28.**—The demand for comb honey is only fair with market well supplied; market is almost bare of extracted, however, and the demand very good. We quote: Fancy white comb, 24-section cases, \$3.25; No. 1, \$3.00; Extracted, white, per pound, 7½¢@8¢; amber, 7¢@7½¢. Beeswax, per pound, 25 cents.  
C. C. CLERMONT & Co.

**CINCINNATI, Nov. 8.**—The market on comb honey seems to be a little quiet; No. 1 sells wholesale for 14½¢; retail by the case, 16¢. Extracted firm; light amber in barrels, 6¢; in cans, 7¢; white clover, 8½¢. Beeswax, 30¢.  
C. H. W. WEBER.

**PHILADELPHIA, Nov. 8.**—While the supply of comb honey is equal to the demand, large quantities of comb honey having arrived in the market in the last few days, the price still remains high. The outlook, however, is that when the season advances and the bee-keepers ship more of their crop to the market, the prices will be a little weaker. We quote: Fancy white comb honey, 16¢@18¢; No. 1, 14¢@15¢; amber, 11¢@13¢. Fancy white extracted, 7½¢@8½¢; light amber, 6½¢@7¢.  
We are producers of honey and do not handle on commission.  
WM. A. SELSER.

**NEW YORK, Dec. 3.**—Comb honey is in good demand, and No. 1 and fancy white stock seems to be pretty well exhausted. Buckwheat is in sufficient supply, also off grades of white, to meet all demands, but there is no overstock as yet. We quote fancy white at 15¢; No. 1 at 13¢@14¢; No. 2 at 12¢; buckwheat and amber at 11¢ per pound, according to quality and style of package. Extracted is firm at unchanged prices. California white sage, 8¢; light amber, at 7¢@6½¢; buckwheat, 6¢@6½¢. Beeswax steady at 30¢.

**C. H. W. WEBER** CINCINNATI ... OHIO ...

Office and Salesrooms, 2146-48 Central Ave. Warehouses, Freeman and Central Aves.

**DENVER, Jan. 5.**—There is practically no honey left in the hands of producers in this State, and barely enough in the Denver market to supply the home trade until spring. We quote strictly No. 1 white, per case of 24 sections, at \$3.20; No. 1 light amber, \$3; and good No. 2, at \$2.80. White extracted, 8¢@8½¢; light amber, 7½¢@8¢. Beeswax, 26¢ for clean yellow, delivered here.

THE COLO. HONEY-PRODUCERS' ASSN.

**CINCINNATI, Jan. 9.**—The comb honey market at the present is very quiet. Holders are not trying to realize a profit, simply disposing of what they have, at cost. Fancy comb honey is selling at 14½¢@16¢. Extracted amber honey in barrels, 6¢@7¢; fancy light amber in cans, 7¢@8¢; fancy white, 9¢. Strictly choice beeswax, 30¢, delivered here. **THE FRED W. MUTH CO.**

**INDIANAPOLIS, Jan. 3.**—comb honey is not plentiful, but demand is slack. Fancy white comb brings 16¢@17¢; No. 1 white, 14¢; amber, 12¢@13¢. Best grades of extracted honey bring 8¢@9¢; amber, 6¢@7¢. Good average beeswax sells here at \$33 per 100 pounds.  
WALTER S. POWDER.

**TOLEDO, Nov. 30.**—The market on comb honey remains about the same as last quotations, but has been coming in much more freely, as bee-keepers seem to be very anxious to get rid of their stock. Fancy brings in a retail way 16¢; extra fancy, 17¢; No. 1, 15¢; buckwheat, 15¢. Extracted white clover in barrels brings 7¢@7½¢; cans the same. Beeswax, 26¢@28¢.  
THE GRIGGS BROS & NICHOLS CO.

## Something New = The Ideal Hive-Tool

□ Bee-keepers have long needed a special Tool to work among the hives during the bee-season. The one shown here was invented by Wm. Muench, a Minnesota bee-keeper, some years ago, but it was not on the market before. We have lately bought this Tool, and all rights, from Mr. Muench's widow, and have had the first lot made. They are ready for delivery now.

(This picture is exactly one-half the size.)

DESCRIPTION.—The Ideal Hive-Tool is made of high-grade malleable iron, much like wrought iron, 8¼ inches long. The middle part is 1-16 inches wide and 7-32 thick. The smaller end is 1½ inches long, ½ inch wide, and 7-32 thick, ending like a screw-driver. The larger end is wedge-shaped, having a sharp semi-circular edge, making it almost perfect for prying up covers, supers, etc., as it does not mar the wood.

### What Dr. Miller and Miss Wilson Say of It:

In the first edition (1903) of Dr. Miller's "Forty Years Among the Bees," page 58, he says: "Of all the hive-tools I have tried, I like best the Muench tool." On Jan. 7, 1907, he wrote us saying he thought "just as much of the tool as ever."

Miss Wilson, Dr. Miller's assistant, says this of the Ideal Hive-Tool: "It is an ideal tool. In fact, I don't see how it could be improved upon. I am sure we would feel utterly lost in the apiary without it. . . . You will have to try one yourself if you want to know its worth."

### The "Ideal Hive-Tool" Free as a Premium.

We will mail an Ideal Hive-Tool FREE as a premium to any present paid-in-advance subscriber to the American Bee Journal, for sending us ONE NEW subscription for a year at \$1.00; or we will send the American Bee Journal one year and the Ideal Hive-Tool—both for \$1.20. Price of the Ideal Hive-Tool alone, postpaid, 30 cents. Address,

## Engravings For Sale

We are accumulating quite a stock of engravings that have been used in the American Bee Journal. No doubt many of them could be used again by bee-keepers in their local newspapers, on their stationery, or in other ways. Also, if we can sell some of them it would help us to pay for others that we are constantly having made and using in our columns. If there is any of our engravings that any one would like to have, just let us know and we will quote a very low price, postpaid. Address,

**GEORGE W. YORK & CO.**

334 Dearborn Street, CHICAGO, ILL

## Trade Notes. The A. I. Root Co., Medina, Ohio.

### Photographic Competition

We are pleased to announce another series of prizes for the best photographs submitted to us, as described below, in two series, American and Foreign, under the following conditions:

**FIRST.**—The competition opens January 15th, and closes October 1st, 1907. All photographs intended for this competition must be in our hands by the last-named date.

**SECOND.**—Competition for these prizes is limited to bee-keepers or some member of the family. Entries may be made for as many different classes as may be desired.

**THIRD.**—A photograph entered in one class can not be entered in any other class.

**FOURTH.**—Each photograph should be marked on the back with the name and full address of the sender, and the class in which it is entered. This is important.

**FIFTH.**—In judging the photographs, the general appearance, neatness, etc., of the apiary, or exhibit, or yard, will be taken into consideration. Photos may be sent unmounted. We rather prefer them this way, and in a solo or reddish-brown if possible. However, send such as you can get most easily.

**SIXTH.**—With each of the photographs submitted we would like a brief statement of the conditions under which the apiary was photographed or honey produced, or similar information regarding the photograph. This should be limited to about one hundred words.

**SEVENTH.**—All photographs and correspondence regarding the same should be addressed to Advertising Department, GLEANINGS IN BEE CULTURE, Medina, Ohio.

**EIGHTH.**—We reserve the right to limit the number of awards or withhold any award if no photo worthy is entered in the class.

#### AMERICAN COMPETITION (Including Canada and Mexico)

AND

#### FOREIGN COMPETITION

The following are the classes in which entries may be made:

**CLASS A.**—Photographs of any apiary in village, town, or city.

**CLASS B.**—View of an apiary not exceeding six hives in town or city.

**CLASS C.**—Apiary in town or country of not less than six hives or more than fifty hives.

**CLASS D.**—Apiary in town or country of fifty hives or more.

**CLASS E.**—Photograph of comb honey produced by a single colony of bees; not less than ten sections, and this preferably in plain sections.

**CLASS F.**—Photograph of a bee-keeper's home, showing some view of the apiary if possible. The apiary need not be prominent in the picture, however.

**CLASS G.**—Photographs of a crop of honey from any number of colonies, six or more.

**CLASS H.**—Photographs of any apian exhibit of bees, supplies, or honey taken at fairs or shows of any kind.

**CLASS I.**—Photographs of any work in the bee-yard, such as hiving swarms, extracting, or any other operations with the hive.

**CLASS J.**—Photographs of any other subject relating to bee-keeping not classified above.

#### PRIZES

	Value, Postpaid
<b>FIRST.</b> —One leather-bound "A B C of Bee Culture," 1907 English edition, or cloth-bound French or German.....	\$2.00
<b>SECOND.</b> —One-half leather "A B C of Bee Culture," 1907 English edition....	1.75
<b>THIRD.</b> —One "How to Keep Bees" and any two Swarthmore books.....	1.50
<b>FOURTH.</b> —One full cloth-bound "A B C of Bee Culture," 1907 English edition....	1.20
<b>FIFTH.</b> —One "How to Keep Bees," by Anna Botsford Comstock.....	1.10
<b>SIXTH.</b> —No. 1 bee-veil, all silk.....	.80
<b>SEVENTH.</b> —No. 2 bee-veil, silk face.....	.50
<b>EIGHTH.</b> —One illustrated book, "Bee Culture in Foreign Countries".....	.50
<b>NINTH.</b> —One Bee Model, Queen.....	.50
<b>TENTH.</b> —One Bee Model, Drone.....	.50

Ten prizes are offered for each class: Ten for Class A, Class B, Class C, Class D, etc.—one hundred prizes for American contest, and one hundred prizes for the Foreign contest; two hundred in all if that number of entries are received, the prizes offered being identical for each class for the American competition and for the Foreign.

If the winner of any certain prize already has the prize offered, we will, on request from him, furnish a selection of other items from our catalogs, of equal value.

### Danzenbaker Prizes

It is to be regretted that so many bee-keepers are satisfied to produce year after year a very ordinary grade of honey as regards its appearance, when by a little more care, and having more suitable fixtures, and by taking the honey from the hive at just the right time, a much larger percentage of "fancy," or "extra fancy" honey could be produced, which would sell at a much higher price. The experience of honey-merchants generally is that there is no difficulty in disposing of large stocks of fancy or extra fancy, even when the market is dull. It is the inferior grades that suffer most at these times. We believe, too, that bee-keepers would be very much better satisfied with their season's work if their best efforts were made to produce a really fine product. To increase further the interest in extra fancy honey, the following prizes are offered for honey produced in Danzenbaker hives during the year 1907, under the following conditions:

**FIRST.**—As above stated, the honey must be produced in a Danzenbaker hive, either the present style or any Danzenbaker hive that has been put out within the last few years. These hives may be had of any dealer in bee-keepers' supplies in any part of the country.

**SECOND.**—For Classes 1 and 2 we require a shipment of approximately the amount stated, to be made by the bee-keeper direct to us at Medina. After the prizes have been awarded the honey entered for competition in Class 1 or 2 will be held subject to the instructions of the producer. We will sell it at 5 percent commission, or we will ship it to

any point direct by freight or express. There being good honey markets in our immediate vicinity, such as Columbus, Cincinnati, Cleveland, Buffalo, and Pittsburg, it can be disposed of without difficulty at good market prices, and the shipper will not have to lose a good market by shipping it here. Neither the honey awarded a prize nor that which obtained no prize is to be our property, but will be sold subject to the instructions of the producer who sends it to us. We are interested only in inspecting it to award the prizes.

**THIRD.**—For all honey submitted for prizes we must have a definite statement from the producer regarding the conditions under which it was produced, whether a light or heavy flow of honey, how the colony was handled, how many colonies in the yard, from what source produced, etc.

**FOURTH.**—For Classes 3, 4, and 5, we must, in addition to the above report, have the signature of two witnesses, certifying to the correctness of the report. If the party who sends us the report for the competition is well known to us we shall not require these witnesses. References may be given instead of the signature of witnesses if desired. All parties intending to compete for these prizes should send for blanks which we will furnish, on which the report may be made out.

**FIFTH.**—It will be noticed in the last three classes, three to five inclusive, that it is not at all necessary to send us the honey—all we require is a report.

**SIXTH.**—We reserve the right to limit the number of awards in each class, or to make no awards in a class if there are no satisfactory entries for the same.

**SEVENTH.**—No contestant will be awarded more than one prize in each class, but may make two entries if desired—one in Class 1 or 2, and another in Class 3, 4, or 5.

The classifications for the prizes are as follows:

**CLASS 1.**—For best shipment of 200 lbs. of comb honey in Danzenbaker sections.

**CLASS 2.**—For best case of comb honey in Danzenbaker sections.

**CLASS 3.**—For best report of yield from single colony in Danzenbaker hive.

**CLASS 4.**—For best report of yield from five colonies in Danzenbaker hives.

**CLASS 5.**—For best report of general results from use of Danzenbaker hive.

For each class there will be ten prizes as follows:

**FIRST.**—\$10.00.

**SECOND.**—\$7.00.

**THIRD.**—\$5.00.

**FOURTH.**—\$2.00.

**FIFTH TO TENTH.**—\$1.00 each.

This is the time to decide to enter this competition. No matter where you live, whether in the United States or elsewhere, you can certainly find one class in which you can make an entry; and as there are ten prizes in each class, we believe that no one will be greatly disappointed in the results unless it is ourselves, and we hope that we shall not be, but see a large number of entries. Even if you fail to get a prize, you will doubtless have increased the value of your own product by your efforts to produce some big results or an extra quality of honey.

(Entered at the Post-Office at Chicago as Second-Class Mail-Matter.)

Published Weekly at \$1.00 a Year, by George W. York & Co., 334 Dearborn Street.

GEORGE W. YORK, Editor

Vol. XLVII—No. 4

### Size and Weight of Sections of Honey

Bearing upon the question of uniformity in the weight of honey in sections of a given size, comes this note from Dr. C. C. Miller:

Here are some "fax and figgers" with reference to sections of honey produced by me, and all of them  $4\frac{1}{4} \times 4\frac{1}{4} \times 1\frac{1}{8}$  bee-way with separators, and all containing first-class honey:

In 1897 the average weight was 14.41 ounces per section.

In 1899 the average weight was 14.942 ounces per section.

The year 1903 was, I think, the best year I ever had. But like most years in this locality, there were variations in the flow—sometimes faster than other. In that year 18,132 sections averaged 14.866 ounces each; the heaviest 12-section-case contained 12 pounds and 14 ounces; the lightest 12-section-case contained 9 pounds and 13 ounces. The honey was piled in piles of 15 cases each, and the heaviest pile weighed 178 pounds; the lightest pile weighed 156 pounds.

Please take these figures, together with those of Mr. Ricketts on page 8, and those of Mr. Hall on page 17, and tell us what you conclude about being able to settle on a certain size of section that shall always produce just about a pound.

It must be admitted that in Dr. Miller's figures there is not much difference in the total averages of the different years, the greatest range being only a little more than half an ounce on a section; moreover, his averages are very close to Mr. Ricketts'  $14\frac{1}{2}$  ounces. But Mr. Hall's 792 bee-way sections averaged 15.414 ounces each, lacking the merest trifle of being an ounce heavier than Dr. Miller's average in 1897. That is bad enough, but nothing compared with Dr. Miller's figures for 1903. Between his heaviest and lightest case there was a difference of 3 pounds and 1 ounce, or a shade more than 4 ounces per section. Almost surely the difference was yet more between the heaviest and

the lightest single section. Even when piles of 15 cases were taken, the difference between heaviest and lightest pile was 1.955 ounces per section, which would make a difference of 244 pounds in 2000 sections.

There is no question that a larger section would give larger average weight, but there is no reason to suppose that the variations in weight would not continue, and with a possible variation of 200 pounds or more in a ton, would Mr. Ricketts be satisfied to call such a section about 16 ounces?

### How to Make Honey-Vinegar

From a bulletin of the Arizona Agricultural Experiment Station is taken the following:

When a barrel of honey-vinegar is to be made for family use or by the small producer, we offer the following formula:

Extracted honey, 40 to 45 pounds; water, 30 gallons; ammonia chloride, 4 ounces; potassium bicarbonate, 2 ounces; and sodium phosphate, 2 ounces.

One-quarter cake of dry yeast softened in luke warm water.

The chemicals for making 30 gallons will cost about 25 cents in a small way, but on a large scale not more than 10 cents. Some-what larger amounts of potassium bicarbonate and sodium phosphate would give even better results, but the amounts are here cut to the minimum to bring the cost low enough to make it profitable.

In from 3 to 4 weeks all visible fermentation will have ceased and the yeast settled out. Now rack off the wine, add 10 gallons of good vinegar, containing a little mother, and let stand undisturbed in a place having as near as possible an even temperature of from 75 to 80 degrees Fahr. The acetic fermentation may be started by floating mother, or the scum from an old cask, on the surface of the mixture by means of thin cork-shavings. Carried out in this way, and a suitable temperature (temperature over 85 degrees Fahr., will retard the process and cause loss of both alcohol and acid), a good honey-vinegar can be produced in from 4 to 6 months.

### Legislation for Illinois Bee-Keepers

We have received the following very important communication from Mr. C. P. Dant, of Hamilton, Ill.:

MR. EDITOR:—I desire to call the attention of the bee-keepers of the State of Illinois to the necessity of helping the passage of the Bills which are now before the Legislature of the State in the interest of bee-culture, as follows:

A Bill making an appropriation for the Illinois State Bee-Keepers' Association.

A Bill providing for the appointment of a State Inspector of Apiaries, and prescribing his powers and duties.

A Bill to prevent the spraying of fruit-bloom.

The first of these Bills passed the Legislature before, and all that is needed is a renewal of the same Bill, in the same way that Bills are passed for the support of the State Agricultural and Horticultural Associations. The appropriations formerly granted have given our State Secretary, Mr. Stone, an opportunity of spreading information on bee-culture, and have made our State Bee-Keepers' Association a permanent institution; besides enabling us actively to fight foul brood.

The second Bill is needed to give power to the State Inspector of Apiaries, who has been thus far employed by the State Association, and has done very good work in the destruction of foul brood, but might be handicapped if it became necessary to destroy diseased colonies of ignorant or recalcitrant apiarists. It is also needed to put a penalty on the shipping or selling of diseased colonies of bees. The proposed law is almost a duplicate of the Wisconsin foul brood law. Twelve States, or more, have foul brood laws now, and it is time that Illinois should fall in line with other progressive States on this point. The proposed law had already passed the Senate of the previous General Assembly, but failed in the House, only on account of lack of time. It should pass during this session.

The third Bill is intended to prevent the wholesale poisoning of bees by a misunderstood or misapplied use of tree-spraying. Fruit-trees should be sprayed when the fruit is forming, but the blossoms should be allowed to be fertilized first. In this way the danger to bees, and to those who might eat of the honey, will be avoided, and the spraying will serve its real purpose, that of destroying the insects which prey upon the formed fruit. Spraying just after the bloom has fallen is the most advisable, though ill-advised dealers in spraying apparatus often recommend spraying during bloom. This is an injury to the pollen, which often becomes diluted in the poisonous liquid and is rendered inert. So, even if the bees were in no danger, it would be unadvisable for horticulturists to spray before the bloom is out.

Senator Berry, who is one of the leading members of the present General Assembly,

# American Bee Journal

urges us to use all our influence upon our respective members of the Legislature in recommending the passage of these Bills. So I trust that all of the Illinois readers of the American Bee Journal will write to the Representatives and Senators of their district, asking careful consideration of these measures. All favorable answers to such requests should be forwarded to Mr. James A. Stone, Route 4, Springfield, Ill., in order to put him in possession of all necessary indications.

A concerted action will surely result in success. We are as yet in the infancy of our institutions, and things that seem difficult today will be taken as a matter of course in a few years; but it is only by a united effort that we can get our industry on a good basis, and become recognized as we should be. Help us, boys; and don't delay.

C. P. DADANT,  
Chairman Committee on Legislation.

The following is a copy of the proposed law against spraying while in bloom:

## AN ACT TO PREVENT THE SPRAYING OF FRUIT-BLOOM.

SEC. 1.—Be it enacted by the people of the State of Illinois represented in the General Assembly, that it shall be unlawful for any one to spray fruit-bloom with any poisonous compound that may endanger the life of the honey-bees that feed upon the nectar of such bloom, or the health of those who eat of the honey produced therefrom.

SEC. 2.—Any person violating the provisions of this Act shall be deemed guilty of a misdemeanor, and shall be fined not less than ten (10) nor more than fifty (50) dollars.

We trust that every bee-keeper in Illinois will write his Representatives and Senator at once. As Mr. Dadant well says, it is united effort that counts in such matters. All three of the proposed Bills should be passed. We believe they will be if only bee-keepers will do their duty.

is not so very much shorter than her husband. They are a delightful couple to meet, and both seem to think that Texas is "it."

Of course, our readers feel pretty well acquainted with Mr. Scholl by this time, as he has been conducting "Southern Beedom" for over a year. He says he has lots of "good stuff" on hand for his department, and is determined that the new conductor of "Canadian Beedom" shall not get ahead of him in any way. It remains to be seen just how close a race Mr. Byer will give Mr. Scholl. No doubt the latter can take longer steps than the former, but he may not be able to take them so fast, so Mr. Byer may stand a very good show of keeping up, even if he doesn't get ahead.

It may be that Miss Wilson will say that Mrs. Scholl's picture belongs in "Our Bee-Keeping Sisters'" department. But we didn't like to run the risk of separating her from Mr. Scholl, especially when the two pictures came on one card, which would indicate that the intention was to keep them together.

Mr. and Mrs. Scholl live in New Braunfels, Tex., which, we understand, is almost a section of Germany transplanted in America. The special car of bee-keepers stopped for a minute or two when passing through New Braunfels. We looked for Mr. and Mrs. Scholl, expecting that they would be "at home," but we found that they were already in San Antonio, waiting to receive the Northern bee-keepers there when they should arrive.

John Doll & Son, proprietors of the Minnesota Bee-Keepers' Supply Company, of Minneapolis, Minn., have sent us a very nicely illustrated calendar for 1907. It consists of a heavy card, 8x12 inches in size, on the center of which is a pretty picture showing a road with a bridge over a ravine, entitled, "Through the Woods." Below the picture is the calendar.

The San Antonio Convention Picture is a good one. It shows over 100 of those in attendance. We are mailing them, unmounted, for only 60 cents. They can be mounted by a local photographer for only 10 or 15 cents more. We will mail one of these pictures with the American Bee Journal one year—both for only \$1.40. Send all orders to the Bee Journal office.

Self-Propelled Vehicles.—A practical treatise on all forms of automobiles, by James E. Homans, A. M., fifth revised edition, entirely rewritten. This popular book fulfills the requirements of the motor vehicle owner, operator and repairer. Price \$2.00. Address, Theo. Audel & Co., 63 Fifth Ave., New York, N. Y.

Our Wood Binder (or Holder) is made to take all the copies of the American Bee Journal for a year. It is sent by mail for 20 cents. Full directions accompany. The Bee Journals can be inserted as soon as they are received, and thus preserved for future reference. Or we will send it with the American Bee Journal a year—both for \$1.10. Address office of the American Bee Journal.

**Wanted—Oct. 4th, 1906, Number of the American Bee Journal.** We are out of that issue, and would appreciate it very much if some of our readers who have it, and do not care to keep it for a complete volume, would mail it to us. We will send either a Queen-Button or 2 of our Souvenir Postal Cards to any one who sends us the Oct. 4th copy in good condition.

**Robert B. McCain**, a bee-keeper at Oswego, Ill., recently spoke at a Farmers' Institute, and gave such complete satisfaction that his name has been placed on the list of Institute lecturers. Mr. McCain has attended the Chicago-Northwestern conventions during the past few years, and is well known to its members. He expects soon to be prepared also to give stereopticon lectures on bees and bee-keeping.

**"The Bee-Master of Warrilow."**—Under this title has been issued in London a small book of 64 pages, with 11 really good full-page illustrations. It is by Tiekner Edwards, who poses for what he perhaps really is, a newspaper man with no knowledge of bees. He visits bee-keepers, principally one old man from whom the title of the book is taken, and recounts what he sees and what he is told.

In the main the book is in accord with facts, but sometimes goes rather wild, the imagination of the writer apparently being allowed full play, as where it is said of the workers in spring that had survived the winter:

"Their task of hatching the new spring generation was over: and now, the power of flight denied them, they busied themselves in the work of sentinels at the gate, or in grooming the young bees as they came out for their

first adventure into the far world of blossoming clover under the hill."

The honey from the 220 colonies was all extracted at night, for fear of the bees, even compelling the night work of a little company of women to fill jars and paste on labels. It took 3 or 4 men to do the uncapping, and the extractor was of sufficient capacity to take 25 or 30 combs at a time!

But these flights of imagination are amusing rather than harmful, and much real information may be gained from the book, which is written in delightful style, so that time will be as pleasantly spent in reading this as in reading the most of fiction, and to better advantage.

**A Call to Indiana Bee-Keepers.**—There will be a meeting of Indiana bee-keepers at Indianapolis, on Feb. 6, 1907, at the State House, in Room 12. One object will be to form a State Association, but the most important business will be the promotion of a foul brood law for that State. There will be a morning and afternoon session, beginning promptly at 10 a.m. The united efforts of Indiana honey-producers are earnestly solicited. It is hoped there may be a large attendance. For further particulars address Walter S. Ponder, Indianapolis, Ind.

**Mr. and Mrs. Louis H. Scholl** appear in the picture on the first page this week. Those who attended the National Convention will remember meeting them in San Antonio, last November. Mr. Scholl was just recovering from a long and severe illness. Mrs. Scholl was quite well, and as they were married only last summer, they seemed to be still "on their honey-moon." Mr. Scholl is 6 feet 2 inches in height when he feels well and straightens himself up. We think Mrs. Scholl

## Contributed Articles

### How to Spend the Bee-keeper's Winter Months

BY G. M. DOOLITTLE.

Most of bee-keepers seem to think that the winter months allow them to "let loose" of our pursuit, for the bees in winter repose are better left undisturbed. Perhaps the bees are better undisturbed, but the bee-keeper who pays no thought or attention to the subject of apiculture from the time the honey is taken off the hives till the following May, cannot reap the richest harvest from his bees.

During the fall he should know that all of his colonies are in the best shape for wintering, that they have plenty of stores, that they are safely housed, and that nothing has been left undone that will contribute toward their most successful wintering. Then, if the bees are wintering out on the summer stands, they should be allowed to fly whenever any chance occurs through the temperature rising to 45 degrees in the shade, with the air still, and the sun shining. If the hives are buried with snow, or the entrance clogged with ice or dead bees, they should have all of these obstructions removed, for an occasional winter flight is of the greatest advantage. Don't be hanging around the "corner grocery" at such times as this, and, if I say never stay there, only as you have business, I would give expression to the thrifty side of life.

Should the bees in the cellar become uneasy during March, it is generally better to put them out for a flight. And if they can be protected by chaff or other packing, I would recommend leaving them out. Otherwise they would better be returned till the weather is likely to allow their flying as often as once a week. With such frequent flights they will be more likely to come out well, than they will if kept in the cellar till the elms and soft maples bloom, as is generally recommended as the time of final taking out. But so long as they remain quiet in the cellar, I would not disturb them till it is time to take them out for good.

When pollen becomes plenty, examine the bees by lifting the frames of each hive, and if the colonies are weak, it is better to confine the bees, by means of a dummy, to the frames which have brood in them, together with one frame of honey, so as to help them in keeping up the necessary heat for brood-rearing. A queen will lay from 700,000 to 1,000,000 eggs during her lifetime, if she is a good one, and lives from 3 to 5 years; but under the present system of manage-

ment, the queen is generally coaxed to lay all these eggs in 2 or 3 years.

Of course, the readers of the American Bee Journal all know that bees gather honey, not make it, and the eggs laid by the queen produce bees; consequently the more eggs the queen lays, the more bees we get, and the more bees we have, the more honey they gather.

Then another item comes in right here, which is, that to gather honey to the best advantage, these bees must be on the stage of action just when the flowers are secreting the most nectar. To have a multitude of bees in the hives when there is no honey or nectar in the flowers amounts to nothing. So we must time our work so as to have the queens laying the most prolifically at the suitable time before the honey-flow.

And this brings in another factor: We must know our locality, so that we are conversant with the time of blooming of all of our honey-producing flora; then bring our maximum strength of bees to meet the flow, and in this way we are sure of success, providing the weather is favorable for the secretion of nectar. Of course, we are largely dependent upon Dame Nature for some of these things, but if we fail through thoughtlessness, ignorance or lack of energy on our part, the harvest will be largely a failure, even where Nature supplies all that is necessary for a bountiful harvest.

As soon as the queen has filled with eggs all the combs which were allowed at the time of manipulation above mentioned, more combs must be given, and whether contracted or not, we should see that the bees have plenty of stores at all times, for brood-rearing can not go on at its best where the bees are scrimping their food to the larvæ on account of a shortage of honey, looking toward starvation to the whole colony.

A little before the hives are filled with brood the surplus arrangement should be put on, not waiting for the bees to swarm, as some do, for it often happens that many colonies will not swarm at all, but stick right to storing honey all the season through, when the supers are put on at the right time.

Now, in order to do all of these things just when they ought to be done, the hives, supers, etc., should all be put in readiness during the winter months—all ready to put on at a moment's notice during the summer's work; so, as soon as the work of the fall is done up, these things should be looked after, and faithfully attended to till everything is in readiness for the oncoming season. As you complete these things, one after

another, store them away in neat and tidy order, so that they will not depreciate by standing, through dust collecting on them, or from the depredations of mice and rats.

If you still have more time, get around the back numbers of the American Bee Journal, and other papers and books on bees, if you have them, and re-read and "post up," and you will be surprised to find how many new thoughts and ideas you will get and find, which escaped your former reading, or else have slipped from your memory since you read them before.

Have a note-book with you when you read, with one or two pages for every month, and as you read jot the thought down under the month for which it is appropriate, and then when summer comes, you will have these things at your "tongue's end," or at your "fingers' tips," ready for use just when they are wanted. Say, if you will do this, you will say that you get double value out of the American Bee Journal, or any other bee-paper or book which you re-read in this way; for new things and new visions will open up and unfold to you which had passed unnoticed before.

Then, if you find out anything new, or can shed any new light on some old subject; in short, if you can add your mite of knowledge to these columns, don't be backward in doing it. No matter if you can't write as well as some, or can't put your thoughts together as you think they ought to be, Editor York is "at the helm," and he can make "the crooked things straight," and the "rough places smooth," for both you and me. Come on, beloveds. Let's make this winter one of great advancement along bee-keeping lines. Borodino, N. Y.

### Selling Section-Honey by the Piece, Etc.

BY WM. DUESCHER.

I am not in favor of selling honey by the piece. The "piece-seller" at the convention in Denver, Colo., gave the example of oranges being sold by the piece. It seems to me the largest or heaviest of anything brings, or ought to bring, the highest price. The most of my honey in 1903 weighed from 24 to 26 pounds per case. This should have brought a good price, as every cell was full of honey, but the honey dealers wrote me they get less for such honey.

I use  $1\frac{3}{4}$ ,  $1\frac{1}{8}$  and 2-inch sections, and have always bought three kinds of shipping-cases. For years I have packed  $1\frac{3}{4}$ -inch sections in 2-inch section-cases, in which they fit better, and which saves me one case in every 6.

#### PIPING OF QUEENS AND SECOND SWARMS.

In the Bee Journal for Feb. 9, '05, Canadian Bee Journal was asked, "When you put your ear to a hive the evening before a second swarm issues, did you ever hear more than one queen pipe?" The queens pipe 3 days before the second swarm issues. When such a swarm has settled in its new hive, sometimes a queen flies out, followed by bees, but returns and is surely killed. My father

left the swarm where he hived it until evening, and often found a dead queen before it.

An old way of keeping colonies from robbing is one used by my father long ago. One of his colonies was being robbed by his neighbor's bees. He told him to destroy some of the honey in the brood-frames; that is, cause it to run out. This prevented the robbing, and saved my father's colony.

#### JOINING THE NATIONAL.

My property here consists of 7 lots, nearly 400 feet long. My bees are no trouble to the neighbors, and I don't expect to need help from the National Bee-Keepers' Association, but I joined it for the benefit of others, thus helping to make it stronger.

#### REPORTS FOR 1905 AND 1906.

In the spring of 1906 I brought my 36 colonies of bees out of the cellar, all alive. One colony had a very poor queen, which left me 35. I had only 6 first and one second swarm. There was not so much clover as in 1905, as the ice in the spring froze out most of it. Nevertheless, I got 70 pounds of comb-honey per colony, spring count. In 1905 I got 80 pounds per colony, spring count, and so many swarms that I got sick of hiving them and let many go.

On Dec. 1, 1906, I put 34 colonies into the cellar.

Wrightstown, Wis., Jan. 7.

## Some Bee-Enemies in New England—Spiders, Etc.

BY ALLEN LATHAM.

Much has appeared of late about ants and their destructiveness to bee-prosperity, and we not infrequently read of the actions of toads, kingbirds, etc., but seldom have I ever read in our bee-periodicals of the worst enemy which our bees have in New England.

Here in New England, except for an occasional toad or "bee-martin," our bees are little molested during the spring and early summer. During those months the colonies hold their own in numbers, and, though the work may be severe, the full force keeps very constant. The reason for this is not difficult to find, for most of the enemies of the bee have lived through the preceding winter in the egg form, or else in such small numbers as adults to make small showing. It is when the pests from the eggs have begun to get their growth, or the few adults have become mothers of full-fledged offspring that our bees in New England begin to suffer.

Among these bee-enemies may be mentioned robber-flies, dragon-flies, various bugs, and spiders.

The robber-flies and dragon-flies are not a serious menace to bees in Norwich, though there is no question that many a honey-laden worker falls prey to these insect-tigers.

Among bugs, I know of two sorts that delight over a meal of honey-bee. One is vulgarly known as the "stink-bug"—the well-known bug which frequents ripe berries, and which affords a revelation when taken into the mouth unseen on

a luscious raspberry. This true bug, of the genus *Capsus*, when mature, frequents flowers, and with its powerful beak will pierce the body of the honey-bee which alights near it; and unless the bee is vigorous the bug will suck out the vital juices and leave the dry carcass.

Another bug, of the genus *Phymata*, is even more serious. This bug is of a peculiar shape, suggestive of the black squash-bug, but more irregular in outline, and it has a wonderfully developed pair of anterior limbs. With these powerful limbs this bug will seize and hold its victim, even though the victim be larger, and suck out its very life. These bugs are very numerous on our fall flowers, and earlier can be found on the thistle blooms.

On our thistles will also be found a spider—so-called crab-spider, family name *Thomisidæ*—which pushes its body into the blossoms and with its inconspicuous legs extended lies in wait for its prey—a honey-bee. This spider of numerous species is usually colored like the blossom on which it rests.

If this were the only spider which preyed upon the bee we should have occasion for joy, but it happens to be only one of the many sorts which fatten upon bees. Some of these I will briefly mention, and state the amount of their destructiveness.

About the hive there are three kinds to be found at almost any time of the year. One is the ugly, slim-legged, brown-bodied beast hanging in its irregular web along with several (possibly) of its egg-cases. The spider is one of the *Theridiidæ*, the most numerous of all spider families. This spider is not serious, because its nest is usually in some out-of-the-way corner where only inquisitive robber-bees are likely to become entangled.

But one of the *Attidæ* unquestionably kills many, many bees, and though I have seen one consuming a bee-moth I have little liking for the beast. This jumping spider builds no web in which to catch her prey, but stalks towards her victim and when within a few inches gives a deadly spring. I once saw a bee spring for the spider at the same instant that the spider sprang for the bee; at any rate, spider killed bee, and bee killed spider. Bite and sting proved equally fatal. The spider is black and white, chunky of body, short of limbs, and moves with quick, jerky motions. Though I love it not, this spider commands my respect, for it is a brave and powerful little huntress. Respect her though I do, I nevertheless crush every one I find about the hives.

The third spider which is common about our hives is, or rather are, for there are two or three species at least which delight to live about the hives—the common, long-legged, hairy spider which builds a flat nest with a tubular den. Doubtless these spiders are of the family *Agalenidæ*. The female, as is generally true of spiders, is the rapacious one, and the back of her den will show the fragments of many a doomed bee. Sometimes this spider will succeed in spinning her web in the very hive and thus live entirely upon bees. As it is harmful to bees only about the hives it is a rather simple matter to

overcome this enemy by tearing down its web and keeping as few nooks and crannies as possible about the hives, especially keeping down all weeds.

During my 5 years of bee-keeping here in Norwich I have wondered at the great loss of field-force after the opening of the fall flow. At first I laid it to the fact that breeding had fallen off during August, and that the bees were simply dying of old age. I still think this to be partly the cause, but only a part, and a small part at that. My suspicions fell upon certain spiders two years ago, and are no longer suspicions but certainties. Two of the round-web spiders, sometimes called geometrical spiders, are beyond any doubt, in my opinion, the cause of immense destruction to bee-life in this vicinity.

Species of *Epeira*, the typical genus of the family *Epeiridæ*, and *Argiope*, the black and yellow spider so common about bushes in the fall of the year, are the members of the innumerable spider-life which do untold harm to the prosperity of the bee-hive. It is hardly necessary to describe these spiders, as doubtless they are already recognized. The first, *Epeira Vulgaris*, and her variously colored sisters, is a huge-bodied, clumsy insect when fully grown. Her round web is known to every one. She stays at home in the center of the web while young, but later builds a den above at one side, by drawing together two or three leaves and binding the same with silk. Here she stays till a victim gets entangled. Down she runs to the center of the web and by means of a telephone developed by her ages before man devised his, she determines where the victim is, and rushes out upon the helpless fly, grasshopper, or bee. Shrouding the prey in silk she cuts it loose from the web, hangs it to one hind foot and "shins up" to her nest to eat it at leisure. This spider is either variously colored, or else there are innumerable species all alike except in color. It is difficult to find two colored exactly alike. Beauties as far as coloring is concerned, they ever attract attention.

*Argiope* is the long-bodied (abdomen not round as in *Epeira*) black and yellow spider of the garden. While at rest in her web she brings her legs together into four pairs, two on a side, so that to a near-sighted person she appears to have but four legs. She is always to be found in the center of her circular web, often partly hidden by a peculiar wavy ribbon of silk, which is run across the middle of the web up and down. This spider catches her prey just as does the preceding, but leaves it shrouded where it is caught till hunger calls for it. Thus more than one victim will be seen in the web at once. A favorite locality with these spiders is a clump of goldenrod.

I firmly believe that these two spiders, especially the last-described one, cause the death of two-thirds of the field-force of all the colonies about here during the fall flow.

One has only to walk through the fields in mid-September and see what is to be seen. I have noted no less than 25 of these circular webs about the goldenrod on a plot of ground which

would not equal a square rod. And in each of these webs at any time during the middle and latter part of the day will be seen from one to 3 shrouded bees. When one considers that bees must range over thousands of such square rods he soon realizes that the 50 dead bees on the square rod noted quickly mounts into many thousands.

The late fall was a remarkable one here both for abundance of bloom, and the many days of favorable weather for nectar-gathering. In Massachusetts, where I used to keep bees, I could surely have counted on a very fair surplus, from all strong colonies. I got no surplus, and many colonies of average strength only a moderate supply for winter. To be sure, brood-rearing was not active in August, and much of the field-force consisted of old bees, but that would not account for colonies strong enough to cover 10 frames, and to be in the sections also dropping down in 10 days to insufficient numbers to cover 5 frames of comb.

Before the season was half over, only those colonies which had happened to breed heavily right up to the flow continued to gather much surplus. So I know that hundreds of thousands of my bees fell victims to those voracious spiders, and I have not the slightest doubt that those spiders cost me hundreds, possibly thousands, of pounds of surplus. As it was, the strongest colony put in about 60 pounds of fall honey. This colony had two sets of brood-combs. Knowing the cause of the failure in producing surplus honey, I am seriously considering hiring boys to go out on the war-path against these spiders. It so happens that *Argiope* builds her nest of eggs right near her old web, and it is easy to find. To find it and destroy it means the destruction of two or three hundred prospective offspring. The nest is circular, about the size of a large cherry, and hangs suspended in open view all through the winter. I am thinking of hiring boys to gather the nests by the dozen or hundred.

These spiders are never noticed in spring and early summer, and only as they grow towards maturity do they become a menace to apiculture. Thus our bees hold their own in numbers through the summer months, but go off rapidly in the fall months.

I recognize the spider as holding a useful place in Nature, but I should be pleased to see her numbers grow less in the next part of **Connecticut**.  
Norwich, Conn.

## Uses of Honey in Foods and Remedies

TRANSLATED BY C. P. DADANT.

The Paris bee-paper, "L'apiculture Nouvelle," quotes the following from a small pamphlet by a French author, Mr. C. Moulin:

The scientific men tell us that honey is an almost complete aliment, very beneficial to man's body, and very easy to digest, because contrary to sugar, it does not need to be transformed in order to be assimilated; because, like sugar, and without having any of the

disadvantages of sugar, and under a small volume, it restores the strength of a fatigued man who still has to perform muscular labor before being able to take food and rest; because, being slightly laxative and diuretic, it helps the functions of the intestines, and of the kidneys, and through this the elimination of used-up substances which are in the organs. This is important with sick people, in whom these functions are often inactive and are yet needed to eliminate the cause of disease.

So honey is much preferable to sugar to sweeten the herb-teas; a single spoonful of honey diluted in a cup of hot water constitutes what might be called a "tea-of-a-thousand-bloom," for the bees have visited even a greater number of them to harvest it. It is an excellent excipient for all medicines, and for this reason is much employed in pharmacy, especially for veterinary medicines.

It contains formic acid—a very antiseptic substance; that is to say, a substance which destroys many ferments and several sorts of microbes; for that reason it was formerly employed a great deal to cure eye-soreness, cuts, scratches, burns and small wounds, and the Romans employed it to embalm the dead, by putting in honey the bodies they wished to transport to a distance.

For the eyes I have devised a mixture of equal parts of rose-water and choice honey, which cured many persons suffering from cold draughts, bruises, irritation of the eye-lids or benign ophthalmia; for recent wounds, scratches, cuts and burns of a light form. I have manufactured an ointment which I call the "apiarist's salve," by mixing thoroughly, over a *bain-marie*, one part of fresh propolis, 2 parts of white beeswax, and 7 parts of honey. Applied with carbolated cotton wadding; this runs less than pure honey, covers the sore better, and better prevents the access of ferments, of microbes suspended in the air, or of the air itself, of which the oxygen is the great disintegrating agent in nature.

A physician of my friends has stated to me that he has cured stubborn cases of constipation upon several of his clients by making them take, every evening, a large spoonful of honey, when going to bed, sometimes for several months together; that this has succeeded fully as well as sending them to Switzerland, to be cured with buttermilk, or to the South or to Italy to be cured by eating grapes and figs, and that this honey-cure may be practiced in any season of the year.

Doctor Pauchet, of Arcachon, substitutes, to cod liver oil, the "butiromiel" composed of 2 parts of fresh butter and one part of honey, mixed and whipped together, which makes a sort of cream, and is used without repugnance by his patients, and produces upon them the same results, approximately, he says.

Doctor Boudard, physician in the Navy, at Marseilles, has stated to me that he and several of his colleagues have relieved many persons afflicted with nervous debility, neurasthenia and other nervous affections that prevented them from sleeping, by advising them to eat but little at their evening meal, and take

2 or 3 tablespoonfuls of honey when retiring.

I must stop, for it would take two more pages to give briefly all that I have been told by doctors, or that I have read in scientific works, on the benefits of honey for the health.

I have been a bee-keeper for 18 years, thanks to the numerous learned works that I have read and re-read and commented upon during an entire winter, and it is now 15 years since I have begun, owing to the above-mentioned reasons, to try to make proselytes in apiculture, and to hunt new uses for honey. I am satisfied that the more men will consume of this beneficent manna, which the industrious bees harvest everywhere, the more healthy they will be.

The most satisfactory and most useful preparations I have devised are syrups of honey, which are not so limpid as those found in commerce, but are much more salubrious. I make these by mixing a quart of water with 8 pounds of honey, which I heat *au bain-marie* (over hot water) and skim. If I incorporate in the syrup from 50 to 100 drops of essence of eucalyptus per quart, it gives me a eucalyptus syrup with which I cured rapidly a great number of persons suffering from colds, hoarseness, sore throats and slight attacks of bronchitis, by directing them to use half a pint of this syrup, which they must take in tablespoonful doses with a tea made of basswood blossoms or orange leaves, according to the case; and I relieved a number of others having chronic affections of the respiratory organs, such as catarrh or asthma.

If instead of essence of eucalyptus I use in the syrup of honey the same quantity of essence of mint, it becomes suitable, in doses of a tablespoonful in a cup of hot water, to help weak stomachs, or prevent indigestion in persons whose digestion is accidentally bad; if I use essence of anise-seed it becomes anti-flatulent. If I use essence of pine-apple or of raspberries, etc., or, better yet, if I use, instead of water to make the syrup, the same proportion of well-filtered juice of currants, raspberries, cherries, etc., I have a syrup which in hot weather makes a splendid preparation for seltzer or soda-water, or other mineral water.

I manufacture pastes similar to jubee-paste, which I also cut into small squares or lozenges. Melt in an enameled skillet, over a *bain-marie*, 2 ounces of gelatin with 3 ounces of water. When by stirring you have brought the gelatin to the consistency of a soft dough, still stirring briskly, pour into it slowly about 14 ounces of honey which has been previously heated also *au bain-marie*; when the parts are thoroughly mixed, pour it into a paste mould, or into a flat dish which has been lubricated with choice olive-oil. If before pouring out we incorporate, into the paste, essences of either eucalyptus, mint or anise-seed, in the proportion of 50 drops per 2 pounds, it acquires the same properties as the syrups, according to the essence used, and I sometimes color diversely both pastes and syrups for the trade of confectioners and dealers.

If I incorporate into the paste from 8 to 12 ounces of cocoa, and a little vanilla, I call it "cocoa-honey," and I pour

it into chocolate moulds. It then resembles chocolate, by taste, appearance, and preserving qualities, and may be used in the same way, either as a dainty or with milk or water at the breakfast table.

By simply mixing one part of the cocoa with 2 parts of honey and a little vanilla, we secure a paste which may be preserved for several months, in a jar, and may be used in a similar way. A mixture of one part of sweet almonds and a few bitter almonds crushed, with two parts of honey, makes a delicate almond-cake paste.

I have succeeded, but moderately, in

making honey-pastry, but I have secured some delicious dishes, such as chestnuts and honey. I first remove the outer shell, then bake them with steam or very little water, then removing the second peel and the diaphragm, I roll them in honey scented with vanilla, while hot, and then in this way I have a dish much resembling the highly-prized iced-chestnuts.

I dedicate this little essay to the kind and lovely women who are the natural nurses and usual housekeepers of the homes, and are very much more intelligent and much more expert than ourselves in the preparation of all these little dainties.

C. MOULIN.

save the bees overcame his childish prudence, and he took chances on being shot down or captured by the wild Indians that were then depredating the country.

We next find "L. B." in Johnson Co., Tex., where his father had moved with the hopes of at least being free from the peril that constantly threatened his family, and the losses he sustained from the red man; and also he hoped to find schools more plentiful. But, alas! in the earlier days of Texas many a youth that might have developed into brilliant manhood grew up like "L. B.," with a very meager education, and lived to regret that an educational opportunity never presented itself.

Mr. Smith has been married twice, and says he owes what little education he has to his first dear wife and her sister—the writer of these lines. He married while just a boy in his "teens," and how vividly the picture stands out before me, of a little vine-wreathed cottage with gay flowers nodding to the breezes, interspersed here and there with a busy colony of bees, and the fair girl-wife reading some periodical on bees, and the boy husband listening and gazing intently at his much-loved pets.

It was in 1881 he saw some frame hives, and becoming much interested in them the farmer kindly loaned him one, as a pattern to make others by. He soon had his bees transferred into frame hives, and subscribed for the American Bee Journal, Gleanings, etc. Nothing escaped his eyes pertaining to bees. He eagerly read every line obtainable on the subject. He lived to learn.

While his education is quite limited, his knowledge of bee-culture is extensive, and I might be safe in saying there is no man in the great State of Texas that has written more letters, and answered more questions in regard to bee-culture, than has L. B. Smith. He says, "I believe if the sheets of paper were layed end to end that I have written on this subject, they would reach quite across the State.

Notwithstanding his style of writing, he has written many articles for the various bee-papers, and today is employed to write for two of the leading ones, which shows that his teachings on apiculture are thoroughly practical and sound. He has several times been offered a neat little sum to conduct a bee-department in the various newspapers, of this and other States, all of which was refused on account of lack of time, education, etc.

Perhaps there is no better informed bee-man in our State than Mr. Smith. Having spent 25 years in search of apian knowledge, his enthusiasm on the subject amounts almost to a craze. There are but few books and papers that he is not perfectly familiar with.

He is a strong believer in the Langstroth hive and frame, and the good old 3-banded imported Italian bees, but says he is sure there is more in the location and management, than there is in either the kind of bees or hives; that he could take any of the frame hives in practical use today and make a success of bees in a good locality.

He has never kept bees in large num-

Conducted by LOUIS H. SCHOLL, New Braunsfels, Tex.

### Hand-Shake to the "New Man."

So a new man takes Mr. Pettit's place "at" "Canadian Beedom." We learn that he is not so tall as his predecessor, so there's no fear of one fellow losing his place on the staff as being the "tallest," anyhow. Sorry Mr. Pettit leaves us. Good luck to him in whatever he now undertakes. To the "new man," a hearty shake.

### Lighting a Smoker with a Gun

W. F. McCready, of Florida, gives the following "hint on lighting smokers":

"I arrived at the out-apiary with a gun, but no matches; took the lead and part of the powder out of a charge, and fired the balance of loose powder into a rag-filled smoker, and instantly had it thoroughly lighted, without the trouble of going to the nearest neighbor for 'a light.'"

This is quite a novel way, but it may "come in handy" for "us Texans," especially since our guns generally accompany us on our trips to the apiaries.

Several times have I arrived at apiaries to find that "the light" was left at home, and not a match within a mile of the apiary. It is better, though, to have a large dry-goods box with a hinged cover, and this covered with tin, in each apiary. The box is fitted with shelves for many things generally used in the apiary, and a small, tight tin-can full of matches is one of these.

### L. B. Smith, Bee-Keeper

Mr. L. B. Smith was born March 13, 1858, in Pontotoc Co., Miss. That year his father moved to Bosque Co., Tex., to what was then known as "The Wild and Woolly West," as at that

time the Red Man roamed at large almost unrestricted. There his father engaged in farming in a small way; and there "L. B." manifested his first interest for the busy little bee, or we might say showed the talent of an in-born bee-keeper. His parents say he would sit for hours and watch the bees

L. B. SMITH.

come and go from the old log and box guns. When only 7 years old he successfully hived his first swarm of bees, taking them down from a limb of a very tall tree. He also followed an absconding swarm (that chanced to leave his father's primitive apiary), and located them in a hollow tree, one mile from home. He was alone, but his enthusiastic love and great desire to capture and

bers, usually keeping from 150 to 175 colonies, and tries to keep from 40 to 50 colonies in each yard. He has never been able to secure the large yields of 400 and 500 pounds of honey to the colony that some report, his best yields being only about 100 pounds to the colony, of extracted honey, and 50 to 75 pounds of comb honey. He has produced many tons of honey in the past 20 years, and has always found a ready sale for it.

Mr. Smith never runs after new fads and fancies in the way of so-called improvements in hives and other fixtures for the apiary, always leaving that for the "other fellow" to test. Yet he is not so "set" in his ways and manner of working that he is not willing to adopt the plans and ideas of others when they are shown to possess real merit.

He is neither saint nor plebeian, but his integrity stands above reproach. He was reared by Baptist parents, belongs to no church, but inclines to the Christian faith. Owing to his jolly disposition and great love of music, he has always been a favorite among the young people, entertaining them for hours with the sweet strains from his violin. He loves Nature in all her charms, nothing delighting him more than a lonely stroll on a balmy spring day among the wild flowers and budding branches, watching the tiny bee gather the pollen, and listening to the warbles of the merry songsters as they flit here and there among the lofty branches that sway above the silvery stream—the Rio Colorado—near his home.

(Mrs.) SALLIE OLIVER.

## Summer Weather in January

We are having peculiar weather here in the South. It is the middle of January, and the thermometer registers 80 degrees Fahr., today—real summer heat. Roses, violets, and carnations are in full bloom in the gardens, and some wild flowers are to be seen in sheltered spots. Occasionally a fruit-tree is covered with flowers, and bees hum about them. We are sleeping with windows open. There have been only a few frosty nights this winter, but cold weather may yet be expected during the next 2 months. However, I shall not venture to predict the weather.

There is an old saying here in Texas that amused some of our Northern delegates to the San Antonio National Convention last fall. Some of them naively tried to "predict" the weather, not aware however that they were in "Texas." The saying is something like this—and you may know how some of them felt about their predictions when they heard it: "A Texan never tries to predict the weather, because it is impossible to tell anything about Texas weather." or what it is going to do. So if you hear anybody predicting the weather in Texas, you may put him down as being one of two things—either he is a stranger or he is a fool.

The above fact as regards our disability to know more about our weather is quite a factor, and of interest to the bee-keeper. Could we know more about

our changes of weather beforehand, or could we foretell the season to a better extent, it would help us to profit much by it. We could plan accordingly. In-

stead, we are left "guessing" most of the time, and left to "take our chances." This, I believe, is more true of Texas than other States.

### Beeswax for Floor-Polish

As a wax-polish for floors, the Irish Bee Journal gives the following :

Cut the beeswax into thin shavings, cover with turpentine, let it stand 12 hours, stir up with a stick, adding turpentine until the mixture is thin like ordinary cream. Apply it in small quantity, and polish with flannel.

### Bee-Keepers—Transient and Permanent

"Leafless trees and meadows bare  
Show the work of autumn air."

Ever since attempting out-apiaries I have found it imperative to keep a horse and conveyance of some kind. Having these, and realizing that many of those compelled to deny themselves of such privileges enjoy a ride even more than I do, I frequently make it a point to give such a treat in the way of a short trip over the country. Among others, a certain little girl delights to accompany me. Little worth notice escapes her bright eyes. She has made herself well acquainted with the birds' nests in trees, hedges, brush, and weeds all along the highway.

By being acquainted, I mean she knows their history from the laying of the first straws to the finishing touches of the lining with soft material for the reception of the delicate eggs, and, later on, the tender young. From the completion of the nests on, she anxiously watches and anticipates the time for the birdlings to take their first lessons in flying. She knows the names of different trees and plants, their time and duration of blooming, the quantity and quality of honey which may be expected of them, perhaps much better than many would-be bee-keepers.

Her innocent prattle along the homeward stretch diverts one's mind from tired and worn feelings, and in forgetting them one is amply repaid for any little extra trouble it has been to give her the outing.

Recently, as the many-colored leaves came scurrying down over us, I asked her if autumn was not the most beautiful of seasons? She replied, with not a little awe, combined with evident distress and much concern, "Oh, no; don't you see the trees are almost bald-headed?"

In so many cases bee-keepers prove

to be most ardent lovers of Nature that the questions, "Are Nature lovers" the more likely to become bee-keepers, or is it because they are bee-keepers they are compelled to be devotees of Nature? are forced upon me.

It is quite easy to imagine the commercial bee-keeper so busy that the beauty so lavishly spread all around him is lost, or to no purpose; but with the average bee-keeper this constitutes one of the principal charms connected with the pursuit.

Right here we have two distinct classes of bee-keepers—those who are in the business for the love of it, and those who are in it for the dollars it brings. Quite a task lies ahead of him who would enumerate all the different kinds of bee-keepers, and I do not propose to attempt it, but the following are a few of them :

Male and female, white, yellow, black, and I may add "green." (Of course, there's no one going to take offence, because only the jocularly inclined, and those farthest from it, are going to be willing to acknowledge they are in the latter class.) But to return to our list: The aged and young bee-keeper; the amateur and the professional; the small bee-keeper with his mere handful of colonies, and the extensive one with his thousands of colonies; the ambitious enthusiast and the aimless stupid; the successful and the unsuccessful; those who are bee-keepers for the fun of it, and those who must needs be in earnest. All these, and many more kinds, may be classed under "transient and permanent." The former a sort of "thorn in the flesh" of the fraternity, and the latter its "bone and sinew."

The shedding of the leaves and the decay of vegetation brings desolate, neglected apiaries of the former to light, and how very prominent they do stand out—a disgrace to their owners, and, for that matter, a disgrace to the whole following. 'Tis plain to see these are they who are on the lookout for something for nothing, and, finding naught but disappointment, are eager to cry down the whole business as a fake and a humbug. They belong to that rapidly growing class who search the newspapers and periodicals for the flaming advertisements which announce "free offers," and repeatedly grasp at the alluring promises, much

# American Bee Journal

the same as does the drowning man at a straw.

The post-office department at Washington is ever on the alert to protect the people, and is constantly combating and extinguishing frauds; but new ways and means are as constantly devised to catch the unwary, who are seeking something for nothing, and the army of victimized innocents grows no smaller. How slow they are to learn that a scoundrel will exercise more ingenuity and more energy in beating another out of a few cents than would be required to make more than as many dollars in a legitimate pursuit. These rogues are watching on the one hand for a "rake off," and on the other making sure of not being "raked in."

The frantic, though fruitless, following of one *ignis-falvus* after another to their final evanescence, teaches no lesson, but rather seems to add fuel to the flame of excitement, until the habit becomes a fixed one, and the appearance of a flickering light in a new location is but the signal for the beginning of renewed chase. Poverty would be known only as a myth, and the world would be overflowed with plenty, were all the efforts which are made to get something for nothing turned to practical pursuits.

It is quite easy to make a fool of one's self, but none of us ever fool Nature into giving us more than we have earned by honest endeavor.

While marketing honey the seller is frequently greeted with, "You can take much less than you are asking for your honey," or remarks of similar import, "because you get it for nothing." But woe unto the man and woman who starts in the business harboring such false notions; the awakening to the truth will stagger them; and if in addition they coddle themselves into the belief that "there's millions in it," they will get a hard fall. The person who satisfies himself or herself with slack methods, or, rather, a lack of method, will in the final round-up find the most dissatisfaction.

I recently read of a banker who refused to lend money to the farmer that permitted his implements and machinery to remain outdoors, subject to the ravages of the elements; and the bee-keeper who allows his capital stock to lie around loose and unprotected deserves no better treatment. To expect returns from bee-keeping that can cope with such drainage is unreasonable. Such habits might almost be termed "criminal carelessness," as the loss therefrom is often most keenly felt by the dependent family.

These are they whose banners bear the legend, "Hard times," and, indeed, the desolate, neglected apiaries belonging to such, cry "hard times" more emphatically than the owners thereof. While we deeply regret that the transient bee-keeper is not awake to his opportunities (hence is of a necessity transient), we comfort ourselves with the reflection that the number of the unconcerned within our ranks is no greater than is to be found in connection with other vocations; and that we have hosts who are making the most

of their opportunities, and are appreciative and thankful—

"Not only for this present store  
In winter storm and blight,  
But for the hope that asks for more,  
And sees that more in sight."

These latter are our permanent bee-keepers, of whom we are all so justly proud, and who, when they fall down, do not stop to "cry over spilled milk," but are up and at it again as if the thought of defeat were not to be entertained for a moment. The inscription on their banners requires but one more little letter, but instead of a

frowning, repellent one, it is smiling and attractive. It reads, "PROSPERITY."

As an industry, bee-keeping owes its very existence to these undaunted stalwarts. The pioneers deserve, of course, the more credit, but there are those among us who are valiantly fighting our battles, and have already earned bright laurels. Why wait until they have passed to the Beyond before we offer flowers? For them we will need to set up no memorials, for, truly, by their works shall they be known.

## Combined Hive-Cover and Bee-Feeder

Here is a drawing of cover and feeder combined. It is an ordinary double-walled cover, but there is a space of 2 inches between the two walls. The crack A in the lower wall is about  $\frac{3}{8}$ -inch wide. This is to allow the bees access to feed, and is about 2 inches in

COMBINED HIVE-COVER AND BEE-FEEDER.

from the side of the cover, which is permanently closed.

The second drawing shows the other side of the cover, which is closed by the door C. This door is a piece of  $\frac{1}{2}$ -inch stuff, one end of which fits into groove B. The other end of the door goes against a little block on the inside of the end of the cover, and is secured by a button D.

The feeder is a common dripping pan of any size, about  $1\frac{3}{4}$  inches deep.

To feed, simply fill the pan, and slide it into the chamber, being careful not to shove it over crack A.

This is an excellent thing to feed in at any season. It is not necessary to break the cover loose after it is sealed, or in any way to disturb the bees. If it is properly made it is nearly airtight, and is not a cold place for bees to go at any time. I believe that bees may be fed with this feeder in weather which would prohibit feeding with any other kind.

Some may object to the extra cost of this cover, but there is little more material in it than in other double covers. When cost of feeders is considered, this is really a cheaper arrangement. Besides, this feeder is always on the hive, and ready for use.

Ontario, Dec. 26. H. A. SMITH.

Truly, it might be said, Of the making of feeders there is no end. Some are good, some bad, and others indifferent. From the description given by Mr. Smith, I don't know but that his feeder deserves to be placed in the first-named class. No doubt it would be good for stimulative feeding, and it certainly is so designed that with its use the danger of robbing would be reduced to a minimum, as there would be no excuse for spilling the syrup, or in any way exposing it to other bees than those for which it was intended.

One objection, if such it can be called, to the Alexander feeder, is the fact that all bottom-boards and hive-stands have to be nicely adjusted, otherwise there will be trouble. I am sorry to say that in my yards the hive-stands are not always *nicely adjusted*, therefore the Alexander feeder does not meet with favor in my eyes. With Mr. Smith's feeder that objection is not present, and to those who practise stimulative feeding, it should be worth a trial, at least.

I would be inclined to think that in

cool weather the bees would be slow to come up through that  $\frac{3}{8}$ -inch opening, but as Mr. Smith intimates that such is not the case, I am willing to withhold judgment until others have tested the matter.

As it seems winter feeding is becoming quite common, even if it is not popular; and as some may happen to have colonies which they know are short of stores, while the "feeder" subject is under discussion, I thought it might be wise to submit the following from the Farmers' Advocate. I happen to be well acquainted with the writer of the article, and know him as one of Ontario's brightest of bee-keepers—in short, a hustler. It is needless to say that anything from the pen of "E. G. H.," I always read with interest. Here is the article referred to:

#### FEEDING BEES IN WINTER.

While all bees should long before this time of the year be snugly tucked away in their winter quarters, with plenty of honey within their reach to carry them through until spring, there are almost sure to be a few colonies here and there which, from one cause or another, have entered the winter "light in stores," and, unless something be done to help them, will starve to death before the winter is over. Perhaps their owner neglected them in the early fall, thinking he would have more time to attend to them later on, or the bees may have become the property, late in the season, of some person who knew nothing of their requirements, and has only very lately become aware of their condition. In either case, the bees must have feed given them, if they are to be brought through the winter.

If the owner of the hungry bees has any combs full of honey in his possession, and the combs on which the bees are wintering are of the movable variety, his best plan is to remove a comb from near the outer side of the hive (if this can be done without breaking the cluster of bees), and to put a full comb in place of the empty one, getting it as near the bees as possible. If the comb can not be gotten into the hive, the next best plan is to lay it flat on top of the frames, placing a couple of narrow strips of wood under it to hold it up from the frames half an inch or so, so that the bees may get at all the underside of it. When the bees have emptied the underside, turn it over; and when both sides are empty remove it and place on another full one.

If no combs of honey are to be had, it will be necessary to make what is known as "hard candy" for the bees. If well made, this candy will winter the bees just as successfully as honey will. To make the candy, place granulated sugar in a vessel and add a little water—just enough to slightly wet the sugar. Melt it on the stove and boil it until it will become hard and white when taken from the stove and allowed to cool. Stir it more or less while boiling. To tell when it is "done," test it occasionally by taking a little from the stove and stirring it on a dish until cold. When it cools hard, smooth, white and dry, it is all right. When it reaches this stage, remove it from the stove and stir while cooling. If not stirred it will harden like taffy instead of like candy, and will daub the bees when they eat it.

When it has cooled to the point where it will just nicely pour, it should be poured into dishes or pans that will make cakes of convenient size for laying on top of the frames of the hive. These cakes are laid on the frames in the same manner as the combs spoken of above. About 10 or 15 pounds of this candy should suffice for an ordinary colony of bees, but they should be examined again early in the spring and given more if they are in anyway nearly out.

The principal thing to be careful of in making hard candy is not to let it get burnt. The

least sign of burning renders it unfit for bee-food, and it will kill them if given to them. Better make a small lot first to learn how.

After the bees have been given honey or candy, they should be covered up well with chaff or leaves if wintered outside, and should then be left severely alone until there is reason to believe their supply of food may be nearly exhausted.

Feeding bees in cold weather is only making the best of a bad job, but if you find yourself with the bad job on your hands, it is better to make the best of it than not to make anything of it; and bees wintered on candy are just as good, other things being equal, as any other bees, and are worth a good deal more than bees that starve to death in February.

E. G. H.

## Report of the Ontario, Canada, Convention

REPORTED BY MORLEY PETTIT.

(Continued from page 53)

### SPRING MANAGEMENT OF BEES

Spring management is a very important part of bee-keeping and the writer will not be able to do it justice.

Spring management depends so much upon fall management that you will not object, I hope, to a few remarks on that subject: Every hive should have a good queen and not less than 40 pounds of good honey when put into winter quarters; then if properly protected during the long winter, spring feeding will not be necessary. Feeding in spring is a disagreeable job for the bee-keeper, and you can not fuss around a hive at any time of the year without annoying the bees, more especially at this season.

Suppose a bee-keeper has about 100 colonies, part having been wintered on the summer stands, the balance in a good cellar; if proper protection and ventilation have been provided for, and the hives left outdoors, there is no need to touch them till we are having nice days in April; about that time those wintered in the cellar may be taken out, but a great deal depends upon the season, some seasons being very much later than others. A good time for removal from the cellar, if the bees can be kept quiet, is when the first pollen is coming on; then choose a fine day. The writer has not tried the Alexander plan, and finds no difficulty with bees. Of course, one must be careful not to put too many hives in one place at the start—put a few at one corner of the yard, then the opposite corner, and so on, until all are placed; then take 4 or 5 sheets of newspaper, previously saved for that purpose, and cover the tops of the hives, taking care that no heat can escape. Then when the bees are done flying for the day, close all the entrances as close as possible; this to keep the cold wind and robber-bees out. If the hives on the summer stands have not had paper put under the cushions it should be done now.

In an average season this work should be finished April 12 to 20; then we may expect the first fruit-bloom about the

same dates in May; and knowing the bees have plenty of stores it is a good plan to let them alone, except to look out for robbing on a day when the weather is suitable for the job.

About the time the first flowers come out a start should be made to examine the hives, clip the queens, spread or reverse the brood-frames, break a portion of the cappings on the honey, making the bees think they are in clover; when this is being done the bee-keeper should have a book and note the condition of every hive; a record of this kind saves lots of unnecessary opening of hives.

When we get to No. 100 we will probably find 80 per cent will be ready for the honey season, 15 per cent a little light, 2 queens and 3 dead colonies. (The dead ones have been found before the examination, or should have been.) The 80 should be watched closely, making sure that there is enough unsealed honey in the hives, and that the queen has lots of room for breeding. A good plan to treat the 15 that are light is to select say 7 or 8 (according to their strength) of the best of them, take out all empty frames, then go to the lighter ones and take out brood frames and bees, fill out the 7 or 8, making sure you leave the queens in their own hives. The few that are left light can be used to shake swarms on, or anything else the bee-keeper can do with them to the best advantage.

We will suppose this work is finished by, say, May 20; in less than a month the clover season will be on, and upon the care given the bees for the next few weeks largely depends the amount of surplus the bee-keeper will get for his work. Some seasons the bees may fill the hives so full of honey in a few days that the queen is crowded out, then another season the bees will be confined in their hives most of the time, and run short of stores, and the queen will stop laying; to avoid either extreme the bee-keeper must be on hand every day to know what is going on, and apply the remedy.

JAS. STORER.

Lindsay, Ont.

"Is it better to give 40 pounds in the fall, or 25 in fall and the balance in the spring?"

Mr. Holtermann—Better feed all in the fall. It may not be safe to have only 25 pounds in the fall. You sometimes

find colonies that consume an exceptionally large amount of stores, so we should, if anything, err on the side of too much stores.

Mr. Deadman—If wintering in the cellar, we would only have that much more to carry in and out. Twenty-five pounds in the fall is ample to last till we can examine them in the spring. Put the light colonies to one side in putting them out in the spring, and feed them.

Mr. Hershiser—How do you feed late?

Mr. McEvoy—Lay oil-cloth over the frames and on this set sealers upside down with sugar syrup. Pack those in the super and they may take down 20 pounds in one night.

#### INTRODUCING QUEENS.

Mr. McEvoy—Introduce in a folded cage on the comb. Where queens are allowed to eat their way out, they are killed, sometimes; but where introduced on the comb, they are always all right.

"Is it advisable to put new queen in the hive before taking out the old one?"

Mr. Couse—To introduce an imported queen, take away all the brood and eggs, and then introduce the queen to the broodless and queenless bees.

Mr. Holtermann—Simply take out the old queen and put the queen-cage and all right in, and the candy is eaten away and queen introduced.

Mr. Timbers—The bees should be taken out of the cage first, because in many cases the bees in the cage cause the queen to be balled.

Mr. Armstrong removes the queen to his own cage before introducing.

"What is the best time to introduce a queen?"

Mr. McEvoy—In August, unless it is necessary to introduce at some other time. To introduce a queen in a super, shut the bees off from the brood-chamber with a fine screen for 48 hours. Then set the super off on another stand and introduce a queen quite successfully.

Mr. Evans—For introducing leave the cork in the cage for 24 hours, if the colony is strong. Then remove it and let them eat out the candy. If it is a weak colony, take out the cork at once. To introduce valuable queens, it is safer to introduce in a nucleus.

#### UNFINISHED BUSINESS.

A vote of thanks was tendered Messrs. Holtermann and Holmes.

A tribute was given to William Couse, who has been secretary for 21 years.

Mr. Holtermann—I have known him for 25 years, and always found him sincere in everything. He has served the Association well, and we regret that, so far as he personally is concerned, he is to remove from the office of Secretary.

Mr. Sibbald—I started to work for him when 11 years old. Mr. Couse loves the Association, and dislikes to give it up, though the work is a sacrifice in view of his other work.

Mr. Couse spoke well-chosen words of appreciation, recollecting when D. A. Jones told him he was to be secretary of the Association. His ambition has been to serve the Association to the best of his ability. He has the greatest asset a man can have for the time spent

—that is, *friends*. He was fortunate to have had men who always aimed to do the best. He spoke a word of tribute

to many of the men who had been President while he was Secretary of the Association.

Send Questions either to the office of the American Bee Journal, or to  
Dr. C. C. MILLER, Marengo, Ill.

Dr. Miller does *not* answer Questions by mail.

#### Getting Straight Brood-Combs

I am new in the bee-business, and find some things I do not understand. I have 5 colonies, 3 from swarms in 1906, and 2 from 1905. They are all in patent 8-frame dovetailed hives except one in a 10-frame hive. I find lots of trouble in changing the frames, or getting them out, for the bees do not build the combs straight. Would it pay me to take out the old combs in the spring and put in full sheets of foundation, mostly worker-comb? Should I put in full sheets of foundation in the new colonies—those just starting? I want to start right, and I depend mostly upon the American Bee Journal and the "A B C of Bee-Culture" for my guides.

PENNSYLVANIA.

ANSWERS.—I think there is no patent on the dovetailed hive. The patent on the movable frame expired some years ago.

Yes, it will pay to have new combs built for the sake of having them movable, but that is probably not necessary. The likelihood is that at least some of your frames can be lifted out, and then by a little cutting you can get the others out, and crowd each comb into its own frame. If you can not do so, you can cut the combs as much as necessary to get them into the frames. A good time to do this is after the bees begin work on fruit-bloom. But I wouldn't put them on frames of foundation till swarming time, and then you can hive all swarms on full sheets of foundation. I have always had my frames full of foundation, and if I had it to do over again I would do the same way again.

#### Queenless Colony—Making Honey Granulate—Shade for White Hives—Ventilating Hives

1. What is the best to do in spring with a queenless colony that is strong and has plenty of honey?

2. What is the best thing to do with honey to make it granulate? Is it usually shipped in the granulated form?

3. Is shade necessary with large hives painted white, and run for extracted honey, with from 2 to 3 supers to the hive, and good ventilation?

4. Would you advise putting an inch piece between the hive and bottom-board at the sides and back end of hive? ONTARIO.

ANSWERS.—1. First let me tell you what not to do. Don't give it brood from some other colony and have it rear a queen. One reason is, that while it is rearing a queen it will be getting weaker all the while, there being none but comparatively old bees present, and it will be a long time before any young ones will be ready for work. Another reason is, that in early spring you will find so many failures in queen-rearing, and often will succeed only after giving brood the second or

third time. Still another reason, and a sufficient one of itself, is that these early-reared queens are very likely to be worthless. There are three things you can do: You can send South for a queen; you can unite with the colony a weak colony having a good queen; or you can break up the colony and distribute combs and bees to other colonies, especially to the weaker ones. If your other colonies are in good condition, and if you are anxious for increase, send for the queen. If you have a weak colony, unite it with the queenless one. Even if you are anxious for increase, this may be better than to send for a queen, as the very weak colony will be very slow about building up, and is not of very much value except for its queen. If you haven't any such weakling, you are pretty sure to have two or more that are under the average, and if you divide the bees among these you will be putting the force where it will do the most good, and will very likely have as many colonies and as many bees in the fall as if you had sent for a queen. You can put a combful of these bees in any hive in the spring without any precaution whatever, as they will unite peaceably.

There is a factor to be considered in the case that may decide in favor of sending off for the queen. It may be that your stock is not up to the mark, and that by sending off you can get a queen of much better quality. In that case the queenless colony gives you the chance.

2. Cold favors granulation; so you may hasten it by keeping in a cool place. Occasional stirring also helps. Probably most of the honey shipped is not granulated; but very much of it becomes granulated before it reaches the consumer, unless pains is taken to reliquefy it.

3. I think not for the bees, although pleasanter for the bee-keeper. It depends a little upon what you mean by good ventilation. I should want a space of at least  $\frac{1}{4}$  inch the entire width in each story.

4. I suppose you mean for wintering in cellar. Yes, it is quite important in some way to have plenty of ventilation in the cellar, and if there is no opening for ventilation except the hive-entrance, a strip to raise the hive an inch or more from the bottom-board is a good thing. My bottom-boards are 2 inches deep, and then in summer I fill part of the depth with a sort of rack.

#### Control of Increase, Introducing Queens, Etc.

Last season I had a fairly good honey crop. The bees wintered without loss. I put out 12 colonies and increased them to 20, the yield of extracted honey being much over 100 pounds from each colony, spring count. But for the American Bee Journal it would not have been half that. I have been doing my best for a few years (with the aid of some of the writers in the American Bee Journal) to

# American Bee Journal

control increase, but so far without success. In fact, the last season their advice resulted the very opposite. Swarm the bees would, everlastingly.

The advice was, after getting the colonies strong in bees and brood in the spring, to lift the hive from its stand and replace it with another having empty frames, and put a frame of brood and honey with the queen among the empty frames, using a queen-excluder, and then placing the hive with the brood on top.

I did that to the best of my ability, and true the queens filled the under part full of brood again, the brood soon filled the upper part with young bees and some queen-cells. Now the honey-flow was on, and oh, my! swarm they would, and I had to rush to market for empty hives, frames, and foundation, and, when short of these, dump one swarm upon another, although several days old.

What is your best and simplest plan for controlling increase? You are long-headed, and I put much value on your answers to questions, generally reading them first.

The man from California who was solving the question by letting the bees swarm, and then catching the queen and letting the bees go back, seemed to have it; but that *but*, like all *buts*, counts for much. If we could not find her in the cluster, we would surely catch her by putting the bees through a zinc queen-excluder. It did not seem to me a very simple process—the sifting of a big swarm of bees through a zinc cage. I could see them going in as fast as I got them out, and the queen still out of sight.

Even if I can not learn just how to control increase through the American Bee Journal writers, it has given many good points in producing surplus honey. My showing is always good. It keeps me in line as to how to have strong colonies and little robbing, and good queens and plenty of them.

I keep empty nucleus hives on hand. These hold 2 or 3 frames each, the same size as the regular brood-frames, and whenever I run across a large, good-looking queen-cell in a bright, strong colony, and in the proper place in the frame, I lift it out with adhering bees and put it into the nucleus hive; and by adding a frame of brood ready to hatch, soon there is a queen ready for work and ready to build up a queenless colony, if any is in the apiary.

My way now of introducing these queens to queenless colonies, or putting two or more colonies in one, is a *sure* and *safe* way: I have a board one inch or  $\frac{1}{2}$  thick, the size of the hive, with a 6-inch piece cut out of the center and covered with wire-cloth, so that no bee can get through. When I want to introduce a queen, I put that board with screen on the hive as a honey-board. Having placed the nucleus with the new queen over the screen for 2 or 3 days, they have now the scent, and I then put the frames with queen below, and all is well, being sure that no queen is below, but if there is they will fight it out all right. With this board I unite any kind of colonies, and no trouble comes from fighting.

We cut off queen-cells. How do you know when the bees are building queen-cells to supersede their old queen? In robbing the colony of cells at that time it may do injury. Are there any signs by which to know?

MINNESOTA.

ANSWER.—If you will allow me to commence at the last end of your letter, I will say that it is not easy to be entirely sure whether the starting of queen-cells means swarming or superseding. Generally, however, you can tell by the number of cells. If you can find no more than 2 or 3 cells, and these with eggs in them, you can't tell anything about it. But wait till the larvae are fairly well advanced, and if only 1 to 3 cells are present, you are pretty safe in saying that superseding is intended.

Your plan of rearing queens and introducing them is good. Some would like it as well or better, instead of having the board with wire-cloth, just to have wire-cloth without any board, as allowing heat to rise more freely.

Now as to the prevention of swarming.

You tried the plan of putting the brood over an excluder, and say it was after getting the colony strong in the spring, and then it sounds a little as if the honey-flow came afterward. Just how late you operated is not easy to tell, but it should not be until about the time the bees begin to swarm. You say, also, that you put a frame of brood below. I think that is not the usual way. There should be nothing in the lower story for the queen but starters, full sheets of foundation, or frames of empty comb. It may be worth while for you to try it again, not beginning until you

think there is danger of swarming, giving no brood below, and in about a week killing queen-cells in the upper story.

If that fails, try this: As soon as there is danger of swarming, remove the old queen, at the same time destroying queen-cells, if there are any; 9 days later destroy all cells and introduce a queen that has not been laying many days. It would be a sure thing "In this locality," but it's not safe to warrant it everywhere. But I *think* it would not fail you.

Thanks for encouraging words.

The "Old Reliable" as seen through New and Unreliable Glasses.  
By E. E. HASTY, Sta. B. Rural, Toledo, Ohio.

## QUEENS AND PICKLED BROOD— STUDYING BEE DISEASES.

I had forgotten, if I ever knew, that the queen always disappears when the colony has "pickled brood." Important. Don't think we were told that when pickled brood was first described in the journals.

Mr. Getaz may be going it a little too strong, but I guess it's timely and proper to remind our Washington savants that a disease must be studied for some length of time, and *in the hives*, before conclusions can be called sufficiently well-founded. A Government appointment is to be respected; but it doesn't make a man blunder-proof. Page 1032.

## "THE UNADORNED FLOWERS."

That's a beautiful editorial from the Toronto Globe, on page 1036—"The Unadorned Flowers." And what a queer circumstance that the Lombardy poplars should all be males—no female or seed-bearing trees ever having been brought over! I imagine that it may be that the female trees spread their branches a little more, and so are not so peculiar as the males, and therefore not so desirable.

## HONEY-KNIFE ELECTRICALLY HEATED.

Here is a bow to the electrically-heated honey-knife. Good thing to have something new once in a while to keep us from going to sleep. The picture of it set me to wondering. How can a current be sent through a honey-knife blade in such a way as to heat it? In fact, how can it be made to go through it at all? However, I am not trying to suggest that it's a sham. Unless the knife was actually heated it is not likely that it would have been exhibited at an Exposition. But would not gum and candy soon stop the operation of a knife kept hot all the time, with no water applied? And if it must be dipped in water semi-occasionally, what's the advantage over the old hot-water method? Page 1046.

## COMBS OF APIS DORSATA.

Be charitable, dear Boss. Might not even the faultless, and slipless, and spotless "Old Reliable" say 5 when it meant to say 6? With that correction, the description of an *Apis dorsata* comb, on page 1046, agrees pretty well with what we have been told elsewhere. They build a single comb under a horizontal bough; and it eventually gets to be 5 inches thick, and extends along the limb for 5 feet or more. Of course, the extra-deep cells are used only to store honey in. And equally, of course, down where they want to rear brood, the comb thins to twice the length of a worker-bee. Why should a journal be bound to mention every self-evident thing?

## MAKING HONEY-VINEGAR AND OTHER VINEGARS.

Yes, sir. We consume vinegar not for the actual amount of acid in it, but for the acid *taste* of it. It's vain for a vinegar to have 4 percent of acid if half of it is neutralized to the taste by the amount of unfermented sweet in it—or do some of us like sweetened vinegar enough better to pay for the loss? The look is that a 2 percent sample unsweetened would serve about the same purpose. We have had a good deal about vinegar lately, and yet C. P. Dadant finds valuable things to say that are not shopworn. Usually the *first* fermentation starts off without anything specially put in to start it; but sometimes total failure comes in right at that point. The example of this given is quite illuminative. Better to put in some crushed grapes at the outset. Idea seems to be that the ferment germs are not all of one species, and that there is such a thing as getting the best or getting the poorest—besides the danger of total failure. Let's have the best. I think it is very common to put sweet water into vinegar that is fully acidulated, or half acidulated. If I get Mr. D. and his authorities aright, that's a very pestilent habit. If you want sweet-

ened vinegar put in the sweet immediately before using. Strong acetic acid is very repressive of the first fermentation; and if the acid is strong enough, and the sweet pure enough, fermentation may be totally suppressed for an indefinite length of time. I suppose the failure or delay of the second fermentation to start is much more common than in case of the first—that is, alcohol and water is a much more stable compound than sugar and water—so most makers expect to put in something as a starter. (I wonder if putting in the second starter at the outset is not common, and also bad.) And he's all right when he kicks the musty barrel with the charge of being a vinegar-spoiler. Must is one of the most ineradicable of bad things. Don't buy a musty barrel; and don't let your empty barrel get musty. But what can be done if it does? I wonder if taking one head out and thoroughly burning the inside would eradicate, or nearly eradicate it. But then I fear, alas, that the fresh carbon would pull back on the fermentations.

His device for cleaning a merely dirty barrel is tiptop—a piece of chain connected with the outside world by a long and strong string. Page 1047.

fore she finds one to suit, then puts her legs in the cell, rubs her legs together, and, when freed, she leaves for the outside by the glass; and a young worker packs those pellets. But the observer can not see how it's done. I never saw a worker having a load of honey and pollen to deliver at the same time. Nor can I account why a loaded bee should examine different cells until she finds a cell to suit her; but it is so. Get an observation hive and see for yourself, and you will find that I am correct. Nurse-bees are full of honey at all times until they commence to work in the field. E. TUCKER.

Bergen, N. Y., Dec. 17.

## Will Italianize Next Season

I received the 3 queens by mail last season in good order, and introduced them successfully. They were all purely mated, as there is not a black bee among their offspring. Although received late in the season, they have their brood-chambers well filled with honey. I noticed when the young Italian bees first take their flying spell, they are much swifter than the blacks and hybrids. December 16 they were carrying in pollen. I have now 175 colonies, which I will requeen from them next spring.

I bought my bees—17 colonies and 36 new hives—from the founder of Maywood Colony, Foster & Woodson, they having put up the money for the late Mr. Osburn, who came from Cuba to start bee-keeping. But Mr. Osburn died the first winter he was here.

JAMES PETERSON.

Corning, Calif., Dec. 19.

## Mild Winter and Clover

We are having a very mild winter here so far, as only twice has the temperature gone below zero. Most of the time it has been from 20 to 26 degrees above. There is one inch of snow on the ground now, which makes good wagon-roads.

Isn't it a little dangerous for white clover or will it stand, or hold its own, with the temperature at or above zero and no snow on the ground?

L. G. BLAIR.

Boscobel, Wis.

[Yes, there is danger that the clover roots may suffer from extreme cold when the ground is not covered with snow. However, we should think the weather has hardly been cold enough yet in your locality so that it would injure the clover.—EDITOR.]

## Bees Wintering All Right

I have 14 colonies of bees wintering on the summer stands, which were all right Dec. 31. Bees did not do well here last season in filling supers, because of severe drouth.

Bay Shore, Mich., Jan. 11. A. M. DEITZ.

## Last Winter Hard on Bees

My bees did not do much last summer, and last winter was hard on bees, when most of them died. One man had 40 colonies and lost all but 3; another had 17 and lost all but one; and another had about the same and lost all.

We have 20 colonies this winter, and they seem to be wintering all right. R. CHINN.

Concord, Nehr., Dec. 28, 1906.

## A Good Report from Vermont

The past season was as good as I ever saw in this section. I had only 80 colonies; 25 of them were nuclei that I wintered with queens. I got 10,032 pounds of honey—4200 pounds of comb, and the balance extracted. I sold it for \$1092. It was all sold, and I had my cash, before Sept. 1. Those nuclei produced just about the same amount of comb honey that the blacks did of extracted. I got no honey after July 20. The Italian colonies were heavy this fall, but I had to feed about \$100 worth of sugar to the blacks. I got an

increase of 50 colonies, mostly by buying queens. Five of the Italians swarmed that I ran for comb honey. I did not get a swarm from the blacks that I ran for extracted honey.

My bees went into winter quarters heavy; that is, the party that put them in so told me. I have been in the house with rheumatism over two months. I never had it before. I suppose it was because my bees were not quite so rapid on the sting as usual!

C. M. LINCOLN.

West Rupert, Vt., Dec. 31.

## Sweet Clover Bloomed Late

I mail some sweet clover that was blossoming around my front yard. We had a cold snap last Wednesday night that froze it, but there was lots of it before that.

A. H. CHELSEY.

Jackson, N. H., Dec. 21.

## Bees Moved Far By Rail

In shipping my household goods and live stock in a chartered box-car from Indian Territory to this place, I also packed 10 hives of bees in Langstroth frames. They were clamped to the floor of the car, and considering the long and rough trip of 12 days, they were in good condition when they arrived, perhaps a pint or so of dead bees to the hive. This was the more remarkable, I thought, as the combs are in loose-hanging frames without any side spacer; however, they were all screened and otherwise protected.

This is a fine country, and I am anxious to see how the bees will work.

Selma, Calif., Dec. 15. L. M. LINDLEY.

## Honey Failure, But Still Determined

If I had been reading all the bee-papers and all the bee-books this year, and had had my bees in rosewood and mahogany hives, constructed after the highest type of the mechanic's art, and my queens had all been purely bred, golden, 5-banded, long-tongued Italians in their maternal prime; my supers provided with choice, polished No. 1 sections filled with sheets of foundation, "bottom starters," etc., and bait-sections, I would still have been compelled to content myself with "hope deferred," and beeswax, fun, and a few stings. But I suppose it's owing to "locality," and I'll just take my share of the "local" applications and a few more copies of the American Bee Journal.

"PERSE VERANCE."

Harrison Co., Mo., Dec. 12.

## No Swarms and No Honey

My bees, the past summer, were all non-swarmer, as I did not get a single swarm from 105 colonies; but the worst of all, I did not get an ounce of honey, either. This is the first failure I have ever had, and I have kept bees since I was 10 years old, and I expect to keep bees as long as I live. It was entirely too wet here for bees. I think all my bees stored enough honey to winter on, but I expect to feed them a lot of "trust" sugar next spring for brood-rearing, as they can not go through until poplar blooms.

I want to tell you how the good old American Bee Journal made, or saved, me \$20 last spring. I noticed an advertisement in it, where a certain company offered No. 1 sections at a reduced price; so I wrote for a price on 10,000, and to my surprise I was offered 10,000 strictly No. 1 sections at the very low price of \$3.00 per thousand. I ordered the sections, and they were as fine as any I ever bought at \$5.00 per thousand. So you can see, at the present price of sections, the American Bee Journal made, or saved, me \$20. It pays to be a subscriber to the American Bee Journal.

B. T. STONE.

Fellowsville, W. Va., Dec. 17.

**Please Mention Bee Journal when writing advertisers.**

## More Than Abundant Rains

We have had, so far, rather more than abundant rains, but rather cool weather with snow, hail, etc. The manzanita is blooming gloriously, and the bees are working on it very actively.

FRIL MAX BORLTE.

Moosa, Calif., Jan. 12.

## Good Prospects for 1907

This locality did not produce a great amount of honey this year, as a large percent of bees died last winter from bad stores and starvation. Most of those fortunate enough to save their bees got a fair amount of surplus. Most bees went into winter in from good to fair condition. The winter has been favorable so far, and the prospects are very good for a prosperous season in 1907.

H. H. BUCHNER.

Maquoketa, Iowa, Dec. 24.

## Observing "How Doth the Bee"

Is this a new race of bees? When coming from the field they deliver their loads of nectar to nurse-bees. What a lot of waste of time to hunt for nurse-bees to deliver their loads of nectar to! Doesn't it make a waste of time? I have observed loaded bees entering the hive so fast that all the nurse-bees would be crammed full in 15 minutes. What, then? All the field-bees would have to take a day off; nothing to do, because all of the nurse-bees were filled full. Shucks! Bees enter their hives and deliver their loads without any assistance from nurse-bees. I have had observation hives, and this is what I saw: A bee would enter the hive, creep up on the comb until above the brood-line, then commence to search for a cell. When found, she would place her tongue at the upper side of the cell with just the tip in honey. When the load was disposed of, she would come outside by the glass and off for more. Now a worker with pollen searches several cells be-

### New Edition of Dr. Miller's

## 40 Years Among the Bees

### FREE as a Premium for Sending Two New Subscribers

The book contains 344 pages, bound in handsome cloth, with gold letters and bees, and illustrated with over 100 beautiful original half-tone pictures, taken by Dr. Miller himself.

The first few pages tell how Dr. Miller got into bee keeping. 21 years ago he wrote

a small book, called "A Year Among the Bees." But "Forty Years" shows in minutest detail how he does things with bees and gets large crops of honey.

### How to Get a Copy of Dr. Miller's "Forty Years Among the Bees"

It is sent postpaid for \$1.00, or with the Weekly American Bee Journal for one year, both for \$1.80.

Or, any present regular subscriber to the American Bee Journal whose subscription is paid in advance, can have a copy of Dr. Miller's new book *free as a premium* for sending us **Two New Subscribers** to the Bee Journal for one year with \$2.00. This is a magnificent offer, and should be taken advantage of at once. Address all orders to

### CONVENTION NOTICES.

**Minnesota.**—The Fillmore County Bee-Keepers' Association will meet in the Court House at Preston, Minn., on Friday and Saturday, Jan. 25 and 26, 1907.  
Canton, Minn. P. B. RAMER, Sec.

**Colorado.**—The 27th annual session of the Colorado State Bee-Keepers' Association will be held in the Chamber of Commerce Building, Denver, Colo., Jan. 22 and 23, 1907. The State Horticultural Association, the State Forestry Association, the Dry Farmers' Congress, the American National Stock Growers' Association, and the Colorado Cattle and Horse Growers' Association, will all hold their annual sessions in Denver during the same week. Besides this there will be the greatest live stock show held in Denver ever west of Chicago. The railroads have made a fare of one and one-third for the round-trip for this week, which should assure us a large attendance. A section-putting-up contest will be a feature of our meeting.  
G. J. TOMLIN, Sec.

FRANK RAUCHFUSS, Vice-Pres.

**Wisconsin.**—The annual meeting of the Wisconsin State Bee-Keepers' Association will be held in the Court House, at Madison, Wednesday and Thursday, Feb. 6 and 7, 1907. Reduced rates on all railroads, but if you cannot obtain them, ask your agent for full fare receipt. By courtesy of Mr. Bacon, of the G. B. Lewis Co., arrangement has been made to have a stenographer in attendance, to take a verbatim report of the entire proceedings, which will be published for the benefit of members and interested bee-keepers. This feature will make this the most interesting convention ever held by the society. The Question-Box will be the main feature, and we want every bee-keeper who has one or more questions of interest to mail them to the Secretary prior to the convention, that they may be properly arranged. Questions may be handed the Secretary at the convention, but mail them prior if possible. We also want a good honey display, so bring your choice samples of honey or anything of interest. Pres. France will speak on the Inspector's Convention in Texas, and Diseases of Bees. Every person may become a member, for one year, by the payment of \$1.00, which will also make him a member of the National Bee-Keepers' Association, which

alone costs \$1.00; and every member of the National, not a member of the State, should pay his dues to the State Secretary, and for the same money, become a member of both. Ladies may become members by the payment of 50 cents for National dues. Kindly make remittance for membership dues before the meeting, to the undersigned.  
Augusta, Wis. GUS DITTMER, Sec.

There seems to be a general complaint of poor galvanizing on fence-wire. The complaint has become so general as to attract the attention of the U. S. Department of Agriculture, and they have taken the matter up with the view of investigating conditions and giving practical information from time to time to the fence users. The time was when galvanized fence-wire could be relied on to last several years, but now, in many cases, it begins to rust soon after put up. Kitzelman Brothers, of Muncie, Indiana, fence manufacturers, claim to have an improved process of galvanizing wire that adds much to its lasting qualities. They have just issued a 96-page catalog fully describing the above process. Upon request it will be mailed free to all readers of this paper. Please mention the American Bee Journal when writing them.

## The Emerson Binder

This Emerson stiff-board Binder with cloth back for the American Bee Journal we mail for but 75 cents; or we will send it with the Bee Journal for one year—both for only \$1.50. It is a fine thing to preserve the copies of the Journal as fast as they are received. If you have this "Emerson" no further binding is necessary.

## Langstroth on the \*\*\* Honey-Bee

Revised by Dadant—Latest Edition

This is one of the standard books on bee-culture, and ought to be in the library of every bee-keeper. It is bound substantially in cloth, and contains nearly 600 pages, being revised by that large, practical bee-keeper, so well-known to all the readers of the American Bee Journal—Mr. C. P. Dadant. Each subject is clearly and thoroughly explained, so that by following the in-

structions of this book one cannot fail to be wonderfully helped on the way to success with bees.

The book we mail for \$1.20, or club it with the American Bee Journal for one year—both for \$2.00; or, we will mail it as a premium for sending us **THREE NEW** subscribers to the Bee Journal for one year, with \$3.00.

This is a splendid chance to get a grand bee-book for a very little money or work.

# TWO YEARS FOR \$1.

After a man succeeds in publishing a good journal, the next step is that of getting it into the hands of the people, of getting them to reading it, and becoming acquainted with its merits. This can be done by advertising, sending out sample copies, circulars, etc. All this costs money. I think I am safe in saying that for every new subscriber I have received, I have paid \$2.00 in advertising; hence, I have always said that a publisher of a good journal could afford to send his paper one year free for the sake of getting it into new hands. It would cost no more than other forms of advertising, and would be more effective; but, for obvious reasons this plan

could not be put into practise; but I am going to come as near to it as I can. I have between 200 and 300 complete sets of back numbers for the present year; and as long as the supply holds out I will send a complete set, and the rest of this year free, to any one who will send me \$1.00 for the Review for 1907.

Back numbers of the Review are different from those of newspapers and some journals. The information they contain is just as valuable now as when first published. In an advertisement like this it is impossible to give much description, but I will mention one or two features of each issue of

## The Review for 1906

**JANUARY.**—The key-note of the Review for 1906 is "**THE CONTROL OF INCREASE**;" and Mr. Gill, of Colorado, starts off by telling how he completely and profitably controls the increase of 1000 colonies run for comb honey.

**FEBRUARY.**—R. C. Aikin shows how, with a knowledge of principles, increase can be controlled; but perhaps the most valuable contribution to this issue is from R. F. Holtermann, of Canada, describing "Some Short Cuts in the Production of Extracted Honey."

**MARCH.**—In this issue is illustrated and described the only really successful non-swarming hive that has yet been invented. Its inventor, Mr. L. A. Aspinwall, secured an average of 140 pounds of comb honey the past season from fifty colonies, and had no swarms.

**APRIL.**—The most valuable article in this issue is from C. A. Olmstead, of New York, in which he illustrates and describes a method of foretelling swarming without opening the hive.

**MAY.**—In this issue is begun a series of the most delightfully and beautifully illustrated sketches that have ever appeared in the Review—that of the editor's experience in locating and managing three out-apiaries in the wild, picturesque, raspberry region of Northern Michigan.

**JUNE.**—The article this month on "Control of Increase," is by that veteran, J. E. Crane, of Vermont, and shows how to do the work when the harvest comes early. This issue also gives the editor's experience in moving his 400 colonies into Northern Michigan—illustrated with four engravings.

**JULY.**—This issue has a beautiful full-page illustration of the Review apiary here at Flint (105 colonies), and the editor gives a resume of his work in this apiary for the first six months of the year—showing where he failed and why he succeeded.

**AUGUST.**—In this number the editor tells of "Reaping the Harvest in Northern Michigan," and gives pictures of the different apiaries, some at old abandoned lumber-camps, one with a tent for a honey-house, while the reading-matter has an actual flavor of the wild northern woods.

**SEPTEMBER.**—Of all the articles in this year's Review I doubt if any one is more really helpful than the one in this issue by the editor, entitled "Conveniences in the Production of Extracted Honey." It has several illustrations, and shows how to use bee-escapes without the back-aching work of lifting the hives by hand; how to make a honey-knife cut as "slick as a razor;" how to make an uncapping-can for 10 cents; how to arrange a cheap automatic strainer, and run the honey directly into the cans; and how to arrange an electric bell, at a cost of 60 cents, that will ring when the can is full.

Instead of mentioning some of the special features for October, November, and December, let me use the space to say that **ONE OF THE GOOD THINGS** that will appear in the Review for 1907 will be a series of articles from E. D. Townsend, Michigan's foremost bee-keeper. All of his writings in the past have been fragmentary, a glimpse here and there, and they have been scattered here and there in different journals. Now he is going to write in a consecutive manner, starting at the beginning of the season and going through the year—just as though he were writing a book. It will give his system of management.

## Advanced Bee Culture

This is a book of 230 pages, beautifully printed, bound, and illustrated, that discusses bee-keeping from a money point of view—shows how to make a pleasant and profitable BUSI-

NESS out of bee-keeping. Price, \$1.20; or, the Review for 1907 (and all of the back numbers of this year free) for only \$2.00.

**W. Z. HUTCHINSON, Flint, Mich.**

## A GREAT IMPROVEMENT

Will be found in

## The American Bee-Keeper for 1907

It is profusely illustrated and enlarged, and contains only articles of the most practical as well as scientific nature. A special corps of the best writers has been engaged. The editors are Harry E. Hill and Arthur C. Miller, than whom there are no more practical or experienced bee-keepers in this country. We have published the American Bee-Keeper continually and regularly since 1890.

Regular subscription price, 50 cents a year. One year to new subscribers, 35 cents; three years for \$1.00.

## Honey and Beeswax

**CHICAGO, Dec. 7.**—There is the usual dullness in the honey-trade at this date owing to most of the retailers having stocked up sufficiently to carry them over the holidays; but the stocks in the hands of the trade generally are below the normal; hence prices are firm at 15@16c for No. 1 to fancy white comb, with off grades at 1@2c less; amber grades dull at 10@12c. Extracted white, firm at 8c for clover and basswood; ambers, 6½@7½c per pound. Beeswax, 30c.  
R. A. BURNETT & CO.

**KANSAS CITY, Dec. 29.**—The demand for comb honey is only fair with market well supplied; market is almost bare of extracted, however, and the demand very good. We quote: Fancy white comb, 24-section cases, \$3.25; No. 1, \$3.00; Extracted, white, per pound, 7½@8c; amber, 7@7½c. Beeswax, per pound, 25 cents.  
C. C. CLEMONS & CO.

**PHILADELPHIA, Nov. 3.**—While the supply of comb honey is equal to the demand, large quantities of comb honey having arrived in the market in the last few days, the price still remains high. The outlook, however, is that when the season advances and the bee-keepers ship more of their crop to the market, the prices will be a little weaker. We quote: Fancy white comb honey, 16@18c; No. 1, 14@15c; amber, 11@13c. Fancy white extracted, 7½@8c; light amber, 6½@7c.  
We are producers of honey and do not handle on commission.  
WM. A. SELSER.

**NEW YORK, Jan. 15.**—The stock of white comb honey is pretty well exhausted, and we do not expect any more arrivals of large lots from now on. Prices are firm, and we quote from 15@16c for fancy white; 13@14c for No. 1; 12c for light amber. There is quite a little dark and buckwheat on the market, but no overstock, and we think that all of it will be disposed of before long at present prices, which we quote from 10@12c, according to quality. Extracted honey very firm, with sufficient supply to meet demand. California white sage is bringing from 8@8½c; light amber, 7½c; amber, 6½@7c; buckwheat extracted in fairly good demand at 6@6½c. Southern in barrels finds ready sale at from 55@70c per gallon, according to quality. Beeswax firm and steady at 31c.  
HILDRETH & SROGLEN.

**DENVER, Jan. 5.**—There is practically no honey left in the hands of producers in this State, and barely enough in the Denver market to supply the home trade until spring. We quote strictly No. 1 white, per case of 24 sections, at \$3.20; No. 1 light amber, \$3; and good No. 2, at \$2.50. White extracted, 8@8½c; light amber, 7½@8c. Beeswax, 26c for clean yellow, delivered here.

THE COLO. HONEY-PRODUCERS' ASSN.

**CINCINNATI, Jan. 9.**—The comb honey market at the present is very quiet. Holders are not trying to realize a profit, simply disposing of what they have, at cost. Fancy comb honey is selling at 14½@16c. Extracted amber honey in barrels, 6@7c; fancy light amber in cans, 7@8c; fancy white, 9c. Strictly choice beeswax, 30c, delivered here. THE FRED W. MUTH CO.

**INDIANAPOLIS, Jan. 3.**—comb honey is not plentiful, but demand is slack. Fancy white comb brings 16@17c; No. 1 white, 14c; amber, 12@13c. Best grades of extracted honey bring 8@9c; amber, 6@7c. Good average beeswax sells here at \$33 per 100 pounds.  
WALTER S. POWDER.

**TOLEDO, Nov. 30.**—The market on comb honey remains about the same as last quotations, but has been coming in much more freely, as beekeepers seem to be very anxious to get rid of their stock. Fancy brings in a retail way 16c; extra fancy, 17c; No. 1, 15c; buckwheat, 15c. Extracted white clover in barrels brings 7@7½c; cans the same. Beeswax, 26@28c.

## Something New = The Ideal Hive-Tool

Bee-keepers have long needed a special Tool to work among the hives during the bee-season. The one shown here was invented by Wm. Muench, a Minnesota bee-keeper, some years ago, but it was not on the market before. We have lately bought this Tool, and all rights, from Mr. Muench's widow, and have had the first lot made. They are ready for delivery now.

(This picture is exactly one-half the size.)

**DESCRIPTION.**—The Ideal Hive-Tool is made of high-grade malleable iron, much like wrought iron, 8½ inches long. The middle part is 1-16 inches wide and 7-32 thick. The smaller end is 1½ inches long, ½ inch wide, and 7-32 thick, ending like a screw-driver. The larger end is wedge-shaped, having a sharp semi-circular edge, making it almost perfect for prying up covers, supers, etc., as it does not mar the wood.

### What Dr. Miller and Miss Wilson Say of It:

In the first edition (1903) of Dr. Miller's "Forty Years Among the Bees," page 58, he says: "Of all the hive-tools I have tried, I like best the Muench tool." On Jan. 7, 1907, he wrote us saying he thought "just as much of the tool as ever."

Miss Wilson, Dr. Miller's assistant, says this of the Ideal Hive-Tool: "It is an ideal tool. In fact, I don't see how it could be improved upon. I am sure we would feel utterly lost in the apiary without it. . . . You will have to try one yourself if you want to know its worth."

### The "Ideal Hive-Tool" Free as a Premium.

We will mail an **Ideal Hive-Tool FREE** as a premium to any present paid-in-advance subscriber to the American Bee Journal, for sending us **ONE NEW** subscription for a year at \$1.00; or we will send the American Bee Journal one year and the **Ideal Hive-Tool**—both for \$1.20. Price of the **Ideal Hive-Tool** alone, postpaid, 30 cents. Address,

## Engravings For Sale

We are accumulating quite a stock of engravings that have been used in the American Bee Journal. No doubt many of them could be used again by bee-keepers in their local newspapers, on their stationery, or in other ways. Also, if we can sell some of them it would help us to pay for others that we are constantly having made and using in our column. If there is any of our engravings that any one would like to have, just let us know and we will quote a very low price, postpaid. Address,

**GEORGE W. YORK & CO.**  
334 Dearborn Street, - CHICAGO, ILL.

## Trade Notes. The A. I. Root Co., Medina, Ohio.

### Photographic Competition

We are pleased to announce another series of prizes for the best photographs submitted to us, as described below, in two series, American and Foreign, under the following conditions:

**FIRST.**—The competition opens January 15th, and closes October 1st, 1907. All photographs intended for this competition must be in our hands by the last-named date.

**SECOND.**—Competition for these prizes is limited to bee-keepers or some member of the family. Entries may be made for as many different classes as may be desired.

**THIRD.**—A photograph entered in one class can not be entered in any other class.

**FOURTH.**—Each photograph should be marked on the back with the name and full address of the sender, and the class in which it is entered. This is important.

**FIFTH.**—In judging the photographs, the general appearance, neatness, etc., of the apiary, or exhibit, or yard, will be taken into consideration. Photos may be sent unmounted. We rather prefer them this way, and in a solo or reddish-brown if possible. However, send such as you can get most easily.

**SIXTH.**—With each of the photographs submitted we would like a brief statement of the conditions under which the apiary was photographed or honey produced, or similar information regarding the photograph. This should be limited to about one hundred words.

**SEVENTH.**—All photographs and correspondence regarding the same should be addressed to Advertising Department, GLEANINGS IN BEE CULTURE, Medina, Ohio.

**EIGHTH.**—We reserve the right to limit the number of awards or withhold any award if no photo worthy is entered in the class.

#### AMERICAN COMPETITION (Including Canada and Mexico)

AND

#### FOREIGN COMPETITION

The following are the classes in which entries may be made:

**CLASS A.**—Photographs of any apiary in village, town, or city.

**CLASS B.**—View of an apiary not exceeding six hives in town or city.

**CLASS C.**—Apiary in town or country of not less than six hives or more than fifty hives.

**CLASS D.**—Apiary in town or country of fifty hives or more.

**CLASS E.**—Photograph of comb honey produced by a single colony of bees; not less than ten sections, and this preferably in plain sections.

**CLASS F.**—Photograph of a bee-keeper's home, showing some view of the apiary if possible. The apiary need not be prominent in the picture, however.

**CLASS G.**—Photographs of a crop of honey from any number of colonies, six or more.

**CLASS H.**—Photographs of any apiarian exhibit of bees, supplies, or honey taken at fairs or shows of any kind.

**CLASS I.**—Photographs of any work in the bee-yard, such as hiving swarms, extracting, or any other operations with the hive.

**CLASS J.**—Photographs of any other subject relating to bee-keeping not classified above.

#### PRIZES

	Value, Postpaid
<b>FIRST.</b> —One leather-bound "A B C of Bee Culture," 1907 English edition, or cloth-bound French or German.....	\$2.00
<b>SECOND.</b> —One-half leather "A B C of Bee Culture," 1907 English edition....	1.75
<b>THIRD.</b> —One "How to Keep Bees" and any two Swarthmore books.....	1.50
<b>FOURTH.</b> —One full cloth-bound "A B C of Bee Culture," 1907 English edition....	1.20
<b>FIFTH.</b> —One "How to Keep Bees," by Anna Botsford Comstock.....	1.10
<b>SIXTH.</b> —No. 1 bee-veil, all silk.....	.80
<b>SEVENTH.</b> —No. 2 bee-veil, silk face.....	.50
<b>EIGHTH.</b> —One illustrated book, "Bee Culture in Foreign Countries".....	.50
<b>NINTH.</b> —One Bee Model, Queen.....	.50
<b>TENTH.</b> —One Bee Model, Drone.....	.50

Ten prizes are offered for each class: Ten for Class A, Class B, Class C, Class D, etc.—one hundred prizes for American contest, and one hundred prizes for the Foreign contest; two hundred in all if that number of entries are received, the prizes offered being identical for each class for the American competition and for the Foreign.

If the winner of any certain prize already has the prize offered, we will, on request from him, furnish a selection of other items from our catalogs, of equal value.

### Danzenbaker Prizes

It is to be regretted that so many bee-keepers are satisfied to produce year after year a very ordinary grade of honey as regards its appearance, when by a little more care, and having more suitable fixtures, and by taking the honey from the hive at just the right time, a much larger percentage of "fancy," or "extra fancy" honey could be produced, which would sell at a much higher price. The experience of honey-merchants generally is that there is no difficulty in disposing of large stocks of fancy or extra fancy, even when the market is dull. It is the inferior grades that suffer most at these times. We believe, too, that bee-keepers would be very much better satisfied with their season's work if their best efforts were made to produce a really fine product. To increase further the interest in extra fancy honey, the following prizes are offered for honey produced in Danzenbaker hives during the year 1907, under the following conditions:

**FIRST.**—As above stated, the honey must be produced in a Danzenbaker hive, either the present style or any Danzenbaker hive that has been put out within the last few years. These hives may be had of any dealer in beekeepers' supplies in any part of the country.

**SECOND.**—For Classes 1 and 2 we require a shipment of approximately the amount stated, to be made by the bee-keeper direct to us at Medina. After the prizes have been awarded the honey entered for competition in Class 1 or 2 will be held subject to the instructions of the producer. We will sell it at 5 percent commission, or we will ship it to

any point direct by freight or express. There being good honey markets in our immediate vicinity, such as Columbus, Cincinnati, Cleveland, Buffalo, and Pittsburg, it can be disposed of without difficulty at good market prices, and the shipper will not have to lose a good market by shipping it here. Neither the honey awarded a prize nor that which obtained no prize is to be our property, but will be sold subject to the instructions of the producer who sends it to us. We are interested only in inspecting it to award the prizes.

**THIRD.**—For all honey submitted for prizes we must have a definite statement from the producer regarding the conditions under which it was produced, whether a light or heavy flow of honey, how the colony was handled, how many colonies in the yard, from what source produced, etc.

**FOURTH.**—For Classes 3, 4, and 5, we must, in addition to the above report, have the signature of two witnesses, certifying to the correctness of the report. If the party who sends us the report for the competition is well known to us we shall not require these witnesses. References may be given instead of the signature of witnesses if desired. All parties intending to compete for these prizes should send for blanks which we will furnish, on which the report may be made out.

**FIFTH.**—It will be noticed in the last three classes, three to five inclusive, that it is not at all necessary to send us the honey—all we require is a report.

**SIXTH.**—We reserve the right to limit the number of awards in each class, or to make no awards in a class if there are no satisfactory entries for the same.

**SEVENTH.**—No contestant will be awarded more than one prize in each class, but may make two entries if desired—one in Class 1 or 2, and another in Class 3, 4, or 5.

The classifications for the prizes are as follows:

**CLASS 1.**—For best shipment of 200 lbs. of comb honey in Danzenbaker sections.

**CLASS 2.**—For best case of comb honey in Danzenbaker sections.

**CLASS 3.**—For best report of yield from single colony in Danzenbaker hive.

**CLASS 4.**—For best report of yield from five colonies in Danzenbaker hives.

**CLASS 5.**—For best report of general results from use of Danzenbaker hive.

For each class there will be ten prizes as follows:

**FIRST.**—\$10.00.

**SECOND.**—\$7.00.

**THIRD.**—\$5.00.

**FOURTH.**—\$2.00.

**FIFTH TO TENTH.**—\$1.00 each.

This is the time to decide to enter this competition. No matter where you live, whether in the United States or elsewhere, you can certainly find one class in which you can make an entry; and as there are ten prizes in each class, we believe that no one will be greatly disappointed in the results unless it is ourselves, and we hope that we shall not be, but see a large number of entries. Even if you fail to get a prize, you will doubtless have increased the value of your own product by your efforts to produce some big results or an extra quality of honey.

(Entered at the Post-Office at Chicago as Second-Class Mail-Matter.)

### Getting Freight-Rates Lowered on Honey

Mr. Fred W. Muth, a member of the National Freight-Rate Committee, sends us the following for publication:

At the annual convention of the National Bee-Keepers' Association at San Antonio, Tex., in November, 1906, there was a committee appointed to secure, if possible, lower freight-rates on honey. Being one of that committee, I wish to make an explanation in behalf of the recognized high freight-rates, and then point out to each and every bee-keeper the steps that must be taken in order that the committee may be successful.

In the course of a year we receive many car-loads, as well as innumerable shipments of both comb and extracted honey. In one year's time we are obliged to enter many, many claims with the railroad companies, and are subjected to experiences which enable me to write intelligently upon this subject.

I am informed by a railroad official that the Classification Committees determine their classifications on an average, based upon the number of claims and the amount of money expended for damages incurred *en route* in the course of one year. Therefore, it is plainly seen that the shippers are responsible for the exorbitant freight-charges imposed upon themselves, and lower rates need not be expected until the losses paid by the transportation companies have reached the very minimum. Consequently, we must help ourselves, by learning how to ship our honey. Other industries have done it; why not we? Take, for example, the packages used by the sugar refineries—they are perfect; as well as those of the coffee importers, cereal manufacturers, and countless others that I could mention. They were compelled to work, and work hard in order to bring their losses down to the minimum, and discovered that it was absolutely necessary to use *perfect packages, and nothing else*. They now have the advantage of lower freight-rates than the honey-shipper.

In order to accomplish our aim to secure lower rates, we must, without one exception, ship both comb and extracted honey in first-class packages. Bee-keepers, if you are producing comb honey for the market, by all

means use *bottom* as well as *top starters* in your sections, so that the honey can not break loose at the bottom. This is the first and a very important step to be taken.

Furthermore, be sure to use the no-drip shipping-case. Wrap each case in paper, so that it will be kept clean *en route*. Pack 6 or 8 cases in one carrier, well supplied with straw in the bottom, and having handles that extend from 4 to 6 inches beyond its sides. Lastly, do not forget the usual "HANDLE WITH CARE" placard.

Now, if every bee-keeper and shipper of honey will follow the above instructions to the letter, it will tend to introduce a method that is both simple and practical, and he will not only realize a greater profit in his product, but will also be assisting those who are giving their time and lending their experience to secure lower freight-rates.

The producers and shippers of car-loads of comb honey appreciate the value and advantage of bottom as well as top starters. For instance, last summer we received two car-loads of comb honey from two different shippers. The one car contained 1170, and the other 1350 cases, and in the entire lot there was not one comb broken! These shippers understand their business. On the other hand, we received quite a number of small shipments, with here and there a broken comb, frequently some badly damaged lots, caused by the failure to use bottom starters. These experiences are trying and disgusting, and were the shipper in question subjected to a few of them, he would, without doubt, pay more attention to the manner in which he produced his honey, and his method of packing for shipment. These are the shipments that are responsible for the high freight-rates. Do not misunderstand me—there are many producers and shippers of honey on a small scale, who thoroughly understand this part of the work, and we must give the credit that is due them.

A word regarding extracted honey: The railroad companies pay more damage claims on account of poor packages used for extracted honey than for comb honey, and it behooves us to ship our extracted honey in *new cans*, if this style of package is to be used; or, if it be barrels, let them be good ones, well coopered, and *first-class in every respect*.

The greatest trouble rests with the bee-keeper; he clings entirely too much to second-hand packages, just because he can buy them a little cheaper; whereas, if he were to ship his product in good packages, the freight-rates would be comparatively less, and, in the end, his cost for shipping would be a great deal less than at the present time, and there would be no trouble with the railroad companies, nor any unsatisfactory transactions.

Therefore, we must ask the bee-keepers to help—each and every one—if they want us to obtain lower freight-rates.

Respectfully submitted,  
FRED W. MUTH,  
Member Freight-Rate Committee.

We are very glad to place the foregoing before our readers. It is exactly in line with the suggestion we made at the San Antonio National convention (see page 90 of the National Report pamphlet), that "the dealers should write something about the proper shipping packages," if they desire the bee-papers to help induce bee-keepers to improve their methods of production and preparation for shipping. For years we have urged putting 6 or 8 cases of honey in large crates or carriers, with straw or hay underneath to break the force of a jar or jolt in handling and shipping, and with properly printed cautions on the outside, so that freight handlers would not handle honey as they would a box of baseballs.

Also, Dr. Miller has for years described his method of using bottom starters (as well as top ones) in sections of comb honey. But so many bee-keepers seem slow to profit by the good advice given in the bee-papers. Or, it may be that many bee-keepers who are helping to cause the continuance of high freight-rates on honey do not read bee-papers. Of course, such are "saving at the spigot and losing at the bung-hole."

But we are very certain that all the bee-papers will be glad to help in every way possible to save money for their readers. Perhaps one of the first things needed is for every present reading bee-keeper to see to it that all his neighbor bee-keepers read the bee-papers also. This would help all around.

### Bees and Grapes

The following has been called forth by Mr. Kennedy's article, page 980 (1906):

John Kennedy seems to think that more should give their experience as to bees work-

ing on grapes. I'm ready to give mine as far as it goes. Some years bees work thickly on my grapes; other years scarcely at all, even when they have nothing else to do. The grapes, when first punctured, appear just as Mr. Kennedy says, "just as if one had stuck the point of a knife-blade in the side of each grape," only there is an enlargement of the cut at each end. Further than this, deponent sayeth not.

Is not Mr. Kennedy in error in deciding that bumble-bees were of different kinds because of different sizes? If I am not mistaken I have seen in the same nest bumble-bees of different sizes.  
C. C. MILLER.

Dr. Miller is over-cautious about drawing conclusions from his meager facts. One fact is that there are times when bees suck the juice of the grapes, and another that there are times when they do not do so, although a dearth may be in existence at the time. That inclines to the belief that some other agency must open the way for the bees.

The incision made in the grape was like that made by the point of a knife thrust in, with an enlargement at each end. Is it likely a bee would make a cut of that kind? It could not make it at a single blow, but a bird could. With an open mouth a bird striking the grape would make a hole with its pointed upper bill and another with its lower bill, and then closing its bill it would make the knife-cut between the two enlarged openings. But why not see the bird actually at work? Some one has said it is done very early in the morning. But why not watch early in the morning? Certainly here is a chance for further investigation.

## The National Association All Right

Mr. M. A. Gill, perhaps Colorado's most extensive comb-honey producer, wrote us as follows under date of Jan. 10, 1907:

EDITOR YORK:—I wish to thank those who voted for me for President of the National Bee-Keepers' Association last November. I appreciate the honor intended, but I think the best man won, as is generally the case. I hereby pledge my aid and support to the National in its efforts to give the greatest good to the greatest number.

I may say that I started on Nov. 4, 1906, to attend the National convention at San Antonio, but was delayed by the trains so that when I reached El Paso I found I could be present but one day, so I switched off for California to visit my daughter.

While speaking of the National Association, I am reminded of the petty strifes and differences of opinions that have sprung up, and want to say that from my view-point I can see no just cause for such differences. I never have anything for sale except honey, and I am quite an extensive buyer of supplies for my own use only (having bought 100,000 sections and 600 pounds of comb foundation in 1906); think I have been watchful with regard to my own interests, and I will say that I have never detected where any editor or manufacturer was trying to corral the interests of our National Association to his own selfish ends.

I hope that every bee-keeper will help the National along until it becomes a bulwark behind which we can all take refuge, and through it secure the enforcement of the pure food law, educate the public on the use of honey, and then secure better prices and a better demand.  
M. A. GILL.

Mr. Gill is quite right, that the "strifes and differences of opinion that have sprung up" among a few members of the National are "petty." In fact, they are so "petty" that really the National's management need only

go forward in its work for the good of all its members, and for the benefit of bee-keeping in general, and not waste any time on those who would sow discord among the membership.

If any member thinks he has a grievance, let him submit it to the Board of Directors for adjustment.

If any member knows that any officer, editor or manufacturer has become rich at the expense of the National's membership, and unfairly so, why, let it be announced publicly who such individual is. It is hardly possible that any one could get very rich in such manner without at least several members being aware of it. We have been fairly well acquainted with most of the officers of the

National during the past 20 years, and we don't know of a single one who made anything for himself out of such official connection. We do know several, however, who made financial sacrifices for the Association; but they were glad of the opportunity to do so.

By the way, we fail to recall anything of any very great importance that any of the few who are now opposing the National ever did for its success! And at least one or two of them were not members at all until some 2 or 3 months ago.

Say, haven't about enough time, attention, and words been wasted on this thing? We plead guilty to a little of it, and expect to drop it with this editorial.

**Loading a Car of Bees.**—The picture on the first page shows Mr. W. O. Victor, of Texas, loading a car of 494 colonies and 296 3-frame nuclei of bees to be shipped to Utah. Mr. V. is a bee-keeper of large experience in the handling and shipping of bees. We had the pleasure of meeting him when attending the San Antonio National convention last November. He is one of the leading bee-keepers of Texas, and spoke a word of cordial welcome to the members of the National convention when it opened its sessions in San Antonio.

**Legislation for Missouri Bee-Keepers.**—We have received the following from the Secretary of the Missouri State Bee-Keepers' Association, which deserves the careful attention of every Missouri bee-keeper:

The Apiary Bill "providing for an inspector of apiaries to assist in the development and protection of the honey-industry, and for the prevention and suppression of diseases among honey-bees, such as foul brood," etc., has been introduced in the Senate of the 44th General Assembly, and is called Senate Bill No. 145.

I earnestly request all bee-keepers of Missouri to write to the Representative of their county in our Legislature; also to the Senator of their district, a letter urging them to work and vote for Senate Bill No. 145, as it is of the utmost importance to the bee-keepers of the State that this Bill may pass and become a law. It would assist me in my work if each one who has written to his Representatives in the Legislature, would send me a postal card stating to whom he has written, as I, when I approach these gentlemen, then will know that they have heard from home.

Bee-keepers, let us all work for the Foul Brood Bill, and we will succeed in having it passed.

There is another Bill before the Legislature now which is of great importance to the bee-keepers—the Pure Food Bill. Bills have been introduced in the Senate, being Senate Bills Nos. 47 and 48, also in the House, being Nos. 215 and 216. Both the Senate and House Bills read alike, which, if they become laws, will

stop the sale of any article under the name of honey which is not the pure product of the honey-bee. It will easily be seen that the demand for honey must increase if these Bills pass and become laws, as it will stop the adulteration of honey by mixing honey with glucose, or by putting a little piece of comb honey in a tumbler and filling it with glucose and calling it "honey."

Bee-keepers, write to your Representatives, and Senators, also, to support these Bills. Write to the Senators to support Senate Bills Nos. 145, 47 and 48, and write to the Representatives to support Senate Bill No. 145 and House Bills Nos. 215 and 216.

Bee-keepers of Missouri, don't miss this chance to do something for yourselves.

ROBT. A. HOLEKAMP,  
Sec. Missouri State Bee-Keepers' Association.

We hope that Mr. Holekamp's earnest call will be heeded by all the Missouri readers of the American Bee Journal. And may they succeed in their worthy efforts!

**An Armful Swarm of Bees** forms an interesting picture on the first page. Mr. W. O. Victor, who is holding the bees on his arm, seems quite unconcerned—just as if it were an every-day occurrence with him. Both of the photographs appearing on the first page this week were given to us by Mr. Victor, at the National convention in San Antonio, in November, 1906. It is hoped that he will soon contribute from his large fund of bee-experience to the department of "Southern Beedom."

**The Minnesota State Bee-Keepers' Society** has sent us a copy of a good circular that is evidently being sent to Minnesota bee-keepers. It says the objects of the Society are the promotion of scientific and practical bee-keeping, and also securing legislation for the encouragement and advancement of the bee-keeping industry. As a body they belong to the National Bee-Keepers' Association, and also to the Minnesota State Horti-

cultural Society, which means that for \$1.25 a Minnesota bee-keeper can become a member of 3 organizations, and is entitled to the benefits and literature of all. From the Horticultural Society literature in pamphlet form is received every month, and at the end of the year the whole in book form; also the programs and reports of bee-keepers' conventions are printed with the report of the Horticultural Society; in addition, 2 plant-premiums are given if the Secretary is notified before April 1.

It would seem that the features mentioned would be sufficient inducement for every Minnesota bee-keeper to become a member of the State Bee-Keepers' Society at once. Chas. D. Blaker, Sta. F, Minneapolis, Minn., is the Secretary, and Mrs. W. S. Wingate, 3013 Fremont Ave. S., Minneapolis, Minn., is the Treasurer. The membership dues of \$1.25 may be sent either to Mr. Blaker or Mrs. Wingate.

#### Summer the Time for Bees

"Summer," said the humming bee,  
 "Summer is the time for me!  
 Richest fields of luscious clover,  
 Honey-cups all brimming over;  
 Not a cloud the long day through!  
 I like summer best—don't you?"

—Selected.

**The Worcester Co. (Mass.) Convention.**—The 7th annual meeting of the Worcester County Bee-Keepers' Association was held Jan. 12, 1907, at Worcester, with Pres. Burton Gates in the chair. After the brief reports, the following officers were elected:

President, Burton Gates; 1st Vice-President, F. H. Drake; 2d Vice-President, Chas. Goodell; and Secretary-Treasurer, Arthur H. Estabrook, of Leicester.

There were nearly 40 bee-keepers present, although the weather was very bad. Particular attention was paid to the status of bee-diseases in Massachusetts. A copy of the proposed Bill for Connecticut for protective legislation against bee-diseases was read and discussed. The Secretary was directed to correspond with the Massachusetts bee-keepers, in order to see what steps should be taken to secure the needed law. The hope was expressed that inspection would not only reduce the bee-diseases of the State, but that it would do much to elevate the bee-keeping methods and eliminate the primitive box-hives which are still used to some extent.

It was decided to hold, on Feb. 9 or 16 (according to the convenience of the speakers), an all day and evening Institute with the State Board of Agriculture. The full program and exact date can be learned from the Secretary. There will also be a banquet. Everybody is invited to attend the meeting and banquet (the price of the latter being 50 cents). All kinds of implements, inventions, and products of bees are solicited for the exhibition. It is expected that there will be present several hundred of the representative bee-keepers of New England. No one who can possibly attend can afford to stay away. Further details may be had by addressing the Secretary, A. H. Estabrook, care of Clark University, Worcester, Mass. Also watch the New England Homestead and Worcester newspapers.

## Bee-Keepers' Supplies — Are they too High-Priced? Gasoline Engines

BY F. GREINER.

I am not absolutely certain that the bee-keepers of our land have good reason to complain about "high" prices of supplies. It may be that too many middlemen are employed. If this is the case, then it is not much different from what we see all around us in other branches of manufacture. Even the products of our farm pass through a chain of hands before reaching the consumer, till the price the farmer receives is doubled, tripled and quadrupled.

The agents which travel from town to town, and store to store, selling the goods of manufacturing concerns, must receive their pay, which comes out of the consumer, eventually. It is true, our large supply-dealers employ no traveling agents, their business being largely a mail-order one, and it would seem that there is absolutely no need of a middleman, but they are there! In view of the fact that some manufacturers, employing no agents, have no branch houses, offer goods much lower than the other so-called "big manufacturers," it would almost seem that the prices the latter class ask for their goods are rather high. On the other hand, it must not be lost sight of that the bee-keepers are not without redress. There is nothing to hinder our making our own bee-hives, sections, smokers, and extractors. I have done so, and still do so to some extent.

Certain goods are difficult to make by the bee-keeper himself; this cannot be denied; the honey-box or section, for example. To make these, as large manufacturers make them, requires special machinery, which is too costly for the small manufacturer. Years ago we saw our sections on a circular saw by horse-power. They were four-piece sections, and had to be nailed, were very rigid, and, when filled, were glassed. Mr. Doolittle, I observe, has adhered to this very section while nearly all the rest of us have adopted the one-piece section or the four-piece dove-tailed. We are not obliged to pay an exorbitant price for the one-piece section as long as we can make a good four-piece for ourselves.

If we, however, find it to our advantage to use the large manufacturer's goods, we have to pay him his price.

The dovetailed hive is another example. I fail to see the advantage of a dove-tailed corner over any other, anyhow. With a plain circular saw we

can make our hives with a "halved" corner, which is much superior to the dove-tailed; or we can simply cut off square and nail together. Hives made thus last a life-time, with good care. Why go to the big manufacturer and contribute to his riches?

Since I began bee-keeping and the manufacture of hives and other necessary supplies, a great change has come about. As mentioned above, we employed "the horse" as the power to serve our purpose; this was 30 years ago. Gas and gasoline engines have now taken the place of the horse, much to the comfort, pleasure and advantage, of both the horse and his owner. It is now a matter of great regret to me that I did not, some years ago, employ the gasoline engine to do my work rather ask the faithful horse to do it; but I was timid, fearing the engine would not prove the thing for me. I also feared the cost of the experiment. There may be other bee-keepers similarly situated as I was, and for their benefit I write this. I would have given quite a little if some one, in whom I placed confidence, could have told me what I know now about gasoline engines for bee-hive work. It was a question with me as to what size engine to purchase. I finally settled on a two-horse power engine. I reasoned thus: One horse having been doing most of my work, although some time the power was hardly adequate, why should not a 2-horse-power engine suffice? True, a horse may be "stimulated" to such an extent as to produce a power equal to a two or four horse power engine for a moment or so; with the engine such a course is not possible, but what the engine can do at all, it can do all the time.

I installed the two-horse power engine with some fears and misgivings, but now I am glad to say that it is answering my purpose perfectly. It is so easily started that I seldom saw off as much as one board with the hand-saw any more. The engine is handy for other work also. What untold hard, backaching work I might have saved myself and hired man had I invested, some years ago, would be difficult to compute.

Since lumber is becoming higher and higher in price, timber getting more scarce, the little engine helps us to save many an expense in this line. We utilize almost any kind of timber, of any size down to 3 and 4 inches in diameter for the bee-hive work. Shipping-cases may be made from basswood, poplar, whitewood, pine, hemlock, chestnut, butternut, and other timbers not too hard. I have even used old chestnut fence-rails which otherwise would have found their way into the kitchen stove. The

manner in which I handle any such material is this:

First, the rails, slabs or small trees are cut on the cross-cut saw about 19 to 20 inches in length; next, on the rip-saw I take off a little slab, turn down on the flat side and split through the middle; in case of slabs or rails no splitting through the middle is necessary, but such are in shape to rip up into desired width at once, after taking a little of one side off.

The tops and bottoms of shipping cases need not be all of one piece. With our rig we can not saw anything much wider than 4 or 5 inches. This is sufficient for our work. While a whole top or a whole bottom may be better for a shipping-case, a 3-piece bottom or top answers well.

Brood-frames should be made of white pine, if possible, but wide frames and the material for section-holders may be of almost any other timber soft enough to nail up easily.

In the years gone by we have wasted and burned a great deal of material that we could now utilize very nicely for hive-fixtures. This is a matter of regret, but cannot be helped now. The high price of timber has made us more careful and saving, and in the future we will have to economize more and more. The gasoline engine will help us do it, and at the same time make us more independent of the supply dealer.

Naples, N. Y.

## Wax-Extracting — The Hershiser Wax-Press and Method

BY OREL L. HERSHISER

Beeswax is the more valuable of apian products. It commands the higher price; there is a steady and constant demand for it; its market value is comparatively stable; it keeps indefinitely and unchanged by the elements, and is not ordinarily subject to damage in transportation.

Notwithstanding its high standard of value, apiarists, generally, have given little thought to its production until quite recent years, producing what they could obtain by primitive methods of extracting, but wasting and destroying more than was produced. This lack of interest and progress in the art of wax-production was undoubtedly due to the difficulty of separating the wax from the refuse, composed of cast-off cocoons from which bees have hatched, propolis, pollen, and other foreign materials, always present in old bee-comb in varying quantities. So difficult and almost impossible was it, by the means employed, to extract more than a small amount of wax from these impurities that it was supposed by many that the old bee-comb contained little else than dross. Because of the unprofitable returns for the work, muss and trouble of extracting what little wax could be obtained, vast quantities of old bee-comb have been destroyed or thrown away, the bee-keeper believing it to be of no practical value.

Thus apiarists in this and other lands

have been throwing away many dollars annually, the aggregate waste to some individual bee-keepers, during the years of their bee-keeping, reaching into the hundreds of dollars, and apiculture generally has lost hundreds of dollars in this way. As a matter of fact, all old bee-comb is rich in fine wax, the quantity varying from 30 percent upwards, according to the quantity of foreign impurities contained therein. New comb in which bees have not been reared or pollen stored is approximately 100 percent pure.

Any of the wax-presses heretofore in common use, when economically operated, will necessarily leave in the slumgum a large amount of wax, the quantity varying from 8 percent to 25 percent of the weight of the slumgum. Slumgum from the solar wax-extractor contains even a higher percentage of wax. All this has been proven many times over by re-extracting the slumgum from nearly every known wax-press, including all the modern and most approved styles heretofore on the market. The difficulty, however, is not that of insufficient pressure, but because the methods are faulty in other particulars. In these presses the interior parts of the mass of slumgum are not subjected to the same compression as the outside portions, the elasticity of the mass opposing and diminishing the actual pressure. As the surface of the mass becomes hard and compact the escape of wax is impeded. Moreover, the power required to compress the slumgum increases greatly toward the end of the operation, as the more the mass is compressed the more solid and less impervious it becomes, especially on the surface of the mass, and hence the greater the force necessary to expel the remaining wax, which by these faulty methods could possibly be obtained; and finally, *except a radical departure be taken from the ordinary and customary methods of compression*, capillary attraction will hold a portion of the wax with the moisture which it will be impossible to expel with any amount of pressure.

If you will saturate a sponge with coloring-matter, which is capable of being washed out, and subject it to pressure, it will be found that no amount of squeezing will remove all the color. Saturate it with water and squeeze again, and more of the coloring-matter will be removed, and if the process of saturating with water and squeezing be repeated several times all the coloring matter will be expelled. It has been washed out. Likewise, in a very similar manner, if a mass of old bee-comb be subjected to boiling water, the wax contained therein will melt, and water and wax may be squeezed out, but no amount of pressure will expel all the water and wax. But let the mass of old comb be saturated with hot water again, and the squeezing repeated, and as the hot water is expelled it will bring out with it a portion of the remaining wax. If the process of intermittent pressure and saturation with hot water is several times repeated ultimately all the wax will be expelled, and the slumgum will hold only water in capillary attraction.

Again, the specific gravity of wax be-

ing less than that of water, if we do the pressing under the surface of hot water, the wax, as it is separated from the slumgum, will rise and float on the surface of the water.

