The bee-keepers involved here, instead of objecting to such inspection of their apiaries, not only willingly allowed this, but insisted not only on a thorough inspection but thorough treatment. "The inspector" was met at the train by them, taken to their homes and cared for. Then preparations were made for the extended over-land trip to inspect the apiaries from 25 to 30 miles west of the town, and lasting over a week. The picture shows the inspection party in one of the "camps." Over 2000 colonies were examined, but only two cases of disease were found, which, only a short time before, had been imported into the neighborhood with a lot of bees shipped from another State. These cases were promptly dealt with and eradicated, thus leaving the district free of the disease.

Location and Management—Not the Hive

I'll tell you, the location and management have more to do with the yield of honey you get than the kind of hive you use, supposing, of course, you use one of the many frame hives on the market to-day.

# American Bee Journal

## A GREAT DIFFERENCE IN LOCALITIES.

I have just returned from a visit to all of my out-yards—3 in number. The bees in No. 1, about 4 miles from home, seemed to be getting a living from fruit-bloom; only 22 colonies in this yard.

Yard No. 2 is 10 miles from home, and has 66 colonies; but the bees at this yard were very cross, and much inclined to rob. There is no fruit-bloom to speak of within 3 miles of these bees.

Yard No. 3 is about 13 miles from home, or say 3 miles the other side of yard No. 2. This yard has 49 colonies, and is almost surrounded by fruit of various kinds, mostly wild fruit. Here I found the bees roaring, and rushing in and out, as if a real June honey-flow were on. And the bees were evidently gathering honey fast for the time of year.

I have given the above so that the

readers can see what a difference only a few miles will often make in a location.

## FIELD-BEES STORING NECTAR IN THE CELLS.

The American Bee Journal comes out with the positive assertion that the field-bees deposit their loads of nectar directly in the cells themselves, and that it is not given to the young or nurse-bees, in the way we have been taught. In this we will have to agree to disagree with that observer, or else his bees act differently from our bees of Texas. I have watched the field-bees deliver their loads to the nurse-bees hundreds of times, and have never yet seen the field-bees go direct to the cell and deposit their loads of nectar. This may not be of much importance, but it is at least very interesting to me. I should like to hear from some of our more scientific writers on the subject.

L. B. SMITH.

Rescue, Tex., March 20.

more than justice. The case of wheat transportation you mention is not exactly parallel. Most well-wishers of the human race (except possibly those whose own toes are pinched) favor the lowest possible rates on wheat, that the poor may have bread as cheaply as possible. No similar consideration works in favor of honey; and it is not likely ever to get into the specially-favored class. Page 168.

## SWARMING AND ENERGY.

C. W. Dayton seems to run his pen through a troublesome truth when he says, "This swarming disposition is an indication of energy. If they lack this energy they will fall short of energy for other accomplishments." Perhaps the case is not quite so bad as that. I think some cases of disinclination to swarm occur among bees of the most energetic character. Page 169.

## HIVE-ENTRANCES IN OUTDOOR WINTERING.

The experience of P. E. I., that a heap of little spruce-boughs piled over the entrance turned out the best of 7 different ways of doing—that novelty is fresh and toothsome. Such boughs will not wad up and obstruct passage as grass and leaves do. Lots of us may some time have opportunity to profit more or less by this if we do not forget it. But covered up deep in snow for all the latter half of the winter—don't believe I would risk that, not even with the boughs underneath. Too much temptation to breed themselves to ruin. Page 174.

## YARNS DOMESTIC AND FOREIGN.

Those two yarns of the London Tribune and the Minneapolis Journal furnish a good "tit for tat" between bee-editors on two sides of the Atlantic. But there is this much to be said in favor of "we'uns": The Yankee yarn was not intended for full belief, while the British yarn was. As to the latter, we have scarcely had so fine an example of how many times the mere writer will "get his foot in it" if he reads up about bees and then tries to write about them. Page 186.

**Why Not Advertise?**—There are many dealers in bee-supplies, and those who have bees and queens for sale, who are not now advertising, that might increase their business by advertising in the American Bee Journal. The rates charged are very low, as will be seen by referring to the second page of this number. During the next 6 months will be done the bulk of the season's business among bee-keepers. Why not begin at once to let the readers of the American Bee Journal know that you have something to sell? Our advertising columns are open only to those who will give their patrons "a square deal." If you are in that class we will be pleased to have your advertisement in our columns.

**Our Wood Binder** (or Holder) is made to take all the copies of the American Bee Journal for a year. It is sent by mail for 20 cents. Full directions accompany. The Bee Journals can be inserted as soon as they are received, and thus preserved for future reference. Or we will send it with the American Bee Journal a year—both for \$1.10. Address office of the American Bee Journal.

## TAKING BEES OUT OF CELLARS.

So Mr. Doolittle, although he has a wheelbarrow with springs, prefers to obviate jars still further by padding the top with folded bed-quilts. With such an arrangement he successfully wheels bees around in July and August. His *modus operandi* of getting bees out of the cellar is perhaps as good as anything published; and yet one kind o' feels that there is something yet to be desired. Would it be worth while to have wet cloths enough for all the entrances, and to put them all on at once? And would a bountiful supply of thin ice be worth saving up (putting it in the ice-house); and slide a dozen square inches of it into each entrance as the cloths are put on? I don't winter bees in the cellar, and so don't draw on much experience in making these suggestions. It seems whatever bees do get out near the cellar-door hang around there, and most diligently attend to a business which even hardened old bee-keepers don't altogether admire. I believe Mr. D. didn't mention open doors the night before, which (under some conditions) is said to help, if my memory serves me right. Page 148.

## INFERIOR WAX FROM STEAM-PRESSES.

This remark of Mr. Byer is not often printed, if at all: "For some reason wax from the steam-presses is never of as good a quality as that obtained by other means." And we shall look forward with interest to see what the 2

years' supply of slumgum pans out in the Hershiser press. Page 150.

## CLEANING SECTIONS RAPIDLY.

"Colorado's" experience is instructive to all that hire help to clean sections, and probably to all of us. Taking the sections out and placing them in a pile so the scraping can proceed steadily just doubled the amount done. Even if we don't hire we find with ourselves that too much changing from one thing to another is wasteful of time. Page 151.

## TOO THIN BOTTOM-BOARDS.

Yes, Dr. Bohrer, I have already improved the manufacturers who give us the too thin bottom-boards and such. Or was it the size of the "lump o' sweetness" you would have us seek that you wanted me to endorse?—not less than 80 pounds nor more than 300. If 300 pounds of "honey" be desirable, why not 400 pounds be more desirable? Tell me that. Page 168.

## LOWER FREIGHT-RATES ON HONEY.

Is that the way you give it to them, Mr. Greiner? Men are indeed selfish; but most of them can—if you go at it in the right way, and keep at it long enough—be made to consent that their fellow-men shall receive justice. The idea is that our Western brothers are working to be relieved from unjust classifications and unjust rates. Let's not dump any logs and boulders in their road until they ask for something

### Spring Management of Bees

BY G. M. DOOLITTLE.

In a letter lying before me I find these words:

"Will Mr. Doolittle please tell us through the columns of the American Bee Journal what should be done from early spring to the first flow of nectar which gives a surplus, which is white clover in my locality? I winter my bees in the cellar, and I wish you to begin with the setting from the cellar."

Some of the articles which I have written lately cover much of this ground, but perhaps I can make matters a little more plain if I try again. As I take it for granted that the questioner has only his one home-yard of bees, I will tell, or answer, him from that standpoint, rather than from the standpoint of out-apiaries. I always set out my bees at the home-yard alone, so have a spring wheelbarrow with a few thicknesses of old carpet or old blankets on it, so that the bees will experience no jar from running the wheelbarrow rapidly. This padded barrow and a lighted smoker are left at the door of the cellar, when the cellar door is carefully opened and I quickly step in, bringing out the hive nearest the door, and placing it on the wheelbarrow, quickly shutting the door again, so that those remaining in the cellar may not be aroused by the light and outside air coming in on them.

The bees in the hive now begin to realize that their long winter nap is at an end, and if I took no precautions, they would be out of the hive and in the air before I could wheel them to the stand they were to occupy, many of them losing their home, and stinging me badly. To avoid this, I blow 4 or 5 puffs of smoke in at the entrance, closing the same by putting a wet cotton-cloth of suitable size sufficient to cover it without any special work of tucking it about, when this colony is rapidly wheeled to where it is to stand for the season. A few more puffs of smoke is given them, when the hive is set upon its stand and the entrance adjusted to suit the size of the colony, which can be very nearly told by the amount of buzzing that occurs on the blowing in of the smoke.

With this treatment the bees will commence to fly as leisurely as they would had they been on the summer stand all winter, and mark their location as perfectly, so that we have no mixing of bees, etc.; while, had not the smoke been given they would have all piled out of the hive with a rush. This go-

ing out slowly is of great advantage to them in marking their location and repelling robbers.

As soon as set out, the next work is to see that all have plenty of stores; and if in a tight-bottomed hive, clean off the bottom-boards. As I use a loose bottom-board it is placed on the wheelbarrow to set the hive on, so I do not have to disturb the bees afterward on this account.

To find out about the honey or stores, the first cool morning go to the hive, take off the cover, and carefully raise the quilt or honey-board, and look for sealed honey along the top-bars of the frames. If plenty is seen they are all right till they are to be carefully looked after 3 weeks later. If little or none is seen, they must be fed; for, if we are to reap good results from our bees they must have plenty of stores at this time of the year to encourage brood-rearing.

For feeding at this time, I prefer combs of sealed honey set in next the cluster, to anything else; and it should be the duty of every apiarist to set apart combs from the extracting hives each year, which are filled with honey, sealed over, especially for this spring feeding. If none such can be had, we must feed sugar syrup, or liquid honey, if we have it; but the feeding of liquid sweets, thus early in the season, entices many bees out to perish in unfavorable weather, and tends to promote robbing, beyond anything else.

Three weeks later the hives are to be opened generally for the first time, the goodness of the queen looked after, and the amount of stores on hand, and to see that the brood-nest is located in the center of the hive. For years I have noticed that brood will not go forward nearly so rapidly where the brood-nest is located next to one side of the hive in early spring, for as the bees increase their brood, it seems natural for them to do this from either side alike, and where the first brood is reared but one or 2 combs away from one side of the hive, after a little they can only extend the brood in one way, on account of the other side of the brood-nest reaching the side of the hive. Where I find brood thus located at this time, I always set it over to the center of the hive, and whether I so find or not, I now place 2 combs which are the fullest of honey next each side of the brood-nest, one on either side, which helps brood-rearing along amazingly.

The great trouble in forcing early brood-rearing, so as to have it in time so that the maximum amount of brood shall be emerged into bees in time for

the harvest of honey from white clover, seems to be to get the bees to feed the queen prepared food in sufficient quantities so that she will lay prolifically quite early in the season; and the placing of combs of sealed honey next to the bees in this way causes them to remove the honey as brood-rearing goes on, and, in thus removing, more food is prepared than would otherwise be the case; and having the food prepared, the queen is liberally fed.

The scrimping of honey in any colony now, is to be "penny wise and pound foolish," for unless there is either plenty of honey in the hives, or plenty coming in from the fields, brood-rearing will go slowly, which means comparatively few bees in time for the harvest. I want as much as 20 pounds of honey to each colony at this time of the year, so that they will not scrimp in feeding the queen or the larvæ now.

As it is about 37 days between the time of the laying of the egg and the time the worker-bee goes out as a field-laborer, I try, if possible on account of weather, to have all the colonies fixed as above 6 weeks before the white clover opens enough for the bees to work on it to advantage.

As the colony increases in size, the entrance should be enlarged so that there is no crowding out of the bees, nor any great amount of fanning done at the entrance. In all of this work with the bees, it is well, each time a hive is opened, to see that it is closed as tightly as possible, so that no cracks are left to allow the wind to blow into the hive, or heat from the hive be carried out into the outer air. To be sure, the bees seem to be able to confine the most of the heat inside of the cluster, but, in a certain sense, the warmer the hive, the more brood there will be reared. The bees seem able to raise the temperature inside the cluster up to the breeding-point, which is about 95 degrees above zero, while that surrounding this cluster is only 40 to 50; but, as a rule, the higher the temperature on the outside of the cluster, the more brood will be reared inside the same. Therefore it is always well to lay emphasis on the matter of keeping the interior of the hive as warm as possible during the spring months.

Borodino, N. Y.

### Queen-Rearing and Nucleus Management

BY F. L. DAY.

On page 194 Dr. Miller and "Iowa" discuss my method of queen-rearing, as briefly mentioned on page 7. In justice to them as well as to myself, I will explain the matter more fully.

Dr. Miller suggests that my failure to secure laying queens in the 4 nuclei in question, was because of commencing too early in the season; but such was not the case, for I obtained a laying queen in each of the 4 nuclei from the first lot of cells given them. The trouble came later.

The doctor also says in his answers to "Iowa's" questions that it would have been as well to have hung the West cell-protectors and spiral cages containing queen-cells between the brood-frames of any colony. Perhaps so with his bees, but not with mine, as I will show further on.

On May 29, 1906, colony No. 11 had a 2-story hive containing 20 good combs, 11 of which were well filled with worker-brood. On that date 3 frames of brood and bees, together with the queen, were taken out and placed in a new hive to form a nucleus for increase. The 8 frames of brood remaining and 2 frames of honey were then put in the lower story, and the upper story removed.

On June 7th, 6 frames of brood and bees were taken from No. 11 to form the 4 nuclei having only one frame each. To this one frame was added one comb of honey from No. 11, the same being well covered with bees. Each nucleus had several queen-cells now nearly ready to hatch. A laying queen was secured in each nucleus from these cells, 3 of them being excellent, the other worthless. The 3 good queens were taken away and used where needed, the poor one being killed. So far all right according to program, but these 3 laying queens were both the first and last, obtained for many weeks.

When I restocked the 4 nuclei with ripe queen-cells, I put one or 2 cells in the West protectors and spiral cages combined, in each nucleus. I put honey in the cup which fits in the lower end of the cage, so that the virgin queen could have it to eat in case the bees did not feed her. At first I put only liquid honey in the cup, and some of the queens went into it head first and drowned. Then I mixed a little comb with the liquid, which made it safe. Some of the virgins were left in the cages a number of days and consumed nearly all the honey. Now note the results.

If I secured a nice lot of virgins in a nucleus, then there was no laying queen to be found. On the other hand, if there was a laying queen, then the virgins in the cages were so neglected as to die or become chilled and worthless. It took me some time to understand this. I kept the nuclei all stocked with bees and got all the virgin queens from them that I needed. I am well aware that as a rule queens should be fertilized in nuclei, and then introduced to full colonies, but I did not have enough nuclei, and the virgins answered my purpose about as well. Most of them were given to full colonies from which the queens had been removed to prevent swarming. These colonies were filled to overflowing with bees, and had from 6 to 10 frames of brood to hatch. A caged virgin was given 8 to 10 days after removing the old queen. Two days later the virgin was released. By the time she got to laying the bees were over the swarming fever. In case the first virgin given was lost, no great harm was done, for the colony had bees enough to carry it through the honey season, which

usually ends here from the 1st to the 10th of August.

After robbing colony No. 11 so severely, it might be supposed it would not amount to much, but it built up strong and gave me about 60 pounds of surplus honey besides being heavy with stores for winter.

Detroit, Minn.

## No. 2—Things to Do, and Why

### Spring Management Continued—Getting Brood—Stimulative Feeding—Retarding Swarming—Making Nuclei

BY R. C. AIKIN.

In the last article I closed with the question of clipping, this work being done with the first spring work when bur-combs are being cut off and all made slick and so the combs can be easily and quickly handled. But as it is not necessary that queens be clipped until the swarming season is almost on, I never spend any great length of time hunting if a queen evades me; still, the longer it is delayed when the colony is getting strong the harder the job.

In order to get somewhat of an approximate date or time when things should be done, I will suppose the honey-flow when surplus and super-work is to begin, June 15th; each reader varying the times to suit location when applying the principles. And let me repeat that what I describe will be true of any location where the conditions are the same, but, if you have other factors, remember that just so surely as a mathematical problem is changed by bringing in a new factor or changing the relations of the same factors, so the change of order or number of factors with the bees will change results. The bee is not a reasoning creature as man, but follows instinct. The apiarist is ever a varying quantity—does things because of some whim or notion growing out of his reasoning faculties, and his action may be wise or otherwise—you do not know where to find him; but the bee you know where to find, and what it will do, if you know its nature and can correctly reason and analyze the problem.

Throughout this spring management the object sought after is the largest possible force of workers. I know there will be a few who will take issue with me and say it is possible to get too many bees in a hive before the honey-flow arrives. Well, suppose we admit that in a given hive we may possibly get too many bees; the remedy is to use them elsewhere—there are always places where they can be added to strengthen weak colonies, or they may be made into new colonies, or in some way kept awaiting the flow. The cost of a bee is in its maturing or producing, and not in its maintenance after grown. For a June flow in temperate-zone latitudes you cannot possibly get too many workers produced prior to the flow, so get as many as possible.

The question of well-bred stock as

against poorly-bred, needs no argument; there is such a vast difference between a stunted, skim-milk calf and a new-milk, well-fed one; the same principle in horses, pigs, chickens and all our domestic stock. Same thing also of poorly-bred farm crops of all kinds, and just as true of bees. A stunted, skim-milk queen cannot be the equal of a well-nourished one, both in the making of the queen in the first place and in her care while in service of egg-laying. But if you have the poor ones in the spring you must put up with them until you can remedy the defect—make the best of all queens in preparing for the coming crop season.

HOW TO GET THE LARGEST AMOUNT OF BROOD.

I have previously spoken of the fact that queens will start brood in January, more in February, and all should have some brood by about March 1st in outdoor wintering, in latitudes of Denver, Omaha, St. Joseph, Mo., Chicago and Indianapolis. In the early spring, and until the colony can begin to cover several combs, not very much can be done except to have the colony as warm as possible, plenty of stores within easy reach, but yet as much empty comb close in about the brood as the queen may be induced to lay in. How much she lays depends upon her vigor as a well-bred, strong individual; upon whether she be in her natural, youthful vigor or failing with age, how well she is fed and coaxed as it were by the workers; upon the supply of pollen and nectar both in the hive and in the fields; and upon the bees' ability to forage and lead an active life. While the stores within the hive are good, yet they are not nearly so good as that which is being daily gathered from the fields.

I have seen many a colony with plenty of stores—yes, too much of them. Remember that brood is reared in combs where there is neither honey nor pollen, and when a colony has to uncap and move honey to give the queen room to breed, they are honey-bound. At times it is well, yes one of the *best possible* things to do to have them *move honey*; the more honey a colony handles, either strictly within the hive or from without, the more brood will be produced, provided the queen is allowed plenty of cells in the right place as fast as she can and will use them. Right temperature, new pollen and nectar coming in just fast enough so the colony never gets much ahead (say 2 or 3 days' supply), yet are kept busy all day and every day, is the ideal condition which will give the greatest amount of brood. Approach such condition as nearly as possible, and you will see much brood, which means much working force.

But some localities do not furnish nectar and pollen early, or continuously, when we want the best results in breeding, and we may stimulate by artificial means. Just how far what is known as stimulative feeding can be profitably used I am not prepared to say. This kind of feeding is to give a limited supply daily or each alternate day; but this takes considerable time and care, and

# American Bee Journal

what is called "fussing." I have many times fed, and that lavishly, in the open air, but I never tried daily feeding. The colony must have enough at all times, but better a limited amount than too much if the brood-chamber is small; with a large chamber, that will hold lots of stores and still give the queen ample brood-room, then much stores do no harm. I am an advocate of *large brood-chambers*.

## THE MANIPULATION OF STORES.

Your colony usually starts the brood-nest near the entrance. If the entrance be the sunny or warmest part of the hive the brood will almost certainly be there. Now if there be no nectar or pollen coming in sufficient to stimulate, it is best to cause the bees to handle honey within the hive; they ought to "get busy," for a busy colony is the one that "gets there" with breeding.

Open the hive, and you will find the brood in the front end of the combs, with usually honey, in the back end. If the colony has brood in say 2 combs, or even 3, and about as much brood as they can cover and care for, just reverse these combs, putting the honey forward; this does not spread brood but puts honey to the entrance, and they get busy moving the honey and will put it back from the entrance. The colony will also stretch toward the entrance, both to guard and in getting outside, yet they will not pull from the brood faster than they can do so safely, but as fast as more comb can be covered toward the entrance it will be done, and occupied with brood. The moving of that honey has caused better feeding of the queen, which means increased desire to lay; has also fed the nurses better, and results in better feeding of brood, and so makes a faster and healthier growth of the colony. The extra effort in moving the honey produces more heat, because of the activity. This, of course, causes the consumption of more stores, but the honey-returns later will pay, by far, better interest and profit than if you had kept the honey, or than to have sold it and put the money in the bank. Activity and good feeding are the foundation on which rapid breeding rests.

If my premises are correct in the foregoing, then it is most likely that stimulative feeding—that is, daily feeding by supplying feed from without—would not be profitable; but to cause the workers to load their sacs and handle stores is profitable; this latter I do unhesitatingly recommend, either by the method recommended above, or by uncapping stores making them run, or in some way cause the bees to load their sacs. Many say it damages a colony to manipulate, but I must differ, and say that proper manipulation is a benefit, for the very reason that it loads the bees, and the activity adds heat, and so aids.

So the foundation of success in brood-rearing is, first, strong, healthy queens, and such are obtained by breeding from colonies that show vigor, and the queens produced under conditions of proper heat, and well-fed and nourished in their developing. After this, proper heat and an *active* hustling,

working condition of the colony—not too much stores nor too little, but the bees must be handling supplies. This is practically all there is to do until the harvest season arrives.

If your location is one yielding nectar and pollen practically throughout the weeks preceding the harvest, and especially the short period just immediately preceding when the colonies have become quite populous; and if the amount of nectar coming in is sufficient to cause the filling of brood-combs at the ends and along the top-bars, together with outside combs, a condition favoring swarming is likely to prevail. Just at this period it is heat—a hive full of bees and great activity causing uncomfortable heat—nurses well fed, and feeding brood and queen well, the combs having few empty cells; with these factors you have swarm conditions, and many will get ready for the act.