If the mass of old comb or slumgum is comparatively thin the wax will have but a short distance to move to become free therefrom, and by applying intermittent pressure, while immersed in hot water, the washing process, as exemplified in the case of the sponge, will be employed.

It is obvious that the methods heretofore in use locked up within the slumgum large quantities of wax, as it were in a strong safe, requiring a certain but simple combination to open and release it into our possession. That combination, embracing the application of scien-

HERSHISER WAX-PRESS.

tifically correct principles, as herein pointed out, is fully comprehended in the Hershiser wax-press, a view of which is herewith presented.

Briefly, this is a construction in which the masses of slumgum within the extractor are placed in comparatively thin layers so that the wax has the shortest distance possible to move to become free therefrom.

Again, the masses of slumgum or old comb are pressed while immersed in boiling water, and the wax rises and floats on the surface.

Further, the structure is designed with the special object of advantageously applying the principle or intermittent pressure.

Finally, in this structure the pressure on the several layers of old comb or slumgum is readily and automatically released, thus affording the best possible conditions for the absorption of hot water for the displacement of the wax by repeated pressings.

Considering the extractor specifically, a boiler or rectangular form is provided, which besides its use in holding the water and bee-comb, or slumgum, to be extracted, serves as the guiding means for the follower, and separating or division racks placed between the cheeses of slumgum. Being constructed out of very strong sheet-metal it enables the operator to apply the maximum amount of pressure required for the extraction of the wax. Across the top of the boiler is a beam, the ends of which extend underneath loops at two of its opposite sides. The boiler is provided at one

end and on the outside with a funnel or spout opening into the same near the bottom thereof, the top of the funnel being nearly on a level with the top of the boiler. The funnel is for the purpose of introducing hot water into the boiler at the bottom. A delivery spout is provided near the top of the boiler for drawing off the wax after the same has been melted and pressed from the cheeses of wax-yielding materials. A cock for drawing off the water from the boiler is provided near its bottom.

The boiler may be placed on a stove, or other suitable means of heating may be provided. Through the beam at the top is introduced a screw engaging suitable screw-threaded bushing therein. The screw is provided with a handle and exerts pressure downward on the follower, which is substantially the size of the inside horizontal dimension of the boiler. In the bottom of the boiler is placed a rack or grate consisting of spaced steel bars on edge, over which is placed a woven-wire screen. On this is placed a cheese of bee-comb or slumgum after the same has been made in proper form, by means of a cheese-box provided for the purpose, and being wrapped and secured in burlap cloth. On top of this bottom cheese is placed a slatted wooden frame, called a division-rack, consisting of cross slats, on the top and bottom of which are secured woven-wire screens. The cheeses and these division-racks alternate until the top is reached, the standard number of cheeses being three, when the follower is placed on top of the uppermost cheese, this follower being provided with cross-slats covered with woven-wire screen on its under side.

In operation, the extractor is placed on a stove or other suitable means of heating, and sufficient water is provided to prevent the heat from injuring the bottom of the boiler, after which it is filled with the cheeses of slumgum or old comb as described. More water is then added until it rises to nearly the level of the delivery spout. The whole is then brought to a sharp boil. Owing to the construction of the division-racks the water is free to circulate between the layers of slumgum or old comb, and, when boiled, melts every particle of wax contained therein. The slumgum, owing to the presence of the burlap covering in which it is wrapped and the screen-covered division-racks, can not pass up between the slatted frames, but the wax, when melted by the hot water, readily passes, and escapes in this way, rising and floating on the surface of the water, where, by means of raising the level of the water, by filling in hot water through the funnel, the wax may be readily and cleanly drawn off, so that no wax will remain on the surface of the water in the extractor. Near the end of the operation some hot water will come out with the last remnants of wax, leaving the surface in the extractor clean. A large delivery spout is provided, which results in cleanly drawing off the wax with the use of a comparatively small quantity of hot water.

In pressing, the screw should be turned down gently at first, allowing

the wax and water to escape from the cheeses. After the screw has been turned down as far as it will go with moderate exertion, allow the slumgum to remain under compression 4 or 5 minutes. Then reverse the screw and release the pressure, allowing 4 or 5 minutes for the slumgum to absorb the hot water. Then press again, turning the screw down a little further than the first time, and leaving the slumgum under pressure 4 or 5 minutes as before; then release the pressure as before, and repeat the process of intermittent pressure a few times until the wax is cleanly extracted from the slumgum, each successive pressing turning the screw down a little further.

To form the cheese, a box without top or bottom is provided, the same being a little longer on the lower than on the upper plane, in order that it may be easily slipped off from the cheese after it is formed. Lay this cheese-box on a plain surface, preferably a wood or cement floor, spread the burlap cheese-cloth over it so it will project uniformly from the four sides of the cheese-box, and then press it evenly down so that it will fit snugly against the four inner sides of the box. Now fill in the slumgum or old comb, tamping it down good and solid, a tamper made of a 2x4 piece of wood being good for the purpose. When the cheese is filled even with the top of the box, fold the cloth from two opposite sides and fasten; then fold the cloth from the remaining sides and fasten. Long, sharp brad-nails, used as pins, have been found to be excellent for fastening the cheese-cloth. The cheese, still within the box, may now be placed in the extractor and the box lifted off.

When rendering comb which contains a large percentage of wax, or in converting cappings into wax by the hot-water process, it is advisable to melt the comb or cappings in another boiler and dip out as much as can readily be obtained. Then place the cheese-box on a division-rack, over the extractor, so the drip will fall therein, and form the cheese by dipping the residue from the boiler into the burlap lined cheese-box until it is full, no tamping being required.

In crowding the extractor to its fullest capacity the beam may be adjusted after the slumgum has been heated sufficiently to settle down where it will not interfere.

By the method here described, practically all the wax may be extracted from old comb or slumgum. By this is meant that after the extracting is finished as per directions for the operation as practiced in every-day commercial use, less than 1 per cent of the residue will be wax. As a matter of fact, thorough and severe tests which have been made of slumgum from which the wax had been extracted as here described have revealed from less than  $\frac{1}{2}$  of 1 percent to less than  $\frac{5}{8}$  of 1 percent.

It will be observed that there is no opening of the extractor after it is filled until the extracting is finished. Hence there is no raking, shaking or pawing over of the slumgum, and no second or subsequent cookings and pressings in order to get what wax it is

possible to obtain by some of the mussy and unsatisfactory methods.

In years past I was one of those who mused and fussed over wax-extracting, and finally came to using a screw-press machine of modern manufacture, reputed to be one of the best. By this machine I was obtaining from 200 to 250 pounds of wax, annually, but the results of extracting were always unsatisfactory, and for good reasons, as, besides the slow and tedious work, involving the use of a comparatively large amount of fuel and the remelting of the wax in order to mould it, I have since discovered that, with all my pains in raking, scraping, stirring and repeated pressings, I had been throwing away in the slumgum a considerable quantity of wax each year, which it was impossible to obtain with the press. This waste amounted to enough to pay a handsome dividend on an investment of several presses. I can therefore fully appreciate the pleasure of being spared all that muss, which has now become unnecessary, and there is added satisfaction in the knowledge that, when the operation of extracting is completed, practically all the wax has been extracted from the slumgum, and that this maximum of beneficial result has been achieved with the minimum amount of labor, muss and expense. It may be added that in the prodigality of wax-wasting I had much good company, as I have had occasion to know that my experience was by no means exceptional. Indeed, a fair estimate would place nine-tenths or more of the bee-keepers in the class to which I then belonged.

A fair average price of wax in Eastern markets is 28 cents per pound. Suppose that after extracting is finished the residue of slumgum amounts to 100 pounds. Now for every pound of wax thrown away with the slumgum 28 cents is lost; 28 cents is 6 per cent of \$4.66 2-3. Then to find how much money at 6 per cent is required to yield the value of a given number of pounds of wax lost in the slumgum, multiply \$4.66 2-3 by such number. For example, suppose we find that we are losing 8 lbs. of wax in every 100 lbs. of slumgum; then \$4.66 2-3x8 equals \$37.33 1-3, which is the amount that at 6 percent would be required to yield \$2.24. the value of the 8 pounds of wax lost; like cases may be solved by this rule. For the benefit of those who have no ready means of ascertaining how much wax they are wasting, it may be stated that perhaps not one bee-keeper in 50 is getting within from 8 to 10 per cent of his wax, and perhaps one in 10 is getting within 15 to 25 per cent.

Deposits of money in banks that pay 4 percent where the money is available for withdrawal is considered an ideal investment. Municipal, State or Government bonds seldom yield more than 6 percent, yet they are favorite investments for capitalists. How much more ideal, then, is an investment by the bee-keeper of a small sum in a good wax-extractor which, after making due allowance for wear and tear on the machine, will yield all the way from 6 percent to many hundred percent, depending upon the amount of wax to be extracted. Bee-

# American Bee Journal

keepers will quickly observe the fact that the additional first cost (over and above the cost of the best of other presses) of a machine that will save anywhere from one dollar upwards to twice or thrice such cost annually, is certainly an ideal and highly profitable investment. The old adage, "The best is the cheapest," may be well and truly applied to wax-extractors.

Wishing to ascertain how much fuel it was necessary to use under the most unfavorable conditions, 200 pounds of slumgum from a solar wax-extractor was carefully weighed out and extracted. The following notes were taken:

The temperature of the water, drawn from the cold-water tap in the cellar, was 33 degrees F. The temperature of the cellar where the slumgum was stored and the extracting done was 37 degrees F. The amount of water used was 45 gallons. The fuel was illuminating gas. The amount of fuel consumed in extracting was 300 feet; additional gas consumed in keeping the wax liquid in a separate tank so the sediment would separate from the wax and make clean cakes, 20 feet, or 320 feet in all. Time of whole operation, extracting and molding ready for market, 6½ hours. The amount of clean A No. 1 wax obtained, 70¼ pounds, all nicely moulded and ready for market. Price of gas \$1.20 per thousand feet, with 20 per cent discount if paid before the 10th of each month. Cost of the fuel for the whole operation, cash basis, 32 cents, or less than ½ cent per pound of wax. Illuminating gas is the most expensive fuel of which I know. It is about four times as expensive as natural gas, and I suppose that wood or coal would be cheaper in about the same proportion, and that under ordinary conditions, this extracting could have been done at an expense of about 8 cents for fuel. Water, as we all know, even hot water, is inexpensive. The fuel item when extracting beeswax by the improved methods is therefore scarcely worth considering. Another point worthy of note is that this slumgum from the solar wax-extractor yielded a trifle over 35 per cent of its weight in wax.

It should be borne in mind that, to say the least, no more work and expense, and far less muss, is required to do the extracting in this practically perfect manner than is required to do it by the use of such extractors and methods as must necessarily leave several per cent of the wax in the slumgum, and hence every pound so saved by the better machine and process may be figured as the saving of the same at its full market value without any allowance for the work and expense of extracting, when comparisons are made with the less-productive methods.

Again, let it be born in mind that the number of pounds of wax produced per hour, or per day, is only one indication of the value of a machine or process, and it may indicate, when all is considered, the entire absence of value. If a machine will turn out 100 pounds of wax per day, and throw from 8 to 15 per cent out in the slumgum, it is not so valuable as one that will throw out one-eighth of that percent,

even though the product, in the latter case, be but 40 or 50 pounds per day, because the difference in the amount of wax obtained will more than hire the help for the difference in the time of extracting.

And, further, it may be added that, having produced thousands of pounds of wax by this hot-water and hot-press process, by re-extracting slumgum purchased from other bee-keepers in a wholesale way, and sold every pound of it in large and small quantities at fancy or highest market prices, and never for less, to experts on the value of the same, it is proper to state emphat-

ically that the quality of the wax produced from this right kind of a hot-water press is not inferior to that produced by the unheated press, or any other wax-extractors known to me.

The boiler of the Hershiser wax-press is also admirably adapted to the important use of liquefying honey in 5-gallon tin cans, the standard size, accommodating 4 or 5 of them at one time. It is also useful as an uncapping can, and as a honey-press for pressing honey out of cappings, and broken combs. It, therefore, may be used for three important purposes, besides its use as a wax-extractor boiler.

Conducted by LOUIS H. SCHOLL, New Braunsfels, Tex.

## Why the High Prices of Honey?

Some are asking why high prices prevail more of late than was the custom in past years. Editor Root, of *Gleanings*, already attributes it to the work of the new Pure Food Law—articles of better quality demanding a better price. I hardly think this is the main reason. It must be the demand—increased consumption—and, in addition to this the past season, the short production. Nearly all will admit that the honey crop was hortover the entire country, with a good demand at the beginning of the season. Therefore, the bulk of the crop was soon sold.

There is *very* little honey in Texas, to my knowledge; while the demand is better than I have known it for years. In our local market the price of honey has just doubled. Nearly all other products are high in price. The whole country is more prosperous just now than it ever has been. There is an increased demand for all commodities; hence, the high prices now prevailing.

## How to Start with Bees

It is the man who thinks he knows all about bees, and begins with 200 or 300 colonies the first pop, who will be saying a year or two later, "Bees are the biggest nuisance on the face of the earth. No one ever made anything out of them." We have seen several do this "trick," even after we had discouraged them all we could; but some people are so "smart," until they get burned. Therefore, be careful lest you do the same thing.

A start should be made with a few colonies, and the increase be made as means and experience permit. The season is approaching when many will want

to get some bees, and now is the time to settle upon the number of colonies best to begin with. Read a good bee-book and a bee-paper or two. Several will be better, as one can not expect to get as much out of one. Then expect to learn something about the bees every day.

## Gathering Light Honey a Trait in Bees

The following from J. E. Chambers, of Vigo, Tex., is of much interest to me:

FRIEND SCHOLL:—Did you ever observe that during a honey-flow from two sources—one dark and the other light—the bees gather very differently, some gathering all light honey, and other colonies gathering all dark. During the sumac flow here I kept a close watch on all of my colonies, and found that some did not work on the sage or dark honey-plants at all, but instead brought in the white honey. I do not know, but I think that this trait is worth a good bit to me. I will rear some queens from those colonies that worked so strong on the sumac while the others were getting sage, and see if this trait is hereditary or not. However, I doubt if such traits are always transmissible, even though largely hereditary. But if measurably so, I think I have found an item of value to me, for I often have a good crop of white honey spoiled by the addition of a little dark honey during a double flow, and, of course, to such there would be no special value in working for such bees.

J. E. CHAMBERS.

This calls to mind an experience I had in the fall of 1905, while extracting honey at one of our out-yards on the Brazos River Valley plantations. The bees were gathering honey from cotton, mainly, which yielded well, and, at the same time, the elms—*Ulmus alata*—were also yielding abundant nectar. The surplus honey that was being taken off was from the cotton, and very light in color. The bees were still bringing in honey from this same source—of light

honey. That from the elms was dark amber, and strong-flavored. A noticeable fact was that, although certain colonies which were apparently of the same strength, and alike in other conditions, they had different supers of honey. While some of the supers were filled with nice, white combs throughout, others would be filled with combs partly discolored by the dark elm honey, while still others would contain nearly all dark honey-combs. The product was all bulk honey, but then supers with the dark honey had to be extracted.

Just why some colonies should have stored much more of the dark honey than others, some of which stored none of it at all, I can not say. It is an important question, however, for the white comb-honey producer.

### Pure Food Law for Bee-Keepers

A reputation for honest goods and honest dealing is bound to bring success; especially since the Pure Food Law has been set to work. The honest bee-keeper should now be able to make an honest living, and he can do it if he sells honest products, for, with the adulterated stuff out of the way, the pure article will find ready sale at good prices. This is as it should be.

The bee-keeping fraternity has suffered long enough—the industry has been hampered. The honest bee-keeper has been robbed of the profits he could have made from his product, and the consumers, of their money, which they paid for the stuff not worth it, by the greedy "manufacturers" of the vile, adulterated goods, which were forced upon the innocent public under some catchy name. Times have changed, and everything *must* be what it should be, and I have no fear that the honest bee-keepers will have any trouble to come up to this.

### Weight of Eastern and South-western Honey

The Arizona Experiment Station, in one of its circulars, "Practical Hints to Farmers," says in comparing samples of native honeys with those from the East:

"The average moisture, 16.85 percent, is seen to be markedly less than that in Eastern honeys, averaging in two instances 19.39 and 18.50 percent. This results from the exposure of South-western honeys before and during extraction to the exceedingly dry air of this region. With our excessive heat and dryness, evaporation quickly concentrates the honeys to a condition of ripeness which insures keeping, also considerably increasing the weight per gallon. Eastern honey usually weighs about 58 pounds in a 5-gallon can; while the Arizona article weighs ordinarily from 60 to 62 pounds."

**The San Antonio Convention Pic-ture is a good one.** It shows over 100 of those in attendance. We are mailing them, unmounted, for only 60 cents. They can be mounted by a local photographer for only 10 or 15 cents more. We will mail one of these pictures with the American Bee Journal one year—both for only \$1.40. Send all orders to the Bee Journal office.

## Report of the Michigan State Convention

REPORTED BY R. F. HOLTERMANN

The opening session of the above Association took place at 8 p. m., Dec. 25, 1906, in the parlors of the Northern Hotel, at Big Rapids, Mich., with President W. Z. Hutchinson in the chair.

### "HONEY POSSIBILITIES OF NORTHERN MICHIGAN."

This was by S. D. Chapman, Mancelona, and was the first topic on the program. Mr. Chapman is in a red-raspberry section, and said there were more bees there now than in any other part of Michigan. He began bee-keeping up there in 1881, and had not known a complete honey crop failure, raspberry being his only source until the year 1895, caused by 16 inches of snow on May 16 of that year, the thermometer dropping to 11 degrees above zero, and killing everything. They had been able to haul saw-logs on the snow that fell for 3 days after. During the past season (1906) the frost had also used them up pretty badly, by a frost May 20; however, they had secured a partial crop of raspberry honey. He had nearly 400 colonies of bees, and, one year with another, he could secure about 100 pounds of surplus honey to the colony. The honey-flow generally began June 1, and closed from July 18 to July 20. The bulk of the raspberry honey came in during the afternoon from 1 to 4 o'clock. During that time he had known a colony in an 8-frame hive to gain 17 pounds, or a total gain for that day being 21 pounds.

When Mr. Chapman first began bee-keeping in Northern Michigan, there was no fall honey-flow whatever, but buck-wheat and goldenrod were now beginning to give some surplus honey. Sumac was also coming in, and where it existed in sufficient quantity, coming in at the close of raspberry, it prolonged the light-flow by a period of 10 days. Both the raspberry and sumac honey gave a honey with good body, color and flavor. Raspberry, when it yielded well, could beat basswood at its best, for rapidity with which the bees could gather it. He had experience in first-class basswood localities.

Mr. Chapman, in speaking of his experience with Carniolan bees as compared with Italian for wintering, stated that the Carniolans were much better winterers than the Italians.

### WEDNESDAY MORNING SESSION.

The session opened with Association business, a goodly number being present.

Elmore M. Hunt, the Secretary-Treasurer, showed a very satisfactory report. From a cash deficit, with his energy he had worked until this year there was a balance on hand.

### THE NATIONAL FOR DETROIT IN 1907

Upon resolution by Messrs. Geo. E. Hilton, Vice-President, and L. A. Aspinwall, it was decided to join the National Bee-Keepers' Association in a body, so that during the present year everyone becoming a member of the State Association will also be a member of the National.

The same gentlemen then brought forward the matter of inviting the National to have its next meeting in Detroit. It was urged that a good turnout would be assured in Detroit on account of railway facilities from all points, including Canada. R. F. Holtermann, of Ontario, said he felt safe on behalf of Canadians to add to the invitation for the convention to be held at Detroit. The convention held so close to the Canadian border would prove a strong temptation to Canadians, and in all probability, a turnout of some 50 could be depended on from that country. A standing vote being taken, the invitation to the National was unanimous.

### PUBLISHING A HONEY-PAMPHLET.

The matter of publishing a pamphlet with a list of members of the Association and the quantity of comb and extracted honey they had for sale, also pointing out the value of honey as a food, and how to liquefy it, was discussed; also the number to be published. Some objected to distributing a pamphlet by themselves, which would give to prospective customers the name and address of rival producers. It was suggested by Mr. Holtermann that the National Association could best get out a pamphlet setting forth the value of honey, how to judge the quality, how to store and liquefy it. That organization could get out the largest number and therefore supply it the cheapest, and such a pamphlet should be supplied at about cost price to other associations in affiliation, or to individuals who were members. A leaflet with names and addresses giving amount of honey each member had for sale could be sent out and supplied by the State organization. It was decided to issue a pamphlet similar to last year for the special benefit of members.

The election of officers resulted as follows: President, W. Z. Hutchinson; Vice-President, Geo. E. Hilton; Secretary-Treasurer, Elmore M. Hunt—all officers being re-elected. They also received a vote of thanks for the hard work which had been done. Mr. Hunt,

the Secretary, being specially singled out for his efficient efforts.

#### "THE NON-SWARMING HIVE."

Mr. L. A. Aspinwall gave an address on this subject which was listened to with very keen interest. He thought he would better confine himself to the advantages of such a hive, but many questions had to be answered as to the construction of the hive, and so he briefly described its construction, saying that the principle was to prevent crowding of the bees by means of slatted separators between the combs.

Turning then to the advantages, in an invention of merit the reality generally ran ahead of the expectation of the inventor, he said; this had been the case with the steam engine, telegraph, telephone, and many revolutionary inventions, and in the invention of the non-swarming hive certain things had come to pass least looked for. Taking an equal number of bees in the 8 or 10 frame Langstroth hive as ordinarily made, and the same in a non-swarm, and the latter would produce double the amount of honey. Why? Put a dozen men in a stone-quarry where they were constantly elbowing one another and they would do much less work than when they did not interfere with each other. He had been testing this hive for years, and in every test the non-swarm had given more than double the surplus the 8-frame ordinary hive had given.

Another feature: Queen-excluding zinc need not be used with this new hive. Out of 3000 sections taken this year, only 2 showed any signs that the queen had been in the super. Why? The queen will not venture into the super until she is crowded out of the brood-chamber. The queen-excluder then offered no obstruction to the bees, and free access to every part of the hive was what is needed for a non-swarm. Next, he used drone and worker foundation in the sections; by putting drone foundation in the central sections, he prevented the bees from storing pollen in the sections. Each section-super contained 45 sections. He was compelled to do this because the warm currents of air rushing into the super on account of the slatted separators between the brood-combs, the bees would rush into the supers more rapidly; but until he used the drone-comb, there was trouble on account of pollen. This had been overcome. In reply to two questions, he said the slatted separators were used only during the honey-flow, and that he preferred for market and use to have drone section-comb.

Mr. Fred Muth, of Ohio, thought that honey in drone-comb would be objectionable upon the market.

Another member present pointed out that sections with drone-comb at present generally had worker-comb started, and from that it was changed to drone. A uniformly built drone-comb would not have the objection that the mixture would have.

In handling the frames the end-lugs of the frames were so far away from the bees that they were never in the way when handling; the frames have the slatted system on the ends, and the outer

piece was close-end, but to this other piece the bees did not get, and none would be crushed in rapid manipulation. In handling this hive there would be no propolis on the fingers.

The bees from 15 to 18 days old largely rule the hive. They take the honey from the field-bees and store it in the cells. The bees of this age are also largely the wax-secretors.

He could operate with the same outlay of labor more than double the number of colonies. He could get more than double the quantity of honey. No one in his neighborhood had averaged more than 30 pounds per colony; he had averaged 100 pounds to the colony.

#### OUTDOOR WINTERING OF BEES.

On this subject Vice-President Geo. E. Hilton said that he combined bee-keeping with other lines of business. Much of bee-keeping had also locality to consider. He wintered his bees outside, and had tried below and above ground, single and double walled hives, and situated as he now was, he was obliged to winter them above ground and outdoors, and he had been obliged to use double-walled hives. He found double-walled hives had many virtues for either summer or winter. Where he lived, they were subject to sudden changes in spring and fall. During intensely hot weather he could keep the bees in the supers. People generally wanted to know how to winter bees better; two or three persons within the sound of his voice had mastered the problem and wintered bees inside.

Plenty of stores were wanted; atmospheric conditions alone were not

enough. Quality, quantity, right stores in the right place, were what was wanted. If the bees had plenty of stores in the fall and few vacant cells, they would be less apt to gather fruit-juices (sweat or sour), or honey-dew; and if there were plenty of sealed stores, in any case the percentage of injurious stores would not be great enough to injure the bees.

To save work, when the winter cushions came off, the supers went on, and *vice versa*—one wheelbarrow to a load of each, each trip. For wintering he folded the enamel cloth half back, exposing the rear half of the combs and bees. Over these he placed a piece of burlap which allowed the passage of moisture, and above this he placed the cushion for the winter. The cushion had a 4-inch rim, cloth at the top and bottom, and wheat-chaff or cut straw to fill the space between. Oat-chaff, or straw, was more liable to mold. He liked these cushions. They kept their shape, piled nicely in the summer, and could be kept free from mice. A gable-end cover with a hole in each end allowed the moisture to pass from the hive as it was carried above the cushion from the cluster below, by a slight circulation of air. We must avoid the appearance of moisture in the hive. In his locality the temperature fell to 20 degrees below zero. He allowed snow to remain as it fell on and about the hive, only removing it as the temperature became high enough for the bees to fly.

A discussion followed, some thinking that for one who would give his bees care and attention, a single-walled hive would be better.

(Continued next week.)

Conducted by E. L. BYER, Markham, Ont.

### Foreign Honey in Canada

Possibly some might think, on reading that item on page 32, relative to prices of honey in Ontario, that *now* would be a good time for foreign honey to gain a foothold in our markets. I have a brother working with one of the largest baking concerns in Canada, and he informs me that they are importing honey, but no great quantity, from Cuba and Jamaica. Even at present prices they prefer the Canadian product, if they can only get it.

Owing to the tariff wall that Uncle Sam and Johnny Canuck have seen fit to erect between the two countries, there is a duty of 3 cents a pound on all honey coming into Canada from the United States. Cuban honey has to pay the same, but Jamaica, under the preferential tariff, pays 2 cents per

pound. Considering a tax like this, added to the freight over such a long distance, it is surprising to know that Cuban honey has been laid down in Toronto for 7 cents. Surely, there can not be much in it for the producer in Cuba at that figure. I believe the figure quoted is a little lower than ordinarily, but I have positive knowledge of Cuban honey being sold in Toronto for 7 cents, 3 or 4 years ago.

### Bee-Keeping—Our "Queer" Calling

In glancing over the "patent insides" of one of our local papers a short time ago, I noticed an item under the caption, "Some queer callings that have journals devoted to their interests." Among the list submitted was

bee-keeping, the writer of the article assuring us that "actually 5 or 6 papers were published in America whose interests were devoted to this peculiar calling."

It is not to be wondered at that bee-keeping should be regarded with such an air of mystery by the masses, when such stuff as the foregoing is scattered broadcast over the land; and not withstanding all the admitted advances made in the last 20 years in the matter of dissemination of apicultural literature, to my mind there is no doubt but the general public are more ignorant of bee-keeping than of any other calling.

I was forcibly reminded of this fact one day last June, when coming through one of my neighboring villages with a few colonies of bees in a wagon. Having occasion to stop at a grocery store for a few minutes, I found, on coming out, quite a crowd of curious people surrounding the wagon and viewing the bees which were clustered to the screens, covering the space provided over the hives. And of all the funny questions "fired" at me relative to what those bees were doing! And among the questioners were some good farmers who knew all about raising well-bred cattle and horses.

After satisfying the crowd's curiosity to the best of my ability, and as far as time would permit, I drove off rather amused, and at the same time wondering if the greenest of green beekeepers would ask such ridiculous questions of those same farmers, if they had their cattle and horses on exhibition.

### Director Ferrier, Not "Fewer"

In the list of Directors of the Ontario Bee-Keepers' Association (page 1036—1906) for District No. 2, there occurs a typographical error. It should read A. A. Ferrier, of Renfrew, instead of A. A. Fewer, as given. Mr. F. is one of Ontario's live, aggressive apiarists, and we would not wish him to be "fewer," but rather the *more* like him the better.

### Mixing Alsike With Red Clover for Bees

A writer in Gleanings thinks that we would not need to try to get long-tongued bees that would work on red clover if farmers would mix more alsike with their clover seed, when seeding their meadows. His theory, of course, is, that the bees in working on the alsike and red clover blossoms back and forth, by the process of pollination, causes the red clover to partake more of the nature of the alsike, which is, as we all know, one of the very best honey-plants. He says:

"The bees will work strongly on the alsike, and will carry the pollen from the alsike to the red clover; and if this method is kept up for a few years the red clover will make a good honey-plant." This, in theory, sounds quite plausible, but I am sorry to say that, in common with many other of our pet theories, it fails to work out in practice. For 25 years Markham and ad-

joining townships have grown thousands of acres of alsike for seed, and clover meadows are generally well mixed with alsike, which comes as a voluntary crop. Yet, to-day, red clover is no better honey-plant with us than it was 25 years ago.

### Bee-Stings and Their Effects

Wm. W. Green deserves a medal (see page 28). Any man who could, in the "interest of science," keep cool under the conditions he describes, must be possessed of considerable stoicism, to say the least. Any one who is not affected much by bee-stings, or who has never seen an acute case of bee-sting poisoning, can hardly realize what a serious matter it is.

Last season, while loading some bees one evening, a small knot dropped out of a bottom-board, allowing a few bees

to escape and crawl around. A young man, who was assisting me, was stung by one on the throat. Although he had only a few days before been stung at different times with no ill effects, yet this time the effect was terrible. Inside of 5 minutes he was rolling on the ground in agony, his face and hands livid, and complaining of an intolerable itching all over his body. We gave him some brandy, which happened to be in the farmer's house, and hustled him off to the doctor—a distance of 3 miles, which was not long in being covered. Two hours after the stinging the patient had about fully recovered.

I have spoken to several M. D.'s, and they all agree that aromatic spirits of ammonia is the best stimulant to administer in case of bee-stings; and from what I have seen of its use, I certainly think it should be in the home of every bee-keeper, to be on hand in emergencies.

Conducted by EMMA M. WILSON, Marengo, Ill.

### The Baroness Burdett-Coutts

The death of the Baroness Burdett-Coutts, Dec. 30, at the age of 92 years, will be felt as a great loss by many, among them British bee-keepers. For years she has been the honored head of the British Bee-Keepers' Association, and, notwithstanding her many activities, she has not failed to cheer this Association on its onward course. To her mortal remains has been given the rare distinction of being deposited in Westminster Abbey.

The following items regarding her are condensed from the Chicago Record-Herald:

With the death of Baroness Burdett-Coutts there passes the greatest philanthropist of England—a woman whose charity was world-wide, and whose life linked a distant past with the present day, for she was born during the supremacy of Napoleon, and lived under the reigns of five British sovereigns. For three-score years she has been the most remarkable feminine figure in the British Isles. Coming into possession of a fortune of \$9,000,000 when she was 23 years of age, she has, since then, expended \$500,000 yearly upon charities and benevolences. In her youth she refused the hand in marriage of the son of Louis Philippe, of France, remaining a spinster until 65, when she married her poor American secretary, William Lehman Ashmead Bartlett, then 30 years of age, and by so doing forfeited the friendship of Queen Victoria, who, in 1871, had created her the first baroness of her name.

A close personal friend of Charles Dickens, she went slumming with him when that was not a fashionable pursuit, and financed many of his great reforms.

King Edward, while Prince of Wales, called

the Baroness "the second lady of the land," giving her the next position after his queen-mother, Victoria.

Prime ministers, ambassadors, the greatest writers and reformers of the day sought her acquaintance and favor, while the queen and crown prince attended her levees. No court function was complete without the Baroness Burdett-Coutts, while the homes of the poor and needy knew her presence, and loved her for her generosity.

In 1872 the Common Council of London presented her with an address enclosed in a golden casket bearing her name and arms, on which were bas reliefs representing her acts of mercy, "Feeding the Hungry," "Giving Drink to the Thirsty," "Clothing the Naked," "Visiting Prisoners," "Lodging the Homeless," "Visiting the Sick," "Burying the Dead."

She was honored in Scotland by being made a "Free Woman" of Edinburgh. For her deeds in Turkey, the Sultan gave her the star of the order of the Medjidieh and the Grand Cordon of the Shafakat, the Order of Mercy, a distinction shared by few Christians, and by no other woman.

Ireland was benefitted greatly by the generosity of the Baroness. Immense sums of money have been distributed from her gifts to relieve destitution and want among the Irish peasantry, and one of the most successful of all the philanthropic enterprises was her assistance of the Skibbereen fishermen when famine stalked through the land.

The Baroness was the pioneer of reformatories for women in Great Britain; she provided funds for the topographical survey of Jerusalem, and she was a chief supporter of the Destitute Children's Dinner Society, an organization which provides 300,000 dinners a year. A conservative estimate of the annual donations which the Baroness made to different charities during latter years would place the figure at not less than \$2,000,000.

The distress of the Turks during the war

with Russia aroused the sympathy of the Baroness, and she employed Mr. Bartlett to distribute \$150,000 among the needy in the Sultan's dominions. There is a story to the effect that she first met him while she was distributing prizes at a school in North London, and that she afterward sent him to Oxford. However that may be, she was satisfied with his work in Turkey, and afterward married him, to the surprise of all England, the rage of Queen Victoria, and in the face of protests from her relatives. Mr. Bartlett is not her heir, the vast estate reverting to Mr. Money-Coutts, but as the Baroness took care to settle an annual income of \$250,000 on her husband, which could not be reached during his lifetime, he is not illy provided for. It is quite certain that their marriage has been happy, and it is known that Mr. Burdett-Coutts is an able man, handicapped, perhaps, because he married such a wealthy woman when there was such a disparity between their ages, but, nevertheless, a valuable member of Parliament, and a clean, honest gentleman, whose investigation of military matters in South Africa created a popular ferment, and resulted in changes for the better in the British army.

### More Misrepresentation of Comb Honey

DEAR MISS WILSON:—Allow me to call your attention to an article written by J. H. Kellogg, M. D., in his "Home Hand-Book of Domestic Hygiene and Rational Medicine," on "Adulterated and Artificial Honey." He says that a large share of "strained" [extracted] honey is glucose, and that they have examined specimens in which considerable quantities of sulphuric acid were present, and then winds up by saying:

"It is stated that another very ingenious form of adulteration of honey has been quite extensively practised. What is termed the foundation of the comb is made of paraffin—a wax-like substance made from petroleum. This saves the bees much labor, as they have but to build up the cells on the foundation furnished them; then, to still further economize their time and labor, they are abundantly supplied with glucose in solution, which they have but to transfer to the comb, thus avoiding the trouble of gathering sweets from distant fields. Of course, no transformation takes place in the artificial sugar, it being simply transferred from the feeding-vessel to the comb. Thus we have honey which is wholly artificial, with the exception of a portion of the wax. This certainly caps the climax of adulterations."

There were no less than 700 of these books delivered in our neighborhood less than a month ago, and 90,000, I believe, have been published. Now, what do you say to this statement of one who is taken as authority?

I feel rather well acquainted with you through the American Bee Journal, therefore I take the liberty of writing to you.

We have about 225 colonies of bees at present.  
ANELIA PETTIGREW,  
N. Ogden, Utah, Jan. 2.

It is a sad thing that a man who can wield so much influence should put forth such erroneous and damaging statements under cover of that mischievous, though apparently innocent, "It is stated." Vicious and damaging statements can be made, which will be taken for truth, while the "It is stated" will be lost sight of.

"It is stated"—certainly, many a lie is stated, but its being stated doesn't make it true, and Dr. Kellogg ought to have more intelligence than to aid in the circulation of such malicious nonsense without knowing what he is talking about.

In the first place, foundation of paraffin can not be successfully used. It stretches out of all shape. In the

second place, has Dr. Kellogg any proof that bees can be induced to store glucose?

It is a matter for rejoicing that the pure food laws will help to settle such misrepresentations, for the people will soon begin to have confidence that nothing can be safely offered as honey except the Simon-pure article.

After all, the thing is not as bad as it might be. Even if people believe all Dr. Kellogg says "is stated," your own reputation for uprightness will prevent them from believing that *your* honey is spurious. At least it is so in this locality, for the belief that honey is largely adulterated has made the people more insistent that their honey should be obtained from the apiaries of men or women whom they believed would not stoop to adulteration.

### Honey-Paste for the Hands

Honey-paste for whitening and softening the hands: Rub together one pound of honey and the yolks of 8 eggs; then gradually add one pound of oil of sweet almonds, during constant trituration; work in 8 ounces of blanched and ground bitter almonds, and perfume with 2 drams each of attar of bergamot

and attar of cloves. This makes quite a large amount. It would be better to experiment with half the portions. Red, rough hands must be kept out of hot water as much as possible. When bathing use the very purest soap you can find, and be sure to thoroughly dry the surface of the hands.

The foregoing is by Mme. Qui Vive, the dispenser of beauty formulas in the Chicago Record-Herald. Even half the amount of materials given may be larger than some of the sisters may care to use. One-eighth the amount is easily figured out, and is as follows: Two ounces of honey; the yolk of 1 egg; 2 ounces of oil of sweet almonds; 1 ounce of blanched and ground bitter almonds;  $\frac{1}{4}$  dram each of attar of bergamot and attar of cloves.

A friend of an economical turn of mind suggests that it is entirely possible that all the hard work of softening and whitening may be done by the first two ingredients; and that the sisters who are not interested in enriching the apothecary might not be far out of the way to try beautifying their hands by beating well together the yolk of an egg for each 2 ounces of honey, anointing the hands therewith before going to bed, and putting on a pair of mittens.

The "Old Reliable" as seen through New and Unreliable Glasses,  
By E. E. HASTY, Sta. B. Rural, Toledo, Ohio.

### THE "KISS" OF THE KISSING-BUG.

Isn't it rather remarkable, Prof. Cook, that all the kissing-bugs should be long-headed? Some at least of our moralists would incline to have them short-headed, and short-sighted, and short of intelligence. However, "kiss" in this case is merely bitter irony for the awful stab which they are able to give—sometimes on your face as they crawl onto it from the "kiver" of your couch. Claremont has had 3 victims in 12 years, it seems. Page 1048.

### DISTANCE BEES GO FOR NECTAR—LOCATIONS FOR APIARIES

And Doolittle among the heretics, too! Thinks it might do to keep 200 colonies in an average location, and 400 in a specially good one.

But there's no getting rid of the mathematics that four times as many bees can find pasture on a 4 mile range as would equally harvest a 2-mile range. If our bees are working 4 miles, and we think they are only working 2, or if they are limiting themselves to 2 miles, and can be taught to work 4 profitably, we would better "sit up and take notice." Doolittle's assertion that, to the best of his observation and belief, his bees worked profitably on basswood 6 miles away, ought to count

for a good deal. One way to teach bees to widen their circle of flight, is to crowd them to it by overstocking the 2-mile circle. I, too, *think* my bees have worked profitably on basswood 4 or 5 miles away. And let us look once more at the Doolittle evidences. With 50 colonies of Italians (the first in the region) 3 miles away, and 300 colonies of blacks much nearer by, the actual count showed every 5th bee to be Italian, as they were working at the apple-bloom. Pretty nearly a knock-down. And at 4 miles, on red clover, the actual count was 10 Italians to 4 blacks—more or less disinclination of black bees to work on red clover here coming in. That there was a vast acreage of red clover nearer to these Italians is here the singular circumstance. Looks as if they didn't care for the difference between 2 miles and 4. (Spend the time during flight evaporating the nectar and so obviate any waste whatever?)

And he wants his ideal location to slope to the southeast. Presuming the prevailing summer wind is southwest there, the same as in most places, I *think* a southwest incline would serve him best—flowers yielding honey much more copiously where the wind is up the slope. This, however, may be only

# American Bee Journal

a notion of mine. Probably he was figuring mainly on warmer mornings and less torrid afternoons. Page 1048.

## THAT SECTION-CLEANING DISCUSSION.

I, too, was amused at the section-cleaning confab. Some of us are expected to clean 960 sections in a day, and some expected to clean 96—with 2016 as mountain-top beacon to encourage us. The range from 92 to 2016 certainly looks as though it ought to be shortened up somehow. By the way, my toes are getting pinched, too. I indulged in a fling at the T-super because it lets the sections get propolized on the bottom, with the inference that cleaning must take longer. Yet, as my favorite brood-frame does not lend itself readily to wholesale scraping 'pears like I haven't even a glimmer of a chance to draw up to the T-super workers—not even near enough to be counted as an "also ran."

The question, What is a clean section? has hardly been finally disposed of—can not be by one person's preference. I take off the propolis, but don't

try to take off the stain which lies under it. I largely *keep* it off, but don't try to take it off. As Miss Wilson uses sandpaper, she evidently doesn't think a section done till the outside flat surfaces are free from stain. I'll guess she doesn't sandpaper the edges—where my propolis lies. Some sections—even some tolerably heavy ones—have half an inside side exposed—pretty apt to be stained and also punctured with small dabs. Looks bad. Wonder if any of the brethren tackle the job of making these spots lily-white—and how, in the process, they keep from breaking the honey that lies so near. Page 1049.

## BEES BUILDING ROUND CELLS.

Before somebody slaps me about bees never trying to build a round cell, I would better follow the luminous example of Davy Crockett's coon and "come down"—far enough to confess that the mouth of a queen-cell, when it is in its contracted state, is round—and that fact damages my whole remark badly. Page 1051.

drels of them—for in every colony with laying workers it isn't a single worker, but a whole lot of them, at the miserable business—but I never could tell which the laying workers were, except one single laying worker that I caught in the act of laying.

## Selling Bees to Farmers—T-Super Questions

1. What effect does selling bees to farmers have on the price of honey, considering that the farmers and local stores buy most of the comb honey produced? With such a practise would bees get so numerous that there would be demand for honey in the neighborhood, or do you think the farmers so neglect their bees, usually, that there would still be a demand for some honey? As you are a comb-honey producer, probably you can give some advice about selling bees to the farmers of the neighborhood.

2. How do you fix the ends of the T-supers to make them as long as the hives, both top and bottom? Do you put 2 cleats or strips on the end, top and bottom? If so, how wide, or how do you fix it?

3. Are the thin strips of wood better than an extra set of tins at top of the sections? I was under the impression that the tins were better.

4. I think you spoke of driving the bent staples in level with the wood. If I understand it rightly, the T-tins are supported just the thickness of the staples above the bottom of the super. Am I right?

5. Do you use a follower in T-supers, or only the plain sawed separators for the springs to press against?

6. I have some 10-frame dovetailed hive-bodies that are  $\frac{1}{4}$  inch wider than the standard, or  $14\frac{1}{2}$  inches inside. Would you advise cutting them down the  $\frac{1}{4}$  inch to prevent thick combs at the sides of the hives, or do you think the space left will allow the use of a thin dummy? I had thought some of using 9 frames and a dummy part of the time if I cut them down, or would you use one at each side? I suppose the T-supers should be made  $14\frac{1}{2}$  inches inside. Then they would not quite fit these bodies. I have not used any of them yet. PENNSYLVANIA.

ANSWERS.—1. If you have enough bees to occupy the field, it is no benefit to you to have bees within your territory owned by others; and if you have not enough to occupy the field, and care to keep more, it will probably be more to your advantage to own the additional bees yourself than to have them owned by others. Besides, there is the objection that slipshod bee-keepers will throw upon the market honey in poor shape at a low price, thus injuring your market. At the same time, slipshod bee-keeping is likely to run itself out. A bee-keeper should not object to others keeping bees near him so long as he has no thought of fully occupying the field, and if he has the field occupied intelligent farmers should have some respect for his claim to the territory.

2. A single strip tacked on at the bottom of the super is enough. No particular matter about the width; I generally use one an inch wide or so.

3. The wood strips leave propolis only at the corners of the sections, while T-tins on top would invite lines of propolis at some distance from the corners. The wood is probably easier to put in place, and it holds the sections square, while a T-tin on top would allow a little variation. Yet these differences do not amount to so very much.

4. The idea is to get the bottoms of the sections as nearly as possible on a level with the bottom of the super, but in actual practise that will vary, for in bending over and driving down the staple it will be sometimes embedded into the wood.

5. A follower. The 1-16 separator would hardly be stiff enough. Possibly it might be an improvement instead of a single follower on one side to have a thinner follower on each side, but I'm not sure there would be room for it.

6. If you want to reduce the width of the

Dr. Miller does not answer Questions by mail.

## Uncapped Sections in Center of Super—Age of Larvae for Queen-Rearing—Hive-Dummies—Laying Workers

1. What causes bees to leave a few sections of honey uncapped in the central part of a super all filled with honey, plenty of bees and warm weather?

2. As a general rule, will bees, after removing their queen, select a larva of the right age to rear another?

3. Is there any way of placing dummies in a hive in place of combs, and have just as good work done in the sections?

4. In appearance are laying workers different from workers? NEW YORK.

ANSWERS.—1. I don't know, and can only guess. There's a difference in nectar, some of it being ripened up more slowly than the majority. It is just possible that when the bees commenced work in the supers the central sections were filled with nectar of this kind, or with honey that possibly for some other reason they were slow about sealing, and then the rest of the super was filled with honey of a character to be promptly sealed. Another possibility is that the central sections were in some way objectionable, possibly from having foundation or comb that had been used before and left too long in the care of the bees when not being filled, and so covered to some extent with propolis. Still another possibility is that there was brood in the central sections; then after the brood hatched out they were filled with honey which, of course, would be later in being sealed.

2. I believe the general teaching is that when bees become queenless they are in such haste to rear a successor that they select lar-

vae of too great age to make good queens. I am very sure that this is a libel on the intelligence of the bees, and it is a marvel to me that honest and intelligent men will go on repeating this hoary error when a very little investigation will show that it is an error. I have proved it so hundreds of times. The only sort of ground for such belief that I know of, comes from the fact that bees are not always satisfied with the number of cells started at first, but will continue to start additional cells perhaps a week after being made queenless, when larvae sufficiently young are no longer present. If left to their own devices, no harm ever comes from this, for these late cells will be destroyed by the young queen reared from the earlier brood. But if you save all the queen-cells, giving them to nuclei so as to have queens reared from them, you will have some worthless queens.

It may be worth while to repeat briefly what I have told in the book, "Forty Years Among the Bees," about getting queen-cells started. To a colony of best stock I give a frame with one or two small starters of foundation, and in perhaps 10 days, when the frame is half filled or more with comb, eggs, and brood up to sealed brood, I give it to a queenless colony. I have reared hundreds of queens in this way, and never yet knew the bees to start cells except around the outer parts where there was only young brood.

3. If you put the dummies at either side, the bees will make slower work over them. If you put the dummies between the combs of brood, it will not make the same difference. During the harvest time I have had 2 or 3 dummies in the brood-chamber (but no 2 together), and I could not see that it made any trouble. But I never tried it a great deal.

4. Not a bit. I suppose I have seen hun-

hive  $\frac{1}{4}$  inch, wouldn't it be easier to tack a piece  $\frac{1}{4}$  inch thick on one of the inside walls than to cut down the hive? But I wouldn't bother about reducing that  $\frac{1}{4}$  inch. It will be only 1-40 of an inch for each frame, and you'll find that space taken up by bee-glue in a little while. If you want to use 9 frames, a thin dummy at each side would be all right. A super  $\frac{1}{4}$  inch narrower than the hive would work all right.

Don't worry about my being tired answering questions about the T-super.

### Storing Pollen in Sections

The bees stored a great deal of pollen in the sections last summer, which spoiled quite a few pounds of honey that would have been salable otherwise. What can I do to prevent them from storing pollen in the sections?

MICHIGAN.

ANSWER.—I know of three things that will encourage pollen and brood in sections. One is to have the brood-chamber too small and crowded. In that case the queen is likely to go up and occupy the sections, pollen following. A second is to have very little or no drone-comb in the brood-chamber and small starters in the sections. In that case the bees will build more or less drone-comb in the sections, the queen will go up for the sake of laying in drone-cells, and pollen will follow the brood. A third is to have shallow combs in the brood-chamber. In that case there is danger of pollen in sections even without any brood in them. Evidently, to avoid pollen in sections, we must avoid the three conditions mentioned. I rarely have any trouble in that way, and I use 8-frame hives with frames  $9\frac{1}{4}$  inches deep, and have the sections filled full with worker-foundation.

### Size of Hives—Transferring—Long-Tongued Italians—Italianizing

Last spring I made a 10-frame hive, and June 16 I bought a swarm of hybrid bees for \$1.00 from an apiarist in this neighborhood. The bees did nicely until Aug. 30, then they cast a big swarm. I hived them back on the old stand. I then extracted 3 gallons of honey to give them more room, and they went on with their work as if nothing had happened. When I put them into the cellar, Nov. 21, the whole weight was 70 pounds, so I think they have plenty of stores to carry them through the winter.

Late last fall I bought from the same apiarist 3 colonies in 8-frame hives at \$3.00 per colony. They were strong, and had plenty of stores, so there is no reason why they should not winter all right, and as I have a good cellar. As the hives of those I bought are poor, I will make new ones. I have been thinking of making 12-frame hives, and running them for extracted honey only.

1. Would you advise making them 12-frame? The apiarist here claims that the 12-frame is the best.

2. When would it be best to transfer the bees from the old hives into the new ones? Will it be all right to do it in the spring when I take them out of the cellar, or should I wait till later, when the weather is getting warmer?

3. Will the so-called long-tongued Italian bees gather honey from red clover?

4. As I would like to get some Italian bees, how would you advise me to do it? Should I send for queens and introduce them? If so, when would be the best time to do this? Or, should I buy some nuclei and rear them that way?

WISCONSIN.

ANSWERS.—1. Yes, if run for extracted honey only, 12 Langstroth frames will be none too large. The Dadants are among the most successful producers of extracted honey, and their hives are fully as large in capacity as 12 Langstroth frames.

2. It depends a little upon circumstances. If you transfer from a frame of one size to a frame of another size, so that there will be

little to do on the part of the bees in the way of building or mending, you can do the work early, on any day when it is warm enough for bees to be flying briskly all day. If there is much building or patching to do, better wait till fruit-bloom. Perhaps you may do still better to wait till the bees swarm, hiving the swarm in the kind of hive desired, and then transferring 3 weeks later, when all the worker-brood will have emerged.

3. I'm afraid not all of them. There are strains that will be better than others on red clover, and there are also times when red clover is in such condition, either by having its corollas unusually full or by having them shorter than usual, when even black bees will work on it. So you see it's a little hard to be very exact and definite about the matter.

4. Probably it will be as well for you to get one or more queens. It will cost less.

### Weather Mild and Rainy

The weather has been very mild and rainy here since the last days of December. I doubled my 133 colonies of bees up (or down) to 108 for winter, fed until all hives were rather hard to lift, and believe that all will come through to the next harvest in good condition.

EDWIN BEVINS.

Leon, Iowa, Jan. 7.

### Sweet Clover Honey Called Alfalfa

I saw an advertisement in a paper the other day of alfalfa honey. That honey came from Emery County, and it was sweet clover honey. There is a great difference in sweet clover honey in Utah, just the same as with fruit. The flavor depends upon the kind of soil the article grows on. It seems the best and clearest honey comes from clover that is grown on heavy and mineral clay or sand land, gravelly or black soil not being so good.

I have 81 colonies of bees, and last year was my first experience with them. I like the study better than any thing else I ever worked at, and I have worked for myself 24 years. I expect to increase my bees to 150 colonies next season. I have one of the best pastures in the State, with willows, sweet clover, alfalfa, and wild flowers in early spring; alfalfa and sweet clover from July 1. My bees have at least 300 acres of clover and alfalfa within 2 miles. If you want any more information about this country, I will be at your service.

C. N. SHINER.

Emery Co., Utah, Jan. 1.

### Very Poor Crop in 1906

We have had a poor season here in the northeastern part of Wisconsin. The crop turned out very poor for 1906. I started out with 65 colonies, but got only 1500 pounds of honey. Bees in the spring didn't seem to build up so fast as they ought to. It looked as if they had brood enough, but the old bees died off too fast till in June, and when we were looking for honey from clover, which is our main flow for surplus

honey, drouth set in, and it got so dry and the result was—no honey. September 12 I went to the Manitowoc County Fair, where some of the members of our Association had some exhibits. On Oct. 3, 1906, the Northeast Wisconsin Bee-Keepers' Association held its annual convention in Mishicot, Wis., and members there reported the crop very small. After coming home from the convention, we took all the supers off the hives which were mostly empty, so no fall honey to bother with. Then we got our bees ready for another winter. We passed the summer and fall living in hopes for 1907 to prove a better year for honey. Our winter so far is mild. Only two mornings it has shown two degrees below zero, but no snow, which may cause the clover to be winter-killed. We will wait for next summer to furnish proof.

C. H. VOIGT.

Tisch Mills, Wis., Jan. 17.

### Many Colonies Needed Feeding

The bee-business has been a failure in this county. A good many colonies of bees were starved out before fall. There will be a good many empty hives by spring, unless there was a good deal of feeding last fall. I had to feed most of my bees. A few of my best Italian bees had a little surplus honey.

ANDERSON YORK.

Bloomfield, Iowa, Jan. 4.

### What is Leading Factor in Cause of Swarming?

Is it zinc excluder or extra room that is the leading factor in the so-called methods of non-swarming?

If I rightly understand, the success in non-swarming is invariably conspicuous when the excluder is used in connection with excess or abundant empty combs or foundation.

It would be pleasant, if not profitable, to know which of the two is responsible—the zinc or the combs.

I would like to learn if any one has made a success of non-swarming in 10-frame Langstroth hives without zinc, or even with zinc. All the experiments that have come to me in *definite* form have been made with 8-frame hives, and colonies in such hives have been regarded as more likely to swarm than larger sized. I wonder if a great many things are not taken for granted.

T. F. BINGHAM.

Farwell, Mich., Jan. 3.

### Favors 2-Pound Sections

On page 48, R. E. Merrill writes on the subject of the size of sections, and it just suits me. I had thought of it a good deal before. I think it would be much better for the bee-keeper, and much cheaper, with a 2-pound section. I would be willing to try 1000 this year if I could get them. I know I could produce comb honey cheaper in a 2-pound section. It would take less comb foundation, and we could put it in a 2-pound section as quickly as in a one-pound. I sell a great deal of honey at home at 15 cents a section, or 2 for 25 cents, and they will take the 2 almost every time. I have always used the  $4\frac{1}{4} \times 4\frac{1}{4} \times 1\frac{1}{8}$  bee-way section. I have kept bees for over 20 years. I had

thought of the subject a good deal before, but did not mention it. Mr. Merrill's article tells my mind exactly. I think all bee-keepers should consider the matter as to the expense of producing comb honey in 2-pound sections instead of one-pound, as it would be a great boon to us. I do not know whether the manufacturers of sections would be against us or not, as it would take fewer sections and less foundation, and a good deal less work for the bee-keeper. I know I can make the change in my supers and other things the first year, and still be ahead some.

JOSEPH RICHARD.

Chautauqua Co., N. Y., Jan. 19.

[Any of the section manufacturers will make 2-pound sections if ordered ahead of the rush season—say any time before May 1.—EDITOR.]

Poorest Season in Over 30 Years

The honey season of 1906 was the poorest since I have been in the business, now upwards of 30 years. I got absolutely no surplus honey. In fact, I had to spend about \$150 for feed for my bees. But I have kept everything in good shape, and I will be ready for a crop when it comes. This is the first entire failure that I have had in my long experience. In 1903 I made \$2000 clear profit out of my bees. In 1904 I made \$1200. In 1905 I made \$800. In 1906, nothing. The average per year for the 4 years, \$1000. Not so bad after all, when you consider that those 4 years include the only entire honey-failure that I have had in more than 30 years; and also when you consider all the other irons I have in the fire, besides.

E. J. BAXTER.

Nauvoo, Ill.

Bees May Have European Foul Brood

I have not been keeping bees for a number of years, but I intend to have some again if I can make a deal for 150 colonies of Italians that are on the place where I live. They seem to have plenty of honey for winter, but are affected with what is called "black brood"—something similar to foul brood—so they tell me here. I have not opened any of the hives to see the condition they really are in. I moved into this valley only a short time ago, and, from appearances, it ought to be a fine locality for bees, since there is an abundance of sweet clover and alfalfa, with plenty of willow and fruit-bloom to give the bees an early start. But from what I can learn, the honey crops of last year and the year before were pretty short ones. I am told, however, that bees used to do very well here. The difficulty might result from the condition the bees are in, since they told me the young bees died in the comb, which, if a fact, would keep the colonies weak; so if there were ever so many blossoms in the field there would not be enough bees to gather the nectar, hence a short crop would result. I will know more about the matter and conditions later.

JACOB WIRTH.

Montrose Co., Colo., Jan. 16.

[It is unfortunate that Mr. Wirth has not been getting the American Bee Journal the past year or two, as we

have had so much in it about black or European foul brood, and other brood-diseases. However, we are sending him a copy of something containing the information he wants. We are always glad to help out any bee-keeper, whether he reads the American Bee Journal or not, but, of course, we have not room to repeat so much as is sometimes requested. When he was a bee-keeper in Illinois, Mr. Wirth read the American Bee Journal for years. We hope he may soon be a regular subscriber again.—EDITOR.]

Peculiar Odor of Aster Honey

The year 1906 was a rather poor one for bee-keepers in this section. I had 37 colonies, spring count, increased to

42, and got 100 pounds of comb honey and 900 extracted. The only sections of comb honey I got last year were the unfinished sections left over from the previous season (1905), which I used for "bait sections," and the rest of the sections in the super were not touched except to daub on propolis and gnaw the foundation. I would not have had any extracted honey if it had not been for a supply of extracting combs which I put away carefully each fall for the next year's use. We had a fall flow that filled the hives with honey for winter stores, and gave a few gallons of extracted honey. This fall flow was from wild asters, and is of good color and weight, but rather strong for table use. It also granulates very quickly. When the bees are gathering this aster honey, the hives give off a rank and somewhat sickening odor, which can be detected for quite a distance away.

American Bee Journal Novelty Pocket-Knife Gold Fountain Pen

All for \$3.00

(This cut is the full size of the Knife.)

NOVELTY POCKET-KNIFE

(Name and Address on one side—Three Bees on the other side.)

Your Name on the Knife.—When ordering, be sure to say just what name and address you wish put on the Knife.

The Novelty Knife is indeed a novelty. The novelty lies in the handle. It is made beautifully of indestructible celluloid, which is as transparent as glass. Underneath the celluloid, on one side of the handle is placed the name and residence of the owner, and on the other side pictures of a Queen, Drone, and Worker, as shown here.

The Material entering into this celebrated knife is of the very best quality; the blades are hand-forged out of the very finest English razor-steel, and we warrant every blade. It will last a life-time, with proper usage.

Why Own the Novelty Knife?—In case a good knife is lost, the chances are the owner will never recover it; but if the "Novelty" is lost, having name and address of owner, the finder will return it. If traveling, and you meet with a serious accident, and are so fortunate as to have one of the "Novelties," your POCKET-KNIFE will serve as an identifier; and, in case of death, your relatives will at once be notified of the accident.

How to Get this Valuable Knife.—We send it postpaid for \$1.25, or club the Novelty Knife and the American Bee Journal for one year—both for \$2.00. (Allow two weeks for Knife order to be filled.)

SOLID GOLD FOUNTAIN PEN

Finally we have found a good Fountain Pen that is reasonable in price. The manufacturers of this pen say that if you pay more than \$1.25 for other fountain pens, it's for the name.

This pen is absolutely guaranteed to work perfectly, and give satisfaction. The Gold Nibs are 14 kt., pointed with selected Iridium. The Holders are Para Rubber, handsomely finished. The simple feeder gives a uniform flow of ink. Each pen is packed in a neat box, with directions and Filler.

Worker

Queen

Drone

3/8 size

We mail this Gold Fountain Pen for only \$1.25, or for \$2.00 we will mail it and the weekly American Bee Journal for a whole year.

Sample copy of the American Bee Journal free; trial trip of three months (13 copies) for 20c; regular yearly price, \$1.00. Address all orders to

GEORGE W. YORK & CO., 334 Dearborn St., Chicago, Ill.

# American Bee Journal

When an apiary contains 40 or 50 strong colonies of bees, and the aster honey is coming in rapidly, the odor from the hives full of raw nectar can be detected a hundred yards from the apiary, if the atmosphere is in the proper condition. This odor disappears as the honey ripens and the flow ceases, and when the honey is extracted and exposed to the air a few days it nearly all disappears; but the strong taste never entirely disappears. It is as strong as the flavor of basswood or linden honey, and not nearly so pleasant. The only way that I can describe the flavor of this aster honey is that it has a somewhat sickening taste, especially when first extracted.

I see articles in the American Bee Journal, and in other bee-papers, on home-made hives, and as I make nearly all my own hives I sometimes feel tempted to "butt in" and give some of my experience in hive-making. I will write a short article on that subject soon.

D. E. ANDREWS.

Bloomington, Ind.

## Honey-Dew on Pine-Trees

We are having a real flow of water-white honey-dew on the pine here in Polk county. It has been on now 2 weeks. Bees in general are in bad condition here.

LUTHER PRESSWOOD.

Reliance, Tenn., Jan. 18.

## Rather Short Honey Crop

The honey crop was rather short last season compared with previous years, but I am living in hopes of a better season coming soon. Our white clover

seems to be wintering fine, so far, but why should it not? We have had no cold weather to speak of yet.

L. W. ELMORE.

Fairfield, Iowa, Jan. 3.

## CONVENTION NOTICES.

**Indiana.**—There will be a meeting of Indiana bee-keepers at the State House, room 12, Wednesday, Feb. 6, 1907. There will be a morning session at 10 o'clock and also an afternoon session. The united efforts of those interested are urgently requested and it is planned to reorganize our State Association. It is expected that some very important business will come up at this meeting, the most important being an effort to secure a Foul Brood Law for this State. I hope you will arrange to be with us on that date, and at the morning session. In case you find it impossible to attend the meeting I wish to urge the importance of having you use your influence in securing the much-needed Foul Brood Law.

WALTER S. POWDER.

Indianapolis, Ind.

**Wisconsin.**—The annual meeting of the Wisconsin State Bee-Keepers' Association will be held in the Court House, at Madison, Wednesday and Thursday, Feb. 6 and 7, 1907. Reduced rates on all railroads, but if you cannot obtain them, ask your agent for full fare receipt.

Every person may become a member, for one year, by the payment of \$1.00, which will also make him a member of the National Bee-Keepers' Association, which alone costs \$1.00; and every member of the National, not a member of the State, should pay his dues to the State Secretary, and for the same money, become a member of both. Ladies may become members by the payment of 50 cents for National dues. Kindly make remittance for membership dues before the meeting, to the undersigned.

Augusta, Wis.

GUS DITTMER, Sec.

## A Word To Our Readers.

Those of our readers who expect to purchase a vehicle of any kind in the near future should pay particular attention to the advertising of the Ohio Carriage Manufacturing Company which appears in this issue.

The Ohio Carriage Manufacturing Company are old and well-known advertisers, and have built up an immense business on their full line of Split Hickory Vehicles. They manufacture every style of Vehicle, and can supply the needs of the most discriminating buyer. They also make a full line of Harness, and can furnish the best there is in that line.

This Company has earned a wide reputation for fair and liberal treatment of all its customers and has succeeded in making SPLIT HICKORY VEHICLES the best-known and best-liked Vehicles on the market.

Mr. H. C. Phelps, the President of the Ohio Carriage Manufacturing Company, is a splendid type of the American business man, and makes a point of keeping in close personal touch with each individual buyer of Split Hickory Vehicles. He is making a particularly attractive offer at the present time—one that cannot fail to interest the most particular purchaser. He is also offering to send FREE to anyone who asks for it his Big Catalogue of Split Hickory Vehicles—and we strongly recommend anyone who is thinking of buying a vehicle of any kind in the near future to write for this book. It contains a lot of information valuable to the prospective purchaser.

Some idea of the size and completeness of this catalogue can be gained by the fact that it brings right into the home of the buyer—where he may carefully select at his leisure—descriptions and illustrations of a line of Vehicles equal to the stock carried by ten ordinary retail buggy dealers. If you are interested in Vehicles of any kind, this Big Book will be of immense value to you.

A Postal Card addressed to H. C. Phelps, President Ohio Carriage Manufacturing Company, Station 322, Cincinnati, Ohio, will bring it to you, Free. You should not fail to write for it.

## Something New = The Ideal Hive-Tool

Bee-keepers have long needed a special Tool to work among the hives during the bee-season. The one shown here was invented by Wm. Muench, a Minnesota bee-keeper, some years ago, but it was not on the market before. We have lately bought this Tool, and all rights, from Mr. Muench's widow, and have had the first lot made. They are ready for delivery now.

(This picture is exactly one-half the size.)

**DESCRIPTION.**—The Ideal Hive-Tool is made of high-grade malleable iron, much like wrought iron, 1 1/4 inches long. The middle part is 1 1/16 inches wide and 7-32 thick. The smaller end is 1 3/4 inches long, 1/2 inch wide, and 7-32 thick, ending like a screw-driver. The larger end is wedge-shaped, having a sharp semi-circular edge, making it almost perfect for prying up covers, supers, etc., as it does not mar the wood.

### What Dr. Miller and Miss Wilson Say of It:

In the first edition (1903) of Dr. Miller's "Forty Years Among the Bees," page 58, he says: "Of all the hive-tools I have tried, I like best the Muench tool." On Jan. 7, 1907, he wrote us saying he thought "just as much of the tool as ever."

Miss Wilson, Dr. Miller's assistant, says this of the Ideal Hive-Tool: "It is an ideal tool. In fact, I don't see how it could be improved upon. I am sure we would feel utterly lost in the apiary without it. . . . You will have to try one yourself if you want to know its worth."

### The "Ideal Hive-Tool" Free as a Premium.

We will mail an Ideal Hive-Tool FREE as a premium to any present paid-in-advance subscriber to the American Bee Journal, for sending us ONE NEW subscription for a year at \$1.00; or we will send the American Bee Journal one year and the Ideal Hive-Tool—both for \$1.20. Price of the Ideal Hive-Tool alone, postpaid, 30 cents.

Address,

GEORGE W. YORK & CO., 334 Dearborn Street, CHICAGO, ILL.

"Songs of Beedom."—This is a beautiful 16-page-and-cover pamphlet, 6x9 inches in size, containing 10 bee-songs—words and music—all the songs so far written specially for bee-keepers, we believe. It is nice, as well as convenient, to have these songs all in one binding. Every bee-keepers' organization should have copies for use at conventions. They could be sold to members after using once, or held by the secretary for use at future meetings. Of course, every bee-keeper's family will want at least one copy. It is sent, postpaid, for only 25 cents, or 3 copies for 60 cents; or, we will mail one copy with the American Bee Journal one year—both for \$1.10. Send all orders to the office of the American Bee Journal.

**Our Wood Binder** (or Holder) is made to take all the copies of the American Bee Journal for a year. It is sent by mail for 20 cents. Full directions accompany. The Bee Journals can be inserted as soon as they are received, and thus preserved for future reference. Or we will send it with the American Bee Journal a year—both for \$1.10. Address office of the American Bee Journal.

# American Bee Journal

## A GREAT IMPROVEMENT

Will be found in

## The American Bee-Keeper for 1907

It is profusely illustrated and enlarged, and contains only articles of the most practical as well as scientific nature. A special corps of the best writers has been engaged. The editors are Harry E. Hill and Arthur C. Miller, than whom there are no more practical or experienced bee-keepers in this country. We have published the American Bee-Keeper continually and regularly since 1890.

Regular subscription price, 50 cents a year. One year to new subscribers, 35 cents; three years for \$1.00.

Send for sample copy and our new illustrated price-list of BEE-SUPPLIES OF ALL KINDS.

Guaranteed highest quality at lowest price. Address,

**THE W. T. FALCONER MFG. CO.**  
JAMESTOWN, N. Y.

[Established 25 years.]

## Honey and Beeswax

CHICAGO, Dec. 7.—There is the usual dullness in the honey-trade at this date owing to most of the retailers having stocked up sufficiently to carry them over the holidays; but the stocks in the hands of the trade generally are below the normal; hence prices are firm at 15@16c for No. 1 to fancy white comb, with off grades at 1@2c less; amber grade dull at 10@12c. Extracted white, firm at 8c for clover and basswood; ambers, 6½@7½c per pound. Beeswax, 30c. R. A. BURNETT & Co.

KANSAS CITY, Jan. 25.—The receipts of comb honey have been more liberal during the last week or two, and the demand light, market weaker. The market is practically bare of extracted, and there is quite a little inquiry. We quote: No. 1 white comb, 24 sec. cases, \$3.10; No. 2, \$2.75; amber, \$2.50. Extracted, white, 7½@8c; amber, 6½@7c. Beeswax, 27c. C. C. CLEMONS & Co.

PHILADELPHIA, Nov. 8.—While the supply of comb honey is equal to the demand, large quantities of comb honey having arrived in the market in the last few days, the price still remains high. The outlook, however, is that when the season advances and the bee-keepers ship more of their crop to the market, the prices will be a little weaker. We quote: Fancy white comb honey, 16@18c; No. 1, 14@15c; amber, 11@13c. Fancy white extracted, 7½@8c; light amber, 6½@7c.

We are producers of honey and do not handle on commission. W. M. A. SELSER.

NEW YORK, Jan. 15.—The stock of white comb honey is pretty well exhausted, and we do not expect any more arrivals of large lots from now on. Prices are firm, and we quote from 15@16c for fancy white; 13@14c for No. 1; 12c for light amber. There is quite a little dark and buckwheat on the market, but no overstock, and we think that all of it will be disposed of before long at present prices, which we quote from 10@12c, according to quality. Extracted honey very firm, with sufficient supply to meet demand. California white sage is bringing from 8@9½c; light amber, 7½c; amber, 6½@7c; buckwheat extracted in fairly good demand at 6@6½c. Southern in barrels finds ready sale at from 55@70c per gallon, according to quality. Beeswax firm and steady at 31c. HILDRETH & SROELEN.

# Headquarters for Bee-Supplies

# C. H. W. WEBER CINCINNATI OHIO

Office and Salesrooms, 2146-48 Central Ave. Warehouses, Freeman and Central Aves.

DENVER, Jan. 5.—There is practically no honey left in the hands of producers in this State, and barely enough in the Denver market to supply the home trade until spring. We quote strictly No. 1 white, per case of 24 sections, at \$3.20; No. 1 light amber, \$3; and good No. 2, at \$2.80. White extracted, 8@8½c; light amber, 7½@8c. Beeswax, 26c for clean yellow, delivered here.

THE COLO. HONEY-PRODUCERS' ASSN.

CINCINNATI, Jan. 9.—The comb honey market at the present is very quiet. Holders are not trying to realize a profit, simply disposing of what they have, at cost. Fancy comb honey is selling at 14½@16c. Extracted amber honey in barrels, 6@7c; fancy light amber in cans, 7@8c; fancy white, 9c. Strictly choice beeswax, 30c, delivered here. THE FRED W. MUTH CO.

INDIANAPOLIS, Jan. 3.—comb honey is not plentiful, but demand is slack. Fancy white comb brings 16@17c; No. 1 white, 14c; amber, 12@13c. Best grades of extracted honey bring 8@9c; amber, 6@7c. Good average beeswax sells here at \$33 per 100 pounds.

WALTER S. POWDER.

TOLEDO, Nov. 30.—The market on comb honey remains about the same as last quotations, but has been coming in much more freely, as bee-keepers seem to be very anxious to get rid of their stock. Fancy brings in a retail way 16c; extra fancy, 17c; No. 1, 15c; buckwheat, 15c. Extracted white clover in barrels brings 7@7½c; cans the same. Beeswax, 26@28c. THE GRIGGS BROS. & NICHOLS CO.

CINCINNATI, Jan. 25.—The market on comb honey is rather easy. Prices rule in jobbing ways from 14@14½c; single cases 16c for No. 1 white; off grades not wanted at any price. Extracted is very firm. Light amber in barrels, 6@6½c; white clover in barrels, 7½c; in cans, 8½c. Beeswax, 30c, delivered. C. H. W. WEBER.

## Trade Notes. The A. I. Root Co., Medina, Ohio.

### Photographic Competition

We are pleased to announce another series of prizes for the best photographs submitted to us, as described below, in two series, American and Foreign, under the following conditions:

**FIRST.**—The competition opens January 15th, and closes October 1st, 1907. All photographs intended for this competition must be in our hands by the last-named date.

**SECOND.**—Competition for these prizes is limited to bee-keepers or some member of the family. Entries may be made for as many different classes as may be desired.

**THIRD.**—A photograph entered in one class can not be entered in any other class.

**FOURTH.**—Each photograph should be marked on the back with the name and full address of the sender, and the class in which it is entered. This is important.

**FIFTH.**—In judging the photographs, the general appearance, neatness, etc., of the apiary, or exhibit, or yard, will be taken into consideration. Photos may be sent unmounted. We rather prefer them this way, and in a solo or reddish-brown if possible. However, send such as you can get most easily.

**SIXTH.**—With each of the photographs submitted we would like a brief statement of the conditions under which the apiary was photographed or honey produced, or similar information regarding the photograph. This should be limited to about one hundred words.

**SEVENTH.**—All photographs and correspondence regarding the same should be addressed to Advertising Department, GLEANINGS IN BEE CULTURE, Medina, Ohio.

**EIGHTH.**—We reserve the right to limit the number of awards or withhold any award if no photo worthy is entered in the class.

#### AMERICAN COMPETITION

(Including Canada and Mexico)

AND

#### FOREIGN COMPETITION

The following are the classes in which entries may be made:

**CLASS A.**—Photographs of any apiary in village, town, or city.

**CLASS B.**—View of an apiary not exceeding six hives in town or city.

**CLASS C.**—Apiary in town or country of not less than six hives or more than fifty hives.

**CLASS D.**—Apiary in town or country of fifty hives or more.

**CLASS E.**—Photograph of comb honey produced by a single colony of bees; not less than ten sections, and this preferably in plain sections.

**CLASS F.**—Photograph of a bee-keeper's home, showing some view of the apiary if possible. The apiary need not be prominent in the picture, however.

**CLASS G.**—Photographs of a crop of honey from any number of colonies, six or more.

**CLASS H.**—Photographs of any apiarian exhibit of bees, supplies, or honey taken at fairs or shows of any kind.

**CLASS I.**—Photographs of any work in the bee-yard, such as hiving swarms, extracting, or any other operations with the hive.

**CLASS J.**—Photographs of any other subject relating to bee-keeping not classified above.

<b>FIRST.</b> —One leather-bound "A B C of Bee Culture," 1907 English edition, or cloth-bound French or German.....	\$2.00
<b>SECOND.</b> —One-half leather "A B C of Bee Culture," 1907 English edition....	1.75
<b>THIRD.</b> —One "How to Keep Bees" and any two Swarthmore books.....	1.50
<b>FOURTH.</b> —One full cloth-bound "A B C of Bee Culture," 1907 English edition....	1.20
<b>FIFTH.</b> —One "How to Keep Bees," by Anna Botsford Comstock.....	1.10
<b>SIXTH.</b> —No. 1 bee-veil, all silk.....	.80
<b>SEVENTH.</b> —No. 2 bee-veil, silk face....	.50
<b>EIGHTH.</b> —One illustrated book, "Bee Culture in Foreign Countries".....	.50
<b>NINTH.</b> —One Bee Model, Queen.....	.50
<b>TENTH.</b> —One Bee Model, Drone.....	.50

Ten prizes are offered for each class: Ten for Class A, Class B, Class C, Class D, etc.—one hundred prizes for American contest, and one hundred prizes for the Foreign contest; two hundred in all if that number of entries are received, the prizes offered being identical for each class for the American competition and for the Foreign.

If the winner of any certain prize already has the prize offered, we will, on request from him, furnish a selection of other items from our catalogs, of equal value.

### Danzenbaker Prizes

It is to be regretted that so many bee-keepers are satisfied to produce year after year a very ordinary grade of honey as regards its appearance, when by a little more care, and having more suitable fixtures, and by taking the honey from the hive at just the right time, a much larger percentage of "fancy," or "extra fancy" honey could be produced, which would sell at a much higher price. The experience of honey-merchants generally is that there is no difficulty in disposing of large stocks of fancy or extra fancy, even when the market is dull. It is the inferior grades that suffer most at these times. We believe, too, that bee-keepers would be very much better satisfied with their season's work if their best efforts were made to produce a really fine product. To increase further the interest in extra fancy honey, the following prizes are offered for honey produced in Danzenbaker hives during the year 1907, under the following conditions:

**FIRST.**—As above stated, the honey must be produced in a Danzenbaker hive, either the present style or any Danzenbaker hive that has been put out within the last few years. These hives may be had of any dealer in bee-keepers' supplies in any part of the country.

**SECOND.**—For Classes 1 and 2 we require a shipment of approximately the amount stated, to be made by the bee-keeper direct to us at Medina. After the prizes have been awarded the honey entered for competition in Class 1 or 2 will be held subject to the instructions of the producer. We will sell it at 5 percent commission, or we will ship it to

any point direct by freight or express. There being good honey markets in our immediate vicinity, such as Columbus, Cincinnati, Cleveland, Buffalo, and Pittsburg, it can be disposed of without difficulty at good market prices, and the shipper will not have to lose a good market by shipping it here. Neither the honey awarded a prize nor that which obtained no prize is to be our property, but will be sold subject to the instructions of the producer who sends it to us. We are interested only in inspecting it to award the prizes.

**THIRD.**—For all honey submitted for prizes we must have a definite statement from the producer regarding the conditions under which it was produced, whether a light or heavy flow of honey, how the colony was handled, how many colonies in the yard, from what source produced, etc.

**FOURTH.**—For Classes 3, 4, and 5, we must, in addition to the above report, have the signature of two witnesses, certifying to the correctness of the report. If the party who sends us the report for the competition is well known to us we shall not require these witnesses. References may be given instead of the signature of witnesses if desired. All parties intending to compete for these prizes should send for blanks which we will furnish, on which the report may be made out.

**FIFTH.**—It will be noticed in the last three classes, three to five inclusive, that it is not at all necessary to send us the honey—all we require is a report.

**SIXTH.**—We reserve the right to limit the number of awards in each class, or to make no awards in a class if there are no satisfactory entries for the same.

**SEVENTH.**—No contestant will be awarded more than one prize in each class, but may make two entries if desired—one in Class 1 or 2, and another in Class 3, 4, or 5.

The classifications for the prizes are as follows:

**CLASS 1.**—For best shipment of 200 lbs. of comb honey in Danzenbaker sections.

**CLASS 2.**—For best case of comb honey in Danzenbaker sections.

**CLASS 3.**—For best report of yield from single colony in Danzenbaker hive.

**CLASS 4.**—For best report of yield from five colonies in Danzenbaker hives.

**CLASS 5.**—For best report of general results from use of Danzenbaker hive.

For each class there will be ten prizes as follows:

**FIRST.**—\$10.00.

**SECOND.**—\$7.00.

**THIRD.**—\$5.00.

**FOURTH.**—\$2.00.

**FIFTH TO TENTH.**—\$1.00 each.

This is the time to decide to enter this competition. No matter where you live, whether in the United States or elsewhere, you can certainly find one class in which you can make an entry; and as there are ten prizes in each class, we believe that no one will be greatly disappointed in the results unless it is ourselves, and we hope that we shall not be, but see a large number of entries. Even if you fail to get a prize, you will doubtless have increased the value of your own product by your efforts to produce some big results or an extra quality of honey.

(Entered at the Post-Office at Chicago as Second-Class Mail-Matter.)

Published Weekly at \$1.00 a Year, by George W. York & Co., 334 Dearborn Street.

Vol. XLVII—No. 7

### Value of Honey as Food

Mr. Harry Lathrop, one of Wisconsin's leading bee-keepers, sends in the following on the use of honey as food:

Happy the man who can eat all the honey he desires—and has the honey to eat!

I have met not a few, who say they can not eat honey, having had an overdose when they were young. I usually find, on further inquiry, that it was on the occasion of the cutting of a bee-tree that they gorged themselves on the sweet, were made sick, and ever after nature rebelled against that which had caused pain and trouble.

It is easy to see how one could overdo in this way, at a time when one has tramped through the forest until tired and hungry, then endured the excitement of felling the tree and having suddenly a lot of honey exposed in the most tempting manner, with combs broken and dripping, and having the delicious flavor of wild honey. The men and boys at such times are apt to forget that honey is a concentrated food, of high nutritive value, and should be eaten with lighter and more bulky foods, unless only a little is taken. If they would take the precaution to carry along a jug of sweet milk, and some nice light bread, they could enjoy a feast there beside the fallen bee-tree that would be fit for a king, and there would be no bad after effects, no disgusted stomach to protest in after years.

But if those who have been indiscreet will teach their stomachs that there is really no harm in a little honey eaten properly, I believe they would soon be able to use honey again with safety and satisfaction.

I find that honey is a good winter food here in Wisconsin. I use it daily, and am almost entirely free from colds and sore throat, of which there seems to be a plenty among the people around me.

If only all the people would leave off the use of tobacco, and other like things, and use the money, so wasted, in the purchase of honey, and nice butter and milk, how much better health they would have; and the bee-keepers would have a much better market for their honey.

HARRY LATHROP.

The foregoing is a good sample of the kind of reading matter that should appear in the

newspapers throughout the country, to help create a more general demand for honey. Mr. Lathrop speaks from experience concerning the value of honey. Such testimony is valuable. No doubt many other bee-keepers could duplicate what he says. Why not all who can, just write something like the above for the local newspaper? Almost any of the editors of such papers would be glad to publish it. It is a work that is helpful in two ways—it benefits the public to know the true value of honey as food, and it should help the producers of honey to secure an increased demand, which doubtless would result in better prices being realized for table honey, at least.

### Black Bees vs. Italians

On page 909 (1906), some comments were made upon a controversy between two British subjects—one in Australia and one in Scotland. Referring to this, the "party of the second part" writes as follows:

"IN ALL THINGS CHARITY."

Yes, Mr. York, your motto, text, a precept—whichever way we regard it—is an admirable one. But the pity of it is that we rarely call it up to memory except when counselling the "other fellow." It is perhaps a vice of the age that too many of us—

"Compound for sins are inclined to  
By damning those we have no mind to."

Now, I have no objection to anything you wrote on pages 909 and 910 (1906), and I will not even cavil at the word "savagely," but charitably presume it is merely a misprint for "severely." Hurriedly written, they are similar! Our Antipodean brother is evidently prepared to write me down an ignoramus, at which I am not greatly concerned; but you kindly stop short of this, for which thanks. Believing with the poet that "there is no darkness like ignorance," I will most readily eat humble pie if I am wrong, and even gratefully thank the benefactor who enlightens

me. Your article all over is very fair-minded, and you in particular grasp two essential facts, viz.: that there are blacks and blacks, just as there are Italians and Italians, and that even the blackest blacks are not so black as they are painted. To confirm you in the first belief, I can assure you that, not only in the British Isles, but over a large area of Continental Europe, they are the predominant race, and *the bees to pay*. To convince you on the second head, let me take you on a trip, in spirit, to far away Australia.

In the corresponding issue of the Australian Bee-Keeper there appeared a glowing account of the excellent returns obtained from about 40 colonies of blacks, and the writer had no word of his hives being wiped out wholesale or otherwise.

Again, in the current number of the same bee-paper, you can have further proof, at first hand, in favor of my side of the question. At the conference of the Victorian Apiarists, the president stated that "he did not agree with the statement that black bees have a weaker constitution than Italians." Mr. D. Morgan, a gentleman who should know, considered that "it was proved, that when an Italian colony gets these diseases it is *worse* with them than with blacks." Mr. Anderson, who read an informative paper, stated decidedly that, as the fruits of a good deal of experience, he could affirm that "he introduced foul brood when he introduced Italians and goldens." Mr. Beuhne, a leading apiarist, insisted on the fact that "too much was claimed for Italians that is not characteristic of the race." Finally, one gentleman even suggested that it might be advisable "to introduce blacks to improve the strain."

It is facts we want, strike as they may. If I am an ignoramus, I err in good company. Quoting from the same book as you did, I would say, "In the multitude of counsellors there is wisdom"—and truth.

That blacks are not an effete race even in Australia, is proved in the last Bulletin, and that, too, by a breeder of Italians who has 40 years' experience behind him. On page 143, Mr. N. Abram writes: "When the bees of an apiary prosper so as to be rather above the average under the prevailing conditions, then, no matter what kind of bees they are, blacks or Italians, there is no need to interfere."

Again, even Mr. Tipper himself goes far to confirm my contention, for on another page of the very same paper, where he falls foul of my condemnation of the unfair treatment accorded to blacks, he tells so woeful a tale of the deplorable condition in which he found his own apiaries, and the heavy losses (50 to 75 percent, I think), that one would conclude that his colonies were all headed by the despised and reviled black queens, unless that we are expressly informed that they were Italians, carefully bred from the best blood in the world, and the result of 25 years' careful selection. No wonder Mr. Morgan, at the

convention, was moved to ask, "Is it possible to import black bees to improve the strain?"

Now, most questions have two sides, and what I would object to is the fact—for it is a fact—that your American bee-keepers write as if blacks were a useless and effete race. The "charity" you desiderate should in the future make you more cosmopolitan. Chicago and a hundred miles around is not the world, and the same, of course, holds true of Banff. Is it not *you*, in light of the facts I have placed before you, that do not take sufficiently into consideration "locality?" I have consistently upheld the good points I have found in blacks, but I have at the same time shown charity to Carniolians and Italians, and am ready to champion their many good points. I am heartily with you in all that has recently appeared editorially in the American Bee Journal on "improvement of stock." If apiculturists would devote more time and thought to developing the good that is in all the 3 races, the apicultural world would be nearer the bee-paradise we sometimes hear about.

Banff, Scotland. D. M. MACDONALD.

That is a good defense of the black bee, Mr. Macdonald—a strong defense—and all the stronger because you are careful to keep truth on your side. Advocates of Italians would say it is one-sided, and it is entirely right that it should be so, because you are not trying to advocate Italians. So it is only fair to present some points that advocates of Italians would be likely to make.

Preliminary to that, a word as to the one point of controversy between us. It is not necessary to suppose that "savagely" was a misprint for "severely." The dictionary gives one definition of "savagely:" "[Colloq.] very severely; as, *savagely* criticised." It may be said that this is an American colloquialism; at any rate, it is a common use of the word here; and in this sense you will no doubt think it correctly used.

Admitting that Messrs. Morgan and others held the opinions quoted, is it not true that the majority of Australian bee-keepers hold the opinion that blacks succumb more readily than Italians, especially to foul brood?

Suppose Mr. Anderson introduced foul brood with Italians; what does that prove? Has any one ever claimed that Italians are immune to foul brood? Suppose Smith had the best bees in the world, and Brown the poorest; that foul brood attacked Smith's bees, and through them the disease was conveyed to Brown's bees; would that prove in the least the superiority of Brown's bees?

Suppose that Editor Tipper lost 50 to 75 percent of choice Italians; is there any proof that if they had been blacks the loss would not have been 100 percent?

It is true that "Chicago and a hundred miles around is not the world," but Chicago and 8000 miles around is all of the world, practically, for American bee-papers; and within that radius it is the right thing for them to say that the blacks are inferior. Perhaps you may not know that on this side opinion is not divided as it is on your side. In England blacks probably take the lead, and at the same time there are leading bee-keepers there who prefer Italians. It is not so in this country. Practically, no one prefers blacks. If, then, an American editor be asked by a beginner as to which is the better bee, he answers, "The Italian," without stopping to add, "but in Switzerland the black is better." What is Switzerland to the American begin-

ner? Likewise the editor of the very excellent bee-paper published in Switzerland would be likely to reply that blacks are the better bees, without adding that the reverse is the case in America.

So you see that so long as there are no "two sides" to the question on this side, American bee-papers are hardly to be blamed for giving only the one side. All this is said, as may be gathered from what was said on pages 909 and 910 (1906), with full recognition of the difference between such matters in this country and yours. If climatic differences have not too strong a bearing in the case, the possibility may even be admitted that the best blacks in England are better than the best Italians in America—at least, such a possibility may be admitted until trial is made. Are you sure you can furnish us the Simon-pure blacks without the least taint of Italian blood?

### Packages for Extracted Honey

Discussing this subject in the Canadian Bee Journal, and largely from the stand-point of personal experience, J. L. Byer says:

While the experience of extensive retailers seems to prove conclusively that for the town trade it pays to put up honey in glass, yet to the writer's mind it seems doubtful whether

this is true as regards the country and village trade. For example, in a village near us of 1200 population, last year, over 2000 pounds of honey was sold in packages of 10 and 5 pound pails. To my knowledge, not a single pound was sold in glass, and I can hardly think that so much honey would have been sold provided the honey had all been put up in 1-pound packages.

On the other hand, it might be argued that some who would pay 15 cents for a single pound would never think of investing 50 cents at one time for a 5-pound pail. In fact, Mr. Hand said he knew of one family who annually bought over 150 pound-bottles, who would never think of buying a 5-pound pail at one time.

Personally, I feel inclined to think if there were no pound packages in sight that more than likely the same family would buy 5-pound pails, and incidentally come to the conclusion that it was much the cheaper way of buying honey.

From the producer's standpoint there is not half so much work in selling in pails as there is in putting up in glass; and in the case of the pails being used, the consumers become educated to the use of honey in the granulated form, and it is surprising how many become partial to honey in that condition.

All things considered, while I would not discourage any way of increasing the sale of honey, yet in my trade, after taking into consideration the demand in my own locality, I feel a bit slow about investing in glass so long as I can sell in tin packages as readily as in the past.

The National Association had 2201 members on Jan. 30, 1907. Why not make it 2500 by April 1—that would be only 150 a month for this month and next? If more convenient, you can send your dues to the office of the American Bee Journal, and we will forward them to Treasurer France.

The Apiary of H. E. Gray, appearing in the picture on the first page, was thus described by Mr. Gray when sending us the photograph from which to make the engraving:

The photograph herewith shows a portion of apiary on Moreau Farm, in Saratoga Co., N. Y., consisting of about 125 colonies, principally Carniolan stock with a few Italian colonies. I run for comb honey mostly, using 1½-pound sections, and a double brood-chamber interchanging with the super, the former taking 8 frames and the latter 24 sections.

My spring count, in 1906, was 76 colonies, which produced not far from 1½ tons of surplus honey, comb and extracted, which I have no trouble to market at near-by towns. This locality produces a fine quality of basswood and clover, with some buckwheat, etc.

I winter my bees on the summer stands in pairs, by closing together, then putting a winter-case around and filling in with dry material, such as leaves, chaff, etc.

Last season was my first experience in bee-keeping, while engaged in the jewelry business. On April 1, I disposed of my business to take up bees with thoroughbred poultry as

a means of livelihood. I have a great deal yet to learn, and look to the American Bee Journal for a good share of it.

H. E. GRAY.

Mr. Freas in a Buckwheat Field.—When sending the picture shown on the first page, Mr. Freas wrote thus:

I send a picture of myself standing in a buckwheat patch on a hillside on the farm on which my great grandfather settled some time in 1700. My grandfather, my father, and myself, were born on this farm, and have lived here all the time. Father is living, aged 71 years.

The bat I am wearing does not go out of style in this locality.

No liquor nor tobacco has been used in our family for three generations.

HERBERT FREAS.

P. S.—I forgot to add "B. A." to my name. That means "Bachelor Apiculturist." I have been a bee-keeper for over 15 years, and have 24 colonies now. The quality of the honey last year was very poor, and not much of it.

H. F.

Mr. and Mrs. Gathright, of California, as they appear when starting for a camping trip, is shown on the first page. The following is what Mr. G. says about it:

I enclose a photograph of two bee-keepers and their outfit starting on a camping trip. The bee-keepers are my wife and myself. We have packed in the wagon our bed, one trunk hay and grain for the mules, fishing poles

guns, etc. The wagon is large enough so we close up the front and back, and sleep inside.

We started the afternoon of Nov. 7, and camped that night in the pretty little city of Santa Paula. This is a very nice place, having some of the finest residences and an air of prosperity and progressiveness. The people had recently voted out the saloons by a large majority, which of itself shows progress.

From Santa Paula to San Buenaventura we passed through the great Lima bean country of California. The acreage planted to Lima beans is said to be about 65,000 acres. Some of the bee-keepers move their bees to these bean-fields after they have gathered the crop of sage honey, and secure two crops a year, sometimes. The honey from Lima beans is almost water-white, and very fine. All through this section of country we see nice farm houses and large barns, and the people appear to be very prosperous. My wife, being a native of Ohio, was astonished at seeing such an abundance of flowers everywhere at this time of the year, this being her first winter in California. In many places we saw geraniums bordering the farms along the roadsides, and in other places neglected and growing wild in the greatest profusion.

At San Buenaventura the places of interest are: The old mission, with its old wooden bell, made hundreds of years ago; the flower gardens of the late Mrs. Theodosia B. Shepherd; the Bard Memorial Hospital, and the beautiful grounds around the court-house.

Leaving Ventura our route lay for 30 miles along the beach. This is a most beautiful drive. The Anacapa Islands can be plainly seen all the way. As we drive along we are impressed with the grandeur of the old ocean, as the breakers roar and send their foam right into the road on which we are traveling.

We pass through the Carpenteria Valley, one of great richness. Here we saw the largest grapevine in the world, and we saw the largest eucalyptus trees we had ever seen. One measured 15 feet in circumference 3 feet above the ground. These trees are natives of Australia, and are planted for shade and wind-breaks around orange orchards. They grow very tall, and do not send out long side-branches as do most other trees. They blossom in December and January, and the bees fill up the hives nicely when there is a sufficient number of trees, but the honey is dark and not salable, but it comes in a good time for bees to breed up on it.

We spent a week in Santa Barbara. Here we met our old bee-keeper friend, Delos Wood, who joined us for a few days' fishing off the wharf. We caught an abundance of small fish, which were very fine eating.

We visited the old Santa Barbara Mission, founded in 1786, and said to be the largest, most important, and best preserved, of all the 21 missions erected in California during the early days of the Spanish rule.

The Potter Hotel is a place of great interest to visitors on account of its extensive grounds, with its wealth of rare flowers from all parts of the world. A more beautiful place I have never seen, and doubt if it can be surpassed in the whole world. "Adios," Santa Barbara! We hope to see you again.

WM. C. GATHRIGHT.

**Notice to Illinois Bee-Keepers.**—We have received the following from the Secretary of the Illinois State Bee-Keepers' Association, which should be of interest to every bee-keeper in Illinois:

The annual membership fee in the Illinois State Bee-Keepers' Association is \$1.00, and by arrangement the National Association allows the members of other associations to come in a body through the secretaries at 50 cents per member. Having received letters from many who were already members of the National, we have resolved to accept such in the Illinois State Association (who already have membership in the National) at 50 cents. This will entitle them to a cloth-bound copy of the 6th Annual Report, which will soon be ready for the press. Those who come in be-

fore March 1, will be in time to get their names in the Report, in the longest list the State Association has ever had. And further, we have about 100 beautiful badges that will be given out to the members joining before they are all gone.

JAS. A. STONE, Sec.

Rt. 4, Springfield, Ill.

### Bee-Song Souvenir Postal Cards.

We have issued in colors, 3 bee-song postal cards for bee-keepers, each card having one of the following songs, about  $2\frac{1}{4} \times 3\frac{3}{4}$  in size, also with illustrated heading on each card: "Buckwheat Cakes and Honey," "The Bee-keeper's Lullaby," and the "The Humming of the Bees." The first two cards have small pictures of the authors of the words and

music. This makes 4 souvenir postal cards we have now issued for the use of bee-keepers, the first being the "Honey-Bear" card. Prices, by mail, are as follows: Sample cards, 3 cents each; 7 for 20 cents, or 10 for 25 cents.

**Putnam & Peake** is the name of a new firm which began to operate a bee-hive factory at River Falls, Wis., about Feb. 1. This is the same factory that Mr. W. H. Putnam conducted for a number of years. Mr. Carl H. Peake, the junior member of the firm, was an employee of the A. J. Root Co. for 9 years, and has the reputation of being a skilled workman. We bespeak a successful career for the new concern.

## Insect Respiration and Circulation

BY PROF. A. J. COOK.

A subscriber asks me to describe the breathing and circulation in insects.

By respiration is meant the taking in of oxygen, and the passing off of carbon dioxide. Oxygen is the most important food in this respect, so we must have a constant supply of it, and if it is withheld but for a very few minutes, death by suffocation is sure. Carbon dioxide is harmless in the blood if in normal proportions, but let it once become present in excess, and it comes to be a virulent poison. We see, then, how important respiration is with all animals.

### RESPIRATION OF PLANTS.

This function, indeed, is not limited to animals, but all plants must breathe in the oxygen and exhale the carbon dioxide. This is certainly true of all but the very lowest of the plants. The higher plants also take in carbon dioxide to use in their plant work and nutrition, and at the same time they give off oxygen, but they do this only in the daytime, when the sunlight aids them in their functional activities. But they breathe in the true sense, by day and by night. We see, then, that plants tend only to vitiate the air at night, though in the day they may make it more wholesome for us to breathe.

### TWO KINDS OF BREATHING.

It is well known, that some animals breathe water, or, better, air from the water, and such animals are called "water-breathers." Others breathe only air, or the oxygen from the air, and would surely die if placed in water. The water-breathers have gills, and the others lungs or tracheae. The first, by the gills or branchiae, can draw the oxygen from the water, while the latter by

their lungs can take the same from the air. Both will soon die if the respiration cease.

### RESPIRATION IN INSECTS.

Insects are all air-breathers when in the mature state. Some, like the dragon-flies, breathe water, by gills, while yet larvae. Bees always breathe air. Insects never have true lungs, but have tracheae instead. These penetrate to every part of the body. The red coloring-matter of the blood is to carry the oxygen from the lungs to the body. We see, then, why insects have white or yellowish-white blood; they have the air in their tubular lungs all over the body, so they do not need to carry it.

### RESPIRATORY SYSTEM IN INSECTS.

In our bees, as in almost all insects, two main air-tubes run along the sides of the body, and these branch and re-branch, and so push into every part of the bee, or other insect. These get the air through breathing-mouths, called "spiracles." These are situated along the sides of the body, and are very conspicuous in the great caterpillar, that works on the tomato, known as the "tomato-worm." Thus the insect takes its air, not through the mouth, but through these spiracles along on the sides of the body. These are guarded by a double valve which is under the control of the insect. The hairs, like the hairs in our own noses, are always keeping dust out, while the other valves act only when the need of protection is extreme—just as we use our thumb and finger, when the dust or noxious gas is too pronounced, or disturbing.

### BLOOD AND CIRCULATION IN INSECTS.

The blood in insects, as in us, is the great nourishing liquid. As I have already said, it is without the red coloring-matter, and so has not the red corpuscles, which hold the hemoglobin, or red coloring-matter. Except in this lack

# American Bee Journal

of the red corpuscles, the blood of bees is essentially like our own.

## THE HEART OF INSECTS.

The heart of all insects, and so of the bee, is a straight tube, which is dorsal; that is, it extends along the back. This heart is all the circulating apparatus that the bee has. It has neither arteries nor veins. The heart has valves along the sides, which open as the heart is relaxed, and close as it contracts. The heart only moves the blood one way—towards the head. It then pushes back, through the intervascular spaces, and again crowds into the heart, to be emptied again near the head. We see, then, that the heart serves only to keep the blood in motion, forcing it ever towards the head. The circulating apparatus is very simple, while the breathing system is very well developed. We should expect this, as the muscular development and function is very high in insects, and good breathing and great activity go together.

## WINTERING BEES IN CALIFORNIA.

The bee-keeper in California has great advantage over his brother in the North and East. There the winter comes with such rigor, that often the bees are swept as with the very besom of destruction. How often the entire apiary has been swept off by the Storm King, from the unwary bee-keeper, who was not careful to protect his bees from its fury. Here in our "Sunny South" land we have no such menace, and do not dread the winter's cold in the least. Here there is never a winter that the bees do not fly at some time each month of the winter. Often the bees fly, gather, and breed up quite strong in the very heart of the winter. As we all know, there can be no danger of death from cold, and unusually poor food would not be harmful in such cases as this.

Yet there is one menace even in California. I refer to starvation. This should never occur, and will never occur, if the bee-keeper is aware of the danger, and gives heed to his business. There is a reason why this occurs far too often. The California bee-keeper, from his distance from the large markets, is very likely to work for extracted honey. This is less likely to be injured in the long transit to market, and is sent often at less expense. If the season is good, the honey comes in rapidly, and the over-ambitious bee-keeper is very likely to extract too closely, and so the bees are robbed of the needed stores for winter. It behooves every bee-keeper to look well to his bees, and be sure that all have enough honey to carry them through the winter. It is a sad truth that many colonies of bees die here almost every winter from this inexcusable neglect.

## ABUNDANT RAINS.

The crying need in California—especially Southern California—is generous rains. We must have them to insure a full honey crop. We have been very fortunate in this respect this winter. We have not only had more than is usual, but we have them in a way to do the most good. The prospects now for next

season are very excellent. With good rains we are almost sure to have a good honey-year. Last year, however, even with rains, we had a dearth of honey. The cold, damp season was the cause. Such seasons are very exceptional.

Claremont, Cal., Dec. 29, 1906.

## Do Bees Freeze to Death?

BY G. M. DOOLITTLE.

A correspondent writes that one of his neighbors tells him that bees often freeze to death in extremely cold spells during winter, and wishes me to tell in the American Bee Journal whether his neighbor is right or not.

Many seem to think that bees often freeze to death in winter, and when colonies are found dead in the spring, after an unusually cold winter, they are quite sure that no other cause besides freezing will account for their being dead, as they have often seen bees on the outside of the cluster somewhat stiffened with the cold when the mercury registered little more than the freezing point. And some are so unreasonable that they will not listen to anything which goes to prove that they may be mistaken. But to the careful student of intricate problems, facts often appear which show that each, in a measure, may be right and wrong, where two take exactly opposite sides in these matters.

That bees will freeze to death, when isolated from the main cluster, no one can deny, for no observing bee-keeper has failed to see single bees, and little clusters of 2, 3, 5, 10, 20, or even 50 to 100 in a place, away from the main cluster, frozen till life had become extinct, long, long ago.

There has been considerable talk of late about freezing bees and queens during the summer, by putting them in a refrigerator or an ice-house, so that in this frozen condition they would not consume anything, nor grow old by wearing themselves out through useless activity, thus prolonging their life indefinitely, and allowing the keeping of extra queens on hand, while the nuclei were worked for more queens, the frozen ones being thawed out at any time when they were wished for use, or successfully introduced while they were partially inactive through not being fully recovered from their stupor, which was brought on from freezing. But I can only look upon that word *freezing*, as used here, during such talk, as a fallacy, for, if I am right, no bee, after being once frozen, ever comes to life again. What was being talked about was bees brought into a dormant condition through a certain degree of cold, which degree was kept up till they were brought out from under that condition into a condition of activity again through a lesser degree of cold. But that degree of cold must always be less than the freezing point, for, with all my efforts to bring a frozen bee back to life again, I have signally failed.

I have picked up thousands of bees which had dropped down and become chilled on the snow, with the mercury standing at from 32 to 40 degrees, and brought them to life again, but with

repeated trials on similar numbers of bees after the mercury had sunken as low as 30 degrees, or lower, not a single one could be gotten to move so much as a single foot or wing. And I have taken these little clusters of bees out on the combs, away from the main cluster, and brought them to life again the same as were those which had not been frozen on the snow, where frost had never reached them, but after they had been once frozen it was always useless to try to bring them back to life again. So much for little clusters and single bees that have become isolated from the main cluster during cold or very cool weather, which all go to prove that my correspondent's neighbor was right, that bees do freeze to death.

But there is another side to this matter, and this other side shows that his neighbor was wrong, if he intended to convey the idea that a good colony of bees with plenty of stores within easy reach could be frozen to death. While it is possible to freeze nearly all animal life by exposure to a very low temperature, the bees seem capable, with plenty of stores near at hand, to stand any amount of cold, so long as food remains within easy reach. To be sure, the bees on the outside of the cluster may become somewhat stiffened with the cold, but those within are as brisk and as lively as in summer. That pioneer bee-keeper, Moses Quinby, than whom there is no better authority, knew this to be a fact when he said that "the bees inside of the cluster, on a zero morning could fly as readily as in July, should the cluster be suddenly thrown apart."

Again, that veteran apiarist, Elisha Gallup, who died only a short time ago, in writing of a winter in upper Canada, where he kept bees a half century ago, said, "The thermometer for 60 days in succession was not above 10 degrees below zero, and for 8 of these days the mercury was frozen, yet my bees, in box-hives, with a 2-inch pole at the top, and the bottom plastered up tight, came through in excellent condition." (See American Bee Journal, Vol. V., page 33.)

Now if colonies of bees will not freeze to death under such conditions as these, pray tell me when they would do so. While bees here in central New York were never put to so severe a test as the above, yet the mercury often drops from 20 to 30 degrees below zero; still it does not seem to affect good colonies of bees in the least. From experiments conducted with a self-registering thermometer, I find that when it is 20 degrees below zero in the outside air, a temperature of 46 above zero is maintained within the hive and close to the outside of the cluster of bees, while the center of the cluster gave a warmth of 63 degrees above zero at the same time, thus showing that the bees were far from freezing.

To test more thoroughly this matter of freezing colonies of bees, I took a colony one evening when the mercury stood from 10 to 15 below zero, and suspended the hive about 2 feet from the bottom-board, taking off all covering from the top of the hive, so they were practically the same as hung in

the open air, for the colony was not large enough so the bees touched the side of the hive in any place. They were left thus all night, during which the mercury went as low as 16 degrees below zero, yet the next morning the bees were all right, even if I did expect to find them dead. And what was more, they survived all of my experiments with them, coming through all right in the spring, and doing good work the next summer.

After all of the above, I came to the conclusion that all talk about freezing a good colony of bees when in a normal condition is a myth, and an impossibility.

Borodino, N. Y.

## Bee-Culture vs. Horticulture

*A paper read before a joint meeting of the Kansas State Bee-Keepers' Association and the State Horticultural Association*

BY C. P. DADANT.

These two branches of agricultural economy are allied to each other, and may be carried on by the same producer, thus forming a profitable combination.

There are, however, some persons who think that these two industries are antagonistic. A demonstration of the incorrectness of these views will make the subject of this address.

There are two points upon which wrongly-informed horticulturists think that bee-culture is objectionable. The first is the bees' influence upon the blossoms; the other, their depredations upon fruits.

The bees are said to work injury upon the blossoms of fruit-trees and shrubs or plants, by removing the honey and the pollen. A very elementary study of the structure of blossoms will enlighten us upon these points.

### BEEs HELP FRUIT-BLOOM FERTILIZATION.

In most of our fruits, the sexual parts of the bloom are both to be found within the corolla, the male part being the stamens or pollen-producing organs, the female part being the pistil or fruit-bearing stem. It is only by the scattering of the pollen in minute quantity, upon the pistil, that the blossom becomes fertile. Pollen is a dust of different shades, according to the blossoms from which it is produced, which has the power of making the fruit productive, or to cause it to "set," as is popularly said. This pollen, under the powerful microscope of scientists, proves to be composed of very minute round balls, having much the shape and appearance of osage oranges. These little pellets are gathered by the bees to be used in the larval food of the immature bee. So it is not consumed by the adult insect in any perceptible quantity. It is carried to the hive upon the third pair of legs in a cavity which nature seems to have provided for this sole purpose. Bees may be noticed laden with it, at any time during the spring or summer when returning to the hives, and many uninformed persons have taken it to be wax-pellets. But beeswax is produced in the hive, from honey, by digestion.

In gathering these pollen-grains, the

bees shake them from the stamens which have produced them and cause a number of them to fall upon the pistil. So eager are they in the gathering of this pollen-dust that they are often covered with it, from head to foot, as if they had rolled in it. They comonly use the first and second pair of legs to brush it off their bodies and pack it into the pollen-baskets on the tibia of the third pair of legs. Not only does the action of the bees scatter this fecundating dust upon the female part of the flower itself, but it also distributes it from one blossom to another, from one tree or plant to another. In this way, in-and-in breeding is avoided. Although in-and-in breeding is very good to intensify certain qualities of plants, it is well known that this, when carried to excess, finally results in sterility, both in plant and animal life.

The action of bees and other insects in bringing about a cross-fertilization is well evidenced in the sporting of peaches, which cannot usually be reproduced exactly from the planting of the stone. A still better evidence of the sporting caused by insects is found in melons, cucumbers and pumpkins, which when planted in sufficient proximity to each other will produce offspring which is not cucumber, melon or pumpkin, but a mixture of them.

It has been ascertained that in numerous fruit-blossoms this pollen transportation and scattering on the part of the insects, and of the bees in particular, is indispensable to the proper fertilization of the bloom. Observing horticulturists have noticed that their orchards are never so full of fruit as when they have had two or three days of warm weather for the blossoms to be visited by honey-gathering insects. In the case of some blossoms, such as the strawberry—of which some varieties are imperfect and carry only pistils and no stamens—it is indispensable that some insect be able to carry the pollen from the perfect blossoms to the imperfect ones. Strawberry growers well know that some varieties must be accompanied by other varieties in order to become productive, but even if they were planted together, there would be but very remote chances of cross-fertilization if it were not for the agency of the winged insect.

So much for the removal of pollen by the bee. But what of their absorption of the honey? Some say that the honey exuded by the blossoms is re-absorbed by these same blossoms, in the support of the young fruit, and that the removal of this honey works injury to the fruit. Whether the honey is absorbed or not, we have a very good evidence that its removal works no injury. The largest crops of honey in our section of country are gathered from white clover and Spanish-needles. In Colorado, and in the West generally, millions of pounds are gathered from the alfalfa. I have yet to learn of a single instance where those plants have failed to produce a bountiful crop of seed after having given a crop of honey. On the contrary, it is proven that they produce more seeds after the bees have had access to them. Mr. Samuel J. Hunter, a State Entomologist, has made

experiments and ascertained that the seed-production is increased three-fifths, at least, by the work of the honey-bee on alfalfa blossoms.

Whether we believe in a fixed purpose of progress in Nature, or in the invariable outcome from the survival of the fittest, or in both of these theories combined, we must acknowledge that existence of honey-gathering insects shows a beautiful adaptation to the conditions of plant-life.

### BEEs AND FRUIT.

Let us now look upon the other objection to the culture of bees, in connection with horticulture—their depredations upon fruits. I think that, if it can be shown that the bees prey only upon damaged fruits, and this only in exceptional circumstances, the verdict will be in their favor, for damaged fruit, when hanging upon the tree or the vines, is of but little value. If not harvested at once it will rot, and the bees gather only that which would be wasted.

But *do* the bees damage sound fruit? Or, better yet, *can* they damage sound fruit? An examination of their mandibles in comparison with those of many hornets and wasps reveals the fact that while the mandibles of the latter are like saws, those of the bee are rounding and deprived of teeth. Their jaws act sidewise, instead of up and down as in animals, and they are shaped like spoons. They can grasp and hold another bee or the stems of plants; they are made to manipulate soft substances like beeswax. They can cut a hole in a piece of cloth or in paper, but an examination of the manner in which they do it will show that they first take hold of some projecting thread and pull it out, then take another, and keep pulling till they have changed the apparently smooth piece of cloth into a rag. But when it comes to the smooth skin of a fruit, all they do is to remove the soft down or bloom of the fruit, if they travel upon it long enough; but they are no more able to bite into it than a human being could bite into a smooth plaster wall.

This may be demonstrated by actual test. The most expeditious method is to place a bunch of ripe grapes inside of a populous hive of bees, previously puncturing a few of the berries and taking note of the number. After 24 hours or more, investigation will show that the bees have sucked the juice out of the punctured grapes, but have left the others intact. They will go even as far as covering with propolis or bee-glue those grapes which they cannot use, as they cover any foreign substance of which they cannot get rid.

Some persons assert that they are sure the bees injure fruit because they have seen them at work upon it, and because large quantities of fruit, especially grapes, have been found entirely destroyed, where bees only were found upon them. This is simply a delusion similar to that of the uninformed human being who denies that the earth revolves around the sun, because he sees the sun rise and set, and because he cannot feel the earth move; and argues also that if the earth moved it would be impossible

# American Bee Journal

for him to live on it when it was bot-tomside up. The bees evidently work upon damaged fruit, and they feel so innocent about it that they do not even attempt to fly away when we catch them in the act. But let us get up with the dawn, before sunrise, and go to the vineyard or the peach orchard, and there we will catch the real culprits that feed upon the fruit—quails, robins, cat-birds, etc. They gather in a vineyard by the hundred, eat their fill, and when no longer hungry they find pleasure in wantonly plunging their beaks in the soft juice. In many instances you will find a bunch of grapes with hardly a sound berry, and they are all plucked on the same side, many of the berries showing two holes, one above the other, a short distance apart. It was done by the two points of the bird's beak.

But the sun rises above the horizon and the bees come to gather the frag-ments, and so does man, and he straight-way puts the blame on the industrious little toiler which works from sunrise till sunset for its board, and never fails to bring its harvest to the hive, to be later robbed by this complaining human miser.

Bees do not work on unsound fruit at all times. Is it because they are lazy at times? No, it is because they some-times find better food. Whenever you see the bees on damaged peaches or grapes, you may be sure that there is no honey to be found in the blossoms. There are seasons of honey scarcity, when they manage to gather quite a little partly-fermented fruit-juice. It is the best they can find, but is not good for them. It will sour in the hive and make bad winter food. The prudent apiarist removes all this unhealthy food from the hive before winter, and gives them good honey instead. There is never any great quantity of it harvested, because many bees are made drunk by its fermentation, and fail to reach the hive alive. So when bees are seen in numbers on damaged fruit, it may safely be asserted that the apiary is more injured than benefited thereby.

## UNTIMELY SPRAYING INJURES BEES.

Lét us look upon the damage which has been occasionally inflicted upon the bee by the horticulturist. It is done by injudicious spraying of fruit during the bloom. Dealers in spraying instruments have asserted that it is necessary to spray the fruit-trees during the bloom. The result has been, in some instances, wholesale poisoning of insects where this method was pursued, the poison in the spray mixing with the honey in the corolla and endangering, not only the life of the bee that sipped part of this liquid, but also the life of those who might eat of this poisoned nectar in the combs.

So the spraying of fruit during the bloom might easily be made a criminal matter. But there is no advantage in spraying fruit during the bloom. What we seek is to prevent the puncture of the fruit by the depredatory insects, such as the codling moth, the curculio, etc. These insects puncture the fruit when it is formed, and their destruc-tion must follow the formation of the fruit. The throwing of any poisonous

mixture upon the blossom can have but one effect—that of destroying the ef-ficiency of the pollen, if it is diluted in this poison.

The assertions I have made in this paper are based upon positive facts gathered in a large orchard and exten-sive vineyards, connected with an apiary of about 100 colonies of bees. I have often taken visitors into the vineyard and the apiary during the maturing of the fruit, and shown them, without any possibility of error, that bee-keeping and fruit-growing are not antagonistic, but are profitable and helpful to one an-other, when carried on together in a suitable location.

Hamilton, Ill.

[Since the foregoing was written and read, Mr. Dadant adds the following in reply to Mr. Hasty:—EDITOR.]

## BEES AND GRAPES.

I am sorry to feel that I must take issue with Mr. Hasty concerning bees vs. grapes. But it has been my misfor-tune to be mixed up with a great deal of trouble in this line, and I have made so thorough an investigation of the work of bees on grapes that I know—absolutely know—that what I advance is true. I have heard people make the same statement that is quoted by Mr. Hasty, about Mr. Pocklington, (page 33) and in every case I proved it to be only an opinion advanced, which the party did not dare back up.

I have starved bees on grapes. I have tried just what Mr. Hasty suggests,

getting the bees to "cluster on the bunch till they cover it all up, out of sight, like they were balling up a queen or try-ing to force a hole into a hive." I have had bees in this way just as long as they had the patience or persistence to stay, and I will tell you that they stayed a long time, for they knew the juice was there, just under the skin. But it was out of their reach. One berry punc-tured, out of a bunch treated in this way, had a depression in it where the juice had been sucked after 3 hours of exposure, but not a sound berry was damaged, except for the loss of its bloom.

Any of my readers can try this, and also try putting sound grapes into a full colony of bees and note the result. To make the test more secure, puncture one or two berries when putting them in. But be sure and do not handle the bunch carelessly, for you may loosen the berries slightly at the stem, and in that case the bees would soon take ad-vantage of it.

I am sure of what I say when I as-ert that bees *will starve* on sound grapes, for I have tried it, not in one instance only, but in a number of in-stances, and with the greatest care in making the tests. Too many people make assertions in this matter without any actual test, and only from a super-ficial investigation, or, as in the case of some grape-growers, because they are anxious to find the bees at fault.

Test this for yourselves, and do not depend upon any eyes but your own. It is not difficult to do.

C. P. DADANT.

**Southern Beedom**

Conducted by LOUIS H. SCHOLL, New Braunsfels, Tex.

## Number of Colonies to Produce \$500.

The following question has been asked me to be answered in "Southern Beedom":

"How many colonies will it take to produce an income of \$500 a year? And what price per colony will they cost?"

The product per colony in my own apiaries has ranged from 50 to 150 pounds for a number of years. A fair average for southwest Texas, and for an average number of years, would perhaps be 75 pounds. For a period of 9 years, of which I kept close account, the total average of my apiaries was 66 2-3 pounds.

As bulk comb honey is produced most extensively, with some extracted honey, a good average price per pound would be about 8 cents. A hundred colonies,

therefore, should, with reasonable care, bring an income of \$500 or more a year.

Full colonies in frame hives range all the way from \$3 to \$6 per colony, depending a great deal upon their con-dition and the race of bees. Box-hives, where such have not already seen their day, and can still be obtained, will cost from 75 cents to \$2 each. It is some-times good policy to buy such, if they can be obtained cheap enough, and trans-fer the bees into frame hives that have been obtained "in the flat," and nailed up by the bee-keeper himself. This is, I believe, the best and the cheapest way to begin bee-keeping, unless a whole apiary, or a large number of colonies in the hives wanted, are bought at once. A start may also be made by buying nuclei and then building them up to full col-onies. This is a cheap way of starting apiaries, but it is rather slow for an income the first season, unless a person has something else to depend upon for

a living. Prices of such nuclei can be obtained from shippers of bees advertised in the bee-papers.

Rains have been quite general over the South, from reports received so far. A good season in the ground means much for the bee-keeper. More rains are needed, however.

### May in Texas in January

It is warm—yes, *hot*—weather here the middle of January, the thermometer registering 75 to 80 degrees through the day, and only once or twice it went below 60 degrees at night for the past month. Agerites (wild currant), black chaparral, and various other early-blooming shrubs are now blossoming, and the bees are working and roaring at night as if it were May here in Texas. This we would very much rather not see, as the bees are rearing brood as if it really were spring. And this, too, more than a month earlier than I ever saw it before. This will cause a large consumption of stores that the bees will be sure to need later, as February is almost always our coldest month here.

#### INTERCHANGEABLE BEE-SUPPLIES.

A marked copy of Dr. G. Bohrer's good article on "Home Hive-Making and at Factories," on page 28, should be sent to every bee-supply manufacturer in the United States.

I have reference to the last two sentences of that article. Now I believe that our bee-supply manufacturers want to have their goods so that they will at least be interchangeable with supplies from other factories, but they are not always that way, by any means.

#### ALL THE BEGINNER NEEDS.

One trouble with the average novice, he thinks he has to buy almost all he sees advertised in the bee-supply catalogs when he starts with bees. So he counts and figures on this and that article until he runs the bill up to hundreds of dollars for making a start with only a few colonies of bees. Then he becomes disgusted and quits right off.

Now let me tell you what I would buy if I had only a few bees and wanted to make a start: Outside of the hives and frames actually *needed* for the bees the present year, I would get a smoker, a bee-veil, an extractor, and an uncapping knife—that's all. I would add a good text-book if I didn't already have one.

#### A CURE FOR BEE-PARALYSIS.

Mr. F. J. R. Davenport, of this State, gives this as a cure for bee-paralysis:

"Take equal parts of honey and granulated sugar. Melt a pint together for each colony that is affected. At sundown remove the top and pull the cloth off and pour this warm liquid over the brood-frames and contract the entrance. The next morning, if it is warm, they will come out and take a cleansing flight, and come back to their hives all right."

I copy the above from the Dallas News. We hardly know from the above which Mr. Davenport considers the cure for the disease, the mixture of sugar and honey, or the cleansing flight. If

the latter, I suppose either alone would answer, as a feed of any kind will cause bees to take a flight. If the mixing of the two sweets performs the cure, I am compelled to say that I hardly see the philosophy in it.

#### THANKS FOR AN ARTICLE.

Mr. Adrian Getaz has my thanks for kindly answering some of my questions asked on page 704, the past season, and, as usual, I think his answers are about as nearly correct as we will likely get. (See pages 1032-1033, 1906, for his replies.) I am glad I fired those questions at Mr. Getaz for we have at least another one of his many good articles that we might otherwise not have had. Rescue, Tex. L. B. SMITH.

Yes, indeed, the weather has been *hot*, and everything has seemed like spring for the last 2 months. Indications are that we will have colder weather soon, and I am fearing a late, cold spring.

Such are disastrous to the bee-keepers. When the stores are nearly consumed and the bees need the flowers to replenish them from, there may be none, and the weather may be such that the bees are kept in the hive. It is then that the bee-keeper must look at and watch the bees, and provide for them. Extra protection to the outside of the hives will also be essential at such times. However, we shall hope for the best.

I should be glad to have some good short articles on "Home Hive-Making," from those with experience. I am sure *locality* plays a big part in this matter. If I had white pine lumber, or anything like it, I'd make all my supplies with a foot-power buzz-saw, but our yellow pine lumber is hard to work, and then it warps, checks and twists very badly.

If I were a beginner, I would not forget to subscribe for a good bee-paper or two. These would be *almost as necessary as any of the other things*.

### Report of the Michigan State Convention

REPORTED BY R. F. HOLTERMANN

(Continued from page 42)

Mr. Geo. H. Kirkpatrick read the following paper on:

#### WHY BEE-KEEPERS SHOULD PEDDLE THEIR HONEY

First, they should do so in order to get the largest amount of cash possible for their product. If a product is sold direct to the consumer, there will be no heavy freight bills to pay, and no middle man to share in the profits at the expense of the producer.

A few cents on the dollar may make a difference between success and failure. An individual may operate a given number of colonies and secure a fair crop of honey. Should he sell his honey to the city merchant at a market price of 7 cents, he would receive for 10,000 pounds, \$700. Had this individual sold his 10,000 pounds direct to the consumer in the country where he lives, at 10 cents per pound, it would have brought him \$1,000.—\$300.00 more than he got for it in the city.

We will now see how many days one must labor to prepare and peddle 10,000 pounds of honey, and what he will receive per day for his labor. It will require 20 days to liquefy 10,000 pounds, put it into pails, and label it. I think it is fair to put the number of sales per day at twenty 10-pound pails at \$1.00 each, or 200 pounds per day. Thus it will require 50 days to peddle 10,000

pounds, or 70 days to prepare and peddle it.

Now, if he will divide the \$300.00 by 70 (the \$300.00 being the difference between retail and wholesale prices) we have \$4.28 per day for labor while peddling 10,000 pounds of honey. The 10-pound friction-top pails will not cost more than the 60-pound cans, for the storage of 10,000 pounds. If we sell at wholesale, the cans go with the honey. If we peddle, we can reserve the pails and gather then up on our next trip.

#### STYLE OF HONEY-PACKAGE.

I use a 10-pound friction-top pail, one size only. I have never found it practicable to carry any pail with a capacity of less than 10 pounds.

Every pail of honey should be neatly labeled, the label giving the number of pounds the pail contains, the source from which the honey was gathered, the body, color and flavor. We should also give notice on this same label how to liquefy honey when granulated.

One pleasant feature of peddling honey is that one becomes more widely known, and makes friends and acquaintances.

#### SPECIAL VEHICLE FOR PEDDLING.

I consider it an advantage to use a special vehicle, neatly painted, and lettered, giving in full in large, plain letters, one's occupation, name and address.

#### ADVANCE NOTICE WHEN SELLING.

As men do not generally leave money with their wives when its need is not foreseen, I give notice to the heads of families on a Rural Route, a few days

# American Bee Journal

previous to my canvass, by mailing a special card that I have gotten out. By so doing it largely increases my sales, as the people are expecting me.

Only the best quality of honey should be sold for table use. If we deliver a pail of honey a little different in color or flavor from a previous sale, call the customer's attention to it when the sale is made.

When canvassing a new route, one should not be too hasty. Take time to get acquainted with customers, and tell them something about your occupation. Be polite, addressing all ladies and gentlemen in a becoming manner. Make friends, if possible, with all the persons you meet. Sell to them a good quality of honey—yea, a better quality than they can get elsewhere, deal fairly and squarely, and success is yours.

Success in life comes from finding out what the world wants and then supplying it in a style and quality a little better than others have done, or are doing. The world will pay for our honey a good, fair price, if we only do our work well enough. GEO. H. KIRKPATRICK.

In the discussion which followed, Mr. Muth advised asking a good price if the goods were first-class, and instanced a case where a man was making \$4.00 a day (short hours) selling extracted honey, of best quality, at 20 cents per pound.

Mr. Kirkpatrick stated that he sold to lumber camps and the agricultural class entirely.

Mr. Holtermann thought Mr. Kirkpatrick's plan excellent; he himself sold at wholesale entirely, but the more retailed by bee-keepers at home, the better, provided a proper margin was left the dealer. As a rule, bee-keepers did not leave margin enough for the retailer. The wholesale and retail prices were too close together, and the storekeeper would push other goods which gave him a better margin of profit. In the address given, a difference between 7 and 10 cents was stated, probably about right. In the cost, expenses on the road and postage in notifying customers would have to be reckoned with.

(Continued next week.)

I had charge of a yard consisting of about 80 colonies in good condition. My prospects looked good, for my brother promised me that if I hived 50 new swarms during the season he would see that my financial difficulties for the next year in the Normal school would be at an end. Each new swarm was worth \$5.00 to him, and he was anxious for me to save them all.

The long rows of white hives stood in one corner of a large apple orchard. The wide branching trees were now loaded with little green apples, but earlier in the spring they had been covered with beautiful white and pink blossoms, and had furnished the bees with a bounteous supply of nectar to nourish their young. Just as the blossoms on the trees had changed to apples, so the tiny white eggs in their little waxen cells had changed to bees, and now the busy little workers were getting ready for their life-work of gathering honey.

As the young bees began to multiply in the hive, the old queen must gather her workers together and seek a new home. It was my duty to give her an informal introduction to the new hive.

I had often seen my brother hive bees, and had studied about the honey-bee in Biology, so I thought I knew all about it and its habits. I soon found out that I had much to learn.

The first few days I had nothing to do but become acquainted with my charges. It was interesting to watch the little workers as they came in from the fields loaded with pollen. Now and then a big drone would come out and buzz around, trying to make me believe he was very dangerous, but I knew he could do nothing but scold, and I soon got used to that.

On the third day, as I sat reading under the shade of an apple-tree, I heard a strange buzzing sound, and upon looking up saw a swarm of bees issuing from a hive not 6 feet from where I was sitting. I hurriedly put on a bee-veil and gloves, lighted the burlap in the smoker, and ran to the back of the hive to watch them come out. They tumbled over each other in their eagerness to get out, and it seemed as though every bee in the hive were going to leave it. The bees circled in the air for a few minutes, and I anxiously waited to see where they would cluster. What was my surprise and delight when I saw them fly straight to the hive I had chosen for them, and enter their new home without any assistance from me. How proud I was of my first swarm, and what a splendid bee-keeper I thought I was getting to be. I changed my mind, however, during the next few weeks, for every swarm seemed to have a new idea about the location of its new home. Some would settle on a bunch of alfalfa, and I would smoke them into the hive. Others would start out and lose their queen in their flight, and return to their old home. When I saw them returning I would turn the old hive around, put a new one in its place, and play a little trick on them in this way. I would give them a frame of brood from one of the first swarms, and let them rear a new queen.

Several swarms were "foolish" enough to cluster on a fence-post, and

## Eating Honey on Meats

Honey poured upon cooked bacon, sausage and some other meats is really very palatable, and much relished by many persons, strange as the combination may sound.—American Bee-Keeper.

Which recalls that some years ago a certain small boy in this locality made a regular practise of eating honey on his potato.

## Nothing Like Honey-Vinegar

The thousands of sisters who take the Delineator will be rejoiced to see an item in the February number, page 332. It appears to be an unsolicited testimonial to the value of an article which is probably not so well known as it should be even among bee-keepers. Here is the item:

### THE USE OF HONEY-VINEGAR.

If you want some fine vinegar, pure in quality, and very tasty, make it yourself from honey. I sampled some honey-vinegar at a friend's house some time ago, and I was so delighted with it that I persuaded her to give me her recipe for making it. Here it is:

Add 1½ pounds of extracted honey to a gallon of water. Then keep in a warm place, and in a few months you will be able to enjoy your vinegar. If it is not strong enough, add more honey, for I have made some vinegar with 3 pounds of the honey to the gallon of water. While not suited for all culinary

purposes, in the making of salads and for ordinary table uses, there is nothing that can be compared to honey-vinegar.

New Auburn, Wis.

MRS. T. C. C.

## My First 6 Weeks Among the Bees in Colorado

A stranger, in the month of June, passing through the beautiful valley which lies between Denver and Boulder, can not help noticing the large alfalfa fields purple with blossoms, the roadsides and ditch-banks bordered with the fragrant sweet clover, and the prairies covered with the many-colored wild-flowers. Yet does he ever associate with these pleasant scenes the fact that these blossoms are the source of the many thousand pounds of pure white honey that are shipped from Denver every year?

If he is a close observer he will see that almost every ranch in the valley has its row of bee-hives located in some secluded spot, and that many of these ranches have large apiaries where the busy little workers, during the month of bloom, are industriously storing the nectar which they find in great abundance in these beautifully colored blossoms.

My brother has 5 or 6 apiaries located in different parts of the valley. It is about my experience in one of these apiaries during the swarming season that I am to tell you.

# American Bee Journal

I would scrape them down on the hive with a honey-board. But most of them seemed to have a fad for seeking the highest branches of the apple-trees. I would mount a tall ladder, carefully draw a large gunny-sack over the cluster of bees, then break the branch off and carry them down to their new home in a sack. This was very nervous work, but I soon learned that the bees would not sting me if I was careful with them. If I were nervous and afraid they seemed to know it, and were much harder to manage.

One day 2 large swarms came out at the same time and clustered together on the topmost branch of a big tree. I could not reach them even with the ladder and gunny-sack, so I shook the branch vigorously, and bees and apples went tumbling down. I then began to work my smoker as hard as I could. Now bees do not like smoke. These, however, did not seem to mind it, and were bound to cluster on that branch. The more I shook and smoked the more determined they seemed to be. This rough treatment, however, made them angry, and a number of them began to sing a war-dance around my head. One angry little bee spied a hole in my veil, and in she flew and stung me on the eye. Then it was my time to become angry. It did not take me long to get down from the tree-top. They had won the battle. I decided to let them hold the fort until I could get some reinforcements.

When the men came in to dinner I got one of them to saw the top off the tree for me, and bring down fort and all. My eye was swollen shut by this time, and that side of my face was very plump and rosy for a few days.

I put the bees all into one hive and watched for a balled queen. I soon found the ball. I had never had this experience before, and oh! how I dreaded to put my hand down among those bees and lift out that ball of bees! But I did it. My hand shook, but they did not seem to notice it. I found the queen, caged her, and waited results. All was quiet in the new home, or seemed to be until about the middle of the afternoon. Then the storm began. I saw them rush out of the hive-door like mad. I thought my swarm was going to the tree-top again. I ran to the hive and placed the caged queen on the door-step. She must have called them home again, for they returned and lived peacefully ever afterwards.

During the whole season I received only 3 bad stings. The swarming season is very short, lasting only about 5 or 6 weeks. During the last week the bees had almost all stopped swarming, and were working in the supers. Some of the stronger colonies had the second super half full of honey.

My brother told me that Saturday would be my last day in the yard. I had already hived 49 swarms, and felt sure of another one before Saturday. Thursday and Friday passed and no swarm appeared. I watched anxiously all Saturday morning, but in vain. In the afternoon the sky began to cloud over, and I gave up all hopes of getting my 50th swarm. I gathered my things together, ready to start home, but before I went I thought I would go

down through the orchard and see if I could find some ripe apples. When I returned I noticed a commotion in the further end of the bee-yard. I went over to see what was the matter. The rain was now falling and the air was thick with bees returning from the field, but there on one of the lowest branches, in easy reach of a hive, was a little afterswarm. All I had to do was to get the hive and shake it in, and my 50th swarm was safe!

A LITTLE BEE-SISTER.

Many thanks for the interesting story of your experience, with the hope that this shall not be the last we shall hear from you.

May it not be that those studies will be just a little more interesting because you earned the money for them yourself? It's much to have so good a brother; and one feels like holding one's breath for fear you might not get that last swarm.

Conducted by J. L. BYER, Markham, Ont.

## North and South in Hand-Grasp

It is with pleasure I grasp the extended palm of Mr. Scholl (page 70). It is a case of "looking up" and "stooping to concur;" factors, evidently, by looks of splendid photograph on that first page, that did not have to be taken into account when Mr. and Mrs. Scholl were considering matrimonial relations.

## Comparison of Southern and Canadian Weather Condition

So they are having summer weather down in Texas, with the thermometer registering as high as 80 degrees Fahr. As I read this I am wondering if those "roses, violets, and carnations" have not been nipped since Mr. Scholl penned those lines, as this past week has been our first taste of real, severe weather, the temperature going as low as 15 degrees below zero.

After reading aloud to Mrs. Byer the nice things Mr. Scholl has to say about Texas weather, I asked her, "Now, wouldn't you like to live in Texas?" and the answer comes decidedly, "Well, no; I guess not." Whereupon she gives as reasons a number of objections to the South in general, among which I might mention earthquakes, cyclones, extreme heat, and drouths; snakes, fleas, and other insects too numerous to catalog.

Come to think of it, I guess no country has a monopoly of all the good, or bad things, for that matter. While our winters are cold, we prepare for them, for we know they are sure to come; and from an apicultural standpoint, we don't seem to have any more trouble to get our bees ready for the honey-flow than do our friends in the South. Winter effectually stops the ravages of the moth, and combs that are stored away in moth-proof boxes in November, are secure for all time to come; and I am told, and can readily believe, that con-

sumption of stores is much greater in the South than in the northern sections.

However, I am free to confess that "bees flying and 80 degrees Fahr.," sounds pretty alluring just now; and from the fact that a former schoolmate of mine is now domiciled in Beeville, Tex., I have no doubt that if *I had to*, I could manage to live there also.

## Honey from Cappings With a Solar Wax-Extractor

In a letter from Mr. George Wood, of Wesley, Ont., speaking about getting honey out of cappings, etc., among other things he says:

"I have used a solar extractor for that purpose, but it takes a lot of time, and in this breezy upland country it does not always work out clean."

Mr. Wood's experience is in common with a great many other apiarists; and especially in wet, cool seasons like the past few years, the solar extractor is not much to be depended upon without the use of artificial heat. As far as I am concerned myself, since using the press (of which more later), I have no use for my solar extractor, as I find it much better, in every way, to allow the cappings to drain off all the honey that is possible, then wash them to secure what honey is left for honey-vinegar. It is then only the matter of an hour or so to melt up all the cappings and run them through the press.

## Cold Winter and Little Snow

Up to date (Jan. 23) we have had a moderately cold winter with scarcely any snow. Although a few days in January were quite mild, yet none were warm enough for the bees to have a flight. Our bees seem to be affected slightly with dysentery, judging by signs at the entrances of some hives, and a few colonies seem to be some

# American Bee Journal

what uneasy, flying out in unseasonable weather. Whether this uneasiness is caused by the bees' food being almost exclusively buckwheat, is hard to say, but there is no question that a nice, warm day (which we are not likely to have for some time) would be welcomed by bee-keepers in this locality.

A nice blanket of snow to cover the clover would also be a benefit, for, although the clover is in no immediate danger, if we happen to get severely cold weather, frost penetrates very deeply into the ground, and this condition greatly tends to produce "heaving" of the alsiike in the early spring. We had no snow last winter, and if the result of last season's honey crop is a safe criterion, certainly prospects are none too assuring for next season's returns.

## Bee-Inspectors for Ontario

As will be noticed in the report of the Ontario convention, next season will see a radical change in methods of foul-brood inspection for Ontario. Whether the proposed changes will work out well in practise remains to be seen.

Formerly, Mr. McEvoy was inspector, with Mr. Gemmill as assistant, who, however, was not often called upon. This year it is proposed to have 6 men in the field, each having a specified territory to work in. At present it is understood, I believe, that Mr. McEvoy is to have a "say" in the matter of selecting the other 5 men; also to have a certain amount of supervision over the work, and act as referee in case of any disputes. However, as far as I am aware, the Department has not as yet definitely decided upon the course of action to be taken.

While at the convention the Minister of Agriculture expressed the view that there would be no difficulty in getting 6 capable men to take charge of the work; and right here I confess to being a bit skeptical about the matter. In the majority of cases the men most qualified for the work would not think of leaving their own business and taking up the work of inspection.

One of the arguments against having one man to do all the inspecting, was that such work should be done during fruit-bloom, or at other times when honey was coming in; and that it was physically impossible for one man to be at all places where his services were required, in these limited periods. As a matter of fact, the same arguments hold good if 6 men are employed, for very few bee-keepers would care to leave their yards during a honey-flow, unless they had competent help to leave in charge.

Of course, these views are merely speculation on my part, and possibly we may be surprised when we learn who are to take up the work. At any rate, this matter of inspection is a work that deserves the earnest, tactful attention of the Government, and it should be gratifying to the bee-keepers of Ontario to know that the Department is taking the interest it is in our business. Certainly, every bee-keeper in Ontario should be ready to lend a help-

ing hand in this matter of eradicating foul brood, whether we have but one

or a dozen inspectors to help us in the fight.

Dr. Miller does not answer Questions by mail.

## How Many Colonies for the Pasture?

My bees have at least 300 acres of clover and alfalfa within 2 miles. How many colonies can I pasture to be safe? UTAH.

ANSWER.—That's one of the very hard things to say. You don't say whether you mean red or white clover. If you mean red, it probably doesn't count for much, while white clover counts heavily in good years, although some years it blooms a plenty and yet yields no nectar. If you had said 300 acres of white clover, meaning 300 acres solidly occupied with white clover, I should guess that 200 colonies might get good picking. Alfalfa varies more. If it is all used for raising seed, then it probably counts as much as white clover. If used for hay, it counts for less, and may count for nothing, depending upon the times when the hay is cut. If always cut just before it blooms, then it counts for nothing; if cut when in full bloom, it may count perhaps on being enough for 100 colonies. You will easily see that as you state it, the whole thing is a varying problem. It may be mostly white clover, or it may be mostly alfalfa, and the alfalfa may be treated so differently as to make a big difference in the amount of nectar got from it. My guesses may not be reliable, and if any one can give anything more reliable I will cheerfully yield the floor.

## Storing and Capping Glucose and Sugar Syrup

I heard a bee-keeper say a few days ago that bees would not carry in glucose, and that they could cap neither glucose nor sugar syrup. I have supposed all the time that they would cap any sweet they stored in the cells. I have had no occasion to test this. What is your experience? ILLINOIS.

ANSWER.—I can give no positive answer from personal experience, for, although, I've done a lot of fool things with bees I never fed glucose. I have, however, fed sugar syrup, and had it sealed. Others have said they could not get bees to take glucose, and I don't remember seeing a report of any one who had been successful in getting bees to store it. Even if they could be induced to store it, it does not necessarily follow that they would seal it, for they have been known to fill cells without sealing them for a long time, if, indeed, they ever did.

## Wood Splints for Staying Comb Foundation

What are your splints for staying foundation? How are they used? P. E. ISLAND.

ANSWER.—They are splints 1-16 of an inch square, of basswood or some other straight-grained wood, about  $\frac{1}{2}$  inch shorter than the distance from top to bottom bar. It would

be full better to have them touch both top and bottom bar, but it would be more difficult to put them in. They are put in something like 2 inches apart, the 2 outer ones within half an inch to an inch of the end-bars. The splints are put in a dish of hot wax and left there till all frothing and bubbling ceases, and then they are lifted, one by one, by a pair of pincers, laid upon the foundation, which must be properly supported upon a board, and an assistant presses each splint into the foundation by means of the edge of a little board kept constantly wet. If put in while too hot, there will not be a good coating of wax on the splints. The foundation enters the groove in the top bar and goes down through the bottom-bar, which is in 2 parts, the lower edge of the foundation being squeezed between the 2 parts. The advantage is that the comb is built down to the bottom-bar. If, however, such a frame of foundation be given at a time when they are gathering nothing, the bees will gnaw a passage over the bottom-bar.

## Colors for Painted Hives

Should I paint my hives all the same color? If so, what color would you advise? I see from reading the American Bee Journal that some bee-keepers advise painting hives different colors, as one color bothers the bees in locating their hive. INDIANA.

ANSWER.—There would be some advantage to the bees in the way of recognizing their hives if they were of different colors, but it is hardly necessary. Bees locate their hives by means of surrounding objects, and except on a bleak plain utterly without any surrounding objects there is very little difficulty where the hives are 5 feet or more apart from center to center. But you can just as well have double the number of hives on the same ground by having them in pairs. Set two hives close together on the same stand, then leave a space of 2 feet or more, then another pair, and so on. Ground may be still further economized by placing another row close to the first, letting the hives stand back to back.

There is probably no better color, all things considered, than white, using good white lead.

## Changing Supers Over to T-Supers—Overstocking

I. I am interested in the T-super. I think it is a good one to adopt. I wish to ask if I can make T-supers out of my 10-frame supers (dimensions 16x20 inches outside) to make it pay, and how to do this the best way. I am a novice, or was 3 years ago, and was somewhat puzzled in the American Bee Journal, as was Mr. M. F. Soule. I think if he can have Dr. Miller's "Forty Years Among the Bees," and read it, he will soon pick it up. At least, I did so, and I am no scholar at all, and am 45

years of age. I have had no schooling in this country.

2. Last year I had 23 colonies, spring count, and doubled them up to 19, and had 7 at home and 12 at Oak Park, 4 miles away from home. They produced 70 and 330 pounds of honey, respectively, so that proves to me there are too many bees in this part of the country. I had my queens clipped, and shook the swarms of one on combs or foundation, and put the brood over the still weaker colonies, and increased to 23. I will move out to Orlevie, 25 miles from here, in the spring, on a small farm, and milk some cows and keep bees.

MINNESOTA.

ANSWERS.—1. Your supers are 16x20 inches outside, and if made of  $\frac{3}{8}$  stuff they are 14 $\frac{1}{2}$ x-18 $\frac{1}{4}$  inside. If you intend to use the popular 4 $\frac{1}{4}$ x4 $\frac{1}{4}$  section, the width of your super will do, but the length, 18 $\frac{1}{4}$ , is  $\frac{3}{8}$  too much. It depends upon how they are made, whether it will be easy to cut off that  $\frac{3}{8}$  and nail them together again; but if it is not easy, all you need to do is to nail in one end a  $\frac{3}{8}$  board. Then if your super is any deeper than 4 $\frac{1}{2}$  or 4 $\frac{3}{4}$ , it must be cut down to that depth. Possibly your supers are extracting-supers, and of such depth that each one can be cut in two, making two supers. Then, for each super, you will need 2 strips of tin  $\frac{3}{8}$  inch wide, and 6 staples, or else 6 pieces of sheet-iron 1x1 $\frac{1}{2}$  inch. You will nail a strip of tin on the bottom at each end to support the sections at each end. On the lower edge of each side, just at the middle, will be a staple, and half way between this and each end another staple. Drive each staple into the lower edge of the side, and about  $\frac{1}{4}$  inch from the inside, and then bend it over, so that when the super stands flat upon a table the staple will be flat on the table. If you prefer to use sheet-iron pieces instead of staples, two wire-nails will hold them.

"That proves to me there are too many bees in this part of the country." Not necessarily. If you have been in the business only 3 years, it may be that those were 3 bad years, and that next year will be a good year. It may be, however, that the locality is overstocked, for all that.

### Bee-Bread or Pollen in Winter—Taking Bees Out in Spring

1. I have a colony of bees which I thought had plenty of honey. I put them into a cave, or outdoor cellar, on Nov. 8, 1906. I took them out Jan. 23, as it was a very warm day, and found a good many dead bees in the bottom of the hive. They have 9 frames full of comb, but the bottom half is empty nearly half way up the frames; but I don't find any bee-bread in any of the frames. Will they winter all right without bee-bread, or can I feed them anything as a substitute for it?

2. They flew out in large numbers until 5 p.m. They carried in water till 4:30. It seems as if the honey is partly candied in the upper part of the frames. It is warm and nice in the cave. Nothing freezes in it. When is the best time to take them out of the cave and put them on the summer stand?

3. We are up on the high table-land where it has been very dry for a number of years. Bees had done no good until the last 3 years. Last year they did fine. Some took off from some colonies 70 to 75 pounds of honey of fine quality. What is the best to feed the bees in case they haven't plenty of stores in the spring to feed the young bees? Do you think that extracted honey is better than granulated sugar? We have had a nice winter, not much snow, but the wind blows a good deal of the time since the sun crossed the line in September.

NEBRASKA.

ANSWERS.—1. Why will winter all right without any bee-bread, but they can not rear brood in the spring without it. It may be that they can get pollen as soon as they fly in spring, and you can easily tell if they do by seeing them carrying in loads of pollen. If so, you need not interfere. But if they get no pollen you can give them a substitute of almost any kind of meal you happen to have.

A very nice thing is ground corn and oats. Set a shallow box of it out in the sun, tipped to one side, and when the bees work it down level tip it the other way. They will use out the fine parts, and you can feed the coarser parts to your 4-footed stock. I wouldn't wonder, after all, if the bees have all the pollen they need in the new hive now. It may be in cells with honey over it and sealed, so that you would not see it.

2. The right time to take out depends upon the season. In this locality I generally take out my bees about the time red or soft maples are in bloom, and that may be from the middle of March to the middle of April. Perhaps you could go by the same sign, although you are in the northern tier of counties in Nebraska, and so you are farther north than I. So long as the bees are quiet in the cave there is no need to hurry them out, and you need not be alarmed at some of the bees dying, for a good many may die from old age.

3. Honey of best quality is probably the best thing for bees, especially when brood is to be reared; but if you haven't that, then syrup of best granulated sugar comes next.

### Proper Temperature of Bee-Cellars

On page 14, R. H. Smith says the best temperature for wintering bees is 45 to 48 degrees above zero. If I remember rightly, all our best authorities agree on 42 to 45 degrees for the most successful wintering in cellars. I have one Standard barometer and 3 Fahrenheit thermometers. One of the latter is filled with quick silver, or mercury, and the others with colored fluids. I have all these in my cellar, and the variation from the one that shows the highest to the one that shows the lowest, is 10 degrees. Upon which can I depend for the desired 42 to 45 degrees which is necessary for successful wintering of bees, as claimed by our best authorities?

WISCONSIN.

ANSWER.—So you're up against that mixed matter of temperature in cellar. If there is anything like a general agreement, it is that the right temperature is about 45 degrees. But, as you have found out, thermometers vary. You will also probably find that cellars vary, perhaps on account of difference in dryness, perhaps for some other reason, so that if the same thermometer is used in 2 cellars, it may need to be higher in one than the other. I don't know which of your thermometers is best; and it doesn't make very much difference, although on general principles it's better to have it correct. But here is what you're to do: Take whichever thermometer you think best, and keep close watch until you find at what degree your bees are quietest; then keep your cellar as near that temperature as you can, whether it be 42, 45, 48, or something else. The idea is to find at what temperature your bees are most quiet by your thermometer, in your cellar, no matter what authorities say.

### Space Below Brood-Frames—Wire-Screening Cellared Bees in the Hives

1. As I expect to make my bottom-boards, I would like to know how deep an entrance can be before the bees will build comb from the bottom-bars to the bottom-board. I have been using them  $\frac{3}{8}$ -inch deep, but I notice the bees alight outside and crawl in, the same as a  $\frac{3}{8}$ -inch entrance; but if 1 $\frac{1}{4}$  inch they don't alight on the bottom-board, but on the combs. It seems to me this must save quite a little of the bees' time. Would 2 inches be too deep?

2. What do you think of shutting bees in the cellar with wire-screen? I use a frame with wire-screen on both sides. I close up the entrance with 2 small nails and a strip of wood. I use another strip to hold all together instead of staples.

IOWA.

ANSWERS.—1. I don't know just how deep a space would do, but I'm sure 2 inches would

be too deep. I have had bees build comb in a  $\frac{1}{2}$  inch space, although from what you say your bees may not yet have built in such a space. I should feel safe with a  $\frac{3}{8}$ -inch space, and likely there would be little building with a space of 1 inch. My bottom-boards, however, are all 2 inches deep; then during the busy season I fill half or more of the space with a sort of rack, which prevents the bees building down, yet gives them the chance for much ventilation. In winter the bees have the whole of the 2-inch space, which is an important advantage.

2. I never tried it, but those who have tried it generally condemn the practice. I remember especially E. D. Godfrey, of Iowa, who, some years ago, suffered loss by it. The editor of *Gleanings* has been trying it lately, and reports that when the bees find themselves imprisoned, they make such a to-do as to stir up the whole colony. I have used wire-cloth at entrances in winter, but it was of coarse mesh, 3 meshes to the inch.

### Wintering Well—Cold Weather

Bees are wintering well. We had a mild winter, with but very little snow, till about Jan. 20. We now have about 6 inches of snow, and it is cold. On Jan. 24, the mercury was 26 degrees below zero. My last season's crop of honey was about 4500 pounds from 63 colonies.

C. F. BAKER.

Belmont, N. Y., Jan. 28.

### Fair Season in 1906

The past season was a fair one here. I secured about 1350 pounds of comb honey, which was my largest yield since keeping bees. I took the 1st premium on a case of alfalfa honey, 2d premium on display of comb honey, and 3d on a case of amber honey, at the Kansas State Fair at Hutchinson. I think that is not so bad for a bee-keeper of only a few years.

JNO. A. DUNN.

Abbyville, Kans., Jan. 23.

### Cold Snap—Material Commotion

We have had our cold snap. Yesterday morning it was 10 degrees below zero, and now it is 14 degrees above, with 2 inches of snow. Bees apparently are all right.

There seems to be a commotion in the material world—"earth shakes," floods, and Minnesota snows. The traditional spiritual calm seems on the "quake" also, in France. Well, bee-keepers are a staid lot, and we can rely on them for honey and perseverance.

Farwell, Mich., Jan. 24. T. F. BINGHAM.

### Indians and Wild Bees

I never kept bees, but no one has had more experience than I and not keep them. I have tried to outdo bees ever since I can remember. First, the bumble-bees—how to rob them and get the honey. I have put in days, while herding sheep in Kansas, killing bumble-bees and pulling them in two and dropping the big drop of honey into my mouth. But not without stings, so you don't have to tell me a bumble-bee can sting more than one time.

Last summer I happened to go into Indian Territory. Stopping over night with an Indian family, they made the remark that if they had some sulphur they would rob a beehive. It made me "come alive," and I asked how they did it.

To cut the tree, burn most of the honey and all the bees, was the plan described. So I made a smoker out of a baking-powder can, etc., and fixed a box for them. They all

# American Bee Journal

wanted to go, children and all, and even called 4 dogs along.

Well, I had lots of fun, but only one boy stayed to help carry the honey, axe, saw, wash-boiler, and a dozen other articles besides a box full of bees—60 pounds (estimated) of capped-over honey.

I cut a tree and let it fall on a pile of brush to save the jar, then I paid no more attention to the bees. As for stings, they positively cured me of rheumatism. I sawed close to the hole, then split out, kept sawing and splitting out to the comb, smoking the bees up the hollow. Then I removed the comb, putting the young bees and comb in the box, and saving the choice capped-over pieces (and I had seen pieces 3 feet long) to eat. The broken pieces I saved for the bees to come on.

Just one week from the time I put these bees in this box they had filled it nearly full of new comb and laid eggs in nearly every cell. I put them in 4-frame hives, cutting out the comb and putting it in the frames.

When I went back, 3 weeks after, they had 3 more trees, and I found 4 trees while hunting squirrels. I put 4 of these queens in a box the size of a suit-case, with a frame of brood and all the bees I could get handy by brushing them off the other frames. I carried that box as a grip (I did not pay express) 3 days and nights before I got them out in larger space in hives.

I gave each frame a new hive and spread them by adding frames of foundation as they needed it. I cut the trees in July. There are 8 colonies of bees now doing fine.

When I returned to see the people they called me a "bee-man," and asked me to rob a hive. I took out a frame of nice capped-over honey. To see those Indians reach out for a chunk of that honey did me good.

Do you think I could learn to be anything of a bee-man? I sold those I carried so far in my hand, so I have no bees.

Wichita, Kan. L. BENSON.

[Yes, there are encouraging signs of a bee-keeper in you. Better get some bees and "do business" with them.—EDITOR.]

## "Erythema" from Bee-Stings

Dr. Miller, after giving his answer in Jan. 3d issue, says:

"If any one can help out, such help will be gratefully received."

"Wisconsin's" wife, without doubt, suffered from Erythema. It is a well-known fact among medical men that external irritants (like a bee-sting), as well as the internal administration of certain drugs, and sometimes certain articles of food, or fruits, will produce in a few susceptible people the condition described by "Wisconsin." I know one person who can not eat strawberries without bringing on the affliction, and yet is otherwise in good health.

In reply to the query as to whether it will occur again, I will say: Yes, it certainly will if the lady is stung again. The attack will last from a few minutes to a few hours, or perhaps 2 or 3 days.

Yes, there is a remedy, but as it varies with circumstances, I will not give it for publication. The trouble can be prevented by avoiding the exciting cause—the bee-sting, or whatever it may be.

No, it is not advisable for "Wisconsin's" wife to try again to work among bees. She should avoid them. F. D. CLEM, M. D.

Cheviot, N. Y., Jan. 12.

## Drones Flying Jan. 5

With the thermometer at 38 in the shade, I saw 4 drones in flight. My boy caught one with his hand in the air, and I picked another off the grass in front of the hive. Doubtless this is no new experience in the history of bee-keeping, but the following facts may be interesting:

I started my little apiary with one colony in May, 1905. In June I took brood-frames and started 2 other colonies by introducing

# American Bee Journal Novelty Pocket-Knife Gold Fountain Pen

# All for \$3.00

(This cut is the full size of the Knife.)

## NOVELTY POCKET-KNIFE

(Name and Address on one side—Three Bees on the other side.)

Your Name on the Knife.—When ordering, be sure to say just what name and address you wish put on the Knife.

The Novelty Knife is indeed a novelty. The novelty lies in the handle. It is made beautifully of indestructible celluloid, which is as transparent as glass. Underneath the celluloid, on one side of the handle is placed the name and residence of the owner, and on the other side pictures of a Queen, Drone, and Worker, as shown here.

The Material entering into this celebrated knife is of the very best quality; the blades are hand-forged out of the very finest English razor-steel, and we warrant every blade. It will last a life-time, with proper usage.

Why Own the Novelty Knife?—In case a good knife is lost, the chances are the owner will never recover it; but if the "Novelty" is lost, having name and address of owner, the finder will return it. If traveling, and you meet with a serious accident, and are so fortunate as to have one of the "Novelties," your POCKET-KNIFE will serve as an identifier; and, in case of death, your relatives will at once be notified of the accident.

How to Get this Valuable Knife.—We send it postpaid for \$1.25, or club the Novelty Knife and the American Bee Journal for one year—both for \$2.00. (Allow two weeks for Knife order to be filled.)

## SOLID GOLD FOUNTAIN PEN

Finally we have found a good Fountain Pen that is reasonable in price. The manufacturers of this pen say that if you pay more than \$1.25 for other fountain pens, it's for the name.

This pen is absolutely guaranteed to work perfectly, and give satisfaction. The Gold Nibs are 14 kt., pointed with selected Iridium. The Holders are Para Rubber, handsomely finished. The simple feeder gives a uniform flow of ink. Each pen is packed in a neat box, with directions and Filler.

Worker

Queen

Drone

2/3 size

We mail this Gold Fountain Pen for only \$1.25, or for \$2.00 we will mail it and the weekly American Bee Journal for a whole year.

Sample copy of the American Bee Journal free; trial trip of three months (13 copies) for 20c; regular yearly price, \$1.00. Address all orders to

GEORGE W. YORK & CO., 334 Dearborn St., Chicago, Ill.

queens. The season was a very poor one, but by liberal feeding they built up new comb, and on Sept. 10 (which was rather late in the season, I am afraid) I decided to experiment with the Ferris system on one of the new colonies, which was then full of bees. I divided it into 2 divisions by a board, and introduced an untested queen on the east side, the hives facing south. About 2 weeks later I examined this side and saw the queen, but could find no signs of eggs or larvae. I then fed each colony with all the bees could take of sugar syrup.

The middle of November I bunched the hives together, and placed a large packing box over all, cutting away on the side about 6 inches opposite the entrances. The hives are protected by at least 6 inches of closely packed leaves on all sides. The board cut from the front overhangs as a shade, so that I must get on my knees if I want to see the entrances.

New Year's day was warm, and I cleaned away a few dead bees that were lying just inside the entrances. I found a young unhatched bee at the entrance of the hive where the young queen had been given, and it suggested that possibly she had started to lay after my inspection.

On Jan. 5 this colony, which occupies the east end of the row, was the first to send out bees, and I suppose it was because the rising sun, striking the east end of the packing box, had warmed up the hive. This was 11 o'clock, and an hour later the colony at the west end sent out a few bees. The center colony made the smallest showing of all.

Bees were flying from both divisions of the east hive, but the great majority were from the one to which was the young queen. The drones came from this. The workers dispersed themselves in front like nurse-bees, and in about half an hour there were very few outside. The drones appeared almost at the start of the flight.

The following day (Jan. 6) the outside temperature rose to 50 degrees, and the colonies showed activity in much the same way as they did before. However, I saw no drones.

In "A B C of Bee Culture," Mr. Doolittle says he has twice seen drones flying in winter during his career, both occasions following very heavy honey-flows, and he assumes they had not been killed off. I watched the slaughter of the drones in my own hive, and I saw none flying for weeks before the beginning of winter.

For a definite conclusion as to the reason of their existence, I feel I must wait until spring, but, in the meantime, I conceive the following possibilities: First, the drones have lived since summer; second, the queen is now laying, but has not been mated, but the flying bees that I examined are small and downy, and I think they are young; third, the queen is laying, but her first eggs were not fertilized. To quote Robert Burns—

"Her prentice haun she tried on man,  
And then she made the lasses, oh."

Perhaps there may be a fourth, and even other possibilities, but I will let men like Dr. Miller add to their number.  
Glencoe, Ill. F. DUNDAS TODD.

### Pollen and Honey in January

Bees are getting pollen and honey from black brush, wild peach, mistletoe, and barberry; also from seedling peaches and early-blooming pears. How is that for January?  
Sabinal, Tex. GRANT ANDERSON.

[We should think that January is pretty early for bees to be working on the blossoms. At this time we have nothing but snow and ice in this part of the country. But 1300 miles south of Chicago it would be quite different.—EDITOR.]

**For Missouri Bee-Keepers.**—Since I sent the call to the bee-keepers of Missouri, in the last issue of the American Bee Journal, to write to their Representatives and Senators

in support of their Apilary Bill, which has been introduced in the Senate, the Bill has also been introduced in the House. The Senate Bill is No. 145, the House Bill is No. 503; both Bills read alike, but in writing to a Senator it will be well to name Senate Bill No. 145, and when writing to a Representative, name House Bill No. 503.

I wish to suggest that Missouri bee-keepers write a letter to their legislators, calling attention to the great need of the apiarists and horticulturists, to have the Apilary Bill passed, and then have this letter signed by all the bee-keepers, fruit-growers, and other prominent citizens who take an interest in the welfare of the vocations named. It will be much easier in this way to get signatures of many bee-keepers to these letters, than to induce them to write the letter themselves. Bee-keepers, do all you can. It is important that our legislators hear from home.

ROBT. A. HOLEKAMP.

Sec. Missouri State Bee-Keepers' Association,  
4263 Virginia Ave., St. Louis, Mo.

### CONVENTION NOTICE.

**Minnesota**—The Southeastern Minnesota Bee Keepers' Association will meet in the Court House at Winona, on Tuesday and Wednesday, Feb. 26 and 27, 1907. Every body is invited.  
E. C. CORNWELL, Sec.

Winona, Minn.

"Songs of Beedom."—This is a beautiful 16-page-and-cover pamphlet, 6x9 inches in size, containing 10 bee-songs—words and music—all the songs so far written specially for bee-keepers, we believe. It is nice, as well as convenient, to have these songs all in one binding. Every bee-keepers' organization should have copies for use at conventions. They could be sold to members after using once, or held by the secretary for use at future meetings. Of course, every bee-keeper's family will want at least one copy. It is sent, postpaid, for only 25 cents, or 3 copies for 60 cents; or, we will mail one copy with the American Bee Journal one year—both for \$1.10. Send all orders to the office of the American Bee Journal.

"Langstroth on the Honey-Bee"—the well-known bee-book revised by the Dadants—has just passed into another edition. There have been some 75 pages added to it, and the whole work brought down to date in every respect. It is certainly a fine book, and should be read by every bee-keeper. It is really a classic. To become acquainted with the great Langstroth through the reading of his book is no small thing. Other bee-books are good, but there is only one "Langstroth on the Honey-Bee." The latest revised edition will be sold at the same price as the one preceding, which is \$1.20, postpaid. We still have a few copies of the old edition on hand, which we will mail at 90 cents each, if preferred, so long as they last. We club the new edition of this book with the American Bee Journal for one year—both for \$2.00. So long as we have any copies left of the old edition, we will send it with the American Bee Journal one year—both for \$1.80.

In justice I should say that the American Bee Journal pleases every member of the family, and all appreciate the Editor's tireless and punctual labors.—THEODORE LOHR, of Colorado.

## Honey and Beeswax

CHICAGO, Feb. 1.—The usual late winter demand is in evidence for comb honey to replace diminished stock laid in during the autumn by the large retailers, but during the dull period there has been very little change, if any, in prices, the offerings being light.

We find No. 1 fancy white comb honey brings 15@16c, and for that which is off in color and flavor from 1@3c less. Amber grades of all kinds are dull and range in price from 10@12c. The extracted perhaps is not quite so firm in price for the California or Western grades, but there is no surplus of white clover or basswood, both of which bring about 8c, and in some cases more. Ambers grade from 6@7½c. There have been some sales of beeswax at 32c, but 30c is about the price for average.

R. A. BURNETT & CO.

PHILADELPHIA, Nov. 8.—While the supply of comb honey is equal to the demand, large quantities of comb honey having arrived in the market in the last few days, the price still remains high. The outlook, however, is that when the season advances and the bee-keepers ship more of their crop to the market, the prices will be a little weaker. We quote: Fancy white comb honey, 16@18c; No. 1, 14@15c; amber, 11@13c. Fancy white extracted, 7½@8c; light amber, 6½@7c.

We are producers of honey and do not handle on commission. Wm. A. SELSER.

NEW YORK, Jan. 15.—The stock of white comb honey is pretty well exhausted, and we do not expect any more arrivals of large lots from now on. Prices are firm, and we quote from 15@16c for fancy white; 13@14c for No. 1; 12c for light amber. There is quite a little dark and buckwheat on the market, but no overstock, and we think that all of it will be disposed of before long at present prices, which we quote from 10@12c, according to quality. Extracted honey very firm, with sufficient supply to meet demand. California white sage is bringing from 8@8½c; light amber, 7½c; amber, 6½@7c; buckwheat extracted in fairly good demand at 6@6½c. Southern in barrels finds ready sale at from 55@70c per gallon, according to quality. Beeswax firm and steady at 31c.

# C. H. W. WEBER

CINCINNATI ... OHIO ...

Office and Salesrooms, 2146-48 Central Ave. Warehouses: Freeman and Central Aves.

DENVER, Jan. 5.—There is practically no honey left in the hands of producers in this State, and barely enough in the Denver market to supply the home trade until spring. We quote strictly No. 1 white, per case of 24 sections, at \$3.20; No. 1 light amber, \$3; and good No. 2, at \$2.81. White extracted, 8@8½c; light amber, 7½@8c. Beeswax, 26c for clean yellow, delivered here.

THE COLO. HONEY-PRODUCERS' ASSN

CINCINNATI, Jan. 9.—The comb honey market at the present is very quiet. Holders are not trying to realize a profit, simply disposing of what they have, at cost. Fancy comb honey is selling at 14½@16c. Extracted amber honey in barrels, 6@7c; fancy light amber in cans, 7@8c; fancy white, 9c. Strictly choice beeswax, 30c, delivered here. THE FRED W. MUTH CO.

INDIANAPOLIS, Jan. 3.—Comb honey is not plentiful, but demand is slack. Fancy white comb brings 16@17c; No. 1 white, 14c; amber, 12@13c. Best grades of extracted honey bring 8@9c; amber, 6@7c. Good average beeswax sells here at \$33 per 100 pounds.

WALTER S. POWDER.

TOLEDO, Nov. 30.—The market on comb honey remains about the same as last quotations, but has been coming to much more freely, as bee-keepers seem to be very anxious to get rid of their stock. Fancy brings in a retail way 16c; extra fancy, 17c; No. 1, 15c; buckwheat, 15c. Extracted white clover in barrels brings 7@7½c; cans the same. Beeswax, 26@28c.

THE GRIGGS BROS. & NICHOLS CO.

CINCINNATI, Jan. 25.—The market on comb honey is rather easy. Prices rule in j bbing ways from 14@14½c; single cases 16c for No. 1 white; off grades not wanted at any price. Extracted is very firm. Light amber in barrels, 6@6½c; white clover in barrels, 7½c; in cans, 8½c. Beeswax, 30c, delivered.

C. H. W. WEBER.

KANSAS CITY, Jan. 25.—The receipts of comb honey have been more liberal during the last week or two, and the demand light, market weaker. The market is practically bare of extracted, and there is quite a little inquiry. We quote: No. 1 white comb, 24 sec. cases, \$3.10; No. 2, \$2.75; amber, \$2.50. Extracted, white, 7½@8c; amber, 6½@7c. Beeswax, 27c.

C. C. CLEMONS & Co.

**SPECIAL DISCOUNTS** on early orders for **Supplies...**

**WALTER S. POUDER**

513-515 Massachusetts Ave., INDIANAPOLIS, IND.

## Trade Notes. The A. I. Root Co., Medina, Ohio.

**Gasoline Engines.**—In the article found on page 87 of the American Bee Journal for Jan. 31, reference is made to the use of gasoline engines for hive-making. These are very useful in every shop and on every farm. Send for particulars of our \$60 engine for this purpose. We have a complete engine and 8-frame extractor ready to run, for \$100. This may be found on page 25 of our 1907 Catalog.

**Danzenbaker Prize Competition.**—We again refer to the Prizes mentioned in these columns for the last few weeks. Please turn to page 84 and read the same, and read the following from a Cleveland honey-dealer which is representative of letters we receive from the honey-trade in all parts of the country:

Mr. Calvert—Cleveland, Ohio, Jan. 26, 190—  
*Dear Sir:*—Send me by next Electric Package Car, cases of 20 sections each, Extra Fancy Comb Honey. These must be Danzenbaker sections, as I cannot use any other kind.

In the Fancy Clover at 17 cents, about half of the sections were fine, while the other half had hollow spaces around the edge, and some empty cells. Yours very truly,  
 THEODORE F. ENSIGN.

There is no question but that it pays bee-keepers to produce Extra Fancy Honey, and with Danzenbaker sections you should obtain

**More Honey,  
 Better Honey,  
 Higher Prices.**

**Catalogs.**—Our 1907 Catalog is now ready for mailing and a large number are already in the hands of our bee-keeping friends. If you haven't received a copy send us a postal card request for the same. When you do this kindly mention the number of colonies of bees you keep.

**Dealers' Terms.**—We have found that it is to the advantage of bee-keepers generally if some one of their number will collect orders and send in to us, saving each party a good deal of trouble and making it a convenience by keeping a stock of goods on hand for the swarming time. To parties who do this we make special prices. If you handle bee-keepers' supplies for your neighbors, write us for our special terms, but do not expect to get special terms unless you give us in your letter some information regarding the amount of business done so that we may know you are entitled to special terms.

**Seeds of Honey-Plants.**—For many years Mr. A. I. Root has devoted much

time and attention to this matter. We have fair stocks on hand, and shall be glad to send prices to any one interested.

**Beeswax.**—We are paying 30 cents in cash, 32 cents in trade, for pure average wax delivered at Medina or our branch offices. Jobbing agents for the most part are allowing the same prices. Do not make the mistake of holding your wax too long, expecting higher prices, for it usually declines shortly after the arrival of the spring offerings.

**Ohio Maple Sugar and Syrup.**—For many years we have each spring supplied quantities of maple sugar and syrup to our friends all over the country. We do not carry much stock on hand, and in order to get some of this, it is necessary that we have your inquiries and orders **at once**. There is a good prospect for a fair season with good quality of syrup and sugar. We can not name definite prices, however, until the season is open.

**Observation Hives.**—We did a large business the past season in observation hives. The Bigelow observation hives have also an increasing demand. We recently sent 4 to Argentine and 2 to South Africa. The Pearl-Agnes hive is also arousing a good deal of interest. Particulars of all of these may be had on application.

**Bees and Queens.**—We have previously mentioned the importance of obtaining good breeding queens. Be sure to send any orders for these early so that you may have a good selection. We recently had the report of safe arrival of 5 colonies shipped from Medina to Buenos Aires, Argentine.

**Hotbed Sash.**—The sash are of regular size, 3 feet 2½ inches by 6 feet, for 4 rows of glass 8 inches wide. If any prefer larger glass we will furnish sash for 3 rows of 11-inch glass at the same price. Made of cypress. These sash are usually shipped from here "knocked down" at a low rate of freight, and can be put together by any body, as they are mortised and tenoned in the regular way. They are 1¾ inches thick, outside bars about 2½ inches wide, and inside bars about 1¼ inches. The bars are grooved to slip the glass in place. Price of one sash in the flat, for sample, without glass, 90 cents; 5 in flat, 85 cents each; 10 in flat, 80 cents each; put together, 10 cents each extra. Glass, 8x10, just right for the above, \$3 per box of 90 lights; 5 boxes, \$2.90 each; 10 boxes, \$2.80 each.

**Catalogs for Supply Dealers.**—If you intend to issue a catalog of supplies, or bees and queens, or have any other job printing done, we shall be glad to quote you prices. With our improved facilities for doing this work and the large number of cuts we have for illustrating, we are probably better prepared to take care of any orders satisfactorily than any local printing office could be. We solicit your inquiries.

**Gleanings Advertising Columns.**—If you think of advertising supplies, bees and queens, or any other goods suitable for our columns, or want to run a classified advertisement of any suitable character, we shall be pleased to give you information regarding the cost of any size advertisement for any length of time. We have some very flattering reports from those who have used Gleanings the past year.

**Clubbing Offers.**—For those who haven't placed their orders for the season's reading we can still make some very low prices. We refer you to the offers made on this page for January 3rd. If you do not have that issue, write us for our premium and clubbing list.

**Weed Process Foundation.**—Increased interest is shown in the use of full sheets of foundation in brood-frames and sections as well, and when these are used it is all the more important that the best be selected; not only that a light weight may be had to save expense, but the best for the desired use should also be considered. There is every reason for using Weed Process Foundation. We shall be glad to send you samples of our make at any time, with prices on any order from one pound to a ton. A single dealer using 3 tons of this, and giving us his renewal order, is the best evidence of the value of our make.

**Section Honey-Boxes.**—We have long been headquarters for section honey-boxes, and yet if you are not acquainted with our product we shall be pleased to send you samples showing the same. We do not attempt to compete with those who solicit their trade on the basis of price only, but even with cheaper goods ours will be found the least expensive in the end. A certain well-known dealer bought a carload of cheap sections, and we are reliably informed that he was obliged to return nearly the entire lot to the factory. Do not make the mistake of buying cheap goods.

(Entered at the Post-Office at Chicago as Second-Class Mail-Matter.)

## Editorial Notes and Comments

### Cleaning Sections—Answering Questions

We have received the following from a California subscriber:

EDITOR YORK:—Kindly read "Colorado's" question No. 2, on page 786 (1906), and you will see that it says, verbatim:

"How many cases of 24 sections does your best hand clean in a day? What should be an average day's work for an average hand," etc.

Then read Dr. Miller's answer. Do you discover either in the one or the other the mention of T-supers? True it is we all, or nearly all of us, who read bee-papers have noticed that Dr. Miller is a great defender and advocate of the T-super system, but the misunderstanding of us here comes from the simple fact that in this part of Southern California we are working *not* the T-super, but the section-holder style. The Colorado inquirer did not speak of the style of supers, and Dr. Miller (being a T-super man) did not think that there are also other (unfortunate) bee-keepers who work the section-holder style. This, I think, you will admit to be clearly the cause of the controversy.

But, if Dr. Miller "as the great experienced bee-authority" is addressed to give an answer, it seems to me that he should have answered it a trifle more to the point; that is, he should have said, for instance: "The average work for an average hand with T-supers is so much; and the same for section-holder supers—it is so much." That, at least as far as I can understand, would have been just as easy for him as the answer given, and would have been hitting the nail fully. It is true that the Colorado questioner uses in his first question the word "you," but in his second question he does not do it. And, as said before, around here—and I think almost generally in our bee-region, where section honey is produced—there are but few who work the T-super. That, at least, has been my experience, and, to be frank, I very much regret it now, that my first "bee-instructor" was not in favor of the T-supers, and when I started the present apiary here, I had to take a certain amount of stock over in section-holder supers, and you know two kinds don't work well in an apiary. I gladly would now adopt the

T-supers, even if the outlay for honey-boards is rather an item when it goes beyond the 100 and last year's dreadful failure does not ease matters for me.

Now, will you please tell me what is considered an average day's work by an average hand to clean sections from section-holder supers?

Yes, we have had, so far, 15½ inches of rain, more—far more—than does us any good; and having fallen so early in the season, we have our doubts about a good honey-year, as former experience has shown us that early rains usually do *not* do any good if not followed up by late rains, in April and May. And though copious rains (2½ inches) fell 9 weeks ago, and ever since followed up by alternating rains and cloudy or half-way clear days, there is no growing of grasses, shrubs, or the fields to amount to anything, because it has been far too cold weather. Manzanita is in glorious bloom, but hardly any nectar formed.

CALIFORNIA.  
San Diego Co., Calif., Jan. 18.

P. S.—The possibility—better say, fact—that by the T-super system 24 sections can be cleaned easier than one section by our section-holder system, would be most assuredly an inducement for me to adopt the T-super. Unfortunately, I have over 250 supers on hand, yet I would not mind the labor if an easy, practical way to change them to the T style could be pointed out to me.

Of course, Dr. Miller would be the man who could give me all needed information, only the fact is present that he does not answer letters by mail, and it takes so dreadfully long a time to get his answer (and then only in condensed form) in the American Bee Journal. And time is short if a change is to be made. You see that here I sit in a predicament hard to solve. Please, Mr. York, kindly give your prompt attention to this matter, and if there is a chance to come to my assistance, then do so.

Jan. 21.—For 3 days we have had—to our surprise—our genuine old California weather, with the sun in a cloudless sky, and we appreciate it, after the terrible sky.

Undoubtedly it did not occur to Dr. Miller that any misunderstanding would be in the

case of his reply, page 786, and you will see that, as always, he tries to answer the particular case in hand. In fact, the trouble in the present case is that he did that very thing.

The question as to "your best hand" was asked and distinctly answered, and in the nature of the case it could have reference only to the T-super. Then the question as to "an average hand" as compared with "your best hand" could only be answered by referring to the same kind of super. Moreover, in Colorado many T-supers are in use, and it is not impossible that "Colorado" was a T-super man. With all this, it would have made it clearer to some if it had been mentioned that he was speaking of T-supers, and Dr. Miller will no doubt regret, when his attention is called to it, that he had not so mentioned.

But are you not a little in error when you think that, in addition to answering the question asked, Dr. Miller should have answered some others that were not asked? If he had, as you suggest, answered with regard to section-holder supers, then those who use some other kind of supers would expect answers, and his effort is to answer the questions asked, and not all the different questions that a number of others might ask but have not asked. You are surely in error in thinking that answering all these other questions he would have answered "more to the point." He answered specifically, and directly to the point, the question asked, and the way is open for any one else with any different questions to send them in without expecting Dr. Miller to anticipate them.

The delay in getting into print the reply to your letter (which is learned from your letter to Miss Wilson, which she has sent in with reply to part of it) is greatly to be regretted. It is an unusual, perhaps unparalleled case. Dr. Miller is always as prompt as possible, and it is a rare thing that he does not send answers within a week after receiving the questions.

Replying directly to your question, and basing the answer somewhat on the answer Miss Wilson has sent in, an average hand, under average circumstances, might be expected to clean something like 1000 sections a day of sections from section-holders.

It is to be regretted that you did not explain what you mean by the outlay for honey-

boards to be used with T-supers, for at least Dr. Miller does not use honey-boards.

With regard to changing to T-supers, you should not forget that there are those who dislike them as much as Dr. Miller likes them, and he would probably advise that you go slow about changing till you know they would suit you. It is possible, too, that the supers you have might be changed to T-supers. Whether this be so or not depends upon the measurements of the super you now have. If you should think of making any such change, it might be worth while to give Dr. Miller the exact *inside* measurements of the super you have, and you may rely that he will take pleasure in advising what may be done in the case. Also he should know the kind of sections you want to use in said T-supers.

### Carnegie and the Bee

Carnegie is reported as saying in an address:

"Don't interfere with the bee when it is making honey; but when it is through, take a big share of the honey."

Which is equivalent to saying: "Don't interfere with a man like Rockefeller, when he is accumulating a 'swollen fortune,' but when he is through with it let an inheritance tax take a share of it."

That's hardly fair to an honest bee, which doesn't get its honey by trickery from other bees, but by honest toil, leaving the way entirely open for other bees to do the same.

### A New Kind of Bees (?)

When the voracious reporter can find nothing else to romance about, he betakes himself to the "busy bee." The latest is a clipping sent by Irving Long, with the comment:

EDITOR YORK:—Notice the new kind of honey-bees. How much some folks know, that they don't know at all. Notice how he introduces his bees. Seems to cross the workers of one kind with the workers of the others. Guess he has hold of some hornets.

IRVING LONG.

The clipping, which has also been kindly sent to us by others of our readers besides Mr. Long, reads in part as follows:

Captain John Holder, who lives in a cabin in the Arbuckle Mountains in Indian Territory, believes he has discovered a new kind of honey-bee, and he is trying to cross it with the ordinary bee.

"It is a strange mongrel honey-maker. They appear to be a mixture of gray coated bumble-bees and yellow-striped honey-bees. Most of them are as large as Italian queen-bees. They gather honey and deposit it in honey-balls in holes which they excavate in the ground. The honey-balls, or sacks, consist of a waxy substance, and are about as thick as morocco leather. Nearly every sack or cell contains about a half pint of the sweetest honey imaginable.

"I have been experimenting with the new-found honey-gatherers. I have been trying to tame them so that they will mix and live with my civilized bees. The new-comers are curiously inspected by the old settlers in the hollow stump or bee-gums. Often a terrific battle takes place. Then, very often, the aristocratic bees enter into amiable relations with the new-comers by letting them crawl into their hives. I am watching this cross-breeding process with keen delight, and will continue to introduce as many of the mongrels as I can capture. I think that, like Burbank in the vegetable kingdom, I may

succeed in producing a new and more profitable honey-bee than is yet known to the world."

Ought not the Government to take hold of this matter? But instead of trying to cross these bees with every-day bees, why not keep them in their purity? Then, instead of fussing with sections, extractors, etc., the honey might be sold in "original packages"—half-pints. Could these bees not be trained to have their holes in the ground in straight rows? Then one could in the fall plow out the balls of honey.

### "Please Answer in Next Number"

That request is not infrequently made by those who send in questions to be answered in "Dr. Miller's Question-Box," a request not often easily complied with. It takes time for a letter to travel through the mail, time to write the answer, time for the compositor

to set up the type, time for an edition of the paper to be gotten ready for the mail, and time for the paper to reach its destination.

Then, too, it must be remembered that the time in the week has something to do with it. A letter may come just in time to get in with a certain batch of questions, and another letter, not 12 hours later, may have to be answered in the issue of a week later. It is the constant effort to have questions answered as soon as possible, but from the foregoing it will be seen that an answer in the next number that appears after mailing a question is asking a good deal of speed.

It is well that questions be sent in as early as possible, for sometimes a question is sent in urgent haste which could just as well have been sent in a month earlier. Also it may be well to mention that when a question is sent direct to Dr. C. C. Miller, Marengo, Ill., it stands a chance for an earlier reply than when sent to this office.

**Mr. Victor's Bear-Wrecked Apiary** is pretty well shown on the first page. Sir Bruin's picture was also taken as he reclined with head on a bee-hive. It was the last apiary that bear ever helped to ruin.

But what awful devastation was made of it! If an earthquake had shaken up that apiary it could hardly have presented a more complete wreck. We didn't suppose there were still any bears in the bee-keeping part of Texas, but it seems there are. But there was at least one bear less after Mr. Victor's apiary of some 50 colonies was destroyed.

Being lovers of honey, it is no wonder that bear meat is so good to eat. No doubt Mr. Victor and his friend enjoyed eating that particular lot of bear steak.

We thought our readers would like to see what a big, healthy bear can do to an apiary when he does his best, hence the picture we have reproduced.

**Mr. Smith and Black-Carniolans.**—When sending us the picture on the first page, Mr. Smith wrote thus:

EDITOR YORK:—Most bee-keepers think that the black-Carniolans are worthless, so I am sending you the picture of a colony in the act of finishing 132 pounds of honey, which you will see is in the sections. My honey retails for 25 cents a section, thus making \$33 for this colony. Counting the stings I got at a cent apiece (which I think is remarkably low), they would be worth \$50 more. But when I want a "good scrap," I stir up my pure Italians. I can almost bear Dr. Miller say, "Serves you right for trying to handle bees while dressed in black." But if he could see the way they jump on, and try to puncture, those white buttons, I think he would be willing to try some other "medicine."

L. A. SMITH.

Flathead Co., Mont.

**Dr. Bohrer and His Bouquet.**—One of the beautiful things connected with the National convention in San Antonio, Tex., last November, was the general good feeling everywhere apparent between those of the South and of the North. Dr. G. Bohrer, of Kansas, who was not only one of the oldest bee-keepers present, but who also had been a federal surgeon in the Civil War, spoke such fraternal words of greeting at the opening of the convention, that many hearts were touched, and the result was that the following morning Mrs. Krebs presented the Doctor with a large bouquet of flowers. These were prized so highly that they were taken to Dr. Bohrer's Kansas home and photographed as shown.

So far as bee-keepers are concerned, "the war is over," and has been over for a long time. It may still exist in the overheated minds of certain politicians, who think they must ever be stirring up discordant memories in order to win, but to the peace-loving bee-keepers of our country this is an undivided nation, and they will stand united for its highest progress and strongest defense.

**Fillmore Co., Minn., Convention.**—This is reported as follows by the Secretary:

The 5th annual meeting of the Fillmore County Bee-keepers' Association was held at Preston, Minn., Jan. 25 and 26, 1907. The meeting was a very interesting and harmonious one throughout. Ever since it was organized its members have been getting supplies at wholesale rates. At the time of its organization no one had an idea that a car-load of comb honey was produced in this section of country, but in the fall of 1905 a car-load was shipped from Harmony, and in the fall of 1906 two car-loads were shipped, one

from Harmony and one from Canton. But owing to a wide range in prices paid by the men who gathered the honey up for car-load buyers, and for other reasons, there was dissatisfaction among the honey-producers.

At this meeting the constitution was changed, and an executive committee of 3 were chosen to act as financial agents in buying supplies and selling honey for the Association; and a strong resolution was passed binding its members to sell through this committee direct to car-load buyers.

If the bee keepers would unite, and cooperate in buying supplies and selling their own honey direct to buyers of car-lots for cash, many more such associations could be formed throughout the country, and the members would realize much more profit in bee-keeping.

P. B. RAMER, Sec.

**Bee-Keepers' Meeting at Yorkville, Ill.**—The afternoon of Jan. 30, some 30 bee-keepers held an informal convention for about 2 hours, at Yorkville, Ill., the discussions being led by C. P. Dadaat, ex-President of the National Bee-Keepers' Association. His part was principally answering questions along practical work in the management of bees. The questions discussed were mainly

these: Wintering, with special reference to comparative merits of cellar and outdoor; stimulative feeding; prevention of the depredation of bee-moth; the use of shade-boards; bee-pasturage, and incidentally the distance of bees' flight; and other subjects of minor value. The discussions were pretty generally participated in by those present. There were quite a number of ladies present also, some of whom are, or have been, bee-keepers.

After the question-box it was found to be the desire of some of those present that a local association be formed, and 8 gave their names. Officers were elected as follows: President, Geo. Elliott, of Yorkville; Secretary and Treasurer, Robert B. McCain, of Oswego, Ill. The time and place of the next meeting was left in the hands of the officers.

In the evening Mr. McCain delivered a lecture on "Bees and Bee-Keeping." It was a larger gathering, and all were interested. There was also a program of music furnished by the Yorkville people.

No doubt more will be heard from this new organization later on.

In the above I have given the essential features of the wide-frame super, which may answer some of the objections raised.

It is immaterial which way the section is placed in the wide frame, the lock-corner up or down. With the T-super it must be used "up," although Miss Wilson wants the weak corner (lock-corner) down.

I infer that the bee-glue in Marengo is of a greasy nature and cleaves off; here it sticks "to beat all." The trouble and difficulty of taking the full sections from the T-super lies in this stickiness of the propolis. It cements the tin to the section, and can not be persuaded or forced to let loose. Usually the bottom of the section comes with it, and often the T's get out of shape. When a T is used on the top and bottom, as Mr. Armstrong prefers, then the trouble is aggravated. I know of no more successful method to cement a lot of sections together than by using T-tins at top and bottom. Other bee-keepers hereabouts seem to have found this out long ago, judging from the east-aside T-tins and T-supers I have found in my travels. The best use some could find for the latter was as "Cucumber boxes" in the garden; for this use they are too expensive, although they protect the cucumber plants, when netting is thrown over them.

No matter how badly a wide frame is propolized, the filled section can be pushed out, whether the propolis is hard or soft. The section moves over the wood of the wide frame as the two blades of a pair of shears work, and the glue is "cut." But when you attempt to "lift" the T off from a block of sections, as Miss Wilson says, and does, it is like pulling an adhesive plaster from one's back. The skin lifts up with it, so also does the bottom of the section when one tries to lift the tin. For that reason I want the lock-corner up in a T-super; the strongest part is needed at the bottom. In the shipping-case I may place the sections as I please. If all honey is sealed one may place them either side up without bad result. I do not need to use full sheets of foundation and bottom-starters to accomplish well-filling, and sealing of sections, either.

I am well acquainted with Dr. Miller's Editor Hill's, and others' method of taking the honey from a super *en masse*. Even if we are not inventive, we read. It is an old practice and we know all about it. A great many things are not mentioned by writers because they think everybody ought to have sense enough to do things in the best manner according to existing conditions. What may work well with one may not work at all with some one else, and I expect these discussions will bring out minor points overlooked before, and not mentioned.

The different supers I have in use which leave the tops of sections exposed (including the T-supers) I have always tried to clean on top with a scraper, like the one mentioned by Miss Wilson and Dr. Miller, and considered it a matter of course. By the way, this scraper is the very best thing to clean wide frames, wood-separators, hives, and supers. I have them in each bee-yard. One can

## Again the Wide Frame vs. the T-Super

BY F. GREINER.

It had been my intention not to say any more on the subject of T-supers vs. wide-frame supers, but since many of my friends hold that, as matters stand now, the wide-frame has received "the black eye," I will once more defend the super which I use.

The wide frame consists of 4 pieces, as follows:

1. The top-bar. It is of the width of the narrow parts of the sections used. A thickness of  $\frac{3}{8}$ -inch is sufficient. It projects over the ends of the frame like a regular brood-frame and hangs in a rabbet.

2. Two end-pieces. They have the width of the wide portions of the sections used, and should not be less than  $\frac{3}{8}$ -inch thick—perhaps  $\frac{1}{2}$ -inch would give a better chance for nailing, but in my own supers I could not very well use them thicker than  $\frac{3}{8}$ -inch, so I have been content to have them thus, and I can assure you that there is no trouble about these frames giving out anywhere. I should judge they might outlast several generations of mankind with fair treatment. When getting out the ends of wide frames, I select the best timber—a medium-hard variety like whitewood or chestnut, if possible, although I have many in use made of butternut, basswood, and pine. By careful nailing with long cement-coated

nails, the frames are made as rigid as if they were all in one piece. There is no tinkering needed ever after; this in answer to what has been said by others as to the frailty of the wide frame. Of course, a *section-holder* lacking the top-bar must of necessity be weak, or at least weaker.

3. The bottom-bar is of the same dimensions as the top-bar, except being shorter.

When these 4 pieces are nailed together properly by the help of a nailing-block, such as I illustrated years ago in different bee-papers, we have a frame that is all right.

A separator may be nailed to this frame, or it may be so arranged as to hang between the frames just like a frame. The latter arrangement would have some advantages. The Betsinger wire-screen separator-super makes use of this feature.

The wide frame can also be adapted to the no-bee-way sections. I use both kinds.

There must be room enough in the super so as to have a space at one side for keying up. Wedges, springs, or screws may be used to tighten the frames and to take up the slack. The closer they come together the better. Of course, proper bee-spaces must be preserved where necessary. If there is room enough a Pettit double bee-space may be had at the sides of the super. The separator should be as wide as possible and still allow the bees freedom to pass from section to section.

# American Bee Journal

make them out of a worn-out cross-cut saw. Grind them on the grindstone occasionally and have the edges straight and square. I want half a dozen of them in the honey-house, then when we are ready to prepare supers for another season, we make "a job" of it. Boys and girls, and other cheap help, can be set to work at once, and in a very few days we have everything clean. Wood-separators may be cheap, but they may be cleaned much cheaper, and are fully as good then as new ones.

Now, while I think the cabinet-maker's scraper is a good thing, it is of no use to me when fitting honey for market from wide-frame supers. A sharp knife answers much better, although I have tried other devices as they have come up from time to time. I must, however, confess that I can not come up to Miss Wilson. I consider 20 to 25 cases (of 24 sections each) a fair day's work, putting in 10 hours a day. I think if Miss Wilson had wide-frame supers, she might clean and crate in the neighborhood of 5000 sections per day, working with the same swiftness and putting in as many hours as she does.

If I were to use supers which did not protect the sections "all around," I would surely make use of a sand-paper-belt or machine, because no matter what other tool is used in freeing filled sections from bee-glue, it is not possible to make them look very nice when they are as badly daubed as a large portion of mine are, or have been, while I had them in.

I have always wondered why the tops and the bottoms of bee-way sections were made as narrow as they are. I fail to see why they were not made as wide as possible, and still give ample room for the bees to enter them. Suppose we make them just  $\frac{1}{8}$ -inch narrower than the sides, there would be  $\frac{1}{4}$ -inch plus the thickness of the separator between them. If we now let the separator come within  $\frac{1}{8}$ -inch of the upper surface of the bottom and lower surface of the top of the section, no matter what the thickness of the section may be, there will be sufficient room for the bees to pass and enter without any danger of the bees building through under or over the separators.

A wider bottom of the section than is ordinarily given protects the honey in the shipping-case and while handling it, and also acts as a queen-excluder—not absolutely, but it tends that way.

Mr. Armstrong misunderstood what I meant by "bees crowding bee-glue in between the top-bars and sections." While this is a bad feature of the wide frame, I want every one to understand both the bad and good features. Dr. Miller knew well what was meant, which is apparent from his answer, but Mr. A. has not used the regular wide frame. What I referred to is this:

When the sections sag a bit, as they do sometimes with weak bottom-bars, they drop away from the top-bar of their holder and there the bees chink the glue into the space thus formed. This sagging has as a sequence "diamond"-shaped section honey. Under no consideration would I attempt to "square" them to make them go into the shipping-cases,

no matter how "warm" they might be. No, don't try it! Crate them as they are. Make room for them in a shipping-case, somehow.

Naples, N. Y.

## Home Made Hives, Supers, Etc

BY EDWIN BEVINS.

With an experience somewhat like, but in many respects different from that of Mr. Greiner's, I feel constrained to enter a protest against the tone and intent of his article on page 963. The article was evidently written with a view to discourage all but a very limited few from the attempt to make their own bee-hives out of any material, and especially out of the material to be found in dry-goods and grocery boxes. It is no doubt true that there are many bee-keepers, and others who would like to become such, who would do well not to try to make their own bee-hives. I will not do any one of this class the possible injustice of supposing or insinuating that the reason why he should not try is because of a lack of intelligence. There are other reasons, which the imagination can easily supply, why some men should not try to make their own bee-hives.

But there is a large class of bee-keepers who ought to make their own bee-hives, and should be encouraged to do so, because they can save themselves much money if they are needing many hives, and have some time not taken up by other pursuits. It is for this class of bee-men who are using the single-wall hives of the 8 and 10 frame dove-tailed size, that this article is most particularly designed. Many of the suggestions and much of the advice I think may be found of use to the users of many other kinds of hives.

Since the commencement of my bee-keeping days in the early '90's, I have made more than 200 hives and the supers for same. When I began to make my own hives, I bought lumber at the near-by lumber yards, but since making the acquaintance of the much-despised grocery and dry-goods box, I make use of it altogether, not only for hive-bodies, but supers, covers, bottom-boards, shipping-crates, and many other purposes.

I believe that Mr. Greiner belittles his own ability when he says that he can not make "something out of nothing," which, interpreted, means that he can not make a good bee-hive out of grocery and dry-goods boxes. I feel quite sure that Mr. Greiner can do it if he will. I know that I have done it myself, and what I have done I am reasonably sure that lots of other men can do. I have hives made from the material found in goods boxes, that are as good as any of their kind that ever came from any factory, and at much less cost than the factory-made hive. Some hive-bodies have been made at a cost not exceeding 5 cents each for material.

Mr. Greiner lays great stress upon the difficulty experienced in getting lumber of uniform thickness out of that supplied by the store-box. How much of the lumber in a hive needs to be of

uniform thickness? The hive-bodies and supers. I never found any difficulty in finding enough of uniform thickness for these. A few shades difference between the thickness of lumber for these and that for bottom-boards and covers cuts no figure. Reasonable accuracy in the make-up of a hive is desirable and necessary, but the bees will be no more comfortable and will store no more honey in a hive, the architecture of which is ideally perfect.

I make a good many hive-covers for 8 and 10 frame hives that are of one solid piece of board with cleats projecting downward at each end, and have no reason to find half so much fault with this kind of cover as Dr. Miller does. Anyhow, I will venture to advise the man who finds some good boards in his store boxes that are wide enough for the purpose to utilize them for hive-covers. He will often be surprised at the little they have cost him. In the absence of this kind of cover, obtained from the source mentioned, I would make covers with dead air space as mentioned in the book, "Forty Years Among the Bees," with this difference: I would have cleats at each end projecting downward. These cleats are an abomination to the Doctor. The absence of them is an abomination to me. I can handle covers just as fast with them as without. I do not have any covers blow off, and I do not have to hunt up weights to hold them on. The material for these covers is generally to be found in store boxes, as much  $\frac{3}{8}$ -inch thick lumber is used to make the sides of the boxes. As the material for such covers does not cost any appreciable sum, one can well afford to cover them with tin or zinc.

Dummies, division-boards and telescope covers may also be made from the box-lumber we are discussing. Read "Forty Years Among the Bees" and learn how to make a dummy. The dummy or division-board we get from factories is too frail a thing ever to have been born into this rough-and-tumble world of ours, and should be relegated to the rubbish heap along with the  $\frac{1}{2}$ -inch square bottom-bar, and some other things easy to mention. I make many dummies out of  $\frac{7}{8}$ -inch lumber sawed with projections at the upper edge for the support of the dummy. No need to nail on a top-bar.

Box-lumber can also be used very satisfactorily for shipping-crates for comb honey. Get the measure for your crate in this way, if you want a crate for 8 shipping-cases: Place 4 cases on a level surface and another 4 close beside the first 4; measure length, width, and height; make allowance in height for at least 4 inches of hay in the bottom; make allowance in measurement for top-frame to take in boards used for sides and ends of crate. I crate my honey so that no glass is exposed, and find it gives best satisfaction.

What I have written has reference to bee-keeping and bee-keepers as they are found under existing conditions. I will modify that by saying that I have written not for the specialist, but for the man with a few colonies, and from that to the 100 and 200 colony man. What I have written is not intended for the age of bee-keeping when the pursuit

# American Bee Journal

has fallen into the hands of the specialist, and bee-keeping territory has been divided and subdivided, and placed by legislative enactment under the specialists' control.

There was an old English worthy (was his name Sir Phillip Sidney?) who went in search of Utopia. I have not heard that he ever found it.

Leon, Iowa.

## Lower Freight Rates on Honey

BY W. H. PUTNAM.

To my mind the most important subject that has recently come up for discussion among bee-keepers is that of better freight-rates on honey.

Mr. Fred W. Muth sprung it on the San Antonio convention, and a committee consisting of Mr. France, Mr. Muth and Mr. Hlekamp, was appointed to go before the various classification committees of the railway rate board, to present the matter. I have had some experience in seeing the rate men, and it is a well-defined habit of railway people to charge all the traffic will bear. It will be necessary for that committee to emphasize the fact that the bee-keepers cannot afford to pay the rates now in effect; that the present rates are keeping men out of the business. It might also be well to point out the fact that honey can be, and is being, shipped in large quantities from Honolulu to the central United States for less money than honey can be shipped from various places in the United States; that Cuban and Jamaican honey is filling the place which the domestic honey should fill.

I have several times been before rate men, and invariably the first question they ask is, "Where is your competition?" The bee-keepers have a good chance now to send this matter home.

Rates on supplies are sadly out of line, also. There are many instances where the freight is greater for a shorter haul than for a longer haul. For instance, Reno, Nev., located on this side of the great range of the Rocky Mountains, pays \$1.15 per 100 pounds in car-loads; while the same road will pull the freight over the same ground and up over the mountains 800 miles farther (to San Diego) for 85 cents per 100 pounds.

Again the rate to southeastern States—Georgia, etc.—is greater than to Cuba or Jamaica.

There is a certain amount of educational work to be done in two directions. It seems to me that we should first educate the bee-keepers to pack their honey in carriers (I mean comb honey). It is the poorly packed honey that goes to pieces, and leaks and daubs the cars, and spoils other goods, that gives the whole honey the bad reputation.

I know that many bee-keepers do not read the bee-papers and that it will be impossible to reach them through that means; but touch a man's pocketbook and his heart is yours, every time. This committee has the best chance in the world to educate the bee-keepers through the pocketbook.

Let the committee point out to the rate people the difference between the risk in handling honey put up in carriers and that shipped in supers. Make a recommendation for a higher rate on

the latter, and a lower rate on the honey packed in carriers; and the expense will fall where it belongs—on those who are too ignorant or too stupid to learn.

River Falls, Wis.

Conducted by LOUIS H. SCHOLL, New Braunsfels, Tex.

## First Bee-Keeping in the South

Grandfather and I have been keeping bees in the South for 91 years; counting the period that my great-grandfather, kept bees it would be over a century, and perhaps the first days of bee-keeping in the South. Arriving here from across the waters, and prospecting a few weeks, he wrote back that he was satisfied, and thought that he could raise potatoes, corn, and tobacco, and from the amount of blooms he saw, he thought he could "raise" honey, too, but could not find any bees, and when he sent for his wife to come over to him, he wrote her to bring along one colony of bees. But she did not succeed in getting here with them, but when her parents paid them a visit a few years afterward, they succeeded in getting over with a small colony and he established the first apiary in the South on the Savannah River, between Savannah and Augusta, Ga.

The hives were made of hollow trees, which, by the way, is a quite prevalent method in some localities here yet. The bottoms of the "gums" were beveled off with an axe so that the bottom edge was nearly sharp; the gum would not decay so soon at the bottom in that way, and would give better access to the insects which were supposed to go in mostly around the bottom. The inside of the gum was cleaned out well, and made as smooth as could be, with an axe. When the bees were hived in these gums, they were set on a block (a short cut of a solid tree sawed off 10 or 12 inches long), and another of the same dimensions was laid on top for a cover, for lumber was not yet sawed here.

Many are the stories handed down, of the Indians and this apiary, for they seemed not to have any knowledge of bees. On one occasion, my great-grandfather left his wife in his cabin, which was a small log-house with the earth as a floor and furnished with 2 one-legged beds and 2 cooking utensils, a frying pan, and a skillet. He had not been gone long down the river in his dug-out for the boat-landing, when an Indian all at once appeared in the cabin for no other purpose than to steal. Looking up at the frying pan as it hung on the wall, and nodding his head a

few times, he took it down. About this time the dog came to the door and the Indian made friends with him and tied him. Going out the door, he saw the ax, and nodding at that a few times, he picked it up and started off with dog, frying pan, and ax, but stopped at the bee-hive. Nodding his head a few times again, he undertook to satisfy his curiosity by prying the top off, and, of course, the bees responded actively. Passing his hands over his face a few times as if he were washing it, he clutched his hands in his long dark hair, gave a few loud whoops, and disappeared as he had appeared, but leaving his stolen goods.

Many times the bees in this apiary died out, but by this time there were some bees in the forest, and they kept drawing from it for "starts," and soon others had "starts," and so on. There was no market for honey, but if there was any left after all the settlers around had had what they wanted, it was carried to boat-landings and exchanged for such things as they needed.

Grandfather fell heir to the apiary at his father's death, and he kept it up for years, receiving good returns, and was perhaps the first shipper of honey to many of the large towns.

He said there was one great drawback to the progress of the bee-industry in his best days as a pursuit, and that was, the combs were not movable, so as to give access to the needs of the bees; and, when lumber was being sawed, he decided to overcome this if possible. He bought some lumber, made some hives, and tried to make the frames from good splitting timber, but was not successful. After many efforts for several years, he gave up and went back to box-hives, but always had a large, well-cared for apiary of this style of gums.

Cordele, Ga.

J. J. WILDER.

How different early bee-keeping must have been from that of today! Who could imagine the life of a bee-keeper with the "red man" all around his apiary and his home, and the old-style "log-gums" for hives? We are glad times have changed, and a narrative like the one here presented, only makes the readers of the present time feel more grateful for the bee-keeper's life we are enabled to live now.

# American Bee Journal

It is amazing how few people know, or even stop to think, that our honey-bee is not a native insect of North America, but that it was imported to our continent. Hence it is that honey-bees were regarded as strange creatures by the native Indians. They called them the "white man's fly," and as the swarms spread on in advance, civilization follows. Thus, as the Indians found bees upon their hunting grounds, they left them and moved further west, knowing that the white man would soon follow.

## A Visit to Bee County, Tex.

On April 17, 1906, I presented myself to the transportation Company here for passage to the bee-paradise of Texas. At 2:15 p. m., I boarded the cars and soon was speeding southward, amid varied scenery, ranging from the best cultivated fields of cotton and corn to the most dangerous-looking prickly pear wilderness. Ere long we were flying through a perfect wilderness of mesquite and other shrubbery. Soon cat-claw and other honey-bearing plants began to appear. The further south we went, the more luxuriant the growth became. A sickening sensation betook me as I beheld the wonderful waste of nectar on every side, while I had to keep a honey or sugar cup under my bees' noses to prevent extermination by starvation.

At 4:30 p. m. I arrived at my destination in Bee County. I knew but two men in the town, Mr. W. H. Laws and Mr. Will Atchley. As I had come a day sooner than I had intended they did not expect me. Not knowing what better to do, I started to walk about the city and presently ran upon Mr. Will Atchley's factory, where he had a good force of men busily engaged cutting beehives. After a short chat with Mr. Atchley and his wife, I went on to see Mr. Laws, the terminus of my trip. I found him running his factory on full time and making hives and other accessories for home use and for the public. It is unnecessary to tell how glad two bee-men are to meet each other, and how each of them is ready to divulge a superabundance of knowledge that has never been told before! and how each wants the other to listen while he propounds his superior knowledge and methods! So both of us had more to talk about than we thought, and passed the evening very pleasantly.

The next morning, after Mr. Laws had shown me around his home place, we started for the apiaries, which are located from 5 to 30 miles from his home. He has 21 apiaries located in and near the Nueces Valley. His apiaries have 1300 colonies of bees, a few of which are in partnership. We started in a westerly direction amid a most luxuriant growth of mesquite, cat-claw, blue sage, etc. After we had traveled about 2 hours, we arrived at the top of a hill from which we could see 7 of the apiaries. Mr. Laws is a bee-man of the first magnitude—born a bee-man, I'm sure, and could not be otherwise. Presently we came to immense patches of wahea bushes in full bloom, and plenty of cat-claw, inter-

persed with horsemint, mesquite, and other honey-bearers.

Now we were near the yards, and Mr. Laws' watchful eyes scanned all the flowers to see if bees could be seen on them. Soon they became plentiful, and soon we drove into a bee-yard that Mr. Laws calls "Lower Burk." This yard was torn all to pieces for queen-breeding purposes. These were Italian bees and we found many queens of all ages, and caged a few.

Next we drove to the Holy Land bee-yard for some examinations, and to catch some queens. Mr. Laws claims the distinction of having the largest Holy Land yard of bees in the United States. After catching a few queens and one swarm of bees, we spent the rest of the day visiting other yards, and catching a few queens, making examinations, etc. We spent the night with a hospitable family, after which we started back, visiting other yards and catching more queens, and arrived at town

shortly after nightfall, about one hour before my train was due, on which I was to depart.

Mr. Laws is one of the United States' best queen-breeders. He has about a half-dozen strains of bees in different yards and sold in the neighborhood of 2500 queens last season, falling far short of orders. He is a very conscientious, Christian gentleman, and always tries to furnish the best to be had. He has his bees located in 3 circuits from his home, which comprise a travel of 130 miles to visit all the yards. There are a few bees kept at home and at Goliad. The last 2 or 3 years have not been at all satisfactory for honey in this locality, but excellent for breeding and queen-rearing.

Among the excellent plants for honey, we list the following: Blue sage, cat-claw, wahea, currant, mesquite, horsemint, rock-brush, white-brush, cleome, broomweed, and "knockaway."

T. P. ROBINSON.

## Report of the Michigan State Convention

REPORTED BY R. F. HOLTERMANN

(Continued from page 112)

Mr. E. D. Townsend, Michigan's most extensive bee-keeper, read a paper on:

### LOCATIONS AND LOCATIONS OF BEE-YARDS

Locations, from an apiarian viewpoint, in Northern Michigan are an uncertain quantity (what I mean is a location that will support say 80 or 90 colonies, spring count, and produce a surplus of 60 or 70 pounds of extracted honey, year after year); for in our great and beautiful State, occasionally we find a location that would hardly pay from a dollar-and-cent view, to keep bees. Generally speaking, Michigan is very broken. There are inland lakes whose waters sparkle in the sunlight, where the pike, bass, and perch are in their element. Innumerable hills, dales, creeks, and rivers, add variety to the landscape. Then there are the marshes made fragrant with their asters and bone-set; and last but not least, the beautiful goldenrod. The soil varies from the veritable sand-dune to the most productive and richest loam the world ever produces. But the soil is only one of many things to take into consideration when looking for a bee-location. While I know several fine locations in old, fertile, well-cleaned-up sections, the better ones are in a rather newer and broken country, where the land is not being cleared off for farming purposes.

These conditions are more likely to be found in the northern half of lower Michigan. While there are some fine locations in the lower part of the State, that produce good crops of honey, they are farther apart, and not so sure of a crop, as farther north in the white clover and red-raspberry districts. I suppose most of those at this convention keep but one yard of bees, and that one right where Destiny has dropped them down, either on the farm or on a city or village lot, and, in this case, the only alternative is to find out how many bees your location will support, and when you have acquired the number of colonies. So, with fairly intelligent handling, your surplus falls to say 40 pounds of comb or 60 pounds extracted honey, in an ordinary year. This, in the opinion of the writer, would be the low-water point of a profitable surplus. What say you, members of the convention?

But we will suppose you are established in a location where bee-keeping does not pay. Perhaps you own a farm, or otherwise it is not desirable to move to a more productive honey-location. In this case the out-yard will solve the question. And right here comes in one of the most important parts of successful bee-keeping, and that is a good location. The great benefit derived from the out-yard is that one does not have to accept any location he may happen to be in, but can go to the best location he knows of and establish his apiary. Of course, it would be convenient to have one's bees as near home as possible; but put them into the best pasturage you know of, even if it is a day's ride by rail between yards.

The best location the writer knows of in the southern half of lower Michigan, is a heavy clay soil. This heavy clay is especially adapted to the raising of clover-seed. Especially would I look for a location where alsike clover is produced for seed. Then, if one could find a place as above, that included quite a quantity of basswood timber, it would make the location somewhat better, although basswood is not a very sure yielder here. When everything is favorable, it does not require a very large tract of basswood timber to produce a nice lot of surplus honey.

Then, in *this* immediate location, and farther north, the wild raspberry and white clover produce our surplus. In looking for a location in the white clover and red raspberry districts, as we have to do in this location, don't forget the raspberry, for I am convinced that much of our supposed clover honey is  $\frac{3}{4}$  wild red-raspberry. Further north, in the hardwood slashings, wild raspberry is practically all there is to look for, and this same wild raspberry is our surest and best yielder. This raspberry is in every way, equal to clover; that is, what is produced on the light sandy loam of northern Michigan. Raspberry honey from the southern counties of our State, on the heavy clay soil, is of an amber color, and can't be compared with our beautiful white honey from the north.

Another point to be considered in locating apiaries, is buckwheat. It does not produce any surplus in lower Michigan, but in favorable seasons yields well when grown on our sandy, loam soil in this locality and farther north.

Now, next to the importance of a good location is a sheltered nook in which to place our bees. Our best outside protection is secured by going into the woods and clearing off an acre or so to put the bees on. This outside protection from the cold spring winds allows our bees to build up much earlier in spring, so as to be ready for the surplus season in June. If one's yard is already located, and it is not desirable to move them to a sheltered place, the next best thing to the natural protection mentioned above, is a high, tight, board fence, 6 or 8 feet high, on the north, east and west sides, leaving the south open. While this is not so good as the natural protection mentioned above, it helps a good deal.

As to the benefits of outside protection, I do not think I can do better than to tell you of the experience of one of our members, Mr. Geo. H. Kirkpatrick. Mr. Kirkpatrick's home yard is in, or was when this experience taught him the value of outside protection—in an unprotected location. The experience was as follows:

A year ago last spring he moved about one-half his home yard to a well-protected location, 3 miles from home. The colonies were not selected, but were taken at random from his home yard, and were all wintered in the same repository. The fact was, the bees were the same when moved, and the location also the same. The results were that the protected out-yard built up strong and were in so much better shape at the opening of the season that they

filled an upper extracting super with honey before the home yard was strong enough to need an upper story, and they kept this upper story ahead clear through the season. The figures would be something as follows (we will suppose the number was 50 colonies): One 8-frame upper story each 40 pounds; that would be 2000 pounds of extracted honey, at 8 cents, or \$160 from 50 colonies in one season, all credited to outside protection. E. D. TOWNSEND.

S. D. Chapman stated that one should be careful as to conclusions. He mentioned a case where, in one locality, from maple cut during the winter, the bees were able to get an abundant supply of maple sap in the spring. These built up into fine shape and were much heavier than another apiary otherwise similarly situated.

Mr. Kirkpatrick stated that he had an apiary in an old, settled district where bees did not have a chance to build up on maple sap from maple timber cut the previous winter. The apiary was located on a spot with only a few rods cleared in standing timber. It was excellent.

A discussion followed on the length of time one raspberry patch would be of use. The facts appeared to be that one patch would exhaust itself in 6 or 8 years; that unless a fresh piece of timber was cut where fresh raspberry canes would spring up, and such a location was the desirable one, the location would be exhausted for raspberry honey. If, however, the patch was burned off in the spring when the ground was wet, a new growth would spring up; but if the fire took place in summer, or when the ground was so dry that the black soil would be destroyed, then neither raspberry nor anything else would spring up.

#### PRODUCING RIPE HONEY.

Mr. Holtermann gave an address on ripe honey. Not enough attention had been paid in the past to having the bees ripen and evaporate the honey. What was known as an inferior-soured honey, if well-ripened, was really a more desirable article, if left to the bees until capped, than the better grades taken away when thin and unripe. A bee-keeper that sold the latter required constant exercise of new energy to get new customers.

Mr. Chapman thought that the bees added something to the comb as they built it, which gave the honey stored in fresh comb a different flavor.

Mr. Holtermann stated that it might be so, although he had never noted the difference.

Pres. Hutchinson said that he had heard that the best honey is secured by giving the bees foundation to build out as they stored, and that such honey would be of a better quality than that taken from previously-drawn comb. He thought it might be because the comb was drawn out while being filled by the bees, and that the honey would evaporate better.

#### FOUL BROOD.

Pres. Hutchinson gave a very able address on foul brood, dealing with a sample he had, so that every one in the room could get thoroughly acquainted with the disease. He also advocated more inspectors for Michigan.

Mr. Walker said that every township should have an inspector, as they had it for the "peach yellows." Foul brood in the State was very wide spread. This appeared to be the general opinion, and steps were taken to endeavor to get a much larger number of inspectors, and a larger grant for the purpose. Mr. Hutchinson, the present sole inspector, led in the move for more men.

#### EVENING SESSION.

The evening session was held in the fine Court House, a thorough credit to Big Rapids, and to the kindness of its officials in putting it at the disposal of bee-keepers. Also a credit to the energy of the Michigan State bee-keepers, and no doubt in no small measure to Mr. Geo. E. Hilton, resident in the locality.

Mr. Elmore M. Hunt gave a demonstration in handling bees in a cage. One or two bees acted as if they had been feeding on plum-pudding or mince-pie the day previous to going to sleep (it was Dec. 26), but the demonstration was entirely successful and no doubt would have interested a much larger audience than the one present.

Thus closed a very successful convention with high hopes in the bee-keepers' breasts that the next Michigan State convention would be held in union with the National, at Detroit.

The "Old Reliable" as seen through New and Unreliable Glasses.  
By E. E. HASTY, Sta. B. Rural, Toledo, Ohio.

#### TESTING VARIOUS RACES OF BEES

If Prof. Scholl is to run a dozen test apiaries next season, and give each of

the current races a test, we shall look for those "reports later" with decided interest. He seems to contemplate only one kind at a location—good for

# American Bee Journal

the most part—but one out of the dozen ought to be Caucasians and Italians, half and half. Only way to bring the former exactly “to book” in the important item of honey-storing. Not absolutely necessary that they should quite equal Italians, but we want to know just where they are at. Page 1051.

## TIME SPENT IN OVERHAULING COLONIES.

So C. P. Dadant has seen bee-keepers who would spend 2 hours overhauling half a dozen colonies. I have seen one such—in the looking-glass. But I guess we won't quarrel much. The aim of all should be to have things in such a condition that the needed manipulations need take but a few minutes. Don't spend 2 hours over 6 colonies when 5 minutes for each might just as well suffice—unless you are overhauling for fun or for self-educational purposes, and then the 2 hours are all right. I was steering toward the remark that the good theory and the actual practise sometimes get wide apart at my yard—and I suspect that mine is not the only one. Page 7.

## GOING INTO SOMETHING NEW.

F. L. Day alludes to an evil, on page 7, that may as well be clubbed a little more. One prominent apiarist does well with something new. Presto, all the rest must be voted ignorant or stupid unless they dive into the same, and make a success of it also. What nonsense! Are men sheep, that they can not be easy an hour except in a flock? I believe one Ohio man once made something of a success of raising figs. Must all Ohio farmers raise figs, then?

## CHANGING TO AN EXACT POUND SECTION.

L. V. Ricketts wants to enlarge the exact section in one direction until a crop of honey will average pounds. When he puts that to vote he'll get a flamboyant *minority*. Such a crop will be necessarily in 3 lots. Lot 1 will be even pounds—and nobody knocking. Lot 2 will be sections less than a pound (else the crop would not average); but these need make no more trouble than the similar ones we now have. Lot 3—liable to be nearly a third of the whole—will be sections weighing more than a pound. Just for once or twice the bee-man can sneakily shove the trouble off upon the shoulders of the unsuspecting grocer by packing over-weights and under-weights mixed; but sooner or later the grocer will hit back, and hit back hard. He doesn't make his living by giving away 2 ounces of honey with a section. And to get a customer to pay for 2 ounces more than a pound when he buys a section, is a troublesome and difficult job. Page 8.

## HOW TO INSURE HAVING REAPERS.

So to put in heavy combs of honey, reserved for the purpose, 40 days before the honey harvest, is Doolittle's “last and best” way to be sure of his reapers—and that far the most important thing of all. A beginner writes to find out what is the prime thing for the likes of him to know. An excellent and comprehensive answer might be given in one well capitalized word—BEANS? But Mr. Doolittle kindly assumes that he already knows beans,

and writes him an excellent article. Page 8.

## THE WAYS AND DOINGS OF MICE.

The mouse experiences of our new brother, J. L. Byer, as given on page 53, do not tally very well with my experiments, page 1036 (1906). Yet, perhaps, there is no real clash. Different members of the mouse family differ about as much as different members of the horse family. No one would insist that the horse, the donkey, and the zebra, must have the same tastes as to food. My experiments as yet extend only to one species of mouse, the universal or house mouse—and, in fact, to only one of the three or more varieties of that species. I have long suspected that the beautiful deer-mouse (fawn-colored above and pure white underneath) had an appetite more like the squirrels. Then there are other species of wide range. Also there are many species of mice not of wide range, but decidedly local. Every once in a while the zoologists get hold of one never before described. All, doubtless, have some differences of appetite. I want

to investigate the deer-mouse—but had better let him alone till I actually finish off the ones I now have. In such a place as Mr. Byer mentions (even if the traps showed some true house-mice present) deer-mice and stub-tails, and rust-tinted fielders are likely to preponderate, and I'll conveniently lay the mischief all to them. I would even hint that a chipmunk may be “in it.”

Two of my mice have just been eating quite a hole in the ice of their water font. It froze up less than 48 hours before. Interesting as showing how peremptory they are to have water if they can get it—and yet are capable of doing without it altogether. I think the fur of the mouse has the same quality that honey has, the power to absorb moisture rapidly from the air. Then (when there is urgent need) the vessels of the skin turn to, and absorb what is absolutely necessary from the fur. The volume of the fur being large, compared with the volume of such a little body, this is brought thereby within the bounds of possibility.

Conducted by EMMA M. WILSON, Marengo, Ill.

## A Kansas Sister's Report

I started in the spring of 1906 with 9 colonies. I increased 4, lost 1, sold 3, and secured 700 pounds of comb honey. So I am going to winter 9 colonies if all goes well. I have not lost my interest in bees or the American Bee Journal, even if I do not write often.

MRS. BEN FERGUSON.

Ft. Dodge, Kans., Jan. 7.

An average yield of 78 pounds per colony, spring count, and comb honey at that, in an unusually poor year, is something well worth while, isn't it? You say, “I increased 4, lost 1.” If that one swarm absconded it may be worth while to consider the advisability of having all queens clipped.

## Small Closed-End Frame or Bingham Hives

I appreciate the ladies' bee-keeping department remarks and grant their soundness. I have no hives to sell, and am in no way interested in their sale. The little hive used by me mainly meets my hive requirements.

1. It is cheap.
2. No one need ever lift more than 25 pounds at one time in its successful management.
3. Managed for section honey it is

the only kind of frame-hive in which all the honey and comb is built inside the frames and sections.

4. It is a box of movable combs, outside of which there is nothing to hinder the easy and quick examination of every frame, or a part of one, without ruffling the bees. It can be opened and closed while the bees are working, and they will not appear to know that anything is happening.

5. Sometimes bees swarm, and if one of these little hives of empty combs weighing about 5 pounds can be held in the palm of the hand, close to the cluster, the swarm can be easily and quickly secured. (One of these little hives will satisfy an ordinary swarm until more room can be given. It is very easy to handle and carry to the place selected.)

6. As the frames, or the hive, handle like a light box, it makes no difference whether the hive is bottom up or otherwise.

7. All the spare combs early in the autumn may be taken from the lower part of the hive—that is, the part where the brood has been altogether—and put in a safe place to keep till spring, leaving only the bees and honey for the winter depository or cellar, which practically increases the capacity of the cellar, as this hive in winter quarters uses only about a cubic foot.

8. The bees occupy all the cells in

the combs in which they are laying, leaving no room for honey, enabling any combs to be removed in autumn from the hive without finding it half-filled with honey—a very great convenience if you wish to store the empty combs for winter. I had a large crockery tierce in which I wished to winter some bees, and, oh dear! how could a man who had spent a whole life making watches put 4 colonies of bees into it alone? Easily done. Each hive was opened in the middle and the bottom part set in, then the other half was replaced. In this way the 4 fine colonies were put in the tierce and packed for winter. I expect to find them all right in the spring.

The man with unusual spectacles deserves a little notice for his optical illusions. Now, that little step-ladder pile of 8 divisions contained 140 pounds of honey, and the hive cost about \$1.00 or less; and one of the divisions was empty, except of brood. It is now in the cellar in a cubic foot of space. The brood-frames referred to above are piled up for next year's use.

Theoretically, more comb honey should be obtained from these little, closed-end-frame hives than from hanging frames, because there are no waste-places in which thoughtless bees inadvertently might store comb and honey, as they sometimes do at the ends of suspended frames.

There are many points in the management of bees in which custom or prejudice unduly figure. There seems to be no real fault in the closed-end movable-comb plan. The lamented Mr. Quinby adopted it on sight. James Heddon, after years of observation in my apiary, and the A. I. Root Co. in the Danzenbaker hive; and last, but not least, the President of the National Bee-Keepers' Association, Mr. Aspinwall, is building or inventing the most extensive and ingenious closed-end-frame, non-swarmling bee-hive that I have seen.

I hope the bee-keepers of the world, and especially the lady bee-keepers, may be benefited by every invention.

Do bees winter well in such hives? Yes, they never starve as long as there is a drop of honey in them.

I had 25 nuclei crowded into the small space of a box 12x6½x12 inches each, and containing 387 square inches of comb and some honey, weighing about 15 pounds each when taken to the cellar. After they had been in the cellar a few days I set another just such a hive full of honey on them. One week later I found all of them not having much honey distributed evenly in each part—the honey as well as the combs on which they had previously been, while those having more honey stayed with their honey. I write this to demonstrate that bees do not starve in this hive with honey in it.

T. F. BINGHAM.

Mr. Bingham's presentation of the case is such that if there were to be a special hive for the sisters, his hive would present strong claims for consideration. So Mr. Bingham thinks attention should be given to the unusual spectacles that gave rise to optical illusions regarding "that little step-ladder pile of 8 divisions" on the cover page for Nov. 22, 1906, referring,

no doubt, to a paragraph on page 9, where the question is asked, "Would it be the lightest kind of work to lift down that 8th story? and wouldn't it be a rather precarious business to use a ladder to get to the top of the pile?" Now, wherein is the illusion? Is it in estimating the height of the pile? or has it reference to the weight of that 8th story, or what? Pity he didn't give us exact figures as to said height and weight. The only data from which we can judge are the appearance in the picture and the fact the 8 divisions, less one containing comb, contained 140 pounds of honey, and the further fact that each little hive of empty combs weighs about 5 pounds. That makes it pretty safe to estimate at 25 pounds that top story and contents.

Easy so far; the rest of the way isn't so easy. Subject to more or less

guessing. Pretty clear case, however, that that 8-story pile isn't as high as it looks. Nothing in the picture to measure by, but the trees, and no telling anything about their size. Why under the sun didn't Mr. Bingham stand smiling beside the pile so we would have something to guess by? Dollars to doughnuts that 9 out of every 10 looking at the picture will think of those little hives as being the size of an 8-frame dovetailed hive. But in that case each story would weigh twice as much as 25 pounds. If each story is only 6 inches high (and there is no telling how much higher or lower it is), then the pile is only 4 feet high. That wouldn't be so very bad.

But next time, Mr. Bingham, please have your picture so that "unusual spectacles" will not be necessary to prevent optical illusions.

Conducted by J. L. BYER, Markham, Ont.

### Don't Spray Fruit-Trees While in Bloom

So they are trying to have a Bill passed in Illinois to prevent the spraying of fruit-trees while in bloom. (See page 66.) Really, you Illinois bee-keepers are behind the times. Over here in Ontario we have had a similar law in force so long that I actually forget the year it was enacted. The best thing about the matter is, that the great majority of fruit-growers would not now spray their trees while in bloom, even if there were no law to prohibit them. They have become alive to the fact that by so doing they would injure their own interests; and I wonder after all is said and done, if appealing to the pocket-books of people is not about the most powerful argument that can be brought to bear in order to convince them.

### Formaldehyde for Fumigating Foul-Broody Combs

David G. West's article on fumigating foul-broody combs with formaldehyde (page 47), contains statements which, to my mind, should not be allowed to pass without comment.

In his first paragraph he speaks of "foul or black" brood, and, if I understood by that that he meant "black" brood, as the term is understood by most bee-keepers, I would not venture to comment on his statements, as I have no experimental knowledge of that disease. But as the term "foul" is used exclusively when speaking of

the disease in the rest of the article, I judge Mr. West is speaking of the genuine foul brood as we have it here in Canada, and it is in connection with this assumption that I wish to enter a protest. Mr. West says:

"To free the combs of the disease, we stack them up 3 or 4 hives high, on a colony that is slightly diseased—so as not to carry the disease farther—with a queen-excluder on to keep the queen in her own hive, and use the combs that season for extracting combs. This saves the good brood, and makes a strong colony, which will clean the combs of the bad brood and fill them with honey" [italics mine]. "The combs are extracted as often as needed, and after the harvest are left to be cleaned out by the bees."

This "cleaning out by the bees" takes place before any attempt is made to disinfect the combs by the formaldehyde treatment which Mr. West claims to be so efficacious. The commonly accepted theory is that the honey is the source of infection, and it seems strange that the disease would not be disseminated by allowing the bees to have access to these wet combs just from the extractor. If this did not spread the disease, I would not think there was much need of disinfecting said combs.

But I mainly wish to protest against the disgusting scheme of using those brood-combs, reeking with the filthy remains of dead larvæ, for extracting purposes. With foul brood as it exists here, the strongest colony will not clean out the dead larvæ dried down on the bottom side of the cells, and it is a common thing for the bees, in affected colonies, to store honey in such cells. I have not the slightest doubt but that

our best authorities will back me up in this statement.

I wonder if Mr. West, or any one else, would knowingly like to eat honey extracted out of such combs. I like honey, but when I think of eating such stuff, my stomach enters an emphatic protest.

An Englishman, who lived near us once, used to say in his broad way of speaking, that he didn't "mind a bit of clean dirt, but he did detest nastiness;" and I think that honey out of foul combs would quite properly come under the latter qualification.

Mind you, I am speaking of foul brood as we have it here in Ontario, but from what I have read of "black brood," I have my doubts as to the propriety of using combs with that disease in them, for extracting purposes.

I have had no experience with formaldehyde myself, but Mr. Sibbald, who tested the drug a number of times, pronounced it a failure. That the great majority of inspectors have repudiated its use, is in itself significant; and while I do not dispute Mr. West's claims, yet I would advise Canadian bee-keepers, at least, *under no circumstances*, to try to save foul-broody combs.

## Skunks and Bees

Official figures show that skunks annually net this State [Maine] between \$125,000 and \$150,000—double the revenue from the honey-making industry. Nearly 25,000 gallons of skunk-oil, which is said to have curative properties, are produced annually in Maine. The wholesale price is \$5.00 a gallon.—Toronto Globe.

There is an old saying that "comparisons are odious," and I should think that to our bee-keeping friends in Maine, the foregoing comparison would be doubly odious. As we have no means of disproving the statement, I suppose we will have to accept it *in toto* until better informed.

This reminds me that just at present skunks are causing me considerable trouble at my "Cashel" apiary. One or two of the "varmints" visit the yard quite frequently, and eat all the dead bees that accumulate on the ground in front of the hive-entrances. If that were all, there would be no harm done, but there is plenty of evidence that they scratch at the entrances, disturb the bees, and cause them to come out, when they are promptly gobbled up by Mr. Skunk. We have had so little snow that it has been impossible to track them to their den, and I hesitate to set traps on account of a number of the farmers' cats which frequent the yard, and do good service in eradicated the mice.

One strange thing I have noticed regarding skunks, is that they invariably confine their attention to the same hives on their different visits. Last season, for some reason that I could not understand at the time, a colony in the home yard kept dwindling down all through June and July. Two or three times during the busy time I took off the super (with no honey in) to see if the colony had become queenless, or perhaps had swarmed. Every time the old queen was seen, everything seemed

normal, with the exception that there were very few old bees as compared with the large amount of brood.

About the end of July I happened to notice the grass all scraped back at the entrance of the hive in question, and I at once suspected skunks. That night I set a trap, and the next morning proved the case without a doubt.

This was the first time I had any experience with these highly-perfumed beauties in the bee-yard, but a neigh-

bor, a few years ago, had over a dozen colonies ruined before he noticed anything wrong, as it was towards fall, and he was busy with the farm work. He also reported that the skunks confined their attentions to the hives all in one row, and never molested the rest of the apiary.

I should think that where skunks are numerous they would be quite a menace to out-yards remote from buildings, which receive only occasional visits.

Send Questions either to the office of the American Bee Journal, or to  
DR. C. C. MILLER, Marengo, Ill.

Dr. Miller does not answer Questions by mail.

## Moving Bees

As I have to move about 3 miles March 1, when do you think it would be the best time to move my bees? I use the dovetail hive. I have them in boxes with chaff packed around them. Will the bees get ventilation enough from the entrance, or would I better put a screen over the top of the hive in moving them?

ANSWER.—It will not do to disturb the winter packing any sooner than necessary, so you would better not move them till bees are flying every few days, possibly well along in April. If you choose a cool day the entrance will probably give ventilation enough, unless it be that it is less than the equivalent of 3 or 4 square inches. Of course, extra-strong colonies may require extra ventilation.

## Feeding Bees in Winter

1. Last fall we bought 4 colonies of bees, 2 in box-hives with a glass box on top for honey, and 2 in dovetailed hives with top super for 24 pound sections. Is it too late to examine to find whether they have enough honey to winter, or would it be better to feed and risk their needing it?

2. What should be fed, just granulated sugar, or a syrup of sugar?

3. They are on the stands sheltered on the north and east by a large building extending out to the west 10 or 15 feet on the north side and 2 stories high. Is there any danger of their suffering here through the winter, as we have no severe cold weather?

4. They fly on warm days. Is this right, or should the entrance be closed so they can not fly except when we want them to? These colonies were very heavy when bought, but no honey on top. One was robbed at that time. One had started new combs in the glass box. The other in the box-hive also started comb, and both stored a small amount which we uncapped and they carried out late. We took 20 pounds off: one of the dovetailed hives after the season was over.

MISSOURI.

ANSWERS.—1. From what you say in the last part of your letter, it is quite likely that the bees are not in desperate need. It will, however, be a good thing to be on the safe side, so long as you are not entirely certain as to their stores. It doesn't matter a great deal whether you feed without much attention to what they have, or whether you look

in the hive and feed only if stores are scarce. It is not too late to do either, so long as the bees are alive.

2. If by "just granulated sugar" you mean dry sugar, that won't do at all. They can't eat dry sugar. This time of year it is better to feed in the form of candy. Stir the sugar slowly into boiling water, having 4 or 5 times as much sugar as water. Keep it stirred, and try it occasionally to see when it is done enough so that a little dropped into cold water becomes brittle; then take it off the fire and stir till it begins to stiffen, and pour into dishes so as to be an inch or so deep. A good plan is to put into the dish a piece of paraffined or oiled paper, or paper oiled with butter, and then, when cold, it will be easily turned out of the dish. Put a cake of the candy over the bees and cover up warm.

3. It ought to be a good place, although it might be better if they were protected from the west rather than from the east winds.

4. It is generally better to let them fly when they want to, although it may be well to set a board as a blind in front of the entrance when there comes a bright sun with soft snow on the ground. But don't think of fastening them in the hive. It will only make them more frantic to get out, and some of them will worry themselves to death.

## Getting Workers for the Harvest—Wiring or Splinting Frames—Honey-Dew

1. The honey-flow here lasts till into September, and it seems to me that the common bees I have crowd the brood-nest early in the season and thus diminish the supply of workers for the later flow. What few Italians I've had seem to have the same fault. (The common bees have a little Italian blood). Which race, or races, would you advise me to try that would be apt to do better? Sometimes my bees would starve in the spring during an inclement spell of weather if not fed, although having a 10-frame hive full of honey in the fall, on account of rearing so much brood. They build up strong, and swarm before enough honey is coming in to live on. Would you advise dividing early to keep them down a little, and then uniting later to keep down undesirable increase?

2. I have used 3 vertical wires in some of my frames, the wire being common baling wire, about the size of the splints you use, or maybe a little smaller, and it was suggested to me by what you wrote about your use of

splints. However, I have a little different object in view than you have. I want the combs stiffened so as to make them stand extracting at a higher speed. Also, I use only starters of foundation in the most of my frames. I want the wires to go into top and bottom bars. Would it work as well that way with foundation?

3. Which do you think would be the cheaper?

4. How is it if your splints touch neither top nor bottom bar, that they keep the sag out of the foundation so well? It looks to me as if the foundation would stretch along the top-bar.

5. My honey is mostly honey-dew. It is gathered from the oak-trees. It oozes out at the juncture of a small excrescence and the twig. The excrescence has a small larva inside. But whether it is a true excrescence formed by the larva, or a blighted and undeveloped acorn, I have not found out yet. My honey has quite a wide reputation for fine flavor, although I have had only one big crop. Some of the honey is too thick to extract. I think it is the first of the honey-dew. All the honey is amber, or light amber. But the flavor is the best I have ever tasted.

California has just had her (about) decennial snow-storm, although in the mountains, where I am, we get a little every year. I guess it is a good thing to be reminded of what we escape.

I enjoy your department more than I used to when younger, and, therefore, wiser!

CALIFORNIA.

ANSWERS.—1. It is doubtful that you would gain your purpose by change of bees. Neither is it advisable to divide early. It's the strong colonies that count. Give them more room, if necessary, by giving another story as an additional brood-chamber, have on hand extra combs of sealed honey to supply any lack of stores, or else feed sugar syrup, and then when harvest-time arrives you can reduce to one story if you like.

2. I don't know for certain just how your plan would work, but if you were going to use wire at all, I think I should use the usual light wire, either fastened the usual way or with nails driven through and the ends bent into hooks.

3. I'm not sure which would cost less, likely the wire; but the cost of either is very little.

4. You will understand that the splints are fastened to the foundation, so there is only  $\frac{1}{4}$  inch at the most at the bottom of the foundation to buckle, and so little as  $\frac{1}{8}$  inch will not buckle, and without buckling at the bottom it can not stretch at the top. At any rate, I never saw any stretching at the top.

5. You will probably find that there is an excrescence or gall that is started in the oak by the insect, and that there is no acorn in the case.

the original hive on this. Now, when is the queen liberated? You call this putting the queen down. It would seem below. Then when you put up the queen you must take this queen and put her in the other hive, as this hive you say will be a good place to rear good queens. You probably see my understanding. Please be a little more definite.

3. In putting bees into the cellar and taking them out, I always stop up the hives before moving them. I always supposed a good many of them would come out and get lost. I keep them in a dark room in the cellar. I go in in the morning when it appears like being a day lit, and stop them in. When I get the hives all out I unstop them. I suppose if I could lift the hives up and go in with but little jarring it might do, but I am not strong enough for that. I have two hooks that my daughter and I get under them, and she takes one side and I the other. Sometimes we have to lift them to get our hooks under them, and sometimes we hit the hive against something on the way, and this irritates the bees. This is the second winter I have had a furnace. Before, it was too cold; now it is too warm. Last winter some bees starved to death, and most of the colonies were weak. This year they went in heavier than last. I have 2 holes cut in the stone wall on opposite sides. One the cats go in, and out of the other, not quite so large. I expect the bees to come out in fair condition.

IOWA.

ANSWERS.—1. It is pleasant to have this bit of history from a comrade of the olden time.

2. I am quite chagrined to find an omission on page 164 of the book mentioned, and much obliged to you for calling attention to it. A sentence in the middle of the page reads, "The supers are now put on the hive with its 2 or 3 frames of brood, the cover is put over the supers, and the 'put-up' hive filled with brood is placed over all;" and then should have been added, "and the queen liberated into it." You see this is putting up the queen, and not putting her down, as you seem to understand. She is put down 10 days after the time the swarm issued. The idea is that the queen can go right on laying in this story above, but although the story is filled with brood, it is weak in bees, and no fielders are bringing anything into it from the outside, so the bees will give up the idea of swarming and will tear down all cells already begun. That's cheaper than for me to go through and destroy cells, and, besides, I might miss some cells, and the bees never miss any. You are right in understanding that the lower hive is a good place in which to rear queens, as it is a strong colony with only a part of its younger bees taken away. And the queen is never put down into this lower story, and only comes down with the upper story when the upper story is put down in place of the lower one.

3. I question the need of fastening the bees in the hives, even with the disturbance you mention. I have disturbed them as much without fastening them in the hives. I count it a very important thing to open windows and doors of the cellar the night before carrying out. If I didn't do that I might want to fasten them in. But the thorough airing out of the cellar all night leaves them so quiet in the hives that they will stand a good bit of joggling before they will come out of the hives. If a hive occasionally gets a tunk that rouses the bees too much, the smoker is always on hand to quiet them, and that's a good deal easier than to fasten all in. When carrying in, of course I wouldn't want to use smoke, but if one gets stirred up it is allowed to sit awhile to quiet down. I have, however, sometimes fastened in a colony, and for this purpose the best thing I know of is a rag wringing wet to throw down at the entrance. When a bee comes against this chilly thing, it seems to think the weather is not favorable for leaving the hive, and it doesn't stir up the colony as it would to fasten them in with a dry cloth. I am not sure whether I fully understand the closing part of your letter, but it sounds as if you thought it would be an improvement to put the sections directly into

the super when the foundation is put into them. Well, that is exactly the thing we do, as you will see by turning to page 146 of my book. Just as fast as the foundation is put into each section, the section is set directly in the super where it is to stay, and you are quite right in thinking that such a course is a saving of time over any other way.

## Uniting Colonies in Spring—Warped Brood-Frames

On page 74, you say that one can unite a comb full of bees without any precaution whatever with any colony. I have some weak colonies to unite in the spring, and I think I will try distributing combs of bees this way.

1. What time should I do this?

2. Say I wanted to put 2 or 3 combs of bees in one hive, how long apart should I do so?

3. What do you think about brood-frames that are warped out of shape? I have some new ones that are warped very badly; that is, the bottom-bar is away out of line with the top bar. They have never been wet.

MINNESOTA.

ANSWERS.—1. In the case of which you refer, page 74, a queenless colony was to be broken up, and in that case the sooner it is done the better; and, in general, when you intend to give bees, or bees and brood for the sake of strengthening, the earlier the better, only it must not be done until there comes a day when it is so warm that bees are flying freely, for there is danger of chilling the brood by opening hives when it is too cool.

2. It depends a little upon circumstances. Suppose you have a colony that you want to help, and it has bees covering 3 frames. It would probably be safe to give it 3 more frames of bees all at once if the bees were queenless. But if you should give it 3 frames of bees from a colony having a laying queen, there might not only be danger of fighting, but the queen might be killed in the colony that is being helped. The safe way would be to give a frame at a time a day or two apart. But you would be safe to give 2 frames at a time if you should take them from 2 different hives. Possibly it might be safe to give it 3 frames from 3 different colonies. In general, it may be said that the stronger a colony is, the more bees can be given it at a time.

3. I think I wouldn't like such frames, and the more out of true they are the less I would like them. The case is worse, too, with loose-hanging frames than with self-spacing ones, for the constant tendency of the latter is to be made straighter by being crowded together. The self-spacers can not be crowded too close together, while crooked loose-hangers may be crowded so close together that the bees glue them fast.

## Early Bee-Keeping—Swarming Management—Uncelling Bees

1. I have received your "Forty Years Among the Bees," and have read it through, and am well on the way in the second reading. You and I commenced bee keeping about the same time. I bought my first colony in the spring of 1861. It was in a basswood gum, and the first honey I got I took the top off and cut it out. The next hive I made were a foot square, and about 8 inches deep, with slats on top, one on top of the other. In 1865 I bought a Langstroth hive with a right to use it. Not liking the 5-pound boxes, I made supers with a division-board in the middle, and put in short frames that I made of plastering lath. And, latterly, the 1-pound sections.

2. In your topic of putting down the queen, you are not very definite. When the colony swarmed you caged the queen and slipped her under the frames on the bottom-board. Then, after taking off the super, you take all the frames and put them into a new hive. Then put 2 frames from some other colony and shake part of the bees from this colony with the frames, and put in 2 or 3 dummies. Put the supers on this, then put the cover on, and

## Bees Wintering Well

Bees are all right, and wintering well so far. I set the hives close together and banked them on the north with corn-fodder, and tin on top, with the south side open. The hive-entrances are open 3 inches, with corrugated tin over them.

N. B. EWING.

Plano, Ill., Feb. 1.

## Season of 1906 All Right

My honey season last year was all right, the average being about 103 pounds to the colony, which is not bad. I have had bad luck for the last 2 years. My bees kept dying, and I haven't found out the cause of it. There was no foul brood. I am sure it was the queen's fault. Some couldn't fly, and others

**Standard-Bred Italian**  
**FREE**  
**PREMIUM QUEENS**

We are booking orders now for those **Fine Untested Italian Queens** that we offer every year **FREE** to paid-in-advance subscribers as premiums for getting **NEW** subscribers for the Weekly American Bee Journal. These orders are taken for May or June delivery.

**What Some Say of our Standard-Bred Italian Queens:**

*George W. York & Co.:*—The two queens received of you some time ago are fine. They are good breeders, and the workers are showing up fine. I introduced them among black bees, and the bees are nearly yellow now, and are doing good work. A. W. SWAN.  
Nemaha Co., Kan., July 15

*George W. York & Co.:*—After importing queens for 15 years you have sent me the best. She keeps  $9\frac{1}{2}$  Langstroth frames fully occupied to date, and, although I kept the hive well contracted to force them to swarm, they have never built a queen-cell, and will put up 100 pounds of honey if the flow lasts this week. CHAS. MITCHELL.  
Ontario, Canada, July 22.

*George W. York & Co.:*—The queen I bought of you has proven a good one, and has given me some of my best colonies. N. P. OGLESBY.  
Washington Co., Va., July 22

*George W. York & Co.:*—The queen I received of you a few days ago came through O K, and I want to say that she is a beauty. I immediately introduced her into a colony which had been queenless for 20 days. She was accepted by them, and has gone to work nicely. I am highly pleased with her and your promptness in filling my order. My father, who is an old bee-keeper, pronounced her very fine. You will hear from me again when I am in need of something in the bee-line. E. E. MCCOLM.  
Marion Co., Ill., July 13.

**How to Get these Queens Free**

To any one whose own subscription to the Weekly American Bee Journal is paid in advance, we will mail a Fine Standard-Bred Untested Italian Queen next May or June, for each new name and address sent to us with \$1.00 for the Bee Journal a year. No one can get for himself the Bee Journal a year and the Queen for \$1.00. The Queen is offered as a premium for the work of getting some one else to take the Bee Journal a year. If you, yourself, want the Bee Journal a year and the Queen, send \$1.50 for the two, and we will book your order for a Queen. Queen orders will be filled in rotation—"first come, first served."

Address,

**GEORGE W. YORK & CO.**  
334 Dearborn Street, - CHICAGO, ILL.

never became mated, and those that did lay never made any headway. The stock I have now is certainly doing its duty, and never seems to get the swarming fever. The way I increase is by dividing.

I am taking care of my bees for one of my neighbors. There are 8 colonies of them that stored 600 pounds of the nicest comb honey. I had only one swarm.

I think it did me good to have a set-back in bees, as I look after them more carefully now. Utica, Ill., Jan. 7. P. H. HARBECK.

**Report for 1906—No Complainer**

I will try to tell how rich I am, or how large a purse I have, from my crop of honey last season:

To begin with, I had 9 colonies of bees, and increased to 11—not a large increase. I received from nothing to 112 sections, or 112 pounds per colony. The colonies that did not produce anything were in as good condition, or as populous, as those that did give good returns.

I make my own hives, sections, and foundation, and all fixtures that I use, but can not make them as described in the American Bee Journal, page 1015 (1906). I want them a little more accurate than a saw, hatchet and nails would construct.

I sell all my honey t home for 20 cents a section, and have no trouble to dispose of it at that price. I could sell more if I had it.

We have not had a good season for 5 or 6 years, but we take things as they come, and do not complain about it. HENRY BEST.  
Hibbets, Ohio, Dec. 29, 1906.

**Waxed Honey Without Granules—Heat Escaping from Cluster**

I wish to give a possible explanation (see page 987—1906) and further proof that a high temperature stops honey, when once started to candy or granulate, from candying solid.

About the middle of March, 1906, when overhauling bee-hives, I cut out about 30 pounds of comb honey, leaving another 30 pounds till wanted. The following night we had a frost, or freeze. Yellow jessamine bloomed in 2 or 3 days, and the second lot was cut out previous to one light, and the last, frost in 1906. The first lot candied, and the second lot waxed. The two lots presented, on the evening following the last frost, quite a different appearance. Lot No. 1 candied solid, granules commencing to form on top, and looked precisely the same grayish color, like pure hog-lard in frosty weather. Lot No. 2 remained wax without any granules whatever, and looked white, not water-white nor water-clear, or any other so-called white—the same color as the royal jelly in a queen-cell. Both lots remained in their respective conditions until used up in June. All this comb honey was carried up-stairs between Nov. 15, 1905, and the middle of March, 1906, during warm spells, I suppose, and the comb was also built. No comb foundation was used, except a narrow guide was left when the honey was cut out in November, 1905.

In April, I also cut out some comb honey, carried above during winter or early spring. One pint was put into a Mason jar—liquid honey—with but a few small pieces of comb (size of a pin-head) to attract flies which passed through a small hole made in the paper cover, purposely. We had a rather cool spring in 1905, but no frost since that last lot was put up. This liquid honey also waxed. When jarred or tossed, it would hardly run out; the honey made an attempt, almost rubber-like, to contract and retain the same shape it originally had in the jar, but failed. I am also of the opinion, although not certain, that a warm temperature following cool nights was the cause of the last lot waxing. Another frost and this year's second lot would have candied. D. J. PAWLETTA.  
Ft. White, Fla., Dec. 24, 1906.

P. S.—The following is some proof that the heat of the cluster of bees does not escape, or

very little, if needed in the brood-chamber, as Mr. Doolittle says it does:

Three supers containing the 60 pounds of honey were jerked loose and the honey cut out at once on a frosty morning. The comb was brittle. Now, if any heat does escape why was this comb brittle? The colonies certainly were very strong, and occupied the whole brood-chamber (10 frames). Very few bees—probably  $\frac{1}{2}$  pint—were above the frames. The last experiment could, it seems, be tried with bait-sections in the North.

D. J. P.

**The Pairing System of Non-Swarming**

I have read with interest the articles on the Davenport non-swarming plan. Some of them may have hit the mark, and others may have not. There is no doubt that Mr. Davenport has one plan, but with the secretiveness of the average American, he keeps the good thing to himself. In 1895, Mr. Heddon, with his sectional hive, kept all colonies, except a baker's dozen, from swarming. Mr. Aspinwall, last year, had 10 swarms from his 40 colonies in non-swarming hives. According to his theory, probably none would have swarmed if he had removed the pollen-filled combs.

I believe the pairing system, as advocated by one correspondent, is as good as any. I shall use a Langstroth 10-frame hive for the feeding colony, and a sectional hive with supers containing plain 4x5 sections for the one to produce gilt-edged honey. Following the Chapman plan, I can lift the brood-frames every 2 or 3 days to a full super above the honey-board, and thus have an immense colony ready for the harvest.

Our hybrid queens lay in a manner (prior to the honey season) good enough to gladden the big heart of Doolittle; and the bees build early enough and nice enough to satisfy him. Also, one of those early-built queen-cells can be put into a West cage in the sectional hive, and inside of its one sectional brood-case, or queens can be had early from the Sunny South.

There is a popular idea that comb honey can not be produced in northern Michigan in sufficient quantities to pay for producing. That this assertion is not true, I have seen proved in this northern country. Mr. James Heddon, Dr. Miller, or Mr. Aspinwall, could easily disprove this idea by their methods.

I have read the articles by R. C. Aikio, in Gleanings, and also Mr. Aspinwall's in the Review, with eager interest. Supers similar to theirs are what the northern Michigan comb-honey producer needs. Mr. Hutchinson and others can embark in extracted honey, but comb honey will suit me. If "W. Z." would tell his many readers to remove across the Straits and locate from St. Ignace to Duluth, all would be benefited. Prices for honey, also eggs, poultry, and strawberries, are higher up there. I have seen a bee-keeper this year produce honey, eggs, and strawberries, and do well with all. Strawberries do best on loamy soil.

GEO. J. MOLONEY.

Onaway, Mich., Jan. 1.

**Purity of Queens**

In 1902 I bought a selected tested queen from a Western breeder. This queen's drones were well marked—you could not wish them better—but the workers were miserably marked. They varied from a bright 4-banded worker to 1-banded, dark worker mongrels. By the looks of the queen's drones, she had mated with a drone having black blood. The grandchildren of this queen are black, both drones and workers.

The same year I got 4 queens from an Eastern breeder. They were warranted for 3 years. I had all the queens accepted. Five days afterward, one came out to meet the drone and got lost. She was a virgin. The other 3 were good breeding queens. In 1903 I bought 6 queens from the same breeder. Two died in the cage. One had mated with a black drone. The other 3 were first-class queens. Those queens bred drones in Sep-

**Something New = The Ideal Hive-Tool**

Bee-keepers have long needed a special Tool to work among the hives during the bee-season. The one shown here was invented by Wm. Muench, a Minnesota bee-keeper, some years ago, but it was not on the market before. We have lately bought this Tool, and all rights, from Mr. Muench's widow, and have had the first lot made. They are ready for delivery now.

Best Hive-Tool

Only 30c, by mail

(This picture is exactly one-half the size.)

**DESCRIPTION.**—The Ideal Hive-Tool is made of high-grade malleable iron, much like wrought iron,  $8\frac{3}{4}$  inches long. The middle part is 1-16 inches wide and 7-32 thick. The smaller end is  $1\frac{1}{4}$  inches long,  $\frac{1}{2}$  inch wide, and 7-32 thick, ending like a screw-driver. The larger end is wedge-shaped, having a sharp semi-circular edge, making it almost perfect for prying up covers, supers, etc., as it does not mar the wood.

**What Dr. Miller and Miss Wilson Say of It:**

In the first edition (1903) of Dr. Miller's "Forty Years Among the Bees," page 58, he says: "Of all the hive-tools I have tried, I like best the Muench tool." On Jan. 7, 1907, he wrote us saying he thought "just as much of the tool as ever."

Miss Wilson, Dr. Miller's assistant, says this of the Ideal Hive-Tool: "It is an ideal tool. In fact, I don't see how it could be improved upon. I am sure we would feel utterly lost in the apiary without it. . . . You will have to try one yourself if you want to know its worth."

**The "Ideal Hive-Tool" Free as a Premium.**

We will mail an **Ideal Hive-Tool FREE** as a premium to any present paid-in-advance subscriber to the American Bee Journal, for sending us **ONE NEW** subscription for a year at \$1 00; or we will send the American Bee Journal one year and the **Ideal Hive-Tool**—both for \$1.20. Price of the **Ideal Hive-Tool** alone, postpaid, 30 cents. Address,

GEORGE W. YORK & CO., 334 Dearborn Street, CHICAGO, ILL.

# American Bee Journal

tember. Just as soon as the workers commenced to gather honey, I observed that one colony acted as if the queen were lost. The next morning I opened the hive. She was on the bottom-board, dead. In one week all the bees were dead. She was a hybrid queen, and was filled with water as large as a drone.

In the fall of 1903, the same dealer sent me a queen. I gave this queen to an 11-frame colony. In the spring of 1904 I took out 2 brood-frames with the queen. The result was, the colony built one queen-cell, and the queen they reared was very good—as good as her mother. I got 5 queens from this queen, and started several batches of queen-cells. The bees would start cells, cap them over, and after 2 days tear them down. This was a puzzle to me. After a few days the hive was filled with drones hatched from worker-cells. So I was "played out" on breeding queens.

In the spring of 1905 I wrote the breeder that I did not want any more dollar queens, but that he was to send a breeding queen. I received 2. The drones from both queens are well marked, but the workers of one queen have black blood. Of the second queen the worker progeny was reared all right. I reared several queens from this queen's eggs, and the drones from those young queens have black blood. The fact is, that the queens from that dealer are reared from a pure mother, as from every queen I have received from him the drones are first-class. But the queens are mated with drones that have black blood, or mongrels. I am well satisfied that those cheap queens advertised are worthless. A breeder offering untested, select untested, tested, and select tested, tells me plainly that his queens are mongrels. If they have a pure queen and drone it is impossible to have those grades of queens to sell.

On page 862 a writer asks, What is a tested Italian queen? A tested, or breeding, queen should be a bright yellow. Every drone must

have 4 yellow bands, and you can not discern any varying in color. The workers must have 3 yellow bands, with light gray on 2 bands. The under part of the abdomen should be bright yellow to the tip. Now let us test this queen. If it is free from any black blood, the drones from every young queen reared from her eggs will have the same number of bands as the mother-queen. Every drone is marked alike. No person can see any difference in the drones. You must trace the pure blood from the drone progeny, not the worker progeny. Where the drone progeny varies in its markings it is a sure sign of black blood. If you breed from such queens you will be sure to get mongrel stock. If a breeder sells you a tested queen, that queen's progeny has been tested by rearing young queens from the eggs of this tested queen, and if like produces like, the drones and workers marked the same as the mother-queen, there will be a tested queen.

NEW YORK, Jan. 7.

## Winter Too Mild—Bees Fly and Get Chilled

This has been a very mild winter on bees so far, although in some respects it has been just as severe as though we had extreme cold. On some of the first days when it began to warm up some of the colonies lost a pint or more of bees, which came out when it was too cool for them to fly, the wind blowing them down on the leeward side of the hive, where they remained and chilled. They were not old, worthless bees, either, as we scraped up several handfuls, made a small nucleus, took them into the house, and to all appearance they will survive until spring.

Bellevue, Ohio, Jan. 20. H. G. QUIRIN.

Please Mention Bee Journal when writing advertisers.

## CONVENTION NOTICE.

Minnesota—The Southeastern Minnesota Bee-Keepers' Association will meet in the Court House at Winona, on Tuesday and Wednesday, Feb. 26 and 27, 1907. Everybody is invited.

Winona, Minn.

E. C. CORNWELL, Sec.

"Songs of Beedom."—This is a beautiful 16-page-and-cover pamphlet, 6x9 inches in size, containing 10 bee-songs—words and music—all the songs so far written specially for bee-keepers, we believe. It is nice, as well as convenient, to have these songs all in one binding. Every bee-keepers' organization should have copies for use at conventions. They could be sold to members after using once, or held by the secretary for use at future meetings. Of course, every bee-keeper's family will want at least one copy. It is sent, postpaid, for only 25 cents, or 3 copies for 60 cents; or, we will mail one copy with the American Bee Journal one year—both for \$1.10. Send all orders to the office of the American Bee Journal.

While the Present Stock of these BEE-HIVE CLOCKS lasts, we will sell them at only \$2.00 each, by express; or \$2.50 for the Clock and the Weekly American Bee Journal one year. Better order at once, before all are gone.

# The Bee-Hive Clock

A \$4.00 CLOCK FOR \$2.50 ... With the American Bee Journal 1 Year—Both for Only \$3.00

We have originated and had made specially for our readers, a bronzed-metal Clock, called "The Bee-Hive Clock." It is 10 1/4 inches wide at the base, 9 3/4 inches high, and deep enough at the base to stand firmly on a mantel or elsewhere. It is a beautiful piece of work, and would be both ornamental and very useful in any house, and particularly in a bee-keeper's home.

The Clock part itself is warranted for 3 years to keep good time. So it is no plaything, but a beautiful and needful article for everyday use.

Clocks like "The Bee-Hive Clock" usually sell in the stores at from \$4.00 to \$5.00 each, but having them made for us in quantities enables us to offer them at \$2.50 each by express, or with the American Bee Journal a year—both for only \$3.00. Either Clock or Journal would make an ideal gift.

## How to get "The Bee-Hive Clock" FREE

Send us 5 New Subscribers to the Weekly American Bee Journal for one year, at \$1.00 each, and we will send you this beautiful "Bee-Hive Clock" FREE (excepting express charges). Or, send us 4 New Subscribers (at \$1.00 each) and 50 cents—\$4.50 in all. Or, 3 New Subscribers (at \$1.00 each) and \$1.00—\$4.00 in all. Or, 2 New Subscribers (at \$1.00 each) and \$1.50—\$3.50 in all.

Only \$2.50, f.o.b. Chicago, by Express.  
Weight, with packing, about 4 pounds.

## What Dr. Miller Thinks of the Bee-Hive Clock

Busily ticking away, in the room where I am sitting, stands a genuine bee-keeper's clock (please understand that the word "genuine" belongs to the clock and not to the bee-keeper) or, as the legend upon the clock has it, "The Bee-Hive Clock." I don't know

whether the idea of getting up such a clock was conceived in the brain of the Editor of the American Bee Journal, or whether he got it elsewhere, but the wonder is that such a thing was not thought of long before.

Setting aside all idea of its association with the business of a bee-keeper, there is a peculiar appropriateness in having the minutes and the hours "told off" in a case representing the home of the busy little workers. The glance at the clock, with its ceaseless tick, tick, tick, can not fail to remind one that the flying moments must be improved now or be forever lost, and that suggestion is reinforced by the thought of the never ceasing activity of the little deuzens of the hive, always busy, busy, busy, working from morn till night and from night till morn, working unselfishly for the generations to come, and literally dying in the harness.

Let us be thankful that the form of the old-fashioned straw hive or skep was adopted, and not that of any modern affair, patented or unpatented. The latter smacks of commercialism, but the former of solid comfort, for no other form of hive has ever been devised that contributes so fully to the comfort and welfare of a colony of bees as does the old-fashioned straw-hive. It appeals, too, to one's artistic sense as can no angular affair of more modern times. As an emblem of industry, artists have always used—probably always will use—the old straw skep.

Thanks, Mr. Editor, for furnishing us a time-keeper so appropriate for all, and especially for bee-keepers.

C. C. MILLER.

**A GREAT IMPROVEMENT**

Will be found in

The  
**American Bee-Keeper**  
for 1907

It is profusely illustrated and enlarged, and contains only articles of the most practical as well as scientific nature. A special corps of the best writers has been engaged. The editors are Harry E. Hill and Arthur C. Miller, than whom there are no more practical or experienced bee-keepers in this country. We have published the American Bee-Keeper continually and regularly since 1890.

Regular subscription price, 50 cents a year. One year to new subscribers, 35 cents; three years for \$1.00.

Send for sample copy and our new illustrated price-list of **BEE-SUPPLIES OF ALL KINDS.**

Guaranteed highest quality at lowest price. Address,

**Honey and Beeswax**

CHICAGO, Feb. 1.—The usual late winter demand is in evidence for comb honey to replace diminished stock laid in during the autumn by the large retailers, but during the dull period there has been very little change, if any, in prices, the offerings being light.

We find No. 1 to fancy white comb honey brings 15@16c, and for that which is off in color and flavor from 1@3c less. Amber grades of all kinds are dull and range in price from 10@12c. The extracted perhaps is not quite so firm in price for the California or Western grades, but there is no surplus of white clover or basswood, both of which bring about 8c, and in some cases more. Ambers grade from 6@7½c. There have been some sales of beeswax at 32c, but 30c is about the price for average.

R. A. BURNETT & Co.

PHILADELPHIA, Nov. 8.—While the supply of comb honey is equal to the demand, large quantities of comb honey having arrived in the market in the last few days, the price still remains high. The outlook, however, is that when the season advances and the bee-keepers ship more of their crop to the market, the prices will be a little weaker. We quote: Fancy white comb honey, 16@18c; No. 1, 14@15c; amber, 11@13c. Fancy white extracted, 7½@8 c; light amber, 6½@7c.

We are producers of honey and do not handle on commission. WM. A. SELSER.

NEW YORK, Jan. 15.—The stock of white comb honey is pretty well exhausted, and we do not expect any more arrivals of large lots from now on. Prices are firm, and we quote from 15@16c for fancy white; 13@14c for No. 1; 12c for light amber. There is quite a little dark and buckwheat on the market, but no overstock, and we think that all of it will be disposed of before long at present prices, which we quote from 10@12c, according to quality. Extracted honey very firm, with sufficient supply to meet demand. California white sage is bringing from 8@8½c; light amber, 7½c; amber, 6½@7c; buckwheat extracted in fairly good demand at 6@6½c. Southern in barrels finds ready sale at from 55@70c per gallon, according to quality. Beeswax firm and steady at 31c.

**C. H. W. WEBER** CINCINNATI ... OHIO ...

Office and Salesrooms, 2146-48 Central Ave. Warehouses, Freeman and Central Aves.

DENVER, Jan. 5.—There is practically no honey left in the hands of producers in this State, and barely enough in the Denver market to supply the home trade until spring. We quote strictly No. 1 white, per case of 24 sections, at \$3.20; No. 1 light amber, \$3; and good No. 2, at \$2.80. White extracted, 8@8½c; light amber, 7½@8c. Beeswax, 26c for clean yellow, delivered here.

THE COLO. HONEY-PRODUCERS' ASSN.

CINCINNATI, Jan. 9.—The comb honey market at the present is very quiet. Holders are not trying to realize a profit, simply disposing of what they have, at cost. Fancy comb honey is selling at 14½@16c. Extracted amber honey in barrels, 6@7c; fancy light amber in cans, 7@8c; fancy white, 9c. Strictly choice beeswax, 30c, delivered here. THE FRED W. MUTH CO.

INDIANAPOLIS, Jan. 3.—comb honey is not plentiful, but demand is slack. Fancy white comb brings 16@17c; No. 1 white, 14c; amber, 12@13c. Best grades of extracted honey bring 8@9c; amber, 6@7c. Good average beeswax sells here at \$33 per 100 pounds.

WALTER S. POWDER.

TOLEDO, Nov. 30.—The market on comb honey remains about the same as last quotations, but has been coming in much more freely, as beekeepers seem to be very anxious to get rid of their stock. Fancy brings in a retail way 16c; extra fancy, 17c; No. 1, 15c; buckwheat, 15c. Extracted white clover in barrels brings 7@7½c; cans the same. Beeswax, 26@28c.

THE GRIGGS BROS. & NICHOLS CO.

CINCINNATI, Jan. 25.—The market on comb honey is rather easy. Prices rule in jobbing ways from 14@14½c; single cases 16c for No. 1 white; off grades not wanted at any price. Extracted is very firm. Light amber in barrels, 6@6½c; white clover in barrels, 7½c; in cans, 8½c. Beeswax, 30c, delivered.

C. H. W. WEBER.

KANSAS CITY, Jan. 25.—The receipts of comb honey have been more liberal during the last week or two, and the demand light, market weaker. The market is practically bare of extracted, and there is quite a little inquiry. We quote: No. 1 white comb, 24 sec. cases, \$3.10; No. 2, \$2.75; amber, \$2.50. Extracted, white, 7½@8c; amber, 6½@7c. Beeswax, 27c.

## Editorial Notes and Comments

### Breeding a Pure Race of Swiss Bees

The bee-keepers of Switzerland appear to be quite unanimous in asserting that the Italian bees are but little if any better than the common bees found in Switzerland. Starting from these premises, they have been trying to improve the common Swiss bee. It appears that there are now established a number of breeding yards in German Switzerland, where they keep choice colonies for the rearing of drones, and they transport their young queens in nuclei to those yards to have them mated with these choice drones. By careful selection they claim to have some improvements already, and hold that they can make much more progress by continuing this method.

We can see only one drawback to this procedure. The breeding yards, or mating yards, are placed  $1\frac{1}{4}$  miles from the nearest apiary. Bee-keepers who have any knowledge of queen-rearing and mating in this country are aware of the fact that the mismatings in a yard of Italian bees located  $1\frac{1}{4}$  to 2 miles from a yard of the common bees will show about half mismatings, all other circumstances being equal.

The distance which seems to be adopted as sufficient in Switzerland, would be entirely inadequate in this country. Queens and drones certainly fly readily, and in a very short time a distance of 1 or 2 miles. Matings often occur at distances of 4 miles and more.

### Some Early Honey-Dealing

Dr. F. D. Clum, of Cheviot, N. Y., sends us the following about one of the earliest large dealers in honey in this country:

The largest and most extensive dealer in honey in the United States in the years 1870

to 1875 was Daniel W. Quinby, a commission merchant of New York City. He was a venerable looking, gray-bearded man, and was known throughout the city commission district as "Uncle Dan." He controlled the honey market in those days, as all the bee-keepers of the time regularly forwarded their honey to him for sale on commission. This, probably, was due to the fact that he was a near relative of the well-known Moses Quinby, one of our pioneer bee-keepers who died in New York State, May 27, 1875.

Thousands of dollars worth of honey was sold in the fall of each year by Mr. Q., and yet none of it was extracted. The public looked upon extracted honey with great suspicion, and do so to-day for that matter. It is hard to convince the consumer that extracted honey, as found in the market, is the strictly pure unadulterated product of the bees. I remember the first can of extracted honey Mr. Q. tried to sell a prospective buyer, who, at the end of a long talk, critically looked at the honey, smelled of it, and tasted it, and then drawled out: "Well, it looks all right, and smells all right, and tastes all right, but I would rather have it in the comb, for then *I would know it to be all right.*"

It is the same lack of confidence that prevents the bee-keepers of to-day from greatly increasing their incomes, for every experienced apiarist knows that it costs less to produce extracted honey than it does to produce comb honey. Our best bees—the Italians—reluctantly begin work in the pound sections; they prefer to work upon large combs, and when we consider that these large-sized combs, after the extraction of honey, can be refilled by the bees over and over again, the saving is apparent.

Nearly every one who eats honey prefers the extracted when convinced of its absolute purity. Even the children at the table take a spoon and dip from the plate the liquid honey which has run from the comb in preference to eating the comb. It is to the mutual interest of the producer and consumer that extracted honey be universally used instead of comb honey, for when the public becomes convinced of the absolute purity of extracted honey, the producer's income not only will be greatly increased, but the public will receive an article that they really like better,

that contains more food value, and at a saving in cost. F. D. CLUM, M. D.

There is no doubt that a larger amount of extracted honey is produced to-day than of comb honey. And we believe, as does Dr. Clum, that when the general public discover how good really well-ripened extracted honey is, they will use it in preference to comb honey. *But it must be well-ripened.* Probably no other single thing has interfered with a wider use of extracted honey than that of putting unripened honey on the market. It not only injures the producer who is so foolish as to do it, but all producers of the best extracted honey are compelled to suffer from its evil effects.

Even for baking and other manufacturing purposes, the unripened extracted honey is a detriment. Mr. R. A. Burnett, the oldest and largest wholesale honey-dealer in Chicago, told us only recently that years ago he used to sell car-loads of buckwheat extracted honey to bakers and tobacconists, but all at once certain Eastern bee-keepers began to "get smart," and thought they could produce so much more by extracting it before ripe. The result was that such honey ruined the bakery goods in which it was used; also caused tobacconist loss, so that they would have no more buckwheat extracted honey—wouldn't risk buying it even if assured that it was well-ripened. The lighter grades of honey were considered too expensive for manufacturing purposes, so that some sweet other than honey was sought and used, thus cutting out a large demand for honey. And all because some short-sighted bee-keepers thought they could fool the buyers. Well, they succeeded to such an extent that not only were the dealers and large buyers fooled, but thousands of honey-producers as well.

It might be a good thing if the National Association would take up this subject, and see what it can do toward putting a stop to the offering of unripe honey on the market.

### Honey-Butter Ruled Out by Pure Food Law

The following has been received at this office from one of our subscribers in Oklahoma:

I have shut down my factory which has been running for several years for putting up all kinds of pickles, chow-chow, pumpkins,

# American Bee Journal

etc., and making honey-butter on a large scale. My goods were all pure, and were highly flavored with extracted honey. I used 19,000 to 20,000 pounds of extracted honey a year. I always bought the most of my honey every fall from other bee-keepers, for the honey I bought from them was pure, only a little dark. The people are very much disappointed here because they can not buy any more honey-butter. They say they like it better than pure honey. I always sold honey-butter for 25 cents a pound. The Hepburn Pure Food Law is a little too strict. I think the law will break up many honest men in business, if I understand it. OKLAHOMA.

Whether the pure food law is to be commended or condemned because "Oklahoma" has "gone out of business" is a question worth considering. It is said that in some places in Europe, about an ounce of honey is added to each pound of butter, and that this addition makes the butter more acceptable to most tastes. If the "honey-butter" in question were a compound of this character, and sold for just what it was, there certainly was nothing wrong in the transaction, and it is hard to see how the pure food law would interfere with it. At the most, it could only insist that the label should be an honest one, and if some other name than "honey-butter" would more accurately describe the product, objection ought not to be made to such change.