## HOW TO RETARD SWARMING.

I have just spoken of the brood-combs getting just about full, so that the queen has limited laying room; and of the activity of the colony, and somewhat uncomfortable heat - conditions. Abundant ventilation given at this time will remove one disturbing factor, and will hold part of the colonies, but not all. Give a set of dry brood-combs underneath the old one, and in this one put a comb having a little brood in it—give this at or near the center. This is equivalent to ventilation, as it spreads the colony as two persons in a warm bed shifting to positions as far apart as possible, or taking separate beds in a hot night. It also gives both store and brood room, and will by all odds control in the great majority of cases. All this should be done *before* any queen-cells are started, yet, if cells are building, their removal with the changes indicated will, in most cases, relieve the bees of the swarming fever. But should the colony still show disposition to swarm, they should either be divided, by taking away some of the bees, or some of the brood, or both. The removed part may be taken clear away, and added to weak colonies, or made into new ones; or the queen may be put in that added chamber spoken of to go underneath with one comb of brood in it, and over this an excluder or a board with a hole in it, or a super between the two bodies; the idea is to make the brood-nest proper, which the queen now occupies, seem to be poor in both honey and brood, but *especially little brood*. If a board with a hole be used, the hole should be covered with excluding zinc. Also provide plenty of ventilation or shade so as not to "cook" the upper chamber in a hot sun. Remember, too, that drones may clog a small zinc; I recommend the use of regular wood-zinc slat honey-boards.

Keep these principles in mind and apply them, getting all the bees possible preceding the main harvest flow, and hold or keep these bees in some way as indicated herein, but get them if possible. And if you are so fortunate as to have conditions that will keep up the continued activity of the colony, and, above all, if you have them so that with

the arrival of the main flow you have the brood-combs just about full of brood and honey, you should be happy indeed. I do not have such conditions, but if I did I should rear early queens, and make small nuclei, and certainly strive to have a large number of nucleus colonies that would have young queens laying by the time the harvest flow came. *Such nuclei are the foundation for next year's business.* Yes, by all means get these early nuclei, if your location and conditions will at all favor such work; and even go to extra trouble to produce conditions that will enable you to get them. The *why* for this, and their value, will appear later. Let me repeat and emphasize that early nuclei, when we can have good, well-reared queens—I say *well-reared*—not bred—will prove one of your very best assets.

Loveland, Colo.

## Honey from European Foul-Broody Combs

BY D. J. WEST.

On page 133, Mr. J. L. Byer criticizes my article (page 47) on the use of formaldehyde on foul-broody combs, and thinks honey from such would be *nasty*.

When speaking of foul brood, I had reference to European foul brood, commonly known as "black brood." Honey from brood-combs where dead larvae are dried to the cells is *nasty*, and I would not like even to taste of it. An apiarist who is so neglectful as to allow brood-combs reeking with filthy diseased larvae to remain in his apiary will not be very successful in treating European foul brood.

My object in the article was to show that formaldehyde has been used successfully on European foul-broody combs. I have cured quite badly diseased combs under the treatment, but it does not give very good results on combs badly affected. I use only badly diseased combs to experiment with.

We go through each colony of our apiaries nearly every 9 days in the working season, and keep good watch for black brood, etc. If a colony is found with one to 10 cells of black brood, it is marked, and if on the next examination they are more badly affected, some kind of treatment is given. Weak, diseased colonies are not allowed to exist, and no combs with rotten brood dried to the cells are used for extracting-combs.

The brood of some strong colonies will become diseased and go down very fast, while other colonies with diseased brood will clean all traces of it. Taking the queen away for about 15 days, and then giving a virgin queen, will often prove a success. This gives the bees a chance to clean the cells of the diseased brood, and good brood will be reared in the same cells by the young queen.

I have 2 combs that were badly diseased, which were placed in the brood-nest of a strong, clean colony 5 years ago, were cleaned up by the bees, and no trace of black brood has been seen in them since.

My claims are that when the combs are stacked as stated in my first article,

the bees clean out the brood that does not hatch—unless the colony is not strong enough or the combs are too badly affected—and make them clean for honey. In badly diseased combs the bees usually cover some of the dead larvae with honey. This makes the honey nasty if extracted.

After the season is over and the honey has been extracted, the combs are put back on the same colony where they were first stacked, and left for the bees of that colony to clean up all the drippings of honey that remain in the combs. We are very careful to let no honey drip from these combs where bees of other colonies can get it. The bees of our apiaries never have access to those combs as they come from the extractor, nor to honey that in any way is liable to carry disease.

I have yet to find a treatment that will always be successful. Formaldehyde treatment has been quite successful with us in saving combs, but we use other treatments more, as we run our bees for comb honey, and prefer comb foundation instead of combs for new swarms, as they work in boxes more readily when put on foundation, and there is less danger of disease.

We produce about one ton of extracted honey per year, of which about  $\frac{3}{4}$  is taken from the unfinished sections and sold to our neighbors and private customers. We can not supply our home trade, and I don't think we have ever received a complaint about our honey.

Middleburg, N. Y.

## Construction and Manipulation of Hives

BY DR. G. BOHRER.

I kept bees in Indiana from 1863 to 1873, and during that time I had bees in 13 different styles of hive, that I can still recall. Among them was the square hanging frame—the Langstroth frame in shape, but hung with the long diameter of the frame perpendicular instead of hanging with the long diameter transversely, as it does in the Langstroth hive-body. The standard Langstroth hive was also among my lot, and mostly what I depended upon. The Quinby, or Jumbo, frame I regarded as equal to the Langstroth in every respect, except that the frames were deeper, and I thought slightly more troublesome to handle, especially at that time. The custom of wiring frames had not then been introduced to bee-keepers, hence these larger combs were more liable to break in handling.

I also had a shallow hive consisting of a bottom-board and frames made of a top-bar and a bar at each end; and, if memory serves me correctly, the ends and top-bars were close-fitting. There was no bottom-bar. A slot was cut in the sides of the top-bar to let the bees pass up into the surplus-honey receptacles. The depth of this frame was 5 1-2 or 6 inches. There was a box that telescoped over the frames, and rested on the bottom-board, with a cleated cover. I left this colony on the summer

stand to winter, and would have lost it had I not moved frames containing honey from the outsides of the hive up to the cluster, the bees having consumed about all the honey in the frames they occupied when severe cold weather came on, which being protracted, would not permit them either to shift quarters to full combs, nor to go after and carry honey to the cluster.

The above facts will point out to the beginner the danger attending the use of a shallow hive in outdoor wintering, especially in a country where very much zero weather is common. In a warm climate a shallow hive may be trusted in outdoor wintering. But there is one other difficulty attending the use of a shallow hive which, to me, seems insurmountable, in case we place a due estimate upon time. I refer to the matter of handling frames in extracting honey. Each frame must be handled separately; and, as I have shallow supers or extracting frames, standard Langstroth, and Jumbo frames, I have by actual test learned that I can not by any means possibly rid 2 shallow frames of bees, uncapped, and extract honey from them as quickly as I can take one standard Langstroth or Jumbo frame through the same process. And as the use of the extractor will become more common, and especially so since the National Pure Food Law has gone into effect, this difference in the time required in handling the different depths of frames should not—and it seems, when viewed from a logical standpoint, can not, with consistency—be overlooked and ignored. For people are rapidly learning that glucose dare not be combined with honey, and labeled and sold for pure honey, and that honey in the extracted form renders it the most wholesome as food. The fact is also gaining ground that extracted honey can be produced in larger quantities and cheaper than comb honey.

I am aware of the fact that it is claimed that bees frequently become frost-bound, and perish of starvation with plenty of honey in the hive. This is true in either a deep or shallow hive. But in outdoor wintering it will occur much oftener in a shallow hive than in a deep one, for the reason that there is less honey in shallow frames than in deep ones, so that as bees go into winter quarters, in the front and lower part of the hive, they will reach the back part of the hive in less time (of course, consuming the honey as they move back) than they will in a deep hive of the Langstroth or Jumbo pattern. I am not unmindful of the fact that an expert can winter bees in almost any shaped hive, but for the beginner to adopt a shallow hive of any name or form is a mistake.

I was in Mr. Langstroth's apiary in 1864 and saw a ring suspended between the top and bottom bars, about 3-4 of an inch in diameter, which was to enable the bees to pass from one part of the hive to another during cold weather. In Indiana I have bored a hole in one side of the hive and with a warm iron rod sharpened at the point, passed it through all the combs, being careful to perform the operation quite slowly, and turning the rod as I would an

auger. Here in central Kansas I have a dry cellar, and put most of my bees away during the three winter months, and have never lost a colony. So I am not fully prepared to state in positive language how much merit to attach to the matter of having openings through the combs near the center as a means of enabling the bees to reach their stores during zero weather. But I am of the opinion that while it may, and no doubt does, afford a source of relief to an extent, it is not a positive guarantee of safety, and nothing short of a frost-proof depository is. And in the light of my present amount of experience and observation I can not say any more in favor of any other form of hive than the Jumbo and Langstroth.

I see that the sectional or transversely divisible hive is held in high esteem by J. E. Hand, of Ohio, and J. E. Chambers, of Texas. These gentlemen say in Gleanings that with this hive, enlarging or contracting the brood-nest, supplying the bees with honey, and finding queens and queen-cells, are much more expeditious than with the deeper frame, or Langstroth and Jumbo hives. Now, while a section of this hive containing honey or brood can be placed over another section requiring food or reinforcement, I am at a loss to know how these gentlemen manage to find a queen, or learn beyond doubt the presence or absence of queen-cells without ocular inspection of every part of every comb, whether deep or shallow; and how they can make an ocular inspection without handling each frame separately. All persons at all familiar with the habits of a queen know that, as a rule, to secrete and absent herself from view is one of her strongest instincts, and that one of the sections, being only from 5 to 6 inches deep, affords ample opportunity to carry out her inclination to absent herself from view, does not admit of a doubt. Hence there is a mistake about this part of their argument. I do not desire to place a wrong construction upon their language, and if I misinterpreted their teaching, I will gladly stand corrected.

But, again, such a hive I see by prices quoted costs more than either the Langstroth, the Quinby, or Jumbo hives. And while I shall not at once condemn this hive, being in favor of investigation and experiments carefully conducted, I will say that I was personally acquainted with Mr. Langstroth (the greatest inventor of them all), and also with Mr. Quinby, that staunch old veteran bee-keeper. I learned from them in personal conversation their reasons for constructing the brood-chamber of their hives as we see them. The difference between them is but little, while the success of all who have adopted them in the largest apiaries in the United States, and elsewhere among the nations of the earth, can not be called second to any. But instead, very many who began bee-keeping with both deeper and shallower hives than either of these old, reliable stand-bys, have endorsed their use and adopted either the Quinby or the Langstroth hive. In fact, all the 13 or more different hives that I have tested were claimed by

their inventors to be superior to the Quinby and Langstroth patterns, but simply ran against a Gibraltar without having made any impression except to shrink the contents of the parties' purses who invested in these so-called improvements.

The greatest harm that has ever come to the Langstroth and Quinby hives has come through cutting good lumber into worthless fragments, and tacking them together as a part of a Langstroth or Quinby hive. The same is also true of hives frequently made of store-boxes and not put together in a workmanlike manner.

But one feature more about the sectional hive, which strikes me as a matter of doubtful propriety, is the top-bar of a frame in an under section, and the bottom-bar of the frame of an upper section, with the open space between them. All added together amount to nearly one bee-space between the combs of the upper and lower sections. That the queen will not ascend to the upper section as long as she can find

space below to lay eggs is a fact. And when she does finally go above in search of laying room, she will be very slow in returning to the section below. The truth about the matter is that a queen when left to be guided by her natural instincts prefers laying-space more than 5 or 6 inches deep, as is so often observed when she has long, deep combs at her disposal. In such cases she will invariably lay eggs in a circle, and go from one comb to another on either side from the comb in which she began laying; thus placing the developing brood in globe form, which is the best possible shape for a colony of bees to place themselves in, to economize the warmth they generate. This in a shallow sectional hive they can not do unless the bee-keeper is ever on the alert to supply an upper section, which the bees and queen will, through force of circumstances, enter. But on account of a bar below and one above, with a 5-16 space between, they will do so as a last resort, and do so reluctantly.

Lyons, Kans.

only when I find my bees getting down. In some apiaries it is necessary to introduce new blood every year, and in others it is not necessary; it is owing to the locality; it is owing to the kind of honey that is produced, whether extracted, or comb honey, and different things that come up in different apiaries; but it is quite necessary for any bee-keeper who is expecting to make a living to look to his queens and bees. When they begin to go down it is time to introduce a good strain of blood, but as long as they are up to the standard it is not necessary.

J. Q. Smith—Mr. President, the gentleman that has just spoken has voiced my sentiments. I don't think it is necessary to introduce new blood every year, you might do worse; but if you find that your queens have been superseded with inferior queens, then introduce new blood.

Dr. Bohrer—The introduction of new blood is that at some time or place degeneration will begin. Now, the question is, when does it begin? I believe that it begins first; that is, in breeding and requeening. I would suggest that good strains of bees be produced from good breeders, and by this means you will have good queens all the time. I sometimes get queens from Texas and other places, but keep them coming in from different directions. I have some queens that I want to get rid of, and I don't want the queen that stands a chance of producing a bad strain of bees.

Mr. Parsons—Those men who have just spoken have given me some idea as to the introduction of these queens, but I think that the person, who asked this question, asked it in the interest of the honey-producer, not from a honey standpoint. If your bees are not doing as well as you want them to; if they don't gather the honey that you think they ought to gather; if they are not as gentle; then I would say that it would be well to introduce new blood, but be sure that it is better than the one you have. It is a very easy matter to get something that is not so good as the ordinary; it will not do to depend upon getting a queen from an experienced and honest queen-breeder and breed from her and requeen your apiary. He may do all he can, but he has not had the time to test that queen to see if she is a good all-around queen; she may look all right, but she may be lacking in that point; so be sure that the queen you get is better than that which you have, else you may make your bees inferior.

Mr. Bergstrom—I think the question has been misunderstood. The question was this, Is it necessary to introduce new blood annually—*every year*? I don't think that there is anything exceeds the importance of introducing new blood occasionally, or only when it is needed.

On motion, the meeting adjourned to meet at 9 o'clock the next morning.

#### SECOND DAY—FIRST SESSION.

The Meeting was called to order at 9:30 a. m. Nov. 9, 1906, by Pres. C. P. Dadant.

### Report of the 37th Annual Convention of the National Bee-Keepers' Association, held in San Antonio, Tex., Nov. 8-10, '06

(Continued from page 285)

#### NEW BLOOD OR NEW STRAIN.

"I hear our queen-breeders talk about new blood in bees. Do they mean new strains?"

Pres. Dadant—I think that can be answered by yes.

#### NEW BLOOD ANNUALLY.

"Is it necessary to introduce new blood annually?"

Mr. Hatch—I would like to speak a little on that point; it seems to me the honey-bee should be just as capable of improvement as any other stock, but as I know invariably we cannot always control them like other stock, so it takes a long time. Now in the matter of gentleness, I have handled them some, and I have proven that entirely to my own satisfaction, and I don't believe that anyone can contradict it, that too close breeding would give bad results, and I believe the same thing would hold in bees; and I believe, as I said, these things may be done on account of the bees mating in the air, not under the bee-keepers' control. I don't know whether I ought to say that it takes a good while to improve them, but I will say that I have better bees than I had several years ago.

Mr. Hilton—Now, is it necessary to introduce at all? But I believe I get

the best results by introducing a new strain annually. The gentleman last upon the floor has made the matter very plain, that it is best not to keep bees to close breeding. Then, if it be true, is it absolutely necessary that we introduce new strains annually?

Mr. Anderson—I am here for what information I can glean. I think this is a matter of importance, and I am not satisfied. Now, the question arises, if you have a strain of good bees, is it necessary to introduce new blood to that strain of bees? Now, there is the point I would like information on; I would like to hear from queen-breeders. Some say if you have got one stock of good bees, keep it pure, neither breed nor introduce another blood. Is it best to keep the strain of blood as you have it, if it is good, or is it better to cross it?

Mr. Victor—I think it necessary to introduce new blood in an apiary annually; it is necessary in a wild state. Bees in their wild state seldom swarm. I say that it is necessary to introduce new blood, even if it is from the same stock.

Mr. Chambers—According to my experience it is necessary to introduce new blood. You will always increase vitality by doing so.

E. J. Atchley—These questions come up at all our bee-meetings, and I think they should be argued very carefully as they come up. I think much depends upon whether it is necessary. If we are producing honey alone, and not breeding queens, I would introduce new blood

# American Bee Journal

Mr. Hilton—I move that the chair be authorized to appoint Committees.

Mr. Hatch—I second the motion.

The motion was unanimously carried, and a recess was given after which the following Committees were appointed:

#### ON EXHIBITS.

Louis H. Scholl, New Braunfels, Texas.  
D. H. Cogshall, West Groton, N. Y.  
A. G. Anderson, Ferron, Utah.

#### ON RESOLUTIONS.

R. A. Holekamp, St. Louis, Mo.  
J. A. Stone, Springfield, Ill.  
C. C. Parsons, Bluff Springs, Fla.

#### ON AMENDMENTS.

J. Q. Smith, Lincoln, Ill.  
W. O. Victor, Hondo, Texas.  
W. H. Putnam, River Falls, Wis.

#### ON QUESTION BOX.

C. A. Hatch, Richland Center, Wis.  
Geo. E. Hilton, Fremont, Mich.  
Fred W. Muth, Cincinnati, Ohio.

Pres. Dadant—The next subject was a paper by Mr. Townsend, of Michigan, on "The Production of Extracted Honey," and the Secretary being sick has upset the disposition of papers; and as the paper may be in the mail this morning, we will therefore take up the question-box at once, unless someone has something else to propose.

#### CLARIFYING BEESWAX.

"How can beeswax be clarified?"

Dr. Bohrer—In order to determine what is used to get the wax clear, the best method of refining wax that I know of is that one used in the United States Depository. Go to your druggist and look up the refinement of beeswax; it is given in detail; the directions are there. I used to do it but I will not undertake to give it today.

Mr. Rouse—I think the easiest way to solve this question is for every bee-keeper to use a solar wax-extractor, and put the wax up in the best possible shape for the market.

Dr. Bohrer—Will it make it white?

Mr. Rouse—Yes, sir.

Mr. Kimmey—I simply wish to inquire the manner in which Mr. Rouse uses his extractor. I purchased one, but it does not work satisfactorily.

Mr. Rouse—Well, I cannot say that I have had a great deal of experience with it, but what experience I have had I will give. It is built on the Doolittle plan. I use it with a double glass as a reflector to put combs on, and I believe that the double glass over the top will produce more heat from the sun, and I have no trouble to get it hot enough, and I am sure it will make it hot enough; so you had better handle it with tongs, and it will make the wax white. When it is first rendered out it is a little yellow, but put it in the sun and it will soon be white.

Mr. Kimmey—This is what I have been trying to get at. I find after the wax is put in the extractor it does not melt; new combs are all right. At the bottom I find a lot of black specks and sediment. I want to find out if anyone had the experience of render-

ing it and getting it into a clarified or refined state—whether you can do it with the solar wax-extractor. I find more or less impurities at the bottom. I have been obliged to cut the bottom off of the cake. I am not giving information, I am asking for information. I would like to have the experience of others.

Mr. Parsons—I wish to give my experience. After the wax has been rendered and run through the extractor once, then fill the pan about half full of water, put the wax back into the extractor, run it through again, and you will not be troubled with that sediment in the bottom.

Mr. Hatch—What kind of an extractor were you speaking of?

Mr. Parsons—A solar extractor. There are a great many extractors. I get hold of a good deal of wax that has been almost spoiled in the rendering, and I find that I can get more of the impurities out by putting it in a large body of water and bringing it to the boiling point, and let it cool as slowly as possible.

Mr. Kimmey—Do you soak it?

Mr. Parsons—No, sir, by boiling it in the clear water, then take it out and boil it the second time in clear water; but I find that it is necessary in the use of the solar extractor to use some water in the pan.

Mr. Hatch—I would like to say a word on this. The first speaker suggested that boiling it in water would help to remove the impurities from the wax; but this will not do up in Wisconsin, at all; there was certain material that would run through the wax. My experience has been, the sooner the wax is taken off the fire after it is melted, the better. I never found any impurities I could not remove by the solar wax-extractor. One-fourth of an inch of water in the pan is sufficient, and I clean out the comb, but leave a little of that there; it will sift out a lot of dust and finer particles. This is a great help, and I say I have seen no wax but what the solar extractor would purify.

Mr. Stone—I have found that the best thing I can do is to place the wax in a deep vessel, and keep it hot as long as I can, or let it cool slowly, and more impurities will come out than in any other way; and the deeper the vessel the more dirt will settle to the bottom, and the more the wax is cleaned.

Mr. Cogshall—As I understand it now, the bee-keepers in our part of the country use oil of vitriol, of a certain per cent, but I don't know what per cent they use; that cleans the wax when it is heated up.

Pres. Dadant—I enter a protest against the use of oil of vitriol. It will not take out the impurities.

Dr. Bohrer—I wish to join the President in advising against the use of sulphuric acids or oil of vitriol, for the reason that it will burn the comb out and take the substance out of it to such an extent that the bees will not work upon it.

Mr. Cogshall—I have had no experience with it, but I understand they use it in small quantities.

Mr. Parsons—Let us hear from the President on this subject.

Pres. Dadant—I only wish to say a few words. I think the great point is the use of plenty of water. One of the gentlemen made the remark that his wax was spoiled by the water. He used hard water; take hard water in an iron kettle and your wax will be black. Use cistern water, and you will have much better results. Don't over-boil wax, let it cool slowly, and in that way you get good beeswax, and by having plenty of water the sediments will go to the bottom; but don't try the plan stated, of using oil of vitriol.

Mr. Bergstrom—I would like to ask a question in regard to melting the beeswax. Have you had any experience with the new extractor, and have you used it?

Pres. Dadant—No, I wish to say that in regard to the wax extractor, the one that I thought gave the best results was the one exhibited by Mr. Hershiser, of New York; but the German wax-press sold by the manufacturers is very good. Have your beeswax very hot, and press slowly; leave it on the fire, and keep pressing. I believe Mr. Hershiser's machine, if manufactured, would be very satisfactory.

Mr. Ripps—I had experience with the wax while using rainwater, and used apple vinegar instead of sulphuric acids. I used that, and it does pretty well.

Mr. Rouse—Is there enough in it, in clarifying the wax, to pay all bee-keepers to do that? The manufacturer of the comb foundation will always have it nice and clear, and I believe he can do it cheap enough; and in the remarks I made awhile ago I mentioned it in that direction, so I believe the solar wax-extractor will clean the wax out enough. That is what I had reference to. I don't believe it will pay individuals to go to so much trouble to get a purifier.

Mr. Johnson—I am one that is not entirely interested in bee-culture, in making money, but I have had some experience these 40 years, and I have found, in regard to the solar extractor—I use my cappings. I take the comb and boil it, and run it through some old gunny-sacks; then I have another vessel full of hot water, say a 6-gallon can, and put the wax into this, and I find when it is cool that I have nice, yellow wax. It gives satisfaction to those that I have sold it to.

#### BEST SMOKER-FUEL.

"What is the best material for smoke to subdue bees?"

G. H. Adkins—I find that the best material for the smoker is the stems from a cigar factory.

Dr. Bohrer—The kind of bees has something to do with the case. With the Cyprians I would suggest sulphur in a mild form.

Mr. Werner—I use dry elm wood, hickory wood, or willow.

Mr. Parsons—I use titi, and find that very good.