At this distance it may not be entirely safe to pass judgment, but there may be no harm in saying just how the matter looks judged from the information given. The statement is that people like "honey-butter" "better than pure honey." That is as much as to say it is not pure honey, and the only thing the law probably does in the case is to make the product sell for just what it is. One would think that "Oklahoma" would hardly need to go out of business on that account, and even if he gave up that one item of his business, pickles, chow-chow, etc., ought still to support the business. That he should go out of business because of being obliged to sell "honey-butter" for what it is, suggests the possibility that instead of any honey or butter being in the case, there may be something like the "honey-butter" of Germany with which bee-keepers in that land have been contending, consisting chiefly of sugar. If that is the case, it will be rather severe on "Oklahoma" to give up selling a cheap mixture for 25 cents a pound, but it certainly will be no great loss to bee-keepers, since he has not been using in his business, pickles and all, more honey than he could obtain from a single bee-keeper.

A law that obliges labels to tell the truth ought not to hurt any legitimate business.

questing that the 3 Bills be supported by them when they come up for discussion in committees or for the passage on the open floor. The Bills are as follows:

## BILL FOR APPROPRIATION FOR ILLINOIS BEE-KEEPERS.

A Bill for an Act making an appropriation for the Illinois State Bee-Keepers' Association.

WHEREAS, The members of the Illinois State Bee-Keepers' Association have for years given much time and labor without compensation in the endeavor to promote the interests of the bee-keepers of the State; and

WHEREAS, The importance of the industry to the farmers and fruit-growers of the State warrants the expenditure of a reasonable sum for the holding of annual meetings, the publication of reports and papers containing practical information concerning bee-keeping, therefore to sustain the same and enable this organization to defray the expenses of annual meetings, published reports, suppressing foul brood among bees in the State, and promote the industry in Illinois:

SECTION 1.—*Be it enacted by the People of the State of Illinois, represented in the General Assembly:* That there be and is hereby appropriated for the use of the Illinois State Bee-Keepers' Association the sum of one thousand dollars (\$1000) per annum for the years 1907 and 1908, for the purpose of advancing the growth and developing the interests of the bee-keepers of Illinois, said sum to be expended under the direction of the Illinois State Bee-Keepers' Association, for the purpose of paying the expenses of holding annual meetings, publishing the proceedings of said meetings, suppressing foul brood among bees in Illinois, etc.

*Provided, however,* That no officer or officers of the Illinois State Bee-Keepers' Association shall be entitled to receive any money compensation whatever, for any services rendered for the same out of this fund.

SEC. 2.—That on the order of the President, countersigned by the Secretary of the Illinois State Bee-Keepers' Association, and approved by the Governor, the Auditor of Public Accounts shall draw his warrant on the Treasurer of the State of Illinois in favor of the Treasurer of the Illinois State Bee-Keepers' Association for the sum herein appropriated.

SEC. 3.—It shall be the duty of the Treasurer of the Illinois State Bee-Keepers' Association to pay out of said appropriation on itemized and receipted vouchers, such sums as may be authorized by vote of said organization on the order of the President, countersigned by the Secretary, and make annual report to the Governor of all such expenditures, as provided by law.

## STATE INSPECTOR OF APIARIES BILL.

A Bill for an Act providing for the appointment of a State Inspector of Apiaries, and prescribing his powers and duties.

WHEREAS, The disease known as foul brood exists to a very considerable extent in various portions of this State, which, if left to itself, will soon exterminate the honey-bees; and,

WHEREAS, The work done by an individual bee-keeper or by a State Inspector is useless so long as the official is not given authority to inspect, and if need be destroy, the disease when found; and,

WHEREAS, There is a great loss to the bee-keepers and fruit-growers of the State each year by the devastating ravages of foul brood:

SECTION 1.—*Be it enacted by the People of the State of Illinois, represented in the General Assembly:* That the Governor, by and with the advice and consent of the Senate, shall appoint a State Inspector of Apiaries, who shall hold his office for the term of two years and until his successor is appointed and qualified.

SEC. 2.—Said Inspector shall, when notified of the existence of the disease known as foul brood among apiaries, examine all such as are so reported and all others in the same locality and ascertain whether or not such disease exists, and if satisfied of its existence, shall give the owner or the person who has the care of

## Miscellaneous News - Items

**The National Association's Annual Report** of the San Antonio convention has been out for several weeks. It is a neat pamphlet of 128 pages and cover. It contains a verbatim report of the San Antonio meeting, a list of the members of the National, the General Manager's Financial Report, an account of cases that have come before him during the past year; also a list of bee-keepers' associations in United States and Canada, besides a copy of the Constitution of the National Association. Every member receives a free copy of the Report, but any one who is not a member can get a copy of it by sending 25 cents to General Manager N. E. France, of Platteville, Wis., with the understanding that if he joins the National Association before the end of 1907, the 25 cents paid for this Annual Report will be allowed to apply on his dues, which are \$1.00 a year.

**To Missouri Bee-Keepers.**—The following comes from Mr. R. A. Holekamp, of the Missouri Bee-Keepers' Association:

DEAR SIR AND BROTHER BEE-KEEPER:—I have just returned from Jefferson City, where I was called to appear before the House Committee on Agriculture to speak for the Bee-Keepers' Bill. The committee gave me a hearing, and recommended the Bill for passage by the House; it will be voted upon at an early day, and I hope it may pass.

All members who have not yet written to

their Representatives, I urge to write a letter now, asking them to vote for the Bee-Keepers Bill No. 503.

Our Bill was passed by the Senate last Wednesday, and when the Bill has passed the House it will be "up to" the Governor for signature.

*I now request all Missouri bee-keepers* to write without delay to Joseph W. Folk, Governor of the State, at Jefferson City, asking him to sign the Bee-Keepers' Bill, being Senate Bill No. 145, and House Bill No. 503.

The Governor was sick when I was in Jefferson City, and therefore I could not see him, but I will have to go there again in a few days to appear before the Appropriations Committee, and I will then call on the Governor, and will try to convince him that we need the law.

Bee-keepers! our Bill is of such great importance to success in our vocation that I hope every one of our members will write the letters, and will also have other bee-keepers and fruit-growers in his neighborhood sign their names to the letters, so we may bring as much pressure on the Governor as possible.

Fraternally,

ROBT. A. HOLEKAMP,

Sec. Missouri State Bee-Keepers' Association.  
4263 Virginia Ave., St. Louis, Mo.

**Illinois Bee-Keepers' Bills**—3 of them—have been introduced into the Legislature now in session at Springfield, and every one of them should be passed. We hope that all of our Illinois readers will write at once to both their Representatives and Senators, re

such apiaries full instructions as to the manner of treating them. In case the owner of a diseased apiary shall refuse to treat his bees or allow them to be treated as directed by the said Inspector, then the said Inspector may burn all the colonies and all the comb necessary to prevent the spread of the disease: *Provided*, Said Inspector shall, before burning, give one day's notice to the owner or other person who has the care of the colonies of bees and comb, that in his judgment should be burned.

SEC. 3.—The Inspector shall, on or before the second Monday in December in each calendar year, make a report to the Governor, and also to the Illinois State Bee-Keepers' Association, stating the number of apiaries visited, the number of those diseased and treated, the number of colonies of bees destroyed, and of the expenses incurred in the performance of his duty.

SEC. 4.—Any owner of a diseased apiary or appliances taken therefrom, who shall sell, barter, or give away any such apiary or appliance, or bees from such apiary, expose other bees to the danger of contracting such disease, or refuse to allow the Inspector of Apiaries to inspect such apiary or appliance, shall be fined not less than fifty dollars (\$50) nor more than one hundred dollars (\$100).

#### ANTI-SPRAYING BILL.

A Bill for an Act to prevent the spraying of fruit-bloom.

WHEREAS, The mutual interests of the Fruit-Growers and the Bee-Keepers of the State make it imperative that fruit-bloom be first fertilized and then protected by spraying, from the injury of insects that prey upon and destroy the fruit; and,

WHEREAS, The fruit-bloom is largely fertilized by the bees, which should not be poisoned by misunderstood and misapplied use of tree-spraying; and,

WHEREAS, Fruit-trees should be sprayed when the fruit is forming, and not till after the bloom has been fertilized by the bees and otherwise; and,

WHEREAS, There is much danger to the health of the consumer of honey made from the nectar of blossoms poisoned by the compounds:

SECTION. 1.—*Be it enacted by the People of the State of Illinois, represented in the General Assembly:* That it shall be unlawful for any person to spray fruit-blooms with any poisonous compound which may endanger the life of those who eat of the honey produced therefrom.

SEC. 2.—Any person violating the provisions of this Act shall be deemed guilty of a misdemeanor, and shall be fined not less than ten dollars (\$10) and not more than fifty dollars (\$50) for each offense, and it is hereby made the duty of the State's Attorney of the several counties of this State to enforce this Act and prosecute all cases brought under this Act.

The first Bill above was referred to the Committee on Appropriations, composed of the following Senators:

Gardner, McKenzie, Hughes, Lundberg, Galpin, Baker, Landee, Lish, Evans, Barr, Hurburgh, Curtis, Juul, Hay, Pemberton, Campbell, Hull, Burton, Cunningham.

The second and third Bills were referred to the Committee on Agriculture and Horticulture, composed of the following Senators:

Dunlap, Hughes, Putnam, Houser, McCormick, McShane, Burton, Jandus.

We do not know the names of the House Committees.

**Indiana Convention.**—The bee-keepers of Indiana met and organized a State Bee-Keepers' Association last week. There was a fair attendance, and much time was taken in the discussion of a Foul Brood Inspection law. A Bill was drafted and put in the hands of a Legislative committee. It is desired that

all Indiana bee-keepers write *at once* to their Representatives and Senators, asking them to support the same.

It is necessary to know something of the headway made up to the present of this dread disease. I would invite correspondence from all over the State as to your locality—a postal card from *you*, if possible—in regard to the following items:

1st. Has foul brood appeared in your county or neighborhood?

2d. If so, how long has it been there, and to what extent has it injured the bee-industry?

To do the amount of good contemplated by this organization, it is very desirable to enroll a large membership. The fees are \$1.00

per year, and include membership in the National Association. So you see that you get the advantage of both for the price of one. We need finances to carry out the lines of work contemplated, and we would appreciate your help in this matter. Send \$1.00 to the Secretary, or to any of the officers most convenient, and your name will be enrolled on the books of the State and National Associations. But the answers on the postal cards should be sent to the President, as they are to be used in making up a plan for fighting foul brood.

GEO. W. WILLIAMS, *Pres.*, Redkey.  
C. M. SCOTT, *Vice-Pres.*, Indianapolis.  
JAY SMITH, *Sec.*, Vincennes, Ind.  
WALTER S. POWDER, *Treas.*, Indianapolis.

## Laws on Spraying During Fruit-Bloom

BY C. P. DADANT.

Since the publication of the proposed law concerning spraying fruit-bloom with poisonous compounds, I have received several communications from different sources upon this matter. The criticism is kindly, but it is nevertheless a criticism. The objectors acknowledge that it is not advisable to spray fruit-bloom, but ask how they can help it, if they wish to make sure of spraying all their fruit-trees in time for the destruction of the codling-moth, which is the principal insect injurious to fruits. Allow me, therefore, to call attention to the conditions either for or against the law. We all want to do the right thing, and when people are agreed upon that, it ought not to be very difficult to come to some sort of understanding, satisfactory to all.

That the spraying of fruit-bloom during full bloom may work great injury to the bees does not admit of a doubt. Instances are on record which show that entire apiaries may be depopulated by the wholesale poisoning of the nectar in the flowers at a time when the bees work upon this nectar in great numbers.

A still more important possibility, though more remote, is that of the poisoning of the nectar that is stored in the combs, if enough bees can manage to reach the hive with their load, after they have gathered juice which has been poisoned by spraying with arsenical or other poisonous preparations. The effect of arsenic is not usually so sudden that it will render the insect unable to reach its home. The nectar is not digested by the bee in any quantity, but is carried in the honey-sac and really remains intact, for the slight mixing with the saliva of the bee can hardly affect it, and there is none digested except the slight part of it which passes beyond the honey-sac into the di-

gesting stomach proper. It will thus be seen that there is great probability of some poisonous honey being stored where it might cause the death of persons eating of it. So much for the apiarist's side of this question.

Now as to the possibility of avoiding the damage. We are all horticulturists as well as bee-keepers, and I dare say the apiarists are very scarce who cannot own to the possession of a few dozen apple-trees or peach-trees, at least. Many of our extensive bee-keepers are large orchardists, and they will tell you that it is quite possible to begin spraying just before fruit-bloom if it is thought best, and continue until quite a few of the buds are open, also during bloom at times when the weather is cloudy or too cool for the bees to fly; and that it is also possible to spray the different varieties in turn, as the bloom opens, since there is a difference between one variety and another in the time of blooming. Thus spraying, if necessary, may be carried on almost uninterruptedly from the time when the first trees begin to shed petals. After the bulk of the bloom has fallen the danger almost entirely disappears, and the occasional death of a bee is nothing to the wholesale slaughter occasioned by injudicious spraying during the height of the blossoming of the fruit-trees—apple and peach, principally.

Concerning the advisability of spraying during bloom, regardless of the interests of apiculture and of the public health through honey consumption, there are strong points against it. The falling of the spray within the corolla of the blossom will often cause the dilution of the pollen by the poison. This pollen is thus rendered inactive, owing to the strength of the mixture, and the fruit which it is proposed to protect is prevented from forming. If the spray comes from above, it falls on the corolla and the fruit is sheltered against it, although it is the very skin of the forming fruit which it is desirable to reach, and that alone. Should the

poison gather within the corolla and flow to the fruit, it will only touch the center of it, and if it is not yet fertilized, it may be entirely blighted by the very thing which is intended to protect it. Not so, if the bloom is over. The fruit is then fertile, and is exposed to the spray, whether it comes from above, from below, or from the side.

To sum up, if it is thought best to spray early, a portion of it may be done before the opening of the blossoms, with a steady continuation after the bloom is about over. But the most important point is the continuation of spraying, over and over, during the first few weeks after the fruit is formed. One of the largest fruit shippers in the country told me that from his observations, the most successful and most perfect crops of apples were secured when spraying was continued two, three and even as many as five times over, after the forming of the fruit.

The proposed law on spraying will work no hardship on the judicious fruit-grower. It is only intended to protect the apiary against the careless and inconsiderate spraying of trees during full bloom.

Hamilton, Ill.

## Putting Bees Out of the Cellar

BY G. M. DOOLITTLE.

I am keeping bees mainly for the profit there is in them, therefore from a matter-of-fact standpoint, for I am sure that one week of practical experience is worth years of theorizing. Believing this to be so, I propose to take the reader right into my apiary, as it were, and show him just how I take the bees from the cellar. It is a little easier to have a man to help you put the bees out, but I often do this alone by the aid of a spring wheelbarrow, and it can be done with a wheelbarrow without springs. However, I think it pays well to procure one with springs for apiary work, as we wish it hundreds of times during the year, and the springs help very materially, not only in putting the bees into and out of the cellar, but in all wheeling of comb honey, or combs at all times when it is cold enough so they are brittle.

But we are to speak more particularly in this article about putting the bees from the cellar, and doing it alone, therefore we commence by lighting the bee-smoker and taking that and the wheelbarrow to the cellar door. Now if we have one or two old horse-blankets, or something of that sort (old bed-quilts are still better), to fold and spread on the wheelbarrow, we will have something that will take off all jar, so that the bees will not even know they are being carried about. With a spring wheelbarrow thus fixed I wheel hives full and running over with bees, right in July and August, no matter how hot it is, and they offer no resistance, unless I do such a bungling job in loading them, that they are aware of being handled before they are safely on the wheelbarrow.

Having the spring wheelbarrow "padded" and at the cellar door, together with the smoker, I go in and carefully take the first hive next to the door and carry it to the wheelbarrow, setting it thereon. The next thing is to shut the cellar-door quickly, so the bees remaining therein will not be awakened from their winter nap. The door being shut, the entrance to the hive is closed by putting a wet cotton-cloth over it, tucking the same closely about it so that no bee can get out, should they become disturbed from any reason so they were inclined to do so. Bees that get out of their hive at this stage of the proceedings are the worst to sting of any time of the year, seemingly, because they are suddenly awakened from their long winter nap.

Then there is another reason why none should get out here at the cellar-door, for such bees as do get out before the hive is placed on the stand which it is to occupy, are lost, as they mark their location where they leave their hive, and hang about the cellar-door trying to sting me every time I come after a hive, till they finally die from cold, starvation or exhaustion.

I now turn back one corner of the cloth a little, just enough so that a few puffs of smoke can be blown in, when the hive is wheeled to where it is to stand during the season, and a bottom-board placed for it. If your hives have bottom-boards nailed to them, of course this clean bottom-board will not be used; but I prefer a loose bottom-board, so that a clean one can be given every colony when it is put out, believing this far better than to allow the filth collected during the winter to remain, or the raking of this filth out with a bent wire, as some recommend.

Having the bottom-board in place, proceed to pull the crate-staples, or whatever kept the bottom-board attached to the hive for carrying to and from the cellar, thus having the hive ready to be lifted to the new stand. But before doing this, blow in a few more puffs of smoke to send the bees up among their combs so that they will be slow in coming out for their first spring flight, thus avoiding the "mixing of bees" many have where no precaution is taken.

The hive is now placed on the clean bottom-board and the entrance regulated to suit the size of the colony, giving 4 inches in length to the strongest colonies, and one inch to the weakest.

I next clean the bottom-board the colony had during the winter and place it "summer up" on the next stand for the next colony to occupy, as soon as it is brought from the cellar, which is the next thing to do, doing the work in the same manner we did with the first one. And in this way the work is done till all are out.

But when shall this putting out be done? is a question often asked. Some tell us to put bees out as early as a good warm day presents itself after the first of March. Others say wait till warm weather comes, so as to hang on for a little while, and till the bees can profitably secure something from the fields; but I prefer to take a "happy

medium" between the two, and so wait till the colony or two, which I generally leave out during the winter as "test colonies," begin to secure pollen quite freely, which is usually done upon the blossoming of the soft maple and red or "slippery" elms.

After years of experience, I find that when the bees are put out earlier than this, we have so many cold spells that the bees dwindle, or in other words, more bees die from cold, and through going out in search of water or sweets in unpropitious weather, than are replaced by emerging brood; and if left in too late, the colony becomes so weak through too many bees becoming restless from desire to get out, this causing them to die from exhausted vitality; and thus there are not enough energetic bees left in the colony, after their first flight, to build up rapidly in time for the harvest of honey from white clover. But when put out on the blossoming of the elm and soft maple, a colony of fair strength seems able to cause 5 to 10 young bees to emerge during the next 30 to 40 days, to take the place of each old bee there was in the hive when it was put from the cellar, and thus the colony becomes prosperous to the highest degree just in time to take advantage of the blooming of the white clover.

Just try this plan of putting out, doing it at the time suggested, and see if you do not find it better than anything you have done before, unless you have practiced what is here given in other years.

Borodino, N. Y.

## Invention of the Honey-Extractor

BY F. GREINER.

There is perhaps many a bee-keeper who makes use of the honey-extractor although he may know little, if anything, about the man who invented it. That the name "Hruschka" may not be forgotten, and to show how a most insignificant "happencence" may sometimes be the beginning of revolutionizing a whole industry, I write the following lines:

Major von Hruschka was an officer in the Austrian army at Legano, Italy. He was born in 1813 in the Austrian province, Moravia; after the war with Prussia, he left the army, lived for a time in Dolo, and finally in Venice, where he died at the age of 75 years, in 1888. During his leisure hours the Major devoted his time to the care of the honey-bee. This afforded him great pleasure.

One day when at work with the bees, he handed a plate of comb honey to his boy to take to the house. The plate was in a small, covered basket, and as the boy started from the apiary the bees were after him. To ward them off he whirled the basket around his head as he was running. When he reached the house, it was found that a large part of the honey was out of the comb and on the plate. The unsealed portion from the underside had

been forced out. The Major, anxious about the boy, followed him, and when he noticed the honey on the plate, and the condition it was in, he marveled.

After some study he concluded that the centrifugal force was the cause of the occurrence, and at once constructed a honey-extractor, which he exhibited in 1865 at a bee-keepers' meeting held in Bruenn, Sept. 12 to 14, by the German-Austrian bee-keepers. Great was the enthusiasm over the invention.

As soon as it was noised about that honey could be separated from the comb by centrifugal force, a good many honey-extractors were thrown upon the market with but slight changes and improvements over Hruschka's first machine. Like many other inventors and benefactors, the Major did not reap the reward which was his due. He died a poor man.—Translated from the Leipz. Bztg.

#### CELLAR-WINTERING OF BEES.

"What is the first requisite in cellar-wintering, temperature or ventilation?"

Mr. Chrysler—Temperature.

Mr. House—Temperature before ventilation.

Mr. Hershiser—Captain Hetherington's first cellar had sub-earth ventilation, but later he discarded these arrangements and much better results were obtained.

Mr. House said his father used to lower the temperature in his cellar by sub-earth ventilation. The cellar was moist, with water on the bottom, but upward ventilation relieved that.

A Member—Too quickly lowering the temperature is apt to disturb the bees.

Mr. Holtermann—Go into a cellar, three or four at a time, and the temperature will rise.

Mr. Hershiser.—My bees are next the furnace, and they don't mind my coming in continually; door is open mostly with temperature 32 to 44 degrees. Last year as high as 72.

Mr. Byer—What about outside bees affected with dysentery?

Mr. Coggsball—Nothing but a slight will help them.

Mr. Byer reported having half a dozen strong colonies quite badly affected, and as Mr. Hershiser and others thought sugar syrup would help them, Mr. Byer was asked to experiment and report results.

A Member—What is the cause of a few colonies getting dysentery, while the rest are wintering perfectly?

No one could give a positive answer to the question, but some thought bees differed in constitutional matters, the same as animals.

Mr. Adams thought the unusual amount of dysentery was caused by the damp season. He was using a gas flame to counteract the dampness of the cellar.

Mr. Laing asked Mr. Holtermann how often he found it necessary to use a stove in his cellar.

Mr. Holtermann—It all depends upon the conditions of the cellar.

Mr. Byer—Are Italians more apt to take dysentery than other races of bees?

Mr. Hershiser—Some strains of bees are more liable than others, but not necessarily Italians.

Mr. Byer said that he had noticed in his yards, that Italians were more subject to the disease than were Carniolans.

#### SNOW AROUND HIVES.

"Is it desirable to allow snow to remain around hives?"

Mr. Smith would not object to snow, but would not want the entrances to get clogged. He recommended a small hole in the hive-front, half-way up, as a safety-valve. Mr. Hershiser endorsed this view.

Mr. Holtermann—The Michigan convention was unanimous in agreeing that it was not necessary to remove snow from hive-entrances. The heat of the bees would melt away the snow.

Mr. Chrysler used a hive with a portico, the entrance of the hive open full width. The portico has a door with a contracted entrance.

## Convention of Bee-keepers' Associations at Brantford

REPORTED BY J. L. BYER.

The annual convention of the bee-keepers' associations of Brant and adjoining counties was held in Brantford, Ont., on Jan. 29, 30, and 31, 1907.

The meeting was called to order by Pres. Shaver, of the Brant County Association, who asked Mr. O. L. Hershiser to take the chair. Mr. Hershiser, after thanking the members for the honor conferred upon him, invited Mr. Holtermann to open the discussion on the subject for the evening, namely: "Hints for present use in wintering; either in repositories or outdoors."

#### HINTS ON WINTERING BEES.

Mr. Holtermann said there were more signs of dysentery among their bees in the cellar than ever experienced before. He attributed it to quality of some honey gathered by the bees on Long Point. Some of this honey showed air-cells under the cappings; it was gathered from a species of mint, had a decided minty flavor, and was of a greenish color.

Mr. Holtermann had a sample of this honey at the convention, and all who tasted it agreed that it was the most peculiar tasting honey they had ever sampled. Several bee-keepers said it reminded them of some samples of foreign honey they had tasted. Mr. Holtermann had been feeding some sugar syrup about a week before, to the 20-odd colonies affected, and thought there was a decided change for the better.

Mr. Hershiser thought that feeding a colony affected with dysentery with thick sugar syrup would benefit every time. Recently during a warm day, some bees fed on sugar syrup did not offer to fly, while those not so fed flew freely.

Mr. House—Outside conditions often have much to do with the matter, but in Mr. Holtermann's case the trouble is undoubtedly being caused by an acid of some nature in the honey.

Mr. Taylor said a neighbor of his had fed sugar syrup all winter to his bees in a damp cellar, and they had wintered perfectly.

Mr. Smith thought that candy made of sugar and honey was a splendid winter food for bees, notwithstanding reports to the contrary. In his opinion, there had been something radically wrong in making the candy.

Mr. Chrysler—Two years ago my bees gathered a large quantity of honey from "spurges." When first gathered, it made any one sick who would taste it; later it lost some of its objectionable features. The bees filled their hives solid, and the winter loss was quite heavy.

Mr. Armstrong—Are you sure, Mr. Holtermann, that the bees had been covering these combs of honey in which the air-cells were noticed?

Mr. Holtermann—Yes.

Mr. Coggsball thought possibly pollen in the honey was responsible for dysentery, but Mr. Hershiser thought not.

Mr. Smith said formerly he thought pollen caused dysentery, and for some years he extracted all honey from the brood-nest and fed sugar syrup. He had discontinued the practise as he thought results did not pay for the extra work.

Mr. Holtermann—Confining bees closely in the summer will bring on dysentery.

Mr. Hershiser—When putting bees into the cellar last fall, I found one colony so badly affected with dysentery that I had no hopes for them, but they appear to be better now.

Mr. Smith—Probably unsealed stores caused the trouble. Now they are on sealed stores and it disappears.

Mr. Craig—Will thin syrup ferment in the combs as quickly as poor honey?

Mr. Holtermann—Yes.

Mr. Craig and Mr. Armstrong said they had had sugar syrup left in vessels all winter and it did not ferment.

J. L. Byer—It is all a question as to how thick the syrup is.

# American Bee Journal

Mr. Byer said it depended a great deal upon the time of the year that snow fell. If a heavy fall came late in the spring on strong colonies, disaster was apt to follow.

Some years ago D. W. Heise had a number of strong colonies smother before the snow could be taken away. This was early in April.

Mr. Smith—Snow is apt to make strong colonies too warm, and cause too much early breeding.

## BROOD IN HIVES IN WINTER.

"Is it detrimental to have much brood in the hive at this time of the year?"

Mr. Smith would not want so much brood so early.

Mr. Byer thought that bees outside had brood earlier in the winter than was generally thought. He had helped to destroy some colonies slightly affected with foul brood about the middle of

January, and every colony had quite a quantity of brood in all stages.

Mr. Hershiser asked Mr. Holtermann his experience with cellar-wintered bees when first put out.

Mr. Holtermann stated that usually he found but little brood, and the less there was, he thought, the better.

Mr. Coggs—Mr. Elthorp of my State, lowers the temperature of his cellar by throwing cold water on the floor, and this discourages brood-rearing.

Mr. Smith one spring had his bees with brood in every colony, and they never did better. In common with other speakers, he, too, would sacrifice ventilation rather than temperature.

Mr. Burke—Last year I wintered bees without ventilation successfully, and this year, by ventilating like Mr. Holtermann, was in hopes my bees would increase. [Laughter.]

(Continued next week.)

saved for the past 2 years, and I am looking forward with interest to having the privilege of testing the same in the Hershiser press. If spared, to make the test I will, at my earliest opportunity, give the readers of the American Bee Journal the result.

## Moving Bees in Winter

In a letter received some time in December, Mr. Whiteside, of Little Britain, says: "I was moving bees yesterday, to-day, and will be to-morrow." Formerly, I was much opposed to moving bees in the winter, and if any one asked my advice in the matter, I always urged them not to undertake such a thing, as it would almost certainly mean the death of the bees. You see, I was going by what the other fellows told me. However, while at the Victoria County convention, 4 years ago, this question came up, and Mr. Whiteside and some others were inclined to laugh at me for the advice I gave a gentleman who was contemplating moving some bees 14 miles on the sleigh in December. Contrary to my advice, the bees were moved and wintered first-class, out-doors, in an extremely hard winter.

The following season, owing to the farmer on whose land some of my bees were, selling his farm and buying another only a short distance away, it became necessary for me to move the bees something less than half a mile. Moving bees such a short distance in the summer season, is always attended with the danger of losing a lot of the field-force, by the bees going back to their old location; so in view of my Victoria county friend's experience, I decided to move them as soon as there was enough snow for sleighing. The bees were packed in chaff, 2 hives in a case, and sufficient snow being on the ground on Dec. 10, teams were secured and sufficient men, and in half a day the 60 colonies were moved without a mishap. Hive-entrances were closed with pieces of wire-cloth, and it was well that we did so, as the bees rushed to the entrance when disturbed, as if it were a summer's day, instead of the thermometer being within a few degrees of zero.

After being placed on their new location, the screens were not removed till near night, as the bees were around the entrances, and numbers would have rushed out and perished in the snow.

As there were some 30 colonies at this place, that had been moved there the previous spring, here was a good test to see if moving in the winter was detrimental or not. Although none of these bees had a flight previous to the latter end of March, yet they wintered in excellent condition, and, as far as I could see, there was no difference in the two lots of bees.

Whether it would be safe to move bees late in the winter, I will not venture an opinion. However, as far as I am concerned, personally, I would hesitate to move bees January or February if they had no flight since say Nov. 1. Yet I have no evidence to prove that bad results would follow, and there is a possibility that it might

## Wax-Rendering Methods

In Jan. 1st and Jan. 15th issues of Gleanings, Mr. H. H. Root gives results of some experiments in wax-rendering, and the conclusions he reaches makes me feel like saying, "I told you so," as they are nothing more nor less than a triumph for the Hatch-Gemmill wax-press.

Some time ago Mr. F. Greiner expressed himself as follows in the American Bee Journal:

"I can make but about 3 runs with the German steam wax-extractor, and the amount of wax at the end of the day will be about 15 pounds. It is a mussy job, and I would gladly give any man half, or more, of the wax that he might be able to boil, squeeze, extract, or get in any way out of the stuff, provided I had nothing to do about it."

From what experience I have had with steam wax-presses, I judge that Mr. Greiner accomplished about an average day's work, and for a long time I have wondered how bee-keepers could have the patience to bother with such a machine, when for a much less cost they could have a press of ten times as much value as far as actual results are concerned.

Mr. Root concludes that he can render, with the Hatch-Gemmill press, from 7 to 10 pounds of wax per hour, and this includes remelting the slumgum and giving it the second pressing. He claims that with but one melting the slumgum, after pressing, will contain from 8 to 12 percent of wax, but after the second treatment only from 1 to 3 percent of wax will be left in the

refuse. The amount left after the second melting was determined by continued pressing and shaking up of the slumgum for 2 hours in the German steam-press.

I have melted up a great many combs and pressed out quite a few hundred pounds of wax with the Hatch-Gemmill press, but have never given the slumgum the second pressing. I did, though, last winter, take the refuse from which 82 pounds of wax had been pressed, and run it through the steam-press by way of experiment (*experience*, rather), securing in the operation 1½ pounds of a poor quality of wax. Needless to say I decided that it was necessary to have some better machine to secure the wax (if wax there was) from slumgum, from the Hatch-Gemmill press.

As to amount of combs that can be handled, I will give the following as an example, but by no means as a record, as any one else could do as well:

About 140 old combs were all broken up small, and brought by the stove. In a little over 3 hours from the time melting operations were started, we (Mrs. Byer and myself) had 71 pounds of wax, which was ready for the market, simply by scraping off the bottoms of the cakes. A Toronto dealer bought the wax, and I think he would vouch for the statement that it was of good, average quality. For some reason, wax from the steam-presses is never of as good a quality as that obtained by other means.

I might add that the slumgum from the Hatch-Gemmill press has been

prove all right, even as it did *unexpectedly* with me, when I moved my bees in December.

### Bee-Keeping for Farm Boys and Girls

Once more the Christmas bells have rung, and again the happy New Year is given to the contented and happy people of Canada. This is the time of year for municipal elections, conventions, and of annual meetings of the different societies of the land, and it is well that the people (farmers included) should take stock of how they are prospering in their calling. The farmers of Ontario have one very great advantage over those of the West, in that they can carry on so many different branches of farming.

Now, Mr. Editor, I propose another line of husbandry which I would recommend, especially to the young men and women, and that is bee-keeping. I see no reason why the farmers' sons and daughters of Ontario could not keep a few hives of bees. I do not know of any greater luxury on the farm than plenty of honey. There are very few people who do not like a dish of honey, but I believe a great many people think it is impossible to keep bees without getting stung. I have kept a few colonies for the last 25 years, and there is no more danger in opening a hive of bees than in leading a young horse to water, when you understand them. In the first place, there is no insect that the temperature of the weather affects so much, and then it is

so very easy to protect yourself that the danger of being stung is nothing.

My outfit consists of a veil fastened to an old hat, covering neck and face, then a pair of harvest gloves and a smoker filled with rotten wood and a coal, and I am ready for business. Of course, the most of the work with bees is done in warm weather in summer.

I do not recommend any one to rush in heavily until he becomes acquainted with them. I trust these few ideas will set some of our young farmers to trying a colony in the spring, and they will find both pleasure and profit in bees.—A FARMER, in Farmer's Advocate.

The foregoing is a sensible suggestion and worthy of the consideration of a good many farmers. True, all farmers will not make bee-keepers, but a few bees on many farms would not only be a source of income, but also an attraction to growing boys and girls, if they are properly instructed. Many farmers follow the practise of giving calves, lambs, etc., to their growing boys, and allow them to manage the same as a source of income for the boys' own use. Why not give the boy a colony of bees for the same purpose?

Methinks, if more of the farmers would follow this or similar plans, a great many more boys than is now the case would be content to stay on the farm.

hand, to do only 4 cases a day seems extreme in the other direction. That would be 2 hours to a case.

I have never sat a whole day at one time cleaning sections, but I have often timed myself in cleaning cases, and I think my average was about half-an-hour to unpack and clean each case of 28 sections. Like you, I find it much easier to clean sections in cold weather, but, then, all the fine honey I could put on the market in July brought me \$2.75 to \$3.00 a case; in October I got only \$2.40. So I had to put extra labor against extra price.

I do not exactly know what a T-super is, but when I read of Dr. Miller and other bee-keepers sitting and standing on their supers, I was glad I used the ordinary section-holders with wood separators.

When I take my supers off the hives I clean roughly with a hive-scraper out-of-doors, and then bring them into the honey-house. There I unpack and handle each section separately, putting it into an empty case as I finish with it.

This year I had girls working for me for a few days. When I unpacked they scraped a super in about 20 minutes each, but when left to unpack and scrape themselves, they did 12 to 14 cases a day, each working 8 hours a day. I did all the grading and packing myself. I do not think it would be possible to do all the work as you do in the bulk. There is a great deal of propolis here. I took a lump from a hive one day and weighed it for curiosity. It weighed an ounce.

Just at present I can not call myself a bee-keeper, for my brother has sold his ranch here and I have sold my bees, and intend going to California next week. However, I am too much interested in bees to do without them for very long, though this may be the last time I shall sign myself—

January 9, 1907. "COLORADO."

That's just the trouble, if you did know what the T-super is, and how to use it, you would not be so well satisfied with the section-holder, I think. I have used both, and *much* prefer the T-super.

Don't let the matter of emptying the T frighten you. It is only an extreme case when you have to sit or stand upon it, and even then it is not so very difficult, as sitting or standing upon them is not very hard work. I am sure you could empty supers very much more rapidly with the T than with the section-holder. You will readily see that they are not so very difficult to handle when I tell you that I have emptied hundreds, yes, thousands of them.

The matter of cleaning sections alone, if there were no other advantages—and I think there *are many*—would decide me in favor of the T. I think I could never be satisfied to use a holder that necessitated the handling of sections singly. I do not know just how bad propolis is with you, but we have the reputation of being in a very gluey region.

So you are going to California to live. I almost envy you. I hope that you will not be long beeless, and that the change will not lessen your interest in the sisters' corner. I trust we may still hear from you often.

Conducted by EMMA M. WILSON, Marengo, Ill.

### Growing Sweet Clover

I have just returned from the annual meeting of the Nebraska State Bee-Keepers' Association at Lincoln, where we had an interesting meeting, with a larger attendance than usual.

Of course, sweet clover was up for discussion, and the point was brought out that it was sometimes difficult to get a stand when seed was sown in spring. It was also shown that sometimes when it did not come up soon after sowing the seed remained dormant until the following spring, and then made a good stand. Now, my experience has been that the seed that falls and stays out all winter germinates much more quickly and evenly than seed that has been gathered and housed until spring.

I have found, too, that it is slow work getting sweet clover if one sows seed in great weed-patches. Sweet clover will run out other weeds if it gets a fair start amongst them, but, like alfalfa, the plant is fine, and rather delicate at the start.

I get sweet clover to grow in weed-patches, but I don't do it with seed, but with *transplanted roots*. Get them out

as early as you can, and they come strong and vigorous, ready to cope with anything, and hardly seeming to know that they have been moved.

I have done considerable transplanting, as well as scattering seed by the roadside, and with excellent results; and, as I told the bee-keepers at our annual meeting, I have not heard any grumbling *from the neighbors*, although it did come to my ears that a certain agent had remarked on the thicket of "weeds" along the road "so a fellow could hardly get through." If I had only bought a sewing machine from him he would have managed to get through, and without grumbling!

(MRS.) A. L. AMOS.

Comstock, Nebr., Jan. 19.

### Cleaning Sections of Honey

DEAR MISS WILSON:—I was much interested in your report in the American Bee Journal for Dec. 27, on the question of cleaning sections for the market. I must confess that Dr. Miller's statement amazed me at the time; it was so far beyond anything I have ever done myself. On the other

## The Care of Bees in February

For the progressive Southern bee-keeper October and February are two of the most important months of the year, for in the first-named all efforts are made to prepare the bees for the winter with plenty of stores, so that the colonies may come up in good shape for harvest time the next season.

In the early spring, as soon as the weather permits, he is anxious to make a thorough examination of his bees and ascertain whether they have "pulled through" all right; and tries to put them all in such condition as will bring them up to the best possible shape for the honey-flow later; that is, he manages his colonies so as to have them strong in bees just at the right time to take advantage of the flow. To attain his purpose, upon which the whole art of bee-keeping depends in producing good crops of honey, he must give his attention to several items:

First, the main examination of all colonies as soon as warm weather in early spring allows it, which generally begins here in February—sometimes even in January in mild winters, and March when the winters have been severe, although this happens very seldom.

The colonies are examined—1st, for their supply of stores; 2d, for their strength of the colonies; 3d, for "queen-rightness" or queenlessness; and 4th, as to the condition of the brood-combs. Of each of these points notes are made in the note-book.

Colonies short of stores would best be fed on full combs of honey, and it is essential to have these at least partly uncapped. By giving such full combs in the spring it will be found how advantageous it is to keep in reserve a stock of them at the time of the honey harvest for use the next season. I do this by leaving a number of *shallow extracting supers* on strong colonies the year around. Whenever a "short" colony is found one of these supers with honey is simply set on top of it—an easy job. In making such exchanges of combs from one colony to another, it is *very important* to know for certain that there are no dangers of scattering foul brood or other bee-diseases. Without the combs of honey, sugar syrup should be fed as previously given.

It is an easy matter to ascertain the strength of the colonies. If the cluster does not spread over the space of at least 4 or 5 combs, it should be marked as "weak," and should be united with another colony. Such

uniting should be practised without hesitancy; even though the number of colonies is reduced, more attention should be paid toward having stronger colonies.

"Queen-right" are all the colonies having brood in their combs. If queenless, they should be united if the colonies are weak, while good, strong colonies should be given a "laying" queen from reserve nuclei kept for that purpose. If no queens can be had

The "Old Reliable" as seen through New and Unreliable Glasses,  
By E. E. HASTY, Sta. B. Rural, Toledo, Ohio.

### NEW COMB HONEY IN CELLAR.

At the Ontario convention they assigned to U. H. Bowen, of Niagara Falls, the part that belongs to the lion among beasts (and bee-keepers), to-wit, the production of comb honey. Was he equal to the job? Yes. But what did he say that might make the rest of us sit up and woggle our ears? Put your newly harvested sections down cellar (!!)—and keep more or less fire there every day as long as the honey stays there. (Ah, possibly that might do.) Page 12.

### FEW UNFINISHED SECTIONS.

I take off my hat to F. W. Hall. He produced 5313 sections and had only 18 unfinished. Consider myself "some" in getting my sections finished up; but I don't seem to be in the same class with Mr. H. Page 17.

### PURE FOOD LAW AND ITS EFFECT.

I, for one, feel a little afraid of the effect of so much triumphe! triumphe! over the Pure Food Law. Make us all think that purity and goodness are sure to come without any effort on our part. Make the rogues all laugh in their sleeves, and set some new sails in the full assurance that nobody will go after them just now. I speak feelingly—squealingly, in fact. I'm an invalid and health-food crank. Before the much-praised law came into

at this time of the year, uniting with another colony should be done, as it is, in most of our seasons, too early to rear good queens for such colonies.

The condition of the combs is of great importance for the progress of the colonies. Only nice, clean, straight combs should be tolerated. Crooked combs, or such as are not straight in the frames, and bulge out on one side, allowing a hollow surface on the other, are detrimental to brood-rearing. In many cases the cells of such combs are not, and can not be, used for brood, especially where there are no cells on the bulged-out side of a comb. All such combs should be removed and replaced with frames filled with foundation in full sheets.

Drone-comb should be cut out. It is only necessary for a colony to have drone-comb of a total space about as large as a man's hand, because it is better for the colony, as they must have some of it. This should be scattered throughout the hive, hence small "batches" can be left in the lower corners of the brood-combs.

force, there was one place in Toledo where I could (and did) get abundance of excellent and pure peanut butter. Since the law came in force I sent (not went) to the same place for 2 pounds more. I received the product of a different firm, and stuff which I can't eat. Adulterated I'm quite sure; and probably more or less of the adulteration is grease, which I hold greatly in abomination. Page 25.

### BEES AND POETRY.

Can't you let a fellow have any poetic license at all? Yes, we can, and lots of it. But when a poet undertakes to write about bees we *are* a little inclined to hold his Pegasus clear down to the actual facts. Will the poet, on page 27, take notice that bees don't die (except by violence) with pollen on their legs? Furthermore, live ones seldom have pollen when working on clover—and when they do it's not golden but dark-colored. Apart from too much license the verses are nice, and the lesson good.

### PARTHENOGENESIS AND OTHER WAYS OF REPRODUCTION.

Many, many thanks to Prof. Cook for setting us right about the claim that other men did more to discover parthenogenesis than did Dzierzon. The other men saw with the microscope what they were told they would

see; but, surely, the man who was able to tell them what they would see was the real discoverer. Hard for people to realize how great that discovery was. Moreover, if I mistake not, it opened the door for other great discoveries. It is now known that there are at least four kinds of reproduction: Sexual reproduction, Parthenogenesis, Gemmation, and Fission. In Gemmation something analogous to a *bud* (*gemma*) forms somewhere on the organism. It grows and develops, and finally separates as a new creature. In Fission the original organism gradually divides into two organisms just alike, or nearly so. Joseph Cook, a distinguished preacher of Boston, once made a stir by claiming that the birth of Christ was a Parthenogenesis. Then he allowed himself to be frightened out of his claim, I believe. In my small field I would renew the claim. The birth of Christ was a Parthenogenesis. The birth of Eve was a Gemmation. Page 27.

#### REPRODUCTION BY FISSION.

And here is another tremendous thought which has just been trying to get abroad in the world. In Fission neither one is parent, and neither one is child. Of the individuals produced by Fission, many die from various causes, but none (it is claimed) die of old age. Life is a continually subdivided stream, but it is the same stream. *Here is practical immortality, not in any heaven, but visible to man's eyes and right here upon the earth.* Why not an institute be endowed to study Fission with a hundred microscopes till the secret is discovered why the cells of creatures that reproduce by Fission do not grow old? And when they get that secret can they not make at least longevity out of it for human beings?

But, alas, the whole thing will probably turn out to be a mare's nest (biggest one on record), although it is not pleasant to say it. More likely it will transpire that the facts have been overstated—observers observed well, but not long enough. It will be found (I can tell 'em) that after a certain large number of divisions there will be a rest, and something analogous to a spore formation. If not so, then some other way. Life will spit on its hands, and take a new and rejuvenated start, much as it does under other forms of reproduction. Page 27.

**Honey as a Health-Food.**—This is a 16-page honey-pamphlet intended to help increase the demand for honey. The first part of it contains a short article on "Honey as Food," written by Dr. C. C. Miller. It tells where to keep honey, how to liquefy it, etc. The last part is devoted to "Honey-Cooking Recipes" and "Remedies Using Honey." It should be widely circulated by those selling honey. The more the people are educated on the value and uses of honey, the more honey they will buy.

Prices, prepaid—Sample copy, for a 2-cent stamp; 50 copies for 70 cents; 100 for \$1.25; 250 for \$2.25; 500 for \$4.00; or 1000 for \$7.50. Your business card printed free at the bottom of front page on all orders for 100 or more copies. Send all orders to the office of the American Bee Journal.

## Pacific Coast Murmurings

### A Visit to the Home of Patrick Keating, Apiarist

I spent a week with a bachelor bee-keeper just after the middle of October, in the Santa Cruz Mountains, California. The place is about as lonely as one would wish to find, though, to tell the truth, there was lots of life not more than a mile away, at the mines.

It was to the little ranch of Patrick Keating up on the Alamedas above Hacienda, Santa Clara Co., that I hid myself. Near by, up on the hills, are the shafts and tunnels of the New Almaden quicksilver mines, for a long time the richest in the world. Of late years, the mines have not been yielding so largely—in fact, there is a belief that they are "petering" out. Yet there is a chance of richer ore than ever being discovered. The hills around were honey-combed for the heavy metal—the prospector's tunnels are to be found everywhere about the hills. This year prospectors are out in every direction trying to "strike" lime and cement quarries. Some have already been found. The possessor of a cement quarry has something that pays better than a gold mine, though, perhaps, not so fascinating. The demand for cement in San Francisco is something enormous and there are millions in it.

My friend invited me to see him. I went expecting to stay but 4 days, but so pleasant and entertaining were my days made by "mine host" that a week's length was reached before I left for home. I will hereafter call my friend by the name that he is known by for a score of miles around. So I shall just say "Pat," though his neighbors know him as "Pat, the Bee-Man." No matter where you go, every one knows "Pat," and he is looked upon as the philosopher of the mountain fastness and of the valley below. He took me in his buggy behind his fine horse, "Teddy," (so named, I suppose, because he likes to take the bit between his teeth, like a distinguished ruler by the same name, and run things to suit himself), and I could see that not only the old settlers but the school-children looked up to Pat as something of a wonder. It may be because he could subdue the bees, and it may be because of his learning and the quaint way he had of discussing the subject he was dealing with.

Pat was a bee-keeper before he came to America where he soon foreswore allegiance to his former sovereign, Queen Victoria. He was reared on a small farm in Tipperary County, Ireland. He says that bees did not do well on the "old sod," owing to the dampness of the weather. He tried keeping bees in Southern California. He found that the yield was phenomenal some years, but there were too many dry, or off years. While his present location is not the best in the world, still he likes the place be-

cause there is plenty of water the year around, even in the driest of dry years. He finds that it is not the dry years in Northern California that fail of honey, but the cool ones, like the past year, which was noted for its abundant rains.

A finer stream of pure, limpid water I never saw than was the Alamedas, which flows right through Mr. Keating's place, and there was such an abundance of it. I walked some 3 miles up the bank of the main stream to near its source to get a better idea of the flora up the canyon. There was an everlasting tangle of plants on both sides, and clean up to the top of the mountain. And there was so much of those *mountains*, you could easily understand that there was no level land within sight. It seemed a shame that so much waste land could be everywhere about. There were no timber-trees in this canyon. One has to get nearer the coast to strike the timber belt. But nearer the coast the honey-plants are not so good, so there is where the law of compensation comes in, I suppose.

Pat lives a quiet life, free from strife and worry, amid the hum of his bees and the babbling of the saucy brook below his cottage door. Companionship he has, in a measure, in his self-willed Teddy; the brindle cow; his dogs, Spink and Stock; a few black cats; and a fine flock of chickens. Almost as a hermit of old, Pat lives with his pets, and, for aught I know to the contrary, he may call them his "brothers," as did that austere poet of old, St. Francis, of Assisi. But how many of us could "batch" it far from the haunts of men, even with such "brothers" and "sisters" about us as the dogs and the cats, and the cow and the horse, and several million of bees thrown in? But the life is a healthy one, and with the work to be done the day passes rapidly enough.

In the evening my friend meanders down the creek to his nearest neighbor for his mail. Here he spends some little time talking with the stockman (for this neighbor is a cattle-raiser) and his good wife. Whether Pat's way is wended nightly to his neighbor's, around many a tortuous bend in the creek, just to get his mail, which is delivered there, may be questioned somewhat when it is remembered that there is a comely young lady dwelling there with her parents. This suspicion has to be set aside for the trick is an old one and something would have come of it ere this. Yet who knows what may happen?

My friend Pat's ways as a bee-keeper may be more interesting to my readers than his life as a citizen. My excuse for this character-sketch is just to show what life out in the hills on a California bee-ranch is like. Other features of such life will appear in succeeding sketches.

With this appears a view of Pat's apiary and honey-house, with himself shown "forninst" the middle foreground. This is from a photo by a San Jose professional. The other view was taken by myself during my recent visit. It gives a pretty fair idea of the bee-ranch and the surrounding hills. The place is rather picturesque, aside from its proprietor.

W. A. PRYAL.

DR. C. C. MILLER, Marengo, Ill.

Dr. Miller does not answer Questions by mail.

### Best Hive Paraphernalia to Start With

1. What hive-body should I use—an S frame or a 10?
2. What should the supers be fitted with—T-tins or section-holders? slatted or plain separators? bee-way or no bee-way sections?
3. What make of hive should I start out with?

MICHIGAN.

ANSWERS.—1. For extracted honey 10 frames, every time. For sections, maybe 8, maybe 10. Unless you expect to pay the closest attention to your bees, there is too much danger of starvation with so small a brood-chamber as S frames, but with fullest attention and the right kind of management you may sometimes do a little better with the smaller hive for comb honey. So long as the frames are the same, it is not a very hard matter to change from one size of hive, so it might not be a bad plan to try each.

2. After trying different ones, I have settled down on T-supers, plain wood separators, and 4 $\frac{1}{2}$  bee-way sections. Of course, you may not agree with me. I'm only saying what I think is best for me.

3. You will hardly go astray to take the hive most in use by men who keep bees for the money that can be gotten out of the business, and more of them seem agreed upon the dovetailed hive than upon any other kind.

### Information on Cellar-Wintering

Q1. A year ago last fall I built a bee-cellar in a side hill, 10x12 feet, with a 2-foot stone wall. It is covered with dirt all around except the front. I have a bee-shop on top. For bottom ventilation I have a 2-inch gas-pipe running from the bottom out 40 feet, 2 feet in the ground. For top ventilation I have a trap-door 18 inches square, which I go in and out. Is the ventilation all right? I wintered my bees there last winter, and they came out in poor condition, with the combs all molded. I went in last week, and the bees were all right except one colony. They seem to be quite noisy for this winter. The cellar seems to be quite damp, but no mold around the hives. My thermometer registers from 38 to 40 degrees. When I put the bees into the cellar I put inch blocks under each front corner on the bottom-board, and quarter-inch blocks under the cover for top ventilation. Is that all right?

2. On looking over my bees I found big drops of water gathered under the covers. What is the cause of it?

3. I keep potatoes in the same cellar. Would that cause any dampness to the cellar?

4. If I put a cement bottom in the cellar would it improve it?

5. I go in about every 2 weeks through the trap door. It doesn't seem to disturb the bees. Is there any harm in going in so often?

NEW YORK.

ANSWERS.—1. With dampness and mold there is certainly something wrong. If your thermometer is at all correct, the temperature of 38 to 40 degrees is too low, especially where there is dampness. Q1; would be a good

thing to raise the temperature in some way. Good banking might accomplish it. Coarse manure would do. A big lot of snow is good while it lasts. The ventilation of the hives would be all right in a dry cellar; but as it is there would be advantage in giving more ventilation at the top or bottom, or both. The cellar might have more ventilation, too; but in that case there might possibly be danger of lowering temperature too much.

2. The drops of water on the cover is the moisture from the bees, and settles there because of coldness and lack of ventilation.

3. There is probably some additional dampness from the potatoes; the harm depending upon the amount of potatoes.

4. I don't believe it would help much, if any, to have a cement bottom.

5. Your going in and out is not likely to do any harm unless you cool off the cellar by it.

### Bits of Cell-Cappings on the Bottom-Board

I have noticed on the alighting-boards of 2 or 3 of my colonies a substance resembling sawdust. What is this? I winter my bees outside in small sheds packed with straw. The sheds face the south.

IOWA.

ANSWER.—That brings vividly to mind the first year I wintered bees, when I was alarmed to find under the bees and at the entrance something that looked like a mixture of coffee-grounds and sawdust, and I didn't know but what it was "all up" with my bees. An old bee-keeper quieted my fears by telling me it was nothing worse than the bits of the cappings that the bees dropped when unsealing the honey. Your bees have the same "disease."

### Control of Increase in a Back-Yard Apiary

Having 5 colonies in a small city back-yard, without room to work in pairs, or have any more colonies, running for extracted honey in 3 colonies and comb honey in 2, with the main honey-flow from the last of May to the middle of July—what is the best way to control increase? Of course, time is no object in the case. I keep bees only as an avocation.

WASHINGTON CITY.

ANSWER.—You haven't asked me about it, and maybe it's none of my business; but I'd really like to know what you mean by "without room to work in pairs." As a rule, working in pairs is the very thing to give one room, and the only way I can think of to have more room with hives not in pairs, is to have the whole 5 standing as close together as possible. But that would give you such poor chance to get at the hives to handle them, that if you're working with bees for the fun of it, I shouldn't think you'd stand it. At least, I don't believe I'd stand it. I'd rather give away one of the colonies, and then there would surely be room for the 2 pairs. There's another way out. I suppose that back-yard isn't roofed over, and you have the right to build up your bees as high as you

like, so long as they don't interfere with the moon. Well, if I wanted more bees, and didn't see any way to manage it, I'd pile one hive up on top of another. That's nothing unusual in Germany, and if you want you can have a pile of 4 colonies.

As to the best way to prevent increase, I—well, really I don't know. One way is to double up in spring, so as to start with only 2 or 3 colonies, and then increase to 5 or so. I wonder, though, if you don't mean to prevent swarming. That's a harder one, but you can have a whole lot of fun trying to head off the bees from swarming, and they can have a lot of fun beating you. With the ones run for extracted honey there ought not to be much trouble. With 2 stories for the queen to range in, room for surplus given as fast as needed, and ventilation given at bottom and top of each story (see page 191 of "Forty Years Among the Bees"), you ought not to worry about swarming. With the comb-honey colonies, if you will allow each colony to be queenless for about 10 days at the beginning of the clover harvest, and then furnish it a queen that has been laying only a few days, there ought to be no swarming. Or, what is practically the same thing, remove the old queen just before swarming-time, as near as you can guess, and 8 or 10 days later destroy all queen-cells but one, and the bees will do the rest. Instead of that, it might be just a little better not to destroy any cells till you can hear the free young queen piping in the evening, and then, or next morning, destroy all cells.

Now, I've taken some liberties with your question, and if they're not to your taste, come back and I'll fix up another prescription for you.

### Feeding Bees in Tenement Hives

I have my bees in Orton tenement hives. 6 colonies to the hive, all in very good shape when put in. One of them is all stirred up from some cause. There is 8 inches of snow now, and the bees make as much noise as in July, both night and day, and will try to fly out in the cold if you go near the entrance of the hive. All the other colonies are quiet. Can it be that they are short of food? Should I feed them sugar syrup?

KENTUCKY.

ANSWER.—It is not certain what makes the bees so uneasy. They may be short of feed and they may not. The right thing is to open up the hive on a mild day and see whether there is plenty of honey present. It is possible, however, that the hive can not be opened without seriously disturbing all the colonies. In that case it will be the safe thing to thrust some candy into the entrance.

### Foretelling a White Clover Yield—Alternation of Good and Poor Seasons—Ratio Between Amounts of Comb and Extracted Honey

1. Do you know of any means of making a reliable guess, during the winter, as to the probable yield from white clover for the next season? If you can tell anything at all about it, I would like to hear how you do it.

2. Have you ever noticed a tendency towards alternation of good and poor seasons? I began keeping bees in 1897; and beginning with that year, the odd years have all been above the average, and the even years all below it, though 1898 was only a trifle below. I have been wondering if it just happened that way, or if alternation were the usual thing?

3. What is your guess as to the ratio between comb and extracted honey? Can you produce more than half as much comb as extracted, from the same bees, on the average?

ILLINOIS.

ANSWERS.—1. I don't know a thing about it more than any farmer who has never kept bees. If there is no stand of clover, of course there will be no crop. If there is a good stand, it may be killed out by freezing when

# American Bee Journal

the ground is bare of snow, and if it is thus killed I know there will be no yield. But if there is a good stand in spring, I don't know whether there will be any crop or not. I can't tell anything about it till the clover begins to bloom. Even then I can't be sure. If the bees begin to store from it, then I know it will yield—and the probability is that it will continue to yield; but it may come to a sudden pause. If it doesn't yield as soon as in full bloom, the probability is that it will not yield at all.

2. No, I have never noticed any sort of sequence in the matter.

3. I think the general opinion is that 50 percent more extracted than comb can be obtained. Perhaps that isn't far out of the way. Of course, there may be a difference in localities, in seasons and in management. One way to tell something about it is to compare prices of comb and extracted. If you'll wait a minute I'll do some figuring in that line. . . . Well, I took the prices in the American Bee Journal for Jan. 24, as that happened to be nearest at hand, and if we are to go at all by comparing prices, that 50 percent is altogether too low. For, taking highest prices for comb and highest prices for extracted in each of the 8 markets quoted on page 79, and making the yield depend upon these prices, there would be, on the whole average, 94 percent more extracted than comb, varying from 77 to 125 percent, according to the market. Something, of course, should be sliced from those figures on account of the greater cost of supplies for comb honey, but it would hardly seem that it would bring it down to 50 percent. But, as before intimated, circumstances will make a great difference, for you know in some cases you can get at least a small yield of extracted when you can't get any comb at all, and each man must decide the matter for his own locality and conditions.

In full bloom at present. They are found only scattered over the country, but nevertheless if the season is right they yield honey immensely, and a beautiful, aromatic honey it is. But this year they are a thing of the past already, as far as honey-yielding is concerned. Our next hopes are horsemint and mesquite, but it is dry here, and for bee-keeping, the prospects are again not at all promising. I suppose hundreds and hundreds of colonies of bees died from starvation in this part of the country the last season. I fed 4 barrels of sugar to 80 colonies last year, and I am hoping for a favorable spring—an early spring with plenty of rain and sunshine, and plenty of flowers. If we should have a late, cold and dry spring like last year, then I fear I will lose many colonies.

OTTO SUELTFENFUSS.  
San Antonio, Tex., Jan. 29.

## Indian Territory for Bees

"Illinois" asks Dr. Miller about Northern Indian Territory as a honey country. I have kept bees here for 12 years, and it is good on

Grand River. My bees have stored as much as 9 pounds per day (average) during aumac bloom. There isn't much clover here yet, but plenty of aumac, grape, persimmon, locust, Spanish-needle in places, goldenrod, and other fall flowers. There is the best market here for honey of anywhere I know. Mid-continental oil and gas fields are near here. Any bee-keeper is welcome that will not cut the price and not market inferior honey. The honey flow has been light and of inferior quality for the past 2 years.

J. T. HAIRSTON.  
Salina, Ind. Ter., Jan. 21.

## Bees in Fine Condition

We have had summer weather since Christmas, and our early honey-plants are in bloom so honey has been coming in freely. Hives are full of young bees and brood, and but little stores have been consumed. We have never seen bees in such fine condition at this time of the year before. We can not tell what the results will be, but they are promising now.

J. J. WILDER.  
Crisp Co., Ga., Jan. 25.

### Fine Winter So Far

We have had a fine winter so far. My bees are in the best possible condition. Still, the most trying time for the bees to winter is yet before us.

WM. STOLLEY.

Grand Island, Nebr., Feb. 12.

### Bees Wintering Fine

Bees are wintering fine in this part of the country with the exception of being short of stores. I winter my bees on the summer stands. I lost one out of 24 on account of being queenless.

NICK JENTGEN.

La Motte, Iowa, Feb. 6.

### Weather Affects Grapes, Etc.

I see a Mr. Kennedy (page 980, 1906) blames some insects or birds for cutting his grapes so that the bees can get the sap. Now I think I know where the trouble is, and that is the weather. If certain kinds of fruit are ripening and a nice rain should come, and the next day the sun shines right hot, the fruit will grow so fast that it will crack. At least I found that out several years ago on certain kinds of peaches, apples, and grapes; and then the bees and wasps have a good start.

Marissa, Ill., Feb. 2. C. A. FINOER.

### Conditions in Texas

Our winter weather has been very injurious, especially to the fruit industry here in Texas. Not because of too much cold, but on account of the prolonged warm weather we had in January. Fruit-trees are in full bloom in many localities, and here in the neighborhood of San Antonio, the catclaw is also

## American Bee Journal Novelty Pocket-Knife Gold Fountain Pen

All for \$3.00

(This cut is the full size of the Knife.)

## NOVELTY POCKET-KNIFE

(Name and Address on one side—Three Bees on the other side.)

Your Name on the Knife.—When ordering, be sure to say just what name and address you wish put on the Knife.

The Novelty Knife is indeed a novelty. The novelty lies in the handle. It is made beautifully of indestructible celluloid, which is as transparent as glass. Underneath the celluloid, on one side of the handle is placed the name and residence of the owner, and on the other side pictures of a Queen, Drone, and Worker, as shown here.

The Material entering into this celebrated knife is of the very best quality; the blades are hand-forged out of the very finest English razor-steel, and we warrant every blade. It will last a life-time, with proper usage.

Why Own the Novelty Knife?—In case a good knife is lost, the chances are the owner will never recover it; but if the "Novelty" is lost, having name and address of owner, the finder will return it. If traveling, and you meet with a serious accident, and are so fortunate as to have one of the "Novelties," your POCKET-KNIFE will serve as an identifier; and, in case of death, your relatives will at once be notified of the accident.

How to Get this Valuable Knife.—We send it postpaid for \$1.25, or club the Novelty Knife and the American Bee Journal for one year—both for \$2.00. (Allow two weeks for Knife order to be filled.)

## SOLID GOLD FOUNTAIN PEN

Finally we have found a good Fountain Pen that is reasonable in price. The manufacturers of this pen say that if you pay more than \$1.25 for other fountain pens, it's for the name.

This pen is absolutely guaranteed to work perfectly, and give satisfaction. The Gold Nibs are 14 kt., pointed with selected Iridium. The Holders are Para Rubber, handsomely finished. The simple feeder gives a uniform flow of ink. Each pen is packed in a neat box, with directions and Filler.

Worker

Queen

Drone

2/3 size

We mail this Gold Fountain Pen for only \$1.25, or for \$2.00 we will mail it and the weekly American Bee Journal for a whole year.

Sample copy of the American Bee Journal free; trial trip of three months (13 copies) for 20c; regular yearly price, \$1.00. Address all orders to

**GEORGE W. YORK & CO., 334 Dearborn St., Chicago, Ill.**

# Langstroth on the Honey-Bee

Revised by Dadant—Latest Edition.

This is one of the standard books on bee-culture, and ought to be in the library of every bee-keeper. It is bound substantially in cloth, and contains nearly 600 pages, being revised by that large, practical bee-keeper, so well-known to all the readers of the American Bee Journal—Mr. C. P. Dadant. Each subject is clearly and thoroughly explained, so that by following the instructions of this book one cannot fail to be wonderfully helped on the way to success with bees.

The book we mail for \$1.20, or club it with the American Bee Journal for one year—both for \$2.00; or, we will mail it as a premium for sending us **THREE NEW** subscribers to the Bee Journal for one year, with \$3.00.

This is a splendid chance to get a grand bee-book for a very little money or work.

## GEORGE W. YORK & CO.

334 Dearborn Street, CHICAGO, ILL.

**"Songs of Beedom."**—This is a beautiful 16-page-and-cover pamphlet, 6x9 inches in size, containing 10 bee-songs—words and music—all the songs so far written specially for bee-keepers, we believe. It is nice, as well as convenient, to have these songs all in one binding. Every bee-keepers' organization should have copies for use at conventions. They could be sold to members after using once, or held by the secretary for use at future meetings. Of course, every bee-keeper's family will want at least one copy. It is sent, postpaid, for only 25 cents, or 3 copies for 60 cents; or, we will mail one copy with the American Bee Journal one year—both for \$1.10. Send all orders to the office of the American Bee Journal.

## Bee-Song Souvenir Postal Cards.

We have issued in colors, 3 bee-song postal cards for bee-keepers, each card having one of the following songs, about 2¼x3¾ in size, also with illustrated heading on each card: "Buckwheat Cakes and Honey," "The Bee-Keeper's Lullaby," and the "The Humming of the Bees." The first two cards have small pictures of the authors of the words and music. This makes 4 souvenir postal cards we have now issued for the use of bee-keepers, the first being the "Honey-Bear" card. Prices, by mail, are as follows: Sample cards, 3 cents each; 7 for 20 cents, or 10 for 25 cents.

I can not be without the "Old Reliable." I think it is worth many times its price. It is a comfort and an adviser to me. It is far ahead of any other bee-paper I have seen so far.—A. L. OLIVER, of Minnesota.

## Standard-Bred Italian FREE PREMIUM QUEENS

We are booking orders now for those **Fine Untested Italian Queens** that we offer every year **FREE** to paid-in-advance subscribers as premiums for getting **NEW** subscribers for the Weekly American Bee Journal. These orders are taken for May or June delivery.

### What Some Say of our Standard-Bred Italian Queens:

*George W. York & Co.*—The two queens received of you some time ago are fine. They are good breeders, and the workers are showing up fine. I introduced them among black bees, and the bees are nearly yellow now, and are doing good work. A. W. SWAN.  
Nemaha Co., Kan., July 15.

*George W. York & Co.*—After importing queens for 15 years you have sent me the best. She keeps 9/10 Langstroth frames fully occupied to date, and, although I kept the hive well contracted to force them to swarm, they have never built a queen-cell, and will put up 100 pounds of honey if the flow lasts this week. CHAS. MITCHELL.  
Ontario, Canada, July 22.

*George W. York & Co.*—The queen I bought of you has proven a good one, and has given me some of my best colonies. N. P. OGLESBY.  
Washington Co., Va., July 22

*George W. York & Co.*—The queen I received of you a few days ago came through O.K., and I want to say that she is a beauty. I immediately introduced her into a colony which had been queenless for 20 days. She was accepted by them, and has gone to work nicely. I am highly pleased with her and your promptness in filling my order. My father, who is an old bee-keeper, pronounced her very fine. You will hear from me again when I am in need of something in the beeline. E. E. MCCOLM.  
Marion Co., Ill., July 13.

### How to Get these Queens Free

To any one whose own subscription to the Weekly American Bee Journal is paid in advance, we will mail a Fine Standard-Bred Untested Italian Queen next May or June, for each new name and address sent to us with \$1.00 for the Bee Journal a year. No one can get for himself the Bee Journal a year and the Queen for \$1.00. The Queen is offered as a premium for the work of getting some one else to take the Bee Journal a year. If you, yourself, want the Bee Journal a year and the Queen, send \$1.50 for the two, and we will book your order for a Queen. Queen orders will be filled in rotation—"first come, first served."

Address,  
**GEORGE W. YORK & CO.**  
334 Dearborn Street, CHICAGO, ILL.

## Caucasian and Italian QUEENS

First Premium at Michigan State Fair, 1906. Circular tells the rest. A postal gets it.

**A. D. D. WOOD, Lansing, Mich.**  
8Etf Please mention the Bee Journal.

### FOR SALE

6 H.-P. boiler and 4 H.-P. engine on one base. The engine is the double cylinder Westinghouse. The boiler burns a gallon of kerosene oil per hour for fuel.

50 Welsbach-light gas-machine, 100 Welsbach-light gas-machine. These generate gasoline into gas; this gas can be used for fuel-gas on ranges; it will illuminate your residence and workshop.

One 15 H.-P. fire-box or locomotive boiler.  
One 10 H.-P. center-rank engine.  
One 10 H.-P. vertical boiler complete complete.

One 4 H.-P. vertical engine.  
Peerless milk separators, from 350 to 1000 pound capacity per hour.

The gas machines to be exchanged on honey for the coming season.

**M. C. GEHL CO., Milwaukee, Wis.**  
4Etf Mention Bee Journal when writing.

## Queens

The finest in the land from DANIEL WURTH & GRANT.

**3-Banded, Red Clover, and 5-Banded Goldens.**

The Goldens took First Premium at every Fair they were exhibited last year.

Prices:—Untested, \$1.00 each; Tested, \$1.50 each. Address,

Mention Bee Journal when writing.

## For Sale

Two bushels of SWEET CLOVER SEED, hulled—\$12 takes it, sack included, F. O. B. Carbon-

dale, 1906 crop. 8A2t John Weir, Carbondale, Kan.

**Best No. 1 Sections** per 1000, \$4.00; No. 2, \$3.40; plain, 25c less. Discounts on Danz. and Root's hives, and other Root's Goods; also Berry Boxes. Bees for sale.

**H. S. DUBY, St. Anne, Ill.**  
6A14t Please mention the Bee Journal.

## Money Earns Money

only when invested in a money-earning business, and I believe there is no good, safe and honest business earning more money on the capital invested than the subscription-book business.

### DO YOU BUY BOOKS?

This is a book-buying age. A house without a library is no longer a home, and most of the home libraries in this country are purchased as a result of direct solicitation.

### BUT FEW KNOW

that during the last six years nearly 150,000 sets of "Modern Eloquence" have been sold for \$7,500,000.00; that "Stoddard's Lectures" have been placed in 250,000 American homes for \$12,000,000.00; that 300,000 sets of the "Century Dictionary" have been sold for \$21,000,000.00; that more than 500,000 sets of "Britannica" have been sold in the United States alone for over \$44,000,000.00; or that the sale of these books still continues. But few know what the profits are on this business. How much of it did you receive?

### A MODERN PUBLICATION

of the highest class, which in sales and profits is destined to exceed the above records, is now being made and sold. This is evident from the actual results now being obtained, although the sale was begun less than six months ago, and you can have full particulars by sending your name and address on a postal card, costing

### ONLY ONE CENT

Let me mail you a letter telling all about this record-breaking, modern American publication; how several hundred eminent American specialists are making it; why the American people find it not a luxury but a necessity, and *what a few dollars will do*—not over a hundred—if now added to the present capital.

### MAKE YOUR MONEY EARN MONEY

### CONVENTION NOTICE.

**Minnesota**—The Southeastern Minnesota Bee-Keepers' Association will meet in the Court House at Winona, on Tuesday and Wednesday, Feb. 26 and 27, 1907. Everybody is invited.  
E. C. CORNWELL, Sec.  
Winona, Minn.

**Notice to Illinois Bee-Keepers.**—We have received the following from the Secretary of the Illinois State Bee-Keepers' Association, which should be of interest to every bee-keeper in Illinois:

The annual membership fee in the Illinois State Bee-Keepers' Association is \$1.00, and by arrangement the National Association allows the members of other associations to come in a body through the secretaries at 50 cents per member. Having received letters from many who were already members of the National, we have resolved to accept such in the Illinois State Association (who already have membership in the National) at 50 cents. This will entitle them to a cloth-bound copy of the 6th Annual Report, which will soon be ready for the press. Those who come in before March 1, will be in time to get their names in the Report, in the longest list the State Association has ever had. And further, we have about 100 beautiful badges that will be given out to the members joining before they are all gone. JAS. A. STONE, Sec.  
Rt. 4, Springfield, Ill.

## The Rietsche Press

Made of artificial stone. Practically indestructible, and giving entirely satisfactory results. Comb foundation made easily and quickly at less than half the cost of buying from the dealers. Price of Press for L. frame sheets, \$2.00. Other sizes, 25 cents extra. Price of the Press making the foundation directly on the wired frames, \$2.50, any size wanted.

JAMESTOWN, N. Y.

[Established 25 years.]

Mention Bee Journal when writing.

## Honey and Beeswax

CHICAGO, Feb. 1.—The usual late winter demand is in evidence for comb honey to replace diminished stock laid in during the autumn by the large retailers, but during the dull period there has been very little change, if any, in prices, the offerings being light.

We find No. 1 fancy white comb honey brings 15@16c, and for that which is off in color and flavor from 1@3c less. Amber grades of all kinds are dull and range in price from 10@12c. The extracted perhaps is not quite so firm in price for the California or Western grades, but there is no surplus of white clover or basswood, both of which bring about 8c, and in some cases more. Ambers grade from 6@7c. There have been some sales of beeswax at 32c, but 30c is about the price for average.

R. A. BURNETT & Co.

PHILADELPHIA, Nov. 8.—While the supply of comb honey is equal to the demand, large quantities of comb honey having arrived in the market in the last few days, the price still remains high. The outlook, however, is that when the season advances and the bee-keepers ship more of their crop to the market, the prices will be a little weaker. We quote: Fancy white comb honey, 16@18c; No. 1, 14@15c; amber, 11@13c. Fancy white extracted, 7½@8 c; light amber, 6½@7c.

We are producers of honey and do not handle on commission. W. M. A. SELSER.

NEW YORK, Jan. 15.—The stock of white comb honey is pretty well exhausted, and we do not expect any more arrivals of large lots from now on. Prices are firm, and we quote from 15@16c for fancy white; 13@14c for No. 1; 12c for light amber. There is quite a little dark and buckwheat on the market, but no overstock, and we think that all of it will be disposed of before long at present prices, which we quote from 10@12c, according to quality. Extracted honey very firm, with sufficient supply to meet demand. California white sage is bringing from 8@8½c; light amber, 7½c; amber, 6½@7c; buckwheat extracted in fairly good demand at 6@6½c. Southern in barrels finds ready sale at from 55@70c per gallon, according to quality. Beeswax firm and steady at 31c. HILDRETH & SEIGLER.

# C. H. W. WEBER CINCINNATI OHIO

Office and Salesrooms, 2146-48 Central Ave. Warehouses, Freeman and Central Aves.

DENVER, Jan. 5.—There is practically no honey left in the hands of producers in this State, and barely enough in the Denver market to supply the home trade until spring. We quote strictly No. 1 white, per case of 24 sections, at \$3 20; No. 1 light amber, \$3; and good No. 2, at \$2 80. White extracted, 8@8½c; light amber, 7½@8c. Beeswax, 26c for clean yellow, delivered here.

THE COLO. HONEY-PRODUCERS' ASSN.

CINCINNATI, Feb. 9.—The demand for extracted amber honey has brightened in the past 3 weeks. Amber honey in barrels at 6½@7½c, according to the quality and the quantity purchased. Fancy white extracted honey selling at 8@9c in cans. Comb honey is a drag on the market, fancy selling at 14@16c. Beeswax, 32c for choice grade. THE FRED W. MUTH Co.

INDIANAPOLIS, Feb. 14.—comb honey is not plentiful, but demand is slack. Fancy white comb brings 16@17c; No. 1 white, 14c; amber, 12@13c. Best grades of extracted honey bring 8@9c; amber, 6@7c. Good average beeswax sells here at \$33 per 100 pounds.

WALTER S. POWDER.

TOLEDO, Nov. 30.—The market on comb honey remains about the same as last quotations, but has been coming in much more freely, as beekeepers seem to be very anxious to get rid of their stock. Fancy brings in a retail way 16c; extra fancy, 17c; No. 1, 15c; buckwheat, 15c. Extracted white clover in barrels brings 7@7½c; cans the same. Beeswax, 26@28c. THE GRIGGS BROS. & NICHOLS Co.

CINCINNATI, Jan. 25.—The market on comb honey is rather easy. Prices rule in jobbing ways from 14@14½c; single cases 16c for No. 1 white; off grades not wanted at any price. Extracted is very firm. Light amber in barrels, 6@6½c; white clover in barrels, 7½c; in cans, 8½c. Beeswax, 30c, delivered.

C. H. W. WEBER.

KANSAS CITY, Jan. 25.—The receipts of comb honey have been more liberal during the last week or two, and the demand light, market weaker. The market is practically bare of extracted, and there is quite a little inquiry. We quote: No. 1 white comb, 24 sec. cases, \$3.10; No. 2, \$2.75; amber, \$2.50. Extracted, white, 7½@8c; amber, 6½@7c. Beeswax, 27c. C. C. CLEMONS & Co.

## SOLID GOLDEN QUEENS

## Langstroth on the Honey-Bee

Revised by Dadant—Latest Edition.

This is one of the standard books on bee-culture, and ought to be in the library of every bee-keeper. It is bound substantially in cloth, and contains nearly 600 pages, being revised by that large, practical bee-keeper, so well-known to all the readers of the American Bee Journal—Mr. C. P. Dadant.

Each subject is clearly and thoroughly explained, so that by following the instructions of this book one cannot fail to be wonderfully helped on the way to success with bees.

The book we mail for \$1.20, or club it with the American Bee Journal for one year—both for \$2.00; or, we will mail it as a premium for sending us **THREE NEW** subscribers to the Bee Journal for one year, with \$3.00.

This is a splendid chance to get a grand bee-book for a very little money or work.

**GEORGE W. YORK & CO.**

## American Bee Journal Novelty Pocket-Knife Gold Fountain Pen

All for **\$3.00**

(This cut is the full size of the Knife.)

### NOVELTY POCKET-KNIFE

(Name and Address on one side—Three Bees on the other side.)

Your Name on the Knife.—When ordering, be sure to say just what name and address you wish put on the Knife.

The Novelty Knife is indeed a novelty. The novelty lies in the handle. It is made beautifully of indestructible celluloid, which is as transparent as glass. Underneath the celluloid, on one side of the handle is placed the name and residence of the owner, and on the other side pictures of a Queen, Drone, and Worker, as shown here.

The Material entering into this celebrated knife is of the very best quality; the blades are hand-forged out of the very finest English razor-steel, and we warrant every blade. It will last a life-time, with proper usage.

Why Own the Novelty Knife?—In case a good knife is lost, the chances are the owner will never recover it; but if the "Novelty" is lost, having name and address of owner, the finder will return it. If traveling, and you meet with a serious accident, and are so fortunate as to have one of the "Novelties," your POCKET-KNIFE will serve as an identifier; and, in case of death, your relatives will at once be notified of the accident.

How to Get this Valuable Knife.—We send it postpaid for \$1.25, or club the Novelty Knife and the American Bee Journal for one year—both for \$2.00. (Allow two weeks for Knife order to be filled.)

### SOLID GOLD FOUNTAIN PEN

Finally we have found a good Fountain Pen that is reasonable in price. The manufacturers of this pen say that if you pay more than \$1.25 for other fountain pens, it's for the name.

This pen is absolutely guaranteed to work perfectly, and give satisfaction. The Gold Nibs are 14 kt., pointed with selected Iridium. The Holders are Para Rubber, handsomely finished. The simple feeder gives a uniform flow of ink. Each pen is packed in a neat box, with directions and Filler.

3/8 size

Worker

Queen

Drone

We mail this Gold Fountain Pen for only \$1.25, or for \$2.00 we will mail it and the weekly American Bee Journal for a whole year.

Sample copy of the American Bee Journal free; trial trip of three months (13 copies) for 20c; regular yearly price, \$1.00. Address all orders to

### Miniature Sections

Considerable interest has been aroused among readers of the British Bee Journal as to getting out sections of honey weighing 1 ounce each, to be sold at 18 cents a dozen, a number of bee-keepers having united in ordering these little sections to the total amount of more than 4000. Years ago something of the kind was tried in this country, but it was found that it would not pay unless a much higher price per pound could be obtained than for 1-pound sections. At 18 cents a dozen the price would be 24 cents a pound; but as 1-pound sections can be sold in England at that price (Gleanings claims that best comb honey can be sold in England at 50 cents a pound), it is not likely that the successes of these miniature sections will be greater in England than it was in this country.

### A Word to Each Illinois Bee-Keeper

If you have not already done so, you should get busy at once in writing to one or more of the men at Springfield that represent you in making the laws of the State. The danger is that you will think that the matter of making the laws that Mr. Dadant tells about on page 65, will be attended to without any word from you, and that it doesn't matter whether you write or not. But numbers count, and it is so important to bee-keepers to have these Bills passed that no one should begrudge the little time and trouble to write, if it be only a card asking favorable attention to the Bills referring to bees and to spraying fruit-trees when in bloom, which we published last week. To be sure, it may do more good to write something more than a card, perhaps referring to matters directly in your own vicinity, as in the following, which is an

actual copy of a letter written to a Representative at Springfield by a bee-keeping constituent:

Hon. \_\_\_\_\_.

Dear Sir:—For several years it has been the practise of Mr. \_\_\_\_\_ to spray his fruit-trees when in bloom. That means a lot of dead bees for me, although he is under obligation to those bees for setting this fruit. The Experimental Stations say that it injures the crop to spray while in bloom, but he says he can't get through unless he begins before the bloom is over. When so straight and intelligent a man as Mr. \_\_\_\_\_ does that sort of thing, you will easily see the need of a law not only for my protection, but to protect him against himself. Illinois should not be behind New York or any other State in this respect.

Twelve miles from here there is—at least there was—a man having bees afflicted with foul brood, and any day there may be a case within a mile of me. If it should be in the hands of an ignorant or stubborn man, it might easily mean disaster to me, for foul brood is to the bees as bad as yellow fever and cholera combined to the human race. A law is needed that will compel that man to kill or cure his bees.

If I think you see the reasonableness of such laws as these, such laws as have been satisfactorily in operation in several other States, and ask your favorable consideration of the Bills now before the Assembly referring to bees and the spraying of fruit-trees when in bloom.

If you can refer specifically to your own case, as in the foregoing, well and good; but as said before, if you can do no more than to write two lines on a postal card, do it, and do it at once.

Don't make the mistake of thinking that because you did not vote for a man he will therefore not heed your word. You are one of his constituents, and you may be sure that your word will have its proper weight.

There may be other States where the foregoing suggestions will apply also.

### Calcium Chloride in the Bee-Cellar

Standing on the platform that "A dry atmosphere in the bee-cellar is almost a certain guarantee that the bees will winter successfully," Allen Latham has been doing some experimenting, as a result of which he says in the American Bee-Keeper:

Let some one who has a rather damp cellar, and whose bees generally come out in spring weak, and then grow weaker by spring dwindling, act as follows: Let him purchase about 100 pounds of crude calcium chloride, not chloride of lime so-called, but the real calcium chloride, fused. Let him purchase a dozen or so of galvanized pans, and enough galvanized netting, 6 mesh or so to the inch, to furnish a piece to rest over the pan. Let him put a pound or so of the salt on each piece of netting, and salt here and there in the cellar, some above the hives, but many below the hives.

If the cellar is very damp the salt may get all dissolved in a few weeks. In this case, the pans must one by one be set in the stove-oven for an hour or so until the water is driven out, the salt again placed on the nettings, and the pans replaced in the cellar. The salt can be used again and again, requiring only a moderate baking to bring it back to its original state.

There can be no doubt that a cellar can be kept very dry in this way, and need have almost no ventilation. Bees need very little air indeed if the air be dry air. Their need of fresh air is like our need of fresh air; that is, plenty of oxygen. They need fresh air mainly that its drying power may help them to get rid of the water which keeps accumulating in their bodies.

The editor adds: Fused calcium chloride costs, in 10-pound cans, 15 cents per pound, and in 100-pound lots, 10 cents per pound.

### The Loose-Hanging vs. Self-Spacing Frames

Editor Hutchinson is out-spoken in favor of loose-hanging frames of the old-fashioned sort. He says in the Bee-Keepers' Review:

I want no attachments on a frame—just a plain, straight, smooth, even,  $\frac{3}{8}$  frame all around. It seems a pity to me that bee-keepers will pay for these extra fixings on frames, when said fixings only make the frames less easy of manipulation. Self-spacing frames, staples, etc., are all right when an apiary is to be moved, but I would rather fasten the frames, even with nails, if necessary, when the bees are moved, if they are to be moved, then to be pestered all the season with all of these contortments.

That sounds as if the chief, if not the only

# American Bee Journal

object, of self-spacing frames were to provide against the trouble of fastening when bees are to be moved. If that were so, the great number of bee-keepers who are using self-spacing frames would probably agree with Mr. Hutchinson. But the moving part is little taken into consideration, and some who probably could not be induced to use loose-hanging frames never move their bees at all. Instead of thinking with Mr. Hutchinson that

the "extra fixings. . . . only make the frames less easy of manipulation," their very object in using them is to secure ease of manipulation. Very likely they would say, "All right, Mr. Hutchinson, if you can space your frames just as rapidly and correctly by finger and eye, then don't have any spacers in the way; but we can put frames in place more rapidly with spacers, and be ever so much more sure that they are always just right."

By the acceptance of its 3 delegates to the meeting, last month, of the Minnesota State Agricultural Society, it is recognized as the State Association.

It has adopted a new Constitution and By-Laws, its objects now being the promotion of scientific bee-culture and of the general interest of the bee-keepers of the State of Minnesota; to assist the State authorities in the enforcement of laws against the adulteration of honey, and for stamping out foul brood; and to co-operate with the National Bee-Keepers' Association in the defense of its members in their lawful rights.

Article VII reads: "Any member shall have the right to vote by proxy on any subject and at the general meeting, provided that no member present shall vote more than two proxies."

The Association is affiliated with the National Bee-Keepers' Association, so that by payment of \$1.00 annually a bee-keeper may become a member of both Associations.

Besides its annual meeting in December, it will in the future hold a spring meeting, and another during the Minnesota State Fair week; and the proceedings of each meeting will be published by circular to the members.

In the future, "Co-operation" will be the watchword of its policy.

Membership dues should be sent to the Secretary, Chas. Mondeng, 160 Newton Ave. N., Minneapolis, or to the Treasurer, Rev. J. Ridley, Monticello, Minn.

W. R. ANSELL, *Chm.*

**The Bee a Sabbath Breaker!**—Mr. C. G. Chevalier, of Maryland, sends us the following from the Philadelphia Press:

"Fust thing ye know," said Deacon Hardshell, solemnly, "we'll have to be tryin' this new minister for heresy. He's been sayin' all Christians should take pattern o' the bee as a model of industry."

"My land!" exclaimed his wife, "whut's wrong o' thet?"

"Why, the bee works on the Sabbath same's any other day."

**"Songs of Beedom."**—This is a beautiful 16-page-and-cover pamphlet, 6x9 inches in size, containing 10 bee-songs—words and music—all the songs so far written specially for bee-keepers, we believe. It is nice, as well as convenient, to have these songs all in one binding. Every bee-keepers' organization should have copies for use at conventions. They could be sold to members after using once, or held by the secretary for use at future meetings. Of course, every bee-keeper's family will want at least one copy. It is sent, postpaid, for only 25 cents, or 3 copies for 60 cents; or, we will mail one copy with the American Bee Journal one year—both for \$1.10. Send all orders to the office of the American Bee Journal.

**Bee-Song Souvenir Postal Cards.**—We have issued in colors, 3 bee-song postal cards for bee-keepers, each card having one of the following songs, about 2¼x3¼ in size, also with illustrated heading on each card: "Buckwheat Cakes and Honey," "The Bee-keeper's Lullaby," and the "The Humming of the Bees." The first two cards have small picturea of the authors of the words and music. This makes 4 souvenir postal cards we have now issued for the use of bee-keepers, the first being the "Honey-Bear" card. Prices, by mail, are as follows: Sample cards, 3 cents each; 7 for 20 cents, or 10 for 25 cents.

**Honey as a Food.**—We are glad to see that some of our readers are acting on the suggestion made in these columns, that they write something on the value of honey as a food for their local newspapers. Mr. W. S. Williams, of Pennsylvania, has written and had published a good article, about 10 inches long, which appeared in a recent issue of one of his county papers. We hope others will do likewise. It will all help when the time comes again for selling honey.

**Mr. D. H. Coggshall,** of New York State, who was one of the car-load of bee-keepers that made the trip to the National convention at San Antonio, Tex., last November, has been in Florida since then, and on Jan. 25th he wrote us as follows, from Stuart:

**FRIEND YORK:**—It is warm and very dry down here. The bees are gathering some honey, and they are whitening the combs. It is more work to take care of the bees here, as the worms and ants are continually on the watch for a chance to spoil the combs and eat the honey; while my combs, in the North, are piled away in the bee-house ready for use next May, and with but little care.

D. H. COGGSHALL.

**Notice to Illinois Bee-Keepers.**—We have received the following from Jas. A. Stone, Secretary of the Illinois Bee-Keepers' Association:

We are holding back from publication until the last moment possible, that part of the Sixth Annual Report of the Illinois State Bee-Keepers' Association that contains the list of members, thus giving all who would avail themselves of the benefits of joining before the Report is printed, the opportunity to do so. This opportunity will probably continue until about April 1st. The membership dues are \$1.00, which also pays the annual dues in the National Bee-Keepers' Association.

JAS. A. STONE, *Sec.*

Route 4, Springfield, Ill.

**The San Antonio Views** on the first page this week will, no doubt, be of interest to many. San Antonio has much of historic value, and one of our regrets is, that when there last November we did not have time to examine carefully more of the things that deserve attention.

Mr. C. J. Thies, of Wisconsin, kindly fur-

nished us the photographs from which pictures Nos. 1, 2, 5 and 6 were reproduced; No. 3 was one of Mr. Coggshall's collection; and No. 4 was one of the two or three of our own that were only fairly good.

Market Hall was where the sessions of the National convention were held. We thought we had secured a good picture of it, but upon finishing the film after returning to Chicago it proved to be so defective as to be worthless. Our attempts at picture-taking on the San Antonio trip were almost all failures. We regretted it very much, as we had hoped to bring back with us some interesting views. But as several of our good friends who were in the car-load of bee-keepers were more successful, we are still permitted to present to our readers at least a few pictures of scenes that will long be remembered by those who were able to make the trip to old San Antonio.

**Words of Appreciation,** as well as the other kind, come to this office from time to time. We welcome both—the former for the encouragement they give us, and the latter for the hope that they may result in improving the weak places pointed out. The following, from a Pennsylvania reader, is especially kind and appreciative, as well as appreciated:

**EDITOR YORK:**—In sending you my renewal for the "Old Reliable," I would like to give you a word of encouragement. I notice that once in a while the kicker gets in a word, and why not allow the faithful readers also a word? Personally, I regard the editor of such a paper as the American Bee Journal as a benefactor to the bee-keeping fraternity. I especially like the way in which you have the American Bee Journal divided into departments; a fellow always knows where to look for what he wants. Many single issues are worth more to me than a whole year's price.

Yours faithfully,

GEO. H. REA.

**To Minnesota Bee-Keepers.**—We have received the following from W. R. Ansell, chairman of the Executive Committee of one of the two State bee-keepers' organizations now in Minnesota:

The Minnesota Bee-Keepers' Association, which was founded in 1888, has made a new departure this year by incorporating, with a membership of 51, under the educational laws of the State of Minnesota.

## The Legumes—Valuable as Nectar-Yielders

BY PROF. A. J. COOK.

There is no family of plants in all the vegetable kingdom that can rank for value and interest with the Leguminosæ. There are many reasons why this family is of peculiar interest, and as it embraces many of the most valued of the honey-plants, every bee-keeper must be interested in an account of its full life history.

### IRREGULAR FLOWERS.

One of the things that interests us at once as we study the legumes is the fact of irregularity of the blossoms. By this we mean that the different flower-leaves are very varying in form. The sepals or green leaves just about the flower are also irregular. The number of petals—the showy parts of the flower—are 5. Thus we say that the flowers are on the plan of 5. If we closely examine the flower of the pea or bean, we note this irregularity. The large upper petal is called the banner; the two lower ones are closely approximated and enfold a pistil and stamens. From their form these are called the keel, because they resemble somewhat the keel of a boat; the other two petals are called the wings, and their spread at the sides makes this name appropriate. There are usually 10 stamens, 9 of which are usually united, the 10th being free. The pistil develops into a pod or legume, and hence the name, Leguminosæ, applies to the whole family. Every one understands the form of a pod. It is the flattened fruit of these plants and consists of two valves, to one of which the seeds are attached.

### ECONOMIC IMPORTANCE.

As stated above, no family of plants rank in importance with this. Even the cereals—Graminæ—fail to equal the legumes in value. Not that the plants themselves are more valuable, but in what they do they are so important that no other plants can at all be compared with them in this respect. Here we have the clovers, the beans and peas, and the vetches. Thus it will be seen that here are found many of our most valued farm plants.

### HONEY-PLANTS.

The bee-keeper is more indebted to this family than to any other, for here we find all the clovers, which rank at the very head of bee-plants. The mesquite is also found here, and besides these we have the red-bud—*Cercis*—and the locusts. The honey-locust certainly ranks very high as a honey-plant, while

the mesquite is what places Arizona and contiguous regions so high in the rank of honey-regions.

### POLLINATION.

The bees are as important to this family of plants as the plants are to the bees. It is now well known, and almost as generally recognized, that without bees these plants will not be fruitful. The red clover must have the bumble-bee, and our white clover, al-sike, and alfalfa could not produce seed at all, if it were not for bees or other insects which carry the pollen from one plant to another. Indeed, as I have before pointed out to our readers, the very fact of irregularity of flower is proof positive that this work of cross-pollination is absolutely essential to full fruitage.

### SHADE OR ORNAMENTAL TREES.

It is here also that we find many of our finest shade-trees. The Acacias, so common in Australia, and which have been imported so largely into California, belong to the pod-bearing plants. These, like the locusts, have double use, for they not only possess rare beauty, but they are also valuable for honey. Some of the Acacias, like the partridge pea of the East, have extra-floral glands, and thus they not only give the bees pollen but honey from two sources. I know of very few trees that are more beautiful than these Acacias, some of the species being not only exceedingly graceful, but the foliage is so delicate that even when the tree is not in bloom it is a thing of beauty. When in full blossom the tree possesses a glory that is indescribable.

### A CURIOUS PLANT.

It is to this family that the Mimosa or sensitive plant belongs. As is well known, this plant is so exceedingly sensitive that a slight brush against the foliage causes the leaves to shut up and the stems to fall. As soon as the irritation ceases the stems rise again and the leaves open. These plants are mainly tropical, and have been admired by all who have crossed the Isthmus of Panama, where they grow in great luxuriance.

### ENRICHING THE SOIL.

But the greatest use of the legumes is that of adding the nitrogen of the air to the soil in combined form so that it can be used by the plants. One of the greatest improvements in agriculture in late years is the free and general use of clover crops to enrich the soil. No soil can be fertile that has not plenty of nitrogen. Every productive soil must also be rich in humus,

by which we mean decaying organic matter. Again, no soil can be very fertile except as it harbors untold millions of bacteria, or minute vegetable organisms. In plowing under great crops of these legumes—clovers, vetches or peas—we bring about all of these conditions.

If we examine the roots of any of these legumes, where they have long grown and are vigorous, we will find them thickly covered with tubercles, often as large as a pea. Examination shows these to be the home of very minute bacteria or vegetable germs. These breathe in, if we may so speak, the nitrogen of the air, and so combine it into nitrates that the plants can use it; and thus when we plow these crops under we are storing our soil with the most costly of the fertilizing elements. This matter of plowing under clover crops is becoming very general in Southern California, and is adding very greatly to the fertility and value of the orchards.

Claremont, California.

## Non-Swarming Hives to Prevent or Control Swarming

BY DR. G. BOHRER.

To make such hives to meet the wants or desires of the bee-keeper is a subject that has called, and still calls, into requisition the thoughts and efforts of many apiarists. And, as far as I have given attention to the line of argument used in discussing this question, the dimensions of the hive, together with regulating its entrance, have received more attention than any other matter affecting the swarming instinct of bees. I say "instinct," because it is a fixed law of their nature, just as it is in any other part of the animal kingdom, to propagate the species; and in every department it is, to an extent, influenced by circumstances. But to stamp out this inborn inclination is one of the impossibilities. Hence, we need not, in our efforts to prevent excessive swarming, entertain a hope of ever being able to "cut out" swarming entirely. A large hive is, according to my observations, one of the most effective means of holding in check the disposition to swarm.

In 1864, I made one of the large Langstroth observation hives which contained either 16 or 18 frames of standard size. While its colony gave me more surplus honey than that in any other hive I ever used, it never, during the 7 years I used it, cast but one swarm, which was a monster. During the last 4 years I have had but 5 or 6 natural swarms. Having adopted the plan of giving my bees room as it seemed to be demanded, I have found it requires less labor and attention to use a 10-frame Langstroth hive, one story early in the season, and when room is required, to add another story.

In order to test this method of controlling the matter of swarming, and to test the merits of a large hive in securing the largest possible amount of honey, I ordered 10 14-frame Langstroth hives. And, as I run almost entirely

# American Bee Journal

for extracted honey, I will add a second story if the season and the numerical strength of the colony demand it. Such a hive must be occupied by a colony headed by a prolific queen. In fact, any colony to be profitable must have a good queen, if profitable results are expected. These hives will, of course, be heavy to handle. But they will require very little handling. For after the bees have been set to work in the upper story, the hive will require but little if any lifting. But in case they do, two persons can, of course, do the work more easily than one.

These hives will be very heavy for ladies; but such ladies, I will suggest, should "commit matrimony," and be sure to "catch on" to a partner who is not afraid of bees. And in case a bachelor or widower keeps bees in this sort of a hive, let him also look up a "honey;" not smaller in avoirdupois, I will suggest, than 80 pounds, nor larger than 300. And my word for it, such an "outfit" can manipulate a 14-frame Langstroth hive even when well stored with honey.

Some practical bee-keeper, who prefers to run for comb honey, can put sections on a 14-frame hive, with both a good colony and a good queen, during a good honey season, and see how far it will outstrip an 8, or even a 10 frame, hive.

Let a number try the foregoing suggestions. It won't cost much, and may benefit us in points of desirable knowledge, more money, and, best of all, more contentment. And, finally, as such hives will cost a little more than a small one, see to it that in making them, good lumber is not ripped into common pasteboard thickness, and used as either a dummy or a bottom-board.

Please, Mr. Editor, don't think I am on the war-path, and after any of our manufacturers, farther than to let them know what I find to be next to worthless about any of their products. I hold it to be our duty to let them know what we want, and to ask them to supply the need. Mr. Hasty, in his "Afterthoughts," will endorse all I have said.

Lyons, Kans.

## Lower Freight-Rates East and West

BY F. GREINER.

It would be difficult to deny the fact that the interests of the Eastern honey-producer are in opposition to the interests of the Western producer as to the lower freight-rates; and when the National is making a fight for lower freight-rates on honey, it is doing it for the interests of the Western fellows. These, of course, are looking to the Eastern market to dump their product upon it, and the higher the rates are—yes, if they were prohibitive, the greater would be the benefit the Eastern producer would receive.

The more Western honey that can be kept out of the Eastern market, the better in all probability would be the price the Eastern producer would receive. It can therefore hardly be ex-

pected that the Eastern producer will become very enthusiastic over the prospect of having low rates for the Western honey-producer, who is enabled by virtue of the better bee-pasturage, cheap lands, etc., to produce cheaper and to undersell the Eastern fellow.

Railroads discriminate between Western shippers of grain, etc., and the Eastern shippers, so that a car of wheat will come from Chicago to New York about as cheaply as from some points inside of New York State to New York City. It is expected that they (the railroads) do the same with the honey-producers. I can say that the farmers did not like the idea of competing with the Western grain-producers when the tariff is the same, and perhaps the Eastern honey-producers will feel a good deal the same way, and will not hail the day with great delight when honey can come to New York at the same price from California, Texas and Colorado as it does from inside the State.

I realize that this is a very selfish view to take in the face of the fact that honey is selling a great deal too high, and that all of us Eastern honey-producers are becoming rich; nevertheless, such is man.

I am glad to learn from Mr. Muth that railroads sometimes pay damages. It is news to me. I have shipped honey for 30 years, and some lots were broken, but I have never yet had one cent of damages paid me by a railroad company. I have shipped tons of comb honey at an exorbitant rate (1¾ cents per pound), and before the railroad accepted the shipment I always had to give them a release of all responsibilities. In view of this fact, of course the rate was a great deal too high. Of late years we obtain rates on the basis of fruit, and so freight counts very little. My admitting that some of my honey shipments arrived in broken condition may be considered as pleading guilty to the charge Mr. Muth makes, that many honey-producers (myself included, perhaps) produce honey illy fitted for transit. I admit that I, and many others, do not use a great deal of comb foundation in sections, and no bottom-starters whatever. Still we produce honey as good as Mr. Muth can possibly wish for. It is not desirable to use comb foundation except as small starters, and absolutely not necessary to produce a honey that will ship. I am sorry that Mr. Muth misleads the bee-keepers by such advice as he gives. It can not fail to hurt the honey-trade if followed.

Honey is of a fragile nature, and it will always be injured in transit when not handled properly. We can not possibly produce a honey that will withstand such usage as bricks or cordwood do, even should we use cast-iron comb foundation. And when we do produce it, it will not be wanted. If railroad men could be induced to handle honey with more care, much loss would be prevented.

A friend of mine bought a case of honey of me last fall, and I defy Mr. Muth, or any other man, to produce anything better than that case was, as far as being well built out and securely

fastened all around; (the weight was 26 pounds for 24 pound boxes), and yet that case was smashed in transit, being shipped 50 miles; there were but 4 or 5 sections unbroken in the lot, veneering being between the combs at that. Did the Railroad Company pay for that honey? No! Railroad companies are in it to make money, not to pay damages; that is my experience, and I would not want to go to lawing with them. It might result in throwing away good money. It does not pay to go to lawing with a railroad company or a commission man; or with any one, for that matter.

Naples, N. Y.

## Requeening Colonies in the Fall

BY EDWIN BEVINS.

In September 1st Gleanings, I find the following from J. A. Green:

"Now is the time to requeen your colonies. If you have only one apiary, and do not mind having your bees swarm, it may be as well to let the bees do the superseding themselves."

I have only one apiary, and do not mind letting the bees swarm, but under no circumstances would I leave the bees to do the superseding wholly themselves. In the time of the white honey-flow, and sometimes earlier, the apiarist will learn where his poorest queens are to be found. If found only a little before the beginning of the flow, there is generally nothing to be gained by requeening at that time, and when the flow is on, the man who does not mind having his bees swarm should let them alone as much as possible. But when the white flow is over, and there comes a season of comparative leisure, then is the time for replacing his queens known to be inferior, with queens reared for the purpose during the flow.

Under circumstances generally prevailing in yards cared for by one man, there is no need, and but little excuse, for the apiarist to send to a distance for his queens to be used for superseding purposes at the time indicated. His queens should be supplied from cells built in strong colonies under the swarming impulse in the early stages of the swarming period. Every bee-keeper is supposed to know how to care for these cells. In order that he may reinforce the supply, lest it be insufficient, he should use one or more of his colonies for queen-rearing, and begin with the beginning of the honey-flow. My experience proves to me that queens thus obtained are the superiors of any obtained from a distance, with rare exceptions.

It is doubtless a fact that some of the queens that one has marked for destruction will be superseded by the bees some time in the course of the season. It is equally certain that some of them will not. The cost of substituting queens reared under the conditions above mentioned, to take the place of the queens supposed or known to be failing, is not great. If one makes the change he may be tolerably sure of re-

sults. If he does not, he will live in some doubt, and, perhaps, in some dread of what the outcome may be. If he does not, it is my experience that he will have some, perhaps many, disappointing colonies in his yard the following season.

I have always some colonies in the yard with queens that I have no means of knowing whether they are in a failing condition or not. These are the colonies that have gone through the season strong at all times and have stored much honey. Some of the colonies that are in this condition now will have failing queens or no queens at all in brood-rearing time next spring. It is hazardous to requeen all such colonies in the fall, as you may destroy many a valuable queen. Therefore, it is better to await developments. By substituting young queens that have in June and before, proven to be failing ones, it may be presumed that the bee-keeper has done neither the colony nor himself any harm, and he is almost sure to reap a balance of gain from the transaction.

Leon, Iowa, Sept. 7, 1906.

[Through an oversight, the foregoing article failed to appear when it should have been published—early last September.—EDITOR.]

## Management of Swarms, Etc

BY C. W. DAYTON.

On page 1035 (1906), Mr. Grant Anderson says: "Don't waste the bees' time by confining the queen in a box for several days." It is given as a caution after reading my article on page 931 (1906). I try to be as explicit as possible, but this swarm management is a whole system, and can not be described in one article. It calls into use plans and fixtures never before used. Nearly all bee-keepers think themselves more or less experts, and they also doubt that an entirely new system could be devised, and on this account they are likely to mix up the new system with their old plans, and this mixing causes trouble.

From one of my articles, which appeared in another bee-paper, I will quote:

"If the swarm issues, say, at 8 or 9 o'clock in the forenoon, I shake the bees from the limb into an empty hive-body, having the entrance closed and a screen over the entire top to give plenty of ventilation, while the bees are confined in it. The caged bees should be set in a shady place. After being in this box an hour or so, or, long enough to become clustered, I can usually raise the screen without any bees taking wing, and cage the old queen. Take the queen away entirely. This will make them very uneasy. Late in the afternoon, or, after they have been in this uneasy state 5 or 6 hours, I raise one edge of the screen slightly to allow the bees to get out slowly and return to their old hive of their own accord, but queenless."

This is my plan or procedure to prevent all increase, and there is no "several days" nor any "as much as one

day" about it. If the bees and queen are to be hived in a new location, or, in other words, if increase is desired, then leave the queen with the bees in the box. But that is not so easy a job as it may seem that it should be, for the reason that the bees are likely to desert the queen and return to the hive from which they came. The reason they desert is either because the bees were not in the swarming mood, or else the queen is nearly worthless. The queen might be a good egg-layer, but egg-laying does not always prove a good queen, for the bees may eat most of the eggs or allow the larvæ to starve while plenty of larval food could be had were the bees in the disposition to provide it. And supplying a swarm with drawn combs, or a comb of unsealed brood, or clipping the queen's wing, as Mr. Anderson suggests on page 1035, aggravates the bad condition.

We can tie a sitting hen on the nest, and adjust a weight on her back to compel her to "sit," but it is not "sitting." The temperature of a sitting hen is several degrees above the normal temperature of other hens. It is often that a hen will sit a few days and then leave the nest. If we undertake to compel the hen to sit, her temperature will be sure to fall lower than the temperature of other hens, which is an ill temperature for the eggs. And the same conditions are in operation with the bees.

It is not the number of eggs, nor the arrangement of the nest, that satisfies the hen, nor is it the arrangement of the combs or hive that satisfies the swarming bees. There is an ingredient which mechanical devising can not supply. It is the presence of this particular ingredient which causes the higher temperature of the sitting hen and the presence of the same ingredient causes a higher temperature in a swarm of bees. If there is an abundance of this ingredient we are sure to get a good "hatch" in the case of hens' eggs, and in the case of bees the new combs will be rapidly constructed, brood will be plentiful and well fed, and supers will soon be occupied and filled with stores of new honey.

In testing swarms in a box we can determine in a few hours' time the disposition and probable utility of the swarm, and if their disposition is faulty it can be altered or corrected. Any swarm can be sent back to the old hive, but as to whether they should be established in a new location depends upon the height of their temperature. The greater their energy and disposition to construct a new domicile, the higher the temperature. This higher temperature manifests itself to the observing and experienced eye because it changes the actions of the bees from their usual actions. It changes the pitch of the sound of their wings. Any expert musician would soon discover this.

If we put the swarms having virgin queens in a box with a queen-excluder on it, to remain until the next day, about half of the swarms will desert and return to the old hive, leaving the queen entirely alone in the box. Where

the queen is old, the bees never all desert, but often there is but a small cluster of bees which remain with the queen.

Now, if the queen is an extra good one, the bees will all stay in the box with her, and when the other bees come home from the fields and find that the swarm has left the hive these bees will search about the apiary and go in with the swarm in the box. By this process we get a good-dispositioned quantity of bees, and good queens in the swarms. When bees perform in this manner we may know that they mean "business," and that they will construct their new combs in haste. Swarms of this kind generally prepare to swarm again in 28 days, by constructing queen-cells on the 21st or 22d day after hiving. If drawn combs or full sheets of comb-foundation are put in when they are hived, there is seldom made any preparations for future or further swarming, at the 28-day period.

Most bee-keepers would prefer the swarm and queen which do not prepare to swarm. But, in reality, this swarming disposition is an indication of energy. If they lack this energy they will fall short of energy for other accomplishments, such as constructing combs, filling surplus-honey supers, or brood-rearing. This energy corresponds to the steam in an engine. We would not oppose but guide it into useful action. This energy starts out early in the season—first, to build up sufficient brood and force of bees to swarm early; not to swarm once, but twice. That is, the swarm is calculated to swarm. In order to swarm the second time it is necessary hastily to fill the hive of the first swarm. Thus there is a chain of succeeding periods of energy. When the chain is interrupted the bees become listless, less industrious, less productive, and have less interest for all the operations of the hive; may even allow a share of the brood to starve, or from lack of heat it may chill, the same as eggs chill through lack of attention or protection by the sitting hen. The brood-cells may not be properly cleaned out, and filth would accumulate in the layers of cocoons, and more dead brood follows. With the introduction of the particular bacilli foul brood results.

By prevailing methods swarms are scooped up and poured out with no more consideration of the wants and notions of the bees than if they were pebbles. Instead of conservation, bee-energy is extravagantly wasted; indeed, the bees are often condemned because they exhibit energy. Though this energy can not be readily seen with the naked eye, it is none the less materialistic and valuable when rightly understood. As the swarming season advances the old and best foragers are estranged from all engaging interests, and become transformed into mere sojourners in a strange land, suspicious at any moment of being ruthlessly torn from home and friends and other ties. It might not be of so much consequence had bees a memory lasting only a few days, but the indications are that their memory extends throughout their lives.

Chatsworth, Calif.

## Convention of Bee-Keepers' Associations at Brantford

REPORTED BY J. L. BYER.

(Continued from page 150)

### WEDNESDAY MORNING SESSION.

#### COMB OR EXTRACTED HONEY—WHICH?

"Which is the most profitable for a beginner to produce—comb or extracted honey?"

Mr. House—Extracted.

Mr. Hershiser—A difficult question to answer. Depends upon the *beginner*. Probably comb, if but a few colonies are kept. More care is necessary to produce good extracted honey than comb.

Mr. Holtermann agreed with Mr. House. He had seen beginners put honey-boards on upside down, and put sections together inside out. Sections produced by beginners are never well-filled, and are put on the market in bad shape.

Mr. Byer—Small producers are not the guilty ones in putting unripe extracted honey on the market.

Mr. Chrysler—A beginner that will put sections together wrong side out will not be apt to produce good extracted honey.

Mr. Edmondson and Mr. Shaver both thought beginners would better start with comb honey. One reason was that they would not be so apt to have their bees starve to death.

A vote showed the members to be about evenly divided on their opinions on the question.

At this point the following resolution was presented, which, after discussion, was passed unanimously:

"While we would encourage people to go into bee-keeping who are prepared to give it the same attention and study that they would give to any other calling, we would strongly advise any who are not so prepared, not to invest in the business, as results are sure to be unsatisfactory to the investor as well as to the industry at large."

Mr. House said certain periodicals were booming bee-keeping as a fortune-maker. Many were being deceived. He would heartily endorse the resolution.

Mr. Chrysler and several others stated that in their locality of all who had started bee-keeping, nine out of ten had made a failure of it.

Mr. Laing—People are influenced a great deal by bee-keepers' conventions and conversation. He heartily supported the resolution.

Mr. Miller then read his paper as follows:

### SHORT CUTS IN THE APIARY

Being at a loss where to start, I may say that I am probably what might be called a crank on short-cut methods, having studied them and fitted in ideas from various systems until they are now saving me the expense of a man's help during the busy working season.

First, the Heddon hive gives me many short cuts in work all through the season. Commencing with queen-clipping, the queens are smoked to the queen-excluder, and there caught without the trouble of removing frames. As swarming-time approaches, a hive-lifting device enables me to diagnose and suppress swarming perfectly, and thus at each stage of the work short cuts follow. During the time of extracting, no brushing of combs is tolerated, the supers are set on and beside the hive, and after setting off a certain number, they are placed on a large special wheelbarrow, with a 30-inch wheel, and taken to the house, and from here they are loaded and drawn home from the outyards. Here the extracting is done by a 2-horse power, vertical gasoline engine, the honey running to barrels in the cellar. In packing the bees for winter, another specially-constructed 'barrow together with two 3-bushel baskets, and a very large, short-handled fork, enable me to pack as many colonies as two men formerly did.

Now a word for my "ready helper" who smokes: This is a sturdy little fellow with a copper fire-box,  $4\frac{1}{2} \times 8\frac{1}{2}$  inches, and lung capacity of  $8\frac{1}{2} \times 11\frac{1}{4}$  inches. The cap is hinged on the left side, and to prevent it from flying open under any and all circumstances while in use, it is held securely by a short piece of chain composed of very short links, one end being riveted to the cap, while the other end is drawn down and into a groove filed in a piece of galvanized iron, which is bent at right angles and riveted to the barrel. This gives an expansive fastening, thus allowing for coking, which takes place at the edges, and yet gives a secure fastening.

Another very useful feature which prevents the grass from falling out of the cap and into the fire, is a piece of metal bent at right angles and riveted just above the lower edge on the inside of cap, projecting in one-half inch. This effectually holds the grass where it is placed, and prevents the necessity of frequently refilling.

F. J. MILLER.

Mr. Hershiser—How do you prevent swarming with the Heddon hive?

Mr. Miller—Pry apart the 2 sections of the brood-chamber and diagnose the condition of the colony. Cells will al-

ways be built between the 2 divisions. If cells are present, simply carry one section of the brood-chamber to another stand. In 4 days examine to see on which stand the queen is, and if not on the old stand, return her there.

Mr. Hershiser—No doubt the division space is a handy place for the bees to construct cells, but on Langstroth frames they sometimes construct them along the end-bars.

Mr. Miller—My frames are closed-end, so that is impossible with me. I never look for number of cells, but simply find out if there are any present; that's all I want to know.

Mr. Chrysler—The Heddon is too small for me. I use a hive equal to 2 8-frame Langstroth.

Mr. Miller had tried using 6 frames in the Heddon hive for extracting purposes, instead of 8 frames, and was well pleased with results.

Messrs. Chrysler, Edmondson, Shaver, and others, favored shallow extracting supers, Mr. Chrysler declaring jocularly that any one who didn't use them was behind the times.

Mr. Holtermann favored the full-depth Langstroth frame, but admitted that Mr. Miller puts up strong arguments in favor of the Heddon hive. Years ago he had tried them and didn't know how to use them. However, he was not in sympathy with Mr. Miller's plan of hauling the combs of honey home for extracting.

Mr. Byer—Heddon hives are a nuisance if an apiary gets infected with foul brood.

Mr. Miller—They need to be made very accurate, and frames wired perfectly to prevent sagging.

Mr. House used super foundation and only one wire in frames the same depth as Mr. Miller's, top-bars  $\frac{1}{4} \times \frac{7}{8}$  inches. Yet he had no sagging.

Mr. Cogshall—End-bars on manufactured frames are made too light. Basswood is better material than pine for top-bars.

Mr. Holtermann catches hold of end-bars when shaking frames, yet he had broken many ends of top-bars off.

### BEE-KEEPING FAR NORTH.

"Can bee-keeping be carried on successfully in Alberta and Saskatchewan?"

Mr. Craig said he had no personal knowledge, but they were shipping a lot of supplies out there.

Mr. Smith—Only where shelter is attainable, bumble-bees are present all through the West. Last season the yield was light, but a year ago a number of bee-keepers had averaged 100 pounds per colony.

Mr. Holtermann said he knew of one man in Alberta who had sold \$600 worth of honey in one season: as more irrigation was used, quite likely the more honey would be produced, as alfalfa was grown and local conditions were quite similar to Colorado.

### CONDITION OF COMBS FOR EXTRACTING.

"What state should combs be in before extracting?"

Mr. Cogshall—In New York State! [Laughter.]

Members agreed that we should err

# American Bee Journal

on the safe side, and be sure the honey was well ripened.

## COMB HONEY OR EXTRACTED?

"Which is best—comb or extracted honey?"

Mr. Hershiser said no difference. We should try to educate people so that they will be willing to pay as much for extracted as for comb honey; was in favor of small packages, and showed a tumbler which, on being emptied of honey, made a handy drinking glass.

Mr. House agreed with Mr. Hershiser. He could, in the clover-flow, produce as much comb as extracted. In the fall there might be a difference in favor of extracted.

Mr. Chrysler—Sell small packages now, and in 10 years the people will be buying in large packages. The Toronto Fair deserves more credit than has been given, for distributing small samples of honey among the people.

In answer to the query as to whether

we should reliquefy honey that had granulated in the store, the opinion was brought out that if the work is properly done at first, there will be no call for the second operation.

Mr. Armstrong—The secret in keeping honey liquid is in heating it after it is sealed.

Mr. House mentioned an extensive apiarist of his acquaintance, who had put up 10 tons in 34-pound jars, without the least trouble of its granulating again.

Mr. Hershiser thought there might be something in Mr. Chrysler's idea of baiting customers with small packages.

Mr. Trinder favored large packages and incidentally put in a plea for buck-wheat honey.

Mr. Holtermann—Greater uniformity of packages for both comb and extracted is desirable.

Mr. E. R. Root came in just as meeting was adjourning, and was heartily applauded.

(Continued next week.)

figures in conducting the present agitation for "pure food." In fact, the good work he is doing in that direction will have a tendency to cause bee-keepers to forget the "joke" perpetrated on them some years ago, relative to the manufacture of comb honey. From a lengthy article in the Toronto Globe, I take the following appetizing morsel. Speaking of gelatin, Dr. Wiley said:

"It is made from the scrapings of hides. These hides go into the tanner's vats, and these hides that smell to heaven, are treated and trimmed, and the trimmings used to make gelatin. The Marine Hospital service found the tanner's germs in gelatin." The best of this gelatin is used in glue factories, and what is not fit for glue is made into commercial gelatin, which "is used for putting into ice cream and candies, and for making capsules that you take your medicine in."

If conditions are to be remedied, well and good. If not, according to some of the old adages, such as, "Where ignorance is bliss 'tis folly to be wise," and "What the eyes don't see the heart does not grieve for," Dr. Wiley, in giving this information to the public, has performed a doubtful service. Seriously speaking, though, I believe the present agitation can not help but bear fruit, and we as bee-keepers should do our part towards helping the good work along.

One thing is certain, as the public gains confidence in other food products, to a corresponding degree will they cease to suspect honey as being a mixture of glucose and other ingredients. As has been pointed out quite frequently, lately, honey and glucose, when labeled as such, will not sell as readily as the same mixture labeled "pure honey;" consequently, if the new law is enforced, bee-keepers are sure to be greatly benefited.

At the same time, I can not help but think that United States bee-keepers are expecting too much for the first installment of good things being brought them by the Pure Food Law. One would think from reading the apicultural press of the United States, that the Glucose Trust was killed and decently buried, whereas, it appears as viewed by the writer, to be simply in a trance, and likely to be resurrected at any time. Personally, I look for the Glucose Trust to *die hard*, and before his demise we look for more spasmodic kickings than have been manifested as yet.

Aside from the matter of adulteration of honey, the bee-keepers of Canada and the United States alike, have another obstacle in the way of selling their honey to the best advantage. I refer to the large quantities of *unripe* extracted honey thrown on the market every year by unscrupulous or *ignorant* bee-keepers. R. A. Burnett & Co., of Chicago, hit the nail squarely on the head when they wrote the following to Gleanings:

"If the bee-keepers will let their honey ripen before taking it off the hives, it will do more than any law passed in furthering its consumption."

I have tested good honey mixed with glucose, and also have sampled more than once unripe pure honey. Neither

Conducted by J. L. BYER, Markham, Ont.

## Number of Ontario Non-Bee-Paper Readers

A year or so ago the statement was made at an Ontario convention, and again repeated at the Brant County convention, held last month, that about 8000 bee-keepers of Ontario do not take a bee-paper. I questioned the accuracy of the statement both times, and since coming home from Brantford, I have been looking into the matter, and I am thoroughly convinced that this (York) county has not its proportionate amount of that 8000. To be sure, we have had a county association for a number of years, and there is no question but that is a powerful factor in the dissemination of bee-culture; and I more than suspect if there are anything near 8000 bee-keepers in Ontario who do not read bee-papers, that the bulk of them reside in counties that have no organization.

## Black Bees vs. Italians

Do you know, Mr. Editor, I have an idea that quite a large number of American and Canadian bee-keepers will be inclined to sympathize with the views of Mr. Macdonald (page 195) relative to the merits of the black or German bees. At any rate, there is no question but that a host of our extensive apiarists do not want the *Italians* in their purity. The *Italians* have been lauded to the skies (sometimes by

interested parties) to such an extent that it is considered almost a crime to write anything in opposition to them. Certainly the black bee has its failings, but who will say that the *Italians* in some respects are not also found wanting?

By far the largest yields in three successive seasons in one of my apiaries, has been from a colony of German bees, as pure, judging from general characteristics, as it is possible to get them. I might add that in this same yard, each season, there has been a number of *Italians* bred from the most *aristocratic* blood in America.

Personally, I think that if half the attention had been given in the past towards eliminating the objectionable features of the blacks, as has been spent in trying to improve the *Italians*, to-day the former bee would be in every way as desirable as the latter. The majority of my own bees are a cross of *Carniolans* and *Italians*, with a considerable admixture of black blood; and, to tell the truth, I am in no particular hurry to get rid of this *mixture*.

## The U. S. Pure Food Law and Its Effect on Honey—Unripe Honey

According to press reports, Dr. Wiley, Chief of the Chemistry Bureau of the United States Department of Agriculture, appears to be one of the chief

# American Bee Journal

appealed very much to the palate, but the first-named was by all means to be preferred.

Unripe honey is a hard thing to legislate against, and the only remedy I see is the education of the bee-keeper to understand that it is to his interest to put only well-ripened honey on the market. Even if you can not appeal to a man's moral instincts, as a gen-

eral rule, if you pander to his pocket-book, you can convince him. It is always easier to tear down than to build up, and in this matter of better honey, it is discouraging to know that some who could be a power for good if they choose, on the contrary use their influence in persuading bee-keepers that it is not necessary to allow the bees to ripen the honey on the hive.

## That Black-Stockinged Little Girl

I note with pleasurable interest the comments on page 1034 (1906), under head of "Our Bee Keeping Sisters," of the picture of a "Black-Stockinged Little Girl." As I scan that criticism, it occurs to me that Miss Wilson should have been a lawyer. That "Doesn't it prove too much?"—if she had said nothing more, reveals what was disturbing the gray matter of her brain. The point was ingeniously made, and, had her hypothesis been correct, might have furnished a basis for an argument; but, the fact is, in taking the picture, I had no other motive than to present the young lady with a photograph of herself holding a frame of bees.

Now, right here, before I forget it, allow me to pay my respects to the Editor for the part he has taken in this matter. He made the question of "Black Stockings" prominent by entitling the picture. To be candid, I think he should be indicted for malicious mischief, and be sent up for life. Nobody can tell what a world of trouble this matter may cause me, for we all know that, to intimate to the majority of bee-keepers that bees are no more inclined to sting persons dressed in black than in any other color, is like flirting a red rag before an infuriated bull. It stirs up an immense amount of nervous energy, and I'm not the fellow to do anything of the kind if it can be avoided, but have my own convictions upon that matter from personal experience and experiment.

But to return to the little girl: When she came into the yard, I put a veil over her face to insure safety, and after going through the hive, finding the queen, etc., and the bees becoming quiet, I risked removing the hat for a snap-shot (as my kodak was near), the wearing of black stockings being a mere incident which I regarded as unimportant.

I am sorry to learn that the bees in the neighborhood of Marengo have a reputation such as is generally given them by those most intimately acquainted; it certainly is anything but flattering. As results follow cause, we are naturally inclined, especially where the results are unpleasant, to try to ascertain what the cause is. My bees are handled gently, neither tobacco in any form, nor intoxicating liquor of any kind used, neither do they give me, nor any one else, any trouble. It is true, they are thorough-bred 3 banders, but are no sleepy-heads by any means, for I could stir them up so that they would go for the whole neighborhood.

Not knowing just what the practise is in handling bees in the neighborhood of Marengo, it would be almost hazardous to offer advice, and especially gratuitous advice. Were one better acquainted with Miss Wilson, we might suggest as an experiment, that she secure a different sort of a helper. You know slight changes sometimes produce surprising results. For instance, some remove the queen, thinking to cure bee-paralysis; others paint the barn red and think the result favorable. "The woods are full" of good material—persons who have none

Conducted by EMMA M. WILSON, Marengo, Ill.

## Women Lead in Bee-Keeping

A. J. Root has found at least one region where women take the lead in bee-keeping. He says in *Gleanings in Bee Culture*:

It is a little peculiar that bee-keeping all through the Black Hills seems to be largely in the hands of the women. Our good friend Mr. Anderson has a harness-shop, and does quite a business; but his wife has been succeeding so well in bee-culture that I believe he contemplates closing up his shop and giving his whole attention to bees. I think they have now something like 130 colonies, and have started a very pretty apiary a mile or so out of town.

Speaking of Bellefourche, S. Dak., he says:

I found quite an excitement in regard to what had recently been done in bee-culture at this place; and, queer enough, bee-keeping there is almost entirely in the hands of women. One lady said that the bees got so much honey they were everlastingly swarming; and there were so many swarms that came out when nobody was around to care for them that they clustered in dooryards and gardens all over town; and now almost every home had one or more colonies hived in dry-goods boxes, kegs, or something else; but the women were taking the lead.

## Honey Sandwiches

Chop together enough seeded raisins and English walnuts to make a large cupful, half and half. Add to them 1½ tablespoons of honey and 1 tablespoon of orange or lemon juice; mix well and spread between thin buttered slices of white bread.—*Chicago Record-Herald.*

## Beginners and the Bee-Papers

I have a great deal of sympathy for beginners in not understanding technical terms, and the more advanced knowledge that comes from practise and experience. I can remember the time when all these things were Dutch to me, and of making some great, big blunders in managing my bees, owing to this ignorance. But after getting

an "A B C of Bee Culture," and applying the knowledge gained therefrom in handling my bees, I soon learned to know the terms, and step along in the more advanced classes, which, in a graded school, would be like keeping back classes to bring up certain new members to a standard equal to those more advanced, in order to go on. I refer to the editorial on page 25.

MRS D. M. BROWN.

Cherry Hill, Pa.

Yes, like any other study there are things a little difficult to understand for the beginners in bee-keeping, even the terms used are not always self-defining. But do you really believe that you would be satisfied to have everything in every number of the *American Bee Journal* so written that the beginner with absolutely no knowledge of bee-keeping, should understand every sentence? Take this sentence: "An excluder is often used to prevent the queen from entering the supers." Probably not one reader in a thousand will have any difficulty in understanding what is meant; but to bring the sentence to the comprehension of such a beginner as has been mentioned, it would be necessary to expand the sentence somewhat after this style:

"An excluder, which consists of zinc having perforations about 1/8 of an inch wide, through which the workers may readily pass, but which prevents the passage of the queen, which is the only perfect female in the hive, and lays all the eggs, is often used to prevent the queen from entering the super, which is the compartment placed over the hive in which the bees may store the surplus honey." Now, suppose that that sort of thing were kept up, and in every number each word not fully understood by the rawest beginner should be fully defined, how long would you be willing to take such a paper?

I can't say too much for the *American Bee Journal*. I can't keep bees without it. I wish it the best of success.—M. A. STONE, of Iowa.

# American Bee Journal

of the habits obnoxious to bees—why doesn't she try the experiment?

Evanston, Ill. WM. M. WHITNEY.

Now, what can Mr. Whitney possibly mean? His bees are gentle "as a sucking dove," their gentleness due to the absence of tobacco and intoxicating liquor, and then he suggests that I get a different sort of a helper. If that means a helper not addicted to tobacco or liquor, would he designate it as a "slight change?" What can he mean? And why can't he express himself so that there will be no doubt as to his meaning? But, perhaps, we

ought not to expect too much explicitness from one of Mr. Whitney's youthful years.

## Smallest Honey Crop

Our crop of honey was the smallest I had ever had here, but the hives were well filled for winter, and the bees have wintered well so far. They had a good flight on Christmas, and one or two in January. Some were flying Feb. 1.

MRS. WM. MIDDLECAMP.

Oshkosh, Wis., Feb. 5.

it for us, although they might not be such for others. One was that it necessitated the removal of one of the combs from the brood-chamber, when inserting the feeder in place of it; and another was that the brood-chamber needed to be opened and the cluster of bees disturbed when feeding, and to ascertain the quantity of syrup in the feeder. This feeder was improved later by cutting away part of the top-bar entirely where only an auger hole was before, through which the syrup was poured.

There are several objections to the combined hive-cover and bee-feeder of H. A. Smith (page 72), for our Southern climate, at least. First, the expense of the cover when not used as a feeder. Of course, a feeder separate from the cover may make the expense of both as much, or perhaps slightly more, yet such a feeder could be stored away and sheltered from the weather, and not be handled every time the cover of a hive was taken off. But one of the main objections would be that such a cover would not stand our blistering sun and changeable weather conditions. It would soon warp and twist, or crack, and admit robber-bees. If made of heavier material the expense would be increased, and the extra weight to the cover itself would be quite an objection, in my mind.

I prefer using an empty shallow super over a bee-escape board, from which the escape has been temporarily removed, so the bees have free access above. With the regular hive-cover on top of the super a space is formed similar to that of the Smith feeder, in which are set several large butter-trays for the syrup. A bunch of excelsior is thrown into each tray to keep the bees from drowning, and I think this is a better and cheaper arrangement without the extra expense.

In place of the bee-escape boards I have used sheets of thick, heavy paper which can easily be obtained from furniture dealers, after it has been taken from the packed goods. Through each sheet, as large as the outside dimensions of the top of the brood-chamber, a hole is made about 1½ inches in diameter for the bees to pass through when it is laid over the top of the brood-frames. It is all-important to keep the warmth of the cluster concentrated below, hence the use of such a partition between it and the syrup fed above. It helps the bees a whole lot.

**Honey as a Health-Food.**—This is a 16-page honey-pamphlet intended to help increase the demand for honey. The first part of it contains a short article on "Honey as Food," written by Dr. C. C. Miller. It tells where to keep honey, how to liquefy it, etc. The last part is devoted to "Honey-Cooking Recipes" and "Remedies Using Honey." It should be widely circulated by those selling honey. The more the people are educated on the value and uses of honey, the more honey they will buy.

Prices, prepaid—Sample copy, for a 2-cent stamp; 50 copies for 70 cents; 100 for \$1.25; 250 for \$2.25; 500 for \$4.00; or 1000 for \$7.50. Your business card printed free at the bottom of front page on all orders for 100 or more copies. Send all orders to the office of the American Bee Journal.

Conducted by LOUIS H. SCHOLL, New Braunfels, Tex.

## No Adulterated Arizona Honey

The following, taken from a circular from the Arizona Experiment Station, is of interest. I believe very little adulteration of honey would be practised in any of our Southwestern States for the same reason. An interesting fact is that I have seen very little honey in the Texas markets that might have been adulterated. If present high prices should prevail, however, it will be seen that such practise might be made profitable, from the adulterators' standpoint; but since the pure food laws are put to use there should be little danger even then. It is interesting, nevertheless, to know that we, of these "far-off" Southern States, should at least be so favorably located as to be safe from the ban of adulteration, even without pure food laws. Here is the item referred to:

"The adulteration of honey, in Arizona, is not commercially possible for the excellent reason that freight-rates so enhance the price of glucose and sugar, that these adulterators can not be profitably used. For instance, the average wholesale cost, laid down, of white sugar during 1902, was 4½ to 5½ cents a pound, and of a good grade of glucose was 4½ to 4¾ cents a pound; while the prices obtained by the honey associations for their product in car-load lots, were from 4½ to 5½ cents. This has been the commercial condition for years past, and while it continues, the fact that honey is from Arizona is sufficient guarantee of its purity. Water, indeed, might be mixed with an especially dry product, but fermentation would be too likely to punish such dishonesty."

## Spring Feeding of Bees

Bees that are found short of stores in early spring need feeding as badly as for winter stores. Not only must they be furnished with food, but as brood-rearing begins the brood must be provided for.

There are many ways of feeding, but the time and the season, the weather and other conditions, must be considered, as, for instance, during midwinter cakes of hard candy laid over the frames above the cluster should be given. Then, again, during warm weather, and in the summer months, outdoor feeding of sugar syrup may be practised. Syrup of this kind, while it should not be fed in winter, can be given in the early spring, but on account of the cold weather it should be fed inside of the hives so that the bees may get to it at all times.

It is bad policy to feed outside early in the season, as much loss to bee-life is entailed by forcing the bees out when chilly weather still prevails, besides the wear and tear to the life of the bees while getting the syrup home from the feeder.

When it comes to the feeder to be used, we must agree with J. L. Byer, of "Canadian Beedom," that "truly, it might be said, of the making of feeders there is no end." (Page 72.) Some of them are all right, some not so good, and some feeders may suit certain persons while they would not suit others. For instance, the Alexander feeder is praised by many, while I could not use it satisfactorily, because there are at least a hundred different kinds of bottom-boards in my apiaries, to only a few of which this kind of feeder could be attached. And even with the right kinds of bottoms, the "hive-stands" will not always "fit."

An entrance feeder of the Boardman type was given a trial, but there is a good deal of danger from robber-bees, hence I do not think such a feeder advisable; indeed, the safest place to feed is within the hive, away from where any outside bees may get to the feed.

The Doolittle division-board feeder was used satisfactorily for several seasons, but there were two objections to

The "Old Reliable" as seen through New and Unreliable Glasses,  
By E. E. HASTY, Sta. B. Rural, Toledo, Ohio.

#### PRESERVING THE FORESTS.

As to the latter part of his article on page 27, we may thank Prof. Cook for showing us the grindstone which we will have to put our noses on not far in the future. Individual initiative is sweet to us, but we can not continue indefinitely to be such utter fools in the matter of forest destruction as we have been. The hold-up will be a law which will say: No cutting of any considerable number of trees (no matter to whom they belong) without a permit from the State Bureau of Forestry; and no permit without satisfactory assurance that the forest area is to be kept good by replanting. I suppose it will eventually be found best to divide each large forest which occupies level, arable ground into a large number of small sections—cut one section at a time, cut it clean, and replant—either with or without a few years of cultivation. Very much more lumber can thus be raised on the same area than in Nature's higglety-pigglety way—and probably more than in any mere modification of Nature's way. (If this is objected to as not bee-matter, I'll claim that basswood for sections is what we're after.)

#### CHICKENS EATING YOUNG ANTS.

The chickens of Pacific Coast "Murmurer," that we hear of on page 16, surprise me. I had supposed that the young of ants, so long as they remain white, are destitute of the biting acidity we are so familiar with. That might well prevent almost any creature from wanting to eat them. I had supposed they were regularly raised as food for high-priced young birds. Quite a backset to find chickens that won't eat them. Still, I can't say off hand that I ever saw chickens eat them. And, scratching out ants in a natural way, chickens would probably find an adult ant clinging on to each pupa. They might honestly enough decide that the white one was not good enough to pay for eating a black one along with it.