Mr. Victor—In regard to the smoker-fuel I use, the most convenient thing is something that is always handy, that is, chips from the woodpile, and the Corneil smoker is what I prefer. With

# American Bee Journal

a few dry shavings, an old gunny-sack, and chips from the woodpile, it is good. It does not matter what kind of wood you use, but chips are as good as I have ever used.

Mr. Stone—I would like to ask Dr. Bohrer, as he suggested sulphur, if he would put it in his smoker. I want to say that some parties were repairing a church in our neighborhood; they found a swarm of bees in the roof, and they came to me to borrow my smoker to smoke the bees out. When they returned the smoker I could smell sulphur, and it did not last 3 months until it was worthless, and I could not use it; it was covered with little holes.

E. J. Atchley—The best material I use is dry moss, which is always at hand; it is in great abundance around our apiaries, and I have found it to work all right.

Pres. Dadant—You will have to ship it to us, because we don't have it up North.

Mr. Holekamp—It would not be necessary to ship moss from Texas. Old rags are plentiful, and the leaves in the fall are as good as moss; they are everywhere, and you don't have to go South for them.

Mr. Hilton—The smoker-fuel depends usually upon the locality. In some localities I can secure one thing, and in another I cannot secure it. In Michigan the best thing I find is rotten elm, that we find in the inner part of the elm tree, and I cut it up into chunks about 4 inches long, and then put in something that the bees don't object to, and that will not injure them in any way. Some of these things that have been talked about would be very objectionable, and I would have something to say to that, as well as the bees.

W. H. Laws—I wish to enter a protest against cigar-smoke; those that live with it under their noses think it is a good thing. I think what we need is something to frighten the bees—something that is not offensive, and will not anger them. We should give them a little that will not frighten but subdue them; that is all right; but this obnoxious smoke is injurious.

Mr. Jouno—I gather rotten wood, post-oak, live-oak, hickory; then I hammer this up and put into the smoker. I find this is a good smoke. I have tried tobacco and I find it does not do at all. I find that you will have to have something pleasant for the bees and pleasant to the breeder. I have tried chips and corn-cobs. As to sulphur, just give them a good charge of sulphur. I don't know about it rotting out the smoker, but it would certainly ruin the bees.

Mr. Hyde—I don't believe our bee-keepers know what is best. These Northern bee-keepers don't know anything about mesquite; they have none, but the best thing in the world to subdue bees is the smoke from rotten mesquite. We can pick it up anywhere; and you can break it up with the hands. Let it be rotten enough to break with the hands, and I think it is the best fuel. I have heard sawdust recommended; we don't have much of that down here. As one gentleman said, different localities have something to do with what

we use, but here in our country we don't find anything equal to rotten mesquite.

D. C. Milam—I have heard it said that the thing that is most convenient is the thing to use. I find the best smoker-fuel is cedar-bark; it is handy, and you carry it around with you; it makes a mild smoke; but there is one objection, it creates considerable creosote; but cedar bark is best I think.

## FREIGHT-RATES ON HONEY.

"Freight rates on comb-honey are too high. Is there any help from the National Bee-Keepers' Association?"

Pres. Dadant—We ought to hear first from the one who put the question. Let us hear from him.

Mr. Muth—I put that question. The classification of comb honey is not even considered by the freight officials on the railroads north of the Ohio River, which could be easily remedied if it would be taken up by the National Bee-Keepers' Association with the proper officials. For instance, the Western classification of freight on comb honey, (this applies west of the Mississippi River), reports a 1½ rate. West of the Mississippi Valley it is a 1½ rate. A 1½ rate means 90 cents or \$1.00 through Wisconsin down to Central Indiana, where it ought to be about fourth-class rate. It is classified 1½, first-class, 1½ rate. We don't take care of the honey in shipping it; you can see it coming in boxes. The railroads don't even know what it is. Mr. France ought to be the man to answer this question better than I.

Mr. Holekamp—Would not the classification on extracted honey be fourth-class, when we get honey from East of the Mississippi River? North of that country is not in the Western classification, but the classification there is second-class. Now, I would think that it is worth while for this Association to take this up and have it uniform. While I can ship extracted honey from parts west of the Mississippi River at 26 cents, the same distance east of the Mississippi costs 56 cents. I have been taking this up with the freight agents at St. Louis, but they tell me this is to be taken up with the others.

Mr. Bacon—The railroads of the United States are divided into three classifications. West of the Mississippi River it is the Western Classification; east and north of the Ohio it is the Eastern Classification; and south and east it is the Southern Classification. Now, we are getting a cheap rate west of the Mississippi River; we are getting a cheap rate from the East, but we found that it cost over \$1.00 to ship into Alabama and Mississippi, where the rate to Havana, Cuba, was 59 cents from Watertown, Wis. It does no good to write letters to the railroad officials; we should send a representative to the different railroads which compose these Classification Committees; it is easy to turn a man down who writes letters, but it is harder to turn a man down who walks into your office in person. If you will send your representative to St. Louis, when the Southern Classification Committee meets, and also advise them in advance, they will hear you. Railroad men know very little about

honey, and I believe if the matter can be properly placed before the Classification Committees, a remedy will be granted.

Pres. Dadant—Can any of you suggest some other plan?

Mr. Boyden—I would not be able to tell you a better plan. I think the plan of Mr. Bacon is the only plan to go by. I know it does not do much good to write letters.

Pres. Dadant—Mr. Putnam is a great shipper, let us hear from him?

Mr. Putnam—I have had experience with railroads on getting rates for supplies. I had our samples of goods at St. Louis, and I set the case before the Western Classification Committee in Chicago; and I accomplished some good at that time, but I have noticed that there are other parts in the United States that are not heard by the Committee, and the rates are very much out of proportion. I think it would be well for the National to take this matter in hand.

Mr. France—If I remember rightly this Association passed resolutions to appoint a committee to go before the Classification Committee and lay this matter before them; but they only partially accomplished what they sought for. The freight-rate on extracted honey at that time had very little distinction as to the package, making the rate very high, no matter what the package was. We secured a rate which would include 65 cents, but on comb honey there had been so many damage claims put in against the railroads for breakage that they would not listen to a change. I do hope that some steps will be taken to take this matter up with the different companies of the Freight Classification. I went to Chicago and asked them to change the rate from 2d to 4th class. They seemed to hesitate, but when I presented the can, "Why, sure thing," they said; "that is entirely in wood." I did not want to change it, because the old square-top left it open so anyone could take out the honey, and then a claim was put in against us for the loss of honey. They gave me a copy of what would be instructions to the agents of the Western Classification Committee, so that honey was changed to 4th-class entirely encased in wood. I was afterwards informed that there have been many damage claims where honey was shipped in cases of two 5-gallon cans, and they changed the freight classification in Kentucky and Tennessee, and I was told also in Texas; that the boxes must be metal-bound, to keep the wood from pulling off.

Mr. Laws—This information came to us, and the cases are metal-bound.

J. F. Teel—We get the metal-bound, but they are not all metal-bound.

Mr. France—But I believe at present the freight is higher on comb honey than it ought to be. I think it would be well that this matter be in the form of a committee, and if that committee will go to work, and accomplish something, and let me know, as soon as any change is made, you will know it.

Mr. Rouse—I would like to know if there is any difference in classifying extracted honey, or should it be called

# American Bee Journal

"strained" honey? I have the idea that being called "extracted honey" makes it higher.

Mr. France—It does not. Some years ago I shipped a case to New York City, and in order to secure a 4th-class rate I had to bill it "syrup."

Dr. Bohrer—Are you not of the opinion that there is a body, if you make an appeal to, they will assist you?

Mr. France—Yes, sir; it would have been done long before now if some other little questions had not come up.

Mr. Kimmey—It seems to me that this is a matter which is not right; it is a wrong we have suffered because it has not been attended to. It seems to me that the General Manager is the man that ought to do it. A committee ought to be appointed to assist him, but we should furnish the General Manager with all the information we can give him. We ought to pass a resolution to act, and then we ought to make a resolution in some way to empower the General Manager. I move that this matter be referred to the Committee on Resolutions for action.

The motion was duly seconded and carried.

Dr. Bohrer—This same object I presented to the Convention in St. Louis, and it was adopted, and the aim of this resolution was the object of what we are taking a vote on now. It provided for a Legislative Committee to be appointed from each of the States, and they in turn to act through the Manager of this body, and ask for a change that might be necessary as to the transportation companies. It is said now, and it is a fact, I have no doubt of it at all, and we, as an organization, ought to look out for the matter at least, and in time. If we apply through the proper officials I believe we could get it. It is an easy thing to appoint a committee, but it is quite a different thing to get them to act.

Pres. Dadant—I believe the greatest trouble is, too many people are appointed on committees. If you have one man from each State you will probably hear from three or four states, and then the matter will drop. Get two or three men together and there will be more action. Now I want to hear other remarks.

Mr. Victor—It may not be in order, but I think there are other questions in regard to transportation that ought to come up before we settle this. For instance, I understand there is a question in regard to rates on bees, and on comb and extracted honey, and the rate on bees ought to be considered generally.

Pres. Dadant—This is a matter of importance. The Secretary will read another question on the matter of rates on bees, and we can include this before we dismiss the matter.

## FREIGHT RATES ON BEES.

"Freight rates on bees from Texas and other states are so very high. Is there any help from the National Bee-Keepers' Association?"

Mr. Bacon—The existing high freight-rates are due to the negligence of the majority of the honey-producers. These railroad men are not familiar with the

production of honey. The best thing is to get your statistics together and show them; get some samples of the shipments of honey from your different apiaries in Texas, and show them where it will be to their business interest to make the rates lower, so they will figure on this, and, consequently, the shipments will be larger, and this will put some more money into their pockets. These railroads are, as I said, divided into three classifications. First, I would suggest, take the Classification Committee that would cover the greatest movement of honey. First, I would say the Western Classification; and if you succeed, then go to the Southern and Eastern Classification, and state that you have got this from the Western; that will be very influential. If you will go before them in a business-like way, and put the matter before them, they will give you just as cheap rates as they can. I went down to St. Louis last year and got them to reduce the rates to the 6th, which got our rate down one-third, so that we can ship to-day into these Southern States for two-thirds of what we used to. I went down there with my boxes and samples, and I told them the amount of honey that had been shipped out of a certain place in Texas, and these men opened their eyes; and I told them what the honey industry was in the South, and they responded.

Mr. Stone—I believe in all of this discussion, that any committee that we will appoint along this line will do us no good until we begin at the other end, and we learn from our General Manager that the trouble was soon gotten over when they got to the 5-gallon cans in a case together, and then it had to be iron-bound, and they got their rates. Now, we will never get rates on comb honey until the bee-keepers begin to do their part. I know men shipping comb honey to customers 200 or 300 miles, and they just ship it in 12 or 24-pound cases with the glass exposed, and not put together; but you pack your cases in a good box, about as heavy as two men want to handle them, then lay handles clear across the sides; and if the bee-keepers will do this they will have no trouble in getting these rates; we will get them for the asking. This is my experience. I have heard railroad men say that men will break the glass and eat the honey, and we will have to pay for it. I believe the trouble all lies with the bee-keeper in the manner he ships his honey.

Mr. Anderson—You are getting pretty close to me now. Why are we members of the National Bee-Keepers' Association? We figure it like this: Because in unity we think there is strength. We think through the united efforts of the bee-keepers of the United States results can be accomplished for the good of the honey-producers of the United States. Now, for instance, Mr. Muth, I understand, says that the Lord gives help to those who help themselves. The good efforts of Mr. Toepferwein did not reach us all; we did not think that we would have to pay full fare to get down here, and when I asked for rates they said, "We have heard nothing from the National Bee-Keepers' Association." Now, then, we have a good

country in the North for producing honey, and there are good localities in the South for the bees, but when we have to pay \$450 to transport a car of bees there, we cannot afford to buy or sell them, when you can obtain a car to transport horses and other live stock for \$150. I know that through the united efforts of the Association, through the Manager, we can obtain better results. Now, I don't want to encourage all the bee-keepers in the South to ship their bees up North when there is a honey flow on, but we expect to buy from them. Now these rates can be obtained if some one—the leading officers of this Association—are empowered, and will go at it with energy. I think we should not rest until we get it.

Mr. Holekamp—The work which Mr. France did before the Western Classification Committee was satisfactory as far as extracted honey goes; but there are these different committees, because extracted honey bears the same identification all over the country, while the Western Classification is 4th and 2nd class; therefore it seems necessary that these different Classification Committees ought to be interviewed wherever their headquarters are, and it ought to be handled through their headquarters.

Mr. Victor—I had a little experience in shipping bees to Colorado. They charged me \$200 per car from Wharton, Tex., to Colorado; the distance we can travel in 36 hours on a passenger train. While we are paying two or three times as much as cattle, the cattle have more attention than the bees, unless we instruct that they be treated right. We only get one transportation while with cattle we get two. I wanted to experiment along the line and take care of some honey in the summer and ship them back in the winter and increase them, but the rates were so high I could not think of it at all. We Texas bee-keepers sometimes have a good many bees to spare; we can look ahead and see if our seasons are not going to be very good, and if the rates were not so high I think we could ship bees from Texas to other points to quite an advantage, and I believe if the railroad companies would take this matter under consideration it would be easy for them to see that by giving us a lower rate on bees, they would have more to handle, which would more than over-pay the difference on the present rate.

Pres. Dadant—We should go, ahead and try to get a better rate, as this matter is of great importance to us. We ought to have a committee all the time interviewing those Classification Committees, so as to get matters reduced; and I believe we ought to require this Association to name the men who are to serve on this Committee. I believe also that the Board of Directors will willingly grant the sufficient amount to pay for the expenses of the men who will interview those Associations. This matter is of importance to the bee-keepers.

J. Q. Smith—I think that that Committee ought to find out from the railroads what sized package would be acceptable to them, and have a satisfactory box, certain weight, and enclosed

# American Bee Journal

in a certain way, that would be acceptable to the railroad companies to handle. Now, in car-lots there is not so much danger, but in small packages is where the trouble comes in.

Mr. Kimmey—I wish to re-state that my motion was that this matter be referred to the Committee on Resolutions. This slip was handed to me; it reads, "Ship your honey in proper packages," and the man who handed it to me said, "I have handled it in small packages, and I have carried the package in my arms on account of the small packages getting broken." It is the duty of this committee to advise us what kind of package to use.

Pres. Dadant—It will save time to refer to the Committee on Resolutions, because they can discuss it and present it to us later.

The resolution was adopted.

## ADVERTISING TO SELL OR TO BUY HONEY.

"Which would be the better way to advertise honey, in a bee-paper that bee-keepers read, or in a public newspaper that thousands of people read?"

Mr. Werner—I asked that question. I have advertised honey for sale, in bee-papers, and not gotten as much as a postal card; and then I have advertised in the St. Louis Post-Despatch and sold as much as 3,000 pounds of honey.

J. F. Teel—If I were going to try to buy a whole crop I might advertise in a bee-paper; but if I want to sell it out in local lots I prefer the newspaper. I have found the Dallas News to be the best medium to sell through, and I have sold something like 3,000 pounds from one advertisement.

Mr. York—I think it depends a great deal upon the class of people. If you want to sell to consumers, advertise in the newspapers; if to the dealers, advertise in the bee-papers.

## ANY PROGRESS IN NON-SWARMING BEES?

"Has there been any progress made in the past ten years towards securing a non-swarming strain of bees?"

Mr. Chambers—I believe from my experience that there has not been any success. For 4 years I have had no swarming in my apiaries. I have had no success as far as I know, and I don't believe that there has been a practical advance in that line.

O. P. Hyde—I don't think the nature of bees today is the same as it was a few years ago. I think the nature of swarming is just the same, and they are swarming just as they used to swarm, because of instinct; and, so far as any progress being made in the bee within the last ten years, none has been made. You will see this in advertising, "A non-swarming bee;" but I think the non-swarming bees and the breeding of the long-tongue bees—there is nothing in them; I think it is only a catch to make a profit and sell bees. I think the bee's tongue is as long as it was a thousand years ago, and they swarm under the same surroundings. Now, I don't know if I have had two swarms this year. It is the nature of bees to swarm; give them plenty of room. If you want your bees to swarm, put on a box of sections and have nothing

above and no foundation in the section, and your bees will swarm right away. Put on new supers, give them plenty of room, and see that they are off the ground.

Dr. Bohrer—Are there not some races of bees more inclined to swarm than others?

Mr. Hyde—Yes, sir; the Holyland bees are the hardest to control. I am glad you mentioned this. Another thing is to go through the hives and clip the queen-cells. I go through my hives once a week—just as soon as I think they are fixing to swarm; and then I go there and clip those cells; but the Holyland bee is the most prolific bee that we have in the South, and it is a bee that will breed up and make a strong colony quicker than any other race.

Mr. Victor—I cannot see why we cannot make selections in regard to the honey-gathering, color, or anything else. As for my part, with the same management I had a few years ago, I would not have over a fifth what I had when I commenced. I think the disposition of the bee can be selected in regard to swarming, and as to stinging; and I think the conditions under which we rear our queens have a good deal to do with the disposition of the queens. If we rear our queens under the swarming impulse, those queens will naturally want to swarm more than those that were not around the swarming bees; and I am satisfied, so far as I am individually concerned, that my bees will swarm fully 50 per cent less than they would six, eight and ten years ago.

## NON-SWARMING AND COMB-HONEY CONDITIONS.

"What is the best plan to keep bees in out-yards from swarming, when running for comb honey?"

Sec. York—Mr. Louis Scholl is asked to answer this question.

Mr. Scholl—I don't know whether I can answer that question, because I do not produce section honey as they do up North, and I always produce comb honey in connection with extracted honey.

E. J. Atchley—I have some experience along that line, producing comb honey in out-yards, and I have failed to prevent swarming, as a rule; but on general principles, the best plan under all circumstances is to try to have a virgin queen in each colony in the out-yard at the beginning of the honey-flow. In other words, I suppose that should mean apiaries where some one should be there daily, and our queen-breeders can nearly always have young queens maturing or hatching at any season of the year. I know but few instances where I had swarms in other sections on black comb where I had a virgin queen in that colony at the beginning of the honey-flow, and this is a pretty easy matter. Every man should study his honey-flow, and know just when it comes, and at the proper time arrange to have the queen in each colony.

Mr. Kimmey—Is the result accomplished by reason of the absence of the laying queen rather than the queen being a virgin?

Mr. Atchley—I like to have colonies that are queenless during a honey-flow. When we have a virgin queen in that colony it is supposed to be a colony that is well organized, and more bees can be supported from the brood, simply because there is less brood to care for and less pollen, and, consequently, the bees in the supers store more honey because they are in shape to do so.

Dr. Bohrer—My own personal experience is that during the swarming and honey-flow seasons, to give them plenty of room has something to do with it. I almost entirely use a two-story hive, and by extracting some of the honey above and using the queen-excluder; and if the queen is confined below, it seems to subdue the inclination to swarm.

Mr. Anderson—There is a matter in my mind that is very important, and now we are in the middle of our convention. It is going to trend towards decline from now on; members are going away because their tickets are exhausted, and they are needed at home, and we all have faith in the good judgment of our President in the appointment of committees. The question of freight-rates ought to come before the body from the Resolutions Committee this afternoon. Could the Committee prepare it this afternoon or this evening? We desire that no one leave until this is settled. Now, then, we produce bees and honey to sell, but the freight-rates are so high we cannot sell them. In the North there are as good members as there are here; they are not here because the tariff is too high. If they were here they would voice their sentiments as affecting the tariff. Now, then, we know that with this matter being put in the proper hands it is going to result in good.

Pres. Dadant—The Committee will make a report this afternoon in regard to the transportation question. Now, Mr. Adkins started to make a statement in regard to a personal matter, let us hear from him.

Mr. Adkins—I ask that we adjourn till 2 o'clock this afternoon.

The motion was seconded and carried.

## SECOND DAY—AFTERNOON SESSION.

The members were called to order by President Dadant, who said, "We are yet without the papers that were to be read, but some one has gone to the postoffice for them, so we will proceed with the questions until the papers come. The Secretary will read the next question.

## YOUNG QUEENS TO PREVENT SWARMING.

"Can I prevent swarming by the introduction of young queens?"

Dr. Bohrer—As no one seems to want to take the matter up, I will give my own observations. I have given a queenless colony a queen just before she was hatched, and was almost white, and sometimes they are well received, and I have never known them to swarm again. I don't know whether there would have been any difference if I had introduced a fertile queen. When I was a queen-breeder, the queens were almost white when they were first

hatched out. Walking about among the bees in Kansas, I think year before last, I tried that sometimes and the bees would not take to the queens instantly, and would not accept them, but I did not try this year, and do not know how they would have received them; if it had been a fertile queen I don't know what the result would have been. I might say that the first time I ever saw this done was in the apiary of Mr. Langstroth, in Ohio, and when she came out she was not yet colored, and in a half or three-quarters of an hour she had begun to turn and seemed to be paying no attention. Mr. Langstroth said, as a rule, they were accepted when they first emerged. But as to a means of preventing swarming, I don't know.

Mr. France—That varies according to the latitude and condition of the season. If a honey-flow is coming in rapidly, and the swarming fever has already advanced, it is pretty hard to stop it. The time to check the swarming fever is before it has fully developed. I think a change would check it.

Mr. Hatch—I have tried almost every kind of method that has been suggested, and all the methods I could think of, and have always found fault with every one of them. One plan would weaken the colony so as to cut off the honey-flow, and another plan would weaken me so I was not fit to get the honey, and so I let the bees swarm. One plan is to put a queen-excluder above the colony, and put a hive on the lower box.

#### PREVENTING HONEY-GRANULATION IN GLASS JARS.

"How can extracted honey be prevented from granulating after being put in air-tight glass jars?"

Mr. Holekamp—There is being put on the market honey from California that is claimed doesn't granulate. Now, our honey granulates, but there is a way of preventing this granulation, because this California honey doesn't granulate. I would like to know if there is any way of preventing granulation without adulterating honey, without changing the character of the honey?

J. F. Teel—I was brought up in Alabama, and in that country there is a grade of honey that never granulates. It is also true in Mississippi. While it is not a real, first-class grade of honey, it is fairly good, and people prefer it, who are accustomed to it, and prefer it to real white honey; but there is a honey that is pure that doesn't granulate.

Mr. France—I will say that of some 60 kinds of honey over the States I have been learning something. I find that the honey from the North has a tendency to granulate much earlier than that in the Southern States, as a general rule, so I believe there is something in the latitude. The flowers and the locality have something to do with the granulation.

Mr. Rouse—My experience is that extracted honey, well ripened, will not granulate. I have had it in an open room, that is, the shop or factory where I work, and I have kept it there all winter and it has never granulated at

all. It was well ripened when it was extracted. Sometimes it granulates and sometimes it doesn't, but I cannot tell you why. I think there is an element in the honey or in the weather, or something.