#### WINTERING BEES IN A TRENCH.

Mr. Whitesides found a few colonies to winter well in a trench. Couldn't be "aisy" till he had crowded some into a trench two tiers deep. That time the lower ones all died. The look of that sort of thing is that the number of bees was too great for the amount of air percolation the pit afforded. The befouled air was heavier than the rest, and so the lower colonies naturally got an overdose of it. Page 13.

#### HOME-MADE HIVES, ETC.

A factory-made hive with a quarter-inch bottom-board—it does seem as if stale vegetables and things ought to be flung at it—if not at its maker. And Dr. Bohrer's experience, that even carpenters do not make hives sufficiently exact in dimensions unless one watches them closely, is worth noting. We'll agree with him as to the rest. Occasionally men make their own hives profitably, and very well. But the usual rule is that the work is poor, and dimensions not exact enough. Page 28.

#### ENDURING BEE-STINGS.

Mr. Wm. W. Green seems to be a rare bird—in his ability to go through so frightful a case of bee-poison with almost no treatment. Better for people like him not to keep bees. But his notes ought to be valuable for comparison with other bad cases—decidedly more valuable on account of his abstention from treatment. That 6 hours after the stinging the skin exuded odor which suggested bees is one of the points of interest. Page 28.

#### SHORT ON STORES AND LESS POLLEN.

Mr. McGuire thinks Paul's "Lay aside every weight, and the sin," etc., is good for us. If the "weight" is useless fixtures, I suppose the "sin" would be useless manipulations—or is

the habit of writing for the bee-papers the sin? Not sure the application is a good one. At least, he evidently doesn't care for the "cloud of witnesses," but only for the coppers.

At first I thought it was a mere notion of his that colonies short of stores brought in smaller pollen-loads. After a while a reason why it should be so occurred to me, and then I was more ready to think it might be a fact. Where there is plenty of honey at home very likely a bee going out for pollen would take some along to be used in making up the pellets. Where there is famine at home the gatherer would go out empty, and trust to finding in the fields some nectar to be used in making the pollen cohere. If little or no nectar was to be had in making up the pellets would be difficult, and they might be small as a result. Page 28.

#### HONEY FROM OAK-GALLS.

Wonder if it's always the case that honey from oak-galls is too dark and poor for human eating, as Prof. Scholl finds. It half-way seems to me that some one has reported eatable honey from that source. Page 29.

#### GLOVES AND BEES.

"Between gloves and defeat, wear gloves." Don't think I ever saw that side of the argument better put than Miss Trevarrow here puts it. Some might add, And get a better tempered strain of bees as soon as you can. Page 30.

#### POLITICAL "BEE-KEEPERS."

And that Murmur, with most atrocious parody of logic, wants to call the politician a bee-keeper because he has a bee in his bonnet! Why, the bee in the bonnet is rampageously trying to keep the man. Man can't keep the bee till he can get the bee away from the region behind his ample ears. If the politicians were all bee-keepers we'd have had all the legislation we could make any use of long ago. Page 35.

Send Questions either to the office of the American Bee Journal, or to  
DR. C. C. MILLER, Marengo, Ill.

 Dr. Miller does not answer Questions by mail.

#### Colonies in Hives Under Snow

On page 67 Mr. Doolittle says, "If the hives are buried in snow . . . the obstruction should be removed, for an occasional winter flight is a great benefit." Would it be an advantage to remove the snow in a country where a chance for a winter flight is almost never known? I have experimented to a limited extent with 7 ways of handling the entrances, and have come to the conclusion that

I lose less bees during the winter with the entrances closely covered with spruce boughs and the hives buried in straw or snow. In one instance, a colony came through all right after having been buried for over 2 months in 6 feet of snow. I have not been able to come to any conclusion as to which will build up best in the spring.  
P. E. ISLAND.

ANSWER.—For a certain time there probably could be nothing better than to have a colony covered with 6 feet of snow or more.

But I think some cases have been reported where the bees were kept so warm and for so long a time that they took to brood-rearing and suffered badly. Your idea of spruce boughs seems a capital one. With enough of these I wouldn't feel anxious, even with an imprisonment of a good deal more than 2 months.

**Feeding Bees in Box-Hives**

I am a beginner with bees. I bought 26 colonies from a neighbor, mostly in box-hives. When I brought them home some seemed to be very light, and I think they need to be fed before bloom comes.

1. How can I tell if they need to be fed?
2. Is there any danger of feeding too long in the spring?
3. What is the best way to feed bees in box-hives?

**ANSWERS.**—1. You can't tell very well; but you can make something of a guess at it by weighing, or hefting, the box, and seeing how much heavier it is than an empty box of the same kind would be. If it doesn't weigh about 40 pounds more than the empty box, then it will be a good thing to feed as soon as a warm day comes in spring. If it weighs only about 20 pounds more than the empty box, better feed right away. But much depends upon what is present. If the hive is an old one, well filled with old combs, and a lot of pollen in it, it should weigh much heavier than one with a light afterswarm that has not much in the way of combs or pollen.

2. No, unless you feed so much that the queen has not room to lay.
3. The best way is to put some combs of honey under the hive. If there is not room for that—and probably there is not—make a shallow box or rim 2 inches or so deep to put under the hive.

**Putting Bees Out of Cellar—Medium-Strong Colony—Controlling Increase True Thermometer, Etc.**

I am wintering 50 colonies of bees in the cellar with the hive bottom-boards off. When I put them out, how can I keep them from dying out? The hives are piled on top of each other.

2. I have no wind-break or shade at home. Would it pay me to move my apiary 60 rods from home and have both?
3. What is a medium strong colony in an S-frame hive on April 1? or, in other words, a colony that is strong enough to hold its own?
4. I run my apiary for comb honey only, and wish to control increase. With reference to your answer on page 74, should I put the super of sections on top of both stories, or between them?
5. Where can a true thermometer be purchased? I have 3 which I hung up side by side, and they stood at 4, 7, and 12 degrees below zero, Feb. 3.

6. Has Iowa any foul brood law, or any beekeepers' association?

**IOWA.**

**ANSWERS.**—1. If in good condition, and carefully carried out, they are not likely to want to fly. It will help matters if you have doors and windows of the cellar wide open to the outdoor air the night before carrying out. If, however, the bees are not quiet enough, blow smoke under to quiet them.

2. I don't know. It depends a little upon how much you care yourself for shade to work in, and how much also for the inconvenience of having them so much farther away. As you winter your bees in the cellar it would make no difference in wintering. It's a toss-up which way to decide.

3. A colony that has 2 or 3 frames full filled with brood and plenty of bees to cover them the first of April is likely to hold its own all right, but it would need to be twice as strong as that to be called medium.

4. I suppose you refer to the last part of my answer to Minnesota. That plan—putting the queen down into an empty story under an excluder—is only used for extracted honey, for you understand that the story of brood that is put over the excluder will be filled with honey just as fast as the cells are emptied by the emerging of the young bees. But if you wish, you could get such a colony to do some work also in sections. In that case, I should put the super of sections between the two stories about 10 days after putting the queen down, perhaps raising the sections on top after the bees were well started in them.

5. I don't know. Perhaps in the larger places they are to be had at a higher price that are entirely accurate. Isn't there in your neighborhood a volunteer Weather Observer to whom the government has furnished an accurate thermometer? If so, you could compare your thermometer with his. But it doesn't matter such a great deal whether your thermometer is accurate or not, if you want to use in the bee-cellar. All you have to do is to try to find out at what degree by your thermometer your bees are most quiet, and then try to hold the cellar at that temperature. And that's what you'd have to do anyhow, even with an accurate thermometer.

6. I think not. Good thing if Iowa beekeepers would stir in the matter.

**Transferring Bees—Italianizing—Requeening—Feeding Common Syrup**

1. A has 20 or 25 colonies of bees that he wants to get rid of so that he can have the combs and honey that are in the brood-chamber to put his first swarms in so that they can go to work at once. Can B take the bees, transfer them to Langstroth hives, and feed them until honey-gathering season comes? If so, how? and how soon? (A wants them taken away as soon as practical.) B can handle the bees all right.

2. Would one good Italian colony furnish drones enough for 60 or 75 colonies by putting drone excluders, or drone-traps, on all of the hives? If so, how? Would answer No. 4 to Pennsylvania, page 389 (1906), answer in this case? There is no apiary near me, and practically no timber, and I want to Italianize my apiary. I have one good, strong Italian colony.

3. How should I introduce the queen-cells? By cage? If so, how, and what cage should be used?

4. Would you requeen at the beginning of honey-flow, or later in the season?

5. My bees are hybrids and brown bees. The brown bees are large and comparatively quiet. I do not think they are the little black bee I hear so much about. What would you call them?

6. I have half a barrel of common syrup that is of no use to me. Would you let the bees have it in the spring? If so, how, and at what time?

**MARYLAND.**

**ANSWERS.**—1. It's a bad time of the year for such business, but it can be done. As soon as bees fly every day, take out all the brood-frames, leaving the bees on empty frames or foundation, put on a Miller feeder with sugar syrup, and the bees will do the rest. But that is objectionable in two ways: It is a loss of brood at a time when brood is of the most value; and it is very objectionable to have the dead brood in the combs when they are to be used for swarms. So you must manage with an excluder. Put all the frames into the upper story over the excluder except one frame of brood that you will leave in the lower story with the queen. In 2 or 3 days, or as soon as the queen has begun laying in one of the new frames below, put into the upper story the frame of brood you left below. Then in 3 weeks all the brood will be out above, and you can remove the frames. I am taking it for granted that the bees are in movable frames. If they should be in box-hives, then the bees must be drummed out, so

as to be sure to get the queen out, then put into the lower story, and the box-hive put over the excluder and left there 21 days.

2. Yea, a single colony can furnish enough drones for 75 colonies or more, providing it is strong enough and has enough drone-comb, say the equivalent of half a frame or more. The answer given to "Pennsylvania," to which you refer, is all right for you. The only difference made by your distance from timber and other bees is that you are less likely to be troubled with outside drones.

3. Generally a queen-cell will be accepted all right by any colony that has been queenless 2 or 3 days, or as soon as it begins building some queen-cells of its own. Fasten the cell centrally on a brood-comb by means of a hive-staple. Lay the frame on its side, lay the cell in place, either horizontally or with the point downward, then put the staple over the cell, not with the cell in the middle of the staple, but at one side, that is, one leg of the staple is touching the cell, and this leg is pushed in only far enough to hold the cell, while the other leg is pushed in deep. It will, however, make the cell a little safer against being torn down by the bees if put in a Miller introducing-cage, and the cage can be held in place by running a slender wire-nail or a very large pin through the cage into the comb.

4. You'll probably do some of both; for if you begin at the beginning of the honey-flow, there will be some failures that will be made up later on.

5. If I were in your place I think I should call them large brown bees. Occasionally such bees are spoken of, although they probably do not differ much from ordinary brown or black bees. But there is no question that some black bees are better than others.

6. Yes, there is generally a time in the spring when bees can fly every day but get little or no nectar. At such a time it will be well to feed such syrup. Either feed in the hive with a Miller or other feeder, or if you are situated where neighbor bees will not get the lion's share you can feed in the open air in shallow dishes with cork-chips on top, or some other arrangement to keep the bees from drowning. Open-air feeding may be a little the best for the bees—more like working in the field.

**The Miller Frame—T-Super, Etc.**

1. Kindly give me a description of the Miller frame so that I can make them or have them made; or can they be purchased of dealers?

2. How is the foundation fastened to the top-bar?

3. How thick should the follower be in order to hold the frames solidly together?

4. Are the T-supers just like yours sold by dealers?

5. I have some new supers made 5 inches deep. Can they be used for T-supers?

**MICHIGAN.**

**ANSWERS.**—1. I think you will get Miller frames by ordering of the leading manufacturers; but here is how they are made, as copied from my book, "Forty Years Among the Bees."

"The frame is of course of the regular Langstroth size, 17 $\frac{1}{4}$ "x9 $\frac{1}{4}$ ". Top-bar, bottom-bar, and end-bars are uniform in width, 1 $\frac{1}{2}$ " inches throughout their whole dimensions. The top-bar is  $\frac{3}{8}$ "-inch thick, with the usual saw-kerf to receive the foundation, and close beside this is another kerf to receive the wedge that fastens in the foundation. The length of the top-bar is 18 $\frac{3}{8}$ " inches, and  $\frac{3}{8}$ "x9-16 is rabbeted out of each end to receive the end-bar. The end-bar is 8 9-16x1 $\frac{3}{8}$ "x $\frac{3}{8}$ ". The bottom-bar consists of 2 pieces, each 17 $\frac{1}{4}$ "x $\frac{3}{8}$ "x $\frac{1}{4}$ ". This allows  $\frac{1}{8}$ "-inch between the two parts to receive the foundation, making the bottom-bar 1 $\frac{1}{2}$ " inches wide when nailed.

"The side-spacing, which holds the frame at the proper distance from its next neighbor, is accomplished by means of common wire-nails. These nails are 1 $\frac{1}{4}$ " inches long and rather heavy, about 3-32 inch in thickness, with a head less than  $\frac{1}{4}$ "-inch across. By

means of a wooden gauge which allows them to be driven only to a fixed depth, they are driven in to such a depth that the head remains projecting out a fourth of an inch.

"Each frame has 4 spacing-nails. A nail is driven into each end of the top-bar on opposite sides, the nail being about an inch and a half from the extreme end of the top-bar, and a fourth of an inch from its upper surface. About two and a fourth inches from the bottom of the frame a nail is driven into each-bar, these nails being also on opposite sides. Hold the frame up before you in its natural position, each hand holding one end of the top-bar, and the two nails at the right end will be on the side from you, while the two nails at the left end will be on the side nearest to you.

"The object of having the nails so heavy is so that they may not be driven farther into the wood when the frames are crowded hard together. Once in a great while the wood is split by having so heavy a nail driven, and if such a nail could be obtained it would be better to have a lighter nail with a head a fourth of an inch thick, so that it could be driven automatically to place without the need of a gauge, and without the possibility of being driven farther in by any amount of crowding.

"The end-spacing is done by means of the usual frame staple, about  $\frac{3}{4}$  of an inch wide. The staple is driven into the end-bar, immediately under the lug of the top-bar. This lug being only half an inch long, there is room for a bee to pass between the end of the lug and the upper edge of the hive-end, so no propolis is deposited there."

2. I prefer what is the usual way at the present time, as suggested in the foregoing description, the foundation being received in a saw-kerf and wedged there; but it can be fastened in any other way.

3. Strictly speaking the frames are never held *solidly* together. They are crowded close together against one side, but there is left a loose space at the other side between the dummy and the side of the hive. No possible harm can come from this except that it allows a little movement when hives are hauled over very rough roads, but I have never had any trouble in that way. The dummy is 5-16 thick.

4. I think some are, and some not. If you say in ordering that you want the same as mine, I think you would get them.

5. Any super consisting of 2 sides and 2 ends without top or bottom can be made into a T-super, the difficulty of adapting it depending upon its measurements. A super 5 inches deep would be for sections  $\frac{3}{4}$  inches in height; but it might be cut down to fit a shallower section, and strips could be nailed on to make it fit a deeper section.

honey that year, but the bees had plenty to keep them over winter.

In the spring of 1905 we again moved them to the summer stands. On examination we found them in pretty bad shape. The hives had been too damp, and the bottom of the hives and some of the combs were blue-molded. Nevertheless, the bees were alive. We now began to enquire about how to handle bees. Before this we had acted on our own judgment, but we knew very little about that kind of business. That summer our apiary increased to 3 colonies, and we got enough honey for our own use. We thought we were doing not too badly. We did not have to feed them that fall. In the spring of 1906, when we examined them we found them all right, but very cross. We were beginning to learn a little about them now, and that summer we increased our apiary to 5 colonies, and got about 60 pounds of honey. We sold about 30 pounds and left them enough to winter on. That fall we bought 6 colonies and an outfit for \$22. We had to feed the new colonies. We doubled our old colonies down to 3 colonies, and so this winter we have 9 colonies.

Molesworth, Ont., Jan. 23.

## Bees Did Fairly Well

My bees did fairly well last summer. I started in with 6 colonies, increased to 12, secured about 300 pounds of comb honey (about half will grade "strictly fancy"), and my hives were put into winter quarters *very heavy* (55 to 65 pounds per colony).

One colony in particular did what I considered extremely well, filling 6 supers (24 sections each) and working a little in the 7th super. Besides being such great workers, these bees are very beautiful and gentle. I tried hard to rear a few queens from this particular queen, but succeeded in getting only one hatched, and she was lost while taking her flight from the hive. If I can keep the original queen through the winter, I am going to try again.

Noble Co., Ind.

## Honey for Curing Bronchitis

We found out last year that honey is a first-class article to cure bronchitis. During the last 2 years my father and mother have suffered greatly from bronchitis. They spent considerable money doctoring, and the truth is our family doctor was at his wits' end to know what to do for them, and matters looked pretty blue until a neighbor came along and told father to take every night, before going to bed, 2 good tablespoons of honey; add 2 tablespoons of whiskey, and put into a good-sized tea-cup and fill with hot water, and drink it hot before going to bed.

Well, in 2 nights he commenced to feel much better. He kept it up for 8 or 10 nights, and the bronchitis was settled. When he had it worst he could get no sleep at night, and mother was as bad off, but now both of them are well.

As soon as father got well, he went down to the doctor and told him what he had done. The doctor had another patient who had bronchitis very badly, and he was not making any headway towards curing him. He was an honest doctor, so he told his patient how sick father and mother had been; that he did not know what to do for them, and what they had used to cure themselves; that this patient should try honey for his bronchitis. He did so, and a dollar's worth of honey consumed in the family and used as a medicine put their bronchitis out of business. I do not think they had to use the whiskey the same as we had to. I would very much like to see this thing tried further, with the honey alone, without the addition of any whiskey whatever; but as I have no more bronchitis around, I can not do any more toward trying its virtue, but it may be the means of helping some other afflicted person. I would like very much to know if honey alone would have as good effect in most cases as the honey and whiskey, because I am not

much in love with whiskey, or anything of its nature as a beverage; but honey is a No. 1 medicine for that kind of trouble.

Galt, Ont., Jan. 19. W. D. HARRIS.

[We will have to refer the above request to Dr. Miller for an opinion.—EDITOR.]

## Hardest Winter Years

The bees seem to be all right in the cellar. The winter was very severe up to the last few days—the hardest one we have had for years.

The American Bee Journal comes very regularly, and I can not say too much in its praise for the helpful information it brings. I feel that I would be nowhere in bee-keeping without it.

ROBT. MCCRADIE.  
Hendrum, Minn., Feb. 13.

## Very Cold Weather—Need Faith

We are having very cold weather here at this date, the mercury having dropped below zero. In some parts of Pennsylvania it has dropped 26 degrees below, which is very hard on bees in this part of the country, and I fear there will be some very severe losses around here.

My bees, so far, are wintering nicely, both in the cellar and outside. My honey crop for 1906 was not extra good, although I got more than my neighbors did. They seem surprised that I get more honey than they do, and ask me how I do it. I tell them to subscribe for the American Bee Journal, as I *credit my success* to it. But they say it is useless to subscribe for a bee-paper, for they know all about bees! So I let them alone in their ignorance.

I am in great hopes we will have a good season this year, for a bee-keeper must never lose faith.

WILLIAM H. BOECKEL.  
York, Pa., Jan. 29.

## Home Hive-Making

I have read with much interest the different articles on hives made from "store" boxes. You will notice that I have used the word "store" instead of "dry-goods" boxes, and now comes the reason:

Nearly all dry-goods boxes are made from lumber from 3 to 8 inches wide, and all tongued and grooved together like flooring. Such lumber is not suitable for hive-bodies or supers, but it is good for bottom-boards and covers when well dried and firmly nailed to cross-pieces at each end; and they are not so apt to warp and get out of shape as when made from a single board.

Now for the hive-bodies and supers: The boxes I am about to describe are sometimes hard to get by any one living in the country or small towns, but in a town of 4000 or 5000 or more, one should be able to get all he wants by keeping his eyes open.

The boxes in question are known as "hat-cases," and will be found in gent's furnishing stores. These boxes are always white pine, the sides of  $\frac{3}{8}$ -inch stuff, planed on one side, and are often as much as 12 inches wide, and come in for a great many uses in the apiary or chicken-yard. The end-boards are one-inch boards from 36 to 45 inches long, and from 12 to 16 inches wide, and are usually quite free from knots, but I always look the boxes over and reject those that are defective.

I pay from 10 to 15 cents each for such boxes, and by a little watchfulness can get all I want. I made 11 10-frame Langstroth hives last winter at odd times from such boxes, and after they are painted they look just as good as any factory hive.

Last week I made one 14-frame hive after the Ferris plan, for 2 queens, and I got it all but the top out of 4 end-boards. The cover will be made later as stated above.

This article is intended only for those who have plenty of time, and are handy with tools. I will tell later how I made an outside case for a super-cover from the  $\frac{3}{8}$ -inch boards of the hat-cases.

Marietta, Ohio, Feb. 10.

## Starting With Bees

In July, 1903, while we were drawing in hay, our mother called to use that a swarm of bees had settled on the end of our old barn used for an implement house. Our uncle had left a number of bee-hives in it the winter before, and it was these that attracted the bees. When we came up from the field we examined them as best we could, and found they had settled in one of the boxes. We left them alone until next day, when one of us went over for our uncle, who came and brought a veil, smoker, and all necessary things with him. We then got the bees out of the barn into our orchard. This was our start in bee-keeping. In the fall of 1903 we began feeding the bees, and in this way we succeeded in wintering them all right.

In the spring of 1904 we took them out of winter quarters, and during that summer our apiary increased to 2 colonies. We got no

**Standard-Bred Italian  
FREE  
PREMIUM QUEENS**

We are booking orders now for those Fine Untested Italian Queens that we offer every year FREE to paid-in-advance subscribers as premiums for getting NEW subscribers for the Weekly American Bee Journal. These orders are taken for May or June delivery.

**What Some Say of our Standard-Bred Italian Queens:**

*George W. York & Co.*—The two queens received of you some time ago are fine. They are good breeders, and the workers are showing up fine. I introduced them among black bees, and the bees are nearly yellow now, and are doing good work. A. W. SWAN.  
Nemaha Co., Kan., July 15.

*George W. York & Co.*—After importing queens for 15 years you have sent me the best. She keeps 9½ Langstroth frames fully occupied to date, and, although I kept the hive well contracted to force them to swarm, they have never built a queen-cell, and will put up 100 pounds of honey if the flow lasts this week. CHAS. MITCHELL.  
Ontario, Canada, July 22.

*George W. York & Co.*—The queen I bought of you has proven a good one, and has given me some of my best colonies. N. P. COLESBY.  
Washington Co., Va., July 22

*George W. York & Co.*—The queen I received of you a few days ago came through O.K., and I want to say that she is a beauty. I immediately introduced her into a colony which had been queenless for 20 days. She was accepted by them, and has gone to work nicely. I am highly pleased with her and your promptness in filling my order. My father, who is an old bee-keeper, pronounced her very fine. You will hear from me again when I am in need of something in the bee-line. E. E. MCCOLM.  
Marion Co., Ill., July 13.

**How to Get these Queens Free**

To any one whose own subscription to the Weekly American Bee Journal is paid in advance, we will mail a Fine Standard-Bred Untested Italian Queen next May or June, for each new name and address sent to us with \$1.00 for the Bee Journal a year. No one can get for himself the Bee Journal a year and the Queen for \$1.00. The Queen is offered as a premium for the work of getting some one else to take the Bee Journal a year. If you, yourself, want the Bee Journal a year and the Queen, send \$1.50 for the two, and we will book your order for a Queen. Queen orders will be filled in rotation—"first come, first served." Address,

**GEORGE W. YORK & CO.**

334 Dearborn Street, - CHICAGO, ILL.

"Langstroth on the Honey-Bee"—the well-known bee-book revised by the Dadants—has just passed into another edition. There have been some 75 pages added to it, and the whole work brought down to date in every respect. It is certainly a fine book, and should be read by every bee-keeper. It is really a classic. To become acquainted with the great Langstroth through the reading of his book is no small thing. Other bee-books are good, but there is only one "Langstroth on the Honey-Bee." The latest revised edition will be sold at the same price as the one preceding, which is \$1.20, postpaid. We still have a few copies of the old edition on hand, which we will mail at 90 cents each, if preferred, so long as they last. We club the new edition of this book with the American Bee Journal for one year—both for \$2.00. So long as we have any copies left of the old edition, we will send it with the American Bee Journal one year—both for \$1.50.

**THE AMERICAN FOOD LABORATORY**

E. N. EATON, M.Sc., Chemist.  
4 years State Chemist, Minnesota.  
6 years State Analyst, Illinois.  
1235-1248 Caxton Building,  
334 Dearborn Street, Chicago, Ill.  
Samples of Honey analyzed. Correspondence solicited.

**The Emerson Binder**

This Emerson stiff-board Binder with cloth back for the American Bee Journal we mail for but 75 cents; or we will send it with the

Bee Journal for one year—both for only \$1.50. It is a fine thing to preserve the copies of the Journal as fast as they are received. If you have this "Emerson" no further binding is necessary.

**GEORGE W. YORK & CO.**

# Money Earns Money

only when invested in a money-earning business, and I believe there is no good, safe and honest business earning more money on the capital invested than the subscription-book business.

## DO YOU BUY BOOKS?

This is a book-buying age. A house without a library is no longer a home, and most of the home libraries in this country are purchased as a result of direct solicitation.

## BUT FEW KNOW

that during the last six years nearly 150,000 sets of "Modern Eloquence" have been sold for \$7,500,000.00; that "Stoddard's Lectures" have been placed in 250,000 American homes for \$12,000,000.00; that 300,000 sets of the "Century Dictionary" have been sold for \$21,000,000.00; that more than 560,000 sets of "Britannica" have been sold in the United States alone for over \$44,000,000.00; or that the sale of these books still continues. But few know what the profits are on this business. How much of it did you receive?

## A MODERN PUBLICATION

of the highest class, which in sales and profits is destined to exceed the above records, is now being made and sold. This is evident from the actual results now being obtained, although the sale was begun less than six months ago, and you can have full particulars by sending your name and address on a postal card, costing

## ONLY ONE CENT

Let me mail you a letter telling all about this record-breaking, modern American publication; how several hundred eminent American specialists are making it; why the American people find it not a luxury but a necessity, and *what a few dollars will do*—not over a hundred—if now added to the present capital.

Will be found in

## The American Bee-Keeper for 1907

It is profusely illustrated and enlarged, and contains only articles of the most practical as well as scientific nature. A special corps of the best writers has been engaged. The editors are Harry E. Hill and Arthur C. Miller, than whom there are no more practical or experienced bee-keepers in this country. We have published the American Bee-Keeper continually and regularly since 1890.

Regular subscription price, 50 cents a year. One year to new subscribers, 35 cents; three years for \$1.00.

Send for sample copy and our new illustrated price-list of BEE-SUPPLIES OF ALL KINDS.

Guaranteed highest quality at lowest price. Address,

**THE W. T. FALCONER MFG. CO.**  
JAMESTOWN, N. Y.

[Established 25 years.]

## Honey and Beeswax

CHICAGO, Feb. 1.—The usual late winter demand is in evidence for comb honey to replace diminished stock laid in during the autumn by the large retailers, but during the dull period there has been very little change, if any, in prices, the offerings being light.

We find No. 1 to fancy white comb honey brings 15@16c, and for that which is off in color and flavor from 10@3c less. Amber grades of all kinds are dull and range in price from 10@12c. The extracted perhaps is not quite so firm in price for the California or Western grades, but there is no surplus of white clover or basswood, both of which bring about 8c, and in some cases more. Ambers grade from 6@7½c. There have been some sales of beeswax at 32c, but 30c is about the price for average.

R. A. BURNETT & Co.

PHILADELPHIA, Nov. 8.—While the supply of comb honey is equal to the demand, large quantities of comb honey having arrived in the market in the last few days, the price still remains high. The outlook, however, is that when the season advances and the bee-keepers ship more of their crop to the market, the prices will be a little weaker. We quote: Fancy white comb honey, 16@18c; No. 1, 14@15c; amber, 11@13c. Fancy white extracted, 7½@8 c; light amber, 6½@7c.

We are producers of honey and do not handle on commission. Wm. A. SELSER.

NEW YORK, Jan. 15.—The stock of white comb honey is pretty well exhausted, and we do not expect any more arrivals of large lots from now on. Prices are firm, and we quote from 15@16c for fancy white; 13@14c for No. 1; 12c for light amber. There is quite a little dark and buckwheat on the market, but no overstock, and we think that all of it will be disposed of before long at present prices, which we quote from 10@12c, according to quality. Extracted honey very firm, with sufficient supply to meet demand. California white sage is bringing from 8@8½c; light amber, 7½c; amber, 6½@7c; buckwheat extracted in fairly good demand at 6@6½c. Southern in barrels finds ready sale at from 55@70c per gallon, according to quality. Beeswax firm and steady at 31c. HILDRETH & SNGLEEN.

DENVER, Feb. 14.—Producers in this State are practically closed out of both comb and ex-

# C. H. W. WEBER

CINCINNATI OHIO

Office and Salesrooms, 2146-48 Central Ave. Warehouses, Freeman and Central Aves.

tracted honey. We have not sufficient good comb honey to supply our local trade, but have a good supply of white extracted of excellent quality. We quote strictly No. 1 white comb honey, per case of 24 sections, at \$3.20; No. 1, light amber, \$3; and good No. 2, \$2.80. White extracted, 8@8½c per pound; light amber, 7½@8c. Clean, yellow beeswax, 27@28c, delivered here.

THE COLO. HONEY-PRODUCERS' ASSN.

CINCINNATI, Feb. 9.—The demand for extracted amber honey has brightened in the past 3 weeks. Amber honey in barrels at 6½@7½c, according to the quality and the quantity purchased. Fancy white extracted honey selling at 8@9c in cans. Comb honey is a drag on the market, fancy selling at 14@16c. Beeswax, 32c. for choice grade. THE FRED W. MUTH Co.

INDIANAPOLIS, Feb. 14.—comb honey is not plentiful, but demand is slack. Fancy white comb brings 16@17c; No. 1 white, 14c; amber, 12@13c. Best grades of extracted honey bring 8@9c; amber, 6@7c. Good average beeswax sells here at \$33 per 100 pounds.

WALTER S. POWDER.

TOLEDO, Nov. 30.—The market on comb honey remains about the same as last quotations, but has been coming in much more freely, as bee-keepers seem to be very anxious to get rid of their stock. Fancy brings in a retail way 16c; extra fancy, 17c; No. 1, 15c; buckwheat, 15c. Extracted white clover in barrels brings 7@7½c; cans the same. Beeswax, 26@28c.

THE GRIGGS BROS. & NICHOLS Co.

CINCINNATI, Jan. 25.—The market on comb honey is rather easy. Prices rule in jobbing ways from 14@14½c; single cases 16c for No. 1 white; off grades not wanted at any price. Extracted is very firm. Light amber in barrels, 6@6½c; white clover in barrels, 7½c; in cans, 8½c. Beeswax, 30c, delivered.

C. H. W. WEBER.

KANSAS CITY, Jan. 25.—The receipts of comb honey have been more liberal during the last week or two, and the demand light, market weaker. The market is practically bare of extracted, and there is quite a little inquiry. We quote: No. 1 white comb, 24 sec. cases, \$3.10; No. 2, \$2.75; amber, \$2.50. Extracted, white, 7½@8c; amber, 6½@7c. Beeswax, 27c. C. C. CLEMONS & Co.

## What Would Be

the condition of bee-keeping had not some ingenious bee-keeper invented and made the **Bingham Bee-Smoker and Honey-Knife?**

Bingham fills orders for thousands, every year, from the largest distributors of bee-keepers' supplies, who say they like to sell Bingham's Goods, because they always give satisfaction.

If you want the **BEST**, and can't get them handy, you can always get them direct from the **original inventor and sole manufacturer**, at regular prices, per mail.

It will always be a pleasure to know that you bought the Best from the original inventor of such a perfect tool.

Respectfully yours,

**T. F. BINGHAM.**

# HONEY FROM THE DANZENBAKER HIVE

## THE FANCY COMB HONEY HIVE

### More Honey

(That is, more honey in the super at the right time.)

### Better Honey

(More honey that will grade fancy and extra fancy.)

### More Money

(No question but what the producer of a fancy and extra fancy grade gets a better price, and does it easier.)

**Carrying Up Dark Honey**

At the Ontario convention Mr. Alpaugh said that under certain conditions there was danger that bees might carry up dark honey from the brood-chamber into the surplus apartment; and Mr. Holtermann said he had known buckwheat to be thus carried up.—Canadian Bee Journal.

**Working at Bees When Sweating**

“Never work at a hive when you are sweating. Bees have a strong dislike to the exhalations of one in a perpiration.”

That is the advice given in a foreign bee-paper. Some bee-keepers in this country, with hundreds of colonies, will smile broadly upon reading such advice. It would work best in a locality where the flowers secrete nectar only in freezing weather, if bees are to be kept on a large scale.

**That *Apis Dorsata* Comb**

Among other interesting paragraphs in “Gleanings from Foreign Fields,” by W. K. Morrison, in Gleanings, is one which reads in part as follows:

The American Bee Journal has a paragraph calling in question the statement that *Apis dorsata* builds a comb with cells  $2\frac{1}{2}$  inches deep; but this is an actual fact, and the thickness of the comb is 5 inches and more where it is attached to the branch of a tree. . . . It is probably true the cells at the top of the comb are not 6-sided, because the stretching caused by the great weight of so large a comb, together with the weight of one whole colony of bees, would serve to draw the cells out of shape.

This undoubtedly refers to a paragraph on page 1045 of the American Bee Journal for 1906, the statement in question being, “They make a large 5-sided cell about  $2\frac{1}{2}$  inches

deep.” It is going rather far afield to defend a general statement of that kind by saying that there may be cells of that depth at the upper part of the comb. The defense of the 5-sided cell is somewhat ingenious, but is it possible that those bees make such bad calculations as to have their combs stretch at the top? Suppose they should stretch, would they be 5-sided? Take a piece of poultry-netting with 6-sided meshes and stretch it. If by any possibility you can stretch it so that there shall be one 5-sided mesh in 1000, then it will be time to talk about stretching the big bees’ cells into 5 sides. Even then would it warrant the general statement that their cells are 5-sided?

**“How Bees Make Honey”**

Mr. M. M. Baldrige, one of the oldest contributors of the American Bee Journal, as well as one or two others, kindly sent us the following which appeared in the New York Tribune Farmer for Dec. 12, 1906:

**HOW BEES MAKE HONEY.**

“A great many people think that bees get honey from flowers,” says the Rev. Theodore Wood, in the London Tribune, but that is quite a mistake, for there is no honey in flowers. It is true that many flowers have sweet juices. But sweet juices are not honey; and before they can be turned into honey they have to be swallowed by a bee.

“When a bee goes out on a honey-making expedition it depends a great deal upon its tongue, which is very long and slender, and is covered all over with stiff little hairs, so that it looks just like a tiny brush. With this the bee sweeps out the nectar from the blossoms into its mouth, and goes on swallowing it, mouthful after mouthful, until it can swallow no more. But the nectar does not pass into its digestive organs and serve as food. It only passes into a little pouch, just inside the hinder part of the body, which we call the ‘honey-bag.’ When this bag is quite

full, the bee flies off to its hive, and by the time that it arrives there the contents of the bag have been turned into honey!

“How this is done I am sorry to say I can not tell you; for nobody has ever been able to find out. If we examine the honey-bag through the microscope, we can find nothing to account for the change. It seems to be just a bag of tough skin, and nothing more. Yet, in two or three minutes after the nectar has been swallowed that wonderful change takes place. And if a bee is fed with sugar and water instead of nectar, it will turn the sugar and water into honey in just the same strange way.

“When the bee gets back to the hive with its load, it goes straight off to a honey-comb, pokes its head into one of the cells and pours out the honey through its mouth until the honey-bag is empty. Then it flies off again to obtain more nectar, and make a further supply. And so it labors busily on from the first thing in the morning till the last thing at night, never being away from the hive for more than a few minutes at a time, and always bringing back a fresh supply of honey in its wonderful little bag.

“Now, perhaps you wonder how it is that the honey does not run out of the cells as soon as the bees have filled them. For these cells do not stand upright, but lie on their sides; and if we were to lay an open barrel of treacle on its side, that barrel would very soon be nearly empty. As soon as the honey is poured into the cell by the bees, however, a kind of thick cream rises to the surface and covers it. And this cream holds the honey so firmly in position that not even the tiniest drop oozes out.

“But when bees want to keep honey for some little time—when they are storing it up for use during the winter, for instance—they are not satisfied with this creamy crust, and are evidently afraid that the contents of the cell may dry up. So they carefully cover it in with a little waxen lid, which makes the cell perfectly air-tight. Next time that you have honey-comb for breakfast, if you examine it carefully you will find that nearly all the cells are closed in this curious way.

“Now, why do you think that the bees take the trouble to make so many small cells in which to store away their honey? Why do they not make two or three really big cells and keep it all in those?

“Well, the reason is that they know perfectly well that if honey is kept in a large vessel it very soon becomes thick, because the sugar in it forms into crystals; and in that case they can not feed upon it. But as long as it is kept in the small cells of the honey-comb it remains quite fresh and liquid, so that all through the winter they are able to use it as food.”

As the foregoing appeared also in the London Tribune, we sent the clipping to Mr. Thos. Wm. Cowan, editor of the British Bee

Journal, in London, asking if he knew of the "Rev. Theodore," and he replied as follows Jan. 15, 1907:

DEAR MR. YORK:—We do not know anything about the Rev. Theodore Wood, but I should think he belongs to a class of professional writers who undertake to write on any subject that they think would be popular, without knowing anything about what they are writing. We do not take any notice of all the rubbish that appears in the secular press about bees, and the Tribune is a paper that is apt to print sensational articles, and is not a paper that we place any reliance upon.

The Rev. Theodore Wood is like the other Rev. J. G. Wood, who wrote a book about bees, as he did on a variety of Natural History subjects, and who confessedly knew nothing whatever about the subject except that he read up in order to write the book. After this book was written and was published, he had a number of inquiries from readers asking him questions about bee-management, and not knowing anything about it, he applied to Mr. Hooker to help him in his dilemma. He admitted that he wrote the book only because he was commissioned to do so, and had read up for the purpose. We have a number of such people, and it is evident that the writer of the article you send is one of these. Such writers are not bee-keepers, and we often wonder at the American bee-editors attributing such rubbish to British bee-keepers.

We wonder what you would think if we attributed such articles as I enclose as a specimen of what American bee-keepers know on the subject. We would not print such rubbish!

Yours faithfully,

THOS. WM. COWAN.

The item referred to by Mr. Cowan, in his last two sentences is this, which appeared in the Evening Telegraph, of Dublin:

#### OVERWORK AMONG BEES.

Lord Avebury should be interested to learn that the snake story and the mosquito story American humor is now adding the bee-story. The Minneapolis Journal issues a warning against placing one's bee-hives too near an arc light. A veracious correspondent reports that his own bees mistook a light of this kind for daylight, and continued working until dawn, when they "turned in." In a few minutes the sun was out, and they instinctively returned to their labors, which continued until dusk. After a short respite the re-kindling of the arc light sent them staggering forth for another round of toil. "They were all dead by the end of the week—victims of overwork, every mother's son of them."

We will have to refer this "arc light bee-story" to our Minneapolis readers.

But we wish to thank Mr. Cowan for his complete reply. Undoubtedly both this and the "mother country" are producing some wonderfully vivid imaginations among some of their writers. If only the truth were adhered to, how much less of literary "rubbish" there would appear.

#### Virgin Queens and Drone-Comb

L. S. C. says in the British Bee Journal:

It is, I believe, Doolittle who maintains that, with a virgin queen, drone-comb is built so invariably that combs in process will show whether the colony has been dequeen. I do not know exactly upon what observation this is based, for I find that such bees build worker-comb, but there may be conditions other than the mere possession of a virgin queen which would overrule the matter.

Has Mr. Doolittle ever expressed such a belief?

I believe that the American Bee Journal is one of the best papers that I have ever read.—G. S. LIGHTNER, Cedar Co., Iowa.

Our Front Page Pictures this week are something of a medley. Most of them were sent to us by Mr. D. H. Coggsball, of New York State, who attended the National convention at San Antonio last November. The pictures may be described as follows:

No. 1 represents Wm. A. Selser, Mrs. Coggsball, and Mrs. Ball, who, with Mr. Coggsball, were returning from an alligator hunt in the wilds of Florida. Mr. Coggsball is not shown in this picture.

No. 2 is said to have been one of the "speakers" at the National convention in San Antonio. If such was the case, he did his "speaking" outdoors. There were many of his kind on the streets of San Antonio. He seemed to be a very useful "citizen."

No. 3 shows 2 children who seem to be somewhat "colored." There are quite a number just like them in San Antonio and in many other parts of the South.

No. 4 shows the oldest cathedral in San Antonio, and also one of the city plazas or parks. This is a very pretty spot. We had the pleasure of walking through it and also entering the ancient cathedral.

No. 5 represents Mr. O. O. Poppleton in his apiary of "Long Ideal" hives. He was for a long time an extensive bee-keeper in Iowa, but some years ago moved to Florida, where he is perhaps the largest bee-keeper now in the State. We have had the pleasure of meeting him at several National conventions. He is a most genial man and an excellent bee-keeper.

No. 6 shows a part of one of Mr. D. H. Coggsball's New York State bee-yards in winter quarters. From this apiary he has obtained as high as 12,000 pounds of extracted honey in a single season.

**To Bee-keepers of Indiana:**—Mr. Walter S. Pouder, of Indianapolis, has sent us a copy of House Bill No. 637, recently introduced in the Indiana Legislature. Bee-keepers of that State are urged to write to their State Representatives and Senators asking them to vote for the Bill when it comes before them. It is as follows:

*Be it enacted by the General Assembly of the State of Indiana:*

SECTION 1.—Upon the recommendation of the officers of the Indiana State Bee-keepers' Association the Governor may appoint for a term of 2 years a State Inspector of Apiaries. Such Inspector shall, when notified of existence of a disease known as foul brood among apiaries, examine all such as are reported, and all others in the same locality, and ascertain whether or not such disease exists, and, if satisfied of its existence, shall give the owner or person who has care of such apiaries full instructions as to manner of treating them.

SEC. 2.—Within a reasonable time after

making such examination the Inspector shall make another examination thereof, and if the condition of any of them is such as in his judgment renders it necessary, he may burn all of the colonies of bees and all the combs necessary to prevent the spread of the disease.

SEC. 3.—Any owner of a diseased apiary, of honey made or taken from such an apiary, who shall sell, barter, or give away such apiary, honey or appliances, or bees from such an apiary, expose other bees to danger of contracting such disease, or refuse to allow the Inspector of apiaries to inspect such apiary, honey, or appliances shall be fined not less than fifty dollars nor more than one hundred dollars, or be imprisoned in the county jail not less than one month or more than two months.

SEC. 4.—There shall be levied annually on the owner of each colony of bees in the State of Indiana one cent for each colony owned, which levy shall be placed on the tax duplicate of the respective counties by the county auditors at the time of the levy of other taxes each year. The amount so collected shall constitute a special State fund, to be disposed of in the payment of the salary and actual expenses of the Inspector.

SEC. 5.—The Inspector shall make at the close of each calendar year a report to the Governor, stating the number of apiaries visited, the number of those diseased and treated, the number of colonies of bees destroyed, and of the expense incurred in the employment of his duties. Said Inspector shall receive three dollars for each day actually and necessarily spent in the performance of his duties, and be reimbursed for money expended by him in defraying expenses: Provided, That the total expenditure for such purpose shall not exceed the amount secured by the special assessment as defined in Sec. 4.

**Luther A. Hammond**, an esteemed resident of Keedysville, Md., and a long-time reader of this Journal, died of pleura-pneumonia the latter part of February, aged a little over 52 years. He was sick only a week. For years he was one of the most progressive farmers and bee-keepers in his district.

**Why Not Advertise?**—There are many dealers in bee-supplies, and those who have bees and queens for sale, who are not now advertising, that might increase their business by advertising in the American Bee Journal. The rates charged are very low, as will be seen by referring to the second page of this number. During the next 6 months will be done the bulk of the season's business among bee-keepers. Why not begin at once to let the readers of the American Bee Journal know that you have something to sell? Our advertising columns are open only to those who will give their patrons "a square deal." If you are in that class we will be pleased to have your advertisement in our columns.

This is the first year I have taken the American Bee Journal. I like it better every copy I read, and will take it, if possible, as long as I keep bees.—A. K. WHIDDEN, of Prince Edward Island.

## Feeding Sugar to Starving Bees

BY G. C. GREINER.

As I expected and feared, the open and comparatively warm weather of last winter (1905-6) induced and compelled bees to use larger quantities of their winter stores than they usually do during steady and colder winter weather. The fall flow from our late honey-sources, such as goldenrod, asters, sweet clover, etc., had not been over-abundant, so that bees had only enough supplies to bridge them over to the early spring flows, if the winter had been one of the usual kind. But under the circumstances, I awaited with fear and trembling, the warm days of the coming spring, that I might find out the conditions of my bees and lend a helping hand where necessary. At last the month of May arrived, and indications were favorable that the warm season had opened to remain so.

All my bees were packed in chaff on the summer stand, making it somewhat unhandy to examine them in a satisfactory way. I therefore stripped them of their winter protection as soon as the settled weather made it safe to do so, which, in this case, was a little earlier than I would have done if possible shortage of supplies had not caused me a great deal of uneasiness.

On May 3, being a warm, ideal spring day, the bees were busily engaged bringing in pollen and honey from early fruit-blossoms, and as I had nothing to fear from robbing or chilling brood, I made a thorough examination of all colonies. The result was a shocking discovery. About one-third of them had plenty of honey so that many could spare in case of an emergency, one or 2 frames, but the rest were practically in a starving condition, not a few so completely destitute of stores that literally not a cell of honey could be seen; all their combs not occupied by brood were as dry as extracting or bait-combs, after they are cleaned out by the bees. But, strange as it may seem, with the exception of a very few, all were strong in bees and had plenty of brood.

To judge from this state of affair, I knew, to prevent a calamity, something had to be done before the rising of another sun, and the only question was how that "something" could be managed to the best advantage. I had no honey in brood or extracting combs; all I had reserved from my extracting combs the previous summer for this purpose I had to use the previous fall in feeding up for winter on account of the unexpected light fall flow, which was so

contrary to my experience of former years.

In Gleanings the editor says: "We have come to the conclusion that we can rear our own bees with sugar-syrup far cheaper than we can buy them." The principle of this assertion I followed to the letter, and I did it in the following way:

In thinking the matter over, I felt anxious to observe these points: To feed all colonies at once (practically) and do it with the least work; to give the least inducement to start robbing; to disturb the colonies as little as possible by opening the hives; and last, but not least, not only to save their lives, but to induce them to start anew and continue brood-rearing, which under the prevailing conditions, I feared they had given up. To hit all these "flies" with one blow seemed quite a puzzle to me at first, but I succeeded beyond all my expectations, as the result plainly proved.

Of course, I had to resort to sugar-feeding. I manufactured syrup in lots of 20 pounds at a time, using 10 pounds of each (sugar and water), and stirring the same without boiling, but slightly warmed, until all the sugar was dissolved. The feeding process was a simple affair. At night, just before dark, I went along the rows of bees, raised the front of their hives one after another to a position of about 45 degrees, turned a soup-ladle nearly full of the prepared syrup into the entrance, and lowered the hive to its proper place. The whole operation was so easily and so quickly done that it complied with nearly all the above requirements.

As an explanation, I will say that all my hives stand level (by test of spirit-level) except a slight pitch toward the front of about one-half inch. To make the above process of feeding practical, every hive had to be pitched at least that much the other way. But that was an easy matter. A little block under the front end of the stand accomplished that, and in many cases, raising the hive on the projecting notch of the alighting-board was all that was necessary.

To test the action of the syrup when being turned in, and make sure that no drowning of bees could take place, I tried the experiment with an empty hive before I undertook the real business. The syrup would run back in a narrow stream, strike against the back of the hive and spread sidewise, filling the corner, formed by the bottom and bottom-rim, with quite a body of the liquor clear across the width of the hive. When the hive was lowered to its level, the syrup would flow forward and form a thin sheet covering one-half or more of the entire hive-bottom. Being satis-

fied that the danger of drowning was reduced to a minimum, I proceeded with the operation.

The following morning I could not resist the temptation to find out how the bees had accepted their ration. I examined a number of the stronger colonies, and a few of the weaker ones, by unhooking the bottom-boards and raising the front of the hives high enough to give a fair view of the bottom. All the former had everything cleaned up; the bottom was perfectly dry, not a sign of the syrup fed the night before could be detected. Although some of the weaker ones had some of their feed left on the bottom, the result of my first night's feeding was so gratifying that I kept it up regularly every night for nearly 2 weeks.

On May 15, bees began to refuse their offered feed, and I could plainly see that another source of sweets drew their attention. The apple-trees had been in bloom for several days and bees were getting quite numerous among the blossoms. In the hives a change was taking place; the white coating of the combs, the well-known and pleasing indications of a honey-flow, and the appearance of new honey were getting quite conspicuous in all the better colonies. These conditions grew more prominent from one day to another, and before I had hardly time to realize what was going on, every comb in many hives was crowded to the last cell with honey; even cells among hatching brood were glistening with their contents. The few surplus cases, both for section and extracted honey, which I had put on when new honey made its first appearance, were full of bees rushing their work at a rate that I never experienced before during fruit-bloom.

As may be imagined, I was rushing things also to get my surplus cases in place, not knowing that a sad disappointment was in store for me. The climax had already been reached, and the drop was as sudden and discouraging as the beginning had been promising. A cold rain set in on the 18th, and continued more or less all through the remaining apple-bloom, with the result that no more honey was gathered until the latter part of June.

Stimulating feeding in the spring to induce brood-rearing is one of the many subjects on which the opinions of our ablest writers are greatly at variance. One sees his only salvation in its practice, while another says it does more harm than good. One reason why the views of our experts run in such opposite directions, is simply because it is a very difficult matter to produce positive proof either for or against it. It is very much the same in the case above stated. To estimate the beneficial results of my 2 weeks' sugar feeding, or the consequence of it had been omitted, is merely a matter of conjecture. However, there are a few facts connected with it from which we can draw a fairly correct conclusion:

1. On May 3, bees were in a starving condition.

2. On account of occasional unfavorable weather at that time, which prevented the bees from flying for days at

a time, honey was coming in too slowly to keep bees and brood from starving.

3. No colonies were lost from starvation.

4. Bees were seemingly in excellent condition to take advantage of the phenomenal honey-flow, lasting from May 15th to 18th, if the amount of honey stored during those few days justifies that assumption.

Since writing the foregoing, Mr. Latham's rejoinder appeared on page 1015 (1906) of the American Bee Journal. Although the opportunity is very tempting to make a detailed reply, I have no desire to do so, for the reason that these long-drawn-out controversies are interesting only to the persons directly connected with them, but not to the general reader. We all know that whoever has the last "say," has all the advantage over his opponent, and it is customary and courteous to give the weak side the benefit of the same. I am willing to let it go in this case.

I wish to thank Mr. Latham for the kind spirit he exhibited in dealing with me. I gladly agree with him on some points brought out in his rejoinder, but on many others—I don't.

LaSalle, N. Y.

## Bees Building Round Cells— Wax-Secretion, Etc.

BY R. C. AIKIN.

On page 1051 (1906) Mr. Hasty expresses doubt that bees ever try to build round cells. He also hints that bees have much more wisdom than some of us are willing to credit them with. Again, page 95 (1907) he refers to the matter and comes down a little, but only so far as to confess that in the case of queen-cells the mouths of them are round.

Well, Mr. H., you would better hasten to come clear down on the question of round cells, for the fact is, every cell bees build is first round until they cannot longer maintain the circular form. You get your old pipe and some soapy water and start to blow bubbles. You can make one round to start with; the second when it joins its mate dents or flattens a strip of one side. The third joins the first and second and makes two more straight lines where they join; this is then kept up until the 7th bubble is made, which forms a complete circle around the first, and if you keep on adding they just keep on forming 6 around 1, and every one of them, barring the outside ones, has become 6-sided.

The bee begins by plastering a bit of wax to the starting-point wherever she means to build a comb; this is lengthened into a sort of ridge, and other little ridges started from this to the sides, all the while wax being added at the starting point on top of the ridge. As the work goes on the various little ridges are formed into circular walls enclosing space after space, but the mouth of every little embryo cell is round, with thickened walls of the crude wax. As the cell begins to rise from the tiny ridge, the bee begins to shave off the surplus wax from these thick walls, and in so doing they straighten

the partition walls, and they become the 6-sided form, very much as do the soap-bubbles. Just take a look at the comb that is being builded and you will see that the rudiment of the cell, that is, the mouth of every cell where the fresh wax is plastered on, is round; you can see this in almost any comb you may pick up at any time, but it shows to best advantage where the bees have just been building, and never finished the comb.

Again, sometimes we find a row of cells built in between two bars where there was just space enough for the one row; there they build circular cells, or very irregular ones. The hexagon cell is not so because of any great wisdom on the part of the bee; if she were wise she might build square cells where but one row can be put in, but she does not. There is no other form so easy to build as the hexagon, when considering the question of blocking one form against another; here Nature helps the bee out. She could build square cells and block them together in solid masses, but the greater length of side wall would be much harder to make and keep straight, and there would be so much waste space in each of the 4 corners of each cell, when the question of brood-rearing was considered.

Neither would the square cells have so great strength, and would almost of necessity have to have flat bottoms, thus entailing another loss of space, and a thing impossible for the bee to build. Given flat-bottomed foundation, and they either change its form or put extra wax into the corners in their endeavors to reach the sharp angle.

No, no, Mr. H., every cell is *started* in circular form, but as the next or adjoining cells are worked up to it the bee is practically compelled to flatten the rib or wall between, though she might want ever so much to round it. The only way to round them is to fill the corners with *extra* wax. Even with the hexagon form there is some extra wax in the corners, as obtuse as they are.

Many people still cling to the old tradition about the wisdom of the bee; they are thought to know when the master dies, or foretell events; which flower to visit and which not; just when to do this or that, and when not; yet wise or not, she constantly blunders, and when she gets on the inside of a window cannot exercise the wisdom of a common house-fly. The bee is governed in no sense by reason or the exercise of wisdom, but in all things is the creature of instinct and of environment. The master, once understanding all conditions, can just as surely tell you what they will do under this or that, if he thoroughly understands bee-nature, as the mathematician can tell the result in figures when you state to him the factors.

We talk of location ("locality"), what do we mean? Localities differ, seasons are not alike, colony conditions do not come in the same relation to weather, hive, management, flora, temperature, etc.; and so there is to be found a regular kaleidoscope because of the ever-changing relation of factors

that influence. If writers could give us an intelligent statement of factors and their relation in their particular cases or localities, thousands of things that seem mysterious could readily be explained. Of course, we are not expected to know everything, and I am not reproaching any one for ignorance of truths; but I am pleading for common-sense. Let me illustrate:

There are hives and hives, and the man who has mastered the science of management, which is nothing else than understanding bee-nature and the relation of factors, can take any of the hives and get results, provided the hive is adaptable to allow the master to bring his management to bear; but ignorant management with the best hive ever invented will not bring the desired results.

We have a swarm of bees. Now it is the commonest rule that when bees swarm they go with sacs full, and when hived they cluster and hang in great bunches. Having entered the new home, why do they not get a hustle on them and begin to get in supplies? Go to the stand of a newly-hived swarm that has at once accepted its new home, and gone in and quietly clustered, and often they are so quiet, and so few bees coming and going, that you will be tempted to look in to see if they have not absconded. But you find they have gone in loaded down with honey, and are tired from their flight with so heavy a load, and not a cell that they can unload into. Hive them on comb, and see how quickly they will go afield, for they can unload, and will get to work. Without the ready-made comb they cluster and wait, and now comes the

### SECRETION OF WAX.

Many think wax-secretion is a voluntary act on the part of the bee, but I do not. You can feed your cow and she gives milk. Skimp her in feed and she gives less of the fluid. The naturally poor milker will not milk well with any kind of feed or care, no matter how good, nor will the good milker do poorly unless you make it hard for her to do well by allowing or making bad or unfavorable conditions. Milk is a secretion of the cow and she never thinks about whether she will give much or little, good or bad; and no more does the bee use reason and voluntarily secrete or refuse to secrete wax. That swarm with loaded sacs cannot field, and so hang and rest well-fed. While resting the wax-secretion starts; with many of them it was already in full operation because of the abundance of nectar handled, and in extra-good flows the same loaded condition of sacs before swarming as after; so the next thing is comb-building—almost forced to do it by environments and instinct.

Some have written of strains of bees that put much or little wax in their comb, as the case may be, as though it were a voluntary or intelligent act on their part. Is it? There may be strains of bees that by reason of more vigor, or some cause, incline to free or scant wax-secretion just as there are good and poor milk secreters in cows, whatever caused it in the first place;

but this alone does not account for heavy waxy or thin brittle combs. Many times a colony may have in process of secretion much wax, and the flow weakens so that there is not the demand to have comb that would be with much nectar coming in. Then, again, there may be an out-of-balance condition caused by varying proportion of fielders to nurses. It is perfectly foolish to condemn a certain queen or colony because it has given different results from its neighbor, without knowing and understanding its conditions—the relation of factors. Relation and number of factors make all the difference, and one must decide intelligently or he may behead the best queen he has, and save the poorest one.

I have heard of a music teacher who set his pupil to playing chords, and kept him at it until he could strike any possible chord or combination of chords, instantly the eye caught sight of them on the staff; but all the time the teacher had strenuously kept the pupil from attempting to play tunes. The pupil kept insisting that he be allowed to play some tunes. At last when the chords were mastered the teacher said the pupil might play a tune, but he said he did not know how, as he had never played one; but he was told that tunes were nothing but combinations of chords and that he could play any possible tune that he might find. This illustrates the bee-business. Once we master and understand the factors and their relation to each other, we can do with the bees just as the music pupil—play any tune we wish.

But it is not possible for man to make all the factors nor dispose of their arrangement or order; we are hampered and hedged about as the bee, but we can make the best of what we can control and adjust. When some one from New York, or from Colorado, or in the white clover regions where there is a June flow, or in some place where the crop is harvested from fall flowers, or from any other of the multitude and variation of localities and conditions, writes and says thus and so is the way, try to put yourself into that man's position and view-point, and make an intelligent analysis, and the disagreement of doctors will vanish, and all will be plain. Many times, when a writer tells of certain experiences, but overlooks some prime factor, I am at a loss to explain his results; but in very many instances, by reading between the lines, the whole thing is as clear as day. Our many differences are because we do not understand one another, because of lack of knowledge, and because of the limitation or incapacity of the human mind.

Man in his actions, both physical and mental, is a bundle of habits. We get into the habit of doing things this way or that way, and should it so happen that the various factors were in favorable relation, a reasonable or even splendid success comes to us, and we are led to think we are "it," and know just how. I know the reader will pardon a personal experience that illustrates the point:

The first 10 to 12 years of my bee-

keeping experience was spent in what was then a new prairie country in south-west Iowa. The only sources of nectar that supplied both winter stores and surplus were fall flowers; sometimes it was starvation even in July, but usually enough spring and summer bloom to supply present needs with a filling of brood-combs in August with the main flow between Aug. 15, and Sept. 15. You see how I had all summer to build up strong colonies; could make early nuclei, and make of them strong colonies before the surplus flow. This relation of factors caused very little swarming at the usual time, or June and July, and when the surplus season did come it was fall, and the bees seemed

little inclined to swarm so late, no matter how strong.

All these years it was no trouble at all to control swarming. In white clover districts the brethren were writing and complaining of swarming, and the awful times they told about was a puzzle to me. At last I decided I would write some, too, and tell of my non-swarming strain of bees, and seriously thought of going into the business of selling such queens. Fortunately, before I got around to it white clover was plentiful, with May and June surplus; my bees of years of non-swarming went crazy, and I imbibed a little more sense. See?

Loveland, Colo.

## Convention of Bee-Keepers' Associations at Brantford

REPORTED BY J. L. BYER.

(Continued from page 171.)

### TUESDAY AFTERNOON SESSION.

"What is the best hive—the 8 or 12 frame Langstroth?"

The majority of the members favored a hive larger than the 8-frame Langstroth.

"Why do bees outside need a flight, while those in the cellar do not?"

Mr. Trinder stated that he wintered his bees outside, packed them very warmly, and they never offered to fly, even if his neighbors' bees were flying freely.

"What is the use of putting honey in 60-pound tins, when they are not to be the final packages?"

Mr. Holtermann—Under certain conditions, they are of considerable advantage. There is no time to put into small packages in the busy season.

Mr. Shaver would not wash 60-pound tins that are to be carried over, but Messrs. Holtermann, Armstrong, Byer, and others would, for fear the honey left in would deteriorate and cause the tins to rust.

### BUILDING UP COLONIES FOR THE HONEY-FLOW.

Mr. House now gave his address on the subject of "Building up Colonies for the Honey-Flow." He stated that every structure must have a foundation. The foundation of a crop of honey was a good, prolific queen. In this, with him, the Italians were a failure; his choice being a cross of Carniolans and Italians. Abundance of good stores, and protection outdoors or in a repository were also essentials. In spring a thorough

examination was made of each colony. Enough stores should be present, but not too much, and he wanted a good telescoping cover packed with some non-conducting material on each hive. In about 2 weeks most of the colonies should have all the brood the clusters can cover. Normal respiration of the bee is 3 or 4 times a minute; under abnormal conditions, as high as 124. The greater the respiration, the greater the activity and the higher the temperature. Honey coming into the hive will bring about all these factors. Hence the thing necessary to increase brood-rearing is "stimulative feeding." A small feeder is used, and the stimulating is done in the evening. Thus the temperature is kept up through the cool night to where it was during the day. If stimulative feeding were started, it was very necessary to keep it up till the honey-flow. To feed a while and stop, was positively harmful, as a great lot of brood was started, and if feeding were stopped, a large amount of this brood would starve or chill to death.

Notwithstanding all the speaker had said, he was glad to know that by a proper selection of the Carni-Italians, queens could be had that would rush brood-rearing in the spring to such an extent that feeding could be dispensed with. He used a sectional brood-chamber, 2 cases 14½ x 18 x 6 inches, to each colony for winter. By fruit-bloom to each colony should be added a third case of 10 Langstroth frames of brood, and at this time he adds a third case to give additional room.

At the opening of the clover flow he treats every colony by taking away the 2 sections of brood, and substituting a case of new combs on which the old queen is left with most of the bees. The brood-chamber taken away can be used as increase, or piled up indefinitely and run for extracted honey. The

# American Bee Journal

bees on the old stand are run for comb honey. Supers are added as needed, always at the top; never more than 4 are left on the hive at once. At the close of the white honey-flow, these colonies all having old queens, are doubled up simply by putting one brood-chamber on top of the other. As these colonies are all to be re-queened during the buckwheat flow, no attention is paid to looking for queens at this time, and they are left to fight it out.

Mr. House considers it of great importance to have *new* combs under the sections in order to produce a fancy article. In fact, he would "throw the old combs into the ditch" rather than use them.

Mr. Chrysler—With me, if I restrict the bees to as small a brood-chamber as Mr. House does, the bees will swarm in about 3 weeks.

Mr. Byer—Is there not a danger of those brood-combs giving an inferior quality of extracted honey?

Mr. House—Yes, there is that danger to guard against, but I am more concerned about the comb honey.

Mr. House stated in regard to stimulative feeding, that where it was practicable, outdoor feeding of honey in small quantities every day was advisable, and mentioned a Dr. Park who had practised this system with immense success.

Mr. Holtermann said he never before fully understood why stimulative feeding stopped suddenly was so harmful. He would caution against feeding honey from danger of foul brood.

Mr. Miller also thought that it was unwise to take the risk.

Mr. Root said he had visited Mr. House and found the quality of his honey away above the ordinary. He asked for a show of hands of those who used divisible brood-chambers. Three held up their hands.

Mr. Hershiser was positive that old brood-combs, even in the first extracting, produced as white honey as would new combs.

Mr. Holtermann and a number of others disagreed emphatically with Mr. Hershiser, and the Chairman, asking for a show of hands on the question, found 20 to 2 in favor of new combs.

Mr. Hershiser asked Mr. Root to conduct experiments along this line and show the people that the 2 were right.

## SIZE OF ZINC PERFORATIONS.

"Are the perforations in this sample of excluding zinc too small?"

Mr. Root said he was glad this matter was brought up; the sample submitted was the Standard Root zinc .162 to .163 of an inch perforations.

On the advice of Capt. Hetherington and some others, they had made the perforations as they are now, instead of .168 to .170 as they were formerly. Lately some evidence had come in that had made him think that possibly the holes were too small. It was no trifling matter to his company, as the dies cost over \$1,000 per set. Carniolans were slightly larger than Italians and the trouble reported was more with the former race of bees. They wanted the truth about the matter, no matter what

it cost. If the zinc was not right it would be remedied.

Mr. Holtermann and a number of others thought the zinc as at present made is all right.

Mr. Hershiser said he believed it would be advisable to increase the perforations slightly.

Mr. Chrysler had sold a large quantity of old-style zinc without a single complaint, but a lot of the new-style zinc (Root) had been returned to him, the bee-keepers claiming that the bees could not get through them.

Mr. House had 300 or 400 Root-zinc-excluders and had no trouble. But with 100 old-style, too many queens got through.

Mr. Miller would not like to see any change made. Attention was called to the fact that it was necessary always to put the rough or burr side of the metal up so that the loaded bees came against the metal on its smooth side.

Mr. Root said it was very difficult to punch steel metal without leaving a slight hurr on one side. The burr was so slight that no harm was done if the zinc were put on right, as had been mentioned.

## RENDERING OLD COMBS.

"What is the best method of getting wax out of the old combs?"

Mr. Coggs—An important question. Pulverize the combs thoroughly and wet them. Then use a press, the more powerful the better. From 20 barrels of slumgum saved up the past 18 months, from which he thought he had got most of the wax, with his kettle and sack process, he had recently extracted 700 pounds of good wax with a Hershiser press. All agreed that in the past thousands of pounds of wax had been wasted. Slumgum from solar extractors invariably contained from 30 to 35 percent of wax, and from other sources large varying amounts.

Mr. Craig read a letter from Mr. France, relative to the Ontario beekeepers joining the National Association. It was moved by R. F. Holtermann and seconded by F. J. Miller that we as a convention, represent to the Ontario Bee-Keepers' Association the advisability of our members joining the National in a body. Carried.

## WEDNESDAY EVENING SESSION.

### FEEDING HONEY-DEW IN SPRING.

"Will it be harmful to use honey-dew for stimulating bees next spring?"

Members differed in opinion. Some intended to try it, while others would not take the risk.

Mr. House had used it once with disastrous results.

Mr. Root thought some honey-dew would be all right, while other grades were unfit for any purpose.

A Member—How can we know when honey-dew is being gathered?

Mr. Shaver—By color, objectionable flavor, and by tracing the bees in their working.

### RELIEFING BUCKWHEAT HONEY.

"Can buckwheat honey be liquefied without injuring the flavor?"

Mr. Holtermann—Yes, but it requires to be done carefully.

At this time Mr. Laing asked leave to present the following resolution:

*Resolved*, That the Secretary of this Association be instructed to request the officers of the National Association to hold their next annual meeting in the city of Detroit, where we believe a great many of the Canadian bee-keepers will attend." Carried unanimously.

Mr. House was asked to explain the general principles of the Betsinger separators. He commented on recent articles criticizing this separator adversely, and said he felt that if Mr. Root had looked into the matter closely he would have found some cause for the trouble reported by Messrs. Burt and Dibbern. Personally, he had used thousands of them and never had the bees build comb fast to the separators. Some of their advantages over other separators were free communication for the bees and equalization of heat through the super. The surface of the sections was always smooth and not ridgy, as was the case when using fence-separators. While the initial cost of them was higher than other kinds, yet he would use them if they cost double.

Mr. House also exhibited a sample of the Betsinger Carton, and said that honey in this carton always brought 2 cents per pound more than the market price. Speaking of the care of comb honey, Mr. House said that if honey were "weeping," if the temperature of the room were raised to 100 or 110 degrees and kept there for 3 days, the honey could be redeemed.

Mr. Root—This is a valuable item and worth coming to the convention for. He wished to say that he had seen some wonderful results from the use of the Betsinger separator, and was at a loss to understand such a difference as reported by Messrs. Burt and Dibbern.

A number of samples of honey—good, bad, and indifferent—had been collected. Grocers of the city were invited to be present, and Mr. Smith was asked to explain the difference in samples, pointing out defects, etc. About 30 samples were on exhibition varying from No. 1 clover honey to the vilest of honey-dew. A sample of unusual interest was 2 sections of fancy honey in perfect condition, in a case; produced by James Armstrong in 1896. Mr. Root and others said they had never seen anything like it before. Another sample of extracted was from Vancouver, B. C. It was also 10 years old and in fair condition, a peculiar thing about it being that the levulose and dextrose had separated—half of the sample liquid and other half granulated.

Regarding grain and flavor of granulated extracted honey. Mr. Coggs and others said that stirring honey just as it is about to granulate will improve texture and flavor, and also change color somewhat. About 45 minutes was spent in an informal manner, discussing the various samples; after which the convention adjourned to meet in the morning.

(Continued next week.)

Conducted by J. L. BYER, Markham, Ont.

## Second-Hand Tin Honey-Cans

"I am done with them," quoth W. Z. Hutchinson in the January Review, speaking of the use of second-hand tin cans for honey. I suspect a good many other bee-keepers have come to the same conclusion; certainly the writer of this has had all the experience he wants with the article.

To be sure, second-hand tins accumulate on the dealer's hands, and it seems too bad to discourage the sale of them, viewing the matter from that standpoint. But as far as the bee-keeper is concerned, I feel sure that second-hand tins are dear at almost any price, especially if the white table honeys are to be stored therein.

The second-hand tins I have bought have been, as a rule, unsatisfactory in many ways. Quite a large percentage have leaked, more or less would be battered and rusty either inside or out, or both, and all were invariably *mussy*. A greater objection is the danger of foul brood, if the cans are received in warm weather. Some time ago I bought some second-hand tins to put buckwheat honey in, and when they came to hand I found the shipping tags of the man who had sold the dealer his clover honey still attached to the tins. As I happened to know that this bee-keeper's apiary was rotten with foul brood, needless to say those cans were "out of sight" in short order. It is only fair to add that the dealer from whom I bought the tins was perfectly honest, and never suspected anything wrong.

## Use of Bee-Smoker and Bee-Veil

While the discussion was on relative to smokers at the Ontario convention last November, Mr. Brunne claimed that he did not use a smoker during the honey season in managing 110 colonies of bees. I am not going to contradict Mr. Brunne, but I want to say that there must be some personal magnetism about him, or else his bees are entirely different from any it has been my pleasure to come in contact with.

But granted that it is possible to do without a smoker, will any sensible bee-keeper contend that that fact would make it advisable to do so? The most of us don't keep bees for the purpose of seeing if we can manage them without a veil or smoker; on the contrary, the veil and smoker are used in just the proportion that their use will help

us to work rapidly, with the least injury to the bees.

During queen-clipping I never use a veil, for the reason that bees are not nearly so cross as later in the season; and, again, it is much pleasanter to work without a veil, when the work consists principally in using the eyes. Later on, in the extracting season in particular, I want a veil, every time; not that I dread the stings so much, but more so as a time-saver, for no matter how quiet a strain of bees, there are sure to be in a large yard some cranks flying around the operator's eyes. While it is quite possible to do without a veil even at such times, the practise of some good bee-keepers proves this. Say, wouldn't there be fun in the majority of cases if the operators tried to take off the honey from 100 colonies without the use of a *smoker*?

Conducted by LOUIS H. SCHOLL, New Braunsfels, Tex.

## Does the Elm Yield Honey?— Other Subjects

So you think the elm, a honey-producer as well as a great pollen-producer, do you Mr. Scholl? I think if you will investigate more closely you will find the bees were at work on the leaves of the elms, gathering this dark honey you mention in a recent issue of the American Bee Journal; that it was "honey-dew" the bees got from the leaves, and not real honey from the bloom. I never could decide that bees got anything but pollen from the elms. I am open, however, to conviction, and would rather *know* you were right than myself.

### FEEDING COMBS OF SYRUP

The way I've been feeding my bees this winter is this: I go over the apiary through the middle of the day while it is warm, lift the hives so as to tell which are the light ones, and mark those that I think need feeding. I then

## Bee-Cellar Heated with an Electric Heater

Mr. E. G. Hand, of Fenelon Falls, Ont., winters his bees in a cave or cellar made by remodelling an old lime-kiln. While he has had fair results in wintering in this cellar, yet the temperature was generally a little too low in severe weather, and the walls were inclined to be quite damp.

While spending a day with me last September, Mr. Hand intimated that he intended to try to remedy these adverse conditions this winter by installing a small electric heater in the cellar. Just a few days ago a friend living near Mr. Hand wrote me that the heater was a success, and said that he had just come from visiting the cellar on the coldest day we have had this winter, and found the thermometer standing at 47 degrees.

I might say that Mr. Hand is only a short distance from where the electrical energy is developed, and I understand the cost is quite low; but doubtless with the spread over the country of electric power, many might avail themselves of a like convenience, even if they should be a considerable distance from where the current is generated.

I hope in the near future to be able to give the readers of "Canadian Beedom" a full description as to how the heater is arranged, and also give results of wintering as compared with other winters when the cellar was unheated.

light the smoker, open the hives, and take out the empty combs right up to the cluster of bees. I make an estimate as to how many combs of sugar syrup each colony will need. Then I fill the combs with warm syrup by using a quart dipper with holes punched in the bottom from the inside. The combs are now filled by holding them over a common wash-tub with the syrup dipped up and allowed to stream through the holes in the dipper so as to fill the empty cells in the combs. When one side is filled reverse and fill the other.

As fast as they are filled hang the combs in empty hive-bodies. The hive-bodies should be above the ground on a bottom-board, and a vessel put under to catch the drip. As fast as the combs are filled stack up the bodies until you have all the combs filled you wish to use. Then about the time the bees stop flying for the day, hang the combs of syrup right up to the cluster of bees, putting in the number you wish each

colony to have. In this way there will be little or no excitement among the bees, and we have the feed right where it is wanted.

#### COTTON-SEED MEAL AS POLLEN

A novice in bee-culture, here in the South, who said he was a reader of the American Bee Journal, wishes me to answer the following questions for him:

1. I notice my bees at work very busily where cotton-seed meal is being fed to stock, collecting it and packing it on their legs like pollen. For what purpose are the bees collecting this meal?

2. Will this meal in any way harm the bees?

3. What effect will this unusually warm winter have on the bees? Will it be detrimental or otherwise to them?

To the first question I will say that the bees are gathering the cotton-seed meal for the same purpose that they use natural pollen. We have often seen bees collecting cotton-seed meal and using it for pollen, and they will start brood-rearing the same as with natural pollen.

2. No, the meal will not harm the bees except in one way—it will cause them to start brood-rearing in winter, and cause the bees to use an unusual amount of stores. If you don't look sharply they will starve before spring.

3. The effect it will have on the bees is given in the answer to the second question—that is, brood-rearing out of season and a large consumption of stores, with the result that many of us will be compelled to feed. So we consider the warm winter detrimental rather than otherwise to bees in the South.

L. B. SMITH.

Rescue, Tex.

Perhaps I am wrong in my conclusions that the bees get the honey from the *blooms* of the elm, but I know the honey comes from the elms all right. We will watch again when they bloom.

### Poor Queens Often Cause Winter Losses

Winter losses are not always due to the shortage of stores as much as to poor queens. In many cases a colony is short of stores because the queen has been a poor one and the bees did not store enough for the winter. In other cases, the poor or failing queen is lost during the winter months, and this results in winter loss.

### Canadian or Southern Weather?

Summer weather still continues, and 85 degrees, Fahr., in the shade has become quite common. To read of the 15-degrees-below-zero weather mentioned by Mr. Byer, on page 113, makes a person shudder even if he is in a "hot" climate. The lowest we have experienced here was 28 degrees—not below but *above* zero—and of such short duration was this cold spell that the "roses, violets, and carnations" bloomed on just the same, besides many other flowers that have joined them since those lines on page 70 were written.

Speaking from experience, having

wintered both in the North and the South, I prefer Southern weather, and "I am free to confess that bees in the air and 80 degrees Fahr. is pretty alluring," indeed, when one must be "cooped up" with cold, snow and ice outside, while here I have been out among the bees in shirt-waists making the spring examinations, and counting the frames of brood. It is true the effect of such mild winters becomes noticeable in the spring, as an increased consumption of stores often leaves colonies short. Fortunately,

very few of my colonies will need feeding, especially since a mild spring means early bloom for them. Hence, it will be seen that what has seemed to be a loss in such mild winters is made up in the spring, unless it is in localities where the bees have no access to early spring blooming plants of some kind.

The weekly visits of the American Bee Journal are always anxiously looked for. W. S. WILLIAMS, of Pennsylvania.

Conducted by EMMA M. WILSON, Marengo, Ill.

### A New Year's Wish to Each Sister

"God keep thee," friend, through all the years,  
Through all the joys, the sorrows, tears  
Of life—its commonplaces, too—  
God keep thee sweet, and brave, and true.

"Amid the doubts and fears that rise  
In every life—the mysteries—  
Things that are hard to understand,  
The movings of a mystic hand;  
God keep thy reason sound and sure,  
Thy mind alert, thy heart still pure.

"God keep thee always—this I pray  
For thee, upon this New Year's day."

FRANCES E. WHEELER.

Miss Frances E. Wheeler, the mistress of Clovernook Duck Ranch, in New York State, amid her many literary cares, as well as the cares of her numerous feathered family, has found time to send the above greeting to each of the sisters. It was a little late in coming, and has been delayed a little more since coming, but it is so beautiful in sentiment that, like many other things, it will keep sweet and fresh indefinitely, and is just as appropriate now as earlier in the year.

### Buying and Selling Honey Between Bee-Keepers

There was lately a very readable article on "Successful Honey Marketing," in the Bee-Keepers' Review. I can endorse much of it from actual experience. It did not, however, touch on the caption above. There is more or less buying of honey between beekeepers, and some thoughts on the ethics of the thing have been forced on me lately.

I take it that to the novice no honey is as good as his own, but as the years go by, and the novelty of being a honey-producer wears off, he is willing to listen more to the praises "the other fellow" showers upon his, and when he

reads of "truly delicious honey—a honey with a flavor all its own—a flavor that smacks of the wild raspberry of the forests;" or when a California brother "blows" about his orange-blossom honey, or says, "I could fairly taste the magnolia in it;" his mouth waters for "something better than he has known." He is now interested. He is willing to try. In fishing parlance, "the fish sees the bait;" but as every fisherman knows, to bait a fish, even to hook him, is not always to land him. To show what I mean, I will relate a little transaction:

A (master of language) offers honey for sale; free sample. B writes for it. He receives a postal card which says, "The ——— honey is all sold. I still have some very fine buckwheat, thick, ripe, and rich, that I can sell at 6 cents. If you can use any of this, I would be glad of an order. I can send a sample if you would care for it."

B feels annoyed, as he says to himself, "Why should he send me a *post-card* that shows me as trying to buy honey, and containing an offer of honey? No doubt it is a good way to advertise, but offers of honey sent into another's territory might well be confidential. I wanted his honey, if at all, for *my own use*. From this postal it might easily be inferred that I wanted it for my trade, and some, at least, of my customers would object to that. They want home-produced honey.

However, B decides to overlook the postal annoyance as a trifling indiscretion, and says to himself: "I have never tasted buckwheat honey to know it as such. I might like it. I may as well sample it, and if I like it I will buy a can." So without losing time he asks that a sample be sent him as offered.

Fully 2 weeks after there comes a second postal from A, saying, "I am about closing a deal that will take all the honey I have. Sorry to disappoint

you. Hope I will have more honey next year than I had this."

If B was annoyed at the first postal, his annoyance is greater at the second, and he says in mental reply to it, "Big crop or little crop, *you don't bait me again.*" Nor is it soothing to his feelings when a bee-paper comes to hand 3 weeks later and he finds that same honey, "ripe, rich, and thick," is still being offered in undiminished quantity!

Bee-keepers, courtesy and honest treatment pay. If you don't want to send samples of honey don't offer to do so. If you do offer, send along promptly even if you are about to make a deal. It may count for a sale another time. And at least it should be worth more than the sample to you to know that your prospective customer can not possibly think that you have trifled with him. Some people are, as is well-known, touchy, and while it is undoubtedly true that "There ain't no sense in gittin' riled," riled they will get if you give them half a show.

(MRS.) A. L. AMOS.

Comstock, Nebr.

Mrs. Amos is right; the Golden Rule should prevail among bee-keepers as elsewhere. It pays in the long run. Let us hope that the transgressors she is aiming at are not to be found among the sisters.

#### Cleaning Sections—A Day's Work

A pleasant letter from Dr. Max Boelte contains the following:

DEAR MISS WILSON:—I offer my best thanks to you for your kind answer about cleaning sections for market, and appreciate very much the pleasant and cheerful way of expressing yourself. Your answer is of greatest interest to me, yet I am compelled to come back to the subject as soon as I shall be able to do so, for even if it is an answer it still leaves sundry points not exactly clear, and does not establish clearly what I had asked. You speak of the work with T-supers, while we here in California use generally the section-holder style of supers—24 mostly, some also 28—and my inquiry was to know about the average work that could be done with *our* style of supers, not the T.

DR. MAX BOELTE.

Valley Center, Calif., Jan. 6.

It is much easier to tell just what has been done right here with what we have than to tell what may be done by some one else with some other fixtures, and under different circumstances. But I'll do the best I can to give some kind of an answer, based on actual experience. Before the adoption of the T-super we used other supers, mostly wide frames containing 2 tiers of sections; that is, each wide frame contained 8 sections, said sections being the 2 bee-way,  $4\frac{1}{4} \times 4\frac{1}{4} \times 1\frac{1}{8}$ . They were, of course, taken out of the frames before anything was done at cleaning them, and if your sections are taken out of the frames before any part of them is cleaned, there may be a chance for comparison. I cleaned thousands of these sections, but, without definite memoranda of work actually done, exact figures can not be given. I feel safe in saying, however, that 1200 to 1500 were cleaned in a day, possibly more.

It is only fair to remember that with

much experience I became somewhat expert, and, indeed, I have been accused of being quick-fingered in general. Just how much should be discounted for that is not easy to say. You, Dr. Boelte, can judge as well as I. Possibly it may not be a very wild guess to say that the average hand ought to do three-fourths as much, or somewhere in the neighborhood of 1000 a day.

But we are talking now about doing the work when the sections are so cold that the propolis is brittle. In California, or anywhere where the propolis is soft and stringy, it is a very different matter. If I were obliged to clean such sections, I don't believe I could get through with more than half as many in a day.

There is another factor in the problem. Some localities are more gluey than others. Indeed, in the same locality some sections have five times

as much propolis as others. I can imagine sections with so little glue on them that they might be cleaned in half the average time. I can also imagine sections so gluey that they would require double time.

You will see, Doctor, that there are so many ifs in the case that it is hard to be very definite; but if there is any point upon which you have any further questions, such questions will be cheerfully answered to the extent of ability possessed.

#### Honey in Infant's Food

At first the child had half milk and half honey, liquefied with water. Then 4 parts milk, 1 part honey, with a little water. The child grew strong and plump, and never had a single pain, while it slept soundly the whole night long.—British Bee Journal.

The "Old Reliable" as seen through New and Unreliable Glasses.  
By E. E. HASTY, Sta. B. Rural, Toledo, Ohio.

#### MEETING OF QUEEN AND DRONE— SIZE OF CELLS, ETC.

I think Dr. Miller is getting a little too near the line of discourtesy in charging me with originality and novelty in what I wrote about the meeting of queen and drone. The Irish Bee Journal has already acquitted me of novelty; and I plead that originality is not what I'm at. I would be happy to quote the publication, page and date about these matters, but a very poor memory forbids me to do so. I have for many years been accustomed to give extra attention to whatever I saw relative to mating, and the whole has "simmered" in my mind. Naturally what seemed to me to be the most illuminative had by far the most powerful effect upon me—while another cast of mind might be swift to forget the very things which moved me the most. There is a decided difference between invention and deductions from a lifetime of reading. When I spin theories out of my own wool, isn't it the fact, Doctor, that I am pretty free to say so—as well as pretty free to do so?

Now as to excess of drones lacking food. So far as honey is concerned, my understanding is that they help themselves to it whenever it is not offered to them in abundance. So, of course, they are supplied—until the dread time comes when the workers decide to make a general onslaught upon them. But I don't believe honey alone is sufficient to keep a drone in best serving trim—do you? If any one thinks so, the burden of proof is upon

him. The presumption is very strongly the other way. Service calls for nitrogenous food; and honey is nearly destitute of nitrogen. Don't believe anybody can be found that will claim that drones eat pollen, or that they could digest it if they did eat it. If not this, then the alternative would seem to be that they are fed nitrogenous food by the workers—with a bare possibility that the nitrogen given them when larvæ suffices for a lifetime. I'm not ready with any further proof, but I think that a few drones in a hive are abundantly fed, fed with stimulating food other than honey; that a larger number are fed more sparingly; and that with too large a drone army the workers stop feeding them almost entirely.

As to the size of cells built, there are times and seasons when you could hardly coax bees to build a drone-cell anyhow; and then there are times and seasons when it seems as if you couldn't make them build anything else. I suppose Dr. Miller (and other people as well) mend combs at leisure times in the spring, and give them to the bees when worker-comb is the only word. Naturally the splicing shows few drone-cells under those circumstances. But when the honey-flow is on, and drone-rearing is the best word—and, moreover, when they have been several weeks engaged in a running fight with you as to whether they shall have a drone out or not—under those circumstances the conditions are very greatly altered, and one should hardly expect them to build a single worker-cell if

they can do any other way. When I wrote "desperately difficult," and, "the work is disagreeable as well as long," sore memories of long ago were backing the thing up. I don't like to get beaten by bees—or bee-keepers, (you may have suspected that much); and years ago a big lot of colonies compelled me to "throw up the sponge" and confess that I *could not* keep them from getting drones. My final defeat was largely owing to this scatt-er-ation of the drone-brood. I tried to shake the combs gently enough that there wouldn't such an awful lot of nectar fly out. The result was that a good many bees would manage to hang on when their comrades were shaken off; and it seemed to me that these remaining bees would consciously hug the scattered cells to keep me from seeing them—but perhaps that was my excited imagination. If Dr. Miller exterminates drones without shaking the bees off, no wonder he doesn't know anything about scattered cells. Half a notion to tweak his nose by claiming that that's just the way he has always done. And (if my frisky adversary wants a categorical answer) a few minutes ago, in the comb closet, I saw a solitary drone-cell on the first comb I came to. And the next time Dr. Miller says he thinks the moon is made of green cheese I shall pull on an apprehensive face and say, "I should like to know how Dr. Miller *knows* this." Page 47.

#### FUMIGATING COMBS WITH FORMALDEHYDE.

David J. West reports success at making foul-broody combs clean with formaldehyde. The treatment, as he describes it, is of a very strenuous sort; and yet he makes a final confession that the combs are not *always* clean. That would be a sickener to some of us. Too dire a danger to stand in doubt about. Page 47.

#### BEES IN THE ENDS OF THE EARTH.

A missionary who notices bees is just the right one to post us about the bees in the ends of the earth. East Africa, which Saeuberlich reports from, is, it seems, the home of a small, light-colored bee whose actions show singular variation from the behavior of ours. We hive our swarms, and rarely fuss with decoy hives. There hived swarms so seldom stay that decoy hives are trusted to almost wholly. And the bear, it seems, is not the only animal whose appetite for honey is so ravenous that he will upset hives to get it. Pity they didn't tell us some name whereby to call this—honey-woodchuck. Page 48.

#### HARDLY GO BACK TO 2-POUNDS.

No doubt, Mr. Merrill, the 2-pound section is better theoretically than the scant-pound section; but (do you mind?) turning the wheels of progress backward is very near to the impossible. The moment we poor darkeys grab the big fly-wheel to reverse it we get "frowed." Page 48.

#### What Bees Make

TEACHER—"What is it that bees make, Tommie?"

TOMMIE—"Sore spots, ma'am."—*Yonkers Statesman*.

### Superseding Queens in Winter

1. Yesterday (Feb. 17) was the warmest day we have had here this winter, 60 degrees in the shade for the greatest part of the day. I took my bees (10 colonies) out of the cellar for a flight, and found on looking them over that one colony had a patch of drone-brood about 3 inches in diameter, partly capped over on both sides of one comb. I found some worker-brood in the rest of the hives, but this one had none. I found the queen but it looked more like a virgin than a fertile queen. Will bees supersede their queen in winter?

2. We expect to move out on to a claim about 5 miles south of Stratton, Colo., this spring. How is that part of Colorado for bees?

3. Do you think it will pay to take the bees along? Iowa.

ANSWERS.—1. In the proper sense of the word I doubt that a queen is ever superseded in winter. If a queen is lost, they may try to replace it almost any time. Your queen is a drone-layer, and so worthless.

2. I don't know about that particular part, but Colorado in general is good.

3. If you ship a car, so freight will be little, it may pay. Even then, if prices at both ends are nearly alike it will not pay.

### Bokhara and Japan Clover

How does Bokhara clover (*Melilotus alba*) and Japan clover (*Lespedeza striata*) compare with sweet clover? Are they related? Are they of any value to bees?

PENNSYLVANIA.

ANSWER.—Bokhara is the same as sweet clover, and so, of course, is valuable. I can't tell about Japan clover. Who can, and will?

### Rearing Queens—Mating, Clipping, Etc.

1. I have never been able to make a success of queen-rearing, either from unfavorable season or bad management. I have in mind to try a plan given on page 7, by F. L. Day, in which he makes two nuclei from one colony by putting a division-board between them in the new hive, and leaving it on the old stand. In taking the queen away, can I give her to another colony by depriving it of its queen? Would they accept her at once, or wait awhile? or how long?

2. He says he has never been able to get many laying queens in that way, but by enclosing the queen-cells in West cell-protectors, with spiral cage attached, and then hanging these between the frames of the nuclei, he secured fine virgin queens. What is the West cell-protector? Is not the spiral cage itself the cell-protector? or is it something else?

3. When these virgin queens hatch out, will they not kill each other if not watched and

taken out? and can I introduce them as I proposed to do with the fertile queens?

4. When these virgin queens come out to meet the drones, would the swarm be likely to swarm out with the queens?

5. Do they ever alight, and, if so (with the bees clustered around the queens), would they ever return to the hive?

6. I shall want to clip the queen's wing when she becomes fertile. When should this be done?

7. What is your opinion of this plan? Will you suggest a better one? Iowa.

ANSWERS.—1. Before attempting to answer I should like the privilege of a little chat with both you and Mr. Day lest I may misunderstand. But I'll do the best I can, and will be glad to be straightened out if I do misunderstand.

You say Mr. Day makes two nuclei from one colony by putting a division-board between them. That is possible, but I rather understood that instead of taking a full colony to make two nuclei, he drew brood and bees from different colonies to make his nuclei, in which case there would be no queen to remove. But taking it as you understand it, I reply that when you remove the queen from the divided colony you can at once give her to a second colony which is deprived of its queen, but she must, of course, be caged or the bees would promptly kill her. After being in the hive for perhaps 2 days, she is said to have the scent of the colony, and if it is arranged so that the bees will free her in about 2 days from the time she is put into the hive, she ought to be received all right. A good way would be to put her in the hive in a provisioned cage a couple of days before the removal of the reigning queen, but not allowing the bees to get at the candy till the removal of said reigning queen.

2. If we had our chat together I should like to have Mr. Day tell us more fully about his failure to get laying queens in his nuclei. I have reared hundreds of laying queens successfully in hives containing 2 nuclei each, and some in hives containing as many as 6 nuclei each. He says he failed to get many laying queens, but plenty of virgins, and it sounds a little as if his effort to get laying queens preceded the getting virgins in the cell-protectors. If that supposition is correct, it may be that the failure to get the laying queens was because it was too early. Getting queens much before swarming time is likely to be a failure, and when one does succeed in getting a young queen to lay very early, she is likely to be very poor.

The West cell-protector is a spiral cage arrangement that allows the bees to get at only the extremity of the cell, for when bees tear down a cell they do not do it at the point but at the side. The spiral cage is separate, and put over the protector, so that when a virgin emerges from the cell neither can she get out nor can the bees get in.

3. If the protector be used without the cage, you may count on all the virgins but one being killed as fast as they emerge; but if each virgin has a cage, of course there will be no fighting. The virgins may be introduced in the same way as laying queens, and if taken when less than a day old will be ac-

cepted as readily as laying queens; indeed, a virgin just out of the cell will be accepted more readily than a laying queen; but a virgin several days old is not easily introduced.

4. No more likely than any other virgins, for you must remember that whether in a nucleus or full colony, every virgin must leave the hive before she is a normal laying queen. It is the general belief that in some cases the bees go out with the virgin on her wedding-flight.

5. According to general belief the bees in such case may cluster and then return to the hive, in very rare cases never returning.

6. She is likely to begin laying when about 10 days old, although it may be a day or two less, and it may be several days more.

7. I am not sure that there is a great advantage in keeping nuclei just for the sake of having virgins hatch out in them without being fertilized. Why not just as well have them in any hive with a laying queen? For in the protector with cage they will hatch out in any hive, whether it has a queen or not. Only if there is a laying queen in the hive there must be food in the cage or the virgin might starve.

If I understand the plan correctly, a virgin is to be hatched in the nucleus, and then given to a full colony where it is to be fertilized. The main thing for which nuclei are used in queen-rearing is to have the virgins fertilized, saving the time of a full colony. Even with the best care a number of cases will be failures, and if a failure occurs in a full colony, there is a serious loss of time before another queen can be got to laying. Either plan will work all right; the only point is that in general it is economy to take the time of a nucleus rather than a full colony to get a queen to laying.

## Bottom and Top Starters in Sections

On page 96 you say, "Have the sections filled full with worker foundation;" and on page 85 I read: "Dr. Miller has for years described his method of using bottom starters (as well as top ones) in sections of comb honey." Kindly explain this method, as I have never seen it in the papers. I have the Daisy foundation-fastener, and would like to try bottom and top starters. Would you make them meet in the center? or how much space between the starters? When they are fastened only at the top, they twist and do not hang true. ONTARIO.

ANSWER.—The matter is very simple, and your Daisy fastener is just the thing to fasten bottom as well as top starter. It wouldn't do at all to let the two starters meet in the center, for in that case the bottom-starter would be certain to fall down and make a mess. When you buy foundation for sections, you are likely to get it in sheets  $15\frac{1}{2} \times 3\frac{3}{4}$  inches. This is just right to make four starters of each kind. The top-starters are  $3\frac{1}{4}$  inches deep, and the bottom ones  $\frac{3}{4}$ . For a section that is four inches deep inside, you will see that would leave a space of  $\frac{1}{8}$ -inch between the starters. In reality the space will generally be more than that, for the hot plate melts a little of the edges of the starters. First fasten the bottom-starter, turn the section over immediately, and put in the other starter. If your bees are like mine, the first thing they do on being given the sections will be to fasten the upper and lower starters together.

## Cleaning Sections for Market

On page 786 (1906) "Colorado" asks, question No. 2:

"How many cases of 24 sections does your best hand clean in a day?" And, also, "What should be an average day's work for an average hand?" etc.

Now, permit me to say that I underscored the *your* and also *average day's work* and *average hand* so as to call your attention to these words. Of course, it can not be either pleasant or interesting to go into a longer con-

trovery about this matter, and I think neither you nor I are of the "hair-splitting" variety. I will then admit that when I first read these questions, and your answers to them that I had not paid any special attention to the word *your*. For years I have known very well that you work with the T-supers, and, therefore, I should have thought of that. The second part of the query, viz.—*average day's work* and *average hand*—that's where the trouble comes from, for, unfortunately, for years I have not seen any T-supers in this part of California, and, worse still, my apiary also is furnished with the unfortunate section-holder style of supers. Around here there are not many genuine bee-keepers—mostly "farmers who keep bees," and who still work them on the "know-it-all," and "rule of thumb" principle, as their forefathers did it. Well, it has happened that once in a while I have met, and do meet, persons who are a trifle above the average "Ignoramus Jake" class, and with whom I can have a genuine "bee-talk," and it nearly always has culminated in this: "Yes, if only this infernally slow scraping were not there!" (I am, myself, of a mechanical turn; can work very neatly in wood and metals, and be it crankiness, or what, I generally make all contrivances myself; and there is an extractor, section-presses, foundation-fasteners, frames, queen and drone traps, etc., all of my make, and in use in my apiary.)

Now, then, you will better understand that my brains have been at work to rig up something to facilitate the scraping performance—save time and labor—and when I read the answers given by you, they stunned me.

1. But why did you not answer that part about *average* a trifle more to the point? For instance, if you had said, "With T-supers, as in my apiary, Miss E. M. Wilson cleaned —; but for section-holder supers only so-and-so much should be the average," etc., would not that have been the better answer? For there are many bee-keepers who do not work the T-super. But enough of this, and kindly excuse my frankness about the matter.

2. I am, unfortunately for myself, the happy (?) owner of an apiary of about 60 colonies, present count (lost only 4 colonies during the terrible spell of 3 weeks' rain, snow, and ice that has visited us), all with the section-holder supers, and a good number of them there are. If the T-super, as you advocate and work it, allows such wholesale scraping and cleaning of sections—well, that one item alone would be an inducement for me to change to the T-super. But, last year was a sad failure for us all, and I, like many of the crowd, am "in it," with lots of material, but a rather small amount of cash at my command. How can I effect a change in a rational and economical way? and when and how should I proceed?

3. Are queen-excluding zincs absolutely necessary for T-supers?

4. Could I use the supers on hand?

5. What are the dimensions of the supers (tight) as you use them by preference?

6. If I can find the answers to these (and other) questions in your book of "Forty Years Among the Bees," please let my know, and I will procure it at once. CALIFORNIA.

ANSWERS.—1. I am painfully aware that I do not always make entirely satisfactory work in replying to questions. Sometimes it is difficult to understand just what is asked for. Sometimes I may not fully understand the conditions attending the question. Sometimes I don't know enough to answer correctly. Yet with all these limitations it is my constant effort to try to put myself in the place of the questioner and answer the *spirit* of his question.

If I understand you correctly, you think it would have been more to the point if I had answered about sections taken from section-holders. Yes, more to your point, but would it have been to the point for "Colorado"? Please remember that besides section-holders and T-supers there are other surplus arrangements, and if I had answered about section-holders, then I ought to have answered about wide frames, and other kinds. But "Colo-

rado" didn't ask about any of these, and please remember that I was trying to answer "Colorado" and not some one else. As nearly as I understood it, I tried to answer the letter and the spirit of his question, and there was nothing to indicate that he wanted to know about section-holders. Perhaps section-holders are not so universally in use as you may suppose, and perhaps there are more T-supers than you suppose. T-supers are in use in Colorado to a considerable extent—perhaps to as large an extent as section-holders. At any rate, that was what I understood him to be asking about, and what you understand him to be asking about in the first part of his question, and I do not yet see that he referred to anything else in the second part.

If it had occurred to me that any one would misunderstand, it would have been better to have specified that my answer was referring to T-supers; but I do not think it would have been the better answer to have answered some other question that some one else might have asked, for if I should follow that plan there would be hardly any end to answering each question. Besides, the way is always open for any one who wishes answers to those other questions to ask them.

I think, although I can not be entirely sure, that the question you want answered is something like this:

"What would be an average day's work for an average hand in cleaning such sections as I have, and in the conditions that I have?"

Frankly, I don't know the answer to that question. Sections in section-holders are not all alike, but I don't think that would make much difference. Conditions may be very different in your place from what they are here, you not having the cool weather we have. That might make a very big difference. When it is cool enough for propolis to be brittle, it separates from the wood readily. When warm and soft, instead of coming off easily, each stroke seems to drive some of the glue into the wood. It is impossible to say just how much difference this would make, but from what you have heretofore said it would be nothing strange if it would take five times as long, or longer. I wonder if you couldn't make a difference by taking some special means to cool off your sections, at least taking them in the coolest part of the day.

We have never done enough at cleaning sections in section-holders here to say what a day's work should be, but when we used wide frames 1000 sections was not too much for a day's work. Probably section-holders would be much the same.

2. I would hardly advise going too fast in the matter of changing to T-supers. While some think them the best, others think them the worst. Better make a trial on a small scale till you know how you like them. I am just a little afraid that you have an exaggerated idea of the gain to be had in the matter of cleaning sections by using T-supers, and I doubt whether that alone would warrant your changing. It will be a simple matter to make a few of them—possibly some of your old supers can be changed—and you can get the T-tins from supply-dealers for about a cent apiece.

3. I doubt that excluders are necessary with any kind of section supers. Certainly, I've never used them with T-supers. But it is probably important that the sections be filled with foundation if the queen is not wanted in them. For if small starters are used then you may expect the queen to go up to lay in the drone-comb that will be sure to be built there.

4. It is entirely possible. I had a lot of Heddon supers that I changed into T-supers.

5. My supers measure inside  $17\frac{3}{8}$  inches long,  $12\frac{1}{8}$  inches wide, and  $4\frac{3}{8}$  inches deep. Being made of  $\frac{1}{8}$  stuff, of course that makes the outside measure  $19\frac{1}{8}$  and  $13\frac{1}{8}$ . They are for 8-frame hives, and take sections  $4\frac{1}{4} \times 4\frac{1}{4}$ , no matter what the width of the section, for different widths can be used in the same super, and, for that matter, at the same time. Mine were made years ago, when  $\frac{3}{8}$  was generally accepted as a bee space. If I were having them made again, I would have them 1-16 or  $\frac{1}{8}$  inch shallower. But I should want to be

# American Bee Journal

very sure that the stuff would not shrink any, for less than  $\frac{1}{4}$  would be likely to induce the bees to glue together the sections of 2 supers. Generally there is no trouble, but sometimes when bees are crowded they build comb in my  $\frac{3}{8}$ -inch space.

6. You wouldn't find all these questions answered in the book, but I think you would find answers to a number that it might be profitable for you to ask.

## Bees Tearing Down Foundation

I have had more or less trouble the past season from the bees gnawing out part of the comb foundation, both in brood-frames and supers.

1. What can I do to prevent bees from tearing down foundation in brood-frames where full sheets are used?

2. I learn from your writings that you use full sheets of thin super foundation in sections. Do you ever have any trouble from having these full sheets torn down in whole or in part?

ANSWERS.—1. I am not sure that I ever had bees gnaw away foundation in brood-frames except at the bottom. Bees seem to have a natural desire for a passage between the comb and the bottom-bar, so much so that even after a comb has been built in the frame clear down to the bottom-bar, if it is not built out very full they will gnaw it out again when there comes a time of idleness. The only secret of prevention that I know of is to give frames of foundation at a time when honey is coming in and when comb is being built. Especially is giving foundation in the fall to be avoided. Perhaps I ought to mention that if foundation comes down to within less than  $\frac{1}{4}$  inch of the bottom-bar the bees will rarely build it down to the bottom-bar. Not only that, but they will gnaw it away until there is a passage-way of  $\frac{1}{4}$  inch or more. Some have succeeded in getting the comb built down to the bottom-bar by reversing the comb, and others have succeeded by getting combs built in an upper story. My way is to have the bottom-bar in two halves, and have the foundation come down between these two halves.

2. Yes, I have had foundation gnawed in sections when they were left on after the bees quit work in them. They are worse about gnawing extra-thin foundation than thin. Not only do they gnaw the lower edge in sections, but also the sides. The remedy is not to leave sections on the hive when bees stop work. Generally I put sections on several days before the bees begin work in them, but somehow the bees don't gnaw before the harvest as they do afterward.

## Uniting Colonies for the Harvest

1. How would it do to shake 2 colonies together at the beginning of the white honey-flow, where each is not strong enough to do good work in sections? Would they fight?

2. If I take away one queen and put on another hive with the beelless brood-frames, and tier the two hives up, would not the brood, when hatched out, make as strong a colony as the one shaken, in a month's time or less; ready to work in sections on the buckwheat flow, which comes here the first of August?

3. I have wished increase. Could I not make 2 colonies from the beelless brood instead of one, by putting in another queen to one hive of the brood?

ANSWERS.—1. It might work all right, for the strong colony would store where neither weak colony would. If you contemplate such management, it would be well to have the 2 colonies on the same stand, and then all the field-force would remain on that stand when one of the hives was removed. At the beginning of the honey harvest there is little danger of any fighting when uniting.

2. I am not sure whether I understood you,

but as nearly as I can guess, you mean to take away all the brood from the 2 colonies, also the queen of one of the colonies, leaving on the old stand one queen and nearly all of the bees, and put the 2 stories of brood with the other queen on a new stand, of course having enough bees with the removed queen to prevent the chilling of brood. That ought to work all right; and the removed colony ought to be in good trim for buckwheat.

3. Sure; but of course neither of the 2 would be so strong for buckwheat as if left together. But there ought to be no trouble about their being strong for winter.

## Moving Bees in the Fall

Can bees be moved in the fall, say the last of September or first of October? I want to move them 75 or 80 miles, either by rail or wagon. Can it be done without damage? I have never had any experience in moving bees in the fall, and would like to know from some one that has had. I have moved them in the spring, but that is the only time.

WISCONSIN.

ANSWER.—For more than 20 years I have moved bees every fall, and never had any trouble. But I moved them only 5 miles or less. In the fall the combs are heavier with honey than in the spring, and there are also more bees. So you will see that there must be a little more care against breaking combs, as well as a little more care to have plenty of ventilation. Aside from this you ought to have no more trouble fall than spring. If you can have your choice as to time, it will be well to wait till as much after the first of October as you can, for the cooler it is the less danger of suffocation, although, of course, if you wait for severe winter weather there would be danger of the combs becoming brittle with the cold, and breaking.

## Queen-Cells and Swarming

I started to keep bees last year. Reading your "Forty Years Among the Bees," I found on page 186, the following passage:

"Generally, however, when eggs are found in cells, the next visit will find cells with grubs well advanced. When grubs are found in cells then the colony must be treated."

Why must the colony be treated? Why is it not sufficient simply to remove cells and grubs the same way incipient cells are destroyed, according to your instructions?

NEW YORK.

ANSWER.—Your question involves more or less the whole matter of queen-cells as connected with swarming. When bees begin to think about swarming queen-cells are started. If there comes a dearth so that the outlook is rather discouraging for a new colony to set up housekeeping, or even if there is an approach to a dearth, the cells are likely to be destroyed, and swarming abandoned. The less advanced the cells are, if I am not mistaken in my observations, the less the discouragement needed to induce the bees to destroy them. After the cells are sealed, or near the sealing stage, it will take a good deal of discouragement in the way of dearth or bad weather to get the bees to destroy them.

Generally, however, there is not sufficient discouragement to make them abandon all idea of swarming, and once cells are started and have eggs in them, you may count on swarming in the great majority of cases, if the bees are left alone. Suppose now you open a hive and find cells with eggs or very young larvae in them, and you destroy them. You may find, on looking 10 days later, that there are cells with eggs or very young larvae in them again. That shows that the bees were not in desperate haste about swarming, and if these cells are again destroyed they will postpone swarming for another 10 days—possibly give up swarming altogether. But if larvae are well advanced, then that shows that the bees were strongly set on swarming, for they had started cells and the queen had

laid in them almost immediately after their previous cells were destroyed. Now if we destroy these well-advanced grubs, the bees will not always—perhaps not generally—wait to have another set of cells well advanced, but will swarm with quite small larvae in the cells; possibly with only eggs in them. Now you get the answer to your question, after all this talk, which is that when well-advanced larvae are in cells, if we destroy them the chances are that the bees will swarm before we get around again.

If I don't get the gist of your question, try again.

## Favorable Winter for Bees

The winter here is very favorable for bees. They have had flights about right for best conditions.

F. A. SNELL.

Milledgeville, Ill., Feb. 25.

## Cellared Bees All Right

Bees are all right in the cellar so far. The weather is fine, but no day so far that bees outdoors would or could fly.

Farwell, Mich., Feb. 28. T. F. BINGHAM.

## Good Prospect for a Crop

The prospect for the coming season is very bright for a good crop of honey. Bees are wintering very well in the cellar and outdoors. Though little snow has fallen, yet the ground has remained frozen for weeks at a time, thus protecting the clovers of all kinds. The many letters I receive every day indicate the same conditions prevailing everywhere—"prospects good." However, I am led to believe that in the case of even a fair crop of honey the coming season, some beekeepers will find themselves not prepared. Last season was very poor on the average, and many bought supplies and had some left on hand; they were sorry they bought so much, and will not get any more until they have used up what they have on hand, which will last until about the middle of the season, or just the time when all factories and dealers are in a rush and are short on just what is wanted. Consequently, there will be much worry, vexation and complaint. Cattle farmers always are provided with enough feed and a little extra for cases of emergency from one season to another; but beekeepers seldom consider the question of extras, or emergencies, until the last moment, and the loss occasioned by the delay very often amounts to a good deal.

H. S. DUBY.

St. Anne, Ill., Feb. 22.

## Oklahoma and Indian Territory as a Bee-Country, Etc.

On page 55, Dr. Mttler makes an inquiry as to the value of northern Oklahoma or Indian Territory for keeping bees for profit. I have lived within a few rods of the north line of the Osage, Indian Territory, for over 26 years, and have kept bees for more than 5 years of that time, and I do not consider this a good country for bees—

1st. Because of a lack of nectar-bearing bloom.

2d. Because of the extremes of this climate; but by selecting a protected locality and raising plenty of nectar-bearing bloom, a fair business might be attained.

POISONED BY BEE-STING.—Remedy: Put oil on the part stung, then cover with common soda. Eat oil sardines, or take broken doses of olive oil. This will fortify the sys-

# American Bee Journal

tem to some extent against insect or ivy poison. (See page 16.)

"A millionaire egg-laying queen-bee induced to deposit her 5 years' batch of eggs in 2 or 3 years." Although I live about 100 miles west of Missouri, I will have to ask Mr. Doolittle to show me. I have heard it said, to make a hen lay, run her up hill; but one of my neighbors says to feed her kafkir corn beats running her up hill; next an Oklahoma man comes to the front and says if you want your hen to lay 2 eggs per day, feed her cow-peas; but how do you work the queen-bee? (See page 67.) I. M. NEWMAN.  
Hewins, Kans.

## T-Super vs. Wide Frames

There seems to be such a fuss between the T and the wide-frame super. I use a cross between both. I use plain sections and fences, and by driving a large flat-headed tack (about 3/8-inch in diameter) into the bottom-end of the 3 center cleats on the fence so that the heads are about in line with the bottom end of the end-cleats, the sections can rest on the tack heads, and the fences rest on the strips of tin that are nailed on the under edge of the super. By placing a row of sections in the super, the fence can be pushed up and the tack-heads catch under the sections; another row, and another fence, and so on, until the super is full. Springs are used for compression. I got 350 pounds of honey and 5 swarms from 5 colonies last year—50 pounds a comb and 300 pounds of extracted.  
Sioux City, Iowa, Feb. 18. PETER BOHM.

## Something on Swarming

"All the experiments that have come to me in definite form have been made with 8-frame hives, and colonies in such hives have been regarded as more likely to swarm than larger-sized. I wonder if a great many things are not taken for granted."—T. F. BINGHAM, page 96.

Mr. Bingham, in the same paragraph, asks if any one has made a success of non-swarming with the 10-frame hive. Thinking that some experiments I have made with a hive much smaller than even the 8-frame dove-tailed, may be of interest in connection with the extract above, I give them, mentioning only such details as could in any way have influenced the results.

Suspecting (1) that possibly there is a minimum of number below which bees will not voluntarily swarm, or (2) that swarming might be traced to the fatigue of the queen after the great spring laying, I began in 1904 a series of tests that would apply to either idea. The hive used is sectional, each chamber 5 3/4 inches deep. In that year I chose 2 rather weak colonies, removed the lower brood-chamber, and confined the queen to 3 frames, or about 975 cubic inches of brood-room. One stood out in the sun, and the other was protected till nearly noon by a peach-tree. Hive-entrances were full width, and 1/2 inch deep, just as in all my hives. They were run for both extracted and comb honey. By June 10 each queen had everything filled, and kept it so till Sept. 1, forcing all the honey, and no little of it, either, into the supers. Nearly all colonies in hives not contracted swarmed—those in little hives did not.

Not feeling so timid in 1905 I selected, in the latter part of May, 30 of my best colonies, taking such only as had queens reared in 1904. Nineteen of these were treated exactly as the 2 had been in 1904, except that 6 of them, after being contracted, were reduced to 3 double colonies, the queens in each double being separated by a zinc board. These doubles soon became powerful colonies, and on June 15, 2 of them swarmed, all 4 young queens coming out; that is, 4 contracted colonies out of 6 that were doubled up by 2's, swarmed. This result seemed to point toward the "minimum of number" when compared with results in the remaining 13, for of these but one swarmed, and this swarm seemed to follow the accidental death of the queen.  
The remaining 11 of the 30 were contracted

to 10 frames, or about 1211 cubic inches. Of these one swarmed.

To recapitulate: Four out of 6 reduced to 975 cubic inches and doubled up by 2's, each colony retaining its queen, swarmed. One of 13 contracted to 975 cubic inches swarmed, appearances indicating the death of the queen. The 13 were singles. One of 11 reduced to 1211 cubic inches swarmed. Of those colonies in uncontracted hives in the same yard, close to 60 percent swarmed.

Inferred from these results that 975 cubic inches was smaller than necessary, and 1211 a little too large, 40 colonies in 1906 were reduced to 9 frames, or about 1080 cubic inches. They were given the same general treatment as to shade, ventilation, and super-room that all others in the same yard received. None of the 40 swarmed, but it was not a swarming season.

It may be well to state that in these experiments every queen used was in her second year, and none was restricted to fewer combs than she had in use when the contracting was done.

Though nothing is established, the results seem to indicate that very low contracting in early spring may tend to prevent swarming. I have a strong suspicion that if the queen can be kept from overwork, bees will not swarm. This is contrary to much that has "been taken for granted," but a great deal might be said in its favor.

E. W. DIEFENDORF.

Otterville, Mo., Feb. 11.

## Honey and Beeswax

CHICAGO, Feb. 1.—The usual late winter demand is in evidence for comb honey to replace diminished stock laid in during the autumn by the large retailers, but during the dull period there has been very little change, if any, in prices, the offerings being light.

We find No. 1 to fancy white comb honey brings 15@16c, and for that which is off in color and flavor from 1@3c less. Amber grades of all kinds are dull and range in price from 10@12c. The extracted perhaps is not quite so firm in price for the California or Western grades, but there is no surplus of white clover or basswood, both of which bring about 8c, and in some cases more. Amber grade from 6@7½c. There have been some sales of beeswax at 32c, but 30c is about the price for average.

R. A. BURNETT & Co.

PHILADELPHIA, Nov. 8.—While the supply of comb honey is equal to the demand, large quantities of comb honey having arrived in the market in the last few days, the price still remains high. The outlook, however, is that when the season advances and the bee-keepers ship more of their crop to the market, the prices will be a little weaker. We quote: Fancy white comb honey, 16@18c; No. 1, 14@15c; amber, 11@13c. Fancy white extracted, 7½@8c; light amber, 6½@7c.

We are producers of honey and do not handle on commission. Wm. A. SELSER.

NEW YORK, Jan. 15.—The stock of white comb honey is pretty well exhausted, and we do not expect any more arrivals of large lots from now on. Prices are firm, and we quote from 15@16c for fancy white; 13@14c for No. 1; 12c for light amber. There is quite a little dark and buckwheat on the market, but no over-stock, and we think that all of it will be disposed of before long at present prices, which we quote from 10@12c, according to quality. Extracted honey very firm, with sufficient supply to meet demand. California white sage is bringing from 8@8½c; light amber, 7½c; amber, 6½@7c; buckwheat extracted in fairly good demand at 6@6½c. Southern in barrels finds ready sale at from 55@70c per gallon, according to quality. Beeswax firm and steady at 31c.

HILDRETH & SARGELKEN.

DENVER, Feb. 14.—Producers in this State are practically closed out of both comb and ex-

Office and Salesrooms, 2146-48 Central Ave. Warehouses: Freeman and Central Aves.

tracted honey. We have not sufficient good comb honey to supply our local trade, but have a good supply of white extracted of excellent quality. We quote strictly No. 1 white comb honey, per case of 24 sections, at \$3.20; No. 1, light amber, \$3; and good No. 2, \$2.80. White extracted, 8@8½c per pound; light amber, 7½@8c. Clean, yellow beeswax, 27@28c, delivered here.

THE COLO. HONEY-PRODUCERS' ASSN.

CINCINNATI, Feb. 9.—The demand for extracted amber honey has brightened in the past 3 weeks. Amber honey in barrels at 6½@7½c, according to the quality and the quantity purchased. Fancy white extracted honey selling at 8@9c in cans. Comb honey is a drag on the market, fancy selling at 14@16c. Beeswax, 32c. for choice grade. THE FRED W. MUTH CO.

INDIANAPOLIS, Feb. 25.—comb honey is not plentiful, but demand is slack. Fancy white comb brings 16@17c; No. 1 white, 14c; amber, 12@13c. Best grades of extracted honey bring 8@9c; amber, 6@7c. Good average beeswax sells here at \$35 per 100 pounds.

WALTER S. POWDER.

TOLEDO, Nov. 30.—The market on comb honey remains about the same as last quotations, but has been coming in much more freely, as beekeepers seem to be very anxious to get rid of their stock. Fancy brings in a retail way 16c; extra fancy, 17c; No. 1, 15c; buckwheat, 15c. Extracted white clover in barrels brings 7@7½c; cans the same. Beeswax, 26@28c.

THE GRIGGS BROS. & NICHOLS CO.

CINCINNATI, Jan. 25.—The market on comb honey is rather easy. Prices rule in jobbing ways from 14@14½c; single cases 16c for No. 1 white; off grades not wanted at any price. Extracted is very firm. Light amber in barrels, 6@6½c; white clover in barrels, 7½c; in cans, 8½c. Beeswax, 30c, delivered.

C. H. W. WEBER.

KANSAS CITY, Jan. 25.—The receipts of comb honey have been more liberal during the last week or two, and the demand light, market weaker. The market is practically bare of extracted, and there is quite a little inquiry. We quote: No. 1 white comb, 24 sec. cases, \$3.10; No. 2, \$2.75; amber, \$2.50. Extracted, white, 7½@8c; amber, 6½@7c. Beeswax, 27c.

C. C. CLEMONS & Co.

These rates are subject to either time or space discounts, at choice, but not both.  
 Reading Notices, 25 cents, count line, subject to the above discounts.  
 Goes to press Monday morning.

**National Bee-Keepers' Association**  
 Objects of the Association.

- 1st.—To promote the interests of its members.
- 2d.—To protect and defend its members in their lawful rights.
- 3d.—To enforce laws against the adulteration of honey.

Annual Membership Dues, \$1.00.  
 General Manager and Treasurer—  
 N. E. FRANCE, Platteville, Wis.

If more convenient, Dues may be sent to the publishers of the American Bee Journal.

**Bee-Keepers' Souvenir Cards**  
 are just the thing.  
 We send them by Return Mail

As most of our readers know, we have gotten out a Souvenir Postal Card for bee-keepers. The cuts herewith show the card in reduced size, and but one color, while the real card is printed in 4 colors. It could also be sent to honey-customers, to remind them that it is time to buy more honey, etc. There are many uses to which this Card can be put.

Prices—postpaid: 3 cards for 10c (stamps or silver), or 5 FREE with the American Bee Journal one year at \$1.00; 10 for 25c. There is a blank space on the card about 2x2 1/2 inches in size for writing. Send all orders to

Now is the Time to Order Your

## BEE-SUPPLIES

AND SAVE MONEY

It will cost you only one cent for a postal-card to get our delivered prices on Dovetailed Hives, Sections, Section-Holders, Separators, Brood-Frames, Foundation, Smokers, Extractors, Shipping-Cases, etc. It may mean a saving to you of many dollars. It is the natural advantage we have over others that enables us to make you the Best Price. There are no better goods than ours, and we GUARANTEE SATISFACTION or REFUND your MONEY.

We MANUFACTURE and keep in stock all standard Bee-Goods, and can ship promptly.

### Minnesota Bee-Keepers' Supply Co.

JOHN DOLL & SON, Proprietors,  
 Nicollet Island, No. 33, MINNEAPOLIS, MINN.

## Dittmer's Gomb Foundation

Why do thousands of bee-keepers prefer it to other makes?  
 Because the bees like it best and accept it more readily.

### Dittmer's Process is Dittmer's

It stands on its OWN NAME and its OWN FOUNDATION, to which alone it owes its reputation and merits.

We are now ready to make prices for next season for WORKING WAX for CASH and for full line of Supplies. Wholesale and Retail. Free Catalog and Samples.

### Queen-Button for Bee-Folks

This is a very pretty thing for a bee-keeper or honey-seller to wear on his coat-lapel. It often serves to introduce the subject of honey, and frequently leads to a sale.

The picture shown herewith is a reproduction of a motto queen-button that we are furnishing to bee-keepers. It has a pin on the underside to fasten it. Price, by mail, 6 cents; two for 10c; or six for 25c. The American Bee Journal one year and 4 buttons for \$1.10. Address all orders to

**GEORGE W. YORK & CO.**

## Standard-Bred Italian FREE PREMIUM QUEENS

We are booking orders now for those Fine Untested Italian Queens that we offer every year FREE to paid-in-advance subscribers as premiums for getting NEW subscribers for the Weekly American Bee Journal. These orders are taken for May or June delivery.

### What Some Say of our Standard-Bred Italian Queens:

*George W. York & Co.*—The two queens received of you some time ago are fine. They are good breeders, and the workers are showing up fine. I introduced them among black bees, and the bees are nearly yellow now, and are doing good work. A. W. SWAN.  
Nemaha Co., Kan., July 15.

*George W. York & Co.*—After importing queens for 15 years you have sent me the best. She keeps 9½ Langstroth frames fully occupied to date, and, although I kept the hive well contracted to force them to swarm, they have never built a queen-cell, and will put up 100 pounds of honey if the flow lasts this week. CHAS. MITCHELL.  
Ontario, Canada, July 22.

*George W. York & Co.*—The queen I bought of you has proven a good one, and has given me some of my best colonies. N. P. OGLESBY.  
Washington Co., Va., July 22

*George W. York & Co.*—The queen I received of you a few days ago came through O.K., and I want to say that she is a beauty. I immediately introduced her into a colony which had been queenless for 20 days. She was accepted by them, and has gone to work nicely. I am highly pleased with her and your promptness in filling my order. My father, who is an old bee-keeper, pronounced her very fine. You will hear from me again when I am in need of something in the bee-line. E. E. MCCOLM.  
Marion Co., Ill., July 13.

### How to Get these Queens Free

To any one whose own subscription to the Weekly American Bee Journal is paid in advance, we will mail a Fine Standard-Bred Untested Italian Queen next May or June, for each new name and address sent to us with \$1.00 for the Bee Journal a year. No one can get for himself the Bee Journal a year and the Queen for \$1.00. The Queen is offered as a premium for the work of getting some one else to take the Bee Journal a year. If you, yourself, want the Bee Journal a year and the Queen, send \$1.50 for the two, and we will book your order for a Queen. Queen orders will be filled in rotation—"first come, first served."

# BEE - BOOKS

SENT POSTPAID BY

GEORGE W. YORK & CO.

334 DEARBORN STREET, - CHICAGO, ILL.

**Advanced Bee-Culture.** Its Methods and Management, by W. Z. Hutchinson.—The author of this work is a practical and helpful writer. You should read his book; 339 pages; bound in cloth, and beautifully illustrated. Price, \$1.20.

**A B C of Bee-Culture,** by A. I. & E. R. Root.—A cyclopedia of over 500 pages, describing everything pertaining to the care of the honey-bees. Contains about 400 engravings. It was written especially for beginners. Bound in cloth. Price, \$1.20.

**Scientific Queen-Rearing,** as Practically Applied, by G. M. Doolittle.—A method by which the very best of queen-bees are reared in perfect accord with Nature's way. Bound in cloth and illustrated. Price, \$1.00; in leatherette binding, 75 cents.

**Bee-Keeper's Guide,** or Manual of the Apiary, by Prof. A. J. Cook, of Pomona College, California.—This book is not only instructive and helpful as a guide in bee-keeping, but is interesting and thoroughly practical and scientific. It contains a full delineation of the anatomy and physiology of bees. 544 pages. 295 illustrations. Bound in cloth. 19th thousand. Price, \$1.20.

**Langstroth on the Honey-Bee,** revised by Dadant.—This classic in bee-culture has been entirely re-written, and is fully illustrated. It treats of everything relating to bees and bee-keeping. No apiarian library is complete without this standard work by Rev. L. L. Langstroth—the Father of American Bee-Culture. It has 520 pages, bound in cloth. Price, \$1.20.

**Honey as a Health Food.**—This is a 16-page honey-pamphlet intended to help increase the demand for honey. The first part of it contains a short article on "Honey as Food," written by Dr. C. C. Miller. It tells where to keep honey, how to liquefy it, etc. The last part is devoted to "Honey-Cooking Recipes" and "Remedies Using Honey." It should be widely circulated by those selling honey. The more the people are educated on the value and uses of honey the more honey they will buy. Prices: Sample copy for 2-cent stamp; 50 copies for 70 cents; 100 for \$1.25; 250 for \$2.25; 500 for \$4.00; or 1000 for \$7.50. Your business card printed free at the bottom of the front page on all orders for 100 or more copies.

**Forty Years Among the Bees,** by Dr. C. C. Miller.—This book contains 328 pages, is bound in handsome cloth, with gold letters and design; it is printed on best book-paper, and illustrated with 112 beautiful original half-tone pictures, taken by Dr. Miller himself. It is unique in this regard. The first few pages are devoted to an interesting biographical sketch of Dr. Miller, telling how he happened to get into bee-keeping. About 20 years ago he wrote a small book, called "A Year Among the Bees," but that little work has been out of print for a number of years. While some of the matter used in the former book is found in the new one, it all reads like a good new story of successful bee-keeping by one of the masters, and shows in minutest detail just how Dr. Miller does things with bees. Price, \$1.00.

**"The Honey-Money Stories."**—A 64-page-and-cover booklet, 5¾x8½ inches in size, printed on best quality paper. Many short, bright stories interspersed with facts and interesting items about honey and its use. The manufactured comb honey misrepresentation is contradicted in two items, each occupying a full page, but in different parts of the booklet. It has in all 33 fine illustrations, nearly all of them being of apiaries or apiarian scenes. It also contains 3 bee-songs, namely, "The Hum of the Bees in the Apple-Tree Bloom," "Buckwheat Cakes and Honey," and "The Bee-Keeper's Lullaby." This booklet should be placed in the hands of everybody not familiar with the food-value of honey, for its main object is to interest people in honey as a daily table article. Price, 25 cents, or 3 copies for 50 cents.

# HONEY FROM THE DANZENBAKER HIVE

## THE FANCY COMB HONEY HIVE

### More Honey

(That is, more honey in the super at the right time.)

### Better Honey

(More honey that will grade fancy and extra fancy.)

### More Money

(No question but what the producer of a fancy and extra fancy grade gets a better price, and does it easier.)

## Editorial Notes and Comments

### Sugar and Honey for Pulmonary Consumption

In European scientific circles interest has been aroused in the experiments of two Italian physicians, Prof. Massalongo and Dr. C. Daino, in the treatment of pulmonary consumption. Besides the ordinary diet, sugar was administered in increasingly large doses, from 100 to 500 grams ( $3\frac{1}{2}$  to  $17\frac{1}{2}$  ounces) per day. The patients increased rapidly in weight, some gaining even 20 to 30 pounds in 2 or 3 months. The honey was well borne, but in some cases it was considered advisable to dilute it with milk, black coffee, or a few teaspoonfuls of bitter tincture.

Commenting upon this in *Praktischer Wegweiser*, Jul. Herter suggests the substituting of honey for sugar, as being pleasanter, and better for weak digestions. One would naturally think that consumptives would prefer honey to the by no means luscious cod-liver oil that has been used in such large quantities.

### Young Queen Swarming, and Leaving Mother

Marking a queen with paint, so as to be able to identify her afterward, has been practised to some extent across the water. In *Prak. Wegweiser* it is said that this practise has led to the astonishing discovery that in one case a young queen went with the first swarm, the mother remaining and going with an afterswarm.

If this be at all a common thing, it surely must have been observed in this country more than once. A large proportion of American bee-keepers clip their queens, and this they have done for years. Has any one a case to report in which the clipped queen has been found doing duty in the mother colony after the departure of a swarm with a young queen?

### Granulated Honey for Bee-Candy

The British Bee Journal says:

Granulated honey may be used as bee-candy if made stiff enough by kneading into it sufficient castor-sugar for the purpose.

C. P. Dadant uses the granulated honey without any sugar; flattening it upon the top-bars toward the back part of the hive.

### No-Bee-Way Sections and Fences in England

In reply to the question, "Is the no-bee-way section an improvement on the old style?" The British Bee Journal replies:

It appears to be definitely settled by the great majority of bee-keepers in this country that the older style of section is preferable to the "no-bee-way" and the fence separator necessary for use with the latter.

### Reliability of Linden or Basswood

*Prak. Wegweiser* copies from *Die Biene u. ihre Zucht* a paragraph which claims that one reason that lindens sometimes fail to secrete is because of peculiarity of soil; but that all lindens fail when they have attained a certain age, and that not such a very great age. Even though very old trees are visited by bees, it is only for their pollen. But does not so careful an observer as G. M. Doolittle say that lindens yield no pollen?

### That Dead Bee With Pollen

A note from a critic of our genial critic, the "Afterthinker," says:

"Mr. Hasty, page 152, questions thus: 'Will the poet, on page 27, take notice that bees don't die (except by violence) with pollen on their legs?' In spite of his 'unreliable glasses,' Mr. Hasty usually has a very keen vision. How does it come, Mr. Editor,

that he has never taken note of bees with loads of pollen lying dead near the hives on chill days? And how does it come that he failed to see the cause of death when the poet said the poor little thing was stiffened with death and with cold?"

Locality, perhaps. It is true that many a bee-keeper has seen such bees lying dead without any marks of violence; but are you sure that such chill days occur in our "Afterthinker's" locality? It may be that he does not need more reliable glasses, only a larger vision.

### Great Value of Alfalfa Pollen

The Australasian Bee-Keeper reports an address by Dr. Cherry, Director of Agriculture, before the Victorian bee-keepers, in which he strongly urged the cultivation of alfalfa, or lucerne, giving as one reason the superior value of its pollen. He said:

The bees will derive very much benefit from the pollen they obtain from it. From the analysis of the samples of pollen submitted to me, it will be seen that cultivated plants give the best result in protein; as much as 27 percent is shown on the table—eucalyptus 20 percent, weeds 10 percent. If we were to generalize we might see the more valuable the fruit the better the nitrogen. Lucerne produces more protein than any other plant that we are acquainted with.

### How Long are Swarms Provisioned?

Three days will perhaps be the general answer; but a case of 5 days is reported in *Prak. Wegweiser*. The swarm was settled on a tree, and held there by rainy weather.

### Spraying Fruit-Bloom

We have received the following from Mr. C. P. Dadant, of Hamilton, Ill., who is a member of the Legislative Committee of the Illinois State Bee-Keepers' Association:

MR. EDITOR:—It appears that in Italy they now have another enemy of the bee in the olive-growers. They have lately been experimenting upon a new preparation to destroy an insect that preys upon the olives, and this preparation also kills the bees. According to the February number of *L'Apicoltore*, of Milan, this matter is mentioned in the *Journal of Agriculture*, of Tuscany, by a bee-keeper, Ippolito Pestellini, of Florence, who asserts that wherever this new method is used the bees are all killed. This is somewhat in the line of the bloom-spray against which the American bee-keepers are aiming to take

action. There is certainly a possibility of destroying injurious insects without at the same time also destroying the useful ones. We understand that the preparation above named is made in part with honey. It is rather bad to use the bee's product to kill bees. But it would be bad in any case, even if no honey were used, to kill the bees in an attempt to save a crop from partial destruction.

I have here a very short letter, just received from an old German, on the spraying subject. Permit me to add it to the testimony already gathered on the same question:

PLEASANT PLAIN, OHIO, Feb. 21, 1907.

MR. DADANT:—I had, 2 years ago, 32 colonies of bees; the farmers commenced to spray their fruit-trees, and killed my bees, so now I have but 2 colonies. So you will see I have quit the business. Don't want to be bothered with them. W. Y.

No comments are needed.

C. P. DADANT.

Since the foregoing came in, we have received this information from Mr. Dadant:

EDITOR YORK:—The Bill to prevent the spraying of fruit-trees in bloom was killed in

the Senate Committee, in Springfield, by Senator Dunlap, chairman of the committee. He positively asserted that intelligent horticulturists will no longer spray their fruit-trees during bloom, because spraying during bloom is an injury to the blossom. He said that it was therefore unnecessary to load the statutes with a measure that would be useless and might give opportunity to ill-intentioned apiculturists to cause trouble to horticulturists if they happened to begin spraying while there still was a trace of bloom on the trees.

In private conversation with the writer, Senator Dunlap said that he knew of dealers in sprayers, who had formerly advised spraying during bloom, and who had become convinced that it was a mistake, and would therefore cease to recommend it.

It behooves the bee-keepers to keep a vigilant eye upon this matter, and inform their neighbor horticulturists of these things. Such a leading horticulturist as Senator Dunlap is authority on tree-spraying, and his public statement is of value to us in helping to stop the practise of misapplied spraying. It may be that this will have the result of putting a stop to bloom-spraying. C. P. DADANT.

as a food. The purpose for which these articles are written need not appear upon the surface. It is better that it should not appear, but there ought to be something about each article that would unconsciously lead the reader to have a better opinion of honey, to have greater confidence in its purity and healthfulness, or knowledge of its economic value as a food; that honey is not an expensive food, requires no cooking, no sweetening nor other special preparation, but is the "whole thing" ready for use; that choice bakings sweetened with honey do not dry up as quickly as sugar-sweetened goods. Also call attention to Pure Food Laws, and no adulterated honey now sold.

These articles should leave the reader with his mouth watering to test the true deliciousness of honey. The articles must be short—not over 300 to 400 words—and will be judged with reference to their value: 1st. Will this article attract attention and interest the general reader? 2d. Will the reader who is not acquainted with the use of honey be likely to investigate and use honey?

Of course, it would be an easy matter for us to employ one man to write a series of articles for this purpose, but the committee wishes to secure the very best that the country can produce, and takes this method of inviting everybody to send in articles of this nature. Not over 400 words, perhaps less to include the thought. Mail each article to W. Z. Hutchinson, Flint, Mich., who will read and mark them according to their merits. The best will be marked 10, next best 9, and so on. They will then be sent to R. L. Taylor, who will also read and mark the same. He will then send them to N. E. France, who will also mark them. The articles receiving the highest markings in the aggregate, will be used and their authors paid \$5.00 each. Everybody is invited to contribute. No limit to the number of articles each person may send in. Perhaps 30 or more articles will be used.

Please write plainly on one side of the paper, or, better still, use a typewriter, if possible.

N. E. FRANCE, Platteville, Wis.,  
W. Z. HUTCHINSON, Flint, Mich.,  
R. L. TAYLOR, Lapeer, Mich.,  
Committee.

We hope our readers will accept the above invitation, and thus help the committee as well as themselves. The proposed advertising should help all producers of honey, although only a few people contributed to the fund of a little over \$1400. But, perhaps, others will be glad to add to the fund by making donations to it from time to time. We suppose the committee would not object to this.

## Miscellaneous News - Items

The Apiary of Otto Banker is shown on the first page. When sending the picture be wrote thus, under date of Feb. 9, 1907:

I did not get any honey last season on account of being so wet the bees could not gather it, and the frogs would sit at the entrances when the bees did work and catch most of them as they alighted. The strongest colonies got enough honey to winter on, but the weaker ones we had to feed. I had 135 colonies, and did not get honey enough for my own use.

My bees are wintering very well so far—54 colonies in the cellar and the rest in chaff hives outdoors.

In the picture I am standing on a hive, and the other two people are neighbors of mine. My storehouse is located back of me, and the other building shown in white is my house. I could not get a full view of the apiary on account of so much shade. OTTO BANKER.

The Far-Western Bee-Keeper is the name of another bee-paper, whose first number (for March) has just come to our desk. It is a 20-page monthly (size of page 6x8 $\frac{3}{4}$  inches), and published at 50 cents a year, by Henry E. Horn, Riverside, Calif. It makes a very creditable appearance.

Lower Freight-Rates on Bees.—Mr. N. E. France, General Manager of the National Bee-Keepers' Association, sends us the following for publication:

The South Texas Bee-Keepers' Association met lately for business at the residence of Pres. E. J. Atchley, and by united effort on the part of the officers, a reduction on freight-rate from \$1.85 per 100 pounds, on live bees in car-load lots, down to 79 cents per 100 pounds to all points in Kansas, Missouri, Oklahoma, and other Western points of the Ft. Worth and Denver railroad; and 81 cents

to intermediate points in Colorado. This makes a bright future for the bee-industry of Southern Texas, and to get the old rate cut more than half gives cause of rejoicing.

We have put in an application to the Railroad Company to the effect that we want a ruling to go along with the reduced freight-rate—not to allow any one to load bees for shipment until such person first screens the car with wire-cloth in such a manner as will not allow bees to escape from the car while in transit. We feel sure we will get such ruling.

The South Texas Association was instrumental in getting a one-third reduction on bees shipped by express from Beeville to all points on the Wells Fargo lines, which reduction was later extended from other points. There are several cars of bees to go from Beeville this spring. This Association also secured a lower local freight-rate on honey several years ago.

We congratulate the Southwest Texas Bee-Keepers' Association on the good work it has been able to do. We regret to learn, however, that its president, E. J. Atchley, suffered a stroke of paralysis about a month ago. He is recovering, and doubtless will soon be "as good as new" again.

Preparing for Honey Advertising.—The committee appointed to advertise honey, and thus use the fund raised for such purpose by the Honey-Producers' League, send this for publication:

ARTICLES WANTED BY THE COMMITTEE ON ADVERTISING HONEY.

The \$1408.27 raised by the Honey-Producers' League has been turned over to the National Association, and a committee appointed to spend that money in advertising honey and otherwise advancing its sales.

The first plan to be put into operation will be that of publishing in the general press, short articles setting forth the healthfulness, deliciousness, purity and desirability of honey

ANDREW D. PRYAL.  
(See next page)

# Biographs of Beedomites

## ANDREW D. PRYAL

Among the few remaining bee-keepers of California may be named Andrew D. Pryal, of Oakland. He was born, as it were, one of Nature's noblemen. His earliest recollections were those of the trees, flowers, bees, and birds when he was a child upon his father's place in Ireland, where his father conducted the Crowhill Nurseries, in County Mayo, and there the son learned the business which he has followed the greater portion of his life. Owing to the harshness of the then land-laws of that land, coupled with the failure of crops, the father lost his holdings, and he and his family removed to England. There the younger Pryal worked as a landscape gardener most of the time, or until he came to America. For several years he lived in Alabama and Louisiana. In 1854 he went to California, where he has since resided.

He was not long in that State before he recognized the fact that gardening and horticulture offered great possibilities for the tiller of the soil in those directions. So he never "went to the mines," as nearly every early Californian did. He soon had a garden in San Francisco, where, in addition to raising plants, shrubs, flowers and strawberries, he also tended a patch of vegetables. In those days it was no uncommon thing to sell a rose-bush for the sum of \$10, and other plants in like proportion.

Mr. Pryal held the first plant and tree auction that was held in San Francisco, and it is needless to say that the financial returns were quite satisfactory. His nursery was near what was then called "Russ's Garden," in the neighborhood of 6th and Folsom streets. Just after the big fire of last April, Mr. P. remarked that he "saw San Francisco almost houseless when he came there in the early days, and he had lived to see it practically houseless again, after it had a half-century of remarkable growth." Recently he made several visits to that city, and he was struck with the rapidity with which it is being rebuilt, and he called it the "old California pluck" that was again exerting itself.

After marrying, he assumed charge of the "Mission" gardens, at Mission San Jose, in Alameda county, the oldest in the vicinity of San Francisco. From there he was called to superintend the planting of some of the largest vineyards and orchards in the celebrated Napa Valley. Being a friend of United States Senator Gwin, that gentleman had him look after one of his big holdings in what is now almost in the center of Oakland. When the war broke out, the Senator wanted Mr. Pryal to purchase the property—something over 160 acres—but owing to its closeness to the bay, and, consequently the climate being more or less cold (he was then slightly subject to rheumatism), he decided not to do so. He, however, purchased from the same person a small tract of land 4 miles further north, and lying close up to the foot-hills, which has been the family home ever since. There the climate is almost perfect. It is considered one of the prettiest spots, naturally, in the country, and it has been improved by judicious planting and cultivation. There Mr. Pryal conducted his nursery business and horticultural pursuits. He loved to experiment, and he has the honor of being the first person in the State to raise new varieties of fruits and vegetables, and this long before Luther Burbank became a resident of that

State. In fact, he sold the latter, in the '70's, some of the trees that he (Burbank) used to help him in his experiments. One of Mr. P.'s worriments during his present illness, is that he can not get out and superintend the planting of a field to a new variety of potato of his originating, that he lays a great store upon.

For years he has been a prominent citizen of his county. He held a position as member of the Horticultural Commission Board of Alameda for 21 years—the longest period any one man has held the office in that county. Then he was a member of the Oakland Board of Trade for several terms.

Mr. Pryal's wife, who died in December, 1896, was an estimable lady, and was the mother of 9 children, all of whom grew to manhood and womanhood, though 2 sons and 2 daughters are deceased. Those, as well as the remaining 3 sons and 2 daughters, attained to more or less prominence in their several callings. The parents gave them, in addition to a public school training, a Christian education—an inheritance they have reason to be thankful for.

It was in 1865 that Mr. Pryal secured his first bees—some 10 colonies in movable-frame hives. This apiary is in existence to-day, and it is probably the only apiary that has been continuously kept in one place for so long a

period in California. Since 1876 the bees have been the care of his oldest son (W. A.), who has considerable reputation as a bee-keeper.

In 1866, Mr. Pryal was one of the trustees of the district school of which Albert J. King, an authority on bees, was teacher. Mr. King was afterwards publisher and editor of the Bee-Keepers' Magazine. The senior Mr. Pryal never claimed to be an expert in bee-matters—he was more of a student of insect life injurious to the plants, trees and vegetables of the Golden State.

Few Californians have rounded out a more honorable and useful life than has the subject of this sketch, who is now well passed the allotted three score and ten, and it is to be hoped that he will be restored to health and live as long as, or longer than, his father, who was over 90 years of age when he died.

The subject of the foregoing interesting sketch is the father of Mr. W. A. Pryal, who "reflects" on bees occasionally, the first installment of which appears in this issue of the American Bee Journal.

"W. A." was in Chicago during the Columbian Exposition, in 1893, when he had the rare privilege of making his acquaintance, which has grown into a prized friendship during the passing years, although over 2000 miles lies between us. He is an entertaining writer, which, with his bee-keeping experience and large familiarity with things apianian in general, make him one of the best contributors a bee-paper can have.

The Chicago-Northwestern Convention Photograph was taken Dec. 6, 1906, which was very good indeed. Price, post-paid, in mailing tube, 60 cents. Send orders to the office of the American Bee Journal, and we will see that the pictures are mailed.

## The Production of Comb Honey

BY ALLEN LATHAM.

A correspondent has requested that I write an article for the American Bee Journal describing the hive I use and the plan I follow in producing comb honey. Now it so happens that I do not depend upon my bees for a livelihood, my work with the bees being my avocation, and thus it follows that my plan and plans are forever undergoing a shake-up due to my love for experimenting. Also my profession—teaching—has occasioned more or less moving about, so that I have had to vary my methods to suit the varying local conditions. My method which I followed so successfully in the home of my youth proves impracticable where I now live. In this article I can give in a general way only the practice which I follow, and in doing this I fully realize that it is the plan generally followed by successful apiarists, and that I shall offer

nothing new of great importance.

As to describing my hive: I hesitate, for space would scarcely allow a complete description, and without a complete description I could not do justice to the hive which I now use. Permit me therefore to state briefly that my hive is one of my own make, in many particulars like the hive I described in these columns somewhat over a year ago. It is double-walled, air-spaced, frames closed-end and hanging crosswise. The hive is set perfectly level, the inner bottom sloping to the front so that space under the front frames is an inch or more deep. The entrance is about one inch deep and full width of hive. I use 11 frames, inside measure 10x12 inches, the follower at the rear held by two st' springs. The super is of such size as to take in a section-case holding 24 plain 4 1-4 sections, or 28 7-to-the-foot sections. Fence separators are used with the plain sections, and no separators with the other sort except on the outside rows. This latter device—sec-

# American Bee Journal

tions all solid with fence separator at each side between sections and side-wall of section-case—I tried during the last season with highly gratifying results, there being no sections but what would readily sell in the home market, and most of them would easily do to ship to distant market.

I have always made use of and advocated double supers, that is, an outer super-shell with separate case of sections to set within. This method gives much better results in comb honey production than can be got in single-walled supers. Formerly I practised letting the bees have access to space between the case and outer shell, but I now exclude the bees from that space.

I rarely wait till the bees begin to whiten the combs before putting on supers. If I did I should be bothered by swarming more than I am. I put on supers of sections in spring just as soon as I see "graduating nurse-bees" crowding into the space back of the follower, regardless of whether there is a honey-flow or not. This first super is usually well supplied with bait-sections, and often continues to be a bait-section case throughout the season.

If this case gets filled with good honey—big IF here—I remove it early; but as it is usually filled with a mixture of inferior honey and honey-dew in this locality, I leave it on as the *top super* till late in the season.

The bees generally take immediate possession of this first super and the hive is thus relieved of crowding. If the honey comes I do not allow the bees to crowd this case full—at the jeopardy of a crowded brood-nest and of swarming—but I early insert between it and the brood-chamber another super of new sections with full sheets of foundation. If the season continues good a third case is inserted. Whether this third case goes between the two cases already on the hive, or between the second case and the brood-chamber, is a matter to be decided by the condition of things about each particular colony, and also by the character of the flow and its duration. If the second super is nearly completed I sometimes raise both supers, and if the second super is only half-filled I insert a third case between the two.

This brings about the completion of the second super before the need of a fourth super comes; and upon the removal of the second super, the first and third supers become the first and second, the fourth being treated as a new third super. Number 1, as will be seen, is sacrificed for the good of the others. Bees will rarely swarm if this top super is filled, or nearly filled, with sealed honey, and between it and the brood-chamber stands a super of empty sections. I would not convey the idea that the top-super is a total loss. Far, from it, for if edible the honey is not hurt by its long stay at the top, and if unedible the poor grade of honey has been paying good interest by checking swarming.

It will be noted that my plan is to keep the bees lifting all honey to the supers, clearing constantly the brood-combs for the use of the queen.

This plan has worked well with me

where there is an early flow with a more or less continuous flow till late in June. In July, when my best flow occurs, I plan, before the flow begins, to have 2 fresh supers ready for each colony. Bees almost never swarm with me during this flow from the sumac, and will fill supers whether they be next to the brood-chamber or away at the top of the tiered supers, provided the flow is of sufficient duration. By this time of the season the economic condition of the average colony is such that the swarming impulse but rarely comes into existence—only in the case of colonies that have "come on late" does it occur.

This method leaves me at the end of the season with a super from each colony which is often of poorly finished and inferior honey, sections badly propolized and not infrequently many uncapped corners with empty cells, but since I am troubled little by swarming, and since I usually get besides this inferior case from 2 to 4 other cases of fair to excellent sections, I willingly make the sacrifice.

I spoke above of using 7-to-the-foot sections without separators other than next the outer rows. This plan gives good results only when such supers are inserted between super and brood-chamber, and only when bees are so plentiful that they take possession of all the 28 sections at one time. Beginning work in the sections simultaneously they will, since the hive is level, make all combs meet half-way even without separators. As far as I can see, I can get 28 sections thus just as easily as I get 24 with fence separators, and the work in preparing the sections is somewhat less. Bottom-starters must always be used in case separators are dispensed with.

I feel somewhat guilty in offering this article, and do so only because I have been asked. I shall during the coming season employ a radically different method, but since it has not been thoroughly put to the test I will not offer it here. In a general way the plan outlined here is what I have followed with slight variations for a score of years.

Norwich, Conn.

ten all of June, with more or less bloom for many weeks later. The bees work on it quite industriously, but, as a rule the crops are very light. Through that district there is but little alfalfa—our great source of nectar.

Having spent 6 years here, the season of 1906 was the first in which white clover gave a good account of itself. Bees in any of our abandoned locations would have done well. I think that irrigation and cool nights are unfavorable to the secretion of nectar in the white clover bloom, as a general rule. Probably "Utah's" conditions are somewhat similar to those here. If he means that much of that 300 acres is sweet clover, even 10 percent of it, and he is so fortunate as to live where that plant yields abundantly, then he might be able to keep 300 or more colonies in one yard, if the alfalfa has also the habit of yielding abundantly.

Alfalfa certainly is a far more nearly constant source of profitable crops in the arid West than is white clover, but I should be seriously discouraged if only 300 acres were within easy range of an apiary. I have seen that much cut before it was of any value to bees, near some yards. If there is 1000 acres or more within 2 miles, some of it is usually allowed to bloom. Sometimes something delays one rancher, sometimes another. One year a tenant may cut early, another year another tenant may have different views and cut later.

I have in mind a range that I have never considered above the average good locality. Just such a range as you or I might risk 100 colonies on. A beekeeper occupied it with 400 colonies in one yard, and has always averaged a fair crop, compared with other yards around him. In a season when no one else within a good many miles got any comb honey, he took 100 cases. Not because of the big apiary, but he had a little spurt of nectar and was prepared for it. Some of my own yards did not have even that little flow, though only 6 1-2 to 12 miles away. The subject of over-stocking is one of which we know but little.

Meridian, Idaho.

## Number of Colonies for the Pasture

BY E. F. ATWATER.

Dr. Miller's reply to "Utah," page 114, (the question being, "My bees have at least 300 acres of clover and alfalfa within 2 miles. How many colonies can I pasture to be safe?") arouses my interest. Surely the nectar-producing qualities of plants must vary greatly in different regions. If Dr. Miller is correct, that 200 colonies might do well on 300 acres of white clover—if it yields—I would add: We have moved all our yards that were between Meridian and Boise, considering the country unfitted for profitable bee-keeping, yet this "tabbooed" district is simply grand for spring breeding, and hundreds, or even thousands, of acres of as fine white clover as one could wish, are covered with a mass of bloom during part of May, of-

## Something More on Hive-Making

BY G. C. GREINER.

As much as I dislike jangles and snappy disputes in publications that are intended to help our fellowmen in their undertakings, I find it sometimes necessary to correct and explain things when our arguments are misunderstood or misrepresented. The general trend of Mr. Bevins' article, on page 128, is plain evidence that we do not see things alike, and this from the simple fact that he takes his views from a very different standpoint from which mine are taken.

I did not mean to say that we *could not* make bee-hives out of all miscellaneous material. Of course we can, if we have no eye for improvements and up-to-date surroundings, and if we have plenty of time that we can not utilize to better advantage. From a financial

standpoint we can not do it. If I have to belittle my own ability to bring out facts, belittle it is. I would not mislead the inexperienced for the sake of keeping or building up a mechanical reputation. At the high rate of wages paid at the present time for intelligent labor, a mechanic's time is too valuable to spend it making hives out of hap-hazard material, and if the person who undertakes it is no mechanic, he would better let the job alone, anyhow.

One of the most astonishing points in Mr. Bevins' argument is this: "A few shades difference between the thickness of lumber cuts no figure." In his way of looking at it, it may not; in mine, it cuts a big figure. The variation of a few shades in thickness would completely upset all our plans and calculations. A few shades difference in the thickness of the end-pieces would necessitate a few shades difference in the length of sides, and a few shades difference in the thickness of sides would necessitate a few shades difference in the length of cleats and cover-end-pieces, and so it would go all along indefinitely.

Reasonable accuracy does not amount to anything if we expect to do systematic work on a paying basis. We must have accuracy as close as mechanical skill can produce it; nothing short of that will insure uniformity in our outfits. And whilst we are speaking of accuracy, I wish to tell Mr. Bevins, that neither he nor any other person can cut one single hive-body end-piece as true as machine-work, or, as is necessary to put up hives in workmanlike manner.

In regard to time, the difference is still more striking. By the time he has his material for one single piece picked out, measured, and marked off, ready to use his handsaw, dozens can be cut by machinery, and before he ever gets the first piece cut, another dozen can be dropped. Where, then, is our gain, the "saving of much money," if we have to make many hives? It is right the other way: The more hives we have to make, the less we can afford to tinker with a lot of rubbish. Then there is so much other work, such as ripping, rabbeting, matching, tenoning, etc., that can not only be done so much faster, but incomparably better than handwork.

When we started bee-keeping some 30 years ago, we decided on 3-4 inch (I wished we had made it 7-8) for all thick hive-material except bottoms, which we made 7-8 inch. After making hives for a number of years, we had sorted out a lot of 3-4-inch lumber that was not adapted for hive-bodies or supers. To dispose of it to the best advantage, we decided, contrary to our established plan of uniformity, to use the same for bottoms. As long as we wintered bees in the cellars, this difference in thickness cut no figure, as Mr. B. says; but late years, since we are wintering bees in chaff-packed cases on the summer-stands, this little variation has caused quite an amount of trouble, and I regret that that change was ever made. The flight-holes don't come right. When packing for winter, I have to watch every hive to see wheth-

er the bottom is 3-4 or 7-8 inch thick, and make allowances accordingly. Uniformity in every particular will save us, soon or later, annoyances of a similar nature.

To cut the matter short, although it may be a repetition, I will give my views and advice in a nut-shell: Any mechanically inclined bee-keeper, who has access to the necessary machinery and can conveniently procure the material, can do well getting out his own hives and appliances. Otherwise, if he wishes to make use of his mechanical skill, it would be more profitable to order his supplies in the flat from one of our regular supply-manufacturers, and do his own nailing, painting, wiring, etc.—in short, do all the rest. If the stock desired should be different from any regular standard goods, then make out a list with exact description of shape and

dimensions and send it to the firm you wish to patronize. You'll be surprised how close they will come to your measurement, to say nothing of the fine quality of their goods. It is a pleasure to work them up. This is my experience.

Outside of shipping-cases, there is only one part of our outfit—the hive-stand—that can be made out of box-lumber to any advantage and make reasonable accuracy answer. But by no means take it that they can be "thrown together." The better they are made, the less annoyances later on. Our leisure hours can be profitably utilized by building a few now and then, but it is the same with stands, and shipping-cases, too, as with all the rest—if we have to make many, the saw-table is the place to get out the stuff.

LaSalle, N. Y.

## Convention of Bee-Keepers' Associations at Brantford

REPORTED BY J. L. BYER.

(Continued from page 190)

THURSDAY MORNING SESSION.

The convention was addressed by Mr. P. W. Hodgetts, Secretary of the Ontario Bee-Keepers' Association, as follows:

### IMPROVING THE BEE-KEEPING INDUSTRY

Since accepting the position of Secretary of the Provincial Bee-keepers' Association last fall I have been looking over your reports for the past 15 years. I have done this with the idea of finding out if possible just what you have been doing in the past, and what your aims are for the future. In 1895 I find that you had thirteen affiliated associations. In 1905, ten years later, eleven associations. In the years between the number varied from nine to twelve. In this respect your experience seems to have been very similar to that of the Fruit-growers' Association with which I have been more closely connected. I want therefore to tell you a little of what they have done in the past, and what they are striving to do at present.

The Ontario Fruit-growers' Association has now been in existence some forty-seven years and is, therefore, somewhat older than the Bee-keepers' Association. For about thirty or thirty-five years the association devoted the greater part of its time to the consideration of questions which are called purely educational. Such, for instance, as "Best Varieties for Planting," "Care of

the Orchard," "Pruning," etc. It seemed as if the officers had got into this rut, if I may call it so, and were content to stay there. However, about ten years ago one of their most enterprising directors suggested that associations should be formed in various parts of the Province in affiliation with the Ontario association.

As the Provincial association was doing considerable work among amateur horticulturists, the first organization work was carried on among the horticultural societies in the cities and towns, with the result that the membership jumped to something over 5,000. The majority of these were, of course, amateur horticulturists only. Following this movement, it was suggested that local fruit-growers' associations should be formed in the larger apple-growing centers of the Province. Active canvassing was carried on, organizers sent out to attend a series of orchard meetings and with such gratifying results that some forty associations were formed, with a membership of almost 700. A constitution was drawn up by the Provincial association for the guidance of these local fruit-growers' associations, and the objects named there were also purely educational. With the formation of these two sets of affiliated associations and societies, the work of the Provincial association seemed to have assumed very great proportions, and the directors and officers were congratulating themselves on the success of both these movements.

Two years later, one would hardly have recognized the Provincial association. The horticultural societies had broken away, and the majority of the fruit-growers' associations had gone out

# American Bee Journal

of existence. The reasons were not hard to find. In regard to the latter, which were organized among purely professional fruit-growers, there was nothing to hold them together. The enthusiasm instilled in them by the organizer brought them to the meetings for perhaps the first year, but afterwards they were content to stay at home and obtain such information from the horticultural publications. The trouble with the horticultural societies was somewhat different. They claimed that it was impossible for them to receive full justice from a board of directors who were largely professional fruit-growers.

The directors of the Provincial association at their next annual meeting discussed the matter thoroughly, and, while not discouraged, decided to proceed more cautiously, and along sounder lines than they had been working in the past. It was discovered that there were in existence in the Province a few fruit-growers' associations, so-called, that had been working along commercial lines for a number of years with considerable success. Mention was also made of the formation of a number of such associations in Ohio and New York States, which had for their main object the better packing and shipping of the fruit grown by their members. As much information as possible was obtained in regard to this work, and at the annual meeting at Leamington, 1903, a manager of one of the largest of these associations in Ohio addressed the convention on the so-called co-operative movement among fruit-growers. One of his main contentions was that to hold fruit-growers together, or, in fact, any class of farmers, it was necessary to show them that it would mean more money in their pockets by joining an association. At the close of this convention a special committee of the Ontario association was appointed to undertake the formation of co-operative fruit shipping associations throughout the Province.

This work has now been carried on for three years, with the result that there were last year over twenty strong associations in existence throughout the Province, and the probability is that this number will be doubled during the present year. Every association reports that instead of having trouble in getting members they have had to turn great numbers away. The success of the movement, of course, lies in the fact that, where in former years farmers had been compelled to accept almost nothing for the product of their orchards, or in many cases had allowed it to rot on the ground during the last three years they have been receiving very handsome profits from the area in fruit. In some cases the profits have been so very high as compared with past methods that we have kept them quiet for fear of inducing too many to rush into the co-operative packing and shipping without proper leadership.

You may say that we have not yet accomplished our end, as these associations are purely commercial. Such is not the case, however, as almost every one of them has one or more meetings during the year, at which addresses are

delivered on purely educational topics. In addition to this the profits from the orchards have so pleased the owners that they have begun to pay attention to the various educational matters in connection with the orchard, such as pruning, cultivation, use of clover, crops, etc. In addition to this, the by-laws of many of the associations compel the growers of the fruit to practice better methods of pruning and spraying, and in this way the interest of the farmer is increased on subjects which in former years he paid no attention to whatever.

The formation of these commercial associations has worked a wonderful change in the aims and methods of the Provincial association. The programme for its annual meeting is now arranged with a view to promoting the welfare of these associations in every way. An opportunity is given to each of them to report on the year's work, prominent authorities on all subjects relating to the packing, marketing, etc., are brought to deliver addresses. The subject of transportation, instead of being a small issue, as in former years, is now one of the leading topics at the meeting, and the strongest committee appointed is one dealing with matters affecting the transportation of the fruit crop.

The sum and substance of this matter from our experience is that some commercial aim seems necessary to get the farmers together and to hold their interest. Along with such commercial idea, there is no trouble in working in educational matter.

I have noticed in your annual reports that from time to time considerable discussion has arisen as to whether it is advisable to form too many of these associations or to increase your membership beyond its present members. The fear has been that production will increase to such an extent as to flood the market and lower prices. The same might have been said in regard to the fruit situation five years ago. The Ontario markets were evidently taking about all that they could handle, and no other markets seemed available for anything except perhaps our apple crop. It was pointed out, however, that large quantities of fruit were going into our Northwest Provinces from the United States. The Ontario men seemed to be lax in their method of handling the fruit, so that the west would not touch our fruit in any considerable quantity. This, however, has been remedied by the organization of local associations, and, where from one point two years ago one carload of fruit was sent to the west, the past season 60 carloads were shipped into Winnipeg for distribution throughout the Provinces of Manitoba, Saskatchewan and Alberta.

In regard to the apple markets, as soon as it was known that our fruit could be purchased in quantities and of even quality, the larger apple firms in Great Britain and France sent their buyers direct to Ontario, with the result that most of last season's crop has been bought f. o. b. here. Under the old system the fruit was gathered together by the packers right from the orchard and sent on consignment to the Euro-

pean markets, with very unsatisfactory results in most cases. A great deal of fruit was wasted in the orchards in many cases and fruit after being barrelled was exposed to all kinds of weather conditions before being placed on board cars, and even then did not receive proper attention en route to the places of destination. Now this has all been changed. The fruit is packed at the proper season, hauled into central packing houses, where it is properly graded and packed by the one set of experienced men. The purchaser now knows that he can depend on getting exactly what he desires, and, as the reputation of the firm is at stake there is very little chance for dissatisfaction from either party.

(Continued next week.)

## Report of the Kansas Convention

The 4th Annual Meeting of the Kansas State Bee-Keepers' Association was held in Topeka, Dec. 27 and 28, 1906.

At 2:30 p. m. Pres. Dr. G. Bohrer called the meeting to order. The minutes of the previous year's meeting were read by the Secretary and afterward approved.

Pres. Bohrer appointed the following committee on amendments to the Constitution: E. Davidson, J. D. Smith, and J. J. Measer. They recommended that the office of treasurer be abolished, and that the secretary act as treasurer.

At the evening session C. P. Dadant, of Illinois, read a very instructive paper in "Bee-Culture vs. Horticulture," showing the importance of bees in the pollination of fruit-growing.

[See page 109 for this paper.—Ed.]

The present foul brood law was discussed, and it was unanimously agreed that it was deficient as a measure to stamp out the disease. Pres. Bohrer appointed the following committee to secure necessary amendments: O. A. Keene, J. J. Measer, and E. W. Dunham. It was thought that the law should allow the bee-inspector at least \$3.00 per day instead of \$2.00 as it now reads, and to have the power to go into any adjoining county if necessary where there is no inspector, should a case of foul brood or any other bee-disease appear that is of dangerous character.

Another change should be in the number of signatures to a petition, which should be reduced from 25 to 5, as many a county could not secure 25 bee-keepers to sign a petition; and if there were only a few, and foul brood be entrenched, it would soon become unmanageable. For this reason, only 5 signatures on a petition is asked.

The second day's session was called to order by Pres. Bohrer at 10 a. m. It was voted to hold the next meeting at Hutchinson during the week of the State Fair.

The following officers were elected for the ensuing year: President, Dr. G. Bohrer, of Lyons; Vice-President, E. W. Dunham, of Topeka; Secretary and Treasurer, O. A. Keene, of Topeka.

Several questions of interest were

discussed by those present, and Mr. J. S. Young explained his system of queen-rearing. It was voted to ask the State for an appropriation for a Pure-Queen Breeding Station at the College at Manhattan. Pres. Bohrer appointed Dr. H. A. Warner and O. A. Keene to investigate the matter.

At 7:30 p. m., a banquet for all the members of the Association was given at the National Hotel, after which an-

other session was held, during which many important questions were discussed.

This was the largest and most instructive meeting ever held by the Association. It is hoped that there may be even a larger attendance at the next meeting, which, as above mentioned, is to be held at Hutchinson during the State Fair.

O. A. KEENE, Sec.

Conducted by EMMA M. WILSON, Marengo, Ill.

### Some Practical Uses of Honey

Some time ago Miss Wilson requested that the sisters give some practical uses for honey. Ever since then I have had it in my mind to comply with said request to the best of my ability, but have kept putting it off until a more convenient season—until now, the convenient season having arrived, I will drop a few suggestions right here before the subject further eludes me.

Sisters, do you have "Boston baked beans" of your own manufacture at your homes? If so, try the use of honey in place of molasses. *De-licious!*

Quite a variation of coatings used in the making of cakes may be obtained by wholly or partially substituting honey for the amount of sugar required. Personally, I prefer a *partial* substitution.

The use of honey in the manufacture of home-made candies renders them more palatable, and adds greatly to the keeping qualities of all kinds, which are inclined to harden rapidly. Cookies also retain their moisture, and remain soft and of apparent freshness much longer when honey is used in their make-up.

In the use of honey in cooking one must be guarded in reference to burning, as it burns more easily than sugar, and a double boiler or similar arrangement comes into play nicely.

We see honey-cured meats advertised as something superior. (Indeed, when did we ever hear of anything which had the most remote connection with honey, advertised as of any quality except superior, from the expression, "The land which floweth with milk and honey," an expression indicative of all sufficiency, down the whole procession?) As I said, these meats are pronounced superior, but as honey is so easily converted into vinegar, I have never ventured along this line, but in cooking meats I have added a little honey with appreciative results.

I am satisfied that the chief reason that honey is not more generally used in cookery, lies not in that it fails to

be an improvement, but that it is generally conceded to be too delicate a luxury for so common a use.

The use of honey instead of sugar doubles the value of any cough syrup, and the family having access to honey in plenty that can not concoct cough syrups equal, or superior, to those found on sale is indeed in straits. The foundation of these may be a decoction of any herb or herbs of known value, with honey added to the strained liquor to form a syrup. One of the most simple is to boil 3 medium-sized potatoes (with their jackets on), and when done remove and pour into the potato water  $\frac{1}{2}$  cupful of honey. Strain, and drink while hot. This preparation may be varied by the addition of anything you know to have been beneficial to yourself or to any of your friends.

Lemon-juice, flax-seed tea, or the two together, flavored and sweetened with honey, are great aids in the way of alleviation and prolonging life in the case of consumption.

A raw egg beaten in a pint cup, and the cup filled with hot water, sweetened liberally with honey, furnishes both nourishment and medicine in case of colds.

I am forcibly reminded of "carrying coals to Newcastle," when I see a bee-keeper coming out of a drugstore with a bottle of world-wide heralded "honey and tar," or "hoarhound, honey and tar," and I can scarcely further analyze my feelings more than to say they are a queer mixture of downright sympathy, not unalloyed, because, as I said before, mixed with vain regrets over the short-sightedness of some people, and vain attempts to repress my risibilities altogether when the ridiculous point of view looms up. Just to think people will do such tricks to the amusement of even the clerk who makes the sale, when an equally efficient remedy might be had at home, by the use of his own unadulterated honey, and hoarhound of his own raising, and that, too, almost without price. But he will tell you there are other ingredients in world-renowned cough reme-

dies which are not, and can not be, produced on the farm, or within the bee-yard. What of it? A few cents worth of the products of the apiary will secure them at a much cheaper rate than when bought already compounded.

Many families cat honey daily as a preventive of colds, and claim its use renders them almost exempt.

How many sisters know that the use of honey in the water used for toilet purposes prevents and cures chapped hands, keeping the cuticle soft and free from dryness, so that it is of almost a satin finish? Honey, almond meal, and lemon-juice, form a fine complexion paste. In fact, honey forms an important factor in all emollients. A little each of honey and flour mixed together, and spread on cloth, applied to boils and similar afflictions, will soon number their days.

Beeswax is a controlling ingredient in many of the most popular salves that have been placed on the market.

I think I now have about performed my duty relating to this subject; and if I have failed to enumerate some of the pet uses of honey with the other sisters, let them make it known.

This is one way to advertise our products, and if all keep their mouths shut, as if it were a sin to herald the value of our commodities, while every other class of people put forward not only claims which can be depended upon, but some which are largely imaginary, we can but expect they will be kept hustling while we stand with our hands in our pockets, as it were, and "nothin' doin'."

In this connection the Pure Food Law will no doubt aid greatly. Dealers are only too glad to buy of the producer, fearing the effects that have so generally borne upon honey that passed through several hands in the past. This tends to cut off the career of the artificial product and make corresponding room for the natural. The new Law will do more for our industry than acting as a good salesman, in the way of compelling bee-keepers themselves to look to the condition and quality of their honey. The publishers of *Gleanings* took the trouble to interview two of our leading dealers as to its effect on honey sales. R. A. Burnett concluded his answer with this sentence: "If the bee-keepers will let their honey ripen before taking it off the hives, it will do more than any law passed in furthering its consumption."

Truth, if ever it was uttered; but is it not humiliating, that we must be reminded there are those among us who are so careless, thoughtless, or dishonest, as to offer such inferior honey?

How long would we ourselves patronize an institution that would insult us by offering us fermented or sour food of any kind? If not already in this latter condition, no one knows better than a bee-keeper how quickly unripe honey will reach this stage. How frequently we meet with those who dare not touch honey, and many times I have thought the trouble from which they claimed they suffered might have been caused by unripe honey.

One of my best customers, at one time, could not be prevailed upon to taste honey, but once his scruples had

# American Bee Journal

been overcome, I succeeded in getting him to make one more test, which was followed by no bad effects; he ever after bought of me all of his honey, of which he was inordinately fond, and hesitated not to discard all other.

Now, why should honey from my apiary be innocent of harm, or after-effects, and that from others guilty? There could not possibly have been any difference except that between *unripe* and *well cured* honey. The honey partaken of was all in the extracted form. Had comb honey been used in one case, and extracted in the other, one would naturally conclude that the *wax* probably produced the distress.

As to unripe honey, Gleanings has this to say:

"The suggestion of Mr. Burnett is a very good one, especially as unripe honey on the market will suggest adulteration even if it

does not make the producer of it actually *liable* under the new law. We should be a little fearful, at least, that some chemist would declare some unripe honey as adulterated, and it might be very difficult for the producer to prove his innocence of the charge. All bee-keepers, therefore, had better err on the safe side by seeing to it that all honey shipped from their yards is thoroughly ripened, with a good body and first-class flavor for the kind of honey sold.

"It is well to remember that the United States standard for honey allows only 25 percent of water, and any in excess of this would *certainly* be construed as an adulteration. Producers generally should 'paste this in their hats.'"

So it is evident that if we are inclined to be the least dishonest, Uncle Sam will be right after us; and as to being careless, we may awake to the fact that there is in existence such a thing as *criminal* carelessness.

## Making Increase for Out-Apiaries

A bee-keeper wishes to make sufficient increase to start an out-apiary, and wishes to know how to proceed, even if he does not get a crop of honey at the out-apiary the first season. At the home-apiary he has about as many colonies as he wants to keep at that place, with perhaps a dozen weak colonies he thinks "not worth considering."

Having started out-yards with these same conditions, I will tell of two ways in which to make the increase, the *weak colonies* "not worth considering" playing a great part in each of these.

The time of our main honey-flow must be considered. If it comes early in the season, all colonies for surplus storing must be built up to populous colonies in time for this flow. Hence, it will be seen that there is not much time in which colonies can be built up; and bearing this in mind we plan making the increase for the new yard accordingly.

The "dozen weak colonies not worth considering" are the very ones that are "considered" in this case. While the strong colonies are left on the old place, and gotten in readiness for the early flow, the weaklings are taken to the new location. Here they are fed on sugar syrup to stimulate them and build up as rapidly as possible. For this purpose out-door feeding in a wholesale way, giving enough syrup each day to make an artificial flow as much as possible like a light honey-flow, works nicely.

The syrup should be fed rather thin, so the bees will be at work all day, and less trouble will result from getting a fracas started which would likely be caused by feeding thick syrup or honey. The feeding should be done a little distance from the apiary, necessitating the bees to carry the feed home, much as when gotten from the fields. If fruit-bloom has been on in addition to the feeding, the bees will be stimulated the more, besides getting a supply of natural pollen, which should otherwise have been supplied them artificially also.

As soon as brood-rearing has advanced well enough, and the weather is favorable, the colonies are increased by dividing them. If possible, laying queens should be procured for this first division, as it is yet too early to rear good queens. Only a dozen queens need be bought of some of our Southern breeders, who generally carry over a lot of them through the winter. Out of these some may prove very good, so that young queens may be reared from them for subsequent divisions, if they are better than any of those already in the yard.

To divide the colonies, about two-thirds of the brood—mainly sealed—is given to the bees on a new stand, since the old field-bees return to the old stand. The old queen is left in the hive on the old stand, while the new colony—which now contains mostly young bees, and to which a new queen is much more easily and safely introduced—receives the new queen. The entrances of the hives are contracted by means of grass, weeds or moss, which is preferable to closing en-

trances with wood or such other material, as the bees can easily enlarge the entrances to the needs of the colonies. To hasten the work feeding is kept up unless a sufficient honey-flow is now on.

As soon as these colonies are strong enough subsequent divisions are made in the same way, but the queens for the new divisions may be reared. Giving laying queens, however, will hasten the work, and give quicker results, although the first expense of the queens may be an important item with the apiarist. Full frames of comb foundation should be used to fill up the hives when dividing, if combs are not on hand. Thus a good use is made of the weak colonies, and an out-yard established which should be in good shape by the following winter.

If, however, the main honey-flow comes later in the season, and there is time in which to build the colonies up for it, I would proceed so: Now the strong colonies are used. New hives are fixed up, one for each colony, and a bottom-board fastened to the brood-chamber with the entrance closed with wire-cloth. Each brood-chamber is fitted with a division or follower board, or a full set of frames filled with foundation. From each strong colony now are drawn 3 combs of brood and honey, and a lot of bees. These are placed in one of the prepared hives, and the cover is securely put on. Frames of foundation from the prepared hives are given to the colonies from which the combs are taken, placing them on each side of the cluster of the brood-nest. These colonies will build up in time for the honey-flow, and there should be less danger of swarming.

From the weak colonies one or 2 combs should have been taken also, and placed in each of the prepared hives, thus making 4 or 5 combs of brood and honey, with the rest full sheets of foundation. These are then at once moved to their location in the new yard, the hives and entrances opened, and a laying queen in an introducing cage given to each, when feeding, to build them up, is resorted to as in the other case. The division-boards are used on the outside of the number of combs covered by the cluster, and is moved outward as fast as more of the frames of foundation are given to the bees from outside of the brood-nest. In this case the colonies have time to build up strong enough in both yards, so that a good crop of surplus honey may be obtained.

**Honey as a Health-Food.**—This is a 16-page honey-pamphlet intended to help increase the demand for honey. The first part of it contains a short article on "Honey as Food," written by Dr. C. C. Miller. It tells where to keep honey, how to liquefy it, etc. The last part is devoted to "Honey-Cooking Recipes" and "Remedies Using Honey." It should be widely circulated by those selling honey. The more the people are educated on the value and uses of honey, the more honey they will buy.

Prices, prepaid—Sample copy for a 2-cent stamp; 50 copies for 70 cents; 100 for \$1.25; 250 for \$2.25; 500 for \$4.00; or 1000 for \$7.50. Your business card printed free at the bottom of front page on all orders for 100 or more copies. Send all orders to the office of the American Bee Journal.

The "Old Reliable" as seen through New and Unreliable Glasses,  
By E. E. HASTY, Sta. B. Rural, Toledo, Ohio.

#### SWEET CLOVER

I half believe that Wm. Stolley's queer sweet clover was a genuine sweet clover, after all. The total absence of nectar may be a freak, not to be expected another year. *Melilotus* is a new genus split out of *Trifolium*; and there are several *Trifoliums* that are annual. Moreover, I think I have read that there is an annual *Melilotus*—but the color, if I remember right, was blue. Developing a yellow kind out of a blue one might not be impossible. Mr. Stolley's testimony, that it looked right, and especially that it smelled right, ought to count for considerable. Page 49.

#### HIVE-LIFTING DEVICES.

At least two needed points in an ideal super-lifter Grant Stanley did not talk about. It should hold the hive proper down as well as lift the supers up. Moreover (and there's the awful rub), it should hold the brood-combs down. In lifting supers by main force it develops that 2 or 3 of the brood-combs will hang on and lift also—a state of things which is very highly to be reprobated, especially the way they change their minds and drop off after a bit. And I think, for this one time, that the wheels Mr. S. has in his head (or, say mind) are also needful and proper if the machine is to pay for its storage-room. Page 49.

#### TEXAS BARBERRY.

The Texas barberry seems to differ greatly from ours—the bush smaller and the fruit much larger; also sweet enough that it can be eaten. Ours is available only for preserves; but preserved with sufficient sugar its reputation is very high. Page 51.

#### CHEMICALS IN MAKING VINEGAR.

Isn't it rather a novelty to put in three kinds of chemicals into sweetened water when you start to make vinegar? Wonder what *object* the Arizona wise-heads have in view in ordering them in. Guessing while on the run, maybe they precipitate some things from the fluid which might otherwise stay in the vinegar to its detriment. Page 65.

#### SPIDERS AS BEE-ENEMIES.

It's rather a new revelation of our enemy (and friend), the spider, that Allen Latham gives. He figures out 50 slain bees to the square rod, and

thousands of such square rods within a range. Pretty serious. I have been calling the spider my friend, on the whole, and not much grudging the occasional bee taken. I still think that in my locality the loss is not *very* great. Still, it may be more than I have thought. Let's "watch out," and so know a little more definitely about it, each for his own corner. Certainly we are well-wishers to our spiders, having a full diet of young cockroaches and newly-hatched moth-larvæ. That Kilkenny cat fight between the leaping spider and the warlike bee was worth forming a ring around—Spider fatally bit the bee, and bee fatally stung the spider. Perhaps we can discriminate between species—hire the boys to war on our big and distant enemies, and at the same time smile on those that are mainly our friends. Page 68.

#### VALUE OF HONEY AS A REMEDY.

If butter and honey well whipped together will produce the same medical effects as cod liver oil, patients ought

to shout for joy. Worth remembering that honey at bed time is highly recommended for obstinate constipation, and also for nervous insomnia. Multitudes of sufferers from the former, and many from the latter. Thanks to C. P. Daudant for his excellent anthology of that French medical pamphlet. Page 69.

#### PUTTING BEES OUT AND IN, IN MARCH.

A trifle surprised to hear Doolittle advising to put bees out in March, and back again. Guess it's all right, though. Different teachers likely to differ some as to *how much* uneasiness is required to justify setting out. Page 67.

#### MAKING BEE-CANDY.

So bee-candy should be stirred *after* the time when it is done and taken from the fire, and on until it gets so cool that it has to be poured. Less sticky and less liable to daub the bees by so doing. Apparently here is a valuable kink which half of us have been losing. Page 73.

#### RAILROADS AND LOWER FREIGHT-RATES.

We rightly blame the railroads for many things; but we can not blame them for studying their damage bills with earnest attention and purpose. No putting any article into cheaper rates so long as there is a constant hurrah of damage claims. In other words, the money received for carrying honey must pay the transportation and the bills for damages, too—as no railroad proposes to do business except at a profit. I hope we hear. Page 85.

#### Loss of Queens in Mating

The substance for the following dialogue was sent me by a friend, with the request that I "fix it up" for Canadian Beedom. In so far as I have been guilty of plagiarism in adopting the conversational style, apologies are tendered Mr. Doolittle:

"Good morning, Mr. Smith. Pretty cold day."

"Yes, Mr. Jones, it is cold; 17 below at our place this morning, and a strong wind blowing."

"By the way, Mr. Smith, I don't believe I have met you since our county convention last April. What was your crop of honey like?"

"Very light, I am sorry to say; and

and to make matters worse, a great many of my young queens were lost while taking their mating flight."

"No doubt you ascribe these losses to the presence of king-birds?"

"No, I do not; and, personally, I don't believe that the king-bird is responsible for half the damage he gets credit for."

"Pray, how do you account for the loss of your queens, then?"

"Well, as you probably know, for a mile and a half on all sides of my apiary the country is mostly pasture land."

"Yes, but what has that to do with the loss of queens?"

"Just wait a moment and I will tell you. Walking over a closely cropped pasture field, one afternoon, I was at-

tracted by a large number of drones flying near the ground, and, on looking down, there on the ground was one of my young queens hopping around with an injured wing. The drones would swoop down towards the queen, flying very rapidly back and forth. As I found a couple more queens in like condition, later on in the season, I have come to the conclusion that quite a number of queens have their wings injured by drones flying rapidly against them while in the air; the queens then drop and perish in the grass."

"Well, Mr. Smith, I must say that your ideas on this question are new to me, and, as far as I know, to the fraternity in general. But, say, speaking of queens, how did those turn out that you got from Indiana?"

"Not very well, and, to tell the truth, I don't care to say much about it; but, as you have asked me, I will tell you the facts of the case."

"If I remember correctly, you had some virgins as well as untested queens sent you?"

"Yes, I ordered 8 virgins and 4 untested; when they came 2 of the former were dead; I returned them, and the dealer seemed to think that 1 live queen was as good as 2 dead ones, so he sent me 1 to replace the 2."

"Not a very encouraging beginning."

"No, and that was not all. Of the virgins left, 4 after 14 days began to lay and did all right, but the others were lost in their mating flight. But where the joke came in, the 4 untested were safely introduced, but not one offered to lay; in fact, they were vigorous, too; and, to cap the climax, when they went out to mate, not a blessed one returned to the hives again."

"Your experience, I must say, Mr. Smith, was far from satisfactory. I suppose you think those queens that never returned were injured by the drones, and lost in the grass, as you have before intimated?"

"Either that, or else by way of protest, they headed straight for Indiana. Don't you think, Mr. Jones, that some of these queen-breeders think we ordinary honey-men are pretty green, and often palm off virgins as untested queens?"

"No doubt there are dishonest and careless queen-breeders, just as you find this same class of men in other lines of business; and I remember getting a number of queens from Texas a few years ago, with quite a large percentage of virgins. I wrote to a prominent Ontario bee-keeper, and he said he had been having the same trouble, and attributed it to a very busy season, and to the fact of the queen-breeder having unskilled helpers in his queen-rearing work. Possibly, Mr. Smith, these same causes would explain your difficulties."

"I don't know the cause, but I do know that I got virgins instead of untested queens, and that the dealer would not make the matter right."

"Well, good-bye, Mr. Smith; the first time you are in Pumpkinville drop in and have a look at my bee-cellar. The temperature ranges from 40 to 43 degrees; this is a little low, but the bees seem to be wintering well; yet I

would like to have an old-experienced bee-keeper, like yourself, call and give your opinion."

"Good-bye, Mr. Jones. I certainly will be glad to call on you if I am down

your way; but, in the meantime, if your cellar is dry, and the bees are quiet, don't worry about them, even if the temperature is a trifle lower than is generally recommended."

BY W. A. PRYAL, Alden Station, Oakland, Calif.

### The Poetry of Life is in the Bee

What a world of melody to the bee-keeper's ear is the hum of the bee during the first warm days of early spring. It is the very poetry of life; there is nothing else like it, for nothing else can compare with it. It is a theme for the poet, so not being a writer of that order, I shall leave the beautiful subject to my poetical friends.

### Early Rain Makes the Honey—Some-times

Copious have been the rains throughout the length and breadth of California this winter; in fact, in some places far above the average has already fallen. With the rains to come there is no doubt but there will be a splendid growth of honey-plants. The honey harvest should, therefore, be good. But the result can not be foretold in advance, as cool weather may prevail when the principal honey-secreting flowers are in bloom. Even if your hens are good don't count your chicks before they are hatched, is a good rendering of the old saw; and so, if the rain comes and the sun shines at times, don't load your wagon with next season's honey.

### Honey Crop of 1906

The man who did the figuring for the New Year's edition of the San Francisco Chronicle, places the honey crop for last year at 7,500,000 pounds. Figures are said not to lie, but in the Chronicle's showing they must somewhere. The writer and computer states that last year was a poor one, yet it was but 1,250,000 pounds short of the previous year's output. In 10 years it was equalled only four times. The greatest crop in that time was secured in 1905; 1903 was nearly as good, but 1904 has a record of only a few tons over a 500-ton crop—the worst year in the decade.

### Early Spring Flowers

The sentimental poet has sung of the "Flowers that Bloom in the Spring," but I have not yet found where the metrical man has essayed to sing of the "Flowers that Bloom in the Winter." Possibly the flower-poet has not been living in California. We have some real pretty wild flowers that bloom in the dead of winter; I was ad-

miring some blossoms of the wild currant that were in bloom in our backyard on New Year's day. The bush is one that volunteered from seed that was brought up evidently in some sand that was carted from the creek. The flowers are very pretty in their pink loveliness. They appear at a time when the plant is practically nude of foliage, so the flowers are all the more showy. They have a very pleasant, "pungy" odor, and when the days are warm the bees hold high carnival amid the bloom. The period of inflorescence of this plant extends over many weeks—away into February. It is a plant that I can recommend for a place in every garden for ornament. Its fruit is not considered edible, though it may be eaten.

It is easy to gather bouquets of garden flowers here in the latter part of February, and from thence on; so, also, may one pluck quite a variety of wild flowers commencing that early. One day in the first week in February, some years back, I went out into the hills and in a few minutes had an armful of Flora's early treasures. I gathered a few of each into an old straw hat, and exposed a photographic plate on them. The result was not fully satisfactory. I submit a print from the negative, as it may give an idea of what some of our winter flowers are like. I wish the photograph were a better one. [See front page.—EDITOR.]

**Why Not Advertise?**—There are many dealers in bee-supplies, and those who have bees and queens for sale, who are not now advertising, that might increase their business by advertising in the American Bee Journal. The rates charged are very low, as will be seen by referring to the second page of this number. During the next 6 months will be done the bulk of the season's business among bee-keepers. Why not begin at once to let the readers of the American Bee Journal know that you have something to sell? Our advertising columns are open only to those who will give their patrons "a square deal." If you are in that class we will be pleased to have your advertisement in our columns.

**Amerikanische Bienenzucht**, by Hans Buschbauer, is a bee-keeper's handbook of 138 pages, which is just what our German friends will want. It is fully illustrated, and neatly bound in cloth. Price, postpaid, \$1.00; or with the American Bee Journal one year—both for \$1.75. Address all orders to this office.

Send Questions either to the office of the American Bee Journal, or to  
Dr. C. C. MILLER, Marengo, Ill.

Dr. Miller does not answer Questions by mail.

### Beginning Bee-Keeping

I would like to know the best possible way to commence bee-keeping the coming season.

MICHIGAN.

ANSWER.—Take my advice and don't wait for the coming season, but begin now, getting a good book on bee-keeping and studying it thoroughly. That's the way to begin, and by the time you have done that you will know pretty well the next step; but if the way is not entirely clear then, I'll be glad to answer to the best of my ability any questions as to your further course.

### Italianizing and Transferring Bees

1. I have 3 colonies of bees to which I wish to give Italian queens. When shall I do this, in fruit-bloom, or earlier, or later? And how?

2. I have one colony in a box-hive, one with movable frame, and one of odd size. I wish to transfer them to my regular Danzenbaker hives. When is the best time to do this? And can I then re-queen? That is, at the time of transfer? And how? IOWA PRAIRIE.

ANSWERS.—1. It doesn't matter so very much when, but a new queen is likely to be received more kindly when honey is coming in more freely; so if you do not introduce in the flush of fruit-bloom wait until the next flow, which in your locality is probably white clover, early in June.

You will receive instructions on the shipping-cage which brings you a queen by mail, generally, and you will do well to follow such instructions. They will tell you to remove the old queen and put the new queen caged into the hive, leaving the rest to the bees. As a possible improvement, it may be well to put the caged queen into the hive without disturbing the old one, but having the cage so arranged that the bees can not get at the candy to liberate the queen. Two days later remove the old queen and give the bees a chance at the candy to free the caged queen.

2. Nowadays the tendency is toward waiting to transfer until 21 days after the colony has swarmed. In your case, however, you are merely to transfer from a frame of one size to another, and I think I should not wait for swarming, but transfer during fruit-bloom. You can also change the queen at that time, in the way mentioned in the preceding answer, or if more convenient, you can wait till white clover is in bloom.

### What Are Weak Colonies in Spring?

On page 152, Mr. Scholl says that at the main examination of colonies as soon as warm weather in early spring allows it, "If the cluster does not spread over the space of at least 4 or 5 combs, it should be marked as 'weak,' and should be united with another colony." If I should follow that teaching it would leave very few colonies not united. Do you think I would gain by such uniting?

SUBSCRIBER.

ANSWER.—If Mr. Scholl is speaking of Langstroth size of frames, it must be that

there is something very different in Texas from northern Illinois. I do not note upon first examination just how many combs the cluster spreads over, but I do note generally the number of combs in which I find any brood, and practically that means the number of combs the cluster spreads over. It may be of interest to give from the book of the very prosperous year of 1903 the condition of 6 different colonies just as found at one opening of the book, at the time of their first examination, April 20. The number of combs having brood in them, and the number of sections obtained from each colony were as follows: 4 combs, 232 sections; 5, 186; 2, 219; 4, 172; 5, 240; 3, 184. It will be noticed that according to the rule of uniting all under 4 combs there would have been united 2 which gave respectively 219 and 184 sections, or a total of 403 sections. If I had united those 2 colonies I feel pretty sure it would have been at a loss, for I have no idea the united colony would have given 403 sections. Looking along I find others with brood in 3 combs each that gave, respectively, 285 sections, 238, 164, 170, 149, 224, 142. But I need go no farther, for I think that is enough to show that the rule would not be a profitable one to follow in this locality.

### Combs of Granulated Honey—Feeding Comb Honey—Strong-Scented Honey—Dummies

1. What is best to do with frames filled with granulated honey? If placed in the hive, will they liquefy so that the bees can use them, or should I place them outside and let the whole force get at them?

2. Is it necessary to uncap combs of honey given in spring? I have scored them with a knife and sometimes the honey would run down and out, causing robbing.

3. Last fall when I opened some hives they had a strong scent. I was afraid there was some disease in them. I could see nothing wrong with the brood, and the combs were well filled with honey and all capped over. The honey is amber, strong tasting, and scarcely fit to use on the table. Will such honey stored by the bees, or fed to them in spring, be fit feed for them? Can it be some poisonous plant food?

4. You are often called upon to explain what dummies are, how they are made, and how used in the hives. In confining a small colony to one end of the hive, do you fill the empty space with anything? NORTH DAKOTA.

ANSWERS.—1 and 2. You can trust the bees to uncap the cells, and as fast as needed. The heat of the hive is not sufficient to liquefy granulated honey, but the bees will make use of a good part of it for all that. You may get them to use all of it by spraying or sprinkling the combs with water, repeating the operation as often as they are cleaned dry by the bees.

3. It is not likely the honey is at all poisonous, only unpleasant tasted, and will be all right for the bees' own use. The most profitable thing to do with some honey that is poor

for table use is to get it turned into young bees.

4. A weak colony, say one that needs only 4 frames, may have a dummy at one side of the frames with the remaining space in the hive left entirely vacant; only the dummy must be moved and a frame or frames added as needed. Generally, however, when one has a weak colony of that kind which is expected to build up, one has enough empty combs to fill up the hive, and in that case I wouldn't use a dummy at all. You may ask whether the bees would not be warmer to have the combs that are occupied shut off from the empty combs by a dummy. One would naturally think so, yet experiments carefully made, if I remember rightly, by Prof. Gaston Bonnier, showed that the empty combs were just as good as a board partition.

### Feeding in Winter—Making Increase—Moth-Worms in Brood-Combs

1. About a week ago we had a few nice warm days with the temperature at 40 degrees above zero in the shade. The bees being active and taking a good flight, I thought I would look into colony No. 4, for I was pretty sure they were short in stores. Did I do wrong in feeding them at that time?

2. Being anxious to increase as fast as possible, I would like to have your opinion about it. I read one article by W. Z. Hutchinson, saying that he made his increase by taking 2 or 3 frames of brood from strong colonies and giving them a laying queen; but not being able to buy my queens, would it do to take a queen from one colony and let the bees rear a new queen? Please give me some of your best plans.

3. Last year I lost considerable by having the moth-worms get into some brood-combs which I had stored away. How can I prevent this? MICHIGAN.

ANSWERS.—1. It is not a good thing to disturb bees in February, but it is a much worse thing to let them starve. So if you were not pretty certain that their stores would last till warmer weather, you were very wise to feed.

2. It is not easy to say what may be the best plan for you. What is best for one is not always best for another. But taking the plan you mention, you can do very well with a little variation. Decide which colony you think has the queen of best blood, and see that it is strong, if necessary giving it frames of hatching brood from other colonies to strengthen it. You may even fill 2 stories with brood. Call this hive A. When the time comes for bees to begin making preparations for swarming, take the queen with 2 or 3 frames of brood and adhering bees, and put them in hive B, on a stand a rod or more distant. Better fasten the entrance for about 2 days, lest too many of the bees return to the old hive. About 8 or 10 days after taking the queen away from A—don't delay longer than 10 days—take out one of the frames with the queen from B, put it in an empty hive, C, and fill out C with empty combs or frames filled with foundation or starters. Take hive A from its stand, and set hive C in its place. You will now make as many nuclei as you can from the brood and bees in A, taking 2 frames of brood and bees for each nucleus, putting each on a new stand. It may happen that without any attention on your part there will be one or more good queen-cells on one of the combs in each nucleus. It may be, however, that most of the queen-cells are on one or two combs, and you must cut out at least one good cell for each nucleus. You can fasten it on the comb by pushing over it a hive-staple. See that it is centrally located where the bees will be sure to keep it warm. A cell must also be given to B, and it will be well that this be given in a cage so that the bees can not get at it for a day or two lest they destroy it before they discover their queenlessness. The bees of the nuclei being queenless, will remain pretty well where put, but you might fasten them in for a day or two. You will find much about increase in the last volume of the American Bee Journal,

and the book "Forty Years Among the Bees" is very full in this respect.

3. In a cool cellar the worms will not trouble them much till quite warm weather, perhaps not till June. Then if you can put them in the care of the bees that will be best. A story or two of combs may be placed under any strong colony, and the bees being obliged to pass through them in going in and out the hive, will keep them clear of worms. You may also destroy the worms by submitting them to the fumes of sulphur or bisulphide of carbon. If large worms are found in any of the combs, squirt a little gasoline on them out of an oil-can.

## Working on the Maples

Bees are working on maple, and peach-trees will be in bloom in a week, or less time if the weather continues as it is at present.

R. E. CAMPBELL.  
Springdale, Ark., March 4.

## The Honey-Flow is On

Our white honey-flow from waxes is near at hand—in fact, already on at some of my out-apiaries. It promises to be good. The weather is warm and dry.

GRANT ANDERSON.  
Sabinal, Tex., March 5.

## Expects Loss from Honey-Dew

I fear that "The Hum of the Bees in the Apple-Tree Bloom" will not be a very noisy hum, on account of the honey-dew. There was one of the best (or, should I say, worst?) flows last summer I ever saw. My 75 colonies stored about  $\frac{3}{4}$  of a ton,  $\frac{1}{2}$  being in the brood-chambers and 500 pounds in the sections. This was of good body and fine flavor, many preferring it to the best clover honey; but, alas, for the bees! They can not subsist on this sort of honey and stand the long winter confinement in this cold north country, where the mercury has dropped the present winter to 54 degrees below zero. Bees are in the cellars, of course, and have been for over 3 months, and will have to stay 6 weeks longer, at least—those that live. I don't expect to take out over 15 percent in good condition.

O. B. GRIFFIN.  
Aristook Co., Maine, March 2.

## "Wild" Honey—Hard Winter for Bees

I have read the letter by Harry Lathrop, on page 105. I would call attention to what seems to me a mistaken idea in regard to the flavor of wild honey (so-called). If any one can tell where the difference in flavor comes in, I should be pleased to have him do so. Having kept bees over 50 years, and hunted wild bees (so-called) nearly as long, I never yet could detect any difference in the flavor of honey from hive or tree; and why should there be any? The bees in the tree that we call "wild," perhaps went from our own apiary, and where can they gather any different honey from those in our own hives? Are not all the flowers visited by the bees from hive or tree alike? Of course, honey from a tree is not in as nice shape as what we get from sections, yet some of the white comb can not be excelled by that in the hive, either in looks or flavor.

Our bees here in southern New Hampshire are having a hard winter, and I fear will not go through till spring in good condition, as they have not had a cleansing flight since some time in November. And their stores were not the best, they having gathered quite a lot of honey-dew, and my bees have not, on

on average, wintered well on that kind of sweet. (I will not call it honey.) Our bees are always wintered on the summer stands, in double hives, with a good packing over the honey-board. Last winter every colony went through the winter in fine shape, and up to the present time (Feb. 9) all are alive, but I judge are in bad shape, as they try to fly when it is too cold for them to do so safely. One colony, yesterday, with the thermometer at 25 degrees in the shade, and hives standing in the sun, were flying, but, of course, many of them never returned to the hive. A little shade made by standing a board in front of the hives soon quieted them. When it is calm, and the sun shining brightly, and it is 42 to 44 degrees in the shade, bees will fly and return to the hive all right.

New Ipswich, N. H. GEO. S. WHEELER.

## A Few Corrections

On page 137, where it says, "by the looks of the queen's drones," I should have said "workers." On page 138 it says, "in one week all the bees were dead;" it should be "queens," not "workers." The half-blood queen's abdomen was filled with water. Those 2 queens I received late in the fall of 1905, so they could not be tested as to their purity until the spring of 1906.

SUBSCRIBER.  
New York.

## Some of the Ups and Downs of a Bee-Keeper

The spring of 1885 a widow living here gave me her apiary of 3 colonies of black bees in box-hives, which I moved to my home about the last week in March. Then I went to a friend who kept bees in frame-hives and borrowed a hive and a frame so I could make some like them. Those hives were 14 inches by 16 and 18 inches, outside measure, and about 12 inches deep. The bees in the new hives stored very little honey, but would swarm and swarm and swarm. The sections were put on the frames crosswise, and the open sides of the sections fenced in with thin boards; the cover of the hive being made deep enough to accommodate the sections.

Twenty years ago either I or the bees, or both of us, had an experience that has not been repeated since. A swarm came out and was hived in one of those 14x18-inch hives. Before the first swarm was in the hive another swarm came out and went with the first, and then another, and still another. There were 4 swarms in and on that hive; the hive was completely covered with bees, so it was left where the first swarm was hived all night. The next morning I was out early to see what arrangements they had made, and found them in the same shape as they were the night before. About 9 o'clock a swarm peeled off and went to the woods; in less than 20 minutes another came off and went in an opposite direction; a few minutes later the third swarm left and went south, leaving a nice swarm in the hive.

I got a catalog from a bee-supply factory in Wisconsin, and ordered the Improved Simplicity 10-frame hives. The supers were arranged so that the section slats would rest on the sections in the super below. No matter how many supers were on the hive, there was only one bee-space, and that was between the first super and the top-bars of the brood-frames. The bees would glue the supers tight together, so if the top super were removed the sections in the super next below would all follow. If the inventor had lived in this corner of the bee-pasture, and put his hive into practical use, he would never have made the second hive. Some of those hives are in use yet, but they have been remodeled so that there is a bee-space between each super. The next hive was the "Wisconsin," which is all right except the Hoffman self-spacing frames, which are a nuisance in this locality, and they are not spaced far enough apart. Next the "St. Joe" hive with metal spacers top and bottom. In my judgment the "St. Joe" hive is the best hive of the three.

The honey season of 1906 was excellent in this locality. The bees have the range of the

Illinois River bottoms, where wild cucumbers, wild asters, and Spanish-needles were abundant, and some buck-brush. I had 22 colonies last spring to start with, and increased to 32. The forepart of the season but little surplus was stored—just enough to keep breeding going on nicely. The hives were running over with bees. On Aug. 9 a marked improvement in bee-circles was noted somewhat out of the usual order, as my bees had always taken a vacation in August, but this year business was the order of the day. My 22 colonies, spring count, filled 2500 sections—an average of over 113 per colony. One colony on 10 frames, in what is known as the "Shirck" hive, filled 168  $4\frac{1}{4} \times 4\frac{1}{4} \times 1\frac{1}{2}$  sections full from top to bottom without separators. One other colony in an 8-frame Langstroth hive filled 165 plain and bee-way sections, and 5 colonies in 10-frame Langstroth hives filled 140 plain and bee-way sections each. I have kept bees over 20 years, but never till last year did a colony in an 8-frame hive fill more than 72 sections.

PEORIA CO., ILL., Feb. 26.

GEO. B. SLACK.

## Late Report—Tall Bee-Men, Etc.

It is rather late to make a report for 1906. Perhaps one reason for my tardiness is because I had nothing to boast of in the way of a honey-yield, the season here being a rather poor one. Forty pounds of salable section honey to the colony, spring count, is about the size of the crop, and an increase from 35 to 55 colonies, which seem to be wintering well in the cellar.

The Editor, on page 66, seems a little inclined to boast of the stature of Mr. Louis H. Scholl. I have a neighbor bee-keeper, Isaac Wayne, who goes him 2 better, as he is 6 feet and 4 inches in his stockings. When it comes to reaching up a tree for a swarm of bees, he gets above me by nearly a (Foote) foot.

Last fall, when taking off the last of my supers after the honey-flow had ceased, I made a little discovery of the "cuteness" of the bees that was new to me, but maybe not to the experts. Three years ago I made a cone about 9 inches long out of wire-screen, and attached it to a bee-escape board so that bees inside could get out, while those outside could not get in. My practise was to place a regular bee-escape on an empty hive, on top of that place 4 or 5 supers, and on top of these put the board with the cone. It was a real pleasure to see the bees chase each other out, one at a time, and it would be only 2 or 3 hours before the supers would be clear of bees. But one fine day last fall I noticed quite a collection of bees on the outside of the cone near the top, so I thought best to look into the matter and find out, if possible, what they were up to. And this is what I saw:

A bee on the inside would come to the top, and to all appearances deliver her load of honey to an outsider between the wires, when the latter would fly away to the hive and the former would back down into the supers after another load of honey.

Another thing I saw: When 2 bees, one inside and one outside meet, that didn't belong to the same colony, they would immediately back away and hunt for their mates.

Of course, I can not say positively that the above conclusions are correct, but appearances go strangely to prove that they are. While the honey carried out of the supers in this manner was probably inconsiderable, it proved to me that while "man proposed" the bees were cute enough to plan ways and means to "dispose."

A. F. FOOTE.  
Mitchell Co., Iowa.

## Bees and Grapes, Etc.

My 33 colonies so far are in fine condition. We have had a very mild winter here. It was so warm and sunny last week that the bees finished one sack of flour as artificial pollen. I mix  $\frac{1}{2}$  bran to keep the flour loose so that the bees can work it better. My bees are in Heddon and Langstroth hives.

For beginners with bees, I would say to go

# American Bee Journal

slow in buying bees, queens and brood foundation. In regard to disease, I have some reason to believe that a good share of the dead brood and foul brood is caused by the chemicals that are used in clarifying the beeswax at the foundation factories. Buying queens is also a fine way of getting disease into your bee-yard. If there is another fellow in the whole world that has less use for yellow bees than myself, I would like very much to know it. If I have ever had any disease in my bee-yard, I do not know it. I am well pleased with brown bees. They swarm less, are good super-workers, and make plump, white combs, and stand the cold best.

I wish to offer a little criticism on what is found on page 108, where Mr. Doolittle says it is all a myth that bees in normal condition do not freeze to death. It is just the reverse, if you please. Those Northern losses are all caused by cold weather, and if those losers will try again with common bees they will succeed all right.

As to bees injuring grapes, they do not. Neither do the birds, but it is the change in the atmosphere that breaks the rind of apples and the skin of grapes; a sort of second-growth. Certain varieties are worse than others. Mr. A. I. Root, of Ohio, some 20 years ago, screened in a grape-vine and so reported; at least it was in Gleanings that I saw it.

As I have taken 3 swarms of bees out of the walls of dwelling-houses, I would like to know how those house-keepers are making it go. My next experimenting will be with little houses, keeping the bees in them in winter and summer.

The good "old reliable" American Bee Journal comes to my office as regularly as clock-work. Surely, it is a fine Journal. Long may it live! **KARL J. LOHMANN.**  
Clinton Co., Mo., Feb. 18.

[We are afraid Mr. Lohmann would find it rather difficult to prove that chemicals used in clarifying beeswax cause dead or diseased brood.—EDITOR]

## Expects More Spring Dwindling

Bees had a fair flight here March 3d. I have not lost any colonies, though a few are more or less affected with dysentery. I look for more spring dwindling here than usual.  
Norwich, Conn. **ALLEN LATHAM.**

**A Correction.**—In the item on page 165, in "Calcium Chloride in the Bee-Cellar," by Allen Latham, in speaking of the bees' need of fresh air, he should be made to say, "Their need of fresh air is *not* like our need of fresh air—that is, plenty of oxygen." Such statement harmonizes better with the rest of the item. Mr. Latham is experimenting this winter still further, and finds that bees need almost no fresh air, provided the moisture is taken care of.

## CONVENTION NOTICES.

**Texas.**—The Northern Texas Bee-Keepers' Association will hold its annual meeting at Ladonia, Tex., on April 3 and 4, 1907. All bee-keepers are invited to attend. No hotel bills to pay. **W. H. WHITE, Sec.**  
Blossom, Tex.

**Michigan.**—The Northern Michigan Bee-Keepers' Association will hold its next annual convention at East Jordan, Mich., on April 10 and 11, 1907. Headquarters will be at the Russell House, where a \$1.00 per day rate has been secured. **IRA D. BARTLETT, Sec.**

## Something New = The Ideal Hive-Tool

Bee-keepers have long needed a special Tool to work among the hives during the bee-season. The one shown here was invented by Wm. Muench, a Minnesota bee-keeper, some years ago, but it was not on the market before. We have lately bought this Tool, and all rights, from Mr. Muench's widow, and have had the first lot made. They are ready for delivery now.

Best Hive-Tool

Only 30c, by mail

(This picture is exactly one-half the size.)

**DESCRIPTION.**—The Ideal Hive-Tool is made of high-grade malleable iron, much like wrought iron, 8 3/4 inches long. The middle part is 1 1/16 inches wide and 7-32 thick. The smaller end is 1 3/4 inches long, 1/2 inch wide, and 7-32 thick, ending like a screw-driver. The larger end is wedge-shaped, having a sharp semi-circular edge, making it almost perfect for prying up covers, supers, etc., as it does not mar the wood.

### What Dr. Miller and Miss Wilson Say of It:

In the first edition (1903) of Dr. Miller's "Forty Years Among the Bees," page 58, he says: "Of all the hive-tools I have tried, I like best the Muench tool." On Jan. 7, 1907, he wrote us saying he thought "just as much of the tool as ever."

Miss Wilson, Dr. Miller's assistant, says this of the Ideal Hive-Tool: "It is an ideal tool. In fact, I don't see how it could be improved upon. I am sure we would feel utterly lost in the apiary without it. . . . You will have to try one yourself if you want to know its worth."

### The "Ideal Hive-Tool" Free as a Premium.

We will mail an **Ideal Hive-Tool FREE** as a premium to any present paid-in-advance subscriber to the American Bee Journal, for sending us **ONE NEW** subscription for a year at \$1.00; or we will send the American Bee Journal one year and the **Ideal Hive-Tool**—both for \$1.20. Price of the **Ideal Hive-Tool** alone, postpaid, 30 cents. Address,

JAMESTOWN, N. Y.

[Established 25 years.]

## Honey and Beeswax

**CHICAGO, Feb. 1.**—The usual late winter demand is in evidence for comb honey to replace diminished stock laid in during the autumn by the large retailers, but during the dull period there has been very little change, if any, in prices, the offerings being light.

We find No. 1 to fancy white comb honey brings 15@16c, and for that which is off in color and flavor from 1@3c less. Amber grades of all kinds are dull and range in price from 10@12c. The extracted perhaps is not quite so firm in price for the California or Western grades, but there is no surplus of white clover or basswood, both of which bring about 8c, and in some cases more. Ambers grade from 6@7½c. There have been some sales of beeswax at 32c, but 30c is about the price for average.  
R. A. BURNETT & CO.

**PHILADELPHIA, Nov. 8.**—While the supply of comb honey is equal to the demand, large quantities of comb honey having arrived in the market in the last few days, the price still remains high. The outlook, however, is that when the season advances and the bee-keepers ship more of their crop to the market, the prices will be a little weaker. We quote: Fancy white comb honey, 16@18c; No. 1, 14@15c; amber, 11@13c. Fancy white extracted, 7½@8¼c; light amber, 6½@7c.

We are producers of honey and do not handle on commission.  
W. M. A. SELSER.

**NEW YORK, Jan. 15.**—The stock of white comb honey is pretty well exhausted, and we do not expect any more arrivals of large lots from now on. Prices are firm, and we quote from 15@16c for fancy white; 13@14c for No. 1; 12c for light amber. There is quite a little dark and buckwheat on the market, but no overstock, and we think that all of it will be disposed of before long at present prices, which we quote from 10@12c, according to quality. Extracted honey very firm, with sufficient supply to meet demand. California white sage is bringing from 8@8½c; light amber, 7½c; amber, 6½@7c; buckwheat extracted in fairly good demand at 6@6½c. Southern in barrels finds ready sale at from 55@70c per gallon, according to quality. Beeswax firm and steady at 31c.  
HILDRETH & SKOELKEN.

**DENVER, Feb. 14.**—Producers in this State are practically closed out of both comb and ex-

tracted honey. We have not sufficient good comb honey to supply our local trade, but have a good supply of white extracted of excellent quality. We quote strictly No. 1 white comb honey, per case of 24 sections, at \$3.20; No. 1, light amber, \$3; and good No. 2, \$2.80. White extracted, 8@8½c per pound; light amber, 7½@8c. Clean, yellow beeswax, 27@28c, delivered here.

THE COLO. HONEY-PRODUCERS' ASSN.

**CINCINNATI, Feb. 9.**—The demand for extracted amber honey has brightened in the past 3 weeks. Amber honey in barrels at 6¼@7½c, according to the quality and the quantity purchased. Fancy white extracted honey selling at 8@9c in cans. Comb honey is a drag on the market, fancy selling at 14@16c. Beeswax, 32c. for choice grade. THE FRED W. MUTH CO.

**INDIANAPOLIS, Feb. 25.**—comb honey is not plentiful, but demand is slack. Fancy white comb brings 16@17c; No. 1 white, 14c; amber, 12@13c. Best grades of extracted honey bring 8@9c; amber, 6@7c. Good average beeswax sells here at \$35 per 100 pounds.

WALTER S. POWDER.

**TOLEDO, Nov. 30.**—The market on comb honey remains about the same as last quotations, but has been coming in much more freely, as bee-keepers seem to be very anxious to get rid of their stock. Fancy brings in a retail way 16c; extra fancy, 17c; No. 1, 15c; buckwheat, 15c. Extracted white clover in barrels brings 7@7½c; cans the same. Beeswax, 26@28c.

THE GRIGGS BROS. & NICHOLS CO.

**CINCINNATI, March 6.**—The market on comb honey has been quite brisk the past week. Entirely sold out of fancy white. No. 2 is selling for 12½@13c. White clover extracted in cans, 9c; amber in barrels, 6c. Beeswax, 30c, delivered here.  
C. H. W. WEBER.

**KANSAS CITY, Mar. 4.**—The demand for comb honey is only fair at present. The market is almost entirely bare of extracted honey. We quote: No. 1 white comb, 24-sec. cases, \$3.10 to \$3.25; No. 2, \$2.50 to \$2.75. Extracted honey, white, per pound, 8@10c; amber, 8c. Beeswax, per pound, 25@27c.  
C. C. CLEMONS & CO.

## SOLID GOLDEN QUEENS

GEORGE W. YORK, Editor

CHICAGO, ILL., MARCH 21, 1907

Vol. XLVII—No. 12

### Swarm Leaving Colony Hopelessly Queenless

The following question and answer are taken from the report of the Ontario convention in the Canadian Bee Journal:

Q.—Will a colony cast an afterwarm with the last queen leaving the parent colony hopelessly queenless?

Mr. Alpaugh—I would say, Yes, once in a while, but not very frequently. I have had them do such a thing several times in my time. I have returned them 4 or 5 times with the young queen back into a colony, and they came out, and they had no queen left, and yet the queen would go out with the swarm. I put her back, and she would do that time after time. I do not know the reason.

### Plan of Giving Sections

D. M. M., in the British Bee Journal, gives this as the plan he followed in giving to the bees supers of sections, or "racks," as he calls them:

All racks were given above the others, rather before there was any clamant need, but these were placed below when taken possession of by the bees, and the nearly-full ones raised above to seal. At the same operation an empty rack was placed above all the others to act as a cooler.

That differs at least a little from the usual practise, and is worth considering.

### Mr. Cowan on Names of Brood-Diseases

In the British Bee Journal, an editorial evidently written by Thos. Wm. Cowan—a man whose word counts for much in regard to brood-diseases—commenting upon the pamphlet, "The Brood-Diseases of Bees," by Dr. E. F. Phillips, takes issue with some of its conclusions in the following words:

That there are two forms of foul brood, a mild and a virulent one, has long been ad-

mitted, but we are certainly not yet prepared to allow that these differ from American foul brood upon the slender evidence adduced. The symptoms and characteristics of American foul brood, as described by Dr. Phillips, correspond with those of foul brood as we have it here, and such as we found in the United States when we first visited the apiaries at Medina, in 1887. We have since that time had the opportunity of seeing specimens of foul brood in the States and Canada, and in every case the symptoms were similar. Slight variations occur, but there was always the distinctive ropiness and unpleasant odor which can be compared to bad glue. We have also seen many specimens from different parts of Europe and Africa always with the same characteristics.

Our first acquaintance with black brood, or "New York bee-disease," as it was at that time called, was made some years ago in California. This was sent from New York State by Mr. West, a State bee-inspector, and on examining it we at once saw that it differed from what we called foul brood, for, although the outward appearance of the comb was similar, the distinctive ropiness and odor were absent. Notwithstanding that our experience with foul brood was pretty extensive, and dated back for more than 35 years, this was the first time we had come in contact with black brood. It was entirely unknown to us except from descriptions in the journals, and not a single sample had been sent to the British Bee Journal office for diagnosis. Last year, however, we began receiving from time to time specimens of dead brood differing in a marked degree from any we had previously seen in this country, and which corresponded in nearly every particular with the description given of black brood, and they at once reminded us of that we saw in California.

Black brood is of quite recent occurrence here, and we naturally hesitate to accept the statement defining it as "European foul brood," or the assertion of Dr. White, that it is caused by *Bacillus alvei*. To say the least, it is quite possible that Dr. White has made a mistake, just as others have done, and has cultivated one of the numerous saprophytic bacteria found in bees. It appears to us that the most important test has been omitted, and until that has been made successfully our judgment must be suspended. The test

we allude to is to prove that the disease can be reproduced in healthy brood from a pure culture of Dr. White's *Bacillus larvæ*, showing the characteristic symptoms of foul brood—that is, the ropiness and odor. We know that this was done by Mr. Cheshire with *Bacillus alvei*, but we can not see that Dr. White has hitherto been able to reproduce the disease with his microbe. Until this has been done the investigations and the conclusions arrived at are of little value so far as solving the question is concerned.

### In Case of Losing All of One's Bees

A reading of the following letter can not fail to arouse sympathy, while raising the question whether our correspondent is making the wisest stand:

GEORGE W. YORK & Co.—I am sorry to say that I will have to ask you to discontinue sending my copy of the American Bee Journal. I have been among bees here and in England on and off for the last 40 years, but never ran up against anything in the bee-line as I have the last 4 years. Once in a while you can not take the honey away fast enough here, but the last 2 years bees have not produced enough to live on.

Two years ago I knew of 250 colonies within a radius of 5 miles of my place, and to-day I can not count 25. I know of two friends who had 20 and 31 colonies; to-day they have none, like myself; so if that is not discouraging, what is?

I got in enough supplies after our big crop, 3 years ago, to carry me through another such a season, and to-day I have the same supplies on hand and not a single bee, but 50 empty hives. If I ever get hold of another colony I will surely subscribe again for the American Bee Journal, for no man with one colony should be without it.

JNO. T. PAINTER.

P. S.—I know you will say I get discouraged too easily. Well, since 1885 or 1886, when we all, around here (the late Mr. Clute included), got barrels of honey, I have known only one good year, and that was in 1904; and that is the average, I find, for around here for good crops.

J. T. P.

There are bee-keepers who accept with complacency a disastrous year, if indeed they do not rejoice over it. And not without reason, for your experienced bee-keeper will tell you: "Even if I should lose every colony I have I don't know but I would gain by it in the long run. For it will drive out of the business some of those slouchy bee-owners who can hardly be called bee-keepers, and when they're out of the way I'll get enough more for my money to make up for the loss."

All this aside, let us consider what is the

# American Bee Journal

wise thing to do when some circumstance, or combination of circumstances, happens to leave beelless a man who has previously had reasonable success at the business.

Let us put the case in a very simple, concrete form. Suppose a bee-keeper has a varied flora of such limited amount that the bees get enough from different sources to give them a good support, but from nothing do they store any surplus for their owner except from the single source—basswood. Now, suppose the demand for that sort of timber has made a clean sweep, and not a basswood tree is left. It is not even necessary to suppose that he has lost his bees, for what good are bees if they yield no surplus? What is the wise thing to be done?

If the bee-keeper be running a large farm successfully, with 10 or 20 colonies of bees as a very subordinate interest, the matter is very simple; the bees can go, and he can do very well without them, unless it be that he can replace the basswood by alfalfa, sweet clover, or some other crop that is profitable aside from its honey.

Suppose, however, that our bee-keeper is a very successful specialist, all other interests being subsidiary to bee-keeping. Loss of pasture simply means loss of location, and he will at once seek another field.

But these are unusual cases. Let us take a more common case, that of our correspondent, which is not unlike what many, many others have experienced. Seasons have been discouraging, and now that he finds himself without bees it is a good time to quit. Rather, he has quit, and the question is whether he shall stay quit. As factors in the problem we have a stock of hives, probably supplied with combs, supplies enough for a good crop, and the experience gained from keeping bees 20 years or more. The problem is to decide whether these are all to be thrown away, or to be continued in use by the investment of enough money to purchase one or more colonies for a fresh start.

The decision depends upon what may be considered the reasonable expectation for the next year and succeeding years. If there are to be no more good years, better stay quit. The fact that 2 or 3 years ago there was a good year shows that the sources are not cut off, but that the freaky thing we call "weather," or some other thing that we do not understand, has caused a dearth in spite of the possible presence of bloom in abundance during many of the past 20 years. No one knew in advance that 1904 would be a good year. Why is not 1907 just as likely to be good as bad? It is a rather remarkable thing that so many years in succession should be bad. It would be still more remarkable if the next 20 years should be similar, and so why may not the next 20 be just as good as the past 20 were bad? Then, too, it must be remembered that within the past 2 years nine-tenths of the bees have been wiped out; practically giving 10 times the pasture there was 2 years ago. Given the expectations that may reasonably be founded on such data, is it not the wise thing to make a fresh start, even if it be by sending hundreds of miles for a nucleus?

Now for the closely related question:

"Shall our correspondent continue taking a bee-paper?" With no bees there is no need of one, although there may be a few with such interest as to continue reading one although never expecting to keep bees again. Our correspondent says:

"If I ever get hold of another colony I will surely subscribe again for the American Bee Journal, for no man with one colony should be without it."

You may put it down as a pretty sure thing that the man that talks in that kind of way is not going to be satisfied till he "gets hold of

another colony." Self-interest at this end of the line would naturally incline to the opinion that in the interim he should continue to take a bee-paper. But is that not really to his own interest? A dollar spent in keeping himself informed as to all the forward movements may keep him in such trim that when he does take hold again he will get back his dollar many times over in increased results. Such being the case, unless he has decided in the most positive manner that he will never keep bees more, is he wise to allow his favorite paper to lapse for a single week?

**Mr. Robert B. Ross, Jr.**, of Montreal, Canada, was a caller at this office recently when on his way home from a business trip to British Columbia. Mr. Ross keeps a dozen colonies of bees, more for recreation and study than for the financial profit derived from them. He is a very pleasant gentleman to meet, and is intensely devoted to the study of the bee.

**The National Association**, on March 11, had 2271 members. So it is still growing. The 2500 mark should be reached very soon.

**General Manager France** has been busy lately helping the bee-keepers of several States to get laws on bee-diseases. This is a good work, and perhaps no other organization can help as much along that line as can the National. We hope that before many more years pass, every State will have on its statute books such laws as may be necessary to stamp out at least the principal bee-diseases.

**The Washington State Convention** of bee-keepers was held at North Yakima, Feb. 4, 1907. The following officers were elected: President, Isaac Hays; Vice-President, Hans Mumm; Secretary, Virgil Sires, of North Yakima; and Treasurer, August W. Sipp. Vice-presidents for each county of the State of Washington will be voted for at the next meeting.

We are informed that there are two Bills now before the Washington State Legislature, one for the appointment of a State Inspector of Apiaries, and another to amend the foul brood law which was passed 2 years ago.

**The Griggs Bros. & Nichols Co.'s Apiary** appears in the picture on the first page. They are successors to Griggs Bros. The Company was incorporated in October, 1906, with a capital stock of \$15,000. The incorporators were S. J. Griggs, D. D. Griggs, J. R. Griggs, W. R. Nichols, and F. W. Neithart. It seems the business of Griggs Bros. had increased to such an extent the last

few years that the Company was incorporated for the purpose of handling the business in a satisfactory manner. The officers of the Company elected for the ensuing year were: S. J. Griggs, President, Treasurer, and Manager; D. D. Griggs, Vice-President; and W. R. Nichols, Secretary. Nearly all of the stock was promptly subscribed, being taken by some of Toledo's most influential business men.

Griggs Bros. were among our advertisers last year, and we hope that they will soon be again represented in our columns through the new concern of Griggs Bros. & Nichols Co., which, we take it, is "out to win."

**Carrying Bees Under Difficulties.**—The following has been sent us by Mr. Irving Long, of Missouri, which we reproduce for our newer readers, as we believe we published the same amusing story several years ago:

A German bee-keeper undertook to carry some of his choicest bees to a bee-show. He took a train in Hanover with his bees in a basket at his feet. The bees escaped from the basket and crawled up his trousers legs. His actions soon aroused suspicions in the hearts of two women who occupied the same compartment with him. They pulled the bell-cord and stopped the train. When the bee-fancier explained the situation he was placed in an empty compartment to have it out with the bees all by himself. Here he removed his trousers and began shaking them out of the window to free them of the swarm. Unfortunately they caught a telegraph pole and were swept away, bees, money and all. At the next station the irate station-master brought forth the reluctant bee-fancier in a rug and he pawed his watch to acquire decent raiment to walk back along the line in search of his bees and his trousers.

**The Apiary of Geo. H. Adkins**, and also his home, are shown on the first page. He sent us the following description under date of Feb. 25:

**EDITOR YORK:**—The photograph shows my home and part of my apiary, located within 2 miles of where Ethan Allen demanded the surrender of Fort Ticonderoga.

As I am writing, our part of the country is covered with snow, and the weather at zero.

I have kept bees for 16 years, and have been a subscriber to the American Bee Journal for that length of time. I would not be without it if I did not have over 5 colonies of bees.

In the spring of 1906 I had 30 colonies, which were increased to 50, and I got 1700 pounds of honey, which brought me \$225.

After returning from the National convention at San Antonio, Tex., last November, I bought 24 colonies of bees, which makes my number 74.

We are having a very cold, hard winter, and the bees have had only one flight since November, and that was on Feb. 15. I am expecting a heavy loss of bees, but I hope I will be disappointed in that regard.

The building at the right in the picture is my honey-house and work-shop, which was not completed at the time the picture was taken.

My trip to the San Antonio convention, and the meeting of my brother bee-keepers, will long be remembered; and also our stay at the Grand Central Hotel. But I feel like saying, "Home, Sweet Home;" no place like home and contentment. I hope to meet my brother bee-keepers some time in the future, in convention, that will be as friendly and as hospitable as were our Southern bee-brethren at San Antonio. GEO. H. ADKINS.

#### Advertising in the Bee Journal.—

We have received the following from Walter S. Pouder, of Indianapolis, Ind., which should be of interest to advertisers and those who ought to advertise:

FRIEND YORK:—Six weeks ago I believed that I was overstocked on extracted honey. I placed a honey advertisement in the American Bee Journal, and for the past 10 days I have been refusing orders and refunding money. Surely, the readers of the American Bee Journal have confidence in its advertisers. I fear I have not enough honey left to supply my local demand till new crop arrives, and I can not replace my stock.

Truly yours, WALTER S. POWDER.

It pays not only to advertise honey in the American Bee Journal, but also bees, queens, bee-supplies, etc.—In fact, anything that bee-keepers and people in general need. You can't expect many people to patronize you unless you first let them know what you have for sale. Of course, we do not guarantee that any one can make a fortune by advertising in the American Bee Journal or in any other paper, but such advertising should help greatly, provided you have something to offer that is wanted, and also that the price is right.

"Langstroth on the Honey-Bee"—the well-known bee-book revised by the Dadants—recently passed into another edition. There have been some 75 pages added to it, and the whole work brought down to date in every respect. It is certainly a fine book, and should be read by every bee-keeper. It is really a classic. To become acquainted with the great Langstroth through the reading of his book is no small thing. Other bee-books are good, but there is only one "Langstroth on the Honey-Bee." The latest revised edition will be sold at the same price as the one preceding, which is \$1.20, postpaid. We still have a few copies of the old edition on hand, which we will mail at 90 cents each, if preferred, so long as they last. We club the new edition of this book with the American Bee Journal for one year—both for \$2.00. So long as we have any copies left of the old edition, we will send it with the American Bee Journal one year—both for \$1.80.

Conducted by J. L. BYER, Markham, Ont.

### Successful Wintering of Bees

"The bee-keeper who has not solved the wintering problem to the extent that he can winter his bees as well as he can his cows, has much yet to learn."—ALLEN LATHAM.

"For it must be said that we can not as yet bring our bees through a winter with that degree of certainty and uniformity that is possible with sheep, horses, cattle, and domestic fowls."—F. GREINER.

The two foregoing quotations are taken from the February issue of the American Bee-Keeper. Naturally, a lot of us will be curious to know who is right, and I expect, as a matter of experience, the majority will be inclined to agree with Mr. Greiner. Yet this does not prove that Mr. Latham is *wrong*, for I believe that the most of us will consent to eat humble pie to the extent that we will confess that we have "much yet to learn," whether it be about wintering or any other branch of apiculture.

But the worst of the matter is, that I fear we do not live up to the knowledge we *have* as regards wintering; in fact, there is no other part of the business that we are inclined to take so much risks in. Nearly all our text-books teach that for outdoor wintering in a cold climate, the bees should be on no more combs than the cluster can cover. No better advice could be given, yet how many put it into practise? The reason is, that in about 3 years out of 4 the bees winter fairly well without going to the trouble of contracting the hive, and that fourth year is apt, very often, to knock things out in bad shape. As we have no means of knowing when this *fourth* year will come, the only sensible conclusion is to prepare the bees every year as though we were sure of a very severe winter. Even if the hard winter doesn't come, I feel pretty sure that the extra work will be well paid for, anyway.

Then as to the matter of stores: Some seasons a lot of inferior honey is stored in the brood-nest; in fact, enough for wintering without going to the expense (?) of feeding. We remember that one year, when wintering on just such stores, over half of the colonies perished; but we also remember that one other *mild* winter the bees wintered fairly well on the same kind of food. As the season had been none too good, and, as a consequence, money none too plenty, we decided to risk the bees wintering on this inferior honey and run chances of another *mild* winter. No doubt many can speak of experiences under like conditions, when

the *mild* winter failed to materialize, and, instead, we had a very severe season.

Personally, I have never had a severe loss in wintering, yet what losses I have had might have been avoided; and I unhesitatingly say that *if* I take the necessary precautions, and do the required amount of work, that one year with another, I can winter my bees just as safely as I can the cattle and other domestic stock. There is no boast about this whatever; on the contrary, as before intimated, we feel that any bee-keeper of ordinary intelligence can do the same, provided he lives up to the knowledge he has, and, in common with your humble servant, cease taking *risks*, whether it be as to quality of stores or any other factor which we know to be a necessary adjunct towards insuring good wintering of bees.

### Making a Cover-Feeder

Since the description of my cover-feeder appeared, it has occurred to me that a great many bee-keepers who make their own supplies will decide that it is too difficult an arrangement to make by hand. The drawing showed the ends to be in one piece with grooves to receive the 2 floors of the cover. As I have a circular saw and power, I make the most of my covers in this way, but I have made some by hand which are equally as good, and which any one can make who can handle a saw and hammer.

The 2 floors are about 1 inch wider and 2½ inches longer than the hive-body. On the under side of the lower floor, at each end, is nailed a cleat 1-inch square and as long as the floor is wide. These cleats are to keep the cover securely on the hive. On the upper side of the lower floor, at each end is nailed a cleat 1 inch thick and 2

inches wide, and the same length as the lower cleat. On top of these wide cleats is nailed the upper floor, and the whole is covered with a heavy grade of felt roofing, and painted with two coats of *thick* whitelead. This roofing is cut long enough to project down over the ends, and is secured there by nails and large tin washers.

Of course, the openings in the sides

of the cover are closed in the same way as described in the cover, on page 72. There is practically no difference in the 2 covers, except the one here described has its floors separated by two 2-inch cleats on edge, while the cover described on page 72, had its ends grooved to separate the floors.

This cover has proven itself so valuable to me that I do not want the difficulty of making the first-described cover to hinder any one from giving it a trial.

H. A. SMITH.

Ontario, Canada.

## A Fire—Canadian Bee Journal Sold

The following is taken from the February issue of the Canadian Bee Journal, which was delayed as explained:

In explanation of the lateness of this issue, our readers will regret to learn that a serious fire occurred in the bee-keepers' department of the Goold, Shapley & Muir Company on the morning of Feb. 11th, which, besides the loss effected, has upset their plans and purposes very considerably. Owing to the injury done to the wood-working part of their building and plant, delays would naturally occur, which might seriously inconvenience their customers and agencies who are depending upon them for the season's supplies, and as a number of large orders are already on hand requiring immediate attention, it was decided on the part of the Company to negotiate with some reliable Canadian firm, fully equipped with wood-working machinery, for the manufacture of these goods. In consequence of this, a sale has been consummated to the Ham & Nott Company of this city, who are extensive manufacturers in the wood lines, and who have large connections throughout the country; all the Goold, Shapley & Muir Company's interests in the bee-keepers' supply business, together with the Canadian Bee Journal. The new Company will issue their circular to bee-keepers, with catalog and price-list, within the next few days, and operations will be commenced at once.

We can heartily recommend our successors, Messrs. Ham & Nott Company, to the bee-keepers of Canada, as business men of fidelity and enterprise, and who will, no doubt, make a success of this business, as they have of other lines. We desire to thank our bee-keeping friends for their patronage and confidence during these many years that we have been doing business with them, and we wish them every prosperity as the outlook for the industry increases and brightens in the Dominion.

[While regretting the loss by fire that has come to the Goold, Shapley & Muir Company, which, seemingly, has necessitated the transfer of their bee-supply business and bee-paper to the Ham & Nott Company, we wish the latter firm every success in their new undertakings.—EDITOR.]

**Why Not Advertise?**—There are many dealers in bee-supplies, and those who have bees and queens for sale, who are not now advertising, that might increase their business by advertising in the American Bee Journal. The rates charged are very low, as will be seen by referring to the second page of this number. During the next 6 months will be done the bulk of the season's business among bee-keepers. Why not begin at once to let the readers of the American Bee Journal know that you have something to sell? Our advertising columns are open only to those who will give their patrons "a square deal." If you are in that class we will be pleased to have your advertisement in our columns.

The "Old Reliable" as seen through New and Unreliable Glasses, By E. E. HASTY, Sta. B. Rural, Toledo, Ohio.

### THE HERSHISER WAX-PRESS.

So 200 pounds of remainders from the solar wax-extractor yielded in Mr. Hershiser's hands 70¼ pounds of wax. I take it, 200 pounds of old combs of the black and heavy sort, in ordinary hands, and with wash-boiler treatment, would have yielded much less than 70 pounds, possibly less than half that quantity. Mr. H. seems to be the head of the procession in wax-matters. On the whole, I guess we must vote him a benefactor. Page 88-90.

### RASPBERRY A HEAVY YIELDER.

The report of 21 pounds in one day from raspberry, as made by S. D. Chapman, is rather surprising—at least to me. I thought that nothing but basswood ran up to figures like that. Page 91.

### NON-SWARMING HIVES.

We would put a low estimate on the man who could not get enthusiastic over his own baby. Let's try and remember that while taking stock of Mr. Aspinwall and his hive. Always more than twice the surplus, as tested with common hives having the same number of frames. Just think of getting non-swarming and such a bonus as that thrown in! He thinks the queen's free access to every part of the hive is needed for a non-swarmers. I guess, perhaps, he is right about that. (Yet Bingham, on page 96, thinks just the contrary.) So Mr. A. dispenses with queen-excluders; and in hives where the combs are well spread out with spacers the queen keeps down without them. But pollen in the sections bothered him; and he keeps that out by filling the sections with foundation of drone size. Page 92.

### RESPIRATION OF PLANTS AND BEES.

I believe the fact that plants in the daytime take in carbon and pour out oxygen, while at night they do just the opposite thing, used to be considered a pretty high-class scientific puzzle. With Prof. Cook's lucid statements it scarcely even looks like a puzzle. Nutrition causes carbon to be taken in; and respiration causes carbon to be sent out. Nutrition can not go on except with sunlight. Respiration goes on all the time, but handles less carbon than nutrition does when that is in full blast.

The reason why bees and other insects do not have red oxide of iron in their blood is also lucid. In animals

it is needed as a carrier of oxygen; while in insects the air itself is piped all over the body, and no carrier of oxygen is needed.

Sounds strange to hear that a bee's heart has no arteries or veins attached to it. Just one long valved tube to take the blood from the tail and carry it to the head—and let it percolate back again as best it may. Curious that so crude and unsatisfactory looking a circulatory system should be found in company with a respiratory system so complex and well-looking. Page 107.

### SOME INEXCUSABLE ERRORS.

In my corner, on page 95, some bumbles worry me: Not "brood-frames," but *brood*-frames hold my sections; and wood surface was not "punctured," but punctuated with dabs of propolis. The former error is so frequent a one that some brother has said we should always say "wide frames." A mirth-provoking error of the same class occurs on page 108, where Mr. Gallup's bees were ventilated through a 2-inch "pole," in lieu of a 2-inch hole.

### BEES THAT "KNOW BEANS."

That beans yield abundance of honey of excellent color and quality in California and rather seldom attract a single bee in the eastern half of the continent, is one of those problems not easy to solve. That the more cosmopolitan bees of the Pacific Coast "know beans" while ours do not—well, we do not take very kindly to that solution. Page 107.

### A COLD EXPERIMENT.

To give 16-degree-below-zero weather free access into a hive at both top and bottom all night is a pretty savage sort of experiment. We are glad to learn, however, that the same colony stored honey all right the next summer. Nevertheless, young brother, don't you travel on that revelation very much. Just make your bees for winter as warm and snug as ever you can. Page 108.

**Our Wood Binder** (or Holder) is made to take all the copies of the American Bee Journal for a year. It is sent by mail for 20 cents. Full directions accompany. The Bee Journals can be inserted as soon as they are received, and thus preserved for future reference. Or we will send it with the American Bee Journal a year—both for \$1.10. Address office of the American Bee Journal.

### No. 1.—Feeding and Feeders —Spring Feeding

BY C. P. DADANT.

During the past season a great many bees have been short of stores, owing to the scanty honey crop. Many colonies were fed for winter, but many more will need feeding during the spring. It must be borne in mind that there is about as much honey consumed after the real cold weather has passed, as is consumed during the hardest of winter, because the bees must spend a great deal to rear brood at a time when the yield from the fields is next to nothing. It is also known that when the bees are wintered in the cellar, they consume even more honey afterwards, because there is no breeding, or very little breeding, in the cellar.

In addition to feeding for the necessary support of the colony in years of scarcity, many people also feed bees in small amounts to induce breeding, in the spring, even if they are not short of stores. It has been stated somewhere lately, that if bees are fed sugar syrup when they are not destitute, they will store a portion of this feed in the supers, and thus run the risk of furnishing spurious honey. Such an occurrence can not take place, for two or three reasons. First, no one should leave the supers on the hive during the fall, winter or spring. If the supers are left on at any other than the time of the crop, they will become soiled by the travel of the bees; they will be glued up with a large amount of propolis which the bees gather in quantity during the months of dearth and fair weather; and in the winter the supers will prevent the bees from concentrating the heat in the brood-nest. In all my bee-keeping experience, I have never committed the blunder of leaving the supers on the hives after the honey crop. Neither should these supers be put on the hive until the crop is at hand, when there is no need of feeding.

Feeding bees in such an amount as would induce them to put honey, or some of the feed, into the supers, would be inadvisable and unprofitable. As long as such amounts of food are given as will induce them to increase their breeding previous to the honey crop, there is a profit in it, because the bee-keeper is then like the wise general who sees to it that his regiments are complete before he marches them to battle. But if an overdose is given, the bees will begin to produce comb from the food given, and, in that case, since it takes no less than 7 to 10 pounds, and perhaps more, of honey to produce one pound

of comb, we will soon find out that there is a loss in overfeeding. In addition, if we overdo the feeding, the cells that should be used for brood may be filled with the honey, and the queen may be cramped for want of room to deposit her eggs. So feeding to induce breeding must be done with a great deal of circumspection.

Yet, there is no doubt that stimulative feeding is advantageous, especially if it is done at a time the bees have only sealed honey left, in moderate quantity. The honey which has been preserved through the winter is thick, and in order to dilute it properly to prepare the larval food, the bees are compelled to go to the nearest water and bring a quantity of this water to the hive. All bee-keepers have seen the bees pumping water from troughs, around wells, or from marshy places, in spring. They will go out on a very cold day, when it is hardly warm enough for them to fly about, and will bring some of this cold water to the hive. It is evidently used to dilute the too-thick honey, for just as soon as nectar is found in the flowers we see a decrease in the number of bees around the horse-troughs. When the crop is well on, this water-transportation ceases nearly altogether, to be taken up again as soon as the crop ceases. The nectar of the flowers is usually sufficiently thin to make good larval food without the addition of water.

Now, many of our practical apiarists save their bees the trouble of transporting this cold water, by giving them a small amount of sufficiently liquid food to fill the requirements. This food is warm when given. Just think of the difference between having to go out in the cold to get water—cold water—and finding this water in the hive, warm and sweet enough to serve the purposes for which it is intended!

Yet the practice of feeding for the stimulation of breeding is not generally followed, and is opposed by some noted bee-keepers. This is because it requires a great deal of care and attention, and in some instances it is overdone. But whether we wish to feed to stimulate breeding or simply to keep the colony from starvation, the fact remains, that feeding is often necessary. Warm food a little thinner than would be given in the fall, and in smaller amounts, is needed in spring feeding. As to the nature of the food, I think diluted granulated sugar is the best—even better than honey—because it has less odor, and is less apt to cause robbing. We must remember that the bees have excellent olfactory organs, that the least odor is noticed by them. But they are

most attracted by the odor of the product they consume—honey—as well as by the odors of the hive, the smell of old combs, the odor of the queen, etc. So it is of some importance to give them food which does not attract the neighbors, for the colonies which need the most nourishment are often the least powerful and would be the most easily robbed. On the other hand, if inexperienced people think that by feeding sugar syrup in spring we run risk of causing adulteration, they may easily be undeceived. The food given by a careful bee-keeper will all be used up before the beginning of the crop. Otherwise he would have an unprofitable account on his hands. If he is in doubt as to what he should do, let him only supply the bees in their needs.

After this preliminary statement concerning spring feeding, I will take into consideration the feeders in use, and their qualities and defects, for no feeder has yet been devised which is exempt from defects.

Hamilton, Ill.

### Effect of the Pure Food Law on Honey

BY W. W. MCNEAL.

The National Pure Food Law may not mean so much to honey-producers, after all, unless it is sufficient to save them from their own follies. The adulteration of honey is a most culpable act, no matter how it is done. But the demand for honey will not be increased materially, nor the price advanced, simply by curtailing the traffic in glucose. It is commonly believed by consumers that pure honey will not granulate, and since glucose retards the natural tendency of honey to candy, it follows, as a matter of fact, that a compound of that kind will be looked upon with better favor than any article which shows a disposition to granulate. The fight for renewed integrity and better prices must be waged more particularly against adulteration with cane-sugar. While the standard of conduct bee-keepers hang up for themselves continues to look bad under the lime-light, the public will not take kindly to anything that may be said about pure honey granulating. Honey-producers should study their occupation more from the standpoint of the consumer; should see themselves as others see them.

The time has fully arrived for the introduction of extracted honey in the granulated form. But it will require something more than the persuasive influence of a new law to convince an incredulous public that some of the lies told about manufactured honey are not true. What does it avail one under present conditions to produce a gilt-edge article when such exceeding taste only serves to confirm the belief of the consumer that it was really manufactured? It is lamentable that such a state of affairs exists; and, moreover, that it should foster slovenly habits in the preparation of honey for market. But it need not be so if the fraternity will act in concert for the betterment of these conditions.

The education of the people to the true nature of honey is most essential at the present time, and, like charity, it should begin at home. Every one who is familiar with honey knows very well that nearly all kinds of pure honey will granulate sooner or later. No real benefit can be derived from trying to devise means to prevent it, while such means only tends to keep alive the old delusion that pure honey never granulates. If every owner of bees in this country would convert a few of the most skeptically inclined among his acquaintances, by practical demonstration in the apiary during the season of 1907, and send them out as eye-witnesses to the methods employed in the production of honest honey, there would soon be a reversal of public opinion in regard to manufactured honey.

There can be no substantial rise in the price of honey so long as the consumer believes it to be largely composed of granulated sugar. He has access to the same source, and granulated sugar makes a fine syrup for table use. He may be expected to exercise the same business judgment in the purchase of sweets as in other things, and the cheaper article will be substituted for daily consumption, and honey only for "state" occasions.

Extracted honey has been regarded with even blacker suspicions than comb honey, for it granulates more readily, and can be adulterated more easily with glucose.

I think adulteration with sugar is more often practiced in the production of comb honey, for its identity is almost entirely lost when blended with pure nectar by the bees while engaged in the process of comb-building. Its identity may be lost in so far as ordinary means of detection go. But a wrong committed cannot be justified by art in the practice of deception. Chemical analysis, if it counts for anything, should be able to tear away the gilded mask and reveal the act in all its ugliness.

I cannot see the fairness in selling comb honey by the piece, or by the case, while extracted honey must be sold by weight. Neither can I see why the latter should be labeled according to the nature of the contents, while anything stored in honey-comb is not subject to the same rule or law. There should be equity in all cases. The consumer who buys comb honey is entitled to 16 ounces to the pound, just the same as when he buys extracted. Those who insist on the right to discriminate when they have comb honey to sell, should be willing to be governed in like manner when purchasing their own table supplies. But it seldom proves that way. No cat-in-the-bag business "goes" with them when the farmer brings butter, or the grocery-man coffee and sugar. It's a poor rule that won't work both ways.

Confidence in one's integrity or veracity is more potent than law in building up a honey market. That which instills confidence of the right sort is not the legitimate fruit of civil law. The people want better reasons for their faith in humanity than laws of their own making. There have been good

laws on the statute books saying "Thou shalt not," ever since our ablest men were little boys, "and then some;" yet people lock their doors just the same, and take no man's word for anything where money is involved. Law is all right in a way, but the power that causes one to do right for right's sake emanates from a source beyond the jurisdiction of civil law. The old, old admonition to do unto others as we would wish to be done by, is a mighty safe rule to follow in all temporal affairs, including the honey-business. But we must advertise and let people know who we are, and what we are. No pains should be spared to enlighten the purchaser in regard to the different colors and flavors of honey, and, above all, its tendency to granulate. If he is allowed to go on his way with no word of explanation, either verbal or by the printed page, he is almost sure to gather wrong impressions, and say damaging things about honey.

Legislation for the restoration of confidence and better prices must in very truth put a ban on sugar as well as glucose. Here is hoping for pure honey and a general toning up in the demand for it. We don't need better prices, for the consumer is already chafing under the burden of high prices. What can we hope for by pushing the price up still higher?

Wheelersburg, Ohio.

## Putting Bees Out of the Cellar

BY G. M. DOOLITTLE.

I see by the bee-papers that bee-keepers have trouble with their bees mixing when setting them from the cellar in early spring. And this is not confined to the novice alone, for I see some of our oldest and most practical apiarists report that through an east wind or hot weather when setting the bees out, some of the colonies become strong beyond measure, and others correspondingly weak, through the bees "drifting" over certain parts of the apiary, or congregating more thickly in certain places than others, until half of the hives are far too populous for the best welfare of both the bees and their keeper; while other colonies become so weak from this loss of bees, that they are unprofitable entirely, unless there is a late flow of honey from fall flowers.

To overcome such mixing of bees on their first flight in spring, various plans have been proposed, such as setting the bees out at night, putting each colony on the stand it occupied before, etc. The putting-out-at-night plan is extremely risky, for we cannot tell with any assurance but what the weather may become so cold by morning that the bees can not fly, and should it continue so for any length of time, as frequently happens, the bees suffer much more than they would had they not been disturbed. And as to putting each colony on the same stand it occupied the preceding season, we more often than otherwise do not want to do it. Those who are familiar with bees know that the young bees, when it comes out

of the hive for the first time, marks its location by turning its head toward the hive upon taking wing, when it commences flying in front of the hive in circles, each circle growing larger as it goes further from the hive, until it is lost from sight. In this way the exact spot of "home" is located, after which no more precaution needs be taken, for it seems to remember ever after where home is. For this reason it leaves its hive on all subsequent times in a direct line of flight, never looking at the hive at all, so that if the hive is afterward carried to a new location the older bees do not seem to know it (unless carried two or more miles away), but sally forth only to return to the exact spot where they first marked their home, there to die a homeless wanderer, unless there are other hives near at hand which will admit their entrance.

Now, while as a rule, this is true, no matter whether the hive is moved at night or in the day time, yet I find that there are two exceptions, one of which is in case of a swarm, and the other is the first flight in spring. While the bees always seem to know where their old location was, so that the swarm, or bees in the spring, can return if they so desire, still a swarm does not so desire except from loss of the queen, nor do bees in spring, if set out in the following manner:

As soon as the hive is brought outside of the cellar door, close the entrance with a wet cotton-cloth, one sufficiently large so it will tuck snugly all about so as to leave no holes through which the bees can see the light. In this way the bees are securely shut in the hive, for there is nothing that a bee dislikes to crowd by more than a cloth saturated with cold water. By having a lighted smoker both at the cellar door, and at the stand we wish the colony to occupy, we are ready to advance our aims further. As soon as the wet cloth is snugly over the entrance, turn back one corner of the wet cloth and blow in smoke till a loud hum greets your ears, when you are ready to carry the hive to its stand. Now put a clean, sweet bottom-board on the stand the colony is to occupy during the season, when you will turn back a corner of the wet cloth again and blow in about the same amount of smoke that you did at the entrance of the cellar, tucking back the wet cloth again, when you will proceed to loosen the bottom-board from the hive by prying out the crate-staples, or whatever fastened it to the hive, when the hive is set on the clean bottom-board and the entrance adjusted to the amount you wish for early spring.

The bottom-board the hive was on all winter is now cleaned and placed on the next stand, when you are ready to get and treat the next colony and all future colonies brought from the cellar in the same way. By this plan the bees do not rush out pell-mell, as they are likely to do in the usual way of setting out, but come out more slowly, as do those of a swarm in marking their location, or as do the bees from a colony which has been wintered out doors, when they take their first flight in spring.

Who ever heard of colonies mixing

on their first flight when they were wintered out on the summer stands? They do not do so to any amount. It is the using of no precaution, but allowing the bees to rush out from their hives when in an aroused condition, brought about by the setting from the cellar, which causes them to stampede out of their hives *en masse*, so that they hardly know where they are, and thus when they come to wish to go back home they go where the most noise is made, or where the wind drifts them, and thus we have one part of the hives overloaded with bees and the others nearly ruined from the loss of bees which have stampeded where they did not belong.

By using smoke as I have given above, the bees are more slow to leave the hive, if anything, than under any other condition, and I have had no trouble since I adopted this plan. And this is especially applicable to the out-apiary. In the home-yard we can set the bees out during several days, as many each day as we desire, or adopt almost any plan that we may choose; but when we travel miles to an out-apiary, we wish a plan that will allow of our setting out the bees on *that* day, and just *when* we are there, setting all out at once, just as fast as we can carry them out.

And after using the plan as above given for six years, with perfect success, I can assure the reader that in it we have something which is of great value, especially for an out-apiary, where the bees are wintered in the cellar there, or in a pit or clamp, as the case may be.

Borodino, N. Y.

## The Behavior of Swarms

BY ADRIAN GETAZ.

In a previous contribution, I stated that the Societe des Apiculteurs du Department de la Meuse had sent its members a series of questions concerning the swarming of bees. The first 21 questions were about the conditions that provoke the bees to swarm. The following questions were in regard to the behavior of the swarms after issuing. These are the subject of this contribution.

### RETURNING TO THE HIVE.

About 2 percent of the swarms issuing return to the parent hive almost immediately after issuing. Several reasons may induce a swarm to return, but the failure of the queen to accompany the swarm is undoubtedly the most common. A swarm that returns is liable to issue again either the same day or the following day. Out of 5 swarms that return, one on an average does not swarm again. In such cases there has been a fight among the queens in the hive and one or more can be found dead in front of the hive. The dead queens or bees are never carried more than 4 or 5 feet from the entrance.

### DISTANCE AT WHICH A SWARM SETTLES.

Out of 100 swarms issuing with laying queens, 12 will settle at less than 15 feet away; 34 between 15 and 30 feet; 23 between 30 and 45 feet; 21 between

45 and 60 feet; 7 between 60 and 90 feet; and 3 between 90 and 200 feet.

As to swarms with virgin queens, they may go anywhere, even a mile or two before settling.

The next question was in regard to where the swarms settle in preference, whether on trees, on the ground, or in empty hives. Unfortunately, the printers left it out in the blanks sent, so it is not answered. But the one following immediately, and asking how high from the ground the swarms settle (except those settling on the ground) brought out the fact that half of the swarms settle at a height of 3 to 6 feet, and a fourth between 6 and 12 feet above the ground, the remaining fourth higher or lower.

### FORM OF THE SWARMS.

Not considering those that settle on the ground, about 70 percent in settling assume the regular shape so often described; the others assume irregular forms.

### DIRECTION OF THE FLIGHT.

The direction taken by the swarms depends chiefly upon the position of the hives in regard to the bees, walls, etc., that may be about them. The information given is very indefinite. It seems that the majority of them go right straight from the hives. The figures given seem to show, nevertheless, a tendency to turn toward the sun, that is, toward the east in the morning and toward the south in the middle of the day.

### COMMENTS.

In considering the above, and drawing conclusions, the conditions under which the observations have been made must be taken into consideration. The majority of the European apiaries are small and usually established in an orchard or a garden. These are ordinarily enclosed by a wall or a tight fence or a hedge. Outside there is often nothing but the open fields, with no kind of settling place at all. The hives, instead of being scattered, are, in most cases, placed close together, sometimes 2 and 3 rows one above the other upon shelves, a roof on the whole, and a wall behind, leaving a passage between the shelves and the wall. Often there is a special wall, the one enclosing the garden or orchard taking its place. The "rucher," as such an apiary is called, is placed against the northern or north-western wall whenever possible, so as to have the hives turned toward the south or southwest.

As a matter of course, under such circumstances the bees settle on whatever tree or bushes that happen to be in the enclosure, and if there is none, they have to settle on the ground, or go away perhaps quite far to find a suitable place.

### IN MY OWN APIARIES.

The situation in my own apiaries is not at all like the above. The one at Middlebrook is situated near some tall trees. In front of it, but at a lower level, are quite a number of cedar trees, about 30 to 50 feet high.

The majority of the swarms settle on the cedar trees usually at some place between the lowest branches to the mid-

dle ones, that means 15 to 25 feet above the ground. Perhaps if the land were level instead of sloping down, they might not settle so high. The few swarms that go to the tall trees invariably settle on some of the lowest branches. But that means 40 to 60 feet from the ground.

The Beaver Creek apiary is situated in a grove of tall oaks sloping toward the southwest. The back of the apiary is on the edge of the grove. The bees either settle on the lowest limbs of the trees in front of the hives or in the orchard which is across the road about 200 yards in the rear of the hives. Once in the orchard, they settle on some of the nearest trees which happen to be some rather low plum-trees with very thick branches.

Right here one may ask why, in the Middlebrook apiary, they almost invariably settle in the cedars in front of the apiary, and in the Beaver Creek apiary they settle at least half the time in the orchard behind the hives. In observing the bees when they swarm, it is easy to see that as they come out they begin to circle round and round. As more bees come, that circle or rather sphere of flying bees gets larger and larger, and finally occupies a space of some 30 or 35 feet in diameter right in front of the hive whence they started out, and, after circling a while, they settle on the nearest convenient tree or bush. If, however, the space in front of the hives is encumbered by trees, and there is a more convenient opening near by, they drift toward that opening and do their circling there. That is what happens at the Beaver Creek apiary; the space between the orchard and the back of the apiary is without trees.

### SENDING OUT SCOUTS.

Yes, the swarm issuing sends scouts, or some of the bees. Perhaps only one, perhaps several go out to see if there is a suitable place; very likely to find out if some place noticed before during their trips for honey is yet available. Perhaps they go several together, perhaps each one goes where she knows a place and the first one that gets back carries the swarm to the place she has selected. If so, the others when getting back, finding the swarm gone, have nothing to do but to return to the parent hive.

But I have no doubt that something of the sort takes place. My Middlebrook apiary is on the pathway to the district school. I am not always there, and sometimes when the boys are passing along and find a swarm hanging on a tree, they throw rocks, sticks, etc., at it just for fun. Usually the swarm is dislodged and re-forms at some distance, usually much higher on the tree selected. In such a case the swarm is apt to stay and begin comb-building at the place chosen. My idea is that the scouts failing to find the swarm go back to the old home, and the swarm not receiving any information concludes to stay where it is. My experience in that line is not very extensive, as I have during the last few years succeeded in controlling the swarming, or rather the swarms, almost completely.

Another fact in this line might be

interesting to the readers of this paper. A swarm had settled on a plum-tree at the Beaver Creek apiary. I got the ladder, smoker, etc., and went up near the cluster with everything ready, without disturbing them in the least. All at once they "got up" and left. What surprised me was the manner in which they started. The cluster was perfectly quiet and seemingly contented. A few bees at one side of it got up (if I can use that expression) and began whirling round and round right by. The others followed in succession, not all at once, neither from all parts of the cluster, but right from next to where the others had started. The appearance of the cluster was as if something were eating a hole in it. When only about a third, or perhaps a half, of the cluster was left, the remainder disbanded altogether, and the swarm departed for parts unknown to me, if not to them.

#### QUEENLESS SWARMS.

During my experiments on the swarming question, I had entrance-guards on the hives, and many times left them throughout the season, except when it was necessary to let a young queen come out to mate. The behavior of such swarms is quite peculiar. The first time they issue, they will stay out only a few minutes, and go back. They are sure to come out again the next day quite early, and, in fact, for successive days if the weather is favorable. But at the second issuing they will stay out longer than at the first; at the third, still longer, and very likely cluster for a while. Later on they may stay out the whole day, and even a part of the next day, before returning.

Their mode of clustering is different from that of a swarm having a queen. Instead of assuming the regular orthodox shape, the cluster is of a more or less ragged, irregular and often scattered shape. The bees are restless, moving constantly and changing the shape of the cluster all the time. Sometimes they break into 3 or 4 groups, change place from one tree to another, fly around a while and cluster again, or do any other unaccountable thing.

Sometimes, just before returning, they take a trip outside. (I wonder if they follow a scout), but much more slowly than a regular swarm, much closer to the ground, and in a less compact form. They scatter more and more as they go, and if the apiarist has followed them, he finally can not tell where the swarm really is. If he then go back, he will often find them going back into the old hive, but in a very straggling manner, not at all as they did during the second or third day, or even the fourth.

#### A FEW KINKS IN SWARMING.

An excellent way to get a swarm that can be reached with a pole is to put a bucket with some honey at the end of the pole and present it to the bees. In a short time they will leave the branch and cluster in and around the bucket, and can easily be taken away.

For several minutes before a swarm issues, a few bees can be seen whirling around right before the entrance of the hive. If the apiarist stoops down, he

will hear inside of the hive, the same buzzing sound that is made by a swarm just out of the hive, and then act accordingly. When the hives are up 2 feet or so from the ground, and especially when the entrances are above the brood-nest, that peculiar sound is easily noticed, even by one merely passing by.

The queen does not often come out until one-third at least of the bees are out. If, when the swarm begins to issue, the apiarist is on hand, the best thing to do is to close the hive at once with anything that happens to be at hand. My veil and handkerchief have often done the duty. Then get some water, open just enough to let 2 or 3 bees come out at a time, and wet them as they pass out. That will fix them for that day. The apiarist can then divide them or remove the queen or the queen-cells, or do whatever he thinks best, and save the trouble of running after the swarm and hiving it.

Knoxville, Tenn.

## Bee-Keeping in Cuba

BY G. C. GREINER.

Strange as it may seem in this enlightened age of profuse bee-literature scattered all over the land, it is a fact, that, to the great majority of people, bee-keeping is yet an impenetrable mystery.

A short time ago I stopped at one of our tansorial parlors for the purpose of having the customary improvement of my physical make-up administered by the hand of the artist. Being well-acquainted with the proprietor, our conversation turned, as is frequently the case when I am in places where my occupation is known, to the subject of bee-keeping. A stranger who was present, and who was also awaiting his turn, seemed to be very much interested in our bee-talk, and at last he said:

"They keep a great many bees down in Cuba, but they don't get much surplus honey down there. The trouble is right here: There it is summer the year around so that bees can work all the time, and they soon find out that they don't need any winter-stores, and consequently don't lay up anything ahead. I knew of one lot of bees that produced an awful pile of surplus honey the first year, but they 'got on to it' and never produced a bit the next year."

Then the following conversation took place:

"My friend, somebody has loaded you down with a lot of the most unreasonable nonsense."

"Nonsense?" he ejaculated with excited emphasis, "No nonsense about this, I have seen it myself. I have been there."

"Well, if you have seen it yourself, I can not dispute your word, but you are certainly most awfully deceived. How could your bees 'get onto it' when you had not a single bee of the first year's stock left to see the second year?"

"I know better. Every bee we took there from Florida the first year was alive the second year—not one of them died; and I know it to be so, for I stayed there all the time."

"Here is where you are deceived

again. You might have had the same hives, and perhaps some of the queens left, but your bees had changed quite a number of times since you took them there. The life of a worker-bee during the summer—which we may call the honey-season—is about 6 weeks, and if Cuba has summer the year round, as you say, you can figure out yourself how many generations had passed up to the time you claim they 'got onto it.' Thus, you see, it is positively impossible that your bees had any recollection of what transpired the year before; and, besides, admitting that you had the same bees, it is not forethought—bees have no reasoning power—that induces them to store winter-supplies, but simply Nature's instinct and desire. As long as Nature provides the nectar, bees are willing and desirous to gather it."

As an additional proof of our friend's unsound argument, I intended to explain to him a few points on Cuba's honey-flows, but he had seemingly lost all interest in bee-keeping, and would not remain any longer. He departed in a very abrupt and unceremonious way, not even waiting his turn in the chair.

A few neighbors, who had listened to our little chat, were anxious to continue the bee-talk, in which I gladly joined, for, in doing so, I generally find an opportunity to turn the conversation into an advertising medium, by giving a few pointers on honey as food and medicine.

LaSalle, N. Y.

## Annual Report for 1906 of the Colorado Honey-Producers' Association

To the Stockholders of our Association:

In order to make my report complete, it is necessary to review the conditions that existed during the year previous. As you all know, the season of 1905 was the most disastrous to the bee-keeping interests of Colorado and adjoining States of any that we have passed through since our industry became of any consequence. With exception of a few isolated localities, no surplus was produced, and in many cases feeding had to be done to insure the wintering of our bees.

In order to supply our home trade with honey until the 1906 crop would come in, it even became necessary for the Association to ship in honey from other localities. The bee-supply business of the Association fell off, in consequence of the crop failure, to less than one-third of its ordinary volume, and as many supplies were carried over by bee-keepers, there was also a light trade all through 1906. The very fact that our Association has been able to keep everything going in good shape under such trying conditions, meet all its obligations promptly, and hold its honey-trade, should be highly satisfactory to the stockholders.

However, we have passed through this ordeal, and the honey crop of 1906 has been a satisfactory one with most of the members of our Association.

Bees have gone into the winter in splendid condition and have a stock of good quality honey in their hives, which should insure their safe wintering. So the prospects for the coming season may be termed "good."

The volume of our 1906 honey-business has been very satisfactory. Besides handling our members' honey, we have also handled quite a quantity for non-members. Many of these will no doubt see that it is to their advantage to come in and become stockholders now, and thereby reap all the benefits of this truly co-operative association of bee-keepers.

Our Association is now well known to every car-load buyer of comb honey in the United States. We have the reputation of shipping a well-graded article, put up in an attractive manner, and of being thoroughly responsible. *This reputation is our most valuable asset, and it behooves every member to do his share in upholding the same by putting out nothing that is not strictly up to grade.*

The prices realized by the Association for honey sold have been the highest of any comb honey shipped out of the West this year (1906). No. 1 honey, graded according to Association rules, has brought an average of \$2.75 per case, and \$2.50 for No. 2 grade. The returns have all been received and turned over to the respective producers by the Association, and, now that the year's business is closed, we are happy to be able to announce that *we will be in a position not only to declare a 10 percent dividend on the stock for the past season, but also for the year 1905, when we had a crop failure. Besides this, every cent of the commission paid by members during the season of 1906 will be paid back to them in the form of a rebate.* This is the best showing we have ever made, and should be highly satisfactory to every member.

We did nearly as well in former years, and in order to give our new and prospective members an idea of this, we herewith give a brief abstract of the account of one of our members. This shows what he has paid in commissions on his honey-sales for the last seven years, what he has received from the Association in rebates and dividends in that time; and that it has cost this member only a trifle over 2 percent to have the Association handle his honey crop for the past 7 years, besides receiving \$136 in dividends on his stock during this period.

Taking into consideration that the Association took the honey into its ware-rooms, paid insurance on it, attended to all the details of selling and collection, it is evident that this producer could not possibly have marketed his honey with as little expense himself. Another matter not to be lost sight of, is the great saving of time that would otherwise be spent by the producer in marketing his product, and avoidance of worry incident thereto.

At the last annual meeting of the stockholders, it was pointed out by the manager that, in order to have our business grow, the working capital of the Association should also grow correspondingly. We now are obliged to

carry a much larger stock of bee-supplies and honey than we formerly did, besides having accounts with reliable firms that average about \$2,000 per month. Our store is inadequate for the business, and we have to warehouse now a portion of our stock of supplies. There is now more money invested in merchandise, etc., than our present working capital justifies, and it is for this reason the rebates are held over until the next December. To remedy these conditions, it becomes necessary that every member should subscribe to more shares of stock. After a discussion of this matter at the annual meeting, a motion was made and passed that every member should be asked by the secretary to take one-third or more of his annual rebates in stock until all the capital stock of the Association has been sold.

It is hoped that every member will not only subscribe for more stock, but will also exert his influence to get other bee-keepers, who produce good honey and grade carefully, to become stockholders in the Association. The stronger we get financially and numerically, the better work can we accomplish. It seems that it should not be necessary to urge bee-keepers to increase their hold-

ing in a co-operative company that brings them such good returns on their investment. That the same is considered perfectly safe by those most intimately acquainted with its working is evidenced by the fact that its Board of Directors, who were already some of the heaviest stockholders, have subscribed for more stock.

For several years it has been a rule of the Association to make the rebates on the commission sales payable on the first of December following, thus allowing the Association the use of this money for another season, and the following plan has been adopted for this year:

1. To pay the 1905 dividend of 10 percent on the stock at once.
2. To pay the 1906 dividend of 10 percent on the stock June 1, 1907.
3. To pay the rebates on the 1906 honey sales of members on December 1, 1907.

Always remember that the business of the Association is your business, and that you should give it all the support you can.

Wishing you all a successful season, I am

FRANK RAUCHFUSS, *Manager.*  
Denver, Colo.

## Convention of Bee-Keepers' Associations at Brantford

REPORTED BY J. L. BYER.

(Continued from page 210)

### IMPROVING THE BEE-KEEPING INDUSTRY

#### BEE-KEEPERS' OPPORTUNITY.

What has been done in regard to the fruit conditions in markets might on a smaller scale be attempted for the honey industry. With the production of larger quantities of honey and wax of uniform grades, with the reputation of an association at the back of it, it seems to me that there should be no trouble in very largely increasing the markets, not only throughout the older parts of the Province, but also in the Northwest Provinces. If the fruit men are so eager to take advantage of the ever-increasing market there, why should not the bee-keepers also be alive to the importance of this same market? The former are arranging to exhibit the best product of the orchards at a number of the larger exhibitions throughout the West this year, with the idea of showing just what can be obtained from our associations. I think it would be a very good idea if our

honey men would, if necessary, ask the Ontario Bee-keepers' Association for assistance to do likewise.

To increase your markets in the older parts of the country it is necessary for you first of all to advertise your wares as extensively as possible. You are already, I believe, working along this line in regard to local exhibits. Extend this as much as possible. If necessary, increase the size of your exhibits. Make them more attractive and have some advertising material in connection therewith. A very good idea was adopted at the exhibition in Massey Hall two years ago, when a small circular stating the value of honey as a food and medicine was distributed to the public. Such a circular might be printed by the Provincial association and given to branch associations for this purpose.

Then take advantage of the shop windows in your nearest towns and cities. Almost any of the best groceries would allow you the privilege of using their windows once or twice during the year for exhibiting the products of the apiaries. In this connection it would be necessary, of course, for you to keep in stock with the groceryman your best goods for the year, allowing him sufficient discount to make a fair profit on

# American Bee Journal

the goods, when he will do his best to aid you in increasing the demand.

In regard to the large exhibition, you have always had a very creditable show of honey and wax. With the advent of a new and better building at the Industrial Exhibition, Toronto, this year it would be wise for bee-keepers' everywhere to put forth extra efforts to make this the best show that has ever been put on display there. There has been considerable criticism in the committees of these exhibitions as to the action of the bee-keepers of the Province. They claim that you have belittled the industry by your action in the past. It behooves you now to show them that you have an industry worthy of a first place in the agricultural progress of the Province.

At your last meeting there was some discussion in regard to the formation of local honey-shipping associations, and the majority were of the opinion that some legislation should be sought after, so that incorporation could take place at very little expense. The fruit-growers have been availing themselves of a shipping act passed some years ago, but this act is to be repealed this session, and one new act to cover all joint stock companies is to be issued. Just how this will affect these organizations I do not at present know. However, it is not absolutely necessary that incorporation should take place, as a great deal can be done under a simple set of rules and regulations signed by those who form the association. While you probably cannot work on the same scale as the fruit-shipping associations, still I believe that under careful management much further expansion can be given to the industry by working along these co-operative lines. You will have to work slowly at first, not attempting too much. A great deal depends on the first association organized. If these are successful there will be no trouble in forming them afterwards in any section of the Province.

## THE PRESS AND HONEY.

Probably one of the best sources through which you can inform the public as to the value of the industry is through the local press. Nearly every household throughout the country takes one or more daily or weekly papers, and in the case of the farming classes, at least one of the great national weeklies and one of the agricultural papers. It is very rarely indeed that you will find in the newspapers any articles on the care of bees or the value of the product for food. Of those that do occasionally appear, the substance is sometimes entirely erroneous. The ignorance of the public in this respect is deplorable. For instance, many people imagine that crystallized honey must necessarily be impure. Many people when buying comb honey in lots will put it in a damp cellar, thinking that the proper place to preserve it. Again, very few realize that a small section of honey will go as far as the ordinary quart jar of preserved fruit. Now, what are you doing as bee-keepers to displace such ignorance?

In this connection it would be wise

for you to make use of your home paper as much as possible, sending in local items from time to time about your crops, your meetings, general items as to use of honey both as a medicine and as food; proper ways of keeping it after it is purchased, etc. The editors of these papers are generally only too glad to use this matter in preference to the silly jokes with which so many of them are padded. Let the people of your vicinity know that you have good honey and lots of it for sale. Put in an advertisement occasionally and ask for a reading along with it. The more we can enlighten the public on this side of the industry the better it will be for our pocketbooks.

There has been considerable discussion in your meetings as to whether you should endeavor to enlighten the public too much as to the other side of the industry, namely, the keeping of bees themselves. It is hardly necessary to say anything about the profits, but the distribution of all kinds of literature which will help improve the products of the smaller apiaries of the Province will tend in the long run to assist those of you who are doing business on a larger scale.

While at a meeting recently I was told by a prominent gentleman in Toronto that he had purchased last week in Toronto a small sample of honey with the idea of buying larger quantities if the sample proved to be of the best quality. He was very much disappointed to find, however, that the honey was tainted with the wax and bee bread. Now this should not be if you have done your duty in enlightening those who are keeping bees as to the absurdity of extracting their honey in this crude fashion. This is where the value of your bee journal comes in. I cannot impress too strongly upon you the value of having a strong, active paper as your representative in the Province. I understand that there are over 8,000 men who are more or less engaged in the business of keeping bees who do not subscribe for any bee journal. This is not as it should be, and you should make every effort to effect a change. Already the members of the Provincial association get the Canadian Bee Journal as a premium, and I think that it would be wise for every local association to extend the same privilege to their members. You bee-keepers must be up-to-date. Your meetings are held probably only once or twice a year, and in the time between, the only way that you can hold together is through your bee-keepers' journal.