Dr. Bohrer—I think the kind of honey has something to do with it. In Central Kansas alfalfa honey will granulate sooner than any other honey. I don't eat anything sweet at the table except honey, but at home I drink hot water, and I season it to taste with alfalfa honey. My folks have a large bottle with a glass stopper, in which they prepare this honey, but I have to superintend it and put it in warm water every two, three or four weeks, so it will not granulate. Now, I have no other distinct and superior variety of honey that I am able to speak of. The fruit blooms are consumed during the breeding season, preparatory to the main honey flow. The kind of honey has something to do with the granulation, and I don't know of any preventive, except warming it in warm water about half an hour.

Mr. Hyde—I have had a little experience with it. I find that there are two conditions that will granulate our honey; that is, the coming of the cold weather will always granulate all of our Texas honey; but we have a honey here we call the "catclaw," and we sometimes get what we call a crop of 30, 40, to 50 pounds to a colony and this will granulate in July or August. We always harvest it before the first day of May, and it will granulate when the thermometer stands at 90 or 100 degrees. Our catclaw or mesquite honey will not granulate until the coming of cold weather; so the cold weather has something to do with it, I think; but the source from which it is gathered has more to do with it. I had a vial of honey shipped from Cuba, from one of our Texas bee-keepers, W. W. Sommers. I kept that honey for two years and it never granulated, and the same can be said of the California honey; it will not granulate under two years. The granulation is caused from the source from where it is gathered. Is there anyone here who knows what the honey is gathered from in California? I would like to hear.

Dr. Treon—With reference to the granulation of honey, I want to give the bee-keepers my experience, while I have not been in the business over four or five years. I had an early crop of honey that comes from the catclaw; this is our first surplus crop, and some of this granulated before it was all seasoned. I don't know of any other honey that granulates as quickly as our catclaw honey. As Mr. Hyde just said, I saw some that was brought from California, gathered from sage-brush, and it had been in a bottle and was as clear as I ever saw. I saw it in Hot Springs Ark., about a year ago. Now in reference to our other honey, the mesquite honey is a little slow to granulate, but as Mr. Hyde said, it will granulate on the coming of cold weather. Horse-mint honey will even granulate in hot weather.

Mr. Laws—My experience is that all early honey will granulate much quicker

than the honey produced in the Fall. Our catclaw and waheah will granulate sooner. I pack the comb in 5-gallon cans, and unless I sell it soon it will granulate. Our fall honey does not do this. Our honey that is gathered in rainy or moist seasons granulates slowly.

Mr. Teel—I went over into Uvalde one day, and slept that night under a catclaw tree. The next morning, when I woke, the first thing I noticed the bees were gathering honey from this brush. By 12 o'clock the temperature was warm and the honey was candied. It candies every 24 hours in August over there.

J. M. Hagood—I think sudden changes of the weather are the causes. If we all had cellars to store our honey in, I don't believe we would be bothered with granulation so soon.

Pres. Dadant—I personally have no objection to this. My experience is that early honey granulates before the fall honey is gathered; it is something in the time in which it is gathered, or the quality.

J. A. Stone—I want to offer an objection to the cellar; it will cause fermentation of the honey. If you had a furnace it will keep it all right; you want a warm place.

Mr. Teel—The cellar won't work in the South.

D. C. Milam—I wish to say from experience, that the waheah granulates quicker than the catclaw. I have extracted honey in the evening and next morning it would be granulated. Catclaw blooms in May, and its honey hardly ever granulates until some time afterwards. In regard to fall honey, I have also extracted fall honey from broomweed, and the next morning it would be granulated, and would not run; so the fall and spring honey granulates alike; but in warm weather it will not granulate as quickly as it does in the fall.

Pres. Dadant—In our climate the early honey granulates and the fall honey remains liquid.

Mr. Jones—I am from Uvalde County, Texas, and I agree with Mr. Milam. Our waheah honey granulates much quicker than catclaw. Now, our fall honey granulates very quickly, and is thick. This is my experience.

Dr. Bohrer—What do you do to turn it?

Mr. Jones—Nothing, only to heat it. As this man stated awhile ago about unripe honey, it granulates on the bottom, but it never granulates on the top; you will always find the granulation at the bottom.

Mr. Parsons—We produce very little extracted honey, but we pack our honey somewhat like the Texas bee-keepers, that is, a portion of it, that which will not injure the comb honey that will do to case, and ship it. We put that into tin boxes and extract a portion of it. I first fill the vessel full of the comb, then pour around it the extracted honey, and where I can put that honey into the cans and seal them as soon as it comes off the hives it does not granulate until the next year, probably late in the spring or the summer. If I wait until cold weather comes, along at this

# American Bee Journal

season of the year, to put it up, then by next spring it is almost a solid granulation; and it does not granulate that year if I pay proper attention to it, and by proper attention I mean keep it dry. I do that by building charcoal fires in my honey-room at intervals, owing to the state of the weather. If the weather should be damp and foggy I then go to the honey-house, build up a fire and keep it there until the house is dried out; but if, from any cause, I neglect it, then it granulates in the comb, and I think probably that would help out in almost every instance. If you will keep the temperature from getting down too low, or getting damp, it will do away with a good deal of the granulation.

Dr. Treon—I want to ask a little information and at the same time make some statements. The way I put up honey in this part of Texas, to prevent granulation of our catclaw honey, which is our first crop, I heat my extractor. We produce chunk honey; we fill the can partially full of comb honey; then pour in the extracted honey, then fill the can clear full. We cannot fill it full of chunk honey. With reference to granulation, I have had catclaw honey that will granulate in the spring and stay that way all the fall. What I wanted to ask was this: About 3 years ago we had a good honey-flow in this country—the majority of it was horsemint honey; we had lots of rain. This honey was sealed up and underwent a fermenting process, and the seals burst. I would like some one to explain this. In two or three weeks the honey would sour in the can.

Mr. Hyde—I didn't make myself quite plain when talking awhile ago. I never designated the different kinds of honey. Our chunk honey will granulate just as quickly as pure extracted honey, but our one-pound section honey will not granulate during the first winter.

Pres. Dadant—Now, we will come to the question of fermenting and the bursting of the caps. I have seen that quite often, which usually occurs with unripe honey; that is, honey that is not matured when capped, and it will ferment and burst the cappings; this is the case with basswood honey, but with no other kind.

Will Atchley—I have had some experience with the honey, and it has mostly been horsemint. I tried some experiments with it and was successful. Before it was sealed up, I carried it almost to a boiling point. The comb honey, I simply stacked it on. You take thin honey that is fermenting and it will improve from heating.

W. H. Laws—The case with this horsemint honey, if left with weak colonies, in my case, when it was placed over weak colonies for sealing and curing them, it failed to do it. I have seen this honey almost boiling out of the cells.

J. A. Stone—I have had honey that was fermented until it was not eatable, not marketable at all, and by heating it I could cure it entirely, and I do not heat it to the point of boiling.

Mr. Teel—I have had a good deal of experience where it was newly sealed, but I believe that it was caused

from combs that had got a little moisture in them, a little wetting in the fall before, and the sour, vinegar-like substance would settle in the spring, which caused the fermentation. The best thing, is to do away with the combs when they get in that shape.

Mr. Jones—I have had some trouble along that line. Maybe it would be in a low place and a wet season, so I attribute it to the moisture that rose from the ground; that the combs absorbed this, and caused them to break. I have seen it in one-story hives often, and where the ground was damp all the caps would swell; but I have never noticed it where I had bottom-boards.

## SWEET CLOVER SEED.

"Where can I get sweet clover seed that will grow?"

Mr. Stone—I think Mr. Holekamp can tell us.

A Member—I just want to say that I bought some sweet clover seed from an Ohio firm, I think about three years ago, and tried it for two years and never got it up at all. The last year I soaked the seed 24 hours, and planted it and it is up, and the clover is growing nicely now.

Mr. Holekamp—Two years ago I bought 100 pounds of sweet clover seed, I do not know who sowed it, but I understand that wherever these men have taken their Sunday afternoon walks that the clover grew all around there, and it must grow there else they would not say that. I don't say that they scattered it!

Mr. Kimmey—It is impossible for me to understand sweet clover not growing. I can not conceive how anybody can not make it grow, except people who don't want it; it grows like a weed. It has just occurred to me that sweet clover ought to be sowed in the fall.

Dr. Bohrer—The question with us is how to keep it from growing. I came very near taking up 100 plants and giving to the bee-keepers; it will grow, and can be transplanted the same as cabbage plants; then take the plants up, set them out where you want them to grow and you will never have any trouble. If you allow the seed to get musty then it won't grow; and I want to say that if any bee-keeper will send me one cent a plant, I will put up a plant and send to him this fall or next spring.

Mr. Stone—In Illinois, one of the professors at the University has discovered that there is a bacterium that is always on the root of the sweet clover. If they can get these bacteria, they say it will grow anywhere. They are advised by the professor to scrape up the dirt where sweet clover has grown, and sow it with the seed.

Dr. Treon—Most of these gentlemen who have been talking about sweet clover happen to live some place where it is raised. We people in this country have such long drouths that it has been impossible to plant it without irrigation, and even the alfalfa does not grow where it is irrigated. It may be due to the lack of bacteria. Now, I have what looks just like a tobacco leaf, and we are calling it clover. That is the only form of clover in this country, and it

grows wild. I have seen sweet, red and white clover, but I never saw anything like that, and the bees gather lots of honey from it. There is very little of it in this country. If we can make sweet clover grow here, this will be an ideal bee country.

The Secretary then read the following paper by Mr. E. D. Townsend, of Remus, Michigan:

## THE PROFITABLE PRODUCTION OF EXTRACTED HONEY

In assigning me this topic, I do not suppose our Secretary had in mind that I would say very much new or startling on this old, worn subject, but we all know that there are probably no two extracted-honey producers who follow the same, identical procedure clear through the season in producing a crop of honey. Admitting this to be a fact, it is evident that we are not all producing extracted honey to the very best advantage, which means at a less profit. Of course, the location, the environment of the bee-keeper, the number of bees one expects to handle—all have a bearing when discussing this subject.

Just a word about hives, then I will be ready to take up the main subject. We have had extensive experience with 10 and 13 frame Gallup, 8 and 10 frame Quinbys, and 8, 10 and 12 frame Langstroth hives. During the whole 30 years we have kept bees, many times the different sizes and styles were in the same yards, so comparison of the different styles and sizes were easily kept track of. The results are the two extremes; that is, the small 10-frame Gallup and the large 10-frame Quinby almost always showed up *poorest* at extracting time, and, on the other hand, those in the 13-frame Gallup and 10-frame Langstroth usually showed up *best*, with the 8 and 12 frame Langstroth and 8-frame Quinby a close second.

After this long comparison, covering several years each, many of the comparisons being with large numbers of colonies, I do not hesitate to say that for this location and my management, there is no size of hive that will produce more extracted honey, one year with another, than the 10-frame Langstroth.

Then, our preference is for a 10-frame body, using 8 of the regular Langstroth frames for our extracting upper-stories. This size and style of hive, and upper-story, suit us best, for our system of management, which I am about to describe.

The system we practice and recommend for this location (northern Michigan) for the profitable production of extracted honey is as follows:

At the close of the season (during August in Kalkaska Co., and September here at Remus), our colonies are all "hefted," and any we think have less than 25 pounds of stores for winter are fed up, to 30 pounds. This gives us from 25 to 30 pounds of winter stores per colony—ample to last until the surplus season opens in June.

Our chaff-hive colonies are packed for winter about Oct. 1; those in clamps the last of November. The latter are set on the summer stands as soon in spring as the frost is out of the ground, usually the last week of March. These

# American Bee Journal

are wrapped in building-paper for spring protection.

There is nothing more done with either paper-protected or chaff-packed colonies until May 20 to 25, when the paper is removed from the clamp-wintered bees, and the chaff removed from the chaff-packed colonies, and upper-stories are given to all the medium and strong colonies. Those familiar with this locality, will recognize this date as being about two weeks previous to the opening of the main honey-flow in June. At this date our freezing nights are usually over, and our colonies are getting strong, although there is no honey coming in during this period. Were we to leave our bees in one single story, many of them would feel crowded, and swarm at the opening of our main honey-flow. Others that did not swarm would sulk, and likely store only a part as much honey as if they had been supplied with an abundance of empty comb-room during this period. This abundance of comb-room keeps the bees in that condition so essential for the best results in honey-production. The old way was to tear down the strong colonies to build up the weak. While the results will be about the same, this handling of brood-frames is neither practical nor profitable in extensive bee-keeping. One visit a week during the honey-flow, to give comb-room to store honey in, is all that is necessary, and as we have comb-storage to hold our crop, and do not extract until a week or 10 days after our white honey crop is over, one man can attend to four or five established yards of 100 colonies each, and do all the work until extracting time, when additional help is employed.

With this system, no queen-excluders are used. Put upper stories on top. While the queen will occupy the first upper story given, by adding additional upper stories on top, she will be crowded down into the hive below long before extracting time; while if this first upper story given, now containing brood, were to be lifted up and empty combs placed between, and were to continue this practice of placing our empty upper stories next to the hive, we would be quite likely to have the whole brood-nest in the upper stories at extracting time. But by placing the upper stories always on top, without extracting, we have been able to keep down swarming, and have an extracting department practically free from brood at extracting time. We have used queen-excluders extensively for several years, and find that about every third year we have excessive swarming when excluders are used; and as we get practically the same results without them, with the above management, we are discontinuing their use.

Each yard is provided with a 12 x 16 foot sectional honey-house, with all the necessary paraphernalia for managing them, so there is no moving of tools from place to place. This makes it possible to run one or more crews at extracting time as occasion demands.

Keep piling on empty combs clear through the season, being careful towards the close not to give unnecessary room, or, in other words, get every upper story sealed and finished that is

possible, as sealed honey is of a much better grade than unsealed, even when left on the hives several days after the season closes, as is our practice.

A week or 10 days after the season closes—usually the last week in July in this locality—we begin extracting. As we have added all our upper stories on top, all our partly full upper stories will be on top at extracting time. These partly full upper stories are all taken off, and extracted separately, and the honey is sold at a less price than our best grade. This second-grade honey is as good as, or better than, most of the extracted on the market.

With this method we get about  $\frac{1}{4}$  of our crop in No. 2 stock. The No. 1 stock

not tried them, still I don't see anything hurt. The hives are heavier this year than usual. Now, I am from St. Louis, and a good many people think I cannot get any good honey. Two years ago I had about 200 colonies of bees, and I extracted from them about 8,000 pounds of honey and left 10 or 12 pounds, for spring feed. This year I have about 110 colonies and got about 4,000 pounds of honey. I put on supers as soon as I think my bees will need them, usually about May 20, and as soon as I think the first supers are about half filled I put another underneath. This year our bees worked all summer. I have some colonies which stored from 100 to 150 pounds of extracted honey,

E. D. TOWNSEND.

is put into new 60-pound cans, and brings about 2 cents a pound above the market price, with more customers than I can supply.

In conclusion, I would say: • Don't do unnecessary work with the bees. Don't do work that the bees can do just as well as you can. Don't handle brood-frames. Produce a superior article of honey, then ask a good, fair price for your product.

This is an outline of the way we are managing in the profitable production of extracted honey.

E. D. TOWNSEND.

Mr. Holekamp—I use the 10-frame hives, and if I don't use queen-excluders my queens will go up all through the hives; besides that, it makes my honey dark. I get a much better grade of honey than I used to get. The honey is clear, and it is easy to do the work, especially when fall comes I do not have to put the frames of brood down; the brood-chamber is in good condition. I raise the front of my hives about one inch, which I believe assists the bees in coming into the hives, at least I find that since I raised the hives that my bees work quicker, I mean they fly into the hives without crawling on the entrance floor. There is only one objection, and that is, a person waits too long without taking it out; but we had an early cold spell this year and I have

while the weaker colonies did not do well. A good many colonies were wild bees, which accounts for the fact of the small crop. If the bees had been kept in a fair condition I believe we would have had a better yield. We have a good deal of sweet clover which helps our honey crop. Comb honey is an entire failure with me.

Dr. Bohrer—Do you get ready sale for the extracted honey there?

Mr. Holekamp—Yes, sir.

Dr. Bohrer—I think it is known by a number of members that I am engaged almost entirely in the production of extracted honey, for several reasons. I believe it to be the most profitable method of managing an apiary where I live, and it is certainly the most wholesome form to be taken into the human stomach. And I think it saves the bees very much time and labor. A great difficulty is taking care of combs, and it requires some care. As to the manner of manipulating the frames during a honey-flow, I use the queen-excluder in order to keep the queens from going above. And I empty the honey out above and put down below for the queen to fill again, and it is the most profitable manner for me. The people are acquainted with me all over the country, and outside of it, and I find no trouble in selling my honey. I don't sell to the merchants, because they want me to take goods in exchange alto-

# American Bee Journal

gether, and I don't live on goods altogether. I put my honey up in 5 and 10 quart vessels, and a great many people will buy a quart or a pint when they use it. But taking it all in all I find it to be the most satisfactory and the easiest manner of managing an apiary. I am not in love with putting sections together.

Mr. Kimmey—The gentleman has stated that the greatest difficulty he has found is in preserving the combs for future use. For myself, I would like to know how he overcomes it?

Dr. Bohrer—I have a house that is closed with ordinary doors, and hang the frames away there. I take the empty hive-bodies and put the frames in them and store them away, and then put them away as near dry as possible, and I don't have a great many millers, yet I have some; they will get in there occasionally.

Mr. Kimmey—Do you cover those hives at the bottom or top?

Dr. Bohrer—I set the hives down on a plain board, and I don't see how anything can get under them, and the hives weight each other down; then put a cover on and put a weight on them. This is as near as I know how to get at it.

Mr. Stone—I would like to have the author of that paper here, so that I could quiz him. I don't see how he keeps the bee-bread out of the upper stories.

M. E. Darby—I will answer this gentleman's question. I just extract my honey and then put the frames right back into the supers, and when the season comes the frames are all dry, all the honey cleaned up, then I take the supers off. I have a honey-house and I have never yet had a moth to get into any of my frames. I live near Springfield, Mo.

Mr. Cook—I first store the hives and empty frames, one on top of the other, but first making it so tight below that nothing could get in there at all. Then I put bi-sulphide in that.

Mr. Hyde—Some are discussing the moth-worms and combs; it seems to me that the subject was the production of extracted honey.

Pres. Dadant—It is the profitable production of extracted honey.

Dr. Bohrer—Mr. Townsend is all right. Now, in our locality that is all right, but he is not all right on the way we do up in this country. My plan is to put the empty frames next to the brood-nest. They will work those empty combs much quicker than above. I also agree with Mr. Townsend as to the queen-excluder, but I said it does not make any difference if we run for extracted honey; we are not going to eat it, and it does not matter about the pollen that goes up there. After I get disgusted with them I call them "honey-excluders," for they certainly will exclude the honey, and exclude the queen, so she cannot lay. Now, that gentleman over there, I agree with him about the size of the hive, a 10-frame hive. I have said why I did not like the excluder, and, as I stated before, I don't care anything about the pollen, because it is not in the way; and if the queen lays up there, she will lay up there an-

nually and go down. And by the time you go to extracting again all the brood will be hatched out, and I don't care if I leave two or three combs in the second-story when I extract the first time.

Mr. Holekamp—I would like to speak about the moths eating the comb. Whenever I have comb without any pollen I have no moths; when I have pollen in the combs I have the moth. Then the second thing, I can taste the honey that comes from the pollen. I don't know how pollen tastes in your country, but it tastes very unpleasant in my country; it has a peculiar taste that I don't want.

Mr. Hilton—May I say a word in regard to the writer of this paper? I did not hear the paper read, but I live less than 50 miles from him, and there are a great many things that I know about Mr. Townsend and his methods, and there are a great many things that I don't know about him and his methods. This I do know, that he is one of the most successful bee-keepers in the State of Michigan; that he can produce the most honey with the least expense, and can run the most yards with the least men. He is a man that would not follow the occupation unless it was successful, and he is successful as to the manner and the matter of the queen-boards. I am not in a position to say why he does some of these things, but I am able to say that he does the things that are successful to him and his efforts. Consequently, he is right, no matter whether it would work in Texas, or Arizona, or any other State in the Union; but in Michigan it is a success.

Dr. Treon—I want to say something in reference to the method of keeping empty combs; that is one of the serious objections to Southwest Texas in producing extracted honey, in my observation. I take a bottom-board first and put it down; then put two sheets of paper on that, then I set the body with combs on it, and between each body put two newspapers. When I take my supers out in the out-yards, put foundation in them, stack them up and set them on a cover, there are no moths there, and they fit pretty well, and I have a number of times found those frames full of webs, that are made by small worms; they got in there and laid their eggs. The only way that I know to keep the combs is to fumigate them with sulphur, or bi-sulphide of carbon. And if there is the least bit of pollen in them, there will be no bees to protect the comb, and the web-worms will be in there in 48 hours. We cannot produce extracted honey as well as you people that are farther north, because we cannot carry over the combs. We cannot use the extractors as you do, for the reason that our bees swarm awfully, and it makes no difference if you shake them or draw brood from them, they will swarm anyhow, and some have swarmed in a day or two after I had drawn two or three frames of brood.

Mr. Parsons—While we are not producing extracted honey at present, I think I will tell you what we did in Florida. At each out-yard we have a bee-house. When the combs were taken

off they were carried off into the woods where the bees took all the honey out of them, and then were carried back to the house. The room was built 8 or 10 feet wide and across the side we put small sticks, say one or two, that extended from one side of the house to the other, enough to take our frames, and they were far enough below so the combs could hang in there. We put in other sticks until we got all the comb in the house. Then every few weeks we opened those sticks and burned sufficient sulphur to kill the larvæ that were there, and the fumes of the sulphur being so strong in there the moths were not very anxious to get in. In that way we never lost any combs. We have some trouble now in taking out the hives that are necessary to keep. We have houses built the same way, and there is no danger.

Mr. Hatch—I lost combs the past summer by the moths, and I was talking to a neighbor bee-keeper who said, "I see you are a fool, and you are as I used to be. If you will take these moth-balls and put among your hives, they will keep them out all summer long." I said, "Have you tried it?" and he replied, "Yes, I have tried it for 6 years."

Mr. Aten—In answer to Mr. Treon, in trying to cut off the moth, I have had considerable experience. I will say that it is impossible, I have taken combs and sealed them up in air-tight jars, and the moth would eat them up. The moth-eggs were laid in the colony of bees, and if you don't fumigate them they will eat the combs up. Fumigation by sulphur is a success with me.

T. P. Robinson—I am a honey-producer exclusively, that is, I produce something like 16,000 pounds of comb-honey, and there were only six or seven cases of extracted honey. In the production of extracted honey I tried to keep my colonies built up very strong. If the combs are too heavy to extract I move them to the super where the bees will hatch out, and the bees will fill them up, and I extract again. This year I extracted from the brood-chambers, and did not leave any honey at all. The bees did all right; in a few days they had filled the combs again. For the last ten years I have had no damage. But as far as the moths eating the combs, Mr. Aten is correct.

E. J. Atchley—I have had some experience in producing extracted and comb honey, and I think the locality has something to do with it. If I lived in Mr. Townsend's neighborhood, I would hardly take time to eat and sleep, or drink, until I found out from him his management for the production of extracted honey, and I believe that if Mr. Townsend were in my locality he would have to change his plans to be as successful in Southwest Texas as in Michigan. Therefore we should run our bees to the best advantage according to our own judgment, and a little brood in the upper stories, or anywhere else in a hive should not bother us. It seems that the pollen packed in the combs can be taken out almost any time. And another thing in the production of extracted honey, my plan would be what is known as the "Dadant Plan." And as to keeping combs from moths, I

think that every practical bee-keeper will keep the moths out of his combs. There are several ways. You can wash the extractor, and you can stack them up on the hives. I have three or four supers stacked on my hives today, and the strong colonies are protecting them. If I were in the North I would practice Northern methods, according to the most successful bee-keepers.

Mr. W. H. Laws, of Beeville, Texas, then read a paper on

### THE COMPARATIVE PROFITS OF QUEEN-REARING AND HONEY-PRODUCTION.

In the discussion of the question of the comparative profits of queen-rearing and honey-production, I realize that it is a question that can not be settled by mere figures, made theoretically, but a question that can be solved only by years of practical demonstration right among the bees, and that, too, by a skilled queen-breeder.

To rear good queens, and to have them for the market at all times during the queen-rearing season, expert labor is demanded; without it, commercial queen-rearing is a failure.

To the man who can secure fair crops of honey, year after year, is not always due all the credit for his success; the bees do the labor, the locality furnishes the nectar, the bee-keeper only furnishing the hives and storage-room, and takes care of the swarms.

I know just such men who make money from their bees by honey-production alone, who give the bees no more attention than that just stated; and these men seldom see a queen-bee from one year's end to the other. It is unnecessary to say that such men, though successful in honey-production, are totally unfit for queen-breeding.

Many persons, successful as honey-producers, and also familiar with the conditions generally with the interior of the hives at all times, become enthused at seeing the multitude of young queens

hatching about the swarming period, and conceive the idea that if they could only get all these young queens mated, and sell them at a dollar each, (by advertising a little), they would see the dollars roll in, while the bees were waiting for a crop of honey!

There is only one reason why a person should embark in the queen-business in a commercial way, and that is environment, coupled with a natural love for the business.

By environment, we mean where a person is so situated that he can not secure a marketable product of honey from his locality, or where the flow of nectar is slow and of long duration, so that the bees use the greater portion of the season in swarming, or as was the case with myself in a former locality where at times the honey was so bitter that it was impossible to dispose of it on any market.

Where the above conditions exist we can readily see where the queen-breeder might do well, while the honey-producer might have a pronounced failure.

On the other hand, any locality that has short, heavy flows, one or more during the season, and between these

flows comparative idleness of the bees, these conditions would be much better for the honey-producer rather than the commercial queen-breeder.

The best possible condition, therefore, for the queen-breeder is one long-continued, slow flow of nectar throughout the entire season.

In my first years of producing honey, for the market, away back in the '80's, I lived in a locality that sometimes yielded bitter honey; this flow of bitter honey would usually come late in the season, after the white honey crop had been gathered. Some seasons, however, the late summer rains would bring the flow earlier, and the bees would store it right along with the white honey. This would spoil all for market. I remember one winter, when my honey-house floor gave way because of the weight of bitter honey stored for use in mak-

W. H. LAWS.

ing increase the following season, before the busy season had arrived, I had figured out that if this bitter honey was to continue to be a product of my apiary, I would better establish some better form of disposing of it than simply making increase of bees by the use of this honey. So before spring I had already determined that it would be better to turn the product of the apiary to first-class Italian queens rather than bitter honey.

Since changing locality, moving 700 miles further south, conditions and honey-flow have wonderfully changed, and possibly had I not been in the business I would not be now known as a commercial queen-breeder.

My present locality, while almost an ideal one for the rearing of early queens, is also one that is ideal for an early white honey crop, providing weather conditions are favorable, which, unfortunately, have been against us for the past two seasons.

Then there are other features of the business that are to be taken into consideration—the ability of the breeder to rear good queens, and have them to

ship promptly at all times, in and out of season, his aptness and fitness to make and hold a market, by prompt and agreeable service; his prompt attention to correspondence; the satisfactory adjustment of all complaints; the proper caging and mailing of queens, which make tedious and sometimes long journeys through the mails; and his determination to stay with the business through adverse as well as through prosperous seasons. It is a combination of all these little details that go to make success, and it must not be forgotten that many long and weary hours must be put in at queen-rearing that are unknown to the producer of honey.

Since the keeping of out-apiaries for honey has become so practicable and popular, the advantage to the honey-producer exceeds that of the queen-breeder. Hundreds of colonies of bees can be run for honey, systematized into out-apiaries, and be made more profitable to their owner than if he were to devote the same amount of labor to the production of queens, and, necessarily, to a fewer number of colonies.

In the foregoing no mention has been made of the progress of modern or expert queen-rearing, for it is possible to rear queens at a greater profit now than in former years; but to figure the difference in the profits of queen-rearing and honey-production—just when and how this is to be done, I do not know where to begin, for so much depends upon conditions, the locality, and the man, that it would be mere guess-work.

We sometimes know of men who have produced 30,000, or 50,000, or 75,000, and occasionally a man that produces 100,000 pounds, of honey, in a single season, which when sold would bring the modest little sum of \$3,000 to \$10,000, I dare say there are none of our leading queen-breeders who realize half this amount from the sale of queens, not counting the fact that every apiary run for queens is weakened—if not ruined—by the excessive sale of this product. All colonies run for honey are easily kept in a normal, thrifty condition, while queen-rearing yards have frequently to be fed.

We now leave this subject to our brother bee-keepers of this Association, who may weigh the matter with their own minds, and render a verdict according to their judgment.

W. H. LAWS.

Pres. Dadant—The matter is open for discussion now. I think the rearing of queens in the South is of great importance.

W. H. Laws—I wish to say that this matter is of but little importance to the honey-producer. I will also say that I have made a few figures. I think that these people have spent on an average of \$40 to \$50, and, figuring it up, it seems about \$40 per hour while we are in session, and I want to call your attention to the fact that a Mexican Supper has been prepared for our members.

Mr. France—I assure you that this is a part of the program that the Northern people appreciate, and in order to make everything satisfactory, Mr. Toepferwein says that it will be wise to go soon. The distance to this first-class Mexican supper is a little too far to

# American Bee Journal

walk, so we are advised to take the car. Mr. Toepperwein will go with the first section, and Mr. Laws with the second.

The meeting then adjourned until 8 p. m., and all attended the Mexican supper, given at the "Original Mexican Restaurant."

## SECOND DAY—EVENING SESSION.

The meeting was called to order at 8:30 by Pres. C. P. Dadant. The first half hour was spent in listening to an address by Judge T. M. Paschal, who went to Los Angeles in 1903 to help bring the National Bee-Keepers' Association to San Antonio, his subject being, "The Bee-Keeping Resources of Texas."

Pres. Dadant—There was to have been a paper read at this time by Dr. E. F. Phillips, of Washington, D. C., on "What Science May do for Bee-Keeping," but as he has not arrived yet we will proceed with other business. The subject for the evening is the report of the Resolutions Committee on freight-rates. We will hear from the Secretary.

## REPORT ON FREIGHT-RATES.

We, the Committee on Resolutions, recommend that the following resolution be passed by the National Bee-Keepers' Association, in convention assembled:

*Resolved*, That a committee of three be appointed by the President, of which the General Manager shall be one and be its chairman, for the purpose of securing more favorable freight-rates on the products of the apiary, namely: honey, bees, and beeswax; That the Board of Directors be requested to pass a resolution authorizing and directing the General Manager of our Association to pay out of the funds of the Association the necessary expenses of the Committee, and such expenses as may be incurred in bringing before the railroad officials such articles as may be necessary to demonstrate the packages on which reductions are desired.

ROBT. A. HOLEKAMP,  
JAS. A. STONE,  
C. C. PARSONS,

*Committee on Resolutions.*

Pres. Dadant—The matter is open for discussion now, and I would like to hear from the members as to their opinion on these resolutions. Let us hear from Mr. France.

Mr. France—So long as my name is mentioned in the resolutions I ought to be quiet. That involves lots of work; it means hard work, and that committee will have more to do than you realize. I feel that it is of the greatest importance who that committee are. As for suggestions, the Resolution Committee has nearly covered it, what is expected. I don't know of any way that we can use the funds of the treasury to a better advantage than for something of this nature; for every one has more or less shipping, and will get direct results, whatever they may be.

Mr. York—Mr. Chairman, in order to do this I move the adoption of the resolutions.

Dr. Bohrer—I would like to hear the resolution read again.

Wm. Atchley—Does that include express-rates, or freight-rates only?

Pres. Dadant—Freight-rates only. It is more difficult to do anything with express companies than the railroad companies.

Mr. Anderson—I see dawning in the distance that which I have hoped for, at least ever since I have been a bee-keeper. The transportation facilities of the bee-keepers' products have been so inconvenient in many localities that it has actually put a stay on the progress of the industry. I have longed to see the time when the National Bee-Keepers' Association would be acknowledged by the railroad companies as a power in the Nation. I want to congratulate the Committee on Resolutions for the work they have done.

Dr. Bohrer—I, like Mr. France, think that when we tackle a question of this kind we have a big question to buck up against. All that can be done outside of actual organization, not only through the State legislative body, must be done by appealing to the railroad companies ourselves, and bringing our committees to their special notice. I believe they are reasonable men, and something may be accomplished in that way. Now, I understand that much is put up in packages that are condemned, but if these packages are more secure the railroads will take them. This committee can bring this matter to bear and present it, not only to the bee-keepers, but to the railroad companies. There is not a man or woman that has any produce whatever but feels that extortions are practiced upon them. Years ago, up in Kansas, our railroads were controlled by the Inter-State Commerce legislation, but the State can only control the railroad company to an extent, and when it passes out of the State we have no control over it; and it is the duty of every bee-keeper to make an appeal to his Representative in Congress. Whenever the interests of the country are at stake it takes the people to do it; you have to appeal to your Representative. What is the condition we find now in our Legislative Assembly? Are the true representatives of all the industries of this country over-whelmingly in majority in the House and the Senate?

Pres. Dadant—I wish to call your attention to the fact that you are getting off the subject. Keep within the limits.

Dr. Bohrer—I will do it. *There* is where you have to commence—you have to put representative men in these bodies, or you will not get justice.

E. J. Atchley—I think the question that is before this Association is one of the greatest importance that can come before this body, inasmuch as we do not consider it at all fair that the railroad companies charge us \$450 per car to transport our bees to Colorado or Utah, when a car of cattle will be carried the same distance for \$110. We have appealed as far as possible to the railroad companies, and the agents themselves have felt a surprise that we would have to pay this amount for a car when we attend to the bees, load them ourselves, take them off the cars, and bear all the burden of the journey, while the cattle are loaded by the railroad companies, unloaded possibly two or three times and fed, and they only pay \$110. Under the existing circumstances, when we take

into consideration the rates on bees, when we want to ship, it cannot be done, and I trust and hope that our President may appoint men that may bring to bear, with the force of himself, such a great need of a lower rate on bees that something will be done, and that we will get this lower rate in the near future. I trust he will use his best judgment in selecting this committee.

Mr. Hilton—The resolution that is before the body is certainly a very important one, and much has been said touching directly upon the subject, and perhaps some things have been said that did not touch directly upon the resolution. Having had some experience from a legislative standpoint, I don't know whether appealing to National Legislation would help us very much; but this I do know, the country is divided up into divisions by the railroad companies, and if we act in concert we must appeal to first one division and then the other, until we get the three divisions of the United States to act in unity, to get the best results. I think that the railroad companies are ready to act when they learn the situation, and I understand that they have been informed to the extent that they have made the concessions asked for, and as a committee-man for two years in my State, I found the railroads were ready to listen to men that would interest themselves, and railroad men and railroad corporations are just as ready to respond to the pleas of good men as the President of the United States, or any other man. And, as I say, if this resolution is carried, and this committee pursues its work diligently and personally, a better state of affairs can be brought about, and it behooves us to do the things that are going to help us and our fellowmen. And I say again, that I believe the railroad corporations will meet us with open hearts and open hands to do those things that will increase their business, and decrease our expenses and increase our profits.

Pres. Dadant—If there are no further remarks, I will put the question: All in favor of this resolution signify by saying Yes. Opposed, No. The motion is unanimously carried. The committee has asked that Mr. France act as Chairman. He is one of the best workers. The man who brought this before this meeting is Mr. Muth; he deserves to have a share in this matter, and should be upon the committee. I so appoint him. The third man ought to be a bee-keeper who understands transportation and who produces a good deal of honey, and is acquainted with the railroad companies. Mr. Holekamp should also be on this committee; he has shown what he could do, and he would make a good member. So I appoint those three men.

Mr. York—This committee is going to have a good deal to do, and nothing would help them as much as to have a large membership in this Association. The railroad men are going to ask them how many are in it, and if they could say that they represent 10,000 bee-keepers in this country, they would prick up their ears and listen. I have understood that in some parts of the country the members are beginning to drop off a little bit. It seems to me that we ought

# American Bee Journal

to go out all over the country and increase the membership. A large membership means a whole lot, and when this committee goes before the Legislature it will stand a better chance of getting what it asks for. I agree with Mr. Hilton, that if we send out these three men, and they are backed up by a large Association, they are sure to win.

Mr. Stone—I don't think anything helped us to secure our Foul Brood Law but the members that were on our roll in the State of Illinois. I believe that Illinois has more members than any other State in the National; it is up in the hundreds.

Pres. Dadant—I wish to say that Mr. Stone knows what he is speaking about and I think it is through him that most of those Illinois names have been gotten on the list. I hope that the members will help add other members to the National through the State associations. Unity makes strength.

Mr. France—While we are on the subject of financial affairs, I will make the following statement, which is a little in advance: Between Nov. 1 1905, and Nov. 1, 1906, I received dues at 50 cents each, from 832, making \$416.00, and I have received the dues of 110 at \$1.00 each, making \$110.00. The resolution that we come in a body was first presented to the National Association by Mr. York at the Philadelphia meeting. The first State to take advantage was New York. My own State (Wisconsin) immediately followed, until nearly all of the States have taken advantage of it. Our expenses this year have been a little more than our total income, and you will see where the expenses have been. On the postal cards calling for reports, I gave suggestions, wherein the National might improve. Too many have looked toward the Manager of the Association to do the work and to make the improvements. I cannot accomplish that alone; it needs your assistance, and those crop report postals with personal suggestions have helped me in more ways than one. I wish more of you would take advantage of the Information Bureau. It is worth more than it costs. I am glad this freight-rate question has come up. Then another question has come up: Cannot the National market the honey? I hope you will never ask the National to sell your honey. It is too big a job. But I do believe that all our State and local organizations can do a great deal in that line. Each bee-keeper ought to sell his own products. This has finally resulted in my getting up what I call a "Seal Label" for the Association's members.

Mr. Muth—Referring back to the committee on freight-rates, don't you think it would be a good idea to have the members write us suggestions?

Pres. Dadant—This you can call for, and let them understand it. Any suggestions to the chairman of the committee will be communicated to the other two members—any information in regard to rates, honey and beeswax.

## THE LEAGUE FUND.

"Has the National Bee-keepers' Association received the fund mentioned at the last meeting, from the Honey Pro-

ducers' League? If so, what is being done with the money?"

Mr. France—There was turned over to me on May 30, 1906, the amount of \$1,408.27. There was to be a committee appointed to use it for the purpose for which it was originally intended. The Board of Directors were to appoint a committee. I was notified as Treasurer of the Association that I would be one of that committee, and was asked to suggest some others to work upon that committee. I said, "Let the President and Secretary of the League be the other two. The Secretary is expected to act conditionally, but the President, Dr. Miller, declined to serve, and until a third man is selected nothing can be done. We want a committee that will give it justice and satisfaction. I think, however, that in the near future the fund will begin to move in the direction intended. It is not wasted, the fund is lying there, and there are no commissions on it.

## SOMETHING HISTORICAL.

Dr. Bohrer—I was at the first National meeting of bee-keepers held in Indianapolis, in 1871. At that meeting we received a telegram from Mr. King the editor of a bee-paper, the name I do not know. He was manufacturing and selling a good many hives known as the "American Bee-Hive." At that time the ability and claims of Mr. Langstroth were called in question, and we received a telegram from Mr. King requesting us to meet the bee-keepers in Cincinnati the following February. We agreed to meet them there. Another association was organized called the American, and we concluded to meet one year from that time in Cleveland and unite the two. Mr. Quinby was elected president. I was elected as the vice-president. Mr. M. M. Baldrige and I were there. Mr. Langstroth was at Cincinnati. And speaking of the matter of pictures, we have the photograph of Mr. Adam Grimm: If any of the bee-keepers would like to see it, I would like for Mr. York to exhibit it, as he has it, I think. I also thought I had given him D. L. Adair's photograph, but I think that possibly I have that at home, and, if so, I will send it to Mr. York and have that published, because Mr. Adair, I think, perhaps, gave the first idea of the honey-section so extensively used among bee-keepers. He gave me one of his hives and sent it to me. I think there, perhaps, originated the idea of the section. That is about as much as I know about the first Association. In Cleveland it was known as the American Bee-keepers' Association. The first one was known as the North American Bee-keepers' Association. I think that the third meeting was at Cincinnati. That is the early history of this Association so far as I learned it.

P. D. Jones—I subscribed for the American Bee Journal in Cleveland, Ohio, in 1871, and have taken it ever since. Captain Hetherington, of New York, was also there.

Mr. Coggs—I have had the American Bee Journal since 1861. It was published in Washington then. I have all the back numbers.

Dr. Bohrer—Does anybody know the name of the editor that published the paper shortly before the American Bee Journal was resumed?

Mr. Jones—I can not tell you now who published it, but I have all the numbers at home. I can tell you when I get home.

Pres. Dadant—These are reminiscences of our old members, and we are glad to hear from them.

Mr. York—I think it ought to be made a matter of record that Mr. P. D. Jones, of New York, and Dr. G. Bohrer, of Kansas, who were present at the first meetings of this Association, are attending this meeting.

## NATIONAL OFFICE-HOLDERS.

"Is it true that some office-holders of the National Association are abusing the confidence of the membership for purely personal gain? A charge of this kind has been made against supply dealers."

Dr. Bohrer—I will inquire who the officers are, except it be the President himself. If they are swindling anybody it has not hurt me.

Mr. Muth—I should think that such sorry questions should be thrown in the wastebasket.

Dr. Bohrer—I want to say this: We ought to be pretty certain that it has been abused, and if anyone knows of an officer that has been abusing this confidence, he ought to speak out.

(Continued next week.)

**Honey as a Health-Food.**—This is a 16-page honey-pamphlet intended to help increase the demand for honey. The first part of it contains a short article on "Honey as Food," written by Dr. C. C. Miller. It tells where to keep honey, how to liquefy it, etc. The last part is devoted to "Honey-Cooking Recipes" and "Remedies Using Honey." It should be widely circulated by those selling honey. The more the people are educated on the value and uses of honey, the more honey they will buy.

Prices, prepaid—Sample copy for a 2-cent stamp; 50 copies for 70 cents; 100 for \$1.25; 250 for \$2.25; 500 for \$4.00; or 1000 for \$7.50. Your business card printed free at the bottom of front page on all orders for 100 or more copies. Send all orders to the office of the American Bee Journal.

**Why Not Advertise?**—There are many dealers in bee-supplies, and those who have bees and queens for sale, who are not now advertising, that might increase their business by advertising in the American Bee Journal. The rates charged are very low, as will be seen by referring to the second page of this number. During the next 6 months will be done the bulk of the season's business among bee-keepers. Why not begin at once to let the readers of the American Bee Journal know that you have something to sell? Our advertising columns are open only to those who will give their patrons "a square deal." If you are in that class we will be pleased to have your advertisement in our columns.

**The San Antonio Convention Picture** is a good one. It shows over 100 of those in attendance. We are mailing them, unmounted, for only 60 cents. They can be mounted by a local photographer for only 10 or 15 cents more. We will mail one of these pictures with the American Bee Journal one year—both for only \$1.40. Send all orders to the Bee Journal office.

Conducted by J. L. BYER, Mount Joy, Ont.

## How to Clip the Queen

By the time this is in print, bee-keepers in some localities will have clipped their queens, but in the more northern parts the majority will be just thinking of starting at the work. Nearly every bee-keeper has the "best way," and as the writer is no exception to the rule, I want to tell you how I proceed in this important part of the work in the apiary.

Nearly all instructors say "catch the queen;" but in my estimation this is entirely unnecessary, as I never think of touching a queen with my fingers unless once in a great while one should happen to leave the combs and be found on the side or bottom of the hive.

However, we have to *find the queen*. This done, the lower corner of the frame is let rest on the hive, and is held by one end of the top-bar in the left hand. In the left hand is held a fine pair of curved-pointed surgical scissors bought expressly for the purpose at a cost of 60 cents. As the queen runs up the comb, slip the point of the scissors under wing or wings as desired, and the work is done quicker than you can tell how on paper. It may seem a little difficult at first, but by practising on drones it is surprising how easily you can become proficient at the job.

The past 2 seasons I have clipped at least 200 queens each spring this way, and have never made a mistake. I am quite sure that every year a lot of good queens are balled and lost after being handled; with the method described the queen very often hardly notices that she has been touched.

One of Ontario's extensive apiarists spent a day with me last year during queen-clipping, and he declared that I "did the work too quick for him to see *how* it was done," and at *different* times I had to point the queen out to him after she had run around on the other side of the comb, in order to convince him that I really had clipped her wings.

I am quite sure that after one has learned "how," that he will never go back to the old way of catching the queen in his fingers.

## Sugar-Maple Sap for Bees

A few years ago, while we yet had considerable forest near us, we usually expected our bees to gather considerable of the sap from the sugar maples, that would evaporate on the stumps of trees cut during the winter. I have

seen them during warm days the last week of March and first week in April, working as busily as though there was a regular honey-flow on, and whenever the weather was fine at this season of the year, the brood-rearing received a tremendous impetus.

I remember one spring the branches of the trees were badly broken by an ice-storm, and the sap was oozing out of the hard maples everywhere. Strong colonies stored as much as 2 combs full of the syrup, and one warm evening there was a roar in the apiary as though we were in the midst of a honey-flow.

I am sorry to say this is a thing of the past here, as we now have very little bush left; but this does not prevent me from *thinking* what I would do if I were located near a large bush of sugar-maples. About the time the boys say "sap's runnin'," I would with a light hatchet score lightly on the south sides as many maple-trees as possible near the apiary. To be sure, if the trees were not on my own property I would first secure the owner's permission to do the work.