Many of you have improved methods of handling your bees during certain operations of the year, and it would be wise for you to extend the benefits of this knowledge to your fellows. There is no better way than through the Bee Journal. Do it at once, so that they may try it before the season is over.

Patronize first of all your own home journal. This treats largely of local conditions, and is therefore specially applicable to bee-keeping in Ontario. We are, as yet, a young country and we have to stand together to support each other. Be loyal, therefore, to the Bee Journal,

subscribe for it, and then if you so wish, to some of the American or British journals. If you have anything to advertise, you should help the Bee Journal in this way, as advertisements are the life of any publication of this kind. Show your neighbors the paper, especially if you come across any article which you think is of value to yourself; let them have your paper to read and then suggest to them to subscribe for it.

If your neighbor is in difficulty about any operations of the year, you should refer him to special publications that will help him out. Pass on your Annual Report to him if necessary and send for another. The department will always be glad to assist you in this way.

## THE DEPARTMENT OF AGRICULTURE.

Two years ago the Honorable the Minister of Agriculture visited the annual meeting of your Provincial association and suggested that the Department of Agriculture would be glad to co-operate with you more closely than in the past. At that time the inspection work for foul brood was put in the care of the department. Last year some further changes were suggested and after being thoroughly discussed by the Bee-keepers' Association, were adopted. This refers to the appointment of additional inspectors to overtake the increase in the work during later years. Now we wish to impress upon you that without the organized co-operation of every bee-keeper we will not be able to do very much to assist you. It is our aim to learn as much about the industry as possible. We are now at work preparing a list of bee-keepers of the Province by counties, together with the number of the colonies belonging to each. This will allow of our corresponding directly with every man interested in the Province. We will be able to distribute any literature which may be published from time to time to a great many people who at present are not touched by your local or Provincial association. We hope in this way to get them so interested that they will become members of some of these associations. We will be able also in this way to impart information in regard to foul brood and perhaps to receive information re infestations of this disease at an earlier date than we would otherwise have received it in the past. We trust also that we will be able to keep a record of the inspection work which will probably facilitate in the suppression of this terrible disease.

The census reports for 1901 show that there are in Ontario 116,403 colonies; in 1891, ten years previous, the number was 146,341. One would naturally inquire the reason for such a decrease. Had this taken place in any of the other agricultural industries in the Province we would have begun at once to inquire the reason why and to have endeavored to repair the loss. With the information which we are now endeavoring to procure, it would have been easy enough to have discovered the reasons for the large decrease. By a conference at the time of the annual meeting, by the help of local conventions, by the distribution of literature and perhaps by the sending

# American Bee Journal

out of competent speakers to meetings all over the Province, such a loss could perhaps be prevented in the future.

There is no doubt that as beekeepers you have an industry to be proud of. The capital invested in Ontario in 1901 was given in round numbers as \$800,000, with a revenue that year of about \$300,000, and a product of about 2,500,000 pounds of honey. There is no doubt that this can be very largely increased, and it seems to me that by working together through the local associations, the members of the Provincial association and the department, the markets can be so increased that there will be no fear of lowering the prices, as many of you have expressed the opinion will be the case. P. W. HODGETTS.

Mr. Root—The Ontario Association is to be congratulated in getting a man like Mr. Hodgetts for a Secretary. I feel like trying to induce him to come over to our country.

Mr. Holtermann—You have too many of our good men over there now.

Mr. Craig suggested an apiary meeting in some yard near Brantford in the spring.

Mr. Holtermann—An individual effort is necessary to help bring about the reforms outlined by Mr. Hodgetts, and let us not forget the caution given by that extensive dealer in honey, Mr. Burnett, who says that unripe honey has done more harm to the bee-keeping industry than has adulterated goods.

A hearty vote of thanks was tendered the bee-keepers of Brantford and vicinity for the hospitality shown visitors from a distance and a vote of thanks was also tendered the American visitors for their help in making the convention a success.

## A Brief Report of the Illinois Convention

Held at Springfield, Nov. 21 and 22, 1906

Tuesday morning, President Smith said: "Members of the Association, I have to congratulate you that we have been permitted to meet again, in our sixteenth annual session. While the year just past has been one of disappointment to bee-keepers, we all look forward to the coming year with hopes that it may be a year of plenty and success. I have met more bee-keepers this year in the State of Illinois than in any other year. They all seem encouraged in regard to wiping out foul brood, wherever it has been known to exist. As to black brood, I have not seen it. Not having learned any difference I call it all foul brood. Being doubtful about it, I sent a sample of it to Washington and it was pronounced, not black, but common foul brood, as I had thought. While our neighboring States—Michigan, Indiana and Ohio—have it, it may develop within our territory, sooner or later.

"I wish to thank you, gentlemen, for courtesies in the past. We will now proceed with the business of our annual meeting. The Secretary will please read the minutes of the last meeting."

Secretary Stone said that the proceedings of the previous meeting all had been published in the Annual Report, and it seemed unnecessary to read the minutes since they were already in the hands of the members.

Mr. Dadant moved that the printed report be accepted as the minutes of last meeting, which motion was seconded, and, on being put by the President, was carried.

The President called for the Secretary's Report:

### REPORT OF THE SECRETARY.

The Association expressed the wish last year that along with the other work of the Secretary he have printed some cards to be used in an effort to increase the membership. The first move in this direction was to have prepared some return postal cards and these were sent to all the Crop Reporters throughout the State. We received in this way 1130 names of bee-keepers. We also secured another list containing 1186 names. After arranging the two lists alphabetically, and comparing them, we found only 94 duplicate names, and a total of 2222 names. In all this number only 94 duplicates is an evidence of thousands of bee-keepers still, whose names we have not been able to get. With 873 names received through the Crop Reporters of the State after canceling duplicates, they reported 20,361 colonies of bees, which was an average of 23 1-3 colonies per bee-keeper.

Number of names reporting number of colonies not known, were 163. Including the numbers recorded in our 5th Annual Report as living in Illinois, with the above-named numbers, we have a list of over 2450 bee-keepers in Illinois, and with an average of 23 colonies we have a total of 56,350 colonies, which with a very low average of 40 pounds per colony would be a possible 2,254,000 pounds of honey in one year.

In letting the bids for our 5th Annual Report, George W. York, of the American Bee Journal, being the lowest bidder, got the contract for 1000 copies—300 of which were to be cloth-bound—for all of the members of the State Association as well as for those who came through other affiliated associations of the State.

As our 6th annual report is not likely to be out in time to place copies in the hands of the legislators, we do not think that more than 500 copies can be used, with as many of that number bound in cloth as we are likely to have members.

In one or two cases our membership blanks were returned to us, wherein the writer said: "My bees have never had foul brood, and I do not see any use of a foul brood law." But when this man's bees got foul brood he was the first one to cry out; "I have just as good a right to protection as you members of the Association have, for I pay as much taxes as you do." To be sure he has in the eyes of the law,—does he get it? It is not reasonable to expect the inspector to leave a man who has done all he can to help procure a foul brood law till last, and go first to the man who did not want the

law, and did all he could to discourage its passage.

Some bee-keepers who live only for self, and know nothing about foul brood, have even told their representatives that they did not care whether we had a foul brood law or not, as their bees had never had it, and they did not fear it.

In concluding, I wish to say, the action which the National Bee-keepers' Association took when it passed a resolution allowing all bee-keepers' associations throughout the United States (or the entire continent, I believe) to join them in a body through their respective secretaries on payment of 50 cents per member, did more to promote bee-keepers' organizations, and increase the membership of those already formed, than any act that we can do to help ourselves. All bee-keepers are anxious to be members of the National, as it assists them when being imposed upon, so long as they are in the right. And every association should sacrifice one-half its fees and thereby help their own and the National Associations.

We were told during the year by the General Manager that our State stood at the head in the list of members to the National. (Later we see in the Report of the National that Illinois stands 2nd, with 282 members; Wisconsin 1st, with 307 members; New York 3rd, with 210, and California 4th, with 206.)

We have great faith that our membership will never be any smaller, but hope for greater numbers as the years of prosperity for bee-keepers come this way. We can ask a bee-keeper with the best of grace to join our Association, because we are getting memberships in the National with the same \$1.00 fee. JAS. A. STONE, Sec.

### FIRST DAY—AFTERNOON SESSION.

The afternoon session was opened with the reading of the following paper by C. P. Dadant, President of the National Bee-keepers' Association, on

### DRONE-LAYING WORKERS

When a colony of bees becomes hopelessly queenless, it often happens that a number of the worker-bees—sometimes only one or two, sometimes dozens of them—begin to lay eggs in the cells here and there. Scientists affirm that the drone-laying ability is found in bees that have probably received a greater amount of the royal jelly than the average larvæ during the course of their development. This jelly or pap, produced by the salivary glands of the nurses, is fed exclusively to the queen-larvæ during the entire time of their development, while a coarser food, containing pollen or bee-bread, is fed to the larvæ of the worker-bees during the last stages of their larval existence. It is asserted that those workers that receive a little more than their share have ovaries partly developed; and while they are entirely unable to become impregnated, owing to the rudimentary condition of both spermatheca and ovaries, yet the rudimentary ovaries may produce eggs in small quantity. These eggs, like those of queens that

have been unable to mate, hatch drones only. It is probably unnecessary to state the well-known fact of parthenogenesis in bees, which is the faculty of laying eggs by virgins, eggs which invariably produce males. This discovery is due to the immortal Dzierzon, and was long doubted by many, but is capable of absolute demonstration.

When a colony becomes hopelessly queenless, that is, when there are no eggs or young larvae from which may be reared queens, such bees as may have the ability to lay eggs seem to consider it a duty to replace the missing queen within the limit of their powers. One or more worker bees assume this duty. But their eggs are laid irregularly, sometimes several in one cell, and sometimes on the side-walls of the cells instead of at the bottom. I have myself seen a half-dozen or more workers laying, at the same time, on a comb which had been taken out of the hive for inspection. Such a sight may be witnessed more readily with the Italians than with the common bees, because they are less excitable and do not become frightened and rush about when the combs are removed from the hive with a little care.

Sometimes the laying of an old queen that has lost her fertility is mistaken for that of drone-laying workers. This is of some importance, for although a queen may be successfully introduced to a colony containing a laying worker, it is almost impossible to succeed in the introduction of a new queen, if there is an old queen in the hive.

The only way to make positively sure of the presence of an old queen is to search for her. But there is a slight difference between the laying of a worn-out queen and that of one or more laying workers. The old queen lays but few eggs, and these are always at the bottom of the cells. She rarely lays more than one egg in a cell, this incongruity being committed only by laying workers, or sometimes by very young and very fertile queens which lack room, and have not yet reached their full ability in regular laying.

I have stated that it is easier to introduce a queen to a colony containing a laying worker than to a colony containing an old queen, unless this queen has been found and killed. I know that this statement will not be concurred in by many others, for I have often seen it stated that it is impossible to introduce a queen to a colony having laying workers; yet I have never failed. I speak from actual experience. Before I state how I have succeeded, permit me to say that a colony having laying workers is rarely worth saving. Yet there are times when such colonies are still powerful enough to make a good colony if a queen is successfully given them early enough in the season. The apiarist must decide this point for himself.

In order to show how to succeed, I will state under what conditions I tried the introduction of queens in drone-laying colonies. We used to import queens on a very large scale. This was in the '80's. We used to receive from Italy about a hundred queens per

month during the summer months. As these queens were fatigued from their long journey, we always introduced them to full colonies of bees in our apiary, before re-shipping them to our customers in the United States. The price obtained was sufficient to reward us for such a course, and when a queen had been for 3 or 4 weeks in a full colony, she had fully regained all her lost vigor, and was much more likely to be satisfactory to the purchaser than if she had been held in a very small nucleus or in a queen-cage. Besides, this introduction gave us new blood in the apiary. Owing to this course we had to kill a number of queens each month, usually of the common race or of the hybrids. These spare queens were quite often prolific, and it seemed a pity to kill them. It was then that I attempted to save a good queen and a worthless colony at the same time,

C. P. DADANT.

by introducing the one into the other, by the ordinary method of caging the queen for 48 hours in the hive, and releasing her by inserting a piece of comb honey in place of the stopper of the cage. This method has never failed, and I attribute it to the fact that the queen introduced was in each instance a vigorous laying queen in the fulness of her power.

In the introduction of queens that have been traveling there is almost always a delay in the laying; the new queen does not take possession of the empty cells immediately, and for this reason the bees that have one or more laying workers will have an animosity towards her that they will not entertain towards a queen that is able to lay eggs at once, and thus show her ability to fill the needs of the colony.

My conclusion, therefore, is that although it is more difficult to introduce a queen to a drone-laying colony than to a normal colony, this may be successfully done by the above method. But I would never risk a queen which has been confined to a cage for some days to any but a normal colony made queenless just before introducing her.

A good laying queen introduced to a drone-laying colony in May—if this colony has still enough bees to take care of her brood—will rear a populous colony for the fall crop of honey, and

will often prove a paying investment. For this reason, queens bought from reliable Southern breeders in early spring are a great help to the Northern bee-keeper.

C. P. DADANT.

Mr. Dadant's paper was received with marked attention and brought out a most interesting and profitable discussion, though Mr. Dadant apologized for his subject. Nearly all the members participated in the exchange of ideas and relation of their successes and mistakes along the line of experience which was under consideration.

Mr. Black asked if the drones produced by working bees were as good for the fertilization of a queen.

In answering the inquiry Mr. Dadant said that such drones were smaller, and on that account less desirable for the purpose.

Mr. Black told of his experience with a very small queen—the smallest he had ever seen—that was with his bees for 4 years, to his certain knowledge, proving herself a good queen. He recognized her by her size.

Mr. Kildow and Mr. Pyles told of putting unfertilized queens into a hive before they had taken their wedding flight, and still proving good queens. There was doubt expressed by some members as to whether they were unfertilized, or whether there might not have been other queens in the hives so treated.

Mr. Stone—I was induced to give Mr. Dadant this subject because of the little experience many of us have had in handling queenless colonies with laying workers, and the questions that arise in regard to their management.

Mr. Johnson said he believed there were generally a good many laying workers in the hive. He had never lost queens, but united them by putting smaller colonies on top.

Mr. Black spoke of his method of uniting colonies; that formerly he was very careful about handling them gently, but experience has taught him it is better to handle them more vigorously.

Mr. Dadant said that in the matter of uniting a colony containing laying workers he thought that the entire secret was in what Mr. Black had said, and in allowing the bees to feed before they were disturbed, in which case they would be much more peaceable when united. In certain seasons the tendency among bees is to fight. When you open a hive, if they are full of honey there will be much less tendency to fight than if they are not well satisfied in that respect. Colonies that have drone-laying queens will be more successfully handled in the spring, both in the matter of uniting them and in the introduction of a new queen.

#### PREMIUM LIST COMMITTEE'S REPORT.

Mr. Stone said he thought the members of the Association were familiar with what had been done last year. Some fault was found with what was done. The premium on beeswax was raised from \$10 to \$20. Mr. Cater, the superintendent of the department said they had \$50 that could be put into that list and no more, without getting the consent of the Board. Mr.

# American Bee Journal

Stone then hastily telephoned Mr. Becker. The meeting of the State Board was within two days. Mr. Cater agreed to have them raise the premium list \$10 on beeswax designs, and add a premium on Samples of Extracted Honey, and one on Case of Amber Comb Honey. The State Board always treats us kindly.

Mr. Becker—I think we had better let it alone for this year. It has been a bad year.

Mr. Black—The State Board wants a show, and they want the worth of their money. They think they are getting no more interesting show anywhere on the grounds for their money.

Mr. Dadant stated that he had been selected as judge of the apiary exhibit at the State Fair, and that one thing he would like to see would be the placing of that exhibit in a hall where there is a platform so placed that when the extracting of honey takes place it might be witnessed by a large number of spectators. As it has been, four or five people can get close enough to see, and they exclude from the same privilege everybody behind them. He strongly recommended the great convenience of having the extracting done where there is a platform, and where people could see the work done. In which case there could be competition in the work of extraction.

Pres Smith—I think that is a good suggestion.

Mr. Stone—I do not believe that anything has been done, or any other exhibit made, at the State Fair that has proved more attractive or interesting than this. Extracting honey on the ground is educational.

Mr. Dadant—I wish to say a few words more in regard to the education of people and the cultivation of a taste for extracted honey.

Mr. Dadant then told of the great difficulty that had been experienced in selling extracted honey in 1868-9, and how they finally succeeded in getting people interested in it by making an exhibition of it in Keokuk. They got business men interested and aroused such an interest that 300 or 400 buggies were to be seen at the place, bringing people from all around the country. And so the value of extracted honey was brought to their notice. And if people can just be induced to use it, they will prefer it to comb honey.

Mr. Black—I recollect being at Keokuk.

Mr. Becker—While we are on this subject I will say that I think the exhibit at the State Fair has done more to educate people than anything else. People do not know how we get the honey out of the comb. I believe if we had honey enough so that we could extract honey for a whole half day, it would be one of the best exhibits we could make, and would be found interesting to more people than you would at first think.

Mr. Becker went on to say that he sold honey in Springfield at a good many stores, and he never had to ask them how much they want. They ask, "How much can you let us have?" People who have used it before want

it. He spoke also of candied honey; that it will sometimes spoil the sale of extracted honey.

Pres. Smith said that matter was discussed at San Antonio.

The advisability of using a label was mentioned and approved. The general opinion seemed to be that if the producer would place on the market a good article, plainly marked with his guarantee as to its purity, it would find a ready sale, and the demand for it would grow.

Mr. Hinderer spoke in favor of the label recommended by the National.

## RELATIVE VALUES OF EXTRACTED AND COMB HONEY.

The relative values of comb and extracted honey were advocated by various members. Mr. Black insisted that the human system needed something besides what is easily digested; and the comb was in no way objectionable. He also quoted eminent physicians as advising the use of milk and honey as better than medicines.

Mr. Pyle thought, while extracted honey should be used, and had advantages over the other, that the taste of comb honey was far superior.

Mr. Kildow thought the same—that take a section of honey and extract it and it was not the same thing, not nearly as good. He never could keep the same flavor outside the comb that it has in the comb.

Mr. Johnson said he thought all the five senses helped each other, and sympathized with each other. Take butter, for example: If it is not a good color it does not taste as well. The eye has the power to control the taste.

Mr. Black spoke of the keeping qualities of comb honey. He had found that some that had been standing for 4 years was as solid and perfect as when taken from the hive.

Mr. Becker mentioned one of his customers who used 60 to 75 pounds a year, who wanted both kinds.

Mr. Johnson said he sold some comb honey because some wanted it. If they would all take it he would rather sell all extracted honey, but we must produce what people want.

Pres. Smith—That is true, and beekeepers must learn that fact to be successful. If consumers want a certain kind, produce that variety.

Mr. Stone thought customers will want just what we educate them to, and he was tired producing comb honey. He thought it impracticable to use the combs again for comb honey. His customers just ask for honey, but few ask for comb honey. Some object to the extracted honey, saying it might not be pure honey, could be more easily adulterated; but after explaining to them how the honey is extracted they like it and do not care for the other again.

Mr. Kildow thought it made a difference where you live, near to or distant from a large market.

From the discussion of extracted honey the talk drifted to the subject of markets, and Mr. Dadant said the sale to private individuals was helping us today. They had been unable to sell through wholesale

grocers. Grocers could handle the product that was labeled.

Mr. Black asked the proportion of comb to honey and Mr. Dadant answered that he could not say positively. From 25 to 40 per cent. The size of the cells has something to do with it. Drone-cells are larger in proportion. Mr. Dadant wished to say that this matter of eating comb depends largely upon taste.

The matter of advertising, whether the daily papers, the large Sunday editions or the bee-papers were the best medium. It was said that the bee-papers reached only men who were in the business and not customers for honey; but some of the members said they had found them to be good advertising mediums. Others had had success from advertising in the large daily newspapers.

At this stage in the discussion Mr. Holekamp was admitted to the hall and a short recess was taken to enable the members to meet and greet him. Then Pres. Smith, who had been speaking when Mr. Holekamp came in resumed his narration of how he secured the local trade, by sending honey to the grocer who would not buy it, but with whom he left it nevertheless, to be disposed of as he might find customers. Within 30 days he telephoned Mr. Smith to bring him more, and Mr. Smith has had no trouble since.

Mr. Holekamp said he thought the better market for extracted honey would have to be made. The demand for it must be created. One great trouble with extracted honey is that it granulates, and then when left in the dealer's hands is not marketable.

Mr. Black said you could not sell granulated honey.

Mr. Dadant said in regard to granulated honey, that there was a class of buyers who wanted honey in glass jars so it could be readily examined. He suggested putting the product up in attractive style with the producer's label and guarantee that it is pure honey, and this helps the grocer to sell it.

Mr. Baxter—I endorse every word Mr. Dadant says. Up our way people know what granulated honey is. Most of our customers like it. I have no trouble with it.

The fact that honey from different kinds of blossoms will prove different in this respect, was brought out. Honey from alfalfa is found to granulate rapidly, while that from sage does not, and that from goldenrod is slow to granulate. And it was said that honey from sweet clover had not granulated, and the next year there was basswood mixed with it. Another gentleman thought basswood honey was likely to granulate. Spanish-needle was also mentioned, and it was said the late gathered honey granulates less rapidly than the early.

## BEES AND FRUIT.

Mr. Black brought up the question as to whether bees will eat fruit. Experiences were related and views exchanged, and the general opinion was that unless the skin has already been broken, bees will not seek for honey on grapes, peaches, etc., but are often

# American Bee Journal

found on over-ripe fruit, left on the trees after it should have been gathered, and which offers them food from bursting skins and soft or rotten spots, and places that have been pecked by birds.

## CONTRACTING FOUL BROOD.

The first question announced by the Secretary was: "Will bees contract foul brood from surplus honey produced on colonies that have foul brood?"

Mr. Dadant—I would like to hear from our President in regard to that matter.

Pres. Smith said it was probable they would. Such conditions would only occur in seasons when the honey-flow was very free.

Mr. Dadant—Is it not true that the bee coming from the field sometimes gives its honey to some other bee to carry to the cell?

President—I do not believe the one stores the honey that gathers it.

Mr. Kildow—Do you believe it is possible for a colony that has foul brood ever to get rid of it?

Mr. Black—If my bees were where they could get honey from any source where there was a bit of foul brood I would not touch it.

Mr. Dadant said that a great deal had been learned about foul brood at the San Antonio meeting, and referred to the very interesting report of Dr. White. Specimens of foul brood were shown there and the bacillus described as in appearance like two tiny sticks held together by a more slender connection between them. The two little sticks end to end, united by the slightest joining. These bacilli develop rapidly, the slender joining breaking, and each end then becoming one by itself, and it developing and breaking in two, becoming two more, and this process is repeated every half hour. And they remain in honey for years, and when conditions are favorable, as soon as they find a proper medium, will begin to develop foul brood.

Mr. Kildow said he was very much interested in this matter of foul brood; that it was one of the things he came to this meeting to hear about. He has kept bees since 1880 and never had any experience with it until the past 3 years. He had bought some bees from a man who wanted to sell out, representing that his bees were all right, but when he got home Mr. Kildow found they had foul brood. He said Mr. Smith was up in 1905. Out of 40 or 50 colonies 31 were infected with the disease, and there it was right under their noses. It is almost useless for one man to clean it out of his own colonies when his neighbors allow it to increase in theirs.

Under these circumstances Mr. Kildow was very much interested in getting a foul brood law, and thinks we might get something like the law they have in Ohio. He would be in favor of making the bees pay what expense there might be attached to the enforcement of the law.

Mr. Johnson spoke at some length on the use of disinfectants, and gave some valuable information relative to experiments that had been tried. He had read a great deal on the subject, and had some correspondence with the

Department at Washington. He said there were just two disinfectants—sulphur and formaldehyde—and told how the latter had been successfully used in disinfecting a house with the windows wide open; his theory being that to secure the best results the air should be freely admitted, the oxygen being necessary to the proper action of the chemical. He advocated the McEvoy theory.

The question as to whether the bacilli were in the beeswax was brought up.

Mr. Dadant thought the only safe way was to melt up all the combs and use up all the honey.

Mr. Johnson thought we should not be satisfied with opinions of others, but leave nothing undone to learn more on this subject. He said: "The inspector of today should be an experimenter all the time. You perhaps all know that I have always condemned the formaldehyde treatment for disinfecting when used in an air-tight compartment. I want to give a little more information on this subject. I find that Prof. Newman, of Kings College, London, as well as Prof. Koch, the greatest German bacteriologist, agree that formaldehyde is not a disinfectant of itself, but that the gas-formaldehyde must be united with oxygen in order to disinfect. The Department at Washington claims that the gas is a disinfectant of itself by its affinity to things nitrogenous. However, last summer there were 3 cases of smallpox in our vicinity in one family. The doctor disinfected that house in 5 days with formaldehyde with the windows and doors open a good share of the time, and the family ate and slept in the house during disinfecting. The children have gone to school all fall and people visited them and slept in the beds in which the patients were treated, no clothing nor bedding being burned. And no spread of the disease resulted. The disinfecting was complete; while about 10 miles north of us, where formaldehyde and sulphur were used in tight rooms for 24 hours, the disease spread in an alarming state. The cases in our neighborhood came from a visitor just out of quarantine where air-tight fumigation was used. So it seems that there is much to learn yet about formaldehyde as a disinfectant, especially among beekeepers. And I want to add with great emphasis that formic acid, and not formaldehyde, is the real disinfectant; and if an air-tight tank be used in disinfecting combs there will be no formic acid produced, consequently no thorough disinfecting. Practice the McEvoy plan until we know more about gas treatment, but let our experimenters not give up formaldehyde, as that will be the 'plan' when better known and properly used."

Mr. Hinderer said he had raised that question, and wanted to know if the practice of allowing bees from clean hives access to bees and the honey from hives infected with foul brood was dangerous.

Mr. Holekamp—I, too, am much interested in this discussion. We have suffered a great deal from this trouble. We formed a club for the purpose of assisting each other in dealing with it.

Mr. Holekamp also said that he had experimented with it, keeping a piece of foul brood a whole year in his office. He thought there was danger of its being carried, and said we could not expect to make much progress in getting rid of it as long as all did not work together to that end. He said any foul brood law should compel inspection. The greatest danger he saw was in the shipment of honey. Comb honey will leak. Boxes will be thrown out in the back yard, and bees will clean them up. There should be uniform laws in all the States, and we should not rest until we get bills passed which will compel inspection. Chemicals may be good enough, but we do not want to be using them continually. He had found that an easy way to destroy bees and the comb. He related some of his experiences with foul brood, and repeated that it was of little use for one bee-keeper to clean up his hives while others were careless of theirs.

Other members said their experience had been similar, and thought the infection was carried by bees and in the honey.

Mr. Dadant—Some think they can cure it by simply changing queens. Some do not believe in this shaking business. Some want to scorch the hive. I advocate the use of the McEvoy treatment.

Mr. Baxter—Two years ago I had a colony I was sure had foul brood. I had never had it in my apiary, and I was thoroughly scared. I asked advice as to what to do. Upon that advice I changed queens and had no more trouble.

Mr. Johnson told of one instance where it seemed apparent that the foul brood was brought by the introduction of a new queen.

As it was getting late Pres. Smith suggested that it was time to adjourn.

Mr. Stone moved that the first thing to be done in the morning be to take up the consideration of a law for dealing with the foul-brood problem, which motion received a second and was carried.

The meeting then adjourned till 9 a. m. on Wednesday.

## SECOND DAY—MORNING SESSION.

At 9:30 a. m. the convention met again.

Pres. Smith—The meeting will now come to order, and we will proceed with the order of business. Upon adjournment last evening it was decided that we should take up the question of foul-brood legislation this morning.

## FOUL BROOD LEGISLATION.

Mr. Dadant—It seems to me you, Mr. President, are the best informed man on this matter, having served the Association as Inspector, and we should have your ideas on the subject as to how best the desired laws for the extermination of foul brood may be secured.

Mr. Stone—I want to say that I have been on that same committee every time, and I made it a business to be at the State House twice a week.

# American Bee Journal

I have seen members of the legislature who have influence, and think they will get this Bill through for us. It has been recommended that when we get a Bill passed that will go on the statute books it will have become a law and will not have to be passed each session, as the Appropriation Bill has to be. They object to our appointing the Inspector, but we need not make a point of that. Let the Governor have the appointing power. If he does not appoint a man who is qualified for the work it will make so much opposition and trouble that he will be obliged to select for the position some one capable of filling it. I believe that we will get a Bill through just as we ask for it, and suggest that we dictate it just as we want it.

Pres. Smith—I will say that the Senate has always been favorable; we will

another way. Ask for no appropriation, but ask for an Inspector and let the bees pay the expense.

Mr. Dadant—I have had some experience in these matters—have helped to get Bills through, and would like to suggest that while it is a good idea to tax the bees, I don't believe that it need be done. If you can get your Bills into the proper hands they will go through. There are certain of the members of the legislature who get things done. Put your Bills in the hands of the right men and they will go through.

Pres. Smith—You might write letters to members of the legislature every day and it would not amount to anything.

Mr. Baxter—I do not agree with you at all. I believe we can get what we ask, and should make our wants known to the members. You put it into the hands of Senators Berry and Dunlap,

of spraying in time of bloom may be beneficial, and result in producing better fruit.

Mr. Johnson—It has been said that writing letters will not do much good. In that regard I would refer to the Ladies' Home Journal which asked its readers to write letters to help create public sentiment.

Mr. Holekamp—I have had some experience in the work of getting Bills through, and will say that I had 3,000 bee-keepers write to members, and then I saw every member of the Senate and nine-tenths of the members of the House, and in many instances they would say to me, "Oh yes, I have had letters from home." I would also suggest that your Bill be so drawn as to provide for the extermination also of black brood and other diseases. Those

PRESIDENT J. Q. SMITH.

1ST VICE-PRESIDENT J. E. JOHNSON.

need some influence in getting it through the House.

Mr. Johnson—I would like to ask just what was the opposition to the Bill presented to the last legislature?

Mr. Stone—There was no opposition. It just failed to pass. In the same way other Bills were killed, it was among those that had not yet been passed when the close of the session was reached, and was simply shut out.

Mr. Johnson—According to this, then, there was no opposition.

Pres. Smith—Mr. Stone and I called on the Governor, who referred us to the Attorney General. The Governor expressed neither approval or disapproval, but said it should be passed upon by the Attorney General, that whatever he recommended as to its requirements would be right. I was advised to drop that Bill. Get the appropriation and let the balance go.

Mr. Kildow—We all have read what our committee have done, and I think they have done all they possibly could. It seems to me we might get at it in

and such men as they are in the House. Another thing that we want is a law in regard to spraying, and we ought to have a similar law for the inspection of importations of queens into the State.

Mr. Johnson—It was mentioned yesterday, that we have this inspection of queens. And a spraying law ought to be had. Spraying trees in bloom should not be allowed.

Mr. Black—In the line of Mr. Baxter's remarks, there are wheels within wheels. The big thing, it seems to me, in this is to have our legislators understand the need of these things. It is well to be wise in the selection of the men who are to present the matter to the committee. We want to be sure to have this Bill pass through the hands of some one who will see that it doesn't conflict with other interests, and do not get it in such shape that it cannot be enforced. I think there should be a law prohibiting spraying in time of bloom. Though from experiences personally known to me, it has been proven that a limited amount

letters help, and call attention to the fact that there are such diseases.

Mr. Stone quoted a member of the legislature as saying, "If you don't quit flooding me with letters I will see that your Bill don't go through;" but in such a manner that it was apparent the letters had done good work in securing his interest in the measure.

Mr. Dadant—I think as time is becoming limited it would be well for the President to appoint a committee to draft a bill to be presented to our legislature, and that the members of the Association be asked to write letters to members of the legislature in the interest of the same. I would suggest that the three things be included—appropriation, foul brood and spraying.

Mr. Dadant made a motion to that effect which was seconded.

Mr. Kildow—Is it left for this committee to do as they see fit, or will you instruct the committee as to their course of action?

Mr. Becker—I am not in favor of introducing three Bills. We are getting

too many bills. It will be like it was two years ago. It was hard to get our Bill through for an appropriation of \$1,000, and too many Bills will defeat us in our efforts, and result in our getting nothing. I think we would better let the spraying matter alone, and get the Foul Brood Bill through.

Mr. Dadant—I would like to insist on giving the committee full scope. Let them use their judgment in drafting the Bill. Do not tell them to get up this or that kind of Bill. We want a Bill that will make sure destruction of foul brood. As to passing three Bills—let them do it if they can. I do not think that we should limit the committee. If the legislature does not pass all the Bills—if they will not enact at one session all that we want, we will go after them next year.

The motion received a second and was carried.

The result was as follows: President, J. Q. Smith; Secretary, Jas. A. Stone; and Treasurer, Charles Becker. First Vice-President, J. E. Johnson of Williamsfield; 2nd Vice-President, S. N. Black, of Clayton; 3rd Vice-President, E. J. Baxter, of Nauvoo; 4th Vice-President, A. L. Kildow, of Putman; 5th Vice-President, W. H. Hyde, of Canton.

Pres. Smith:—The appointment of foul brood Inspector is next on your list of business coming before you.

Mr. Stone—I move that our present Inspector, Mr. J. Q. Smith, who has served so acceptably, be appointed for the coming year.

The motion having received a second the question was put by Mr. Johnson,

courage us so that we neglect our bees, and thus lose many colonies, so that when a good honey-year comes we are not prepared to meet it to the best advantage.

You have perhaps noticed that unless we exert ourselves to follow our best judgment, we naturally fall into a habit of doing a good deal as others do. The man who merely follows the crowd will never succeed as well as he who does what, after careful consideration, he concludes to be the right thing to do, whether others do it or not.

Let us review our present situation. We have had an exceedingly poor honey year, and last year was not extra good. The blue-grass in the pastures is in many places killed out by dry weather, and, should we have a wet year, which we usually do after a dry one,

SECRETARY JAS. A. STONE.

TREASURER CHAS. BECKER.

Mr. Black—If they do not pass all, they might pass one.

Mr. Baxter—Leave the committee absolutely unfettered. I believe these Bills will not conflict with others. We are as much entitled to an appropriation as other State societies. I believe we can show the legislature the importance of bee-keeping in this State.

The question was called.

Pres. Smith—The motion is carried. I will appoint as such Committee: Mr. Dadant, Mr. Johnson and Mr. Stone.

Mr. Pyles—I move that the Secretary send to the members of the State Bee-Keepers' Association the names of the committees on appropriation in the Senate and in the House and ask them to write to their members, personal letters.

The motion received a second and was carried.

Mr. Pyles—Mr. President, I move that the rules be suspended, and that we proceed at once to the election of officers for the ensuing year.

the newly elected 1st Vice-President, and unanimously decided in the affirmative.

A very sensible and interesting paper was read by Mr. Johnson on:

**IN THE POOR YEARS PREPARE  
FOR THE GOOD YEARS THAT  
ARE SURE TO FOLLOW**

As we come together to discuss things of interest to bee-keepers at this convention, we come not as bee-keepers having just reaped a bountiful harvest, but we come, at least most of us, having cause for discouragement, as in most parts of Illinois there is this year almost a honey-famine. As bee-keepers, we usually get enthusiastic when we are in the midst of a prosperous year, and when in the midst of a good honey-harvest, we at once begin to plan to increase the size of our apiary, and usually we increase our number of colonies only to find that when we are best ready for a big honey-flow we don't get it. Then the poor years will dis-

the white clover will spring up unhindered; not only so, but many people have thinned out their stock so that it will not be pastured so closely as usual next year, and it is only when the white clover gets ahead of the cattle that it can yield its best. Not only so, but during a wet year there will be much more abundance of heartsease, Spanish-needle and other fall flowers; so, taking all things into consideration, I think we have a fair prospect for a moderately good year in 1907. So let us not forget that in the time of a poor honey-year is the time to keep up courage and prepare for the good years that must certainly follow.

Let me cite another feature. I have quite a few neighbors that keep from 4 or 5 to 15 or 20 colonies of bees. Three years ago they would stop me in the road to talk bees, but now those who have any bees left don't give them a thought, because they don't bring in an income. I talked with a man the other day who had had from 20 to

25 colonies of bees until this year. He said he did not know whether they had enough honey to winter or not, as he had not looked through them since last spring, but he believed there were only 8 or 10 colonies left now, as several died in the summer.

Another man lost all of his bees last winter and spring, and so on. So we have that advantage. These men with their small apiaries won't be in the business when the next good year comes along, to glut the country store market with 10-cent honey in 2 or 3 year old section-boxes. None of us know what the future may bring forth, but one thing we do know, and that is, in the past the good seasons have always come after the poor ones, and it is reasonable to expect that history will repeat itself in this respect. And if we are faithful during our trials and hardships in bee-keeping, we may expect to reap the profits when the good times come.

The man who has a good-sized apiary, and has his bees in shape to meet the next good honey-year, is going to make some money at bee-keeping. So let us then carefully prepare our bees for winter, and look after them well in the spring, so that we may be prepared for whatever may come. Anything that is worth doing is worth doing well. Let us apply this rule to bee-keeping at all times, and if there be such a thing as success, we will be sure to make its acquaintance.

In most parts of Illinois, 50 to 60 colonies are enough in one apiary in average years. Let us be careful that the good years do not catch us with 15 or 20 colonies and the poor ones with 100. If we have 50 colonies in a very

good year, they can be increased easily; and if we have 50 colonies in a fairly poor year, we will get more honey than if we had a hundred, as we will have many thousand less consumers of honey. We should each study our locality, and aim to keep the number of bees our locality will support well in an average season.

J. E. JOHNSON.

The foregoing paper was followed by a discussion which was participated in by Mr. Black, who said that bee-keepers were becoming fewer in number, year by year, but those engaged in the business were carrying it on more intelligently; and by Mr. Souer, who asked of the President the advisability of putting a cushion on colonies where two were united. This question brought out interesting remarks from Messrs. Baxter, Dadant and Holekamp, and, like other practical discussion of living questions, a valuable exchange of ideas resulted.

As it was nearing the noon hour when some of the members had to leave the city, Mr. Dadant and Mr. Black asked to be excused, and after a little more general discussion an adjournment was taken to 1:30 p. m.

At 1:30 o'clock the meeting was called to order with Vice-President Johnson in the chair.

Mr. Kildow moved that each affiliated bee-keepers' association in the State be allowed to send a delegate to the State convention and that their railroad fare be paid by the State Association. Carried.

After an hour or two spent in friendly discussions, the meeting ended its session in a *sine die* adjournment.

JAS. A. STONE, Sec.

duster for years, and have found it to be very satisfactory.

Feather dusters are made of split feathers, mostly used from turkeys, and are therefore very soft, and will not injure the bees or combs in the least, even though you use it with force. On the other hand, dusters made of horsehair are very dense, and when brushed over the bees it doubles them up and rolls them over in a miserable way.

MRS. CAROLINE ZELLER.

Spring Bay, Ill.

There is a difference of opinion in regard to feather brushes. Some think that feathers irritate the bees, somewhat as fuzzy woolen cloth does, while others like them.

We like the Coggsball brush, also the long grass brush. But, better still, a brush made of something green, as goldenrod, aster, sweet clover, asparagus, etc., if it were not for the trouble of making a new brush each day.

#### Resolution in Behalf of the Baroness Burdett-Coutts

In the report of a meeting of the Council of the British Bee-keepers' Association, given in the British Bee Journal, occurs the following:

On taking the chair, Mr. Cowan alluded in feeling terms to the loss sustained by the death of the President, the Baroness Burdett-Coutts, who had occupied that position, to the great advantage of the bee-keeping industry, for nearly 30 years. . . . In conclusion, Mr. Cowan moved the following resolution:

"That the Council of this Association desire to place on record their sense of the irreparable loss they have sustained in the death of their revered President, to whose continual practical interest and generous liberality they have been indebted for so many years past; and to convey the same to Mr. W. Burdett-Coutts, together with their sympathy with him in his loss."

The resolution was seconded by Mr. Weston and adopted.

#### Cellar-Wintering of Bees at Low Temperature

On page 115, "Wisconsin," whose thermometers varied 10 degrees from highest to lowest, was told in the Question-Box, "The idea is to find at what temperature your bees are most quiet by your thermometer, in your cellar, no matter what the authorities say." Miss May G. Devine takes heart from this, as she had fears previously that her bees had not been behaving in an entirely orthodox manner in consideration of the temperature shown in her cellar by the thermometer. She says:

My bees have always wintered with what appeared to be absolute success, but this is the first intimation I ever had that they were conducting themselves with perfect propriety in so doing, for so far as I can judge by thermometers that vary something as "Wisconsin's" did, the mercury averages about 37 degrees—quite likely lower—certainly no higher.

I keep about 50 colonies, and you could stay in the cellar an hour almost any time from the middle of November till nearly time to take them out, and I doubt if you could say there was a bee there. The cellar where they are is large (under our living rooms), a solid rock bottom, dark as Egypt, no windows, and both doors always closed. The rock on the bottom slants a good deal, and much of the year a

Conducted by EMMA M. WILSON, Marengo, Ill.

#### Another Misrepresentation to Be Corrected

On page 94, reference is made to a statement contained in a work of Dr. Kellogg that was being widely circulated, said statement being to the effect that foundation of paraffin was given to the bees, and also glucose, and "Thus we have honey which is wholly artificial, with the exception of a portion of the wax." Thanks are due to our correspondent who called attention to the matter, since it has brought from Dr. Kellogg the following frank and candid letter which needs no further comment:

BATTLE CREEK, MICH., Feb. 10, 1907.

EDITOR AMERICAN BEE JOURNAL:—My attention has been called to an article from one of your correspondents referring to a state-

ment in the "Home Hand-Book," with reference to honey. The paragraphs referred to were written 30 years ago, and at that time I had every reason to believe that the statements made were true. I am glad my attention has been called to the matter, and I will see that the text is corrected if not in harmony with the facts as they exist at the present time.

I believe honey is an excellent food, and is very much superior to cane-sugar. The latter is often a cause of disease.

Very truly yours,

J. H. KELLOGG, M. D.

#### Feather Duster for Brushing Bees

I have noticed several inquiries in the American Bee Journal from subscribers in regard to brushing bees from combs. I have used a feather

stream of water trickles over it—after a heavy storm, or, in spring, quantities of it.

I knew the bees were always quiet—practically no bees ever crawling around the entrances, still when without exception every "authority" said "not below 42 degrees," I had a sort of uncomfortable feeling that something should be done.

(Miss) MAY G. DEVINE.  
Sandy Hill, N. Y., Feb. 13.

This is exceedingly interesting. It is perhaps the lowest temperature ever reported in the cellar with such good results. The question arises as to whether the authorities are to be ignored as of no account. By no means. It is useful to have something to go upon in trying to settle the right temperature for each cellar; and it helps to know that for the average thermometer in the average cellar 45 degrees is about the right figure, just as it is useful to know that so many yards make a dress-pattern for the average woman; but that does not hinder any one from getting more or less than an average dress-pattern if occasion demands.

In the present case, there is a possibility that even with varying thermometers no thermometer was used that registered sufficiently high. Most likely, however, the peculiar conditions of the cellar have something to do in the case; and Miss Devine is to be congratulated that her bees behave to her heart's fondest wish, even if she did not succeed in getting her thermometer to "speak the piece" she thought it ought to speak.

## "Freyhoff" Honey-Cakes

In *Praktischer Wegweiser*, Mrs. Emma Freyhoff (is she perhaps the wife of Editor Freyhoff?) gives the following recipe for a kind of honey-cakes that she esteems highly:

One and ½ pounds of honey of good quality and 1 pound of good butter are melted together, then into the blood-warm mass gradually add, stirring vigorously: 1 pound sugar, ¼ pound beaten almonds, some grated lemon-rind, 3 heaping teaspoons soda—in 10 cents worth rosewater—and 4 pounds of wheat flour. Knead thoroughly with the hands, and roll out the dough an inch or more thick. Bake in cakes with moderate heat.

## Horseradish and Honey for Hoarseness

This is one of the quickest-acting remedies known for hoarseness. Let the patient chew a small piece of the root, a piece about the size of the little finger. For a severer case, make a syrup of grated horseradish and honey, or horseradish and sugar and water, and give one teaspoonful every 1 or 2 hours as a dose.—Selected.

It is said that the celebrated Dr. Asada, attending physician to the imperial family of Japan, uses the above.

**Amerikanische Bienenzucht**, by Hans Buschbauer, is a bee-keeper's handbook of 138 pages, which is just what our German friends will want. It is fully illustrated, and neatly bound in cloth. Price, postpaid, \$1.00; or with the *American Bee Journal* one year—both for \$1.75. Address all orders to this office.

By W. A. PRYAL, Alden Station, Oakland, Calif.

## The "Harvest" of the Bee-Fathers

The great bee-keepers who placed the occupation of tending bees for profit in the high position it now occupies, have almost all passed away. Verily, when we cast our mind's eye over the field of bee-culture, it first appears to us that all the eminent workers of a few decades ago have been translated to the great "Bee-Pasture" beyond this life. Still, we have a few of these workers with us, but we hear but little of them. They have nearly gathered their last crop of honey and have gone into "winter quarters," as it were.

These reflections came to me as I was reading, a few minutes ago, "The Bee-Keeper's Directory," a pretentious volume issued from the press of San Francisco, in 1861, by J. S. Harbison.

FATHER HARBISON STILL WITH US.

J. S. Harbison! This was a name to conjure with 30 years ago; how seldom

J. S. HARBISON.

do we hear of it to-day! Harbison, the great! Harbison, the man who owned more bees than any other one man, and whose apiaries were scattered upon a hundred hills in Southern California! Yes, Harbison, the man who sent the first car-load of honey to the London market, and who previously had the honor of sending the first train-load of California sage-honey East. This was the man who did great things in California. And, strange to say, he never published anything to speak of about bees since the

appearance of his "Directory," 46 years ago—a long time, indeed!

Harbison was the father of California bee-culture, though he was not the first to import bees to this State; but in this he was only antedated by a few years by other persons. He, however, was the first to make big money out of bees in the Golden West.

## THE FIRST HONEY-SECTION.

J. S. Harbison is given the credit as the inventor of the surplus honey-section. It was a good, fat section—not small and skimpy, like the section now so common in the honey markets. If the pioneer inventor had made all-in-one-piece sections in the early days, and used separators as now in use, there is no doubt, in my mind, that the interests of bee-keeping would have been better off. A larger section should always have been on the market. The fault has been with the factories that turn them out, as the fault of queer styles in men's clothes lay with a tailor somewhere or another in one of the big cities of the world. Such is fashion; fashion, however, often does ridiculous things! Harbison says he invented the section on Christmas day, 1857—a splendid gift to bestow upon the bee-world and mankind; it was a great gift given on a great day. Just think, it will be a half century next Christmas day since the honey-section was invented.

## High Prices for Honey

I have noticed, as I have passed many stores in our cities lately, that comb-honey is marked higher than I ever knew it to be before in Central California. I saw it quoted at 20 cents per pound section. It has been usually a dime, though more often 15 cents, or 2 sections for 25 cents. But that price is nothing to brag about, though many a bee-keeper would like to get it for his entire crop. Twenty cents per pound is nothing to get for honey, compared with the price G. D. Heyford, of Nevada county (this State), received for honey in 1857, as reported in the *Pacific Rural Press* of November, 1889. Fifty years ago Mr. Heyford says that he and another person were bringing 10 colonies of bees from Maine to California. The bees were lost in a car-wreck on the isthmus, but the honey carried along to feed the bees arrived at Marysville all right, where it sold at \$5 per pound; and was not considered much of a luxury even at that price. The price obtained was sufficient to

pay the carfare (\$470) for each of the importers. Surely, if one had much of such sweets, and could realize as well on all of it as did those early bee-enthusiasts, he would have something better than a gold-mine. The price mentioned was better, however, than that obtained in San Jose for the first crop of honey produced in the State, so far as known. One pioneer bee-keeper had 400 pounds of box honey in 1856, which was sold for from \$1.50 to \$2.00 per pound. That price was not bad, either; (in lieu of \$5.00 I think I would be satisfied with the \$1.50 figure.)

## The Coming Honey Season

That is a hard thing to speak of, though nearly all of us drop into talk-

What will the crop be? I don't know; better ask the Man in the Moon. No one knows what a crop will be several months ahead in California, any more than he can tell elsewhere. One thing, everything is very favorable for an abundant harvest. A succession of cool nights may retard nectar-secretion in the flowers, so that the honey output will be small. We can not bank upon it, so we shall wait and see.

## Bee-Keeping at Berkeley

I learn that Ralph Benton is giving a series of lectures at the University of California upon bee-keeping. The lectures are given Saturday afternoons at Berkeley, and are free to all who may

this paragraph I may remark that it was hoped for a long time that the California University would call Prof. A. J. Cook to the Chair of Entomology. I trust it will do so. Then what a strong showing bee-cultural this already prominent seat of learning will make!

“Songs of Beedom.”—This is a beautiful 16-page-and-cover pamphlet, 6x9 inches in size, containing 10 bee-songs—words and music—all the songs so far written specially for bee-keepers, we believe. It is nice, as well as convenient, to have these songs all in one binding. Every bee-keepers' organization should have copies for use at conventions. They could be sold to members after using once, or held by the secretary for use

A CHARACTERISTIC SOUTHERN CALIFORNIAN SCENE—EAST SAN BERNARDINO VALLEY.

ing of the weather and the season quite often. 'Tis a habit we all sort of fall into—perhaps we learn to do so at the barber shop—a bad place to learn anything much, to tell the truth. But, to the season:

Well, so far it is all that any bee-keeper could desire. Plenty of rain, and more. February opened up in fine style; vegetation boomed ahead as if it were in a hot-house with bottom-heat. In the hives brood-rearing spread out fairly rapidly; honey and pollen came in so plentifully that a surplus of it was stored. By the middle of March some swarms were expected in the central portion of the State.

wish to attend. It has not yet been my privilege to meet this gifted young gentleman, withal he does not live a hundred miles from where I am writing this. (I wonder if he can hear the click of my typewriter, as I run off these lines.) I am glad the Regents of the University have secured some one that knows something practical about bees. Heretofore the entomological part of the bee was well considered by the department, but never was a capable person in charge of the practical side of bee-culture. As Mr. Benton grows older, I have not the least doubt but the bee-world will hear something remarkable from him. Before I close

at future meetings. Of course, every bee-keeper's family will want at least one copy. It is sent, postpaid, for only 25 cents, or 3 copies for 60 cents; or, we will mail one copy with the American Bee Journal one year—both for \$1.10. Send all orders to the office of the American Bee Journal.

**Our Wood Binder** (or Holder) is made to take all the copies of the American Bee Journal for a year. It is sent by mail for 20 cents. Full directions accompany. The Bee Journals can be inserted as soon as they are received, and thus preserved for future reference. Or we will send it with the American Bee Journal a year—both for \$1.10. Address office of the American Bee Journal.

Conducted by LOUIS H. SCHOLL, New Braunsfels, Tex.

## Texas BloomGalore and Swarm- ing in March

While the bees are still in the cellar "up North," their Southern "cousins" have a great variety of bloom to keep them busy. There are over 3 dozen bloomers for our bees during this month of March, of which I have specimens in my collections, and there are a few that have been added that occur in other parts of the State.

Some of these plants are not of great importance, but every little bit helps during the early spring months when brood-rearing is going on rapidly and the stores are consumed. Especially does the bee-keeper value the coming of these bloomers when he is aware that his colonies are running short, and, unless they do come, feeding must be resorted to. New pollen, and lots of it, is also a valuable thing during this season of heavy breeding, especially when the main honey-flow comes early and the bees must be "hurried" to populous colonies in "short order." For this reason many of the plants that yield only pollen are of considerable value; even though some of these yield small quantities of it, the fact that bees visit them is sufficient, or the bees would be "out" just so much.

Of course, those plants which yield both honey and pollen are of most importance, for nothing, in my mind, stimulates early brood-rearing more than both new honey and new pollen.

The following list is given, as the blooming periods of the plants follow each other, the time of each blooming period being given for each plant:

*Greggia camporum*, Gray, is a low-growing plant, bearing small white flowers in umbel-like clusters, in mountains, waste fields and fertile prairies of West Texas. Honey and pollen early, but not abundant, in the latter part of February and well into March.

*Quercus*.—This includes all of the Oak family; yielding pollen and honey from the "oak balls" made by a "gall insect." There are a great many species of oaks, but the most common ones are here given. Of these, *Quercus virginiana*, Mill—the Live oak is the earliest here, and occurs abundantly in the forests from the Gulf States through southern and west Texas to the mountains of New Mexico. *Q. minor* (Marsh), Sarg., or the common Post oak, is very plentiful on sandy or sterile soils, extending from the Atlantic States to central and southwest Texas. *Q. nigra*, L., Black Jack or Barren oak, has about the same range and habitat. *Q.*

*palustris*, Du Roi, Swamp, Spanish or Pin oak, is found on low ground extending in Texas to the valley of the Colorado River west; *Q. rubra*, L. (Red oak), and *Q. aquatica* Walt. (Water oak), with about the same range and habitat. Of these, the four last named are not so abundant, but all aid in early brood-rearing.

*Melia azadarach*, L., our umbrella shade trees, naturalized and much planted throughout central and southwest Texas, furnish an abundance of bloom, and help early brood-rearing during the month.

*Rubus trevialis*, Mx., or Dew-Berry, southern blackberry, common in eastern, southern and western Texas, upon which bees work busily for honey and pollen.

*Acacia farneciana*, Willd. (Huisache)—a tree much like the mesquite, but having smaller leaflets, dark green; the branches and limbs bearing long thorns. The flowers are globular, about ½ inch in diameter, yellow, and very fragrant. Honey and bright yellow pollen is obtained from this source. Its distribution extends from San Antonio to the Gulf Coast and lower Rio Grande, where it is very plentiful in the richer soils.

*Salix nigra*, Marsh—Black willow, and several other species, are well known for their value as stimulators in the spring, both for honey and an abundance of pollen. March and into April.

*Marubrium vulgare*, L., common hoarhound, often begins to bloom in March, and continues until late in summer, thus aiding in early brood-rearing, and later furnishing surplus honey where plentiful. It is found pretty well distributed over the South in fertile places, fence-corners and pens. The honey is amber in color, and sometimes of very nauseating sweetness, while it is claimed to be bitter by some persons.

*Vitis monticola*, Benkley—a common mountain grape, besides others of the grapes; they yield pollen to some extent.

*Juglans nigra*, L. (Black walnut), extending from the East to the valley of the San Antonio River, is not very abundant, but yields some honey and pollen.

*Hicoria pecan* (Marsh), Britton, is our Pecan Nut tree, and extends from the Gulf States to the streams of central and southwestern Texas. Much pollen is obtained, and I believe some honey, bees fairly roaring in the blooming trees, and colonies are much stimulated in brood-rearing.

*Hicoria atba* (L.) Britton, and other species, are hickory-nut trees, abundant in the sandy land sections of the southern part of the State, and yield some honey and pollen.

*Asclepias*, or Milkweed, yields some honey, and the sticky and cleft pollen clings to the bees' feet, often in such masses as to cripple them, to cause death to the tortured insect. The milkweeds are widely distributed.

Space this week does not permit me to give all of our March bloomers, so half of them are given which generally bloom by the middle of the month. The rest will be given later.

A trip to some of my yards a few days ago showed that colonies were getting along fine, new honey dripping from the combs when handled, and some colonies so strong that they were preparing to swarm soon. Supers were given to provide more room, and the entrances of the hives were raised to ¾ inches deep for better ventilation, so as to retard swarming until further manipulations to prevent it can be administered.

**Honey as a Health-Food.**—This is a 16-page honey-pamphlet intended to help increase the demand for honey. The first part of it contains a short article on "Honey as Food," written by Dr. C. C. Miller. It tells where to keep honey, how to liquefy it, etc. The last part is devoted to "Honey-Cooking Recipes" and "Remedies Using Honey." It should be widely circulated by those selling honey. The more the people are educated on the value and uses of honey, the more honey they will buy.

Prices, prepaid—Sample copy for a 2-cent stamp; 50 copies for 70 cents; 100 for \$1.25; 250 for \$2.25; 500 for \$4.00; or 1000 for \$7.50. Your business card printed free at the bottom of front page on all orders for 100 or more copies. Send all orders to the office of the American Bee Journal.

**Why Not Advertise?**—There are many dealers in bee-supplies, and those who have bees and queens for sale, who are not now advertising, that might increase their business by advertising in the American Bee Journal. The rates charged are very low, as will be seen by referring to the second page of this number. During the next 6 months will be done the bulk of the season's business among bee-keepers. Why not begin at once to let the readers of the American Bee Journal know that you have something to sell? Our advertising columns are open only to those who will give their patrons "a square deal." If you are in that class we will be pleased to have your advertisement in our columns.

**Bee-Song Souvenir Postal Cards.**—We have issued in colors, 3 bee-song postal cards for bee-keepers, each card having one of the following songs, about 2¼x3¼ in size, also with illustrated heading on each card: "Buckwheat Cakes and Honey," "The Bee-keeper's Lullaby," and the "The Humming of the Bees." The first two cards have small pictures of the authors of the words and music. This makes 4 souvenir postal cards we have now issued for the use of bee-keepers, the first being the "Honey-Bear" card. Prices, by mail, are as follows: Sample cards, 3 cents each; 7 for 20 cents, or 10 for 25 cents.

The Chicago-Northwestern Convention Photograph was taken Dec. 6, 1906, which was very good indeed. Price, post-paid, in mailing tube, 60 cents. Send orders to the office of the American Bee Journal, and we will see that the pictures are mailed.

Send Questions either to the office of the American Bee Journal, or to  
 DR. C. C. MILLER, Marengo, Ill.  
 Dr. Miller does *not* answer Questions by mail.

### Buying Bees or Making Increase

I am 21 years old, and I own 4 colonies of bees. I am as interested in the bee-business as I think any person can be. I have read all the bee-literature I could for 3 years. At present I am taking 4 bee-papers. Would you advise me to buy more bees, or to wait until those I have increase? WISCONSIN.

ANSWER.—That depends. If you want to increase to a considerably larger number, and have an opportunity of buying a few colonies at a bargain, as sometimes happens at an auction, or when some one wants to get rid of his bees, it will be well for you to buy. But if you can't buy for less than \$5.00 a colony, then it will be more profitable for you to run your bees for increase than for honey. Only don't make the mistake of having a number of weak colonies on hand in the fall. It would, no doubt, be an easy thing to increase those 4 colonies to 20 or more by fall, and then lose most of them in the winter because too weak, but in the long run you will get on faster to move a little more slowly and surely. Of course, something depends upon the season. In a very poor season it may not be safe to increase at all, unless you do a good deal of feeding. But if you reach next fall with 10 or 12 strong colonies, another good season ought to bring you up to 40 or so.

### Queerly Acting Colony Perhaps Queenless

I have one colony the bees of which seem to be making a noise at the entrance and running up and down the front of the hive, and all over the alighting-board. They will fly off just a little and then back. In fact, they act queerly—as if they had been disturbed or dequeened. I have 16 colonies, all on the summer stands, and all are quiet except this one. What is the matter? KENTUCKY.

ANSWER.—It is very much to be feared that the colony is queenless. By this time there ought to be in your locality brood in any colony that has a good queen. If you find no brood present it is pretty certain they have no laying queen. I don't know just how early matters are in your part of Kentucky, but another possibility is that a young queen has been reared, and that the bees were excited, as you found them, when she took her wedding-flight. Give the colony a comb containing young brood, and if they start queen-cells it is fair evidence that no sort of queen is present, though, sometimes, bees start cells when a virgin is present.

### Putting Full Supers on the Hive

On page 121, is a picture of L. A. Smith and a colony of Carniolans. How is he going to put those supers back without smashing a lot of bees? CALIFORNIA.

ANSWER.—Not often will enough bees be in the way to make much trouble. When a few are on the upper edges of the sides and ends

of the brood-chamber, suggest to them that they better get off by means of a little smoke. Don't blow down upon them, but blow upwards against the outside of the brood-chamber, and enough smoke will come up at the top. But when the bees are piled over the top as they appear to be in the picture to which you refer, a quicker way is to use no smoke, or, at most, only a little on the edges, and set one end of the super on the brood-chamber, keeping the other end raised 6 inches or so. While letting the first end down, don't do it quickly or you'll mash a lot of bees; but with an up and down and also a sort of sliding motion, until you can get at least one corner to rest without any bees under it, then you will gradually let down the whole super, playing it up and down, gradually letting it down a little and a little lower until clear down, and you need not kill a bee although they may be clustering an inch thick all over the hive.

### Growing Basswood Trees

1. I have just ordered some basswood trees. How close can I plant them together?
2. Will they grow well in this climate; that is, hot and dry in the summer-time, subject to strong winds in winter, no snow, and temperature never falling very low?
3. How long will it be before they yield nectar to amount to anything?
4. How much water do they need when growing? CALIFORNIA.

ANSWERS.—1. When they get to be large trees, 20 to 25 feet is close enough. It is not a bad plan to plant only half as far apart as you want the trees finally; then when half grown, to cut out three-fourths of them. The danger is that you will be too tender-hearted to cut them at the right time; but you will not have so much nectar from large trees that are too crowded. You will easily see, however, that up to the time they get half their full growth there would be a gain in nectar by having the larger number of trees.

2. I don't know. One would think that conditions are all right; yet I don't remember that any one has reported planting basswoods on a large scale in California.

3. Not before 8 or 10 years in this locality; but things move faster in your pushing climate.

4. At a guess, I should say the same amount as crops in general, particularly other trees.

### Requeening from a "Star" Colony

I have 8 colonies of bees, one of which gives me more honey than all the rest together. I want to requeen all colonies from that one "star" colony. How am I to do it and still get returns from all? My surplus never begins until Aug. 1. NEW JERSEY.

ANSWERS.—Build up the colony with the best queen by giving it brood and bees from other colonies, making it so strong that it will swarm before any other colony. Call this colony No. 1. and let No. 2 be the

strongest of the other colonies, No. 3 the next strongest, and so on down to No. 8, the weakest. When No. 1 swarms, put the swarm on the stand of No. 1, put No. 1 on the stand of No. 2, and put No. 2 on a new stand. In about 8 days No. 1 will swarm again with a virgin. Put the swarm in place of No. 1, put No. 1 in place of No. 3, and put No. 3 on a new stand. A day or two later, when No. 1 swarms again, proceed as before, and let No. 1 take the place of No. 4, and then in succession of Nos. 5, 6, 7, and 8, provided No. 1 is complaisant enough to swarm so many times, which would be nothing strange. You will now have 8 colonies of the same stock, 7 colonies with the other old queens, and you ought to have as much honey as if each colony had swarmed once.

Perhaps you would rather proceed another way. A little before there is danger of swarming, put in the central part of No. 1 a frame with a starter of foundation not much more than an inch deep. A week or 10 days later take out this frame (it wouldn't be a bad plan to put in its place another frame of the same kind in case it should be needed later), and trim off the edge of the comb that contains only eggs, but not trimming away any of the young larvae. Put this frame in the middle of No. 2, at the same time removing the queen of No. 2. Ten days later—be sure not to wait longer than that—you ought to have a lot of fine queen-cells. Put each one into a cage, having the cage provisioned so the bees can eat into it, the same as in introducing a queen, remove the old queens that you want to replace, and at the same time put in the caged queen-cells. If all goes well, the bees ought to do the rest. This plan will change the queens without any increase, and there ought to be no swarming with young queens so reared. Of course, you can combine the two methods in a variety of ways.

Another way is to make nuclei and rear young queens, introducing them afterwards.

### Pollen from Red Cedar

My bees gathered pollen from red cedar today (March 4), and as I have failed to find cedars referred to as a source of honey or pollen, it struck me as something rather unusual. Is that a common occurrence? ARKANSAS.

ANSWER.—I don't know; but it is quite likely that it is nothing unusual, even though no mention may have been made of it. It is only the plants from which unusual quantities of either honey or pollen are obtained that are generally mentioned as honey-plants.

### Do Bees Get Disease from Comb Foundation?—Superseding Queens

1. Is there any danger of introducing foul brood, or any other disease, into my colonies by using freely of comb foundation?

2. Is it not a fact that many combs affected with foul brood and other diseases are rendered into wax, and that the foundation on sale by all dealers is contaminated more or less with this same wax?

3. In Doolittle's "Queen-Rearing," page 111, he says: "To supersede a queen, hatch a young queen in an upper story over a zinc excluder, and after she is hatched remove the excluder and your old queen is superseded." Will the plan work invariably?

4. How soon after the young queen hatches, as mentioned in No. 3, shall I remove the excluder to make success certain? INDIANA.

ANSWERS.—1. I don't believe there is any danger.

2. Undoubtedly much wax is made from foul-broody combs, and just as undoubtedly much of it must fall into the hands of the manufacturers of comb foundation. But it does not necessarily follow that the foundation is contaminated so as to make it in the least dangerous. I have bought hundreds of

pounds of foundation, and there has never been any foul brood among my bees. Hundreds of others have done the same. The continued high temperature to which the wax is subjected when being made into foundation, destroys even the spores in foundation. I think that some hold, too, that even if a spore were not destroyed by the heat it could not germinate after receiving an impervious coating of wax.

3. No; and I do not think Mr. Doolittle claims invariable success. Remember that in the natural course of events every queen is superseded by the bees, and that such superseding usually occurs somewhere in the neighborhood of the close of the harvest. Now when any colony has a queen that it is about to supersede, if you will get in a little ahead by having over the excluder a virgin before one has been reared below, you may be practically certain of success. If you do the same thing early in the season, especially where a vigorous queen is doing duty below, you may expect failure.

4. From what has been said, you will see that the time of taking away the excluder has little to do with success. If you want to take advantage of the plan, about the close of the harvest, give a cell from the best stock to each queen you want superseded, and take away the excluder immediately after the virgin emerges, or a day later, or 2 or 3 days later, and where you succeed you will have better stock than if you had left the bees to themselves; and where you fail you will only have lost a queen-cell. But you stand a chance of many successes.

## Best Bees for Comb Honey—Full Sheets of Foundation

1. What kind of bees do you consider the best for the production of comb honey?
2. Is it better to have full sheets of foundation in the brood-frames? Also in sections? If so, why?

MAINE.

ANSWERS.—1. In general, the best workers, that is, those which will store the most honey. Yet there are two things to be taken into account that might make one prefer bees that are not the greatest storsers. Suppose we have a colony that stores a certain amount, and another that stores 5 percent more, but the latter daubs its sections very badly with glue, while the former leaves them practically clean. In that case we would be likely to prefer the poorer gatherers. Again, there is a great difference in the whiteness of sealing. Some colonies seal snowy white, while others make sections look watery or greasy. The latter are not satisfactory for sections, no matter how good storsers. The Punic, or Tunisians, are the worst I ever knew for both glueing and watery sealing, and it is possible that the two go together generally. Black bees are said to seal whiter than Italians, but I suspect that Italians are not alike in this respect, for my Italians and hybrids have made very white sections. On the whole, you probably can do no better than to get a good strain of Italians for section work. Possibly Caucasians may prove to be desirable, but at present reports about them are too contradictory to recommend them unreservedly.

It may not be out of place to suggest that you can do well to watch which colonies do best at giving a big lot of very white sections, and breed from such colonies.

2. Yes; because you will then be sure of having combs entirely straight, and no drone-cells.

The San Antonio Convention Picture is a good one. It shows over 100 of those in attendance. We are mailing them, unmounted, for only 60 cents. They can be mounted by a local photographer for only 10 or 15 cents more. We will mail one of these pictures with the American Bee Journal one year—both for only \$1.40. Send all orders to the Bee Journal office.

## Gathering Clover Pollen—Fission

On page 152, Mr. Hasty says, "Live ones (meaning bees) seldom have pollen when working on clover." It is all very different here. I believe at least  $\frac{1}{3}$  of all the pollen gathered is from clover. In my locality but very little buckwheat is grown. Frequently I have found the combs over-stocked with late clover pollen—even the extracting combs sometimes contain sickening quantities of clover pollen. Clearly a case of conditions and locality.

REPRODUCTION BY FISSION.

When Mr. Hasty gets his endowed institute in successful operation to study Fission with a hundred microscopes, till the secret is discovered why the cells of creatures that reproduce by Fission do not grow old, I guess it will be found out that they do grow old, and that new ones are constantly forming. Meekly and lowly, I beg to suggest that it may not be profitable or wise to discuss the birth of Christ in the fashion found on page 153.

S. T. PETTIT.

Aylmer, Ont., Feb. 25.

## Very Early Season

Our season is very early. Bees are at the swarming point. First eggs were found in queen-cells on Feb. 27. Prospects for honey are fine.

J. W. K. SHAW & Co.

Loreauville, La., March 11.

## A Beginner's Success

I am a young man, who, by lucky chance, got a couple of colonies of bees 2 years or more ago. And having good luck last summer I increased to 4, had lots of honey for our own use, and sold some \$12 worth of comb honey. I am in favor of the T-super, which I use with plain sections and fence-separators.

WALTER M. ADEMA.

Berlin, Mich., Feb. 23.

## Large Hives Are Best

On page 167, Dr. Bohrer, in an article under the heading, "Non-Swarming Hives to Prevent or Control Swarming," says that in 1864 he used a hive with 16 or 18 frames Langstroth size. From my experience with many sizes and styles of hives, the Jumbo 10-frame comes nearer filling the bill than an odd-size hive-body will. By all means let us have uniform sizes of hives, except as to depth; that is a matter of choice. If one desires to produce extracted honey, supers 6 $\frac{3}{4}$  inches deep, with frames 6 inches deep, will give better results than deeper ones. The combs will not break down in hot weather, and are sealed over, and you can give surplus-room as it is needed.

THOS. M. CHERRY.

Quincy, Ill., March 1.

## Starting With Bees, Etc.

I started a year ago with 7 colonies in box-hives, and with the aid of "ABC of Bee-Culture" and reading bee-papers I increased them to 50 colonies, and took off about 500 pounds of nice section-honey. This year, with an extractor, I expect to make them do much better. The \$1.00 queens I bought in the spring did not do well. I suppose it was too hot. But in August I got 2 dozen from a Louisiana breeder. They all did fine.

The last 3 winters we have had plenty of rain in Arizona. Spring is here now with all of its beauty. The bees are just as happy

and busy as they can be. I do love to see them come in with their loads of pollen. The little birds are building their nests under the eaves of the porches. I want to kill them, but my wife says, "No, no; you must not kill them; they are just as happy as your bees;" and so they are, bringing sticks, straws, and strings. I am afraid they will eat my bees, but the good lady and the birds will have to have their way about the matter.

I make my own hives, and I believe every beginner, if he is not able to buy them, should make as many of his bee-fixtures as possible. I think every bee-paper should give instructions, simple and plain, how to make a good hive, with drawings and cuts of every part of it, so as to make it easily understood by any one; and keep these instructions continually in the bee-papers. It is the poor people who need help. The rich can and will get on all right.

T. J. RIGGS.

Teviston, Ariz., Feb. 16.

[We imagine if the same instructions and drawings were kept in Mr. Riggs' bee-paper for a year or two, he would get pretty tired of seeing them. The better way would be for the beginner to get one hive all complete, nailed and painted, and then use it as a sample.—EDITOR.]

## Feeding Bees in Winter

I have 6 colonies of bees, and they are doing nicely. I fed them all through the winter. In January I fed them on 15 days, and in February, 17 days. I fed them outdoors, taking 2 pounds of sugar and 2 pounds of water to make the syrup, and put it in old brood-combs, and then laid them on top of 3 one-gallon jars. It is great sport to watch them work.

J. F. McCLURE.

Gaylord, Kans., March 1.

## Bees and Grapes

I have seen a good many men discussing the question of bees destroying grapes and fruit. I have often read of this but I think none of them are correct. I believe the cause of grapes cracking open is their ripening in a dry spell or a drouth. Last year they cracked open in this part of the country more than they have for years, and the bees worked on them so badly that it was a disagreeable job to cut them without getting stung on the fingers.

The grapes ripened in 2 or 3 weeks in dry weather, and when they did get ripe there came a heavy rain a week afterward; then the vines drew more moisture out of the ground, causing the ripe grapes to get more juicy and riper, and they began to crack.

The same is true of a tomato. If a tomato gets ripe in one week and is left on the vine until the next week, and there comes a rain, it will crack just the same as do the grapes.

MILAN, Ill., Feb. 28. JOSIAH JOHNSTON.

## Increasing 1 Colony to 7, and Getting a Crop

How I happened to be reduced to one colony might be more interesting, but a hundred or more empty combs and stacks of empty hives and fixtures would be a strange contrast with the reports given in the bee-papers for the past poor season. So I will start with my one Italian queen of the red clover strain, in a 10-frame hive packed in a chaff case of large dimensions. When I found myself reduced to this in the spring of 1906, I held a "bee-convention" all by myself, and resolved to devote the remainder of my life to the science and art of bee-keeping; that I would turn over a new leaf and pay more attention to queen-rearing; that I would attend to the wants of the bees, no matter what else was neglected.

I commenced the season by getting one more queen. I gave 2 frames of brood and bees, and one of empty comb, to the new queen, and some D. section-cases to the old one. About as soon as they got well started

In the sections, a large swarm came out and clustered in the old apple-tree, under whose branches I had held my "bee-convention." Then I took the hive of brood and queen-cells and made 3 of it, putting the extra cells in West queen-cell protectors.

The old queen with the swarm filled the empty combs and did some work in the sections and swarmed again. I hived them again on more empty comb and sections, and the combs of brood and bees I divided again, making 7 in all. These small colonies were built up by feeding, and given empty comb, one frame at a time as needed. When the golden-rod began to bloom all were built up strong, and all filled up for winter. The crop of honey was not over 25 pounds, but was all engaged at 25 cents per pound before it came off the hives. Three or 4 dollars worth of sugar was fed, and 3 bee-papers subscribed for.

My ledger account would stand something like this: Cash paid, \$7 to \$8; honey sold, \$5 to \$6. Given away and used, \$2 to \$3. As my hopes are banked on 7 colonies this winter instead of 2, I shall have to wait until spring to see if my bee-keeping has been a paying business or an expensive luxury.

E. B. WHIFFLE.

Hillsboro Center, N. H., Feb. 20.

### Bees Wintering Well

Winter here has been quite severe, but it seems to have broken. I had my bees in a dark room where the temperature was even, but very cold. Last Sunday was an unusually bright and warm day, so I got out one colony and let it fly. I found the bees clean and healthy, but short on stores. Still, if I can help them to hold their own from this time till spring actually opens, I will have a good start for the summer's campaign.

I ran across the American Bee Journal away up in the mountains of Montana last October. It was like meeting an old friend.

S. E. FARNHAM.

Madison, Minn., Feb. 20.

### Black Bees vs. Italians

In the discussion of the black and the Italian bees with Mr. Macdonald, on page 105, there is no hint of a variation in type, in either. Two types of Italians have been recognized in this country from the beginning, and these differ in those characteristics that make for profit, as is shown by the fact that honey-producers, as a rule, prefer the one and queen-breeders the other.

There are 2 types of blacks, also—the one black, small and vicious; the other brown, large and gentle. Intermixture in some districts has nearly effaced these distinctions, but in others they are as real as the band of the yellow bee. Now, why is it that in all later references to the black this well-known difference of type is ignored? As well group all the yellow races as one, and judge them by the Cyprian.

In these discussions is not the word "strain" often misused? Would not type, or, better still, race, be more to the point? You may condemn a bee whose ancestors ages ago swarmed in the Black Forest, while Mr. Macdonald may commend a bee whose ancestors never crossed the Channel. There may be a British bee. If Nature, through ages of isolation, has produced races on the Continent, why not in the British Isles? Certainly, their geographical situation and climatic conditions should seem fully as favorable as the corresponding conditions in Carniola. Personally, I use the Italian, but think that careful breeding might eventually put the brown bee in the lead.

Clifton City, Mo. E. W. DIEFENDORF.

The Chicago-Northwestern Convention Photograph was taken Dec. 6, 1906, which was very good indeed. Price, postpaid, in mailing tube, 60 cents. Send orders to the office of the American Bee Journal, and we will see that the pictures are mailed.

## TEXAS QUEENS

The Famous Honey-Producers

## Texas Queens

The Famous Honey-Producers

I am booking orders now for April, May and June delivery, for Carniolans, Italians, and Goldens—equal to the best, regardless of price. PRICES:

Teated Queens	.... \$1.00 each; \$10.00 per doz.
Warranted " "	.... .75 " 7.00 "
Untested " "	.... .50 " 5.50 "

6Atf GRANT ANDERSON, Sabinal, Texas.

## How to Make Money Easy

Restock your apiaries with Atchley Queens; they do the rest. We breed all of the leading races in their purity. Untested, \$1 each; \$9 per doz.; \$60 per 100. Tested, \$1.50 to \$2.50 each; Breeders, \$3 to \$5 each. 1, 2, and 3 frame Nuclei, and bees by the car-load, our specialty. Get our prices before you buy. We manufacture standard bee-supplies cheap. Catalog free. Will exchange queen-bees or bee-supplies for honey. Beeawax wanted at all times. **The Bee & Honey Co.**

WILL ATCHLEY, Mgr.

11Atf Box 218, Beeville, Bee Co., Texas.

## Something New=The Ideal Hive-Tool

Bee-keepers have long needed a special Tool to work among the hives during the bee-season. The one shown here was invented by Wm. Muench, a Minnesota bee-keeper, some years ago, but it was not on the market before. We have lately bought this Tool, and all rights, from Mr. Muench's widow, and have had the first lot made. They are ready for delivery now.

Best Hive-Tool

Only 30c, by mail

(This picture is exactly one-half the size.)

**DESCRIPTION.**—The Ideal Hive-Tool is made of high-grade malleable iron, much like wrought iron, 2½ inches long. The middle part is 1 1-16 inches wide and 7-32 thick. The smaller end is 1¼ inches long, ½ inch wide, and 7-32 thick, ending like a screw-driver. The larger end is wedge-shaped, having a sharp semi-circular edge, making it almost perfect for prying up covers, supers, etc., as it does not mar the wood.

### What Dr. Miller and Miss Wilson Say of It:

In the first edition (1903) of Dr. Miller's "Forty Years Among the Bees," page 58, he says: "Of all the hive-tools I have tried, I like best the Muench tool." On Jan. 4, 1907, he wrote us saying he thought "just as much of the tool as ever."

Miss Wilson, Dr. Miller's assistant, says this of the Ideal Hive-Tool: "It is an ideal tool. In fact, I don't see how it could be improved upon. I am sure we would feel utterly lost in the apiary without it..... You will have to try one yourself if you want to know its worth."

### The "Ideal Hive-Tool" Free as a Premium.

We will mail an Ideal Hive-Tool FREE as a premium to any present paid-in-advance subscriber to the American Bee Journal, for sending us ONE NEW subscription for a year at \$1 00; or we will send the American Bee Journal one year and the Ideal Hive-Tool—both for \$1.20. Price of the Ideal Hive-Tool alone, postpaid, 30 cents. Address,

**GEORGE W. YORK & CO., 334 Dearborn Street, CHICAGO, ILL.**

## Langstroth on the Honey-Bee

Revised by Dadant—Latest Edition.

This is one of the standard books on bee-culture, and ought to be in the library of every bee-keeper. It is bound substantially in cloth, and contains nearly 600 pages, being revised by that large, practical bee-keeper, so well-known to all the readers of the American Bee Journal—Mr. C. P. Dadant. Each subject is clearly and thoroughly explained, so that by following the instructions of this book one cannot fail to be wonderfully helped on the way to success with bees.

The book we mail for \$1.20, or club it with the American Bee Journal for one year—both for \$2.00; or, we will mail it as a premium for sending us **THREE NEW** subscribers to the Bee Journal for one year, with \$3.00.

This is a splendid chance to get a grand bee-book for a very little money or work.

**GEORGE W. YORK & CO.**

334 Dearborn Street, CHICAGO, ILL.

## SAVE YOUR QUEENLESS COLONIES

Introduce a vigorous Tested Queen; we can furnish them by return mail, from our fine strain of 3-band Italians; Queens reared last fall, and wintered in 4-frame nuclei. None better.

While the Present Stock of these **BEE-HIVE CLOCKS** lasts, we will sell them at only **\$2.00 each**, by express; or \$2.50 for the Clock and the Weekly American Bee Journal one year. **Better order at once**, before all are gone.

# The Bee-Hive Clock

A \$4.00 CLOCK FOR \$2.50 ... With the  
American Bee Journal 1 Year—  
Both for **Only \$3.00**

We have originated and had made specially for our readers, a bronzed-metal Clock, called "The Bee-Hive Clock." It is 10 $\frac{1}{4}$  inches wide at the base, 9 $\frac{3}{4}$  inches high, and deep enough at the base to stand firmly on a mantel or elsewhere. It is a beautiful piece of work, and would be both ornamental and very useful in any house, and particularly in a bee-keeper's home.

The Clock part itself is warranted for 3 years to keep good time. So it is no plaything, but a beautiful and needful article for everyday use.

Clocks like "The Bee-Hive Clock" usually sell in the stores at from \$4.00 to \$5.00 each, but having them made for us in quantities enables us to offer them at \$2.50 each by express, or with the American Bee Journal a year—both for only \$3.00. Either Clock or Journal would make an ideal gift.

## How to get "The Bee-Hive Clock" FREE

Send us **5 New Subscribers** to the Weekly American Bee Journal for one year, at \$1.00 each, and we will send you this beautiful "Bee-Hive Clock" **FREE** (excepting express charges). Or, send us **4 New Subscribers** (at \$1.00 each) and 50 cents—\$4.50 in all. Or, **3 New Subscribers** (at \$1.00 each) and \$1.00—\$4.00 in all. Or, **2 New Subscribers** (at \$1.00 each) and \$1.50—\$3.50 in all.

Only \$2.50, f.o.b. Chicago, by Express.  
Weight, with packing, about 4 pounds.

## What Dr. Miller Thinks of the Bee-Hive Clock

Busily ticking away, in the room where I am sitting, stands a genuine bee-keeper's clock (please understand that the word "genuine" belongs to the clock and not to the bee-keeper) or, as the legend upon the clock has it, "The Bee-Hive Clock." I don't know

whether the idea of getting up such a clock was conceived in the brain of the Editor of the American Bee Journal, or whether he got it elsewhere, but the wonder is that such a thing was not thought of long before.

Setting aside all idea of its association with the business of a bee-keeper, there is a peculiar appropriateness in having the minutes and the hours "told off" in a case representing the home of the busy little workers. The glance at the clock, with its ceaseless tick, tick, tick, can not fail to remind one that the flying moments must be improved now or be forever lost, and that suggestion is reinforced by the thought of the never ceasing activity of the little denizens of the hive, always busy, busy, busy, working from morn till night and from night till morn, working unselfishly for the generations to come, and literally dying in the harness.

Let us be thankful that the form of the old-fashioned straw hive or skep was adopted, and not that of any modern affair, patented or unpatented. The latter smacks of commercialism, but the former of solid comfort, for no other form of hive has ever been devised that contributes so fully to the comfort and welfare of a colony of bees as does the old-fashioned straw-hive. It appeals, too, to one's artistic sense as can no angular affair of more modern times. As an emblem of industry, artists have always used—probably always will use—the old straw skep.

Thanks, Mr. Editor, for furnishing us a time-keeper so appropriate for all, and especially for bee-keepers. **C. C. MILLER.**

Address all orders to **GEORGE W. YORK & CO., 334 Dearborn St., CHICAGO, ILL.**

*Millions of Dollars*

are made every year in the book business. Every family, rich or poor, must have books. During the last few years, \$7,500,000.00 have been expended for Modern Eloquence, \$12,000,000.00 for Stoddard's Lectures, \$1,000,000.00 for the Century Dictionary, and the tremendous sum of \$14,000,000.00, covering over half a million acts of the Encyclopedia Britannica. These books were sold by subscription in American homes and sales are still going on.

We have a subscription publication which sells more readily than any of the above. The demand is already so tremendous that more capital is required to swing it, or get behind on orders. Profits are enormous, several times savings bank interest.

We have arranged a plan whereby **Any Progressive Man or Woman Can Share These Profits**

becoming stockholders in a profitable business, based on twenty years' experience. Remember, the success of this publication is not away off in the future—it is not prospective, but it is a success at the present time and growing in demand every hour. Sales of this publication at the time of publishing this advertisement

**Often Exceed \$2000 a Day**

This is an exceptional opportunity for those of small means to get in on the ground floor in a business which legitimately pays large dividends and is as solid as the Rock of Gibraltar. It cannot be held open for long as the response is certain to be so great that we shall have all the capital we need to increase the number of our presses and secure stock to be turned out in completed books, which are selling like wildfire.

You owe it to yourself to investigate this opportunity. You will never have a chance like this again to become

**Part Owner in a Mammoth Publishing House**

which is already in successful operation, already earning big dividends, and which is led to sell a small amount of its stock simply because the business is already so tremendous as to exhaust the working capital. But if you would grasp this opportunity you must

**Write Quick—Only a Few Can Come In**

Address your letter to me personally, like this—

**A. G. WOODMAN CO., Grand Rapids, Mich.**

Mention Bee Journal when writing.

**American Bee Journal Novelty Pocket-Knife Gold Fountain Pen**

All for **\$3.00**

(This cut is the full size of the Knife.)

**NOVELTY POCKET-KNIFE**

(Name and Address on one side—Three Bees on the other side.)

Your Name on the Knife.—When ordering, be sure to say just what name and address you wish put on the Knife.

The Novelty Knife is indeed a novelty. The novelty lies in the handle. It is made beautifully of indestructible celluloid, which is as transparent as glass. Underneath the celluloid, on one side of the handle is placed the name and residence of the owner, and on the other side pictures of a Queen, Drone, and Worker, as shown here.

The Material entering into this celebrated knife is of the very best quality; the blades are hand-forged out of the very finest English razor-steel, and we warrant every blade. It will last a life-time, with proper usage.

Why Own the Novelty Knife?—In case a good knife is lost, the chances are the owner will never recover it; but if the "Novelty" is lost, having name and address of owner, the finder will return it. If traveling, and you meet with a serious accident, and are so fortunate as to have one of the "Novelties," your POCKET-KNIFE will serve as an identifier; and, in case of death, your relatives will at once be notified of the accident.

How to Get this Valuable Knife.—We send it postpaid for \$1.25, or club the Novelty Knife and the American Bee Journal for one year—both for \$2.00. (Allow two weeks for Knife order to be filled.)

**SOLID GOLD FOUNTAIN PEN**

Finally we have found a good Fountain Pen that is reasonable in price. The manufacturers of this pen say that if you pay more than \$1.25 for other fountain pens, it's for the name.

This pen is absolutely guaranteed to work perfectly, and give satisfaction. The Gold Nibs are 14 kt., pointed with selected Iridium. The Holders are Para Rubber, handsomely finished. The simple feeder gives a uniform flow of ink. Each pen is packed in a neat box, with directions and Filler.

# HERSHISER WAX-PRESS

Manufactured Exclusively by

**G. B. LEWIS CO., Watertown, Wis.**

"NOT IN ANY TRUST."

We are offering to our customers this year for the first time the Hershiser Wax-Press, a cut of which is herewith given. It has just been invented, and consequently has never before been offered for sale.

The Hershiser Wax-Press is not only the best wax-press ever put on the market, but it is an almost perfect device for extracting wax. We will guarantee it will extract within 1 percent of all the wax contained in the slumgum placed in it, if properly operated. All the other wax-presses now in common use will necessarily leave in the slumgum a large amount of wax, the quantity varying from 8 to 25 percent; in other words, the Hershiser Press is able to get about 7 percent of wax out of slumgum after the very best of all other wax-extractors has obtained the greatest possible amount of wax from it.

**For Sale Everywhere  
Ask Your Dealer About It**

**Read what One of the First Users, who is an Experienced Bee-Keeper, says of the Hershiser Wax-Press:**

Mr. O. L. HERSHISER, Buffalo, N. Y. GROTON, Tompkins Co., N. Y., Jan. 2, 1907.  
*My Dear Sir:*—I have had one of your wax-presses for about 30 days, have used it about one-half of the time and got out 700 pounds of nice wax from the slumgum and refuse that accumulated in 18 months from the kettle and boiling process of getting out wax that I have used for years and thought I got out all the wax. The machine more than paid for itself in 5 days. Mr. Hershiser, I think I am safe in saying that I have thrown out in the field \$100 to \$150 worth of wax each year for the last 10 or 15 years. You surely have them all stopped on wax-presses.  
 W. L. CORTSHALL.

## A GREAT IMPROVEMENT

Will be found in

# The American Bee-Keeper for 1907

It is profusely illustrated and enlarged, and contains only articles of the most practical as well as scientific nature. A special corps of the best writers has been engaged. The editors are Harry E. Hill and Arthur C. Miller, than whom there are no more practical or experienced bee-keepers in this country. We have published the American Bee-Keeper continually and regularly since 1890.

Regular subscription price, 50 cents a year. One year to new subscribers, 35 cents; three years for \$1.00.

Send for sample copy and our new illustrated price-list of **BEE-SUPPLIES OF ALL KINDS.**

Guaranteed highest quality at lowest price. Address,

**THE W. T. FALCONER MFG. CO.**  
JAMESTOWN, N. Y.

(Established 25 years.)

## Honey and Beeswax

CHICAGO, Feb. 1.—The usual late winter demand is in evidence for comb honey to replace diminished stock laid in during the autumn by the large retailers, but during the dull period there has been very little change, if any, in prices, the offerings being light.

We find No. 1 fancy white comb honey brings 15@16c, and for that which is off in color and flavor from 1@3c less. Amber grades of all kinds are dull and range in price from 10@12c. The extracted perhaps is not quite so firm in price for the California or Western grades, but there is no surplus of white clover or basswood, both of which bring about 8c, and in some cases more. Ambers grade from 6@7½c. There have been some sales of beeswax at 32c, but 30c is about the price for average.

R. A. BURNETT & Co.

PHILADELPHIA, Mar. 11.—The comb honey market has been quite active in the last two weeks, and the continual cold weather has kept things moving. Many cheap lots have been sent in from the producers, which have had a tendency to bear on the market and weaken the prices somewhat. Fancy white comb honey, 15@16c; No. 1, 14@15c; amber, 12@14c. Fancy white extracted honey, 7@8c; light amber, 6@7c. Beeswax very firm, 32c.

We are producers of honey and do not handle on commission. WM. A. SELSER.

NEW YORK, Jan. 15.—The stock of white comb honey is pretty well exhausted, and we do not expect any more arrivals of large lots from now on. Prices are firm, and we quote from 15@16c for fancy white; 13@14c for No. 1; 12c for light amber. There is quite a little dark and buckwheat on the market, but no overstock, and we think that all of it will be disposed of before long at present prices, which we quote from 10@12c, according to quality. Extracted honey very firm, with sufficient supply to meet demand. California white sage is bringing from 8@8½c; light amber, 7½c; amber, 6½@7c; buckwheat extracted in fairly good demand at 6@6½c. Southern in barrels finds ready sale at from 55@70c per gallon, according to quality. Beeswax firm and steady at 31c. HILDRETH & SARGELKEN.

DENVER, Feb. 14.—Producers in this State are practically closed out of both comb and extracted honey. We have not sufficient good comb honey to supply our local trade, but have

# Headquarters for Bee-Supplies

Complete stock for 1907 now on hand.

# C. H. W. WEBER CINCINNATI OHIO

Office and Salesrooms, 2146-48 Central Ave. Warehouses, Freeman and Central Aves.

a good supply of white extracted of excellent quality. We quote strictly No. 1 white comb honey, per case of 24 sections, at \$3.20; No. 1, light amber, \$3; and good No. 2, \$2.80. White extracted, 8@8½c per pound; light amber, 7½@8c. Clean, yellow beeswax, 27@28c, delivered here.

THE COLO. HONEY-PRODUCERS' ASSN.

CINCINNATI, Mar. 11.—There is very little demand for extracted honey at this writing, which is only natural, owing to the unsettled weather at this time of the year. However, we are looking forward with interest to a revival of trade, as soon as the warm spring days are here. We quote amber extracted honey in barrels at 6¼@7½c, the price depending upon the quantity purchased. Fancy table honey in crates of two 60-lb. cans each, at 8@9c. There is little demand for comb honey owing to the lateness of the season. Choice yellow beeswax, 32@35c, delivered here.

THE FRED W. MUTH CO.

INDIANAPOLIS, Feb. 25.—comb honey is not plentiful, but demand is slack. Fancy white comb brings 16@17c; No. 1 white, 14c; amber, 12@13c. Best grades of extracted honey bring 8@9c; amber, 6@7c. Good average beeswax sells here at \$35 per 100 pounds.

WALTER S. POWDER.

TOLEDO, Nov. 30.—The market on comb honey remains about the same as last quotations, but has been coming in much more freely, as beekeepers seem to be very anxious to get rid of their stock. Fancy brings in a retail way 16c; extra fancy, 17c; No. 1, 15c; buckwheat, 15c. Extracted white clover in barrels brings 7@7½c; cans the same. Beeswax, 26@28c.

THE GRIGGS BROS. & NICHOLS CO.

CINCINNATI, March 6.—The market on comb honey has been quite brisk the past week. Entirely sold out of fancy white. No. 2 is selling for 12¼@13c. White clover extracted in cans, 9c; amber in barrels, 6c. Beeswax, 30c, delivered here. C. H. W. WEBER.

KANSAS CITY, Mar. 4.—The demand for comb honey is only fair at present. The market is almost entirely bare of extracted honey. We quote: No. 1 white comb, 24-sec. cases, \$3.10 to \$3.25; No. 2, \$2.50 to \$2.75. Extracted honey, white, per pound, 8@10c; amber, 8c. Beeswax, per pound, 25@27c. C. C. CLEMONS & Co.

## SOLID GOLDEN QUEENS

Why do thousands of bee-keepers prefer it to other makes?  
 Because the bees like it best and accept it more readily.

### Queen-Button for Bee-Folks

This is a very pretty thing for a bee-keeper or honey-seller to wear on his coat-lapel. It often serves to introduce the subject of honey, and frequently leads to a sale.

The picture shown herewith is a reproduction of a motto queen-button that we are furnishing to bee-keepers. It has a pin on the underside to fasten it. Price, by mail, 6 cents; two for 10c; or six for 25c. The American Bee Journal one year and 4 buttons for \$1.10. Address all orders to

**GEORGE W. YORK & CO.**

334 Dearborn Street, CHICAGO, ILL.

## Marshfield Goods

When you buy those goods you can be assured of good, honest goods. We make nothing but PERFECT SUPPLIES. Sections made of young basswood timber. Hives and Shipping-Cases are Beauties. If you have not received our Catalog of Supplies, please write for it.

### Bottom-Starters in Sections

Some discussion has lately taken place in other bee-papers with regard to the necessity for bottom-starters in sections, the discussion being started by the statement of Fred W. Muth, that the use of bottom-starters was one of the factors in securing lower freight-rates. Editor Hutchinson held them unnecessary. Editor Root thought only experts could manage without them, but accepted the following amended statement which was given in a Stray Straw:

"Any one can get along without bottom-starters by crowding the bees enough; but it is more profitable to use bottom-starters than to crowd them so. Without bottom-starters, fastening to the bottom is about the last work done on a section, and with room enough it may not be fastened at all; with bottom-starters it is about the first thing, room or no room."

### Production of Bulk Comb Honey

When Texas bee-keepers first began to talk about cutting up sheets of comb honey, packing in cans and filling up with extracted honey, it was considered a fair subject for quiet amusement. That consumers should show any strong desire for such messy stuff was not to be seriously considered. Yet the production of bulk comb honey has not passed away as a 6-months' fad, and to-day it seems to be a pretty well settled belief that it is the most profitable form in which to produce honey—at least in Texas.

Upon hearing the enthusiastic praises of bulk comb honey sung by its advocates, it is inevitable that the question will arise in the minds of others, "Will it not be a profitable thing for me to adopt this form of honey-production?" A number of different factors enter into the problem.

We are told that one-third of a can of bulk honey is extracted, and that the price obtained for the combination is 3 or 4 cents more than the price of extracted honey. That gives a basis on which to figure, and it will not take much figuring to show that much depends upon the relative prices of comb and extracted honey as to whether it is more profitable to sell them together or separate. Take the Chicago market, with 16 cents for best comb and 8 for best extracted. If 2 pounds of comb and 1 of extracted be sold together as bulk honey at 3½ cents more than the price of extracted, that will make 3 pounds sold at 11½ cents a pound, or 34½ cents in all. If sold separately, the 2 pounds of comb honey would bring 32 cents, and the 1 pound of extracted 8 cents, or 40 cents in all. On the face of it, the man who depends upon the Chicago market would lose 5½ cents on 3 pounds of bulk honey, or nearly 2 cents a pound.

The printed report for any other market will likewise show a loss, the most favorable case being that of Cincinnati, with comb at 14½ and extracted at 8½. Sold separately, 2 pounds of comb and 1 of extracted will bring 37½ cents; sold as bulk at 12 cents a pound, it will bring 36 cents; still a loss, but only ½ cent a pound.

But suppose comb is 10 cents and extracted 5. Sold separately, 2 pounds of comb and 1 of extracted will bring 25 cents. Sold as bulk at 8½ cents, it would bring 25½ cents—a gain of 1-6 cent a pound.

In general it will be found that the smaller the margin between the price of comb honey and the price of extracted, the greater the chance for gain by selling as bulk.

If comb honey be produced in frames and cut out, the cost of sections and separators

will be saved—an important item. Bees will probably produce more honey in large sheets than in small sections; just what percent more has probably not been determined.

The readiness to accept bulk honey on the part of consumers is another item. In Texas, the popularity of that kind of honey is said to be so great that the supply is not up to the demand. In some localities it might not be easy to dispose of bulk honey at any advance over extracted.

All this is said with no thought that it gives a direct answer to the question whether it be profitable to enter the lists as a producer of bulk comb honey; it only gives a hint as to some of the things to be considered by any one who seriously enters upon its consideration.

### Migratory Bee-Keeping

In Germany this is practised to a large extent as compared with this country, bees being hauled to the buckwheat fields or the heath fields, either by wagon or by steam cars, and left in charge of a keeper. In England, also, bees are taken to the moors. A writer in the British Bee Journal says he pays 25 cents per colony "for standage and looking after," which does not seem a very large amount. There is a good deal in fashion, and possibly it might be a profitable thing if more bee-keepers in this country would get into the fashion of moving their bees for a particular flow.

### Electricity for Bee-Cellars

Electricity has been suggested, if not used, for heating bee-cellars. Editor Root seems quite pleased with results obtained by ventilating a cellar with a small electric desk-fan; and now if we can have electric cars to take the bees in and out, we will be well started on the way toward electric bee-keeping.

### Advertising Honey

H. B. Phillips, who says he is "the largest bottler of pure high-grade honey in Maine," is doing some advertising of honey along the line so often suggested in these columns. Here is what he says about it in a form letter:

Dear Sirs:—With the idea of creating a larger demand for comb and extracted honey

I have inserted an advertisement in the Portland Evening Express and Portland Sunday Telegram, to be run quite a period of time. The Feb. 23d number of the Evening Express, also the March 3d number of the Sunday Telegram will each contain an interesting article about honey and its value as a food; and possibly later on there may appear more of these articles, which, together with my advertising, should create a good demand for honey bearing my label, which I guarantee to be straight *bees' honey* of the best quality and flavor.

Yours, for Pure Honey and a larger demand for it,  
H. B. PHILLIPS.

We think Mr. Phillips is following the proper methods—advertising in the daily newspapers, and also securing the publication of articles about honey as food, etc. But this ought to be done all over the country. And if enough of it should be done before the next crop of honey appears, no doubt the demand will take the honey about as fast as it comes on the market—if it isn't all rushed to one market at one time.

### Specify the Page, Please

Dr. Miller makes a special request that when, in asking a question, the inquirer refers to something in a preceding number of this Journal, the page should always be given. Otherwise it may take a long time to find the matter referred to, if indeed it be found at all; and oftentimes no clear answer can be given if such reference be not found.

It would be for the pleasure of the readers if this rule were always followed when anything on a previous page is referred to, whether any question be asked or not. Don't speak indefinitely of something John Jones said some time ago, but mention that it was on such and such a page. It may take a little hunting up sometimes on the part of the writer, but it is better that one writer should take the time of hunting up than to have all the readers thus troubled.

### Distinguishing Laying Workers

The idea that a single culprit is responsible for all the mischief in a colony afflicted with laying workers seems hard to be overcome, and with it there is more or less tendency to think that a laying worker is different in appearance from other workers. The following from the British Bee Journal is an instance:

Can any one tell us how to distinguish these? I have never had one in my hives before this year. But several times, although I examined the combs, I could not spot it. I judged by a number of eggs being seen in each cell, and drone-brood reared in worker-cells.

In a colony of laying workers, dissection has shown that eggs were present in a large number of the workers, and it is reasonable to suppose that in general such is the case. Neither is a laying worker different in appearance from any other worker. Probably the only way judgment can be pronounced with confidence is to see the worker in the act of laying.

**Amerikanische Bienenzucht**, by Hans Buschbauer, is a bee-keeper's handbook of 138 pages, which is just what our German friends will want. It is fully illustrated, and neatly bound in cloth. Price, postpaid, \$1.00; or with the American Bee Journal one year—both for \$1.75. Address all orders to this office.

**Mr. J. C. Calvert**, of the A. I. Root Co., Medina, Ohio, called at our office last week when in Chicago as a delegate to a conference which had for its object the planning of a union of three church denominations of this country—the Congregational, Methodist Protestant, and United Brethren. Mr. Calvert represented the first-named.

**Splendid Rains in California.**—Prof. A. J. Cook, of Claremont, Los Angeles Co., Calif., March 14, wrote us as follows concerning the rains and prospects in Southern California:

In all my sojourn in Southern California, now more than 13 years, I have never known such splendid rains as we have had the past season; and the end is not yet. Our average here is about 15 inches, and we have already had 22.22 inches this winter. As we have still to have the best of our rains, we may be sure that this will be a record-breaker, not only as to rainfall, but in fruit, grain, and honey. It looks now as if we should have one of the best honey-years that we have had in the State.  
A. J. COOK.

If the present prospects result as anticipated, the bee-keepers of California will be greatly encouraged again. We are wishing that this year there may be the largest and best honey crop all over our great country, that the oldest living bee-keeper has ever seen. Now, what more than that can we hope for for our readers?

**Some Pleasant Memories** will be suggested to at least a few readers when looking at the front-page pictures this week. As we mentioned once before, we are indebted for certain pictures to D. H. Coggsball, of New York; J. J. Measer, of Kansas; and C. J. Thies, of Wisconsin.

The present six reproductions may be described as follows:

No. 1 shows bales of cotton ready for shipment. It seemed as if there were almost acres of such bales at different shipping points along the way.

No. 2 represents a part of the famous Alamo, and from left to right, C. J. Frank, of Illinois; J. J. Measer and Dr. Bohrer, of Kansas; and D. H. Coggsball—all "looking pleasant" while they wait to have their "pictur taken."

No. 3 is a tree with hanging gray moss. This is a beautiful sight in reality, but the picture doesn't do it justice. It is a very pretty as well as common sight in the South.

No. 4 shows (from left to right) Geo. D. Caley, of Nebraska, and again Mr. Measer and Dr. Bohrer. This picture was taken in one of San Antonio's beautiful city parks.

No. 5.—Mr. Coggsball standing by one of

the cotton-wagons, such as they use in the cotton-fields when picking. A picker's bag is hanging at one corner of the wagon.

No. 6 is the Santa Rosa Infirmary in San Antonio, where Mr. Louis H. Scholl was sick for quite a while last year. It is just opposite Market Hall, where the National convention was held last Nov. 3 to 10. There is a beautiful grove in front of the Infirmary, which is also shown in the picture.

**The Missouri Bee-Keepers' Law**, as passed by the State Legislature and signed by Gov. Folk, has been sent to us for publication by Mr. Robt. A. Holekamp, who worked so hard for its enactment. When sending the copy, Mr. H. wrote as follows:

DEAR MR. YORK:—Enclosed find our Missouri Bee-Keepers' Bill, which has been passed by our Legislature, signed by the Governor, and is now the law.

There is an emergency clause which brings this law in force without requiring the usual 90 days after its approval. It will be well for all bee-keepers of Missouri to become acquainted with it.

I am glad that after so much work we have finally succeeded in getting the needed protection, and hope that the Inspector may be supported by all bee-keepers, so he may succeed in clearing our State of the diseases among the honey-bees.

ROBT. A. HOLEKAMP,  
Sec. Missouri State Bee-Keepers' Association.

The law referred to in the foregoing reads thus:

#### AN ACT

To provide for the appointment of a State Inspector of Apiaries, and to regulate the duties thereof; providing a penalty for disposing of, or importing into this State diseased honey or bees, or for hindering the Inspector in the fulfillment of his duties, with an emergency clause.

Be it enacted by the General Assembly of the State of Missouri, as follows:

SECTION 1.—The State Board of Agriculture of the State of Missouri shall appoint a State Inspector of Apiaries to aid and assist in the development and protection of the honey industry in the State of Missouri, and for the prevention and suppression of contagious or infectious diseases among honey-bees, such as foul brood, black brood, paralysis, etc., which is said to exist at the present time among some of the apiaries of the State. Said Inspector of Apiaries shall be a practical apiarist, and shall give to the said Board of Agriculture, before his appointment, satisfactory evidence of his practical knowledge of handling bees and their diseases, and shall hold his office for the term of 2 years, unless removed for cause.

SEC. 2.—Said Inspector shall, when notified of the existence of the disease known as foul brood, or other infectious disease among apiaries, examine such reported apiaries and all others, in the same locality, and if satisfied of the existence of foul brood, or any other infectious disease, shall give to the owner or person having charge of any such apiary, full

instructions as to the manner of treating them. Within a reasonable time after making the first examination, the Inspector shall make a second examination, and if the conditions of any of the colonies affected is such as, in his judgment, renders it necessary, he may personally treat the disease, or, in his opinion, it is necessary to prevent further spread of the disease, and the owner refuses to treat them according to the instructions of said Inspector, then the Inspector may burn or otherwise destroy such diseased bees, comb or other material that might cause the spread of the infection.

SEC. 3.—Said Inspector shall have the right to enter any premises where bees are kept, for the performance of his duties.

SEC. 4.—The Inspector shall make a full report to the Secretary of the Board of Agriculture at least once each year, stating the number of apiaries inspected, the number found to be diseased, and the number treated, and such other information as he may deem important. The Secretary of the Board of Agriculture shall publish, in his annual report, or otherwise, such of the information as he deems of importance to the apiarists of the State.

SEC. 5.—Said Inspector shall receive four dollars for each day actually and necessarily spent in the performance of his duties, and shall be reimbursed for the money expended by him in defraying the necessary traveling expenses: Provided, the total expenditure for such purposes shall not exceed one thousand dollars in any one year: Provided further, that the said Inspector shall render to the Board of Agriculture an itemized account of his per diem and expenses, and upon approval of the same by the Executive Committee of the Board of Agriculture, the President and Secretary of the Board are instructed to draw a warrant upon any available funds for the amounts allowed.

SEC. 6.—Any owner of a diseased apiary, or any person, persons, company or corporation who shall knowingly sell, barter, give away or import into this State any colony or colonies of bees, honey or other article infected with disease, or expose other bees to the danger of contracting such disease, or refuse to allow the Apiary Inspector to inspect or treat such apiary, honey or other articles so infected, or shall resist, impede or hinder him in any way in the discharge of his duties, under the provisions of this Act, shall be guilty of a misdemeanor, and shall be fined not less than ten nor more than twenty-five dollars for each offense.

SEC. 7.—It being necessary to treat the diseases herein provided for in the spring or summer, in order that satisfactory results may be obtained, creates an emergency within the meaning of the Constitution, and this Act shall go into force and effect upon its passage and approval.

**Our Wood Binder** (or Holder) is made to take all the copies of the American Bee Journal for a year. It is sent by mail for 20 cents. Full directions accompany. The Bee Journals can be inserted as soon as they are received, and thus preserved for future reference. Or we will send it with the American Bee Journal a year—both for \$1.10. Address office of the American Bee Journal.

**The San Antonio Convention Picture** is a good one. It shows over 100 of those in attendance. We are mailing them, unmounted, for only 60 cents. They can be mounted by a local photographer for only 10 or 15 cents more. We will mail one of these pictures with the American Bee Journal one year—both for only \$1.40. Send all orders to the Bee Journal office.

**The Chicago-Northwestern Convention Photograph** was taken Dec. 6, 1906, which was very good indeed. Price, post-paid, in mailing tube, 60 cents. Send orders to the office of the American Bee Journal, and we will see that the pictures are mailed.

## Contributed Articles

### Testing the Purity of Queens

BY G. M. DOOLITTLE.

On pages 137-8 is an item on the purity of Italian queens, under the above heading, written by one signing himself "Subscriber" and having "New York" at the bottom, by which I infer that he is a resident of New York State. If only the older bee-keepers of the world were living, I should not feel called upon to say a word regarding the matter touched upon by "Subscriber," but being aware that two-thirds of the readers of the American Bee Journal have commenced their bee-keeping life inside of the past 15 years, it does not seem best to allow so erroneous an item as the following from "Subscriber's" pen to go unnoticed. Hear what he says:

"What is a tested Italian queen? A tested, or breeding queen should be a bright yellow. Every drone must have 4 yellow hands, and you cannot discern any varying in the color. The workers must have 3 yellow bands, with light gray on 2 bands. The under part of the abdomen should be bright yellow to the tip. Now let us test this queen. If she is free from any black blood, the drones from every young queen reared from her eggs will have the same number of bands as the mother-queen. Every drone is marked alike. No person can see any difference in the drones. You must trace the pure blood from the drone progeny. Where the drone progeny varies in its markings it is a sure sign of black blood."

Now, it will be noticed that "Subscriber" starts out by asking "What is a tested Italian queen?" which leads us to infer that he is talking about *Italian* bees. Therefore the first question that comes to us is, What is an *Italian* bee? This question can have only the one answer; "A bee which descended from parents reared in *Italy*, and from that part called 'Liguria,' where they were first found by Spinola, and named by him as *Apis Ligustica*." (See page 293 of "Langstroth on the Honey-Bee," as revised by Dadant.)

Now, do the bees which come from Liguria, Italy, correspond with the description given by "Subscriber?" By no means. In fact they are almost as far from it as daylight is from darkness. Queens imported direct from Italy vary in color all the way from being nearly or quite as dark as the German or black queens, to those approaching some of our best golden queens as to color; while the workers from many of these queens are so dark that they have to be placed upon a window after being filled with

honey, in order to discern that they have any yellow (?) bands at all. Talk about pure Italian worker-bees having the under part of the abdomen "bright yellow to the tip!" As far as I could ever see there was no difference as to the color on the underside of the abdomen of workers from an imported Italian queen, from that on the underside of the abdomen of workers from a black queen. The color on the underside of both varies but little from a very dark brown.

But I do note that when we are to decide as to the purity of the Italian bees we have, the *drones* are to be what we are to look at as to their markings. "Subscriber" says: "Every drone must have four yellow bands, and you cannot discern any varying in color."

Every drone is marked alike. No person can see any difference in the drones. You must trace the pure blood from the drone progeny, not the worker progeny. Where the drone progeny varies in its markings it is a sure sign of black blood." This certainly is a *new* test for Italian purity to us older readers who date back to where the first Italian bees came to this country. The drones from those original importations were so nearly like the drones from a black queen that it was often like a "Chinese puzzle" to tell "which from t'other." Talk about drones from an imported queen having four yellow bands! Not a drone had four bands of any kind on them. The best show only a leather or chestnut color in spots or splashes, varying as much as to their markings as did the sheep that Jacob was to have from his father-in-law, Laban, in old Bible times.

Paragraph 555 in "Dadant's Revised Langstroth" reads thus, where speaking about Italian bees: "The drones and the queens are very irregular in markings, some being of a very bright yellow color, others almost as dark as drones or queens of common bees." And this should be the best of authority, as the Dadants have probably imported more Italian queens into this country than any others.

Another large importer is the A. I. Root Company. Listen to what they say regarding this matter: "The drones and queens from queens obtained direct from Italy, vary greatly in their markings." ("A B C of Bee Culture," page 222.)

And I might go on and give authority after authority, which perfectly agrees with both Dadant and Root in this matter.

No! No! There is no such thing as perfect markings with pure Italian drones or queens as they come direct

from Italy. And the bees that come from Italy are the only origin for *pure Italian* bees. Consequently "Subscriber" must be mistaken in what he gave us in the *American Bee Journal* as to "what is a tested Italian queen." And it was necessary that a few words be said on this matter, else all beginners who read "Subscriber's" account of what a pure Italian queen should produce, would be disappointed in the queens they bought, and condemn queen-breeders as frauds for sending out impure stock.

Of course it is understood by the older readers that our American queen-breeders, or some of them at least, have been breeding toward the yellow side of importations, until we have in this country at this date, what are known as "golden Italians," some of which will conform pretty well to the description given by "Subscriber," but these bees are no more pure, if as much so, as are those that are a dark leather color, adhering more perfectly in breeding to conform with such bees as are gotten from our many importations.

Now, I wish to call attention to "Subscriber's" statement that "Where the drone progeny varies in its markings it is a sure sign of black blood." Here he is mistaken as elsewhere, for let the best golden queen mate with a drone from an imported or *pure Italian* queen, and her young queens will give drones varying almost, if not quite as much in color, as would be if said queen had mated with a black drone. I have little doubt but what the queen-breeder from whom he obtained his queens was so near some other apiary having imported or leather-colored stock in it, that part of the queens he received mated with those imported drones from the leather-colored branch of the Italian bee. And if this were so, then he could have no reason to talk about "mongrels," for each branch of these Italian bees is as pure as the other.

This color-matter has mystified and bewitched many, and a little explanation of it will help breeders and customers to have a little more charity for each other.

Borodino, N. Y.

## No. 2—Feeding and Feeders Various Kinds

BY C. P. DADANT.

We will divide bee-feeders into four classes: Outside feeders, bottom feeders, body feeders, and top feeders.

The most elementary way of feeding bees is to put the feed outside—anywhere—and attract the bees to it. Some hold that this is the best and only method to feed bees as a stimulant to breeding, because it is the only feeding that resembles a honey crop, and in which they must take wing in search of the food. Troughs put out in the sun, jars inverted over a dish and filled with liquid food, and also combs of honey have been fed in this way. Years ago a European clergyman, the Rev. Father Babaz, devised an outdoor feeder which he called "the bee-keeper's cellar" be-

cause he locates it in the doorway of a cellar, and which he proposed to use to supply the bees with different sorts of food from which they were to produce honey. Such cranks have been met with, from time to time, who thought that bees could transform any sort of sweet into good honey, and who thus imagined that they had found an infallible method of getting rich. But they soon find out that there is no royal road to wealth, even by feeding bees.

I think that the only advantage of the method of outdoor feeding is the one stated above, that it resembles a honey crop more than any method of indoor feeding, as far as the bee's imagination may be concerned, and perhaps leads it to more activity. But there are several very evident drawbacks, not the least of which is the probability that when you are feeding your bees in this way, you run a very great chance of also feeding any bees that may have their home in the neighborhood, sometimes even as far as a mile or two from your apiary.

Of course, you can bait your own bees, by presenting the food to a few bees and while they are sipping it carry them to the spot where the food is kept. In this way, you may give such colonies as you wish to feed the advantage over the others. But, when there is any feeding going on out-of-doors, the bees make more or less noise in carrying it back and forth, the other bees which notice it begin to roam about and never stop their search until they have found the spot, to which they are easily led by the flight of the others. Not only is it possible that you may feed your neighbor's bees in this way—fully as much, and to the detriment of your own bees—but you will also feed unwillingly some of your own colonies that may not need it at all.

As a rule, the colonies which are most in the need of food are the weak ones. In outdoor feeding you will surely feed the strongest as well as the weakest, because the strong colonies have bees out early and late, and in greater numbers than the weak. If the feeding spot is not of great extent, it is quite possible that one or two of your best colonies will go there in such numbers that they will monopolize the feeder, by driving the other bees almost entirely away, or at least may make it difficult for the latter to get their share by fighting them when they alight on the feeder. In any case, it is out of the question for you to control the feeding. Still, this method may be pursued on a small scale without bad results.

In the month of August, 1885, I paid Mr. Langstroth a visit, and had the pleasure of witnessing the feeding, out-of-doors, of 3 or 4 weak colonies which he desired to stimulate to breeding. He had the feed—only 2 or 3 spoonfuls of sugar syrup—in saucers with a few blades of grass over the top, so the bees would not drown in the liquid. The feeding was done about sunset, when the other colonies were quiet. Each of these weak colonies had been fed for some days previous, at the same hour, and they were expecting it, for several bees were flying about in the grass, in front of the hives. As soon as

the food arrived, they went to work on it, and Mr. Langstroth, the next morning called my attention to the fact that those colonies were entirely quiet. They knew the hour of feeding, and expected the supply each day at the same hour and in the same spot.

When bees are short of pollen, in early spring, they may be given flour—either rye or wheat—in this way, and they will come from day to day until pollen is found in the blossoms. There is no objection whatever to feeding the flour out-of-doors. In fact, we have never been able to have it accepted by the bees in any other way, and the supply of flour thus furnished is so inexpensive that we need not begrudge our neighbor's bees a portion of it.

There is no doubt that feeding, when continued too regularly, will render less service than if intermittent, because the bees—some of them, at least—will become used to it, and will not even look elsewhere for food. It is the same in the case of flour as a substitute for pollen. You will see bees still coming to the flour, when the greater number have deserted it and are finding pollen in the blossoms, but the number of the flour-gatherers decreases every day, and whether you feed flour or honey, the interruption of a single day in the feeding will send the laziest ones to the fields. It can hardly be called laziness, but they get into a habit from which you must break them after having nursed it, when you find that they no longer need the help.

Hamilton, Ill.

## No. 1—Things to Do, and Why Management in Spring—Clipping—Bur-Combs—Stores, Etc.

BY R. C. ATKIN.

We are prone to think our way is the best and the only right one. Some incline to the opinion that the hive is the thing that will give results, with management secondary. Others lay much stress on the strain or race of bees, age of queen, locality, and many other things.

Yes, I have hobbies, too—hives and methods peculiar to myself; but it is not my intention to tell you that my way is the only one, or the right way; my purpose is to tell of things to do, and the *why* of doing; tell you of principles, relation of factors, combinations that will produce results. I cannot tell you that March is the time to do this or that; latitude, altitude, temperature as affected by moisture and in its high or low degrees and rapid or slow changes; the time of year, whether the flow be slow or fast or intermittent, etc., and a great host of things that cause the problem to change—I must deal with the subject in such a way as to lead the reader to a knowledge of factors and their relation, then he must use reason and judgment, and do this or that when the doing of it will produce the result desired.

I remember reading years ago a little rhyme or verse—its wording has

# American Bee Journal

gone from me these many years; the substance of it was that if water and grease were put together there was war, and no amount of coaxing would bring peace or union, but just add some potash—immediately the whole became one mass—soap. That is about the way things go in a bee-hive; some things will not mix at all, with all the coaxing and persuasion the apiarist can bring to bear; put in the right elements or factors and all is peace and prosperity.

Read a former article which I wrote for these columns about cell-building, wax-secretion, etc., and let it be a prelude to these following articles; it will save me some repetitions. I do not know all about bees, hives and nectar-secretion, nor have I yet met all the conditions and factors that enter into this complex business known as bee-culture. I am just one of the many, and will try to tell what appears to me to be the truth, and you are to put with this what you know, and arrange the various blocks of wisdom and knowledge into workable form or combination.

We may learn many things, however, from a fool; *we* may have an unlimited store of knowledge and yet be without wisdom—a fool. The man is wise who can properly apply his knowledge. My desire is to add to the fund of knowledge of many readers.

## SOME THINGS TO DO IN SPRING.

There is much that can be done in spring that will aid in the work that must be done later when time is very valuable. About the very first thing, where bees winter on the summer stands, is to look up all colonies that have died, and remove from the yard the hives that may have stores in them; if left to be robbed it stirs up the entire yard and may cause much annoyance, as causing weaker colonies to be robbed, or the bees to be cross and sting people if in exposed locations, or where there may be people passing near. Gather in all such hives.

Not so very long ago I read a dispute—I think it was between R. L. Taylor, and probably Mr. Doolittle—about when or what time bees began breeding in the spring—or winter. I thought at the time the dispute a foolish one as location and several things had to do with that action on the part of any colony. I do not profess to know all about this matter, but about 30 years ago I read in "Kretschmer's Bee-Keeper's Guide" that usually in the latitude, say of Iowa, or similar climate, that it was not uncommon to find normal colonies breeding a little in the heart of the cluster in January, the amount increasing as the season advanced and the colony grew stronger; and I think he said most of them should have brood by February. I made examinations in those days, in southwest Iowa, and found just as Mr. K. had described—a small patch of sealed brood in January; then in a climate in which bees seldom got out of their hives in winter, and where the first pollen was gathered about March 1st, usually from soft maple, there is rarely very little flying before that date. Well, since those days, as the years went by, I have seen many colonies with

brood in the month of January, even hatching bees.

This is Feb. 14, and today I shifted a colony from one hive to another, comb by comb, and there was sealed brood in 2 combs with a few bees hatching; I should judge there was 50 to 75 square inches of sealed brood in the combs, and I did not look to see how many more of eggs and larvæ. About the first of this month I saw almost as much brood in another colony in a different yard. Within the past 2 weeks I have seen brood in several colonies.

## STRONG COLONIES.

If you will examine you will find that it is the colonies strong in bees and with plenty of stores that are breeding freely so early. Many weak colonies have not yet started any brood; others are just starting. In this climate where there is much sunshine and a minimum of cold winds the strong, direct and undimmed sun rays so warm the hives and atmosphere that bees fly freely. I should guess that with average weather, as we have it here, they will fly more or less half the days of February and March. Last night the thermometer was down to 15 or lower; there has not been a night so far this month that it did not freeze, but in mid-day it would be from 40 to 60, and March is likely to be much the same, only a little warmer.

Now here is what I wish to teach: With bees flying so much they rapidly decrease in numbers, especially by March. That colony I transferred today that showed so much brood I count as safely wintered, the bees hatching now, and that within the next few days will be sufficient to keep up the forces and maintain heat for such brood as will be reared from this on, and which will be required to do spring foraging. The weaker colonies that are just starting brood will be so few in numbers by early March that it will be almost impossible for them to rear brood at all. For such length of winter as may be found in Nebraska, Iowa, Illinois, Ohio, and similar latitude and conditions, here is what I consider a necessity to safe wintering:

First there must be enough bees in the hive in the fall to make a large cluster, such as will usually occupy about 2-3 of the spaces in a 10-frame hive, and these bees in their prime of life; such will have enough bees in January and February, to start and mature brood which furnishes the life and strength of the colony to withstand the vicissitudes of spring life. To have such colonies the one thing above all others that will get this condition—other conditions being normal—is a large brood-nest, and this brood-nest so arranged or provided that the queen is not hampered in her breeding by being crowded with honey. A full discussion of this will come in its proper place: fall is the time to make the colony that will be strong in the spring.

We have weak and strong colonies in the spring as well as at other seasons—that is, in comparison. The poor weaklings in late winter and early spring—it is pitiable to see them struggling to mature enough brood to save

the life of the colony; but pity is about all we can do for them; we sigh and hope for steady warm weather until they get on their feet—that is grow strong. If a man has but a few colonies, and can put these weaklings into some warm place where they will never have to endure cold—say in a temperature that would almost mature the brood,—such colonies may become some of the very best in the coming harvest. Do not condemn these queens when their only fault may be that their bees were such good honey-gatherers that they filled up the combs in the fall to the exclusion of the brood they would have put there, which in turn would have been the making of a strong colony in the spring. Very many queens and colonies die in winter and spring, victims of environment.

## CLIPPING QUEENS.

I will not ask you to consider me authority on this subject. However, I have clipped for about 30 years—of course, I have always had unclipped queens in more or less numbers. I have just stopped to make a mental calculation, and I think it a very conservative estimate to say I have clipped 5000 queens, and I doubt if 10,000 would cover it. I have been over 30 years at it, and some years I clipped several hundred.

Some think it causes supersedure, but I do not. I do not think it makes one iota of difference about superseding, simply the fact of a wing being off. The clipper may so frighten a queen, or by some other way make things go wrong and cause a queen to be killed, then, of course, another one is reared, but that is *not* supersedure. For years I have used the fact of clipped queens to determine their age, together with the record, and, besides, I have been such a crank to open and manipulate colonies that I have had almost unlimited opportunity to discover if the clipped queens were sooner superseded but I have never been able to discover that they were. Very many queens are superseded unbeknown to the apiarist who does not clip and does not make frequent examinations of the colony.

Well-bred queens should be good for 3 full and vigorous seasons of laying, some for the fourth, but some for only 2 seasons. It is scarcely safe to trust a queen after she has produced rousing colonies for two harvests, yet I do trust many of them for the third, but I do it after judging of them after many years of observation. I do not believe I can tell you how to judge if she is capable for a third active season; you will have to get that by observation and practice.

So I clip for two purposes, perhaps the main reason being to keep them from going off with a swarm, if I should be a little late in getting to work the colony. Then I rarely ever allow a swarm hived, either a natural or forced one, without clipping the queen to prevent loss by absconding. When a swarm is hived, if the queen was clipped the previous year, she gets this record: "6—20, S. hived—o. q." If she has not been previously clipped, or if a past season's queen, but recently

# American Bee Journal

clipped, the record is "6-15 s. hived, clipped." The first two numbers of course are the month and day; the first entry for the colony for that season should be preceded by the year date.

I have given you the main reasons why I clip; now I will tell you when. I do this in the spring whenever I can get sight of the queen. In April or May (or whenever in your locality you can safely handle the bees previous to the honey-flow, and before they get very strong) go through every colony and trim off bur-combs and otherwise slick up things so that the combs will handle very freely without catching and scraping. Every bur-comb and brace-comb should be removed, and this done in the early season before there are many bees to be in the way. Now when doing this work, watch for the queen, and, when found, if her wing is already clipped enter the fact on the record as "o. q." If the colony record shows two consecutive seasons "o. q." she is ready to be put out of commission after that season's crop of bees for the harvest has

been produced, unless she shows unusual vitality, when she may wait for the third "o. q.," but lots of them will not be found for the third one, or, if so, will disgust the owner by failing just when he can least afford to have the failure. But do not hunt too long; if not found with reasonable effort or disturbance wait until the next overhauling, when the bur-combs being out of the way, and combs handle so slick and easy, you can locate her without trouble.

For clipping I carry a little pair of scissors in my vest-pocket; they are about as long as my finger, and, when I locate the queen, out comes those scissors, and they follow her until I get a blade under a wing, when off it goes. I don't cut one leg in many hundreds of queens; I think I have never clipped but one leg. I never attempt to catch the queen to clip, except in rare cases, as in swarms, or when she is frightened so I cannot follow her with scissors. Many never are aware when clipped.

Loveland, Colo.

## Foul Brood Inspection

At the San Antonio Inspector's meeting, J. M. Rankin said:

"Bee-inspectors are born, not made. It is an easy matter to learn to detect the disease and to effect a cure. Any man of ordinary intelligence can do this, but it is only a small part of bee-inspection. The difficult part lies in handling the bee-keeper, and, without antagonizing him, get him to comply with the law because he sees the advantage it brings him in doing so."

This is true, indeed, and those who have had experience in inspection work well know the difficult parts that had to be "worked" at some time or another. It is, indeed, a difficult task to approach a man who refuses to have his bees inspected, and tact and patience are necessary in handling cases of this kind.

There are bee-keepers, and other bee-keepers, and while some of them are ever ready to assist in the inspection of their apiaries, others can be so stubborn as to make it quite disagreeable for the inspector. It is amusing to me sometimes to think of some of the "scrapes" experienced while inspecting apiaries, and, although in some instances the situations seemed of a very serious nature at the time, yet it may not have been so bad in reality. However, to receive "notes of warning" like those here given, while inspecting in certain districts, would in all likelihood be heeded somewhat by any inspector. Here is one:

MR. FOUL BROOD INSPECTOR:—I heard you were inspecting the bees of our neighborhood, and am sending you this note of warning to inform you that I will not have my bees inspected, and any trespassers will be properly dealt with if a shot-gun has to be resorted to.

Respectfully,

On another occasion the leading newspaper of the town had the following in one of its columns the next day after arriving on a trip of inspection:

### A NOTE OF WARNING.

We, the undersigned bee-keepers, having learned that the bees of this section are to be inspected, will make it hot for any foul brood or other inspectors, or would-be and assistant inspectors, trespassing on our premises or bee-yards.

(SEVERAL NAMES.)

Such things might have seemed ridiculous to inspectors of some of the other States, but when it is remembered that this happened in "the wild and woolly west" of Texas, it may not seem that way. Of course, ignorance on the part of these men, who were honest in their opinions otherwise, caused them to take such steps. This was made manifest in each case after "the inspector" called around and approached them with a broad smile and a hearty "How do you do," just as if meeting an old friend; and as if without any knowledge whatever about the "notes of warning" received.

What an inspector should strive to do in the majority of the "hard cases," is to "bluff right," and overtake the victim by surprise. Have no recollection of the "notes of warning," and he will think you failed to get them before you came. Then talk weather, crops, market prices, and the latest news, and show an interest in "every-

Conducted by LOUIS H. SCHOLL, New Braunsfels, Tex.

## Something in Favor of Black Bees

On page 106, it says that "the blacks are inferior." I agree that they are inferior to Italians in most respects, but not in all.

The German, or black, bees have been our honey-gatherers for over a century, and it is time that we were finding out their merits, if they have any, and they surely have. I say that they have a place in apiculture that the Italians can never fill with the same amount of labor or capital. In the production of a nice article of comb honey they can not be excelled. Also, they can easily be brought up to a non-swarming point and a large comb-honey business operated with but little labor or expense.

It also says, "If, then, an American editor be asked by a beginner as to which is the better bee, he answers, 'The Italian.'" This is true, but it may not be the best bee for the beginner. If he lives in a location where there are no blacks the Italians are the best for him, perhaps; but if his Italian queens are exposed to black drones, they are the worst for him, for their crosses with blacks are furious stingers, and nothing but a veteran bee-keeper, or one toughened to stings, can stand them. It is widely circulated that the Italians are by far the gentlest bees, but we have found this true:

There is many a bee-keeper who makes a start in bee-keeping, and, not content with the strain he or his neighbors have, buys some bees of another strain, introduces or sets them down with his others, believing it is the best thing for him from what he has read or heard. Soon his apiary is "fired up," and he is, too, and soon is gone "where the woodbine twineth," so far as bee-keeping is concerned. This has been the case hundreds of times here in the South, and, to some extent, is the cause of the bee and honey industry being as it is here.

There are many bee-keepers who regret that they ever mixed their bees; and, beginners, if your neighbors keep Italians, you start with them; or if your neighbors keep blacks, you start with them until you have mastered enough about bees to keep your stock pure. If your neighbors have hybrids or a mixed race of bees, better start up bee-keeping in some other location, or stand the stings.

I advocate pure stock for the beginner, whatever it may be, or wherever it may be found.

I operate Italians, blacks, and Caucasians for honey, and give credit where it is due.

J. J. WILDER.

Crisp Co., Ga., March 9.

I would not do without the American Bee Journal for ten times its cost.—F. L. DAY, of Minnesota.

thing on the place"—his stock is fine, and the cattle, hogs—even the chickens, if the bee-keeper be a farmer also.

Ask for a drink of water, and tell him how you used to be on the farm at one time or another, and by this time, if he has not already invited you to stay for dinner with him, there is your opportunity to ask him something about his honey-prospects and *his bees*. Nine times, if not ten times, out of ten you will gain your point. Most likely dinner will be ready by this time, and it will be proposed by the bee-keeper, of course, that "we'll have dinner first, and then we might take a look at my

apiary." Then, of course, he will show you the bees, while "the Mr. Inspector, who got the 'note of warning,' does the rest." See?

It must be remembered, however, that not all cases can be "handled" alike, and one manner of approaching a bee-keeper who does not want the inspector on his place, may succeed with one and not with another. If possible, study your subject, and then plan your "attack" accordingly; and if the plans are the right ones, the battle is easily won.

Such is the more difficult part of bee-inspection.

loads of pollen, filling the combs with honey and humming as if it were spring.

Two weeks ago, while standing under an elm-tree, I thought there must be a swarm on an upper limb, but there were bees about all the elms, and I discovered that they were in bloom. The prairie is bright with flowers, and my bees have given me more honey than ever before—such beautiful amber-colored honey, all nicely capped.

Many times I feared my pet would have to be given up, as my husband (who is in poor health, and for whose benefit we moved to the country, he giving up his practise as phylarian) would get so nervous every time I went near the hives; but little by little he overcame his fear when he found I did not get stung; and this spring he was so interested in them himself that he helped me a great deal. I was delighted, for this year I have been able to work without him begging me to "come away."

RICE BOBINET BEE-VEIL.

I wonder if any of the bee-keepers have tried the rice bobinet for veils. It is so much stiffer than other kinds, and stays stiff. After making the veil with an elastic band for the hat, and one in the lower hem, I stitch about 6 inches of broad elastic on the latter at the back. Opposite the underarm it has a loop at the end of tape. After drawing the broad elastic forward, the loop is slipped over a button stitched on the front lower hem. It is so easy to fix, and the veil is held in place.

Mrs. A. E. ST. LEGER.

It is a turning of the tables as compared with the usual way, to have one of the lords of creation become interested in bee-keeping so as to play "second fiddle" to one of the sisters. Mrs. St. Leger is to be congratulated, and it is to be hoped that bee-keeping may prove so favorable to her husband's health that he may become an equal partner.

Mrs. St. Leger's plan of making a veil seems to be good. The favored bee-veil in this locality is made after this fashion:

One end of the veil is sewed firmly to the outer brim of the hat (of course, an elastic to slip over the hat may be used if preferred); this keeps the veil smooth, avoiding wrinkles in front of the face. An elastic cord is run in the lower hem. A safety-pin is caught through the hem in the front, taking in the elastic cord. This is always left hanging in the veil, then when hat and veil are on, all that is needed is to pull the elastic down until taut—not only taut, but stretched until *very tight*—and then to fasten the safety-pin to keep it so. If a rigid cord were used instead of an elastic, when the body was bent it would become slack and allow bees to pass under, but if the elastic is drawn down *tight enough* no bee can get under, no matter what change is made in the position of the body. Nothing can be simpler as a fastening, and it is perfectly safe. Try it.

**Bee-Song Souvenir Postal Cards.**—We have issued in colors, 3 bee-song postal cards for bee-keepers, each card having one of the following songs, about  $2\frac{1}{2} \times 3\frac{1}{2}$  in size, also with illustrated heading on each card: "Buckwheat Cakes and Honey," "The Bee-Keeper's Lullaby," and the "The Humming of the Bees." The first two cards have small pictures of the authors of the words and music. This makes 4 souvenir postal cards we have now issued for the use of bee-keepers, the first being the "Honey-Bear" card. Prices, by mail, are as follows: Sample cards, 3 cents each; 7 for 20 cents, or 10 for 25 cents.