While we do not often hear anything of the sugar-maple's value to the bees in the early spring, yet there is no question that they are a great help, and at least a few bee-keepers every spring follow the plan I have just outlined.

## Mr. Craig to Continue as Editor of Canadian Bee Journal

On Feb. 11 the bee-keepers' department of the Goold, Shapley & Muir Co.'s establishment was badly damaged by fire, as mentioned on page 228. At the Brantford convention a number of us visited the factory, and while walking through the storeroom where a very large supply of frames, sections, hive-bodies, etc., was stored, I remarked that this would be a bad place for a fire, little thinking that within 2 weeks all of the stock would be destroyed. Fire is bad enough at any time, but particularly so in an establishment of this kind in the early spring, when the bulk of the next season's stock is all ready for shipment.

The bee-keepers' supply business was merely a side-issue with the Goold, Shapley & Muir Co., their firm being extensively engaged in the manufacture of windmills, galvanized tanks, concrete mixers, etc., and in view of the fact of their wood-working plant being destroyed, they decided to sell

out the bee-supply business to Messrs. Ham & Nott, a firm that has engaged in the wood-working business in Brantford for some time. This firm has also taken over the Canadian Bee Journal, and I understand that Mr. W. J. Craig will continue as editor.

The Messrs. Ham & Nott have our best wishes, and we trust that the supply business may be a success with them; and also that the Canadian Bee Journal, under their management, will be a live medium, and truly representative of the calling to which it is devoted.

## Contracted Hive-Entrances in Winter

Allen Latham says that colonies that have entrances contracted to one side of the hive, if the cluster happens to be on the opposite side, die every time. Editor Root agrees pretty much with this view, and yet, not so very far from here, lives a well-known bee-keeper who winters from 300 to 500 colonies with the hive-entrances all at one corner of the hive. Where he lives the thermometer often falls to 20 degrees below zero, and the bees are generally confined for 4 months or more without a flight. Yet he winters the bees as successfully as any other bee-keeper in the vicinity.

It would be interesting to have Mr. Latham explain why his theory does not work out in practise, here in Ontario.

## New Pure Food Law

Under "scare" headlines a well-known bee-keeper and chemist advertises in one of our papers as follows:

"The new food law takes effect Jan. 1, 1907."....."Even that gathered from your own bees is not sure to pass inspection if it is near a city or honey-dew localities, or you feed your bees sugar syrup in the fall."

It appears to the writer that this is pretty strong, and if the Pure Food Law is going to work down fine like that, there is a possibility that it may act as a boomerang.

As to honey-dew, if a small quantity of that in honey would come under the ban, I suspect very little Ontario honey would have passed muster last year. Anyway, suppose a bee-keeper sent a sample to said chemist for analysis, and the verdict was "genuine," how would he be sure that a sample taken from another tank would turn out the same? Suppose, in a pinch, he might send the whole crop for analysis in order to be positive. This might be a good thing for the chemist, particularly as the bee-keeper would likely be glad to turn over the honey to pay the fees for analysis!

Joking aside, I believe there is a possibility of "straining at a gnat and swallowing a camel" in this matter, and while I have no sympathy with adulteration, it is to be hoped that United States apiarists will not be in such a dilemma as the advertisement quoted from would lead us to believe was the case.

Send Questions either to the office of the American Bee Journal, or to  
 DR. C. C. MILLER, Marengo, Ill.  
 Dr. Miller does not answer Questions by mail.

### Bee-Keeping in North Dakota— Trouble With Queens

1. Do bees do well in North Dakota? started last spring with one colony and increased to 4. Each hive was full in the fall besides 30 pounds of surplus honey which took away. The hives are 10-frame, each frame about 17x6½ inches. One frame of honey weighed 9 pounds. The honey is as clear as water and of fine flavor. It is obtained mostly from a flower that looks like sage which grows in the wheat-field. My bees are in the cellar and are doing well so far.

2. I had bad luck with one colony. Their first queen was lost in mating. I gave them brood, and their second queen was lost. Then I sent for 2 queens. I placed one in on top of the frames in the cage and let the bees eat her out. In a few days I examined and she was missing. Then I gave them the other. She went also. Then I gave them more brood. They reared a queen, but it was so late she failed to be fertilized. What should I do with that colony in the spring?

NORTH DAKOTA.

ANSWERS.—1. It seems to be a very good place; at least your bees did well last year. If you can have such success every year you will have no occasion to complain.

2. The best thing is to unite with other colonies, unless you want to send off for a laying queen. Very likely you'll not be willing to take such advice, but will give the queenless bees a frame of brood to have them rear a queen. That looks on the face of it a wise thing to do; but if you're wise you'll not do it. In the long run, you'll be the gainer to unite now, and not try to rear any queens till later on.

### Bees Died in Winter—Swarming Out— Spring Management—Robber- Bees

1. I put 6 colonies into my cellar last fall; 3 strong in bees and stores and 3 that were rather weak in both. The weak ones came out all right and the strong ones died. My cellar is rather warm, and those large colonies were very uneasy all the fore part of the winter; the bees died very fast, and they were all dead 6 weeks ago. What was the cause of their dying?

2. I set the bees out of the cellar March 22, the thermometer being 60 above zero in the shade. They had been out but 2 hours when a swarm came out of one of the hives and settled on a bush and was there about an hour. Then I put it into another hive with some old combs that I took from the hives where my other bees had died. Was that all right? By the way, the old combs had plenty of stores.

3. Isn't it a rare thing to have a swarm so early in the spring and so quickly after setting out, especially in this northern locality? What was the cause?

4. I have about 25 old combs that I took from the 3 hives where the bees died the past winter. About ¼ of the lot of combs are filled with good honey and considerable pollen that is very sour, and the bottom part of the comb is rather moldy. Will the bees clean them up, or will they do to give to a newly-hived swarm later on?

5. Will they do to put into my other hives this spring for stimulative feeding?

6. Do you contract the entrance in the spring during cool nights? If so, how much? Is it not a good plan to contract the entrance on account of robber-bees in spring?

7. What is a good sign of bees being robbed, and what will stop them? IOWA.

ANSWERS.—1. The warmth of the cellar may have had something to do with it, but probably still more the closeness, and lack of pure air. The stronger the colony the more this would cause uneasiness, and the more rapid the deaths. If there was light in the cellar, that would make it worse.

2. Yes, that was all right, although it probably would have been as well to have given

### Growing White Sweet Clover

Have you any white sweet clover seed for sale? If not, where can I find some. Also at what time of the year should it be planted?

MICHIGAN.

ANSWER.—I have none; but you should generally find it advertised in the bee-papers about this time of year. It may be sown spring or fall, or any time when red clover may be sown in your locality. The principal point to look out for is to have the ground rolled or tramped down hard after it is sown. If the ground is soft the sweet clover is likely to be heaved out the first winter. It seems to do best on a hard roadside, and the nearer to that you get your ground the better.

### Testing the Purity of Italian Queens

Please turn to page 259 and tell us whether your views as to the purity of Italians agree with Mr. Doolittle or "Subscriber."

WISCONSIN.

ANSWER.—When a man as prominent in apicultural literature as Mr. Doolittle comes out in a positive manner on any particular point, especially when he controverts what some one else has said, he must expect to receive some whacks in return unless he has somewhat reliable facts to back him up. More than once he and I have crossed swords, and there are few men I'd rather have a spat with than the same G. M. Doolittle, for when the smoke of battle clears away we're always as good friends as ever; so I have no need to hesitate to give my opinion in the present case. And that opinion is that you can swallow every word that Mr. Doolittle has said in his article, page 259, and he has done good service in writing just as he has written. I'll call attention to only one point. "Subscriber" says, "Every drone must have 4 yellow bands. . . . Every drone is marked alike." I've seen a good many drones in my time, have reared them from a number of queens imported from Italy, and I don't recall that I ever saw one that could be fairly said to have one yellow band, if indeed a band of any kind, to say nothing of 4 yellow bands. Yes, indeed, Doolittle in all right in that article.

### Keeping Bees in a Back Yard

1. I live in town and have ordered 2 strong colonies of bees to be delivered in May. I expect to put them in my back yard, which is 30x40 feet, with a good building on the alley 6½x9 feet and 9 feet high; or would you advise me to put them in this building? The building has house-siding and floor laid with flooring and a shingle roof. There is a door in one end and a good window in the other.

2. There is a dwelling house on the next lot, about 10 feet from the fence, which is 6 feet high. There is a 6-foot tight board fence all around my yard except the side which my house is on. Is this fence high enough to protect people driving along this alley, and

the people who live in the house close to the fence?

3. In case I put these bees in the building it will be necessary to connect the hives to the outside of the building with a 2-inch tube. Will they do as well in the building as outside?

4. Will not rats or mice crawl into this tube in the summer at night and damage the combs in the brood-chamber?

5. If I should nail coarse wire-cloth over this hole would that interfere with the bees while working?

6. Do you think I have made a mistake in attempting to keep bees in town?

I do not know anything about bees except what I have read in text-books.

PENNSYLVANIA.

ANSWERS.—1. Very likely it will not be as well as to put them outside.

2. Very likely it will protect successfully. The mere fact of being in a building would be no protection to outsiders against the bees, provided the bees arose from the same height in each case, and the likelihood is that they would be higher in the building than on the ground. A bee rising from the ground to cross that 6-foot fence would not be as likely to interfere with a passer-by as one starting from a point higher up.

3. I'm afraid not quite so well.

4. No; the bees are thoroughly competent to protect their combs night or day in summer.

5. No; 3 meshes to the inch would allow free passage to the bees, while barring mice. But as already intimated, it would be useless to do anything of the kind in warm weather; the bees ask no help from you.

6. Likely not; yet you can tell better after trying. Much depends upon the character of your bees. There are bees so cross that they would be sure to make trouble for you. Something also depends upon your management. You can stir up even gentle bees by untimely handling so they will sting everything within reach. Be careful about opening hives when bees are not gathering much. There may be an advantage in working rather late in the day, for if you make bees cross in the morning they have the whole day to trouble the neighborhood. If you find your bees are not gentle you ought to introduce queens of gentle stock, pure Italians, or possibly Caucasians.

### Lake Superior District for Bees

Please give me any information you can concerning the State of Wisconsin near Lake Superior for bee-keeping. I am thinking of going there about April 1. KENTUCKY.

ANSWER.—There are many fine locations in Wisconsin, especially where basswoods are plenty. The chief trouble is that in general such locations are fully occupied. It would not, of course, be wise toward yourself nor right toward others, to locate where the ground is already occupied, so the thing to do is to look over the ground personally to find the proper opening before settling. Of course, as to individual locations, I can give you no information.

them at least part of their own combs, for likely they were cleaner than the combs of the strong colonies that died. That is, you would return them to their own hive, and then give them enough full combs from the dead colonies.

3. Unfortunately such swarming out is not so very uncommon. It is not swarming in the way of usual swarms later in the season, but merely deserting the hive, and may have been what is called a "hunger swarm," deserting the hive because near starvation, although sometimes colonies desert in spring, leaving plenty of stores in the hive, and it's not possible to tell why they desert.

4. Yes, the bees will clean them up, and they will do to have a swarm on, unless too sour and dirty, in which case the swarm would desert.

5. I'm not sure whether it would be exactly classed as stimulative feeding, but you can do nothing better with them than to give them to settled colonies to clean up. Don't give too many at a time, if they are pretty bad; but 2 or 3 at a time in the brood-chamber will be cared for all right, giving them in place of combs that are very light in honey. Or, you can give a whole hive-body filled at one time, putting it under the colony, only you must have things pretty well closed up so as not to invite robbing. Everything must be close and snug except the one entrance at the bottom of the lower story, and that should be as small as possible without troubling the bees about getting out and in.

6. Yes, just as soon as my hives are taken out of the cellar the entrances are contracted to a hole  $\frac{3}{4}$  to 1 inch square. It helps against robbing, and keeps the bees warmer, day and night.

7. When you see unusual activity at the entrance, especially if the colony is weak, catch one of the bees that comes out with considerable bustle, kill it, and see if it has honey in its sac. If it goes out with a full sac, you may count there's robbing. Close the entrance so that only 1 or 2 bees can pass at a time, pile hay or straw at the entrance and at the sides till as high as the hive, and drench it well with water. In a large number of the cases of robbing that occur in spring, it is because the colonies are queenless and practically worthless, and the best thing in such case is to let the robbers carry out all the honey without disturbing them. About the worst thing is to take the hive away, for then the robbers will pitch into the adjoining hives. If you take the hive away, put in its place another hive just like it, with a comb or combs having just a little honey in them, letting the robbers clean out the little honey without disturbing the neighboring colonies.

tracted. It is all sold. I work alone with the bees from spring until the harvest is over, about the first of August. Then after that I work at my trade some, which is that of a carpenter and joiner.

It seems to me that the Editor of the American Bee Journal, on page 66, is inclined to boast of Mr. Louis H. Scholl, and that Mr. A. F. Fonte, on page 216, is somewhat jealous of him, his man, Mr. Isaac Wayne, being 2 inches better—6 feet and 4 inches tall. Well, now I think that I must blow my own horn, as there seems to be no one else to do it. I am 6 feet and 8 inches in height now, and until 5 or 6 years ago I stood 6 feet  $9\frac{1}{2}$  inches in my stocking feet. I was born of German parents in East Troy, Walworth Co., Wis., in February, 1844. I am not a fleshy man, but at present tip the scales at 257 pounds. In the latter part of my teens and twenties I challenged the State of Wisconsin for a Badger of my equal or superior, through the Fond du Lac Reporter, but they did not produce him, and I still hesitate to take a back seat. THEO. REHORST.

Campbellsport, Wis., April 2.

### Fears Chilled Brood

We have been having fine weather until the last 3 days. White clover has started and promises to be abundant.

I took my bees out of the pit, or trench, March 28. Of the 42 colonies buried I took out 39 in good shape; but the sudden chill that has struck us here in Michigan makes me fear chilled brood. C. H. BENSON.

Bellevue, Mich., April 2.

### Results of Last Season

From 26 colonies last season I took over 1600 pounds of section honey, realizing something over \$200. I had only one swarm. Here is the report of one colony I kept on the scales: It was No. 13. First week of May, 3 pounds; 2d week, 3; 3d week, 17; 4th week, 13 $\frac{1}{2}$ ; 5th week, 19; 6th week, 15; 7th week, 7; 8th week, 4 $\frac{1}{2}$ ; 9th week, 4; 10th week, lost 2 pounds; flew over. There was a loss of from  $\frac{1}{2}$  to  $\frac{3}{4}$  pound per night by evaporation. The total yield was 84 pounds of section honey from this one colony. The best day's work was the last of May, gaining 6 $\frac{3}{4}$  pounds.

I commence this spring with 29 colonies. Bower Mills, Mo. A. E. PATTON.

### The Farmer Trade in Honey—Early Spring

This is about the closing of the season for selling honey, and my honey is about all sold. The farmer trade has been good. I have a good many customers among them that buy a 60-pound can of extracted honey at a time. Just the other day I received an order from a prominent farmer not many miles distant, saying that they were going to build, and had decided that honey was cheaper than butter, and ordered two 60-pound cans. The price was 8 cents, and he paid the freight. Now if farmers generally should tumble to the fact that honey at 8 cents is economical, what a change it would make in our business. We would hardly be able to supply the demand. It is the duty of each producer to do his share to educate the public along this line.

I have sold a good share of my honey the past season in the 10-pound self-sealing pails. I like the package, and shall try each year to sell an increasing percentage in this package unless I can dispose of smaller lots. I get 10 cents per pound in the 10-pound pails, and, of course, it pays me to sell as much as I can in that way. I think the paper package described recently would be a good one, and I wish to try it. I don't see why it would not work just as well for a 2-pound or a 5-pound package as for a 1-pound.

I am not at all opposed to comb-honey production, but I think the extracted form is the one in which the greater part of it should be used, and always will be. The scarcity of

comb honey will bring the price up to that point where it will pay me to go to the trouble of producing it, and thus the demand will be supplied.

On March 21 our bees were out of winter quarters here and carrying pollen, although there were many heavy patches of ice along the river. This is early for this latitude, and may not be for the best advantage of the bees. They may get too much brood started, and, cold weather coming on again, they would be liable to suffer. However, indications are that spring has come to stay. We hope so.

HARRY LATHROP.

Bridgeport, Wla., March 23.

### Wintered Well in Small Hives

I have had the bees out of the cellar 2 days. They have had a fine airing, and seem to be all right. I don't know that any have died. We have taken them out about 3 weeks earlier than usual for us, while the weather was cool, so as to prevent the crazy first flight and mixing up, and have avoided it. I don't think they have mixed worse than if they had wintered on the summer stands; and they are only 4 days later in getting their first flight than the few I had packed in leaves and hay outside. All seem to be strong. I shall know more about them in a few days. Our cellar arrangement has many advantages in this climate, the principal one being that of saving the labor or trouble of heavy hives or packing. A small man, weighing about 125 pounds, carried out 64 hives in about 2 hours; and the evening before carried out 40 in about the same time. Smaller hives have some redeeming qualities besides requiring less lumber to make them.

T. F. BINGHAM.

Farwell, Mich., March 25.

### Requeening a Laying-Worker Colony

I have read C. P. Dadant's article on page 235, as given before the Illinois convention, on drone-laying workers, and how to introduce a queen to such a colony. By this method I have never succeeded in introducing a queen to such a colony, but by the following method I have never failed:

Of course, I have never used the comb-honey stopper. My method is to use a queen a year or more old. I first select the queen to be used, put her into a cage without any feed and keep her there for 30 or 40 minutes. Then I take her to the laying-worker colony and gently lift out a comb with no honey, if possible, or little of it, and also with few bees on it. I allow her to crawl from the cage onto the comb where there is no honey or bees. She at once searches for honey, and will soon run up against some bees that will at once supply her needs, then gently replace the comb and close the hive. Let them alone for 4 days or so. She will be laying at once. I have used this plan for a long time and have never lost a queen. It would not do to use a young queen, nor do I think it pays generally to try to save a laying-worker colony. Better unite them with another colony by putting the one over the other with a couple of newspapers between, making a few holes in the center of the paper with a lead-pencil or some other small article. Any colony you wish to unite that way should be reversed, or the end that was front put back, as they will usually eat down through the paper at the end where they think is their entrance, and consequently they come into contact with the bees of the lower colony at the back, and away from the guards. A laying-worker colony of bees must have a frame of emerging bees given to them in 4 or 5 days after the introduction of a queen.

Bees came through in poor condition generally here, owing to lack of young bees. We should have fed a substitute for pollen last fall, consequently they did not breed up through the winter. All strong colonies are doing well now on mesquite and catclaw.

Calaveras, Tex., March 29.

H. PRYER.

### Wintered Poorly—His Best Adviser

□ On March 25 I put my bees on the summer stands with but little encouragement. Out of 27 colonies I have only 8 left. That is the result of bad fall honey. I will not do like Mr. "J. T. P.," on page 225, discontinue my best adviser. I will stay by the "old reliable" American Bee Journal.

CHAS. O. BEROSTRAND.

Amery, Wis., March 29.

### Poor Season in 1906—Another Tall Bee-Keeper

Last year was a poor season for bee-keepers here. I secured 1150 pounds of comb honey and 789 pounds of extracted from 74 colonies, spring count. I now have 90 colonies in good condition. I sell all of my honey around the country and at home at from 14 to 16 cents a pound for comb honey, and 10 $\frac{1}{2}$  cents for ex-

# American Bee Journal

## CONVENTION NOTICE.

**Minnesota.**—The Minnesota Bee-Keepers' Association will hold its spring meeting on Saturday, April 20, 1907, at the Old State Capitol in St. Paul. The afternoon session will commence at 1 o'clock, and the evening session at 6 o'clock. Free refreshments will be served from 5 to 6 o'clock, by the lady members of the Association. A leading feature of the afternoon session will be a practical demonstration of the modern method of queen-rearing, by Chas. Mondeng; and at the evening session the simplest way to cure foul brood. Papers will also be given on, "Spring Management," by Wm. McEwen; "Production of Comb Honey," by Chas. Blomquist; "Shipping Bees and Honey," by Mr. Gent; "Bee-Keeping in Connection with Farming," by Pres. H. V. Poore; "Bee-Keeping for the Beginner," by W. R. Ansell; and a paper by Mrs. E. E. Merrill. Questions on bee-keeping by any one interested will be fully discussed and answered. Lay everything aside and attend this meeting; you will never regret it. We want every one to come, whether a member or not. Brother and sister bee-keepers are all cordially invited. The membership dues are \$1.00 a year, including membership in the National Bee-Keepers' Association.

CHAS. MONDENG, Sec.

# Science in Hive-Making

You will find the bee-spaces in Lewis hives absolutely accurate.

This means something.

Some bee-keepers think a bee-hive is a bee-hive, and that's the end of it.

Thus they are misled by cheap prices, and the dealer making the lowest price gets the order.

But after all, more than all the honey that they think they have saved, the bees have lost for them in one season.

Because the bees have spent their time building over the wrongly constructed hive.

Men can make hives better than bees.

Start right with Lewis hives.

Thirty years at the business have made them perfect.

There is no "Just as good."

G. B. Lewis Co., Watertown, Wis.—  
*Gentlemen:*—The goods have been received, and I am greatly pleased with them. The hives are a model of perfection, both as to material and workmanship. It is a pleasure to have material go together as yours do. I bought hives from you 16 or 18 years ago, which were very satisfactory, but I notice a marked improvement as you now make them.  
 Very truly yours,  
 E. W. LYLES,  
 CHARLOTTE, N. C.

G. B. Lewis Co., Watertown, Wis.  
*Gentlemen:*—About 2 months ago I bought 25 of your 8 frame Dovelited Hives with Colorado Covers; these I put together without losing a single piece. I find these hives to be better than any other I have ever used. Although I have a gas engine and good tools, I can buy hives cheaper and more accurately made.  
 Yours truly,  
 E. K. MEREDITH,  
 BATAVIA, ILL.

## Honey and Beeswax

CHICAGO, April 4.—Market is quite bare of best grades of comb honey. When sales are made it is on a basis of 15@17c, with very little outlet for the off-grades. Extracted, 7@8c; off grades, 6@6½c. Beeswax in good demand at 30@32c. R. A. BURNETT & CO.

PHILADELPHIA, Mar. 11.—The comb honey market has been quite active in the last two weeks, and the continual cold weather has kept things moving. Many cheap lots have been sent in from the producers, which have had a tendency to bear on the market and weaken the prices somewhat. Fancy white comb honey, 15@16c; No. 1, 14@15c; amber, 12@14c. Fancy white extracted honey, 7@8c; light amber, 6@7c. Beeswax very firm, 32c.

We are producers of honey and do not handle on commission. WM. A. SELSER.

NEW YORK, Jan. 15.—The stock of white comb honey is pretty well exhausted, and we do not expect any more arrivals of large lots from now on. Prices are firm, and we quote from 15@16c for fancy white; 13@14c for No. 1; 12c for light amber. There is quite a little dark and buckwheat on the market, but no overstock, and we think that all of it will be disposed of before long at present prices, which we quote from 10@12c, according to quality. Extracted honey very firm, with sufficient supply to meet demand. California white sage is bringing from 8@8½c; light amber, 7½c; amber, 6½@7c; buckwheat extracted in fairly good demand at 6@6½c. Southern in barrels finds ready sale at from 55@70c per gallon, according to quality. Beeswax firm and steady at 31c. HILDRETH & SROELKEN.

DENVER, Feb. 14.—Producers in this State are practically closed out of both comb and extracted honey. We have not sufficient good comb honey to supply our local trade, but have a good supply of white extracted of excellent quality. We quote strictly No. 1 white comb honey, per case of 24 sections, at \$3.20; No. 1, light amber, \$3; and good No. 2, \$2.80. White extracted, 8@8½c per pound; light amber, 7½@8c. Clean, yellow beeswax, 27@28c, delivered here.

THE COLO. HONEY-PRODUCERS' ASSN.

CINCINNATI, Mar. 11.—There is very little demand for extracted honey at this writing, which is only natural, owing to the unsettled

... OHIO ...

Office and Salesrooms, 2146-48 Central Ave. Warehouses, Freeman and Central Aves.

weather at this time of the year. However, we are looking forward with interest to a revival of trade, as soon as the warm spring days are here. We quote amber extracted honey in barrels at 6¼@7½c, the price depending upon the quantity purchased. Fancy table honey in crates of two 60-lb. cans each, at 8@9c. There is little demand for comb honey owing to the lateness of the season. Choice yellow beeswax, 32@35c, delivered here.

THE FRED W. MUTH CO.

INDIANAPOLIS, Feb. 25.—comb honey is not plentiful, but demand is slack. Fancy white comb brings 16@17c; No. 1 white, 14c; amber, 12@13c. Best grades of extracted honey bring 8@9c; amber, 6@7c. Good average beeswax sells here at \$35 per 100 pounds.

WALTER S. POWDER.

TOLEDO, Nov. 30.—The market on comb honey remains about the same as last quotations, but

has been coming in much more freely, as beekeepers seem to be very anxious to get rid of their stock. Fancy brings in a retail way 16c; extra fancy, 17c; No. 1, 15c; buckwheat, 15c. Extracted white clover in barrels brings 7@7½c; caust the same. Beeswax, 26@28c.

THE GRIGGS BROS. & NICHOLS CO.

KANSAS CITY, Mar. 30.—The demand for comb honey is light, as also are the receipts. The market is about bare of extracted. We quote: No. 1 white comb, 24-sec. cases, \$3.10 to \$3.25; No. 2, \$2.50 to \$2.75. Extracted, white, 8@9c; amber, 7@8c. Beeswax, 28c.

C. C. CLEMONS & CO.

CINCINNATI, April 3.—The market on honey is entirely bare of fancy comb honey; No. 2 selling at 12¼c, and slow sales. Light amber extracted sells in barrels at 5¼@6c. Beeswax, 32c, delivered here.

C. H. W. WEBER.

# How I Built a World-Business

By the Bee-Crank.

Why should a bee-keeper know or care how the business of a successful supply-man was built up to such a point that he is known throughout the entire civilized world?

Because if he is not dealing with him he is missing something that his fellow workers are making use of—that it will pay him to get "next" to.

The secret is not a deep one—good service, fair treatment, honesty, square dealing—call it by whatever name you please. It is the golden rule of business that many business men know but forget to apply.

When an order is received at this establishment it is attended to immediately. When goods are packed for shipment they are carefully inspected, and whatever is defective thrown out.

Knowing how easily such goods are damaged in handling I use extreme care in packing, and try to make my goods proof against the

roughest freight roustabout, and foot-proof as well.

These methods are slow business builders, and not very spectacular, but they are sure.

I carry a full line of bee-supplies, and sell Root's goods at Root's prices, saving freight and time in transit.

I buy beeswax, and pay the highest market price, in cash or trade, as you prefer. Send it in and mark your name on the package. Get my new catalog—it's free.

Albion, Ind., April 2, 1907.

WALTER S. POUDEK, Indianapolis.

Dear Sir:—The two nuclei which you sent me last year have wintered successfully. One is now a full colony, the other not quite so strong, but the prospects for increase are excellent, as they are busy gathering pollen.

Respectfully, Mrs. J. D. BLACK.

### Fertilizing-Hives for Queen-Rearing

Probably there is very little dissent in any quarter from the belief that to get the best queens the queen-cells should be started by a strong force of bees, and contained under such care at least until the cells are sealed. This can be the more readily afforded, as up to the time the first young queen emerges a number of cells can be cared for by the same lot of bees. But after a young queen emerges from her cell, and from that time till she begins to lay, she does not cheerfully brook the presence of anything in the shape of a rival; and, moreover, there does not seem the same need of a strong force of bees as during the earlier period of her development, so fertilizing-hives much smaller than the ordinary hive have been used, or else a full-sized hive without the full complement of frames.

While some are confident that so-called baby nuclei, with no more combs-surface than that of a one-pound section, will produce as good results as anything larger, others are skeptical. Even among the ranks of those who were at first enthusiastic as to baby nuclei, there are those who seem to have a leaning toward something larger; one of them, Mr. E. R. Root, now advocating something by no means so "baby" as it might be. Instead of a single comb the size of a pound section, he now advocates two combs, each of them one-third the size of a Langstroth frame. This is getting back very nearly to the small fertilizing-hives used by Adam Grimm and others more than 40 years ago. Mr. Root has virtually a larger mass of bees by having two of these nuclei side by side in the same hive, thus giving the advantage of mutual heat.

While some say success can not be attained with a very small quantity of bees, it is hard to dispute the word of honest men who say

they have succeeded. "Locality" is that pervading something which explains a great many discrepancies; why may it not account for different views in the present case? In other words, may it not be that in the warmer regions, as in the South, a smaller number of bees are needed to keep up the proper heat? Or is there some other way to account for the differences in results?

### A Cheap Weed-Killer

Salt is sometimes used to kill the grass and weeds in front of hives, but in some places it has the objection that it attracts cattle and horses. Here is something not open to the same objection, and, at a cent a gallon, cheaper, as given by A. H. in the British Bee Journal:

The cheapest I know of is: Two ounces of carbolic acid (98 percent) to  $1\frac{1}{2}$  gallons of water, preferably hot water. This is also an excellent vermin-killer, and the cost for 120 gallons 5s., or  $\frac{1}{2}$ d. per gallon. This will destroy even thistles and nettles, and the seeds, too.

### Ventilation of the Hive

Prof. Cook says this in Gleanings in Bee Culture:

The bees ventilate so effectively, as they fan the hive-entrance, that it is found entirely unnecessary to arrange for any further ventilation. It is, without doubt, best to have only the one opening to the hive. In the bee-tree or rock cavity the bees have but this one opening, and yet from their great activity they must have great drafts of pure air, and so they have developed their ventilating habit, which is very perfect. Without doubt we serve them best when we leave the matter of ventilation entirely with the bees, only arranging to give them an ample opening.

The novice, upon reading the paragraph, will feel that he need give no care to the

matter of ventilation, only so that the bees have an ample opening for an entrance, but he is likely to feel a little uncertain as to what is meant by an ample opening. If he has been accustomed to box-hives with 2 or 3 notches in front, making the equivalent of a square inch and a half or less as the entrance, his idea of an ample opening may be rather unsatisfactory to the bees.

In actual practise, the opening during hot weather varies from the size mentioned all the way up to 2 inches deep the entire width of the hive, while some raise the hive on blocks so as to make an opening on all 4 sides. But not all are agreed that only one opening is best. It is argued by some that it saves labor for the bees if there is an opening at top as well as bottom. Certain it is that in that case there will be a change of air in the hive without effort on the part of the bees whenever it is warmer in the hive than out—just so certain as that there will be a draft up a chimney whenever there is a fire at the lower end.

Will not that automatic change of air be a saving of labor for the bees, or does the instinct for making the air go in and out of the same hole hold them in so strong a grip that it will only make extra labor for them to keep the air from going through the second hole?

It might also be urged against an upper opening that in some localities the nights are so cool that ventilation is a damage, and the colder the night the stronger the current of air through the hive, and against this current the bees are helpless.

### An Industrious Bee

The correctness of the general belief as to the industry of the bee having been called in question, Allen Latham comes to its defense in the American Bee-Keeper, and gives the following remarkable instance:

There were thrown out from a hive late one afternoon and early evening a hundred or more dead and dying bodies of some stranger bees. They lay in front of the hive, scattered over a space of 2 or 3 square feet, some having crawled before dying not less than 2 feet from the hive. The following morning, while standing by the hive, I saw a bee tugging at a dead worker on the ground. She pulled this way and that, and finally, by a great effort, mounted with her burden and disappeared in

the distant air. I naturally thought that she had just brought the dead bee from the hive, but in less than a minute back she came and hovered about the ground as if in search of something. Then alighting by another dead body she grasped and pulled at that, and flew away with it. Again and again I saw her repeat this act, never once entering the hive; never once seeking the society of her living sisters, but plodding away by herself, clearing the ground in front of the hive of the dead bodies. Later on another bee joined in the task, and a few hours later, when I took note of the progress of the work, I found the ground completely cleared of the dead bees that had been thrown there the evening before.

The task was a self-imposed task. An amount of work was done which relatively

would be beyond the possibilities of the strongest human being. It would only be fair to say that to do a proportionate amount of work a man would need to carry 50 bodies of his fellow men to the top of a high hill in a space of 3 hours.

That a bee should drag out of the hive the dead body of one of its comrades, even should it continue to struggle with it after some yards from the hive, would seem nothing very strange; but a bee that would return again and again after the dead bodies lying entirely outside of the hive, with never a word of cheer from its sisters, certainly can not be called lazy.

**Getting New Subscribers for the American Bee Journal** is something every reader can do if he makes a sincere attempt. No one knows better than does he its value to every would-be successful bee-keeper. And we offer valuable premiums, to those of our present readers whose subscriptions are paid in advance, for the work of going out and getting new subscriptions. Your neighbor bee-keepers perhaps have never heard of the American Bee Journal, although it is now in its 47th year. Why not try to get them to subscribe? You may be surprised how readily they will do so upon your invitation.

## Miscellaneous News - Items

**Hon. R. L. Taylor**, of Lapeer, is now the Michigan inspector of apiaries, succeeding Mr. Hutchinson, who felt that he could no longer continue the work owing to other duties that press upon him. Mr. Taylor has had large experience with foul brood among bees, and is otherwise in every way specially fitted for the work of bee-disease inspector. Michigan bee-keepers are to be congratulated on the efficiency of their inspectors.

crossing of different varieties looking to the production of a superior honey-producing strain. The diseases of bees are also receiving thorough investigation.

Dr. Phillips has already proven himself the right man for the place which he occupies. The American Bee Journal will be glad to cooperate with him in his efforts in behalf of the progress of beedom.

**Mr. E. K. Meredith**, of Batavia, Ill., died with hemorrhage of the brain March 12, 1907. He had been sick for 2 weeks with inflammatory rheumatism, but apparently was improving. Mr. Meredith was an active member of the Chicago-Northwestern Bee-Keepers' Association, and attended the last meeting with his wife and daughter. His many friends will join with the American Bee Journal in extending sincerest sympathy to his family in their bereavement. As Mrs. Meredith also understands bee-keeping, doubtless she will continue in the business.

## Contributed Articles

### No. 3—Feeding and Feeders —Bottom-Feeders

BY C. P. DADANT

**Dr. E. F. Phillips** is now "in charge" of "Apicultural Investigations" in the Entomology Bureau of the Department of Agriculture at Washington, D. C. We learn this from a Government pamphlet on the "Organization of Department of Agriculture, 1907," which details the work of the Department and gives the names of those in charge, etc. The particular paragraph referring to the work in the interest of bee-culture reads thus:

The importance of the apian interests of America are recognized by the establishment of an office for special investigation in this field. Inquiry is under way to determine what crops may be profitably employed to fill the gaps in the honey yield, or to create artificial pasturage for apiaries, and efforts are being made also to introduce new honey-producing plants from abroad. The different races of bees are being tested to determine their relative availability for this country, and experiments are being conducted in the

The next style of feeders that we will consider is the bottom-feeder. Feeding under the bottom, on the bottom, or in the bottom, is practised considerably. Feeding on the bottom, without a feeder, has been practised in two ways, by raising the hive in front so that the feed can not escape through the entrance. It may be done with granulated honey poured between the frames at the back, or if the hive is absolutely tight at the bottom, by pouring liquid food so that it will lie at the back end of the hive. In such cases, the hive must be entirely water-tight and nailed to the bottom-board. It is a very expeditious way. The main objection is that the hive being raised so as to slant backward, the rain may beat in and mix with the feed. This was practised more with the old-style portico hive than with any other, owing

to the shelter furnished to the alighting-board by the portico ceiling. Urgent requirements may be filled in this way with almost no preparation. As to the feeding of granulated honey in this manner, it is objectionable when the intention is to stimulate breeding without necessitating the bees' visit to water supplies, for granulated honey seems to make an increased supply of water desirable.

Bottom-feeders are made to be attached under the bottom, with a connection through a hole with the brood apartment, or may be a part of the bottom-board with an extension on the side at the back so as to be refilled without opening the hive, as in the Alexander feeder.

The only fault of these feeders is in placing the food below the brood-nest, and sometimes remote from it, as weak colonies sometimes neglect to visit the feeder if the weather is unfavorable. I have often found food untouched in a bottom-feeder, when the colony evidently required help. Yet, in many ways those bottom-feeders are com-

"Songs of Beedom."—This is a beautiful 16-page-and-cover pamphlet, 6x9 inches in size, containing 10 bee-songs—words and music—all the songs so far written specially for bee-keepers, we believe. It is nice, as well as convenient, to have these songs all in one binding. Every bee-keepers' organization should have copies for use at conventions. They could be sold to members after using once, or held by the secretary for use at future meetings. Of course, every bee-keeper's family will want at least one copy. It is sent, postpaid, for only 25 cents, or 3 copies for 60 cents; or, we will mail one copy with the American Bee Journal one year—both for \$1.10. Send all orders to the office of the American Bee Journal.

**Amerikanische Bienezucht**, by Hans Buschbauer, is a bee-keeper's handbook of 138 pages, which is just what our German friends will want. It is fully illustrated, and neatly bound in cloth. Price, postpaid, \$1.00; or with the American Bee Journal one year—both for \$1.75. Address all orders to this office.

mendable, especially as they do not cause the escape of heat from the hive, since it is not necessary to open the top in order to give the bees an additional supply.

Of course, the best feeders are made in narrow sections and very shallow, so that the bees may not drown in the feed. These feeders, as well as others which will be mentioned farther on, must be made so that they will not ab-

ALEXANDER FEEDER.

sorb or soak the food. They are commonly made of pine, which is coated with paraffin. In some parts of Europe propolis is gathered, melted and used for this express purpose. A bee-keeper who desires to make his own feeders, and wishes to coat them with some preparation, may be able to make them honey-proof by using a preparation of beeswax and tallow—about half and half—which is poured in the feeder while hot, and poured out again, leaving a slight coat on the wood.

Pure beeswax might be used, but aside from the fact that pure beeswax is more expensive, it is noticeable that it does not soak into the pores of the wood as readily as a preparation containing tallow or even lard. This preparation, melting at a lower temperature than pure beeswax, is also less apt to crack or peel off when the weather is cold. It may be used for a number of requirements. Mixed with a small quantity of wood ashes and rosin it will make a liquid cement which is used to stop large cracks in wood, whether feeders or other implements; even such things as water-barrels that are damaged may be made whole by using it. But in any case, remember that the wood must be dry before any such preparation is applied, for the least amount of moisture would prevent the soaking of the wax in the pores of the wood. Water is used to prevent wax from sticking to objects that are dipped in it while hot.

You must also be careful to keep the cake of tallow-wax thus prepared separate from your beeswax, for there would be a row if you should happen to send it by mistake to a comb foundation manufacturer. We keep a small iron kettle with some of this tallow-wax already mixed in it all the time, so that all we need to do is to warm it up for use. When it is melting keep a close eye on it, for it will run over and give you trouble if allowed to get too hot.

But I notice that I have gotten clear away from the description of bottom-feeders. There is still another kind which has been highly commended, but of which I do not approve. It is the entrance-feeder, made in the shape either of a jar enclosed within a box—the Boardman feeder—or of a trough, opening into the entrance and closing this entrance. The entrance-feeder is

suitable only if used on a strong colony, otherwise there is a great risk of strange bees helping themselves to the food, or, to say the least, of being attracted there and induced to rob the weak colony which it is intended to help. The feeder, which is placed at the rear of the bottom, has at least the advantage over this, that the robber-bee, if attracted by the smell, is induced to hunt about the rear of the hive, around the crevices near the feeder, and can rarely go in at the entrance and cross the length of the bottom-board without having to take up the gauntlet with a number of the inhabitants of the hive.

Front feeding, therefore, unless carried on with the greatest circumspection is not desirable. If the entrance be closed with the feeder in position, it is necessary to look after it and release the bees in warm weather before they become worried. Yet, one small advantage of the entrance-feeder which has perhaps served to make it popular with some apiarists, is that it is located at the spot most often traveled over by the active adult bees, and that it will therefore not be so readily neglected as a rear feeder.

Hamilton, Ill.

## Successful Wintering of Bees

BY ALLEN LATHAM

It is possible that the sentence which Mr. Byer, on page 227, quotes from my writings may need no further defence, inasmuch as Mr. Byer himself offers in his last paragraph so strong a support for the statement. I write now more to impress upon the readers of the American Bee Journal the truth of what Mr. Byer has to say, and to urge upon them the desirability of wintering our bees as well as we should hope to winter our cows and other domestic stock.

It so happens that all farmers do not winter their cows without loss. There are still some who house their animals poorly, either with too slight a protection or else with too little ventilation and cleanliness, and on top of such treatment economize (?) by feeding them upon meadow-hay and water. That such men bury two or three scrawny beasts the next spring is no surprise to their thriftier neighbors.

Suppose, for instance, that a farmer persisted in keeping every animal that came his way, whether healthy or weak, young or old. Suppose he did not practise what most do, namely, to get rid of undesirable stock, make into beef those that are not strong, or else, if conscientious, sell them to those who will turn them into beef. If we suppose these things then we know that it would be inevitable that every winter would see a loss of from 10 to 25 percent of all such domestic animals. The fact is that domestic animals are wintered successfully only because most of us strive to keep our stock uniformly vigorous. But such is not the case with our bees, for, unless I am much mistaken, the majority of beekeepers think more of the number of colonies they possess rather than of the quality. It is not, therefore,

strange that their spring count falls so much below their fall count?

Leaving out the first year of my bee-keeping, a year in which winter cost me 100 percent of my bees, as my only solitary colony was lost, I think that I can say that my spring count has not averaged more than 5 percent less than my fall count. Of this falling off, moreover, almost none should be laid to winter directly, as much of it came about from loss of queens. In fact, I can remember only one colony the loss of which should be laid wholly to winter, and I allow that one only because I never could find any other cause for the loss.

One winter I lost more than 60 percent of my apiary, and might lay the loss to winter; but it so happened that the fall before the hives were very light in stores, and I followed some directions about feeding by laying a cake of candy above the frames. Such a sight as there was the following spring, I never wish to see the like again! These cakes of candy were made of honey and syrup and were not grained. *Never feed with cakes of candy over the frames unless those cakes are fine grained like the inside of a chocolate cream.* Never put honey in with the sugar of which these cakes are to be made, for the honey will prevent the graining. Cook the syrup to a temperature of about 233 Fahr., and set aside where it will cool. When nearly cool, stir it slowly till it grains. Just before it gets too stiff turn it into dishes to harden. A temperature of over 233 will make the cakes too hard, while under 231 the cakes will be rather soft. The cakes which I made in that disastrous winter ran down over the combs and daubed the poor bees, resulting in the stickiest, daubiest mess that ever I saw.

So with all the colonies which I ever lost in winter, I find that in every case (save one) I did something wrong. By correcting these errors I now no longer have any fears of winter, as far as my bees are concerned. That one exception was a colony which was abundantly strong in fall and had lots of honey. In the spring the bees were dead with honey not an inch away. The hive was rather moist, but aside from that I could find nothing wrong. Twenty-nine other colonies in the yard wintered all right.

The past winter here was rather severe, called very severe by old natives. I am inclined to think that my bees would have come through in poor condition had it not been for a flight-day in early January. I count my bees safe if January furnishes a flight, and I can remember but one January during the last 23 years which has not furnished a flight for the bees. The winter of 1903-4 furnished no flight from the middle of November till late in March. There was, according to reports, a loss of 75 percent of bees in the New England States. I lost 2 colonies out of 38, and each of these died from an entirely different cause, the entrance of one getting accidentally hopelessly closed, the other starving by a peculiar mischance. That winter the bees had good stores. This past winter the bees had miserable stores, having failed of filling up with the

usual white honey. Hence, I conclude that a mid-winter flight this year saved colonies from coming out weak, if not from actual death.

Thus do the years run. There is almost never a winter in which all the bad conditions combine, for if the stores are bad the bees are more than likely to have a good mid-winter flight. If the winter is severe, then the bees are more than likely to have good stores, and so be able to endure the confinement.

Let any one who fails to winter his bees successfully put more brains into his methods of wintering. Let him see to it that all colonies are reasonably strong in bees. Let him see that all colonies have plenty of stores—the better the stores the more likely the bees to survive. Let him house his bees well, protecting them from the winter blasts. If he puts them into the cellar, let the cellar be properly fitted for their welfare. If he leaves them outside, then let each hive be adapted to keep the bees in it dry and warm. If any fail to winter well, let him study the matter, pondering over everything that could possibly have to do with the poor result. If observant, he will more likely than not find the cause of his failure, and can in future avoid it.

I can shake hands with Mr. Byer in all that he says in the last paragraph. Though I recognize the possibility of bad results in wintering even with the best of care, I do not recognize any probability of such results. I consider that in the vast majority of cases bad wintering should be considered a disgrace to the apiarist rather than a misfortune. It is a misfortune, and a sad misfortune, to have our bees die because of a combination of circumstances which lies beyond our control. It is a mighty good bit of fortune that such a combination is so rare that it scarcely falls more than once in a lifetime.

Norwich, Conn.

## Getting Ready for the Honey Harvest

BY G. M. DOOLITTLE

In nearly all localities where bees can be kept there are certain plants and trees which give a yield of surplus honey at a certain time of the year, while, aside from this, there is little more honey obtained by the bees than is needed to supply their daily wants and that consumed in brood-rearing. Some localities give a surplus at three stated periods—from white clover, basswood and buckwheat; others at two, white clover and basswood, or white clover and buckwheat, or, perhaps, basswood and buckwheat; while quite a large number give only one, as from white clover, or basswood, or buckwheat, or other fall flowers. Hence it must be apparent to all that if such a honey yield, or yields, should pass by without surplus, none can be obtained during the season.