Conducted by EMMA M. WILSON, Marengo, Ill.

### A Sister's Experience in Folding Sections

DEAR MISS WILSON:—One day I noticed an invitation to bee-keeping sisters to "rise in meetin'" and tell their experiences. So I thought I would begin mine at the beginning, and if you consider me at all interesting, I will tell you several things that happened. I can not give any learned or scientific papers on "Why is a bee?" but for plain, every-day facts, I can tell a few.

The way I became interested in bees was one day papa said, "I need section-boxes very much, and I don't see how I will find the time to make them." I said, "I'll make 'em." Papa thought it over, and finally concluded I might. So he showed me just how to proceed.

The boxes were in two pieces, and I laid quite a bunch across a pan, and poured hot water into the grooves with a spoon, always having one bunch soaking while I made up those previously soaked. Picking up a piece I took hold of both ends and carefully bent it into shape, holding it with my left hand. I laid the short piece into place, and with a light blow from a tack-hammer, it slipped into the notches on one end. Then I fixed the other end. Of course, it sometimes happened that it did not work smoothly, but I got along very nicely, so papa offered me 10 cents per hundred for all I would make. He generally told me several days in advance how many to make.

Well, one day I wanted some extra money, and I decided to earn it by making boxes. There being no one at home, I pitched in. I took my materials on the rear porch, which, by the way, was not large. I worked faithfully, and when mamma came home I had the porch piled so full of boxes she could not get indoors. Of course, she made me stop and carry them to the

basement where papa had his workshop. There were something like 700 made up, so I piled them up on the work-bench, putting what was left in wash-tubs and anything else that would hold them. When papa came home and saw the mess, he said the market was overstocked, likewise his work-bench; and not only was the price cut in half, but I must work overtime and clear off his bench, so he could fix supers to put the boxes in.

I filled everything I could find with boxes, and thought I was done with them, but, oh dear! I had completely forgotten wash-day, so the next day I moved those boxes again, but this time I *strung* them, putting 50 or more on each cord, and hung the cord over nails driven in the joists. Yes, and every time any one went to the cellar for anything, he or she was sure to "butt into" those boxes, and from the dark and stilly depths would come something that sounded suspiciously like "confound it," or "doggone it."

That was the beginning of my bee-business, and I have never been out of it since. Some time, perhaps, I'll tell you how I *used* to hive swarms.

SISTER ESPERANZA.

I think your papa was very generous to give you 10 cents per hundred for making boxes—yes, or half that price. Would it not be economy to adopt the one-piece sections and get a machine to make them?

Let us hear from you again.

### A Texas Sister Wins Success—Bee-Veils

In the American Bee-Keeper Mrs. A. E. St. Leger, of Wooster, Tex., says, under date of Oct. 18, 1906:

By this time, I suspect, many colonies have gone into winter quarters in the North, while here the bees are working, carrying in big

Conducted by J. L. BYER, Markham, Ont.

### Pollen from Clover

See here, Mr. Hasty, you are (page 152) altogether too severe on the author of those pretty verses on page 29. While he is accused of indulging in too much "poetic license" (if I dare to use the phrase), I would say that you are indulging in considerable "prosaic license," in making the assertions you do. Here in Ontario, not a few, but fully 50 percent of the bees, in some seasons, gather pollen from clover. Last year fully more than that number would have pollen when they came to the hives. True, this is not a good sign that the clover is yielding much honey, but that does not change the situation any.

As to bees not dying "(except by violence) with pollen on their legs," why, dozens of times I have noticed bees with small pellets of pollen crawling aimlessly around among the blossoms, and often found others in a position as described by the writer of the verses in question—

"Under a large head o'er hanging  
A little dead bee I found."

Then, again, it is not said that the pollen is "golden" in color—

"Full were her bags with the gold,"

can mean in figurative language, honey; or the term "gold" can be used as signifying the value of the pollen, if we choose to couple it with the latter commodity.

Please, Mr. Hasty, put on your thinking cap, and see if you do not recollect ever seeing a dead bee in the clover having pollen attached to it.

### Making One's Own Hives

While I am at it, I want to mention something in which I do agree with Mr. Hasty more heartily. On page 132 he refers to the habit of some bee-keepers (the habit is not confined to the bee-keeping fraternity, either) who vote all others who can not see as they do, or make a success with plans advocated and put into practise by themselves, as being stupid or ignorant. A case in point:

Not long ago certain men were discussing factory vs. home-made hives. One writer claimed that all bee-keepers were not capable of making their own hives; whereupon the other retorted with language in effect, that such people should not keep bees. I happen to be one who would come under the ban,

and yet, even if it is the case, as I often jokingly assert, that I can not nail two boards together true, I would ask whose business is it, anyway, if I choose to keep bees for a living, and at the same time refrain from doing anything that would be a menace to the industry?

Some people are constantly fretting and bewailing the shortcomings of other poor mortals, when, the chances are, if they looked closely enough for defects in their own make-up, they would find work enough to engage their present attention without going to the trouble of putting strictures on others and saying, "Do as I do, or else get out of the business."

### Why Does Honey Granulate?

There is room yet for scientific work towards determining just why honey granulates so quickly sometimes, and at other times can not be induced to granulate at all. Some 7 years ago we had a tank of 500 pounds of honey, that was being kept for home use. It was kept in a small building, single-boarded, and no protection was given whatever towards keeping out the cold.

As it showed no signs of granulating during the fall months, through pressure of other work the matter was neglected till cold weather. But we didn't use much of *that* honey that winter, for the simple reason that it could not be gotten out of the tank during the cold weather. It would stick and hang to a spoon or other implement just like the thickest of taffy, and it was worth all you could get to pay for the work.

When spring came it would run slowly from the tap, but it never offered to granulate, although some of it was not used for nearly two years.

That same year Mr. D. W. Heise, of Bethesda, Ont., had a 600-pound tank of clover honey that acted very peculiarly. During October the lower half of the honey in the tank granulated solid, but the rest remained liquid, and as clear as crystal. Samples were sent to Prof. Shutt, of Ottawa, for analysis, and he reported that the dextrose and levulose had separated. Both the granulated and liquid samples were of good body and splendid flavor, the liquid portion being especially *mild*, resembling alfalfa honey a great deal. Only a few days ago I met Mr. Heise, and he reports that he has some of that honey yet, and to date there have been no signs of granulation.

While I do not know why some honey granulates and some does not, yet I do know that all the honey I have ever seen that *did not* granulate has invariably been well ripened on the hive, and has always been honey of the very best quality.

While granulation no doubt is, as claimed, a proof of purity, yet it is well to be suspicious of honey that granulates very early in the season. Of course, there are exceptions, but, as a rule, you will find that if clover or basswood honey granulates quite early, said honey is pretty sure to have been extracted in an unripe condition.

The "Old Reliable" as seen through New and Unreliable Glasses,  
By E. E. HASTY, Sta. B. Rural, Toledo, Ohio.

### POLLEN—BEES AND FRUIT.

On pages 109 and 110, C. P. Dadant has an excellent article on pollen, bees and fruit. As I once spent a good deal of time examining different sorts of pollen with the microscope, I'll venture to "hold up" one of his statements about pollen. The non-microscopic reader would infer that *all* pollen-grain were shaped like little osage oranges. There is a very great variety in the shapes. Also, there is a great range of sizes. The sphere with rough surface is not even the commonest form. The shape of a grain of wheat (with crease down

one side all natural as life) turned up oftenest in my observations. High power of microscope may be used to make out markings and details; but mere general outlines require but small power. In fact, my mind is (although my memory may be giving me away on that) that sharp eyes without the glass can faintly make out hollyhock and tiger-lily pollens. These, and a few others, are in the Jumbo class for size. Hollyhock is a perfect shape, yellow, and covered thickly with stubbed spurs or straight thorns. Tiger-lily is kidney-like both in shape

and color. The very irregular shape of raisins just dug out of a pressed cake of raisins is often met; but I think that most of these, with time and warmth and moisture, will expand into some definite shape.

And Mr. D. is hardly at his best when he intimates that a scoopful of bees made to hang on a bunch of grapes is any fair representative of a cluster that forms there themselves, knowing what they are after. (He says "any of my readers can try this.") Only a few times in a dozen years is there—for the most of us—a chance to try any such thing.

#### TESTING THERMOMETERS.

Tell "Wisconsin" to test his wandering thermometers. Put a wash-dish of water out in the cold till it freezes over lightly. (Don't trust water with more or less ice floating in it.) Put in your thermometers, and quite possibly one of the lot will prove to be right—reading 32 degrees, or nearly that. If not, choose the most convenient one and note how many degrees wrong it is. Say it reads 29 degrees when it ought to read 32 degrees. As the further aberration in the course of 13 degrees can not be very large, assume that it will read 42 degrees when it ought to read 45 degrees. I take it that careless workmen at marking thermometers let their freezing water get too warm and their boiling water too cold. Also, I guess they twist the tops when not hot enough; so no real sealing takes place. The result of this last is that the fluid in the tube slowly evaporates out; and the thermometer comes after a while to read much too low. Page 115.

#### THOSE WINTER DRONES.

F. Dundas Todd does very well for a beginner in trying to account for his winter drones. I'll add the guess that the bees were queenless when the drones were reared. Possibly the queen laid a few eggs and then died off. Thereupon the bees developed the eggs for what they were worth, drone-eggs to drones, and if there were any worker-eggs, tried to rear a queen from one. Page 117.

#### A HIVE-RIFLING BEAR THAT WAS RIFLED

Bully for the bear! He lies in state amid the evidences of his prowess, and gives us the visible evidence of his bigness. He is a Samson resting his head on the ruins he has made. What a pity "Teddy" could not have been presented with a chance to kill such a whopper! Five rifles bear mute testimony to the force considered appropriate to send against him. Page 121.

#### T-SUPER DISCUSSION.

Mr. Greiner's earnest hit-him-again forniust the T-super is sufficient to account for a smile or two. His charity is great—great enough to think the propolis of Marengo is greasy in its nature—not sticky like the rest of us have to agonize with. It slips right off when it sees Miss Wilson press her teeth together and go for it! And 500

a day, more or less, will satisfy Mr. Greiner as a day's scraping. (There, that gives me some sort of a sight.)

And it seems from a closing remark of his that there are among us tomtinkers of the 33d degree that try to press honey into shape when somewhat out of square. Don't? Well, if advice has any impression on that sort of chaps, I'll say don't, also. Page 127.

#### FIRST APIARY IN THE SOUTH.

So a "claim is filed" for the honor of first apiary in the far South. Place on the Savannah River; time a little over a hundred years ago; and keeper the elder Wilder. Very good till somebody can ante-date it. The fact that he could hear of no bees, and therefore

sent across the ocean for some—that fact weighs much heavier for those early days than it would now. Now we hardly know what our next neighbor has, or has not. That Indian who had never seen bees before, very likely thought the hive was a *contrivance* of the white man's to defend his premises in his absence. Page 129.

#### IS THERE HONESTY AMONG BEES?

It sounds nice to say "honest bee"—who wouldn't increase the size of his rose by suppressing the buds of other people's roses—but how about the accuracy and truth of it, dear Boss? In hot weather with no honey-flow, and lots of idle bees out, whoever saw any signs of honesty among them?

Send Questions either to the office of the American Bee Journal, or to  
DR. C. C. MILLER, Marengo, Ill.  
Dr. Miller does not answer Questions by mail.

#### Some Varieties of Bees

Describe the Golden, Carniolan, and Caucasian bees. Also, which is the best variety? What was the origin of the Golden and the Carniolans? IOWA.

ANSWER.—The standard Italian bee has 3 yellow bands. In this country these bands have been increased by selection to 5, and such bees are called "Goldens." Carniolans are brought from Carniola in Austria. At a hasty glance they might be taken for black bees, but have a brighter look because they have a whitish plumage on the edges of the abdominal segments. Caucasians have somewhat the look of Carniolans or blacks. Dr. D. E. Lyon says: "The bands which, in my strain of Caucasians are so distinct, are of the pronounced light gray, which, with the slight shade of orange on the abdomen, make it easy to tell these bees from the blacks." Prof. Frank Benton says: "The dark color is of a peculiar dull leaden gray, and gives the bees a very ringed appearance. You have doubtless noticed Carniolans or blacks which have fallen into water-troughs, crept out, and become partially dried. These might be taken to resemble in color the Caucasian workers, as you will notice that the dark rings around the body show more distinctly when the fuzz is dampened."

There are advocates for each, and it would be hard to say which of the 3 is best. What might be best for one might not always be best for another. The majority of bee-keepers probably prefer Italians to any of the others.

#### Doubled Colonies—Moving Bees—Queen-Excluders, Etc.

1. I have 8 colonies. I doubled up late last fall and failed to break the comb in the upper hive so that the bees could carry the honey to the lower hive. So I set one on top of the other. They are in 8 frame hives. I wintered them in a house 6x10 feet in size, 2 feet between walls, with sawdust between the

walls, and with double doors. I prefer to confine them to the lower hive, or will the queen lay in both hives?

2. What do you call "shook swarming"?
3. I have 12 colonies 2 miles distant at a neighbor's. When will be the best time to move them—before snow goes off, or should I wait until willow blossoms?
4. Will it pay me to get an extractor for 20 colonies?
5. I want to run more for extracted honey. How many bee-escapes will I have to have?
6. Are not queen-excluders a hindrance to bees, or will I have to get some excluders? If so, how many?
7. What is the "Dongolian" bee? Is it a good honey-gatherer? I have the Italian. I am in a good location. It is timber country. Clover does well here, also alfalfa, alsike, and white clover. MINNESOTA.

ANSWERS.—1. If you merely set one hive on the other, you may find the bees all in the lower story, or you may find them all in the upper story, and it is possible that you may find the 2 colonies still separate, each one in its own story. If strong enough, the queen will lay in both stories. If you want to confine the queen to the lower story, you must use an excluder, first finding the queen to make sure she is below. Or, if you don't want to look for the queen, brush all the bees from the upper combs into the lower story, put an excluder over, and then the upper story of combs without any bees.

2. "Shook swarming" is bad English that has, I am sorry to say, grown into quite common use in place of "shaken swarms" or "shake-swarming." Perhaps a more appropriate name would be one used in Germany, "anticipatory swarming." A little before you think a colony will swarm you take the matter into your own hands, and take away from the colony all its frames of brood, putting them elsewhere with only enough bees to be sure the brood will not chill. That leaves, as you will see, on the old stand, the same as a swarm with the old queen, only it will be stronger than the natural swarm would have been.

When the distance is as much as 2 miles, it

matters little when they are moved, up to fruit-bloom. A mile or less would be better earlier.

4. Yes, or for 3, especially if you expect to increase.

5. Many do not use escapes at all in running for extracted honey. If you make the experiment with 1 or 2 at first, you can better tell how many you want, if any.

6. While it is generally thought best to use excluders for extracted honey, some do not use them, such prominent men as C. P. Dadant and E. D. Townsend being of the number. The latter says that by giving additional supers always on top he has no need for excluders. If you find it is better to use them, you will need one for each colony.

7. I know nothing about Dongolian bees. If you have good Italians you needn't worry.

### Comparison of Sections—Drone-Comb

1. Under ordinary conditions will  $4\frac{1}{4} \times 4\frac{1}{4} \times 1\frac{3}{8}$  inch sections contain as much honey when used without separators as  $4\frac{1}{4} \times 4\frac{1}{4} \times 1\frac{1}{8}$  inch sections when used with separators?

2. Do you advise cutting out all drone-comb in the brood-chamber in spring?

3. Will bees repair the damaged comb with worker-comb? IOWA.

ANSWERS.—1. A fair way to decide would be to try the two side by side in the same super. I have never tried that, but we ought to approximate the right answer by a little figuring. Under ordinary conditions the bees leave a space of about  $\frac{1}{4}$  inch between 2 filled sections, and the same space between the face of a section and the adjoining separator. According to that, a  $1\frac{3}{8}$  section without separator ought to produce a comb  $1\frac{1}{2}$  inches thick, and a  $1\frac{1}{8}$  section with separator ought to produce a comb  $1\frac{3}{8}$  inches thick; thus making the first 1-11 heavier than the second.

2 and 3. If you cut out either drone or worker-comb, or if in any way there is a hole to be filled up by the bees, they are pretty sure to fill it with drone-brood; so there's no use in cutting out drone-comb and allowing the bees to fill it afresh with the same kind of comb. My advice would be to cut out the drone-comb and at the same time fill the holes with worker-comb or worker-foundation.

### The "Dovetailed" Hive

What is a "dovetailed hive?" I notice that a number of hives are made with what is commonly understood in bee-keeping as the "dovetailed" corner, although it is not a true dovetail, according to the dictionary definition of the word. ILLINOIS.

ANSWER.—I'm not sure I know enough to answer your question in a satisfactory manner. It would be easy to say, "I don't know what a dovetailed hive is; look at the catalogs and see;" but I think I do know a little about what a dovetailed hive is, only it isn't the easiest thing in the world to write definitions. But I'll brace myself and try:

A dovetailed hive is one that has no dovetailing about it, but its corners are fastened with what would commonly be called square tenons, lock-tenoned or fingered; it has frames  $17\frac{1}{8} \times 9\frac{1}{8}$ , outside measure; any hive coming under this description is a dovetailed hive, provided it has no other name. Mind you, though, I'm not to be held liable for any damage that may occur from any incorrectness in the foregoing description. I might consult a number of the catalogs, and try to make out from them more clearly just what a dovetailed hive is; but I don't want to do that, for I don't want to get myself so muddled that I'll be standing on my head the rest of the day.

Next thing you'll be firing at me a question to this effect: "Why is it that any one ever did such a thing as to call a hive a 'dovetailed hive' when it's not dovetailed, and when the part that's called dovetailed is found equally

on almost any other hive that's not called dovetailed?" Please don't insist on an answer to that question; I don't know. It's an unfortunate name, but I didn't make it, and it has come into such general use that it's hardly likely it will now be changed. "John White" may not be the most appropriate name for a negro; but if it's his name, why it's his name, and that's all there is about it. But there's no law against your trying to get up a better name—I mean for the hive, not for John White. And say, before we part, allow me to ask you a question: What would you suggest as a better name for the hive that is now called "dovetailed hive?" If you want to think over it, just send your answer by mail.

### "Hansen Ventilator"—Alexander Feeder

1. Where can one procure a "Hansen Ventilator?"

2. If I have a correct idea of the Alexander feeder, it is used under the bottom-board of the hive. How do the bees get access to the feed? IOWA.

ANSWERS.—1. I have seen it mentioned in print I think once, but have never seen any description, so far as I remember, and do not know where it is to be obtained.

2. The feeder is, so to speak, part of the bottom-board, at the back end of the hive, on

the plan of the simplicity feeder, so the bees come directly down from the frames into the feeder.

### Getting Straight Combs—Hive-Covers—Races of Bees

We have had a fine winter, the snow is about 4 inches deep at present, and the coldest weather was about 26 degrees below zero. Our bees are in the cellar, and seem to be doing nicely. I have 6 colonies—2 in box-hives and 4 new colonies from last season in Langstroth hives, but as we neglected to put foundation in all the frames, the bees soon made immovable-frame hives out of all but the last one. Now we want all these on straight combs, as soon as practicable, and expect to transfer the bees in the boxes by means of the Heddon method during fruit-bloom.

1. The box hives have only one opening (the entrance), so that when turned wrong side up and a box set on top of the hive to catch the bees when they are drummed out, how are the bees to get into the box on top?

2. What will be the best way to get the other colonies on straight combs?

3. Will an empty hive with wired frames of foundation be safe if left "standing around any old place?"

4. What kind of hive-cover do you prefer?

5. What do you think of the "Colorado" cover?

6. Which race of bees do you think best for this locality, or for any place in this latitude?

7. Are Carniolans as good as Italians, in your estimation?

8. What about Mr. Byer's idea of the blacks being as good as Italians? or are we beginners simply to overlook such talk as that? IOWA.

ANSWERS.—1. Turn the hive upside down and with a cold-chisel pry off the bottom just as if no bees were in the hive; the only difference being that you will have to use enough smoke to subdue the bees and keep them out of the way. You will have less trouble with bees in the way if you allow the

bees to swarm (of course hiving the swarm in a movable-frame hive, setting this on the old stand with the old hive close to it, and 8 days later moving the old hive to a new stand), and cut the combs out of the old hive 21 days later. That's the up-to-date method in England now, and they do more transferring there than here.

2. Hard to tell that without seeing them. It may be that they are not very bad, and that by a little cutting apart you can get the combs out, straightening each one into its own frame, and cutting out entirely any that can not be otherwise coaxed into place. If you can not do that, and even if you can, you may take a hand-saw and cut down so as to sever all comb attached to the sides of the hive. Turn the whole upside down, and it may be that by a little bumping the whole contents will fall out of the hive and you will lift it off. Perhaps, however, the bees have built combs so as to fasten the frames to the ends of the hive. Pry off the hive-bottom if it is nailed on, and with the saw separate everything from the ends. Then you have full chance to cut the combs out of the frames or do whatever may be needed.

3. Almost entirely safe in this locality. In warmer localities it might not be so safe, but with occasional looking-after there would be little danger.

4. The best I have found yet is a double cover with a  $\frac{3}{8}$ -inch space between upper and lower parts, and covered with tin or zinc. The objection is that they cost 25 or 30 cents apiece. But the cover is the last thing about a hive to economize upon.

5. It's a good cover.

6. All in all, it is pretty safe to tie to the Italians.

7. Taken as a whole, probably not.

8. Quite a number of level-headed men are to be found among those Kanuck bee-keepers, and J. L. Byer is one of them. He may be right in saying that if as much pains had been taken with blacks as with Italians, the blacks would be as good as the Italians. But the pains has not been taken, and the average black is behind. He has mixed blood, and he says he is in no hurry to change it. Maybe he will continue in that mind; maybe he won't.

### Hard Year on Beginners

This has been a hard year on beginners. I had 14 colonies and there were only 4 that I got any surplus from, and I had to feed some of them in the fall to keep them from starving. It has been too warm this winter for bees to do well—they have worked nearly every day. They have brought in pollen every month during the winter, but they consumed a lot of honey.

While it has been discouraging to the beginner, you will find enclosed \$1.00 to have my subscription renewed for the "Old Reliable," as I can't keep bees without it.

Deport, Tex., Feb. 26. C. B. McDANIEL.

### Tests of Purity in Bees

As I am a lover of peace, and a very busy man, I seldom dispute any man's statement, but pages 137 and 138 contain an item that can not pass unchallenged. That writer has pasted up his ignorance for a target for queen-breeders to shoot at. He evidently thinks that a queen must cost a big price to be worth having. He says he is satisfied that those cheap queens advertised are mongrels or worthless.

Now I advertise cheap queens, and I am satisfied that he does not know what he is talking about. If he did, he would talk less.

Then, he attempts to tell us what a tested

# American Bee Journal

queen la. I don't believe he ever saw an imported Italian queen and her colony of workers and drones. Any man who knows anything about bees knows that Italian queens are not all bright yellow. Neither do all Italian drones have 4 yellow bands. We all know that pure Italian drones vary in color from a yellow copper color to nearly black. So our New Yorker wants 4 yellow bands on drones and 3 on workers.

Now, Mr. New Yorker, if you can test a queen by her drones only, you can do more than most bee-keepers. You say a pure Italian queen is bright yellow; her drones and workers are marked just like her. But just before, you say her drones have 4 yellow bands and her workers 3. How is this?

Well, if some breeder should send our New Yorker a Texas yellow wasp marked "Italian," I doubt if he could tell whether it were a tested Italian queen or a cheap mongrel.  
Uvalde Co., Tex. GRANT ANDERSON.

## Bees Stealing Pollen

We are having a cold winter, but my bees don't know it. I have 71 colonies in the cellar under the kitchen.

I have never read of bees robbing pollen, but had such a case last summer. The robber-bees would stay outside on the alighting-board, and as a bee loaded with pollen would alight it would run against her and cause her to lose part of her load, which it would gather up and carry away. While this would cause but little damage to the colony, it shows a reasoning power which can hardly be called instinct.  
T. PROCTOR OTIS.

Coaticook, Que., Feb. 17.

## Bee-Keeping in Central and Northwest Arkansas

Twenty years ago I located in Pope Co., Ark., near the central part of the State, north of the Arkansas River. About one-fourth of the inhabitants there had bees—some pure Italians, some hybrids, and a few blacks. I found no bee books, papers, nor professional apiarists to instruct them; still they were comparatively successful. It was certainly a good bee-country, and their bees swarmed a great deal. Those men could transfer, make "artificial swarms," and introduce queens. Their hives were made by carpenters in the pine lumber mills that were numerous all over that country. They were made of soft yellow pine, very porous, and the planks were sawed  $1\frac{1}{2}$  inches thick, probably were  $1\frac{1}{4}$  inches thick when run through a planer. Those hives resembled the Dadant style, and were made well. I never saw a section-honey box used. They all produced comb-honey in the full size frames which they cut out, saving no comb, and trusting to the bees to make more.

Those bee-men never bothered about selling honey, and never tried to make it a financial income, as they were all "well-to-do" cotton-raisers, who had sufficient means to live easy, and did not regard the "apiary" sufficiently important to bother about selling queens, joining a "bee-society," nor subscribing for a bee-paper. Still, several of those men had "bee-orchards" (almost all had their hives in apple or peach orchards) as large, and some a great deal larger than several of our apiarists who write and illustrate for our leading bee-papers.

There are a great many bees in Arkansas, but those quiet, conservative, soft-talking Southerners do not "blow" about it. They are among the best men in the world. There is no deceit nor hypocrisy about them, and in their saber-ashed, bullet-pierced thorax beats a magnanimous heart.

Bees in that locality gathered their honey from various flowers that bloomed in profusion along the water-courses and in the fields. Cotton-blossoms furnish a great deal of excellent honey, and the theory that it "explodes" or ferments is all bosh. It makes an excellent, rich honey, oily, but by some it is not liked so well until they get used to it. Most of the honey is flavored with peach and apple blossom, and with the aroma of the

famous muscadine, which surpasses all the known flavors. You can smell an apiary where bees use the syrup that exudes from the ripened fruit a half mile on a damp, still day. The wax is very nice—more oily than the wax in the North, as it contains more or less cotton-oil, and is more easily "broken down" in warm weather.

Well, I joined in with those fellows in the bee-business. I bought 12 colonies (hybrids), and with an old-style knowledge of bees obtained from my father, who had a whole apple orchard filled with hives, I began with "A B C of Bee-Culture" as a guide. I did well, although I never trusted enough in my own skill to run into the full details of queen-rearing by nuclei, nor uniting "fall swarms." I could divide in the spring, and feed and exchange brood-combs, and speedily build up weak colonies. I reared my own queens in strong colonies dequeen for the business, and I inserted cells, mostly. Sometimes I inserted queens without trouble. My apiary became so large, and as I never tried to sell my honey, I gave it away! I am a physician, and my practice became so great in that malarial country that I could not be bothered with bees. My experience with bees there was for about 7 years. Of course, that was some time ago, and I am informed that the people have advanced "out of sight" in the mode of handling bees. I hope so, at least. I am now located in one of the most beautiful "spots in Dixie"—oh, so lovely! I wish that Mr. Doolittle could see those beautiful springs, parks, orchards, lakes, bluffs, and valleys all in bloom with almost every kind of flower that can bloom on this mundane sphere, interspersed with grapes, strawberries, blackberries, raspberries, pears, apples, peaches, buckwheat, and clover. My "bee-brothers" will see that I can not help doing well here with bees. I have just begun, having bought up a few colonies over the country and have not moved them home yet. I am going to be nice this time and "put on style" with my hives. I will use 2 Jumbo with half supers. I will describe the *modus operandi* in my next article, and will also tell of the "bee-men" and "bee-women," and also their bees and their mode of management. An "old maid" near me has sent for me to help her with her bees—and I must go and help her—provided my wife doesn't see me!

JULES BELKNAP, M. D.

Sulphur Springs, Ark.

## Laying Workers, Introducing Queens, Etc.

Last fall I put some colonies of bees into the cellar. They had not a great deal of honey, so I took a tin pan 4x9 inches and 3 inches deep, filled it with the best white sugar, turned on enough cold water to moisten it all, and the next morning I had a fine block of sugar. I gave each colony a block, and they are all alive now.

### TREATMENT OF LAYING WORKERS.

Give them a good whiff of sulphur. In 1906 I had 3 laying worker colonies. I gave one colony a queen-cell, but after the young queen had mated with the drone they killed the queen; 2d, I sprinkled them with sweetened water and oil of peppermint. Next I saw drone-layers on the ground.

### HOW TO INTRODUCE QUEENS.

Take off the honey-board; capture the old queen; place the new queen in a wire cage 4 inches long and 1 inch wide; fit a wooden plug into the end of the cage; bore with a  $\frac{3}{16}$ -inch bit in the end of each plug  $\frac{1}{8}$  inch. Fill the holes with sugar and honey. Mix not too soft to daub the queen. Don't give any nurse-bees. Place the cage in the center of the cluster of bees. Let it lie between 2 top-bars. If there is any sealed honey press the wire into the comb and let it stay 48 hours. In the evening, after the 48 hours, mix  $\frac{1}{2}$  teacupful of honey and water. Don't make it sticky. Blow smoke on top and below. Then sprinkle the bees with the mixture and give them time to fill themselves. When they

commence to hum blow a little more smoke on them; free the queen; close the hive, and don't disturb them. Place a shallow box under the hive-entrance, and then if they destroy the queen you can see her.

Bergen, N. Y., Feb. 20. E. TUCKER.

## 70 Colonies of Bees For Sale Cheap

In large quantities, \$3.00 per colony, and \$3.50 in small lots. The bees are in 10-frame Langstroth hives, and in excellent condition.

## CONVENTION NOTICES.

**Texas.**—The Northern Texas Bee-Keepers' Association will hold its annual meeting at Ladonia, Tex., on April 3 and 4, 1907. All bee-keepers are invited to attend. No hotel bills to pay. W. H. WHITE, Sec. Blossom, Tex.

**Michigan.**—The Northern Michigan Bee-Keepers' Association will hold its next annual convention at East Jordan, Mich., on April 10 and 11, 1907. Headquarters will be at the Russell House, where a \$1.00 per day rate has been secured. IRA D. BARTLETT, Sec. East Jordan, Mich.

**Connecticut.**—The 16th annual convention of the Connecticut Bee-Keepers' Association will be held in the State Capitol, Hartford, room 50, on Saturday, April 6, 1907. We believe that every wide-awake apiarist in the State knows that our Association is unselfishly seeking to assist and protect the bee-keepers in every way possible. During the past few months apiculture has probably been more generally discussed than at any other

period in the history of the State, because of our attempt to secure proper bee-disease legislation. Bee-keeping now, as never before, is regarded as an important agricultural industry in Connecticut, and our Association proposes to continue its campaign of education. A lengthy program has been prepared for the next meeting, and it is expected that several noted speakers will be present. Every bee-keeper is cordially invited to attend. Please bring choice samples of honey, or anything of interest, for the apiarian exhibit. Membership in the Association is but 50 cents a year. We want 500 new members. Please make remittances to the undersigned before the date of the meeting, and be sure to come yourself. J. ARTHUR SMITH, Sec. Box 33, Hartford, Conn.

**Utah.**—The Utah Bee-Keepers' Association will hold its spring convention in the Mayor's office in the City and County Building, April 5, at 10 a. m. A revision of the bee-protection law, reports on the smelter settlement, and other questions of interest will be taken up. All are cordially invited. E. S. LOVESY, Pres. A. FAWSON, Sec.

## American Bee Journal Novelty Pocket-Knife Gold Fountain Pen

All for \$3.00

(This cut is the full size of the Knife.)

### NOVELTY POCKET-KNIFE

(Name and Address on one side—Three Bees on the other side.)

Your Name on the Knife.—When ordering, be sure to say just what name and address you wish put on the Knife.

The Novelty Knife is indeed a novelty. The novelty lies in the handle. It is made beautifully of indestructible celluloid, which is as transparent as glass. Underneath the celluloid, on one side of the handle is placed the name and residence of the owner, and on the other side pictures of a Queen, Drone, and Worker, as shown here.

The Material entering into this celebrated knife is of the very best quality; the blades are hand-forged out of the very finest English razor-steel, and we warrant every blade. It will last a life-time, with proper usage.

Why Own the Novelty Knife?—In case a good knife is lost, the chances are the owner will never recover it; but if the "Novelty" is lost, having name and address of owner, the finder will return it. If traveling, and you meet with a serious accident, and are so fortunate as to have one of the "Novelties," your POCKET-KNIFE will serve as an identifier; and, in case of death, your relatives will at once be notified of the accident.

How to Get this Valuable Knife.—We send it postpaid for \$1.25, or club the Novelty Knife and the American Bee Journal for one year—both for \$2.00. (Allow two weeks for Knife order to be filled.)

### SOLID GOLD FOUNTAIN PEN

Finally we have found a good Fountain Pen that is reasonable in price. The manufacturers of this pen say that if you pay more than \$1.25 for other fountain pens, it's for the name.

This pen is absolutely guaranteed to work perfectly, and give satisfaction. The Gold Nibs are 14 kt., pointed with selected Iridium. The Holders are Para Rubber, handsomely finished. The simple feeder gives a uniform flow of ink. Each pen is packed in a neat box, with directions and Filler.

Worker

Queen

Drone

3/8 size

are made every year in the book business. Every family, rich or poor, must have books. During the last few years, \$7,500,000.00 have been expended for Modern Eloquence, \$12,000,000.00 for Stoddard's Lectures, \$2,000,000.00 for the Century Dictionary, and the tremendous sum of \$4,000,000.00, covering over half a million sets of the Encyclopedia Britannica. These books were sold by subscription in American homes and sales are still going on.

We have a subscription publication which sells more readily than any of the above. The demand is already so tremendous that more capital is required to swing it, or get behind on orders. Profits are enormous, several times savings bank interest.

We have arranged a plan whereby **Any Progressive Man or Woman Can Share These Profits**

becoming stockholders in a profitable business, based on twenty years' experience. Remember, the success of this publication is not away off in the future—it is not prospective, but it is a success at the present time and growing in demand every hour. Sales of this publication at the time of publishing this advertisement **Often Exceed \$2000 a Day**

This is an exceptional opportunity for those of small means to get in on the ground floor in a business which legitimately pays large dividends and is as solid as the Rock of Gibraltar. It cannot be held open for long as the response is certain to be so great that we shall have all the capital we need to increase the number of our presses and secure stock to be turned out in completed books, which are selling like wildfire.

You owe it to yourself to investigate this opportunity. You will never have a chance like this again to become

**Part Owner in a Mammoth Publishing House**

which is already in successful operation, already earning big dividends, and which is led to sell a small amount of its stock simply because the business is already so tremendous as to exhaust the working capital. But if you would grasp this opportunity you must

**Write Quick—Only a Few Can Come In**  
Address your letter to me personally, like this—

## Standard-Bred Italian FREE PREMIUM QUEENS

We are booking orders now for those Fine Untested Italian Queens that we offer every year FREE to paid-in-advance subscribers as premiums for getting NEW subscribers for the Weekly American Bee Journal. These orders are taken for May or June delivery.

### What Some Say of our Standard-Bred Italian Queens:

*George W. York & Co.*—The two queens received of you some time ago are fine. They are good breeders, and the workers are showing up fine. I introduced them among black bees, and the bees are nearly yellow now, and are doing good work. A. W. SWAN.  
Nemaha Co., Kan., July 15.

*George W. York & Co.*—After importing queens for 15 years you have sent me the best. She keeps 9 1/2 Langstroth frames fully occupied to date, and, although I kept the hive well contracted to force them to swarm, they have never built a queen-cell, and will put up 100 pounds of honey if the flow lasts this week. CHAS. MITCHELL.  
Ontario, Canada, July 22.

*George W. York & Co.*—The queen I bought of you has proven a good one, and has given me some of my best colonies. N. P. OGLESBY.  
Washington Co., Va., July 22

*George W. York & Co.*—The queen I received of you a few days ago came through O.K., and I want to say that she is a beauty. I immediately introduced her into a colony which had been queenless for 20 days. She was accepted by them, and has gone to work nicely. I am highly pleased with her and your promptness in filling my order. My father, who is an old bee-keeper, pronounced her very fine. You will hear from me again when I am in need of something in the bee-line. E. E. MCCOLM.  
Marion Co., Ill., July 13.

### How to Get these Queens Free

To any one whose own subscription to the Weekly American Bee Journal is paid in advance, we will mail a Fine Standard-Bred Untested Italian Queen next May or June, for each new name and address sent to us with \$1.00 for the Bee Journal a year. No one can get for himself the Bee Journal a year and the Queen for \$1.00. The Queen is offered as a premium for the work of getting some one else to take the Bee Journal a year. If you, yourself, want the Bee Journal a year and the Queen, send \$1.50 for the two, and we will book your order for a Queen. Queen orders will be filled in rotation—"first come, first served." Address,

**GEORGE W. YORK & CO.**  
334 Dearborn Street, CHICAGO, ILL.

# Mr. Beeman, what do you get for Your Money?

---

That's the question to consider when buying your bee-supplies?

Simply because you have bought from some other firm for years and years, and because you perhaps think that you are satisfied is no reason why you should not look around to see if you can't buy from a better firm.

You don't know what satisfaction is until you get it.

By a better firm we mean a firm selling better goods in better packages, giving better service; a firm who can and will do not only better by you than the concern you have been doing business with, but who will do the best of them all.

"I bought 50 Lewis hives from a fellow in our town last year, and I never saw nicer, whiter, better-fitting bee-hives in all my life. I have always bought my supplies from \_\_\_\_\_ so I had no idea you made such fine goods until I stumbled onto them by mistake. Now I want Lewis Beeware and nothing else."

The above is only a sample of what bee-keepers think and have to say about Lewis goods. Thousands of our customers come to us in just this way.

They come to stay.

Now, we are going to ask you to buy just 5 Lewis hives and 500 Lewis sections—even less, if you do not care to run that risk—just to see what they are. We leave the decision entirely with you. If after getting a sample you are not convinced that Lewis goods are the goods for you—we don't ask your business. That's fair, isn't it?

## A GREAT IMPROVEMENT

Will be found in

## The American Bee-Keeper for 1907

It is profusely illustrated and enlarged, and contains only articles of the most practical as well as scientific nature. A special corps of the best writers has been engaged. The editors are Harry E. Hill and Arthur C. Miller, than whom there are no more practical or experienced bee-keepers in this country. We have published the American Bee-Keeper continually and regularly since 1890.

Regular subscription price, 50 cents a year. One year to new subscribers, 35 cents; three years for \$1.00.

Send for sample copy and our new illustrated price-list of BEE-SUPPLIES OF ALL KINDS.

Guaranteed highest quality at lowest price. Address,

**THE W. T. FALCONER MFG. CO.**  
JAMESTOWN, N. Y.

(Established 25 years.)

## Honey and Beeswax

CHICAGO, Feb. 1.—The usual late winter demand is in evidence for comb honey to replace diminished stock laid in during the autumn by the large retailers, but during the dull period there has been very little change, if any, in prices, the offerings being light.

We find No. 1 fancy white comb honey brings 15@16c, and for that which is off in color and flavor from 1@3c less. Amber grades of all kinds are dull and range in price from 10@12c. The extracted perhaps is not quite so firm in price for the California or Western grades, but there is no surplus of white clover or basswood, both of which bring about 8c, and in some cases more. Ambers grade from 6@7½c. There have been some sales of beeswax at 32c, but 30c is about the price for average.

R. A. BURNETT & Co.

PHILADELPHIA, Mar. 11.—The comb honey market has been quite active in the last two weeks, and the continual cold weather has kept things moving. Many cheap lots have been sent in from the producers, which have had a tendency to bear on the market and weaken the prices somewhat. Fancy white comb honey, 15@16c; No. 1, 14@15c; amber, 12@14c. Fancy white extracted honey, 7@8c; light amber, 6@7c. Beeswax very firm, 32c.

We are producers of honey and do not handle on commission.

WM. A. SRELSER.

NEW YORK, Jan. 15.—The stock of white comb honey is pretty well exhausted, and we do not expect any more arrivals of large lots from now on. Prices are firm, and we quote from 15@16c for fancy white; 13@14c for No. 1; 12c for light amber. There is quite a little dark and buckwheat on the market, but no overstock, and we think that all of it will be disposed of before long at present prices, which we quote from 10@12c, according to quality. Extracted honey very firm, with sufficient supply to meet demand. California white sage is bringing from 8@8½c; light amber, 7½c; amber, 6½@7c; buckwheat extracted in fairly good demand at 6@6½c. Southern in barrels finds ready sale at from 55@70c per gallon, according to quality. Beeswax firm and steady at 31c.

HILDRETH & SROBLEEN.

DENVER, Feb. 14.—Producers in this State are practically closed out of both comb and extracted honey. We have not sufficient good comb honey to supply our local trade, but have

# Headquarters for Bee-Supplies

# C. H. W. WEBER

Office and Salesrooms, 2146-48 Central Ave. Warehouses, Freeman and Central Aves.

a good supply of white extracted of excellent quality. We quote strictly No. 1 white comb honey, per case of 24 sections, at \$3.20; No. 1, light amber, \$3; and good No. 2, \$2.80. White extracted, 8@8½c per pound; light amber, 7½@8c. Clean, yellow beeswax, 27@28c, delivered here.

THE COLO. HONEY-PRODUCERS' ASSN.

CINCINNATI, Mar. 11.—There is very little demand for extracted honey at this writing, which is only natural, owing to the unsettled weather at this time of the year. However, we are looking forward with interest to a revival of trade, as soon as the warm spring days are here. We quote amber extracted honey in barrels at 6¼@7½c, the price depending upon the quantity purchased. Fancy table honey in crates of two 60-lb. cans each, at 8@9c. There is little demand for comb honey owing to the lateness of the season. Choice yellow beeswax, 32@35c, delivered here.

THE FRED W. MUTH CO.

INDIANAPOLIS, Feb. 25.—comb honey is not plentiful, but demand is slack. Fancy white comb brings 16@17c; No. 1 white, 14c; amber, 12@13c. Best grades of extracted honey bring 8@9c; amber, 6@7c. Good average beeswax sells here at \$35 per 100 pounds.

WALTER S. POWDER.

TOLEDO, Nov. 30.—The market on comb honey remains about the same as last quotations, but has been coming in much more freely, as beekeepers seem to be very anxious to get rid of their stock. Fancy brings in a retail way 16c; extra fancy, 17c; No. 1, 15c; buckwheat, 15c. Extracted white clover in barrels brings 7@7½c; cans the same. Beeswax, 26@28c.

THE GRIGGS BROS. & NICHOLS CO.

CINCINNATI, March 6.—The market on comb honey has been quite brisk the past week. Entirely sold out of fancy white. No. 2 is selling for 12½@13c. White clover extracted in cans, 9c; amber in barrels, 6c. Beeswax, 30c, delivered here.

C. H. W. WEBER.

KANSAS CITY, Mar. 4.—The demand for comb honey is only fair at present. The market is almost entirely bare of extracted honey. We quote: No. 1 white comb, 24-sec. cases, \$3.10 to \$3.25; No. 2, \$2.50 to \$2.75. Extracted honey, white, per pound, 8@10c; amber, 8c. Beeswax, per pound, 25@27c.

C. C. CLEMONS & Co.

## How About Selling at Cut Prices?

He is a wise man that knows when he has been "stung." But not all bargain-hunters are wise. Some of them have been stung repeatedly and still do not know how it happened.

It costs nothing to promise bargains. It takes no more printer's ink to describe a gold-brick than a Government bond. The real trouble begins when the gold-brick arrives. When staple goods are sold for less than they are worth the difference has to be made up in some way.

This house has never found it necessary to sell goods at cut

prices to secure trade. My business is growing all the time, on the simple proposition that I give a dollar's worth of value for every dollar received, and here is the way this proposition appeals to a whole lot of people besides this one:

Russell, Iowa.

Walter S. Pouder, Indianapolis, Ind.

CHICAGO, ILL., APRIL 4, 1907

Vol. XLVII—No. 14

### Quoting the Honey Market

We have received the following criticism of the honey-market quotations that appear in the bee-papers:

EDITOR YORK:—Most of the large honey-portions in this country sell again the greater portion of their stock to wholesale houses, and when making such sales, must, of necessity, quote other prices to the wholesaler so that there is a fair margin of profit (usually 10 percent) to such party, and so that the latter can sell to the retail dealers at the same price as the jobber would sell to that class of trade.

Looking over the market quotations in the bee-papers, it appears that some firms quote their prices to the jobbing trade and others quote the prices they make to the retail dealer. Now this should not be. It is necessary, in order to make the quotations of any value, that they should be based either on jobbing prices or on the prices to retail merchants. We should prefer the latter, because then these prices would be a guide to the producers as to what figures they should sell to their local merchants.

A standing explanation should be given at the head of the market column so that everybody would know what the quotations signify, and so that the shippers would not expect that all of their honey would be sold at those figures.

Another suggestion that could stand a little airing, is the manner in which commission merchants render account sales to their consignors of honey. In all my experience I have found only one instance where the statement gave the information that the consignor is entitled to have, according to my way of thinking. Therefore, when we organized our institution, we decided to adopt a plan of keeping consignment accounts with our members and others, that would give all the details of each transaction that any reasonable person would want. We use two sheets for each consignor, the original remaining in the ledger; the carbon copy, when complete, going to the consignor and taking the place of statement. Invoices are numbered, being made in triplicate on an automatic register, the original invoice going with the goods, the first carbon copy being filed away numerically,

and the second carbon copy alphabetically. Our check numbers are also posted in the ledger, so that it is an easy matter to verify the correctness of each entry.

For the purpose of saving space, we start posting consignment sales at the bottom of the page, and go up. When the page is filled the number of cases of honey should tally with the number of cases sold and on hand. The unsold portion taken with the debits and credits is then transferred to a new sheet in the ledger. Each consignor's sheets have their own numbers.

We are of the opinion that every merchant handling goods on consignment should be obliged to furnish a satisfactory account of sales.

BUSINESS MANAGER.

We thought best to submit the foregoing to those who quote the honey market for the American Bee Journal, and the following are their replies:

GEORGE W. YORK & Co.:—In compliance with yours of the 26th, we will say that this is a good idea. We quote the price we sell to jobbers; that is, what we get in a jobbing way, and I think this is the best.

C. H. W. WEBER.

Cincinnati, Ohio, March 5.

GEORGE W. YORK & Co.:—Your favor of the 26th received, with criticism on the honey quotations, which we have carefully noted.

In reply we will say we deal with the jobbing trade exclusively, consequently our quotations are just what we get from the jobbers. We sell nothing to the retail trade here.

C. C. CLEMENS & Co.

Kansas City, Mo., March 5.

GEORGE W. YORK & Co.:—In reply to yours of the 26th ult., we wish to say that we are entirely in harmony with the sentiments expressed in the article referred to, and as for our own market quotations we will say that we always state the price at which we sell to the retail dealers, with the exception of beeswax, on which we quote the price that we pay delivered here.

THE COLORADO HONEY-PRODUCERS' ASS'N.  
Denver, Colo.

E. RAUCHFUSS, Mgr.

GEORGE W. YORK & Co.:—Complying with your request under date of the 26th, relating

to the market quotations as published in the various bee-papers, we wish to say that the prices quoted by us are what we receive when selling. Naturally the prices for which we buy are lower than those quoted in the bee-papers.

We are aware that the market reports as published to-day are confusing to the honey-producers, and you can not make these quotations too plain for them.

THE FRED W. MUTH CO.,  
FRED W. MUTH, Pres.

Cincinnati, Ohio, March 5.

GEORGE W. YORK & Co.:—With an experience in the honey-business extending over a period of a quarter of a century, and following the quotations in the markets very closely for the last decade, I can see where quotations might be very misleading to the honey-producer and bee-keepers in the Eastern market. The prices among commission men for honey shipped in, as a rule, are very unsteady, and Philadelphia is an exception to other Eastern cities in the fact that we do not have any large commission men who make a specialty of dealing in honey. So various commission men who deal in other lines occasionally get shipments of honey from different parties, and in order to make quotations that would be satisfactory to the producer, I have always tried to average up these sales with a steady market that our dealers are having from the grocery trade. I believe it would be advisable, however, to quote prices that, if the producer were to ship on commission in this market, he could expect to realize after deducting commission, freight, carting and expenses. I would advise all producers who have any quantity of honey on hand always to write the commission men, giving them a clear statement of the quantity and quality, before making the shipment.

WM. A. SELSER.

Philadelphia, Pa., March 11.

GEORGE W. YORK & Co.:—Replying to yours of recent date concerning the method of making quotations in the American Bee Journal, we would say that in a general way the market report is made up from actual sales, but a commission house is considered to be a jobbing house. There are houses who do both a jobbing and a small wholesale business, i. e., they receive consignments from different parts of the country and sell it to smaller dealers in the same line of business, who sell it by the individual package to small retailers, all of the large retailers buying the goods at the same price that the small jobber does, or the man who buys it and peddles the same out of a wagon to a retailer. The percentage of profit begins when the commission merchant sells the consignment, as his margin is the commission. Charge on car-lot consignments is usually 5 percent, but on small lots 10 percent, and the 5 percent pays the commission merchant a better net profit than the 10 percent (strange as it may seem), for in the case of the car-lot, where the goods run

uniform, an exhibit of a few cases is sufficient to make the sale; on a lot of honey of 100 pounds to 1000 pounds it takes as much of an exhibit to sell it as it does the car-lot, and frequently many times as much expensive labor is employed in selling the small lot as the larger one, as there are often different grades of honey in the same shipment.

All commercial houses of any standing, including commission houses, keep a record of the sales, and when returns are made to the consignor, a copy of the original entries accompanies the remittance, so that the owner may know just how his consignments sold. A wholesale buyer usually understands what he is doing; therefore, presuming the seller is equally well versed in his business, a sale is more quickly effected than in the case of where a wholesaler is selling to a retailer who has more or less of a limited knowledge of what he is buying, and needs to have much more information imparted to him concerning the merits of the merchandise under consideration.

R. A. BURNETT.

Chicago, Ill., March 5.

GEORGE W. YORK & Co.:—We are in receipt of your favor of the 26th, enclosing the article in regard to market quotations in the American Bee Journal. The quotations as they appear in the different papers, are intended to represent as nearly as possible the prices realized at that time in a jobbing way. This leaves a wide range as to quantity. While one man will not want to buy more than 5 or 10 cases, another might take 100 or more.

Where a party buys very largely, even the quotation prices are very often shaded in order to make the sale, especially so when there is plenty of supply and the demand not very active. There are quite a few firms, we believe, who do strictly jobbing business only, who, perhaps, are not in position, nor have facilities, to sell to the retail trade.

Your correspondent seems to think that the quotations as they now appear are not right, and that they should be based on the prices sold to the retail merchants, so as to guide the producers as to what figures they should sell to their local markets. We can not quite agree with your correspondent. Take, for instance, all quotations in the Journal of Commerce and Commercial Bulletin of New York, which, we are pretty sure, are wholesale figures or jobbing prices, and are generally understood this way.

Of course, where merchandise is sold in a small way it is generally sold at a little higher than quotation prices, and then the shipper would derive the benefit anyway.

While we can only speak for our own market, we are of the opinion that quotations for other markets signify wholesale prices. The vital point is, it appears to us, that the shipper should have confidence in the firm to whom he consigns his goods, leaving the handling of same entirely to their discretion and judgment.

HILDRETH & SEGELKEN.  
New York, N. Y., March 9.

GEORGE W. YORK & Co.:—We have your letter of Feb. 26th, enclosing a criticism from "Business Manager," and will state that we consider the way we handle honey the only way; that is, to buy it outright. We, perhaps, are in a little different position from some dealers, but we have secured a fair market of our own, on our own goods, and therefore have always handled honey on an out-and-out sale, and not on commission. From experience that has come to our view, handling honey on commission or consignment is very unsatisfactory. A great many commission men in the country take advantage of the bee-keeper. We have known instances where commission men would receive a nice lot of honey, would get a fair price for it, and then when they made their report to the bee-keeper they would report 2 or 3 cents less than they actually sold it at, deducting freight, cartage, breakage, etc., and in the end the bee-keeper does not get as much out of it as if he sold it to some good merchant that makes a specialty of handling it. We do not insinuate that all commission men are alike, but we have seen so much of it done

that we are frank to state that it is not the right way for any man to market his goods.

When quoting the honey market for bee-papers we always quote what honey brings here, or what we term the "retail trade"—the grocers. We never quote our price to the jobbing trade, as this varies according to the quantity bought, and our quotations have always been just what honey was bringing here in a retail way. We do not think that any producer of honey in the United States has any business to sell his honey on consignment or commission, as there is no one that produces so much that some jobber in honey can not buy it outright and pay for it; then he knows just what he is going to get for it.

It is true that a great many bee-keepers never read the bee-papers, and never know what honey is worth. Invariably they sell their crop without even investigating as to what it is worth.

We think the matter is an important one, and we are satisfied that our view will be agreed to by the majority of honey-dealers.

THE GRIGOS BROS. & NICHOLS Co.,

Per S. J. GRIGOS, Pres.

Toledo, Ohio, March 5.

GEORGE W. YORK & Co.:—I have read with much interest the letter written by Mr. Business Manager, and I am heartily in sympathy with him. Market quotations should be very valuable to producers, but privileges to wholesalers in quoting the markets have been seriously abused. To me it seems that an explanation should be at the top of the column stating that quotations are the wholesale prices being made to retail dealers.

It appears that some quote the market as regards their own stock, without referring to the general market of city named. Some have used the space as a free advertisement, quoting what he, individually, pays for beeswax, leaving the public to guess what his near competitor is paying, and saying nothing about what he is selling at. Such quotations do not enlighten the producer in any manner.

In quoting my own city I realize that I am not the only one in the honey-business by a

long ways, and I look around to see what is being offered the retailer in a general way, and quote accordingly, regardless of any stock that I may have on hand. I have always believed this to be the correct method.

It is a question in my mind whether or not the producer of honey is ever justified in sending out his goods on the consignment plan. Better have a definite understanding about prices before shipping, and such arrangements can be made with responsible commission houses as well as with cash buyers. I recently saw an instance where a producer refused the price offered by a cash buyer, but agreed to consign his honey to a commission house in the same city. The commission house later offered the same honey to the cash buyer at a less price than had been offered the producer by the cash buyer. I am a believer in having an understanding about prices before shipping, and then a cash basis, for this is the remedy to guard against disappointments. In every large city the cash buyer has a struggle to compete with the commission man, but the cash buyer is the best friend of the bee-keeper.

A reform in market quotations is much needed, and will be welcomed by all who are interested.

CASH BUYER.

There seems to be considerable agreement among those who quote the honey-market for the American Bee Journal. It is as we have always understood, that the prices quoted are those which the shipper might expect to receive for his honey, after deducting the freight, cartage, and commission charges.

The letters given herewith are certainly interesting reading, particularly the emphatic manner in which some urge the cash buyer's method. It would seem to be a pretty good way. And always write the dealer before shipping the honey, no matter whether it is to be sold on commission or for cash at an agreed price.

**The Suburban Apiary of Wm. Robert Shannon, of Brooklyn, N. Y., is shown on the first page. Mr. S. writes as follows concerning it:**

The little apiary represented in the enclosed picture is located in a Brooklyn suburb of "Greater New York." My little girl, boys, and myself, may be seen in the picture. Not having trees to shade from the hot sun I use a canvas covering, having space inside this cover to move about and do any needed work among the bees.

Last season, colonies having plenty of stores and a young queen, were very successful, giving 80 to 103 pounds of section honey Aug. 1; the same colonies sealing afterwards in the brood-chamber 40 to 50 pounds in September and October from wild aster.

I would say that queens after their second year are very uncertain. It is a waste of time to permit a weak colony to rear a queen. Such a queen will be small and delicate in these circumstances, and the bee-keeper will experience poor results. No queens can compare with those found in the parent colony from which a prime swarm has issued in June. Such queens are good for 2 years.

To be successful, attend to the common-

sense known facts. Winter your bees with plenty of stores, and a young queen in each colony. Weather conditions must be very bad if one does not reap a plentiful harvest.

WM. ROBERT SHANNON.

**A Fair Exhibit, made by O. K. Rice, of Washington, is shown on the first page. When sending the picture, Mr. Rice wrote thus:**

Enclosed you will find a picture of our local grange fair exhibit of my honey. It took first prize. It had to, as it was the only honey exhibited. There were some bee-keepers that would have exhibited, but when I had mine ready they did not come. I sold \$30 worth the day after the exhibit, and as a prize I got an 8-day clock which strikes the hours and half-hours. You can see it in the picture at the right. At the left you will see a volume of the American Bee Journal with the pictures of Dr. Miller, N. E. France, and Wm. McEvoy. It is the first issue for 1906. In the exhibit, the top row of honey is pint jars; the next is  $\frac{1}{2}$ -gallon, and third  $\frac{1}{4}$ -gallon jars. The fourth or last in the center  $\frac{1}{2}$ , and next  $\frac{1}{4}$  and pints. On the table is a cake of

wax (10 pounds), and 3 pint-jars on top of it. I will leave the reader to guess the rest.

The year 1906 was a fairly good year for bee-keeping. I took about 1600 pounds from 24 colonies. It was all extracted honey. I sold it all at about 10 cents a pound.

Bees are doing well on the summer stands.  
O. K. Rice.

Gray's River, Wash., Jan. 10.

**The Clean and Upright Character** of the American Bee Journal is thus referred to by Mr. Charles R. Smith, of Scranton, Pa., when commenting on it as an advertising medium:

EDITOR YORK:—Your reference to advertising in the American Bee Journal, on page 227, is of more than passing account. The important part of the whole article, however, is in Mr. Poulder's lines—"the readers of the American Bee Journal have confidence in its advertisers." And he could well have added, "and that confidence is established chiefly by the clean and upright character of the paper."

I keep a few bees for the pleasure and recreation I get from them and the honey for my table, and have occasion, sometimes, to buy of your advertisers, always with satisfactory results. Here is an instance: Never having had, or tasted, alfalfa honey, I ordered a 60-pound can of one of your advertisers. I suppose I shall never be without it on my table hereafter; and that firm may expect an order every year for a long time.

Yours very truly,

CHARLES R. SMITH.

We are very certain that more advertisers would patronize the American Bee Journal if they knew as well as Mr. Poulder about its value in that regard. Unless those who have good things to sell, let people know it, they can't expect to have much demand.

**Proportion of Comb to Honey.**—We have received the following from Mr. C. P. Dadant, calling attention to an error in reporting:

MR. EDITOR:—I see on page 237, at the top of the third column, that I am made to say that the proportion of comb to honey is about 25 to 40 percent. This was at the Illinois State convention at Springfield. I do not remember this matter, but I am sure I could not have said that, for the proportion of comb is certainly a great deal less.

I am often made to say, by the reporters, things that I blush to be credited with. I fear, however, that I am to blame for the mistakes thus made. I speak too fast. At the San Antonio convention I was several times cautioned by our stenographer, who said it was out of the question for her to report correctly words that came so hurriedly. But I wish to warn the readers against accepting as gospel truth all the small talk of the conventions.  
C. P. DADANT.

In referring to the original report as furnished by the stenographer to the secretary of the Association, we find it is just as we printed it. But any one who gives the matter any thought at all will readily know that over one-fourth of comb honey is not comb. At a guess we should say the proportion of honey to comb might possibly be as "16 to 1." And that might be rather more comb than there really is.

**Amerikanische Bienenzucht**, by Hans Buschbauer, is a bee-keeper's handbook of 138 pages, which is just what our German friends will want. It is fully illustrated, and neatly bound in cloth. Price, postpaid, \$1.00; or with the American Bee Journal one year—both for \$1.75. Address all orders to this office.

## How Far Do Bees Fly for Nectar?

BY J. E. CHAMBERS

During the past year I have noticed many inquiries and comments in the different bee-papers with respect to the distance bees fly in search of nectar. To all of these inquiries there has never, to my certain knowledge, been given a definite answer. It would seem as if some of the teachers should be able to tell us if the time-taught doctrine that bees seldom fly over  $1\frac{1}{2}$  miles in search of honey is true or not.

Editor Root, in a late number of *Gleanings*, gives the result of certain observations made by him during the time of their basswood flow. These observations, though limited in extent and place, lead him to the conclusion that bees do not generally go beyond the distance specified; however, he says this was probably due to the fact that they were able to get all they wanted within that range. Among all the writers of note I recall at the present time only Doolittle and Alexander, who claim that bees from choice fly farther than the orthodox  $1\frac{1}{2}$  miles. Of course, there are others who know that such belief, though time-honored, is all bosh, and that bees often go over 3 miles, and that, too, when honey can be had nearer. But many who know, laugh and let it go—not careless, merely, but indifferent to the right or wrong of an idea that gets scattered broadcast over the wild bee-keeping world. And I may here remark that this is also true of many other current, but nevertheless false ideas. Those who know are not disposed to correct false impressions.

During the past 6 years I often have called the attention of my neighbors to this idea, that bees go only  $1\frac{1}{2}$  miles, when the merest novice could see my bees 3, 4, and even 5 miles from home, and literally by the thousands, too. This was easily evident from the fact that in all the surrounding country there is not another large apiary, and neither are there any Carniolan bees except mine. Aside from this, I have been peculiarly well situated to make accurate observations during the past several seasons.

My home apiary is located on land covered sparsely with oak timber. To the east just one mile the sumac growth, large and small, sets in; the ground is hilly, sloping gently to the westward; ranging far eastward the country is one dense sumac thicket. But to the southwest the ground is open  $2\frac{1}{2}$  miles. At that distance there rises a high hill, and beyond this hill there is a very thrifty growth

of sumacs. During the period of sumac bloom I have observed the bees going to those sumacs, the line of flight passing about 50 feet to the west of my door, and I have often watched the streaming lines of bees moving swiftly toward this hill, gradually rising in order to surmount its eminence. At the foot of this hill the roar of the bees high in the air can be heard fully a half mile to either side, and beyond the thousands of great creamy blooms are covered with the busy little workers, the silver-gray bands of the Carniolans showing up very distinctly against the creamy white of the flowers.

I have often watched the bees as they rose from the flowers with their loads, and whirled upward in a slow semi-circle, then swiftly darting downward on their homeward flight, nearly 3 miles away.

During all these years the closest watch has failed to show any great flight of bees toward the sumacs on the east only a mile and over. Why this is I am not able to tell, but, nevertheless, it is a fact; at any rate, I know that they go this greater distance from pure choice, as it would be the height of absurdity to imagine that the sumacs of the same kind growing on the same kind of soil did not yield honey in exactly the same locality. However, I think the location of the apiary with regard to the surrounding country has something to do with it.

Another thing I have noticed, which is, I believe, contrary to the generally accepted belief. The bees in my home yard give yields as great as the best in my out-yards, that, in many cases, are entirely surrounded by sumacs; and this honey is mostly brought from a distance of 3 miles and more. In short, my observations have satisfied me that those who claim that bees go only  $1\frac{1}{2}$  miles don't know, have a poor strain or race of bees, or else there are many conditions governing these things about which we know but little. At any rate, I have learned to despise a race of bees that are not good for a crop of honey if it is to be had only 3 miles of them. Choice colonies of Carniolans gathered 210 pounds of honey in 14 days, bringing it from a distance of 3 miles. How is that by the side of your  $1\frac{1}{2}$ -mile stock?

Never in a single instance have I known my home bees to get less than the bees in my out-yards; but if there were as much as some think in the  $1\frac{1}{2}$ -mile claims, they could be expected during the time of sumac bloom to get almost none, as there are but few sumacs within less than a mile, and not a very great many within less than the limit; but within 2 miles there is a great abundance. Concho Co., Tex.

## Beginners—A Queen-Introduction Method

BY WM. M. WHITNEY

The complaints of a beginner, referred to on page 25, and comments thereon can not fail to attract the attention of experienced bee-keepers—especially those who occasionally give their views on subjects pertaining to bee-keeping in some of the papers. It may be, and doubtless is, true that many subjects that are discussed by writers appear of little or no value to the beginner; but after having had pre-experience—if he remembers what he reads—he may make a practical application of what at first seemed unintelligible. What we read is often scarcely less valuable, though we may not be able to put it into immediate use. Even mere theory sets one to thinking, and often is of much value. It is true, doubtless, that the more advanced apiarists often forget their kindergarten days, and write for the benefit of the more advanced pupils; yet there is something always that may be appropriated by the novice; at least, I have found it so.

Lest I may be liable to the charge of having talked a great deal and said nothing, I will stop theorizing and conclude by attempting to give the best method I know of for introducing a queen. It is a modification of the instructions that go with every queen-cage, and, to me, is of sufficient importance to be worthy of emphasis. It may be of use to some beginner during the season near at hand. I have never observed it in any work on bee-keeping, nor in any paper, if I'm not mistaken. I think that Emerson T. Abbott is entitled to the credit for originating the idea. At any rate, the first I ever heard of it was when he gave it to the members of the Chicago-Northwestern Bee-Keepers' Association in convention in Chicago something over a year ago, substantially as follows:

When the queen arrives (without removing the protection to the candy) place the cage over the center of the brood-frames of the colony whose queen you desire to supersede; allow it to remain long enough for the bees to become acquainted with the caged queen, and for her to acquire the scent of the hive—say 24 to 48 hours; then remove the old queen, also the protection to the candy, and with a pencil, or anything handy, carefully puncture the candy and place the cage over the frames again, covering it up, and in the course of 2 to 4 hours the queen will be in quiet possession of the brood-chamber.

But queries the beginner, "What's the advantage of introducing the cage before removing the old queen?" There is this advantage (and in the season of greatest brood-rearing it is very important)—it gives the colony the benefit of her egg-laying during the time the caged queen is becoming acquainted, so that there is no slacking of brood-rearing at a time when a large force of workers may be very much needed.

Again, should a number of queens be received at a time when not conven-

ient to attend to the work of requeening, or the weather should be unpropitious, the cages may be placed over the frames of the respective colonies till a convenient time to do the work, which may then be done as above directed, remembering all the time to examine carefully for the formation of queen-cells, which, of course, should be removed to insure success.

Evanston, Ill.

## Bee-Keeping in California

BY PROF. A. J. COOK

Dr. Wilson and son have come here from Chicago for the sake of health, and ask some pertinent questions regarding bee-keeping in this section. They desire to be much out-of-doors, and wish to find some pleasant employment that may occupy their hands, and at the same time receive some financial returns for their labor. Our friends have done well to come to this region, especially if they have lung trouble. Here we can live out-of-doors, virtually, winter and summer, and diseased lungs must be pretty bad that can still cling to disease in the face of such out-of-door life. I know of many who have come here with serious lung ailments who are now well and vigorous. Outdoor air is the great panacea for incipient tuberculosis and asthma, and those who are suffering from either of these diseases find the dry, pure air of Southern California a very great, and oftentimes absolute relief. In case of tuberculosis, people from the East who come here in time, and exercise reasonable care after they get here, are almost sure to make good and speedy recovery.

The first question that Dr. Wilson asks is: What can one hope to gain net per colony, in case of intelligent management? I am glad that he added the last, as very much depends here, as elsewhere, upon the energy and skill that one gives to the business. I know of an able bee-keeper who has kept bees here many years and his record is about 75 pounds of honey per colony per year. As he has averaged about 6 cents per pound for his honey, it is easy to compute what he has secured. Some years the profits are very great—greater than anywhere else I know of in the world. But over against this we must remember that not infrequently, because of slight rainfall, there are no profits at all; and sometimes such seasons are not single, though I have never known but two failures to come in succession, and one of those was not absolute. The worst is not yet though, for in these seasons of greatest honey dearth, the bees must be fed, and so there is not only no gain, but absolute loss.

Dr. Wilson's second question had to do with method. He asked if it would be better to engage with some bee-keeper for a year and take what he might be able to get for his service, or buy a few colonies and commence at once "on his own hook." Without doubt he would learn faster by the first method, and perhaps would be as rich at the end of the year, but there is a pleasure in working the thing out for one's self, and by thoroughly reading

the best bee-books and taking one or two good bee-papers he might hope—certainly after visiting one or two good apiaries, and observing carefully the work with the bees—to get on without making any very serious blunder, especially if he had some bee-keeper near by with whom to counsel if the case required.

These friends wished also to know how many colonies I should advise them to purchase in case they concluded to go ahead at once. I answered 10, and certainly not more than 20. The coming season, because of our generous rains, promises to be admirable, and if one started with 20 colonies and cared not to secure much honey the first year, it would not be difficult to increase these to 60 colonies or more the first year; and thus, another season, he would be able to have a fairly good-sized apiary, when he could again work for honey or increase, as would most suit his pleasure.

I was also asked to give the probable expense, kind of hive, and location that I would advise. I replied that I had known good colonies in desirable hives to be purchased at \$5 each, and that I did not think that he ought to be obliged to pay much more than that for good, strong colonies. I urged that he take special pains to see that there was no foul brood in the colonies purchased.

In case one works only for increase the other expenses need not be great for the first year. A good smoker, beehat, and other necessary implements are not expensive, and, besides these, there would be little else than the hives.

I also strongly recommended that he adopt the Langstroth hive, with the Langstroth frame; not that these were necessarily any better than some of the other hives, but they are doubtless as good, and, being most used, have more to recommend them than any other hive that I know of.

As to location, I made only two points: One is, care to be in the midst of good forage, preferably near the mountains; and, second, to be as far from other bee-keepers as possible, though this last is not so important in California as in other sections. When we have good honey seasons there is so much nectar that we find bees do well even though somewhat crowded. I should wish to have an abundance of sage (both black and white), and should like to have these not only on the plains and mesas, but should like to have them extend well up into the canyons, that the honey season, always long here, might be further extended. It is also very desirable to be in the region of large orchards, for the nectar from such source is always valuable for stimulation if not for market.

### VALUE OF HONEY AND BEES.

I have often remarked that honey is very valuable food, that we must have some form of sugar and starch in our nutrition. No carbohydrate ranks above honey in its food-value, therefore bees, in giving us one of the very best articles of food, are always to be recommended, and I am always glad to recommend bee-keeping where there is

# American Bee Journal

reasonable expectation of success. Bees are much more valuable in pollinating plants, without which work agriculture would be a sad failure.

There is a third point worthy of mention: It takes people out-of-doors, and

so is health-giving. This is specially to be desired by ladies who, in this, find work that is not too taxing to their strength, and yet gives the needed fresh air and out-door exercise.

Claremont, Calif.

losses, in cold weather. Keeping warm pre-eminently a matter of economy with bees. And a colony of bees doesn't compare well with a fire, or even with a lamp, as a commercial source of heat. Page 136.

## PURE BLOOD AND DRONE PROGENY.

And now a writer on page 138 says we must trace pure blood by the drone progeny. It's not for me to scoff; but I should say that was pretty high doctrine. Perhaps common folks might be pardoned for holding off until a considerable body of experts agree to that. Get some "brethren" in your empty church before you ask us to "jine."

## HONEY-BUTTER AND PURE-FOOD LAW.

It may be the rendering now given to the pure-food law does here and there go a little "into the pictures" in forbidding certain words to be used at all concerning compounds whether they describe correctly or not. The butter crowd are powerful, and possibly a little ugly—and possibly our officials are a trifle too much "afear'd" of them. Not sure things are getting to that pass, but have kind o' smelt it, that the word "butter" was to be held too sacred to be used at all except the article were pure—and also unmingled, and untreated. But even if the charges are partly true a little annoyance for a while may well be borne. Considering how long we have been waiting for the chance, we should be glad to bear something. Things will come right eventually to every honest maker. If apple-butter and peach-butter have to give up their "butter," honey-butter need not waste many tears. If honey mixed with butter can not be called "honey-butter," call it "Honey—and," with not a letter more—and a shrewd pusher of products wouldn't ask for any more captivating label. Page 146.

**Honey as a Health-Food.**—This is a 16-page honey-pamphlet intended to help increase the demand for honey. The first part of it contains a short article on "Honey as Food," written by Dr. C. C. Miller. It tells where to keep honey, how to liquefy it, etc. The last part is devoted to "Honey-Cooking Recipes" and "Remedies Using Honey." It should be widely circulated by those selling honey. The more the people are educated on the value and uses of honey, the more honey they will buy.

Prices, prepaid—Sample copy for a 2-cent stamp; 50 copies for 70 cents; 100 for \$1.25; 250 for \$2.25; 500 for \$4.00; or 1000 for \$7.50. Your business card prints free at the bottom of front page on all orders for 100 or more copies. Send all orders to the office of the American Bee Journal.

**Why Not Advertise?**—There are many dealers in bee-supplies, and those who have bees and queens for sale, who are not now advertising, that might increase their business by advertising in the American Bee Journal. The rates charged are very low, as will be seen by referring to the second page of this number. During the next 6 months will be done the bulk of the season's business among bee-keepers. Why not begin at once to let the readers of the American Bee Journal know that you have something to sell? Our advertising columns are open only to those who will give their patrons "a square deal." If you are in that class we will be pleased to have your advertisement in our columns.

The "Old Reliable" as seen through New and Unreliable Glasses, By E. E. HASTY, Sta. B. Rural, Toledo, Ohio.

## BEES WITH POLLEN LYING DEAD.

A pretty humble apology I owe to that poet, if bee-keepers—lots of them—have seen bees with pollen lying dead near the hives on chill days. The fact that I had not seen it (or thought I had not) doesn't let me out any. Poet had a perfect right to say so, if it is a thing to be seen to any extent. Nevertheless, I thank the Boss for suggesting mercy (instead of immediate execution) on account of my locality. The pollen season is right at hand, and I must watch out to see if I can not notice the same—and settle it whether it is locality or obliviousness that led me astray. Page 205.

## DON'T EXTRACT FROM FOUL-BROODY COMBS.

I gladly second Mr. Byer's protest against using foul-broody combs to extract from. The people are half awake on such subjects now, and looking around for impurities and uncleanness. Let's clean our own Chicago stock-yards out, before they turn the lime-light and the laws loose on us. Page 133.

## LOCATION FOR AN OUT-APIARY.

E. D. Townsend, in a splendid paper, thinks that to get a tip-top location for the out-apiary, it may pay to put it off as far as a day's ride by railroad. For another thing, he seems to think clay soil the best for us—providing southern Michigan be the location and clovers the crop. I think so, too. Alas, I'm on sand! I'm not exactly in Michigan, but my bees sometimes are, I reckon. If the raspberry honey of northern Michigan is white, and that of southern Michigan a good way off from being white, that is a little curious—although not at all incredible.

Going inside thick woods and clearing just space enough for the apiary is a taking scheme—paying scheme, if in one season it put 50 colonies ahead to the amount of \$160. Bees will undoubtedly winter and spring much better in such a spot. But my glasses have the word "swarms" scratched on them. Wouldn't prefer 100 swarms shut down to the choice of forest tree-tops or no place at all. This, by the way, is a personal point with me. My

own apiary is by the old apple-trees and old ornamental trees of an old homestead, and I do not own the ground there. Brother inherited that. Not far away are nice thick woods which I do own. Great gain in one respect should I move. But whatever would I do with my ocean of swarms there? With better wintering I'm convinced there wouldn't be quite so many. Page 131.

## SKUNKS AND BEES.

The puzzle alluded to on page 134, ought not to be a hard one—why the skunk confines his attentions to the colonies he has been to before. I often feed bees at the entrance after night-fall, and thump them out, lest they fail to find the feed. Often it is a long, hard job to get them out the first time. After a few such experiences they come promptly and with a rush. Well, now, Peter! it will have to be confessed that coming out to eat and coming out to be eaten are not the same identical thing. But the general effect is the same. Bees often disturbed at night (as long as they have half a force left) are prompt to come out. And Sir Strong Essences, having a lazy streak about him, is disinclined to the delay and extra scratching it takes to get the others out.

## SOME SWARMING.

We read on page 137, that Mr. Aspinwall had last year 10 swarms from 40 colonies. That stumps me again. Somehow I got it in my mind that he didn't have any. No "great shakes," if the above report is right! *Some years* if you tried your best to make colonies in common hives swarm, you wouldn't get so many as 10 from 40.

## HEAT FROM COLONY BELOW A SUPER.

It is true, as D. J. Pawletta found, that a strong colony below does not do nearly as much as we would expect to keep honey in a super above from getting cold. I have often noticed it—and sort o' kicked at nothing on the subject. I guess the explanation is that we figure much too largely on the total amount of heat which a colony has in store for any possible uses, or

Conducted by EMMA M. WILSON, Marengo, Ill.

### Bees in a Dining-Room Decoration

Mrs. C.G. Chevalier sends the following item:

Mrs. Spender Clay is very busy just now with the decorating of her house on Berkeley Square, London. She has secured a mantel-piece for the dining-room which is quaint, if not beautiful. It represents a bear being chased by a swarm of bees, and the carving is down to details. Each particular bee represents much labor and skill.

If the artist had been at all faithful in his representation, what an interesting study this would be. Good thing that Mrs. Clay's artistic tastes run bee-ward instead of in some other directions; but how much more interesting she would find the real little creatures in full life.

### Honey-Sandwiches

Chop together English walnuts and raisins in equal proportions. To each cup of this mixture add 2 tablespoons of honey and 1 of orange juice. Spread between lightly buttered slices of cream bread and cut into dainty shapes.—Good House-Keeping.

### A Sister's Success With Poultry

It is undoubtedly a breach of trust to put in print, without permission, part of a private letter; but the temptation is too strong to be resisted to give as a text the following extract from a late letter of Miss Frances E. Wheeler, of New York State, under date of Jan. 28:

DEAR MISS WILSON:—We have had a very uncommonly cold winter; but bees and birds are fine. Our 27 White Holland turkeys are sleeping in a woodshed and thriving with the mercury below zero for days, and at one time 40 below. Not a toe is even frosted! We are running 200-odd ducks, and in 2 of our houses have not lost a bird; in the other, just 3 young ones. That is a remarkable record; but I don't expect you to appreciate it as much as if I'd got off a big thing on bees.

FRANCES E. WHEELER.

That's the text: now the sermon—at least the application:

Since a sister who shows herself so successful and capable in the poultry business has told us on page 50 that in the struggle for continued existence between the bees and one branch of the chicken business, the bees won, it seems very evident that there must be something either quite profitable or quite fascinating, or both, in the business of bee-keeping for women.

### Bee-Keeping Woman's Work

The new book, "The Bee-Master of Warrilow," has a chapter entitled, "Chloe Among the Bees." A woman of philanthropic turn has established a bee-farm which seems to furnish occupation for quite a number of the gentler sex, and she thus explains the object of her enterprise:

"This is an attempt, and, we believe, a real solution to a very real difficulty. There are thousands of educated women in the towns who have to earn their own bread; and they do it usually by trying to compete with men in walks of life for which they are wholly unsuited. Now, why do they not come out into the pure air and quiet of the countryside, and take up any one of several pursuits open there to a refined, well-bred woman? Everywhere the laborers are forsaking the land and crowding into the cities. This is a farmers' problem with which, of course, women have nothing to do. The rough, heavy work in the cornfields must always be done either by men or machinery. But there are certain employments, even in the country, that women can invariably undertake better than men, and bee-keeping is one of them. The work is light. It needs just that delicacy and deftness of touch that only a woman can

bring to it. It is profitable. Above all, there is nothing about it, from first to last, of an objectionable character, demanding masculine interference. In poultry-farming, good as it is for women, there must always be a stony-hearted man about the place to do unnamable necessary things in a fluffy backshed. But bee-keeping is clean, clever, humanizing, open-air work—essentially woman's work all through."

Speaking of one girl who seemed to awaken especial admiration in the mind of the visitors, the bee-mistress said:

"That girl came to me out of a London office a year ago, anemic, pale as the paper she typed on all day for a living. Now she is well and strong, and almost as brown as the bees she works among so willingly. All my girls here have come to me from time to time in the same way out of the towns, forsaking indoor employment that was surely stunting all growth of mind and body. And there are thousands who would do the same to-morrow, if only the chance could be given them."

Here is a picture of what was seen in the apiary:

"Here and there in the shade-dappled pleasance figures were moving about, busily at work among the hives, figures of women clad in trim Holland blouses, and wearing bee-veils, through which only a dim guess at the face beneath could be hazarded. Laughter and talk went to and fro in the sun-stepped quiet of the place; and one of the fair bee-gardeners near at hand—young and pretty, I could have sworn, although her blue-gauze veil disclosed provokingly little—was singing to herself, as she stooped over an open hive, and lifted the crowded brood-frames one by one up into the light of day."

I wonder how many of the sisters sing while working over an open hive. But isn't it a pretty picture? The whole chapter, as well as the rest of the book, is beautifully written, and although it would hardly do for a textbook, it is very pleasant reading.

By W. A. PRYAL, Alden Station, Oakland, Calif.

### Honey and the "Yellow" Press

An editorial in Gleanings states that "the honey-business is not the only one which suffers from the yellow press." As the Ladies' Home Journal, and several others of that ilk have been called to account at divers times by the aforesaid editor for publishing untruths about the honey-business, I suppose Editor Bok, of the aforementioned ladies' publication, is a yellow journalist, and his paper a deep-dyed saffron sheet, too. Let's take up a subscription and buy a load of chemicals and present the purchase to the Ladies' Home Journal, that the Curtis Publishing Co. may remove the offensive color from their paper. And while we are about it, we may help the other

papers to get rid of the nasty color, also.

From a long, practical experience with daily newspaper work, I can say that no paper, daily or otherwise, reviles an industry for the very lust of lying. No reputable publisher wishes to tell an untruth about an industry, for it is not good policy in the first place. Some managers, however, make it a rule of their office to let a misstatement of fact go uncorrected rather than let the readers know that it was in error. This may be good policy for the paper; morally, it is not.

I am not an apologist for sensational journalism, but we must give some of these publications the credit of leading the strongest fight ever made by the daily press of the country against the

evil of drunkness. And it has been done by the page—a whole page in bold type at a time. And there are other evils it has fearlessly attacked, too, one of the greatest being the trusts. Let the good work progress.

## Hives in California

How the hive question crops up ever and anon. And well it may. We have what we call a "Standard" frame in

frame thrust upon us. But we must grin and bear it until the factories come together and give us something better.

This calls up the factory versus the home-made hive. I've tried both. 'Tis an interesting occupation to make one's own hives, and I've done it; and, unfortunately perhaps, I did not let my hand and fingers come in contact with a buzz-saw. Maybe that's one reason why I never got over the bee-fever during these 40 years and more. If I were asked what I would rather have, a factory hive or one made by myself, I would answer: If you could give me a factory hive without so many parts to it, I would rather have the factory hive. For simplicity, I would rather have a hive made after my own idea—and it would be perfect.

Perhaps if I were running a planing mill in the East, where wide boards are not so common as they are here, I would be compelled, for economy's sake, to work up a lot of odds and ends, and thereby turn out a hive with as many pieces to it as had Joseph's coat. I like the old-fashioned hive with a single-piece bottom-board; ditto for a cover. The latter could be enhanced by having a piece of prepared roofing tacked upon it. Leaky roofs are an abomination. I've had to contend with them, and although they are not so bad

on the bees here as they are in worse climates, still it is far better to have tight covers.

Any old box with good rabbets for the frames to rest upon with tight cover, single-piece bottom-board, and uniform frames is all that is needed to build up a successful apiary. Of course, I should have every other "old box" like its brother. There's nothing like interchangeability in the bee-yard. That's one thing to the great credit of the factories—they make all parts alike.

I herewith furnish 2 photographs of home-made hives from 2 apiaries in California. In No. 1 we have a hive built pretty much upon lines laid down by Prof. Cook some years ago in his valuable work on bee-culture. It was somewhat modified, as the user had an extractor that used the size frame it was designed to take. The hive is plain as plain can be, and has given satisfaction for a score of years. The colonies in these hives are run for extracted honey.

In No. 2 is shown a solidly built Langstroth hive, and like the usual California "home of the honey-bee," it is not built for its good looks. The bees seem to appreciate them just the same, for they load them up to the gun-wales when run for either comb or extracted honey.

HIVE NO. 1.

America, but, to my mind, it was a badly chosen one—one that will have to give way to a more common-sense one in years perhaps not so far distant. I believe if it were not for the hive-

HIVE NO. 2.

factories, which, for the most part, are not run by practical apiarists, we would not have such an ill-shaped

### Report of the 37th Annual Convention of the National Bee-Keepers' Association, held in San Antonio, Tex., Nov. 8-10, '06

The opening session was held Thursday, November 8, 1906, at 8 o'clock, p. m., President C. P. Dadant, of Illinois, occupying the chair. Mr. W. Z. Hutchinson, the Secretary, being unable to attend the convention, Mr. George W. York of Illinois, was elected Acting Secretary of the Association.

Pres. Dadant called the meeting to order, then the following address of welcome was made by Pres. W. O. Victor, of the Texas Bee-Keepers' Association:

#### PRES. VICTOR'S ADDRESS

"Texas is the greatest bee-keepers' State in the Union. It is the greatest in a great many other things. Texas raises more cotton, more rice, more cattle, than any other State; has a fine flow of oil, and is rich in mineral deposits. It has as much to make the people prosperous as any State in the Union. San Antonio is known all over the State as the best residence city in the State. The banks of the City have more money in their vaults than any

other Texas city. It is of great historical interest, and we will have more of it to show you before you leave. We welcome you to the best city in the best State in the United States, and invite you to become citizens of it."

A response was made by Pres. Dadant, saying the bee-keepers outside of the State of Texas were glad to meet in the South, as but once before in the 35 years' history of the Association had it met so far South, and that meeting was held in New Orleans, La., in 1885.

As there was very little business to discuss the first night, the question-box was opened, but before that was done, at the request of N. E. France, Dr. Bohrer, of Kansas, one of the two charter members of the Association present, was called upon to deliver a short address, which was as follows:

#### DR. BOHRER'S ADDRESS

I am a good deal like a gentleman was, that one time went into church, and was somewhat intoxicated. He sat down and went to sleep. At the close of the services the minister desired all to stand up that wanted to go to Heaven. All stood up except this man. He woke up about this time and

# American Bee Journal

the minister asked all those that did not want to go to Heaven to stand up. The man didn't know exactly what the question was, but said, "Parson you and I are fearfully in the minority;" so I am fairly in the minority, and I do not know what was talked about.

I was a bee-keeper in the State of Indiana, and moved from there in 1873 to Kansas, which was not adapted at that time to bee-keeping. Many of the flowers were non-honey-producing plants. Now we have thousands of acres of alfalfa in Kansas. The weeds grow and the bees take possession of it, and gather a good deal of honey from it. Like Texas, Kansas is getting to be one of the best honey-producing States.

I am certainly glad to visit the State of Texas. It has been more than 40 years since I was here, and it is not so warm as it was then. I have had a warm reception, but not so warm as I had then. I happened to be a soldier, and was probably in the last engagement of the war, at Brownsville, Texas. There was one man killed. I was in the medical department of my regiment. Another soldier, a Texan, was dangerously wounded. Both were splendid men, and each had a wife and six children at home, and I never will forget the conversation I had with the wounded man. I went into the hospital and he said, "I suppose you are one of the doctors." Then he said, "Will I be neglected because I am a Confederate soldier?" I said, "Not a particle, you and I are not responsible," and that I was but one of those who had to settle the great question, and that we did not hold a personal grudge. Since then the North and the South have united. I never think of Texas but what I think of that unfortunate occurrence. There was a gulf between the two sections of the country at that time that seemed to be impossible to fill up and bridge over. Now, tonight I don't think there is a man here or elsewhere but what would be willing to concede that it is not only bridged over, but almost entirely obliterated.

The daughter of the Confederate soldier falls in love with the son of the Federal soldier, and they are mixing up and making the grandest people the world ever knew. No other country has ever reached that high degree of civilization that has built it up, but the end has not come yet; everything, like bee-keeping, is in its infancy. When bee-keeping was introduced in this country, it was my lot to buy the first queen that was ever purchased in the State of Indiana. The people did not know what that meant,—the idea of sending off and getting a select queen and introducing it to a black colony of bees; that it would change that colony to a colony of Italian bees! Why, the man that considered this idea was not considered of sound mind, and they laughed at me. I was a physician, and several families refused to employ me. But after I had succeeded they would come 15 and 20 miles to see my bees, and one man said, "the blinded fool has actually done it!" I paid \$10.00 for that queen, and I paid \$20.00 for the second one. We have advanced in the

matter of queen breeding so the finest queens can be bred for \$5.00.

I want to say to you that I am not engaged in the business of bee-keeping with the hopes of making a single dollar, but I do hope and expect to benefit somebody, and engaged in that pursuit for pastime. I have only about 30 colonies but they keep me busy.

I want to say that a great many Italian bees in this country are not so good as the bees from Mr. Langstroth. We are too careless as to how we handle them. We take great pride in advising with a man who wants to do the best he can. If you can breed two superior and distinct breeds, don't breed them less than 20 miles apart. There is something in the Carniolan blood that makes them a little crosser than I want bees to be. I have gotten from one of the best queen-breeders in the United States, and from a gentleman of the South, too, a Carniolan queen. I went on for some length of time, thinking it was due to some imperfection of the queen; the brood would begin to die, and keep on from the time they began to hatch; many of the queens did not fly. I simply pounded the life out of that queen and gave them brood from another queen that I got from a Tennessee queen breeder. I say to you, gentlemen, that there is great danger of this thing happening in this country, and in my opinion this has gone on long enough. If the queens are worthy of being introduced, let them be tested, and don't you breed them less than 12 to 15 miles apart.

## QUESTION-BOX.

"Will a list of bee-keepers' names be printed for distribution, as at Chicago?"

Pres. Dadant—I make this explanation, that it costs us a little each year to make this distribution; our daily papers are only too glad to report who were at this convention.

Mr. France—Last year there was a motion that but two answer a question briefly and decidedly. I don't think that is the intent this year, but to make the question-box the most important of the whole meeting.

Mr. York—That was done near the close of the last session, and because our program was long. We lacked time.

## 1906 HONEY CROP IN TEXAS.

"How many carloads of honey did Texas produce this season?"

Pres. Dadant—That is a question for our Texas bee-keepers to answer. I would like to hear from them.

Mr. Victor—Texas did not have a heavy crop this year. I think it was all shipped locally, and it would be hard to say exactly. Some seasons we ship a good many carloads, but I did not try to make an estimate this year. Possibly Mr. Toepperwein could give us the information.

Mr. Toepperwein—Mr. Atwater is up on this. He can tell us.

Mr. Atwater—I can hardly answer the question, because the season is not quite over yet. I think at the close of the season we will make a very good report.

## FEEDING QUEEN-LARVAE.

"How long do bees feed the larva before the queen-cell is sealed? Does the age of the larva have anything to do with it?"

H. Piper—I would like to say that in Texas it takes only 4 days. Then again, the age of the larva has something to do with it. If I use a larva over 4 days, it does not take so long.

Mr. Dadant—Mr. Root, let us hear from you on this subject.

H. H. Root—These queen-breeders can answer this question better than I.

Mr. Victor—I don't like to talk on every subject. I think, though, in a matter of this kind, it would be as the first gentleman said. It is from the time the larva hatches, or until it is sealed as a queen. I would say from the time it hatches from the egg into the larva would be between 5½ and 6 days, and usually about 4½ days after it is transferred from the queen-cell before it is sealed over.

J. E. Chambers—I wish to say that my experience is limited. I find that a larva is used from 12 to 14 hours.

## PROGRESS IN GETTING BETTER-NATURED BEES.

"Has there been any real progress in getting better-natured bees within the last ten years?"

Mr. France—I think there has been progress in the bee-keeper being better-natured in handling the bee.

Mr. Hilton—There is no question in my mind but there has been progress. The bee-keepers do not retrograde, and they either advance or else they do retrograde as do all institutions, and from that standpoint I say there has been progress. I know that I got good results by introducing new blood into the apiary annually. It is one of the best investments a man can make, consequently I answer in the affirmative, that there has been progress made in the bettering of the nature of our queens and bees in the last ten years, in accordance with the question asked.

Mr. Aten—I do not believe they have. I believe the gentleman was just talking about the people, that some people get better blood amongst their black bees, but I cannot see that the new blood they are introducing is as good as the bees we had ten years ago.

Mr. Hilton—I certainly take exceptions to the gentleman's stand, and I say that we do get more gentle bees by introducing new strains of gentle blood, and I am sure I can bring to bear the experience of other men that have introduced a more gentle strain. I am glad the gentleman called me out, I like discussions, and it is good for us; it is good for us to dwell together in harmony while there is harmony in good, honest discussion, and there is information, and there are those of us who have come 2,000 miles that don't care to go home with empty minds, but we may go home with empty pockets. I want to say that I have been taught something while here.

Mr. Adkins—I believe that the introduction of new blood has made our bees better-natured. I was not a bee-keeper 20 years ago, but I heard my neighbors

talk about bees, and they said my bees were gentle compared to those that they had then.

Mr. Aten—I differ from those gentlemen in this way: I say that I had just as gentle bees ten years ago as I have today; I say there were just as gentle bees in the United States as I have today, and I will stick to that.

Mr. Coggshall—Mr. President, my experience has been that my bees have been crosser by every blood that I have introduced. I have had bees from different queen-breeders, and I take it no better blood.

Mr. Parsons—I can see, as I understand, applying to the last ten years, that there has been an improvement in the bee's gentleness. My experience is that it is an unknown quantity when you introduce a new race, or a new blood, as to whether that will be an improvement in the crossing of blood; but there has doubtless been great improvement, and there are constant improvements in the rearing of queens and cutting out of ill bees. And there is where the great improvement is made, cutting out the ill bees instead of trying to get a new cross by introducing new blood; and where I find a queen on a colony of bees that is ill I do away with that queen; and a cross of one race with another, so far as I have observed, almost invariably makes an ill-natured bee, and is hard to handle.

Dr. Bohrer—I will say that 42 years ago, in 1864, I got my first Italian queens, and I used to handle those bees without any protection whatever on my face and hands; but in 1901, when I again fell into line with the bee-keepers, I did not find it that way. The bees were cross, and stung me on every side if possible, but not always. Those bees that I speak of 42 years ago, once in awhile they would sting me, but on other days they would not; but I never undertake such a thing now as to handle them without my face and hands well protected, and sometimes they do not sting me at all while other times may be too will sting me, but whether it is due to the climatic influence or the nature of the bee I am unable to say. These good bees were rare in Indiana, but I do know that they are crosser as a rule. I have got rid of some of those cross bees by introducing a new strain, but taking it all in all I doubt whether I have succeeded. I say, push it to its fullest extent, so that nobody will be deceived, and if they prove as good as I think they will, as good honey-producers and not so good-natured, it would be wise to adopt them, but it would be premature to conclude that they were an improvement upon another bee in disposition; they may be, but will they prove to be a profit? I don't think we are prepared to answer this question.

Mr. Kemper—I think I made an advancement so far as gentleness is understood. Is it to introduce a bee that will not sting, or one better-natured? I don't believe that I have made an advancement as to introducing a gentle strain of bees.

Mr. Smith—Now the question is, Has any progress been made in improving

the gentleness of the bees by breeding for that result? I want to ask the queen-rearers, How many of you have bred queens for that single purpose? I, as a rule, have found that most queen-rearers have been breeding queens for color, and long tongue and honey-gathering. Now, conditions depend a great deal upon the gentleness of the bees. Take a year like this, in Illinois you never saw bees crosser than they are this year. I visited probably 1,000 apiaries over the State and I want to say there were very few places I was not secure as to hands and face and sometimes it was almost impossible to control them with dense smoke. I think it depends a good deal upon conditions. That has been my experience.

Mr. Reed—So far as the queen-breeders of Texas are concerned, I am bound to take the negative side of this question, so far as those I have patronized. I don't believe that the breeders of Texas are breeding as gentle a race as they did a few years ago. I attribute it to the Cyprian blood they are introducing.

E. J. Atchley—I think that question can be answered in one word. There has been progress made, and it seems to me that queen-breeders ought to answer this. If they think it is the part of the honey-producers to answer this, from my own part I think there have been improvements within the last ten years in the rearing of queen-bees.

Mr. Jouno—I think it is due to having better facilities for handling bees, and a better understanding of them. As to ten years ago, it seems to me they are more gentle.

Mr. Chambers—I wish to say that for my own work within the past 6 years I have used improved Carniolan queens, and they produce strong honey-gatherers. There has not been a year that I have not introduced new stock, and I find them to be more gentle than when I allow them to run on for several years.

O. P. Hyde—I have had some experience in the queen-breeding business for several years, and I have had several races. I had a yard with 5-banded and 3-banded, the Carniolan, Italian and Holyland, and my experience has been that where I stuck to the Italian bees I have improved the gentleness considerably over the black bees; but where I find a breeder that recommends the Cyprian and gets them mixed up with other bees, they are a very cross bee. I know this by experience. I went to a Cyprian colony and I know by experience they will sting. If we will stick to the Italian bees, I claim that the gentleness is considerably better than it was ten years ago.

Mr. Victor—In answer to Mr. J. Q. Smith, as queen-breeder, I would like to say that the first thing I consider is selecting a queen-mother with the honey-gathering qualities first; looks next, and gentleness for the third place; and I will say that I used to breed three different strains of Italians, that I called improved Italians; then home bred Italians, and then the goldens. I decided the goldens had nothing but looks, and I quit them, and since then I have bred the 3-banded Italians, and I think I have better results in queens and honey-gatherers also.

(Continued next week.)

Send Questions either to the office of the American Bee Journal, or to  
Dr. C. C. MILLER, Marengo, Ill.  
Dr. Miller does not answer Questions by mail.

### Prevention of Swarming—Getting Most Surplus Honey

1. How would you prevent swarming? I have 15 colonies and they do nothing but swarm. I give them supers with starters, and they will go up and fill 2 or 3 sections and then swarm. One of my colonies swarmed 4 times in a week and a half. What would you do to stop them from swarming?
2. And what kind of hive would you advise me to use?
3. How can I get the most surplus honey?  
MINNESOTA.

ANSWERS.—1. It is not an easy thing to prevent a first or prime swarm. Perhaps what will suit you as well as any way is to allow the first swarm to issue, and then prevent afterswarms in the following way: Set the swarm on the stand of the mother colony, putting the old hive close up beside it, both hives facing in the same direction. A week

later move the old hive to some new place 6 feet or more away. That's all; the bees will do the rest, and you are not likely to have any further swarming from a colony thus treated.

2. The best thing is a hive with movable frames, and it matters little how simple. For success does not so much depend upon the hive as it does upon the man and the pasturage. Perhaps as good as any for you is the plain 10-frame hive that you will find listed in the catalogs under the name of "10-frame dovetailed hive."

3. That's a thing that can not be told in a few words. The main object of every number of this publication is to help toward getting more honey, and the bee-books are all for the same purpose. So you can hardly expect me to tell in a few lines what occupies hundreds of pages. It will do no harm, however, to say that the chief thing on your part is to do all you can to get all colonies strong enough for the harvest, and to keep them

strong. You will see that the answer I have given to your first question runs in this line. If your bees are all divided up by excessive swarming, you can not expect much surplus. But by proceeding according to the first answer you will keep nearly all the force with the first swarm, and that's the one that will give you the honey. A couple of days after giving the swarm, you will take the surplus arrangement from the old hive and put it over the hive containing the swarm.

### Dental Wax

What is the difference between dental wax and ordinary beeswax, if any? If so, how do you prepare the dental wax?

RHODE ISLAND.

ANSWER.—I don't know. I think the principal ingredient is beeswax, but I suspect other things are also in it. Perhaps some of our dentist friends will tell us.

### Protecting Bees With Tar-Paper

How can I protect my bees after putting them out of the cellar, with tar-paper? and when should it be put on, when taken off, and what is accomplished for the benefit of the bees?

IOWA.

ANSWER.—Whatever protection of the kind is given should be given just as soon as possible after the bees are taken out, as it is likely to be colder then than afterward. The time for taking off depends upon the weather; no harm to leave it on until fruit-bloom, or even till the first bloom is seen on clover. The advantage is that the bees are kept warmer, especially cold nights. Just how much that advantage is it would be hard to say, no reports being yet given as to comparative results with and without protection. While probably very few practise such protection, some think it wise to protect supers throughout the season.

### Probably Bee-Moth Larvae

What is the matter with my bees? They are golden Italians. I just ordered the queen from Florida. I see from 3 to a dozen young bees, which look as if they were just hatched, dragged out on the alighting-board every morning. Some of them are not yet quite dead. The ground in front is covered with dead bees. They are not starved for they have honey in the hive. What is a remedy?

ARKANSAS.

ANSWER.—If you will examine the frames you will likely find that the larvae of the bee-moth have built their galleries through the combs, not killing the young bees in the cells, but injuring them enough so the older bees throw them out. Probably they will come out all right if you will let them entirely alone, but if you like you can help the bees to clean out the unwelcome intruders. Take a pin or a sharp-pointed nail and prick a hole in one end of the silken gallery; then begin at the other end, tearing open the gallery as you go, and the worm will pretty soon crawl out, and then you have your choice as to what death you wish it to die. One way is to let it drop on a hive-cover and then mash it.

### Getting Straight Comb from Starters in Wired Frames

My boy and myself wired about 200 Hoffman frames with the intention of putting in full sheets of brood foundation. Suppose I put in only starters an inch or 2 in depth; will I get reasonably straight combs, or will the bees build on one side of the wires? In other words, having wired frames is it necessary to use full sheets in order to get straight combs?

NEW YORK.

ANSWER.—Some claim that when there is

only a starter in a wired frame, the bees will build down their comb so as to make the wire come in the septum of the comb. I would not like to be too positive about it, having had little direct experience in the matter, but I think that without foundation they steer the septum straight for the center of the earth, and if the wire happens to come in that line it will be in the septum, otherwise not. Whether your frames are wired or not, with an inch starter you may count on reasonably straight combs, except that they will be somewhat corrugated, provided hives are level from side to side. But are you willing to run the risk of having as much drone-comb as the bees are likely to build without foundation? In the long run, I suspect you will find it economy to fill the frames with foundation. At any rate, it may be well for you to fill most of your frames full, trying only a few with starters, and if you succeed well with the starters you can work on that plan afterward.

### Taylor Comb-Leveler

I send you herewith a picture of the Taylor Handy Comb Leveler. Is it necessary to use one on bait-sections? I see no mention of such a contrivance in any of the bee-books. What is your opinion of it? CALIFORNIA.

ANSWER.—I have made considerable use of the Taylor Handy Comb Leveler, and consider it a very fine thing. But the statement in the advertisement that you enclose, which

says concerning unfilled sections left over at the close of the season, that "without being leveled they would be practically worthless" is altogether too sweeping to be true. An unfinished section that is clean generally needs no leveling. But when the surface of a section is soiled or glued, then the leveler is a nice thing to melt away the objectionable part. It is also good where a section is too thick and would be built to the separator.

**Bee-Song Souvenir Postal Cards.**—We have issued in colors, 3 bee-song postal cards for bee-keepers, each card having one of the following songs, about  $2\frac{1}{4} \times 3\frac{3}{4}$  in size, also with illustrated heading on each card: "Buckwheat Cakes and Honey," "The Bee-Keeper's Lullaby," and the "The Humming of the Bees." The first two cards have small pictures of the authors of the words and music. This makes 4 souvenir postal cards we have now issued for the use of bee-keepers, the first being the "Honey-Bear" card. Prices, by mail, are as follows: Sample cards, 3 cents each; 7 for 20 cents, or 10 for 25 cents.

### Early Fruit-Bloom

The bees have come through the winter so far all right. They have been quite busy carrying in pollen from the elms and the maples. I don't know whether they get any honey. Plum, cherry, and peach trees are almost in bloom—just ready to burst out. If frost holds off we will have a fine lot of bloom. Some of the soft maples were in bloom a couple of weeks ago, but the frost killed all of it.

Pana, Ill., March 25.

D. C. McLEOD.

### Japan Clover Not Favored for Bees

On page 194, Dr. Miller asks who can and will tell "Pennsylvania" about Japan clover as a bee-plant. It is now about 23 years since Japan clover made its appearance here, and I have never seen a bee working on it. Being a bee-keeper I have observe closely what plants are honey-yielders, and I am sure that Japan clover is worthless as a honey-plant, at least in this locality. There may be places where it yields, as you know some plants are good honey-yielders in some localities and worthless in others. It is a low-growing annual, and is a splendid fall-grazing plant, always maturing an abundance of seed to reseed itself, no matter how closely grazed.

Tupelo, Miss., March 9.

J. D. ROWAN.

### Expects Early Swarming

I live in the northwest corner of Grayson Co., Tex., and I think this country is very good. But last year was hard on bees here. I got some surplus honey. I have Italian bees and like them very much. Fruit-blooming time is here, and the bees are singing their sweet songs and are storing some honey. They are rearing brood in great quantities, and if nothing happens they will be swarming by April 25, and that is pretty early for this country. I rear my own queens, and have had good luck with them. I have all my colonies with young, prolific queens for this season. Alfalfa and cotton are our main honey-plants. I am keeping bees on a small scale, as I think that no one should jump into the bee-business before he knows what he is doing. I think every farmer should have a few colonies of bees, as they are not in the way, and they will bring him some sweet returns.

C. E. ALEXANDER.

Gordonville, Tex., March 4.

### Keeping Moth-Worms Out of Brood-Combs

On page 215, "Michigan" asked how to keep moth-worms out of brood-combs. My way is to take out the combs, clean off the frames, then wrap them up in newspapers about 3-ply, and tie them up closely. I have kept them for 3 years and had no moth-worms.

W. H. HOBERT.

Fairport, Iowa, Feb. 16.

### Construction of Bee-Cellars

I will give a description of my bee-cellar that I am putting the finishing touches on, and ask a criticism of its construction, if you find anything that calls for it.

The basement is nearly 8 feet deep, with brick walls. The floor is concrete, 6 or 8 inches deep, and then finished with one inch of cement. The side-walls are cemented about 6 feet in height. The size is  $14\frac{1}{2} \times 22$  feet, north and south, with one window in each end. I have a board chimney 8x10 inches out of each window, and on the outside extend-

ing up 8 feet, and on the inside down to within 6 inches of the floor. There is no ventilation above 6 inches from the floor. By tiering them up I could put 250 colonies in it. I expect to put 100 colonies in. There is a space of 16 inches between all the hives and the floor.

In 1887 I put 65 colonies into a similar cellar, 12x14 feet, with a wooden chimney 8x12, which came down to within 3 inches of the floor. I did not lose one colony, and every one of the 65 was fit to divide when taken out in the spring.

The bee-industry of Milwaukee county was a total failure last year. We hope for a good season this year. W. F. KENNICOTT, Milwaukee, Wis.

[The first cellar mentioned ought to give good results, especially as a similar cellar did so well. As it is a matter of importance to provide as much as possible against changes from outside temperature, it might have been well to fur out and make a hollow wall, at least as far down as the wall is unprotected by the outside ground.—EDITOR.]

**Good Wintering Record**

I have just commenced taking my bees out of winter quarters. Last Saturday I took out 190 colonies, all alive. To-day I have taken out 140 colonies, 3 being dead. To-morrow I expect to put out another yard, and keep on until all are out. N. D. WEST, Middleburg, N. Y., March 26.

**Early Pollen-Gathering**

Four pretty days all right together, and the bees are bringing in pollen lively. They did it only once earlier than this in 20 years. That was on the 13th. S. A. MATSON, Barnard, Mo., March 17.

**CONVENTION NOTICES.**

**Michigan.**—The Northern Michigan Bee-Keepers' Association will hold its next annual convention at East Jordan, Mich., on April 10 and 11, 1907. Headquarters will be at the Russell House, where a \$1.00 per day rate has been secured. IRA D. BARTLETT, Sec. East Jordan, Mich.

**Connecticut.**—The 16th annual convention of the Connecticut Bee-Keepers' Association will be held in the State Capitol, Hartford, room 50, on Saturday, April 6, 1907. We believe that every wide-awake apiarist in the State knows that our Association is unselfishly seeking to assist and protect the bee-keepers in every way possible. During the past few months apiculture has probably been more generally discussed than at any other period in the history of the State, because of our attempt to secure proper bee-disease legislation. Bee-keeping now, as never before, is regarded as an important agricultural industry in Connecticut, and our Association proposes to continue its campaign of education. A lengthy program has been prepared for the next meeting, and it is expected that several noted speakers will be present. Every bee-keeper is cordially invited to attend. Please bring choice samples of honey, or anything of interest, for the apiarian exhibit. Membership in the Association is but 50 cents a year. We want 500 new members. Please make remittances to the undersigned before the date of the meeting, and be sure to come yourself. J. ARTHUR SMITH, Sec. Box 38, Hartford, Conn.

**FOR SALE**

50 colonies Italian BEES in 8-fr. L. hives at \$3.50 each. Also a number of Supers, 1/2-frames, etc. Combs built on fdn., and wired. 14A2t GUSTAVE GROSS, Lake Mills, Wis. Mention Bee Journal when writing.

are made every year in the book business. Every family, rich or poor, must have books. During the last few years, \$7,500,000.00 have been expended for Modern Eloquence, \$12,000,000.00 for Stoddard's Lectures, \$5,000,000.00 for the Century Dictionary, and the tremendous sum of \$4,000,000.00, covering over half a million sets of the Encyclopedia Britannica. These books were sold by subscription in American homes and sales are still going on.

We have a subscription publication which sells more readily than any of the above. The demand is already so tremendous that more capital is required to swing it, or get behind on orders. Profits are enormous, several times savings bank interest.

We have arranged a plan whereby

**Any Progressive Man or Woman Can Share These Profits**

becoming stockholders in a profitable business, based on twenty years' experience. Remember, the success of this publication is not away off in the future—it is not prospective, but it is a success at the present time and growing in demand every hour. Sales of this publication at the time of publishing this advertisement

**Often Exceed \$2000 a Day**

This is an exceptional opportunity for those of small means to get in on the ground floor in a business which legitimately pays large dividends and is as solid as the Rock of Gibraltar. It cannot be held open for long as the response is certain to be so great that we shall have all the capital we need to increase the number of our presses and secure stock to be turned out in completed books, which are selling like wildfire.

You owe it to yourself to investigate this opportunity. You will never have a chance like this again to become

**Part Owner in a Mammoth Publishing House**

which is already in successful operation, already earning big dividends, and which is led to sell a small amount of its stock simply because the business is already so tremendous as to exhaust the working capital. But if you would grasp this opportunity you must

**Write Quick—Only a Few Can Come In**

Address your letter to me personally, like this—

**W. B. Gilbert**  
Dept. G 28 Jackson Blvd., Chicago

**70 Colonies of Bees For Sale Cheap**

In large quantities, \$3.00 per colony, and \$3.50 in small lots. The bees are in 10-frame Langstroth hives, and in excellent condition.

13A4t G. PROGNOW, Mayville, Wis.

**BIG STOCK**

**DOVETAILED HIVES,**

28Etf Please mention the Bee Journal.

# “WHAT’S IN A NAME?”

That depends whose name it is.

Did it ever occur to you that it means something to order bee-supplies with a reliable name back of the goods—a name that has stood for over 30 years for the very best in bee-goods?

When you see **LEWIS** on a hive or on a crate of sections you know what you are getting. You also know that if the goods are not just exactly what they are sold to be, back goes your money to you. The G. B. Lewis Company or its distributing houses do not want your money if you are not satisfied.

They do not want you to take any chances, either. Before you buy your bee-supplies, order a sample crate of Lewis Sections and five Lewis Hives or less, just to see what you are going to get when you do buy. If **Lewis Beeware** does not win out on the trial, give some one else the order. That’s fair, isn’t it?

Lewis Beeware is sold at consistent prices, and is the cheapest beeware because it is the best beeware. A season’s trial will convince you,

**G. B. LEWIS CO.,** The Original Beeware People  
 “Not in any Trust.” **Watertown, Wis.**

**A GREAT IMPROVEMENT**

Will be found in

The  
**American Bee - Keeper**  
for 1907

It is profusely illustrated and enlarged, and contains only articles of the most practical as well as scientific nature. A special corps of the best writers has been engaged. The editors are Harry E. Hill and Arthur C. Miller, than whom there are no more practical or experienced bee-keepers in this country. We have published the American Bee-Keeper continually and regularly since 1890.

Regular subscription price, 50 cents a year. One year to new subscribers, 35 cents; three years for \$1.00.

Send for sample copy and our new illustrated price-list of **BEE-SUPPLIES OF ALL KINDS.**

Guaranteed highest quality at lowest price. Address,

**THE W. T. FALCONER MFG. CO.**  
JAMESTOWN, N. Y.

[Established 25 years.]

**Honey and Beeswax**

CHICAGO, Feb. 1.—The usual late winter demand is in evidence for comb honey to replace diminished stock laid in during the autumn by the large retailers, but during the dull period there has been very little change, if any, in prices, the offerings being light.

We find No. 1 to fancy white comb honey brings 15@16c, and for that which is off in color and flavor from 1@3c less. Amber grades of all kinds are dull and range in price from 10@12c. The extracted perhaps is not quite so firm in price for the California or Western grades, but there is no surplus of white clover or basswood, both of which bring about 8c, and in some cases more. Ambers grade from 6@7½c. There have been some sales of beeswax at 32c, but 30c is about the price for average.

R. A. BURNETT & Co.

PHILADELPHIA, Mar. 11.—The comb honey market has been quite active in the last two weeks, and the continual cold weather has kept things moving. Many cheap lots have been sent in from the producers, which have had a tendency to bear on the market and weaken the prices somewhat. Fancy white comb honey, 15@16c; No. 1, 14@15c; amber, 12@14c. Fancy white extracted honey, 7@8c; light amber, 6@7c. Beeswax very firm, 32c.

We are producers of honey and do not handle on commission. WM. A. SELSER.

NEW YORK, Jan. 15.—The stock of white comb honey is pretty well exhausted, and we do not expect any more arrivals of large lots from now on. Prices are firm, and we quote from 15@16c for fancy white; 13@14c for No. 1; 12c for light amber. There is quite a little dark and buckwheat on the market, but no overstock, and we think that all of it will be disposed of before long at present prices, which we quote from 10@12c, according to quality. Extracted honey very firm, with sufficient supply to meet demand. California white sage is bringing from 8@8½c; light amber, 7½c; amber, 6½@7c; buckwheat extracted in fairly good demand at 6@6½c. Southern in barrels finds ready sale at from 55@70c per gallon, according to quality. Beeswax firm and steady at 31c. HILDRETH & SROGLEN

DENVER, Feb. 14.—Producers in this State are practically closed out of both comb and extracted honey. We have not sufficient good comb honey to supply our local trade, but have

**Headquarters for Bee-Supplies**

Complete stock for 1907 now on hand.

**FREIGHT-RATES FROM CINCINNATI**

are the **LOWEST, ESPECIALLY**

**C. H. W. WEBER** CINCINNATI OHIO

Office and Salesrooms, 2146-48 Central Ave. Warehouses, Freeman and Central Aves.

a good supply of white extracted of excellent quality. We quote strictly No. 1 white comb honey, per case of 24 sections, at \$3.20; No. 1, light amber, \$3; and good No. 2, \$2.80. White extracted, 8@8½c per pound; light amber, 7½@8c. Clean, yellow beeswax, 27@28c, delivered here.

THE COLO. HONEY-PRODUCERS' ASSN.

CINCINNATI, Mar. 11.—There is very little demand for extracted honey at this writing, which is only natural, owing to the unsettled weather at this time of the year. However, we are looking forward with interest to a revival of trade, as soon as the warm spring days are here. We quote amber extracted honey in barrels at 6½@7½c, the price depending upon the quantity purchased. Fancy table honey in crates of two 60-lb. cans each, at 8@9c. There is little demand for comb honey owing to the lateness of the season. Choice yellow beeswax, 32@35c, delivered here.

THE FRED W. MUTH CO.

INDIANAPOLIS, Feb. 25.—comb honey is not plentiful, but demand is slack. Fancy white comb brings 16@17c; No. 1 white, 14c; amber, 12@13c. Best grades of extracted honey bring 8@9c; amber, 6@7c. Good average beeswax sells here at \$35 per 100 pounds.

WALTER S. POWDER.

TOLEDO, Nov. 30.—The market on comb honey remains about the same as last quotations, but has been coming in much more freely, as beekeepers seem to be very anxious to get rid of their stock. Fancy brings in a retail way 16c; extra fancy, 17c; No. 1, 15c; buckwheat, 15c. Extracted white clover in barrels brings 7@7½c; cans the same. Beeswax, 26@28c.

THE GRIGGS BROS. & NICHOLS CO.

CINCINNATI, March 6.—The market on comb honey has been quite brisk the past week. Entirely sold out of fancy white. No. 2 is selling for 12½@13c. White clover extracted in cans, 9c; amber in barrels, 6c. Beeswax, 30c, delivered here. C. H. W. WEBER.

KANSAS CITY, Mar. 4.—The demand for comb honey is only fair at present. The market is almost entirely bare of extracted honey. We quote: No. 1 white comb, 24-sec. cases, \$3.10 to \$3.25; No. 2, \$2.50 to \$2.75. Extracted honey, white, per pound, 8@10½c; amber, 8c. Beeswax, per pound, 25@27c. C. C. CLEMONS & Co.

**SOLID GOLDEN QUEENS**

Ready for delivery April 1st. Select Untested Queens, \$1 each; Tested Queens, \$2; Select Tested, \$3. You can only get good Queens from the South in the early spring. Book your orders NOW.

# A Big Lot of the Newest Dovetailed Hives

By the Bee-Crank.

I have just unloaded into my warehouse a carload of Root's newest Dovetailed Hives, and they are as handsome a lot of goods as were ever seen. These hives have special covers, special bottom-boards, and, in fact, special features throughout that have been tested and indorsed by leading and successful bee-men everywhere. Not only are they right in principle, but they are built of clear, bright stock, finished like a piece of cabinet work, and perfectly fitted throughout.

I have them ready for immediate shipment, and can fill orders quickly. Indianapolis is so situated that goods from here make quick time on through freight trains, saving transportation

charges and saving time. I make a specialty of careful packing, and receive many letters like the following:

BLOOMINGDALE, IND.

WALTER S. POUDEIR, Indianapolis, Ind.

Dear Sir:—The supplies you have been sending me could not be excelled in workmanship. I have secured surplus honey from new swarms in Danzenbaker hives when others failed to secure surplus, even with old colonies.

Yours truly, D. W. TUCKER.

Root's goods at Root's prices. New Metal-Spaced Frames, Danzenbaker Hives, and all other desirable bee-keepers' supplies. Catalog free.

Beeswax Bought.—I pay cash or take in trade at highest market prices. Send shipments by express or freight, according to amount. Be sure to attach your name to package.

## Editorial Notes and Comments

### "Keep Your Colonies Strong"

This motto, under the title of Oettl's Golden Rule, is given in the closing paragraph of Langstroth's classic work as the essence of all profitable bee-keeping. It is generally agreed that the strong colonies are the profitable ones; and probably few would dispute the statement that 2 colonies of 30,000 bees each will not store as much as the united force of 60,000 bees in one colony.

Yet some modify the motto by saying: Know the honey-resources of your locality, and have colonies strong for the harvest; but do not have a lot of bees reared to come upon the stage as a lot of idle consumers when there is nothing for them to do. Certainly it ought to be worth while to avoid needless consumption, when it is considered that the annual consumption of a colony is somewhere from 100 to 200 pounds of honey. But when we come to particulars, the problem does not seem so easy. It is not easy to tell in advance at what time a given plant will be ready to offer its nectar, nor indeed whether it will offer any. If one knows about when a flow may be expected, one may figure when the queen should lay eggs to be ready for it; but how is one to manage to have a small force in the hive during a dearth between two flows? Those who can so control matters as to have a strong force when a flow is on, and a strong force only then, are wise to use such control; the average bee-keeper will do well to get his colonies strong as early as he can in the season, and then try to keep them so.

### Narrow Frames for Extracted Honey

E. D. Townsend says in the Bee-Keepers' Review that manufacturers list no proper frame for extracting purposes, which, he

thinks, should have neither top-bar, end-bar nor bottom-bar more than  $\frac{3}{8}$ -inch wide. He says:

With this style of frame in our supers, spaced  $1\frac{1}{4}$  inches from center to center, we get great, fat combs; then, with a long uncapping knife, cut clear down deep, clear to the frame. In this way we get more wax in the uncapping tank; but the greatest advantage is, we can uncap a whole comb at *one stroke*.

That seems reasonable, and perhaps there's nothing original about it. But did you ever think of such narrow frames as affecting the *quality* of the honey? Here's something well worth thinking over:

In producing honey for exhibition purposes, we insert full sheets of foundation in between our extracting combs, in the supers of some of our most powerful colonies; and, after quite an experience along this line, we have never found a better way to produce a superior article of extracted honey. While it would not be practical to produce all our extracted honey direct from foundation, the next best plan is to fill our supers with these *deeply* uncapped combs. With these the cells are only about half an inch deep; and this drawing out of the combs when being filled with honey, gives the bees an opportunity to cure the honey *nearly* as well as they would in drawing out foundation. Never give *thick* extracting combs during a heavy flow of honey.

### How Much Nectar Per Acre?

The man who should make out a reliable table showing the number of bees that could be supported upon each one of the more important honey-plants on a given surface would be entitled to a high niche in the bee-keepers' hall of fame. The data are so changeable, so elusive that no one can say with any degree of certainty how many acres per colony are needed in any given case; and the worst of it is that with the passing years we seem to

be making no progress in gaining the desired knowledge. Here comes a note from Dr. Miller, saying:

"MR. EDITOR:—Before we get to blows will you please settle a little matter between Mr. Atwater and me? On page 208, he takes exception to my guess that 200 colonies might have good picking on 300 acres of white clover if said white clover happened to be in the mood of yielding. He doesn't say just what the figure should be, but evidently he thinks I expect too much of white clover. Which of us is right?"

"I may say to you privately that after getting a little additional light from his article, and after thinking over the matter a little more fully, it begins to seem to me that he's nearer the right of it than I am; but please don't side with him any more than you have to, for I don't want him to crow over me too much. The only datum I can give you on which to work, is a rough guess at how thick bees are on a piece of white clover when bees are doing good work on it. Of course, it can only be a rough guess; but just as I now recall, I should say that when bees are 5 feet apart all over the field they are doing good work."

It is not an easy thing to decide between two guessers, with no foundation to work upon except a single item, and that a guess. Other things being equal, Mr. Atwater ought to make the closer guess in the case, for "Utah's" conditions are probably more like conditions in Idaho than in Illinois. Certainly in Illinois, when "hundreds, or even thousands, of acres of as fine white clover as one could wish, are covered with a mass of bloom" covering a period as long as "during part of May, often all of June, with more or less bloom for many weeks later," one would expect as a rule good crops, whereas in Idaho Mr. Atwater says they are light.

It may be well in passing to note the one point on which Mr. Atwater makes a definite guess. It is that in favored locations each acre will support one colony of bees, provided 10 percent of it is covered with sweet clover and the other 90 percent with alfalfa. That guess stands till some one gives reasons for a different one, and it is of value, even though somewhat vague.

As between white clover and alfalfa, it may be mentioned that unless a field of alfalfa is used for raising seed its seasons of bloom, however abundant, are likely to be short, the mower being likely to level it as soon as it is of most value, if not before; whereas white

# American Bee Journal

clover, being subjected almost entirely to grazing, yields continuously for weeks.

Coming directly to the case in hand, let us do a little figuring, estimating that 20,000 field-bees belong to each colony. If 200 colonies are working on 300 acres, that makes  $1\frac{1}{2}$  acres for each colony, or for each 20,000 fielders. In  $1\frac{1}{2}$  acres there are 65,340 square feet, giving 3.27 square feet to each bee; so if they are evenly distributed over the field they will be about 1 foot 10 inches apart. If we take Dr. Miller's guess of 5 feet apart, each bee will require 25 square feet of territory, making for 20,000 bees 500,000 square feet, or nearly  $11\frac{1}{2}$  acres. According to that, instead of 200 colonies for 300 acres, only 26 colonies would be supported on that number of acres.

If Dr. Miller doesn't like the decision, he must either make bees work with less elbow-room than 5 feet, or else he must show that 20,000 is not the right estimate for the number of fielders in a colony.

## "Honey" from Buttermilk

In Praktischer Wegweiser it is related that in a North Germany newspaper an advertiser offered for the modest sum of 28 cents to send a recipe by which one could easily make out of a quart of buttermilk 2 pounds of the finest, best-flavored honey. The enterprising editor sent the required amount, and then published in Prakt. Wegweiser the recipe verbatim. Explicit instruction is given as to the right kind of vessel in which to cook the honey, and just how to stir, etc., one item being that to each quart of buttermilk must be added 1 pound of sugar! We may expect to hear shortly that German bees are cut out of business!

## Cleaning Up Wet Extracting Combs

Sometimes when wet extracting combs are given back to the bees to clean up, instead of carrying the honey all down into the brood-chamber, the bees mass it in a few cells of the extracting combs. H. Potter says in the British Bee Journal that he makes sure of having the extracting combs left entirely empty by returning them to the bees upside down. Not many, however, will find it necessary to resort to such an inconvenient method.

## Reversed Brood

According to an item in Prak. Wegweiser, the occasional finding of brood with heads in the bottom of the cell is due to the presence of minute parasitical insects, which trouble the larvae and cause the abnormal position.

"Songs of Beedom."—This is a beautiful 16-page-and-cover pamphlet, 6x9 inches in size, containing 10 bee-songs—words and music—all the songs so far written specially for bee-keepers, we believe. It is nice, as well as convenient, to have these songs all in one binding. Every bee-keepers' organization should have copies for use at conventions. They could be sold to members after using once, or held by the secretary for use at future meetings. Of course, every bee-keeper's family will want at least one copy. It is sent, postpaid, for only 25 cents, or 3 copies for 60 cents; or, we will mail one copy with the American Bee Journal one year—both for \$1.10. Send all orders to the office of the American Bee Journal.

## Miscellaneous News - Items

**A Bee-Keeper's Epitaph.**—Mr. R. B. Ross, Jr., of Quebec, Canada, sends the following clipping taken from the Rochester (N. Y.) Herald, referring to the epitaph of a man who was stung to death:

Among the many curious inscriptions that are to be found on the tombstones that mark the last resting places of the early pioneers of the town of Manchester, one of the most curious is in what is known as the old Greenhouse cemetery, on a tombstone erected in 1814, to the memory of Timothy Ryan. On May 12, 1814, he was attacked by his bees and stung to death. The following epitaph appears on his tombstone:

A thousand ways cut short our days,  
None are exempt from death.  
A honey-bee by stinging me  
Did stop my mortal breath.  
This grave contains the last remains  
Of my frail house of clay;  
My soul is gone—not to return—  
To one eternal day.

## Bees at the Jamestown Exposition.

—Mr. Charles Koeppen, of Fredericksburg, Va., has been granted a concession by the Jamestown (Va.) Exposition Co. to make a demonstration with live bees in a wire-cloth cage, and also a motion-picture apparatus in addition to the privilege of selling standard bee-books. Mr. Koeppen is erecting a structure 30x50 feet, and the whole display, when installed, will cost him about \$1400. The price of a single admission to this part of the Exposition will be 10 cents.

We can not conceive of anything better to advertise the bee and honey business than what Mr. Koeppen has undertaken to do at the Jamestown Exposition. We hope to hear of his success all through the months during which the Exposition will be opened. Of course, every bee-keeper who attends it will be sure to take advantage of Mr. Koeppen's demonstrations.

**Honey and Noisy Enthusiasm.**—The Youths' Companion contains the following which seems to have a lesson in it taken from the bees:

### HONEY IN IT.

When the Salvation Army first came to America, 25 years ago, says the author of "The Prophet of the Poor," it found a ready advocate of its methods in the Rev. Thomas K. Beecher. Mr. Beecher had just had a lesson, in parable form, from a certain "Bro." Anderson, which he never forgot.

Brother Anderson was at that time the pastor of a colored congregation which was noted for the noise and enthusiasm of its services. Incidentally the old man wielded a whitewash-brush, but he was known as an exhorter of no mean ability. One day he persuaded Mr. Beecher to address his congregation.

The occasion seemed a good one for reproving the congregation for their uproarious methods, and Mr. Beecher did so. "Let all things be done decently and in order," he

concluded. Then Bro. Anderson rose to speak.

"I love Brudder Beecher; I love to hear him preach dis afternoon," he said. "He's our good frien'. And he say dat some folks goes up to glory noisy'n' shouting, and some goes still like, 's if they's ashamed of what's in 'em. And he say we better be more like de still kind, and de white folks'll like us more. He say de boys and gels stan' in de do' way and laugh. at us, and mock at us 'cause o' de way we goes on.

"Yas, I see de boys and gels stan' all las' winter roun' de door, an' under de windows, an' laff; and dey peep in and laff. But I 'member what I saw las' summer among de bees.

"Some of de hives was nice an clean an' still, like 'spectable meetings, and de odders was a bustin' wid honey. De bees kep' a-goin' and a-comin' in de clover; and dey jes' kep' on a-fillin' de hive till de honey was a-flowin' like de lan' o' Canaan. An' I saw all roun' de hives was ants and worms an black bugs, an' dey kep' on de outside. Dey wa'n' bees. Dey couldn' make de honey for darselves. Dey couldn' fly to de clover an' to de honeysuckle. Dey jes' hung roun' de hive and lib on de drippin's.

"So de boys an' gels hang roun' yar. Come in—we'll show you how de gospel bees do. Come in an' we'll lead you to de clover.

"You won't come in? Well, den poor things, den stan' roun' de outside an' have de drippin's. We's got honey in dis hive."

"As he spoke," said Mr. Beecher, "I seemed to see my own sermon shrinking and fading away."

**To Foreign Subscribers.**—We wish to say that none of our special offers apply to foreign subscribers, on account of the extra postage, except Canada, Mexico, Cuba, and the United States possessions. Also, we send to foreign countries only the American Bee Journal.

**Honey as a Health-Food.**—This is a 16-page honey-pamphlet intended to help increase the demand for honey. The first part of it contains a short article on "Honey as Food," written by Dr. C. C. Miller. It tells where to keep honey, how to liquefy it, etc. The last part is devoted to "Honey-Cooking Recipes" and "Remedies Using Honey." It should be widely circulated by those selling honey. The more the people are educated on the value and uses of honey, the more honey they will buy.

Prices, prepaid—Sample copy for a 2-cent stamp; 50 copies for 70 cents; 100 for \$1.25; 250 for \$2.25; 500 for \$4.00; or 1000 for \$7.50. Your business card printed free at the bottom of front page on all orders for 100 or more copies. Send all orders to the office of the American Bee Journal.

**Amerikanische Bienezucht,** by Hans Buschbauer, is a bee-keeper's handbook of 138 pages, which is just what our German friends will want. It is fully illustrated, and neatly bound in cloth. Price, postpaid, \$1.00; or with the American Bee Journal one year—both for \$1.75. Address all orders to this office.

Conducted by LOUIS H. SCHOLL, New Braunsfels, Tex.

The "Sages" of Texas and of California—Color of Sumac Honey

MR. LOUIS H. SCHOLL:—I notice in your department of the American Bee Journal (page 90), a letter from J. E. Chambers, in which reference is made to sage honey as dark, and I inferred that sumac yielded white honey. With me sage is the principal source of surplus, and if taken off before other honey is mixed with it, it is water-white, and the finest-flavored honey in the world. I think sumac comes later, and is amber. Soon tar-weed comes in, and the honey is then darker and considerable off flavor. I have black or button sage and white, coming in the order named, 2 or 3 weeks apart. The black sage yields the whitest honey. Can you account for the difference?  
A. J. BURNS.

Lusardi, Calif., Feb. 5.

Mr. Burns' letter was forwarded to Mr. Chambers for reply, which is given here:

MR. LOUIS H. SCHOLL:—I note what you have to say about the different local names for plants. I am sorry indeed to learn that any one could be misled by such trifles. I have always known that the little common sage, found to a great extent all over Texas, was not the same as the white, blue, and black sage of California, and I have never said that it was. While I am no botanist, there is no man in Texas who watches the different flowers more carefully than I do, and I think there are few who follow the bee-papers more closely. This being true, I would indeed be a pretty one not to know the difference between these plants.

The sage we have here is a small bush—red sage with dun-colored flowers; and white sage with larger leaves but flowers of the same color; the leaves of a strong mint flavor. I know you have seen it. In this locality it blooms in the latter part of June, and in seasonable years until August, and yields a very dark, strong honey, in Southwest Texas. There is a large kind common to East Texas. It has a seed-pod, which, when broken, shows two flat sides and a round side. It is dead at this season, but I am sending you a lot of the dried leaves. Now, this is about all I know about it, and, though not much, is perhaps sufficient to enable you to identify it. I am also sending you a sample of the honey from it.

I note Mr. Burns says that sumac is amber in color; it may be in his locality—I can't answer for California. I am not keeping honey records for that part of the country, but here it is, if not white, so very close to that color that we all call it white. I saw sumac honey at San Antonio, but none of it was as light as ours when pure; however, as you know, it is not often that we can get honey that is absolutely free from any admixture. I think there are but very few apiarists who know how much bees move and change honey about in the hives, and this is one reason why it is so hard to get honey all clear of admixtures. And you know how impossible it is to get every particle of honey out of the combs when extracting, or even to uncap every cell. The only way I could ever be

sure of getting all honey from a given source was to hive a swarm on starters during a flow, and when there was only one kind of plant in bloom such swarms, if given combs that are new, will, of course, get all the honey from the desired source. But time must be given for them to use up the honey that they carried in their honey-sacs before the new combs are given, or else an admixture will result.  
Vigo, Tex. J. E. CHAMBERS.

In writing to Mr. Chambers I mentioned the inadvisability of using common or local names when speaking of honey-plants of different localities, as a name may mean one thing in one locality and quite another thing somewhere else. I believe there is hardly anything else in this respect like common names of plants. Just as it happened, that what was called "sage" in Texas was not the sage of California, so well known to the bee-keepers. Here in Texas it is exactly one of those cases of using common names wrongly for plants that do not obtain that name in botany; hence, such names can not be relied on, and should never be used unless the name is a universal one, and means one and the same thing everywhere.

Instead of the real sage of California,

ANOTHER KIND OF INSPECTION WORK.

that mentioned by Mr. Chambers is not a sage at all, but a croton instead, belonging to the Spurge family (*Euphorbiaceæ*). These crotons are quite common in our State, and there are many species. That referred to as "red sage" is very probably *Croton glandulosus*, L., while the "white sage" is *C. texensis*, Muell. or Texas Croton. The one of eastern Texas,

spoken of, is *C. capilus*, Michx., a large croton. I have seen bees on all of these, but the "red sage" seems to give more honey than the others, at least in the localities where I have observed it.

Here is an instance again that shows that it behooves us, as bee-keepers, to study botany, or at least so much of it that we may be able to know our honey-plants by their right names. The study of botany has not only been valuable to me in my bee-keeping, but of great interest as well.

One of My Inspection Trips

The picture here shown is a reminder of one of my trips of inspection, and shows to some extent the hospitality shown "the inspector" upon this occasion, quite different from some of the experiences on other occasions.