From this it will be seen that in order to be a successful apiarist, a person must have a knowledge of his locality, and also know how to secure the laborers (bees) in the right time, so that the

largest or maximum number can be on hand just at the time that the flowers giving the greatest yield of surplus nectar are in blossom. Failing to do this, no one can expect to attain to the highest and best results in the production of honey, and the object of this article is to set those to thinking who have not thought on this subject, so that they can obtain the best possible results from their bees.

First, then, we have the location. Here, in central New York, our honey crop comes mainly from linden or basswood, which blooms from July 1st to 12th, and lasts from 10 to 25 days, according to the weather. In other localities in this State, white clover is the main crop, coming in bloom June 15th to 20th; and again in others buckwheat, yielding honey in August; and in a few localities there comes a surplus from all three of these sources. But as nearly all have a yield from basswood, I will speak of that as the source from which we obtain our honey harvest. Bear in mind, however, that it devolves on the reader of this to ascertain, by careful watching, just when and what is the source of his surplus honey crop, so as to work accordingly.

When you see by opening one of your hives that the bees are storing honey so that they are lengthening out the cells with new white comb along the top-bars of the frames, with plenty of nectar glistening in any empty cells there may chance to be in and about the brood, then is your time to go out in the fields and in the woods till you find what the bees are at work upon; then watch as the years go by to see if a yield comes from this source nearly every year, and, if so, work for the bees in large numbers at that time of the year. Do not depend upon the "say so" of some old citizen, for he may not know any better what he is talking about than did the old bee-keeper whom I asked nearly 40 years ago, when I first began bee-keeping, where the bees got their first pollen; and he told me that all the pollen which the bees gathered before fruit-trees bloomed came from the willows. I believed this till I came to look for myself, when I found that the very first pollen came from skunk cabbage, the next from elms and soft maples, with a still more bountiful yield from the hard maples a little later on, with very little from the willows at all, and that only from the pussy willow, all the other willows yielding honey but no pollen.

After having determined when we may expect our harvest of honey, the next step is to work for the bees so they may be in just the right time for the harvest. If you have a field of grain to cut, you hire the laborers when the grain is ripe, not before or afterward; yet in keeping bees very many pay no attention to the matter of securing the laborers, so that, as a rule, they are more often produced so as to become consumers rather than producers, and thus we quite often hear persons claiming that bee-keeping does not pay.

The queen is the mother of all the bees there are in a colony, she laying from 3000 to 4000 eggs a day when coaxed to do this, either by a moderate

honey-flow being on from the fields, or the bee-keeper so fixing his colonies that the bees feed the queen abundantly just when he wishes the queen to be depositing these 3000 or 4000 eggs in the cells each day in preparation for the maximum amount of bees just in time for the harvest. And yet the queen often lays only from 500 to 1000 eggs daily at the very time she should be doing her very best, just because this moderate flow of honey is not in line with our wants, or else the would-be bee-keeper is paying no attention to this matter of securing laborers in time for the harvest.

After the egg is laid it takes 3 days for it to hatch into a larva. This larva is fed about 6 days, during which time it has grown so as nearly to fill the cell, when it is capped over and remains hid from view for about 12 more days, when it emerges a perfect bee; thus making a period of about 21 days from the laying of the egg to the perfect bee. When the colony is in a normal condition, this bee now works in the hive for 16 days more, doing such work as feeding the larvæ, evaporating nectar to the consistency of honey, building comb, etc., when it is ready to go outside as a field-laborer, and at 45 days from the time it emerges from the cell it dies of old age and another generation takes its place.

From the above it will be seen that the egg must be laid at least 37 days before the time which we have ascertained by watching that our honey harvest is to begin, in order that our bee has the opportunity of laboring in that harvest to the best advantage. Now, if the harvest is basswood, commencing to bloom say July 8, the eggs for the laborers should be laid on or before June 1; and if from white clover then they should be laid on or before May 10, provided we have ascertained that white clover blooms so the bees can work on it to advantage about June 16.

But how shall we coax the queen to lay the eggs just when we want them? There are several ways of doing this, such as spreading the brood, feeding the bees warm syrup every night, etc., but I will speak of the one I find just as good as any, and one which requires the least labor of anything I know of.

About a week before we wish the queen to be at her height of laying, take combs which are filled nearly or quite full of sealed honey to the amount of 20 pounds or more (that is, see that each colony has at least 20 pounds of stores in the hive), and break the sealing of the cells of 2 of these combs, after which one of these is to be set in the hive right up next to the outside combs of brood on either side of the brood-nest, doing this work just at night so that no robbing need be started by attracting other bees than those in the hive where you set the honey. Put the other frames of honey outside of these 2 frames, when the hive is to be closed up as warmly as possible by stopping all cracks, etc. There is nothing that incites brood-rearing like this, as it incites the bees to the greatest activity in removing this running honey from the cells, thus causing them to feed the queen freely

on prepared food, so that in 2 or 3 days she is laying her maximum amount of eggs; and, after this, brood-rearing is kept right up from the bees feeling so rich in stores that they see no need of retrenching; they thus keeping on uncapping and removing the honey from the combs, while the queen keeps right up depositing eggs in the cells as fast as the honey is removed, which results

in doubling the amount of brood there otherwise would have been had the bees been allowed to take their own course.

In this way the best possible result as to honey is secured, provided we have our supers and everything else ready and on hand when the anticipated harvest arrives.

Borodino, N. Y.

that side finished, too. Look out for too hot a sun for the comb's sake.

I wonder if the moth-eggs can stand the heat, too? I expect to experiment in this direction some time.

## The Pepper-Tree—Getting 'em Mixed

The pepper-tree (*Schinus molle*), while a native of Peru and Chile, has been largely planted in California, where it is thoroughly at home. It is one of the most ornamental trees that can be grown. In many respects it resembles a weeping willow, though it is not so funeral-like. It is a good honey-tree. Prof. Cook, in his excellent "Bee-Keeper's Guide," classes it with the honey-secreting trees that bloom in April. 'Tis a fine tree, 'tis true, but he is too previous; it blooms in the fall, usually in September.

But the Professor is not so badly mixed as was the writer of the article on "Eucalyptus," in the "ABC of Bee Culture," page 131, edition of 1905. Two entirely different trees are described under one head; the article begins with the word "Eucalyptus," and ends with "pepper-tree." Talk about Irish bulls!

## Mice Fond of Moth-Larvae

In looking over some combs lately that were stored away in the honey-house, I found that mice had gotten to them. The only ones that the little varmints seemed to injure were some that had moth-larvæ in them. Out in the apiary I discovered a hive that became beeless during the winter, and moth-larvæ had commenced to work through the combs. As the hive had a rather large entrance, a mouse made its way into the hive and just cleaned out all the embryo moths. None of the comb, save that where the larvæ were tunneling, was injured by the "foxy" little animal. Here seems to be a new use for the despised mouse. Maybe some one can breed a strain of mice that can be recommended to beekeepers as moth-exterminators. I will pass the "problem" over to our Hasty Afterthinker.

**Honey as a Health-Food.**—This is a 16-page honey-pamphlet intended to help increase the demand for honey. The first part of it contains a short article on "Honey as Food," written by Dr. C. C. Miller. It tells where to keep honey, how to liquefy it, etc. The last part is devoted to "Honey-Cooking Recipes" and "Remedies Using Honey." It should be widely circulated by those selling honey. The more the people are educated on the value and uses of honey, the more honey they will buy.

Prices, prepaid—Sample copy for a 2-cent stamp; 50 copies for 70 cents; 100 for \$1.25; 250 for \$2.25; 500 for \$4.00; or 1000 for \$7.50. Your business card printed free at the bottom of front page on all orders for 100 or more copies. Send all orders to the office of the American Bee Journal.

 You let me know that my time has expired for the American Bee Journal. Now for the life of you, never stop it till I tell you, for I can not bear to lose it. Enclosed you will find money order for same.—IGNATZ KOCH, of Wisconsin.

BY W. A. PRYAL, Alden Station, Oakland, Calif.

## A Wet Season

The season has been a real wet one; long and continuous rains fell since my last reference to the season. In this vicinity the rainfall has been close upon 30 inches—it will, no doubt, exceed that amount before the end of May. Further north, and in the mountains, the precipitation has been twice as much as here—in a few cases, perhaps, as is often the case, especially in Humboldt Co., the rain-gauge records three times the amount of rain that fell hereabouts.

In the southland the "heavenly dispensation," as a certain news-writer wrote it once upon a time, has been ample, fully as good as any that ever favored that sunny land. But will the honey crop be large? That's the question. The long-continued rain has been the means of retarding breeding, so that it may be that there will not be as full a work-force to garner the nectar as there should be when the main honey-flow comes.

The growing of the plants went on apace, regardless of the rain, so that the flowers will be out almost as early as ever. It is probable, however, that the period of inflorescence will be longer drawn out than it is during a dry, or comparatively dry, year.

As matters now stand, I do not remember seeing a season when there was such a promise of a big flower-crop. Now for the bees to capture the nectar!

## Bees on the Islands

On the large islands formed by both the Sacramento and the San Joaquin rivers near their mouths, many large apiaries have been kept for years, and they also yielded a sure crop, even when there was a honey-famine in other portions of the State. The reason that bee-keeping on these islands never became popular, is almost entirely due to the fact that the nectar gathered by the bees yielded a rather dark honey—too dark, generally, to command a satisfactory price. The

honey was usually purchased by the large manufacturing bakeries.

The excessive rains of this spring, and the flooding of nearly all of these islands, has ruined most of the apiaries, many of the hives being carried away by the surging waters. These islands are the great garden-spots of northern California—no richer land is to be found in the world. Some of the islands were almost entirely given over to the growing of asparagus—a vegetable that attains its highest perfection in the sandy and peaty soil of these reclaimed islands. The canning of this vegetable was mostly conducted by an Oakland firm, and its output was said to be the largest in the world. I understand the flooding of their fields has practically bankrupted the firm. This is too bad, for many reasons, one being that asparagus bloom is not a bad forage for bees.

In this flooded district there were immense fields of alfalfa which yielded the best honey obtained on the islands. These fields are ruined. It will be a couple of years, I understand, before the land is restored to its original fruitfulness. Thus, where the rains have helped many, others have been practically ruined.

## The Sun vs. Moth-Larvae

One hot day toward the end of March I was overhauling a hive in which the bees, for some unknown cause, had "given up the ghost," and I found the combs badly infested with moth-larvæ. I shook some of the "worms" out on the black cover of an adjoining hive. The larvæ soon began to squirm, and in a few minutes died. That gave me an idea; it may not be new, for 'tis hard to find anything new nowadays under the sun. (No joke intended.) Why not let "Old Sol" get in his work on the moth-pest?

I thereupon set several "wormy" combs in the hot sun. The result was magical. Larvæ came hustling out of the comb and soon died under the hot rays. The comb was reversed, and

Conducted by EMMA M. WILSON, Marengo, Ill.

### A Sister Starting With Bees

DEAR MISS WILSON:—I want to keep a colony or so of bees, but as our place is new—not a tree nor a shrub—how am I to manage when the bees want to swarm?

When is the best time to get a colony? Can you give me the address of a reliable person handling bees?

Any point that would be of particular importance to a novice would be appreciated.

(MISS) GENEVA WELBORN.

Jackson Co., Mo.

You are to be congratulated that you have no large trees to bother you at swarming-time. If, however, you wish a place for swarms to cluster, you might stick a pole in the ground with a bunch of dark rags attached to the point; or, better still, a piece of old honey-comb, as a substitute for the trees and shrubs. But the simplest way would be to clip your queens' wings, and then no alighting-place would be needed.

In the spring or early summer, after bees are flying daily, would be a good time to get your bees.

Look in the advertising columns of the American Bee Journal. You will no doubt find what you want there.

The first thing to do is to get a bee-book and study it, and no bee-keeper can afford to do without the bee-papers. If any special point comes up that is not made clear in the book, it will be a pleasure to answer any questions in this department.

### A Man's Idea of a Woman's Bee-Dress

In the Irish Bee Journal D. M. M. quotes from a book by John Keys, 1796:

"Women should not meddle with bees without a headdress, nor then without a man's coat, and I had almost said breeches also."

Poor women; pretty warm work to have to wear a man's coat with the thermometer in the 80's or 90's.

### Preserving Oilcloths With Beeswax and Turpentine

Oilcloth looks better and lasts longer if polished with beeswax and turpentine than if washed. To make polish, dissolve an ounce of beeswax in a pint of turpentine. Apply with one piece of flannel and polish with another. To get a good effect quickly be careful

always to use clean cloths. Old woolen vests, etc., will answer the purpose, and it is really a saving of time in the end if they are washed each time they are used.—A. R., in Vick's Magazine.

### The Sting-Trowel Theory Again

DEAR MISS WILSON:—The following appears in one of our local periodicals:

#### REAL USE OF THE BEE'S STING.

"The bee's sting is a trowel, not a rapier," said a nature student. "It is an exquisitely delicate little trowel with which the bee finishes off the honey-cell, injects a little preservative inside and seals it up. With its trowel-like sting the bee puts the final touches on the dainty and wonderful work. With the sting it pats and shapes the honey-cell, as a mason pats and shapes a row of brick. Before sealing up the cell it drops a wee bit of poison into the honey. This is formic acid. Without it honey would spoil. Most of us think the bee's sting, with its poison, is a weapon only. It is a weapon secondarily, but primarily it is a magic trowel, a trowel from whose end, as the honey-cells are built up, a wonderful preserving fluid drips."

I would like to inquire if "Nature Student's" bees are a new species, or are they just common *Apis*, like yours and mine? It is an entirely new idea to me, that a full-fledged—i. e., barbed—bee-sting is a secondary matter. I have been under the impression

all these years that when the little busy bee "patted" me with her delicate little trowel it was primary, very.

As for formic acid, the "ABC of Bee-Culture" calls the poison secreted by bees, "*Apis mellifica*," and the same author says further, "that the bee-sting poison frequently relieves certain forms of rheumatism, paralysis, and perhaps dropsy;" but he neglects to mention that the bees use the poison as a preservative for their honey.

This has been the hardest winter on bees in my experience. I winter them outdoors with chaff cushions, and protected by sheds and evergreen hedges; but I found 5 out of my 21 colonies dead this spring. The remaining 16 are to-day (March 27) bringing in their first pollen from willows, and are just booming with bees and surplus energy.

MRS. BUEL BILLYARD.

Millgrove, N. Y.

Some years ago Rev. W. F. Clarke, a Canadian bee-keeper now dead, published a little book of verse in which he put forth the theory that the sting of the bee was used as a trowel, and that before sealing a cell of honey the bees put into it a droplet of poison from the sting. No proof whatever was given; it was a flight of imagination pure and simple, with no shadow of foundation. With an observation-hive one can see the work of the bee, yet no one has ever seen a bee working wax with its sting, or letting fall from it into a cell of honey the tiniest bit of poison. So you are quite safe to stick to your "primary" view.

Formerly formic acid was believed to be the poison in a bee's sting, but later investigations show it to be something separate. "*Apis mellifica*" is the scientific name for our bees, not for the poison, although a medicine prepared from bees' stings may be called by that name. Formic acid is found in honey, but it gets into the honey while the honey is in the bee, not after the honey is deposited in the cell.

The "Old Reliable" as seen through New and Unreliable Glasses,  
By E. E. HASTY, Sta. B. Rural, Toledo, Ohio.

### ROUND-CELL BUILDING—NON-SWARMING AND SWARMING LOCATIONS.

No, Mr. Aikin, I guess I won't climb clear down from that round-cell tree yet. Some other time—maybe—maybe not. Strikes me you have a pretty compression theory—that hardly tallies in every point with the facts. Still I'm not ready with any reply. At present I enjoy more seeing you up a tree than I suspect almost any man

could be compelled to climb down from—unless he belongs to the sect of never-climb-downs. Your tree is where you say, "The bee is governed in no sense by reason." How would it do to say the dog is governed in no sense by reason? When the dog turns around several times before lying down, it is not probable that he is governed by reason. But when he sees his master take his gun, and he forthwith begins to dance and caper like a wild creature,

# American Bee Journal

he reasons that there is some hunting going to be done—and he likes the job. The dog knows why he does things for the most part; and the things he does not knowing why are comparatively few. But when we pass from the dog to the bee we find the reverse the case. Very many things which superficial view would call wisdom, are simply automatic or habitual; and the bee does not really think or question as to what object is in view. But for all that there is still a remainder of things which bees do just as intelligently as other non-human creatures do. Of course, we know that there are still some folks eager to jaw, jaw, jaw to the end of time in defense of the proposition that no creature but man has a particle of reason. By some odd hocus-pocus they have made this a tenet of their religion. Venture to hope that not many of this tribe of theologians are bee-keepers.

That was a narrow escape you had from getting up the no-trouble-to-control-swarming tree. Your experience in the natural change of a non-swarmling location into a swarmy one is valuable to us. Page 188.

## RESPIRATION OF THE BEE.

I wonder a little what Mr. House was at when he said, "Normal respiration of the bee is 3 or 4 times a minute; under abnormal conditions as high as 124." As a bee has no rib bones and no diaphragm, it might be asked how the respiration trick is performed. Say perhaps a general contraction of the muscles, causing part of the air in the spiracles to go out, followed by general relaxation causing fresh air to come in. The highest rate mentioned would be about 2 per second—same rate at which some clocks tick. My memory dimly confesses to having seen something like successive undulations, not far from that rate of speed, slightly stir the anatomy of highly active bees. At least I'm not going on record as denying that the bee has what amounts to a timed respiration. But I guess most of the brethren either don't know this or else so ignored it that it amounts to about the same. Page 189.

## CARNIOLAN BEES SLIGHTLY LARGEST.

Pretty positive evidence that Carniolans are slightly the largest, if perforations .162 of an inch give satisfaction in most other yards, but are returned as too small from yards where Carniolans are kept. Strikes me I would rather have an occasional queen get up (as they have been doing) rather than have the last one kept down at the cost of having all the workers at their work go through "with a squeeze and a grin." So I still incline to the old .168 of an inch zinc. Put the zinc smooth side down, and so get decided advantage at no cost. Page 190.

## TEXAS ELM HONEY FROM THE LEAVES.

Mr. Smith, of Texas, thinks elm honey comes from the leaves, being in fact "honey-dew." Here's "locality" again with a vim. Do Texas elms have leaves at blooming time, or is that a

slip of the writer's memory? Up here elm leaves do not appear till later on. However, the inflorescence of the elm furnishes lots of surface on which an aphid might breed. Page 191.

## RENDERING BEESWAX.

In wholesale way, with Mr. Cogshall's kettle and sack rendering of beeswax, the slumgum contained 35 pounds of wax to the barrel. That's more than we enjoy throwing away. Page 190.

## HONEY-DEALING ANNOYANCES.

The way Mrs. Amos trims a certain bee-man is somewhat amusing. But "we're all poor critters!" She feels real annoyances on one side. He feels the pinch of severe conditions on the other side—the difficulty of making the days have a hundred hours each. Still I suppose we shouldn't mortgage a hundred of to-morrow's hours unless

we are prepared to deliver that many. Page 192.

## ELECTRIC HEAT FOR BEE-CELLAR.

An electric heater for the bee-cellar! Well, well, we are coming on. And I see no reason why electric heating should not be the best possible—in this case where heat is often needed, but hard to apply without doing mischief. Page 191.

## USE BEST HONEY FOR INFANTS' FOOD.

If honey is to be used in an infant's food, let it be done with care, and by a judicious person, until it proves itself all right. And *in heavenly mercy* don't let it be such poor, half-spoiled honey as is sometimes sold. Sadly too many outsiders think honey is honey, and don't discriminate. Still, I guess there's not danger of any such deadly harm to the little fellows as bad milk sometimes brings. Page 193.

## Report of the 37th Annual Convention of the National Bee-Keepers' Association, held in San Antonio, Tex., Nov. 8-10, '06

(Continued from page 316)

### DISTANCE TO BREED PURE QUEEN-BEES.

"How far should a breeder of pure queen-bees be isolated from all other bees?"

Dr. Bohrer—I don't know of my own personal knowledge how close queen-breeding apiaries are situated to each other, but my own idea has been this: As different races of bees are being brought into the United States, these apiaries should be 12 or 15 miles apart. I know this, that bees will go 7 miles. I have timed queens that have left a hive and have been out  $\frac{3}{4}$  of an hour. Now how far they have been I have no knowledge. How far the drones will go I don't know, but I have reason to know that queens and drones will go a greater distance than 12 miles. I have known of two races being bred in the same yard and sent out over the country. Now, whoever these bee-keepers are, they have not been sending out pure queens, and they ought to quit the business. Now, I have no ax to grind; I have no queens for sale and don't intend to have any. I am not in the bee-business to make much money out of it, but for pastime, and I don't want to quit it now. I am not going to give any names, but there are parties here who know something about it. If they are sending out different queens from the same hive, they ought to be notified to quit business, or be exposed.

I know of one man that I understand had foul brood in his apiaries, and considerable money was sent in for queens, and he had the honor to notify them that he had foul brood and would not send out a queen. I don't believe that he is the only man that would do this. But these are matters that we want to hunt up. If you have foul brood in your apiary, you need not be scared about this matter, nor ashamed of it, but it is harmful to keep it. It may be your fault, it is a misfortune, but go to work and get rid of it. The man who is sending out different races of bees, and breeding them side by side, is not working for the interest of the bee-keeping of this country. I don't know the names of these parties, and especially those who are sending out four different varieties of bees bred in a small apiary of 24 or 25 colonies, all kept in one yard. We should work together and find out who those parties are, and quit patronizing them until they do better. I don't want queens badly enough to get them from a man who will do business in this way.

Pres. Dadant—Are there members who have any experience in this matter, in regard to distance?

W. H. Laws—I have been wondering who in the world such charges could be brought against. Dr. Bohrer is very earnest in what he says. Since the introduction of the baby nuclei, I have known an honest man who breeds the Carniolan, Caucasian and Italian, and keeps them all in one yard. But he takes 200 or 300 of these baby nuclei and goes out far in the country with them, and these queens are mated to

those drones. A few days afterwards he brings those drones in, and those bees come from the same yard. He is doing a good business, and a man that buys queens from him is getting fine stock. He has a few bees all kept in the same yard, but the mating ground is in a separate place.

Will Atchley—I have had the same complaints come from a party, that I think he refers to, and I visited the same place and I found what Mr. Laws says is true.

A Member—I want to say that Dr. Bohrer is talking from what he knows, but that party was not from Texas. It has been asked that the National Association should look after the queen-breeders, and know that bee-keepers are getting stock true to name; that the Association appoint a committee to investigate this matter. There are some who are doing everything that is possible to breed true to name; we send to them and their bees are true to name when we get them; they are not satisfactory, and I think many times it has been in getting tested queens that have been hurt in transportation. Would it look reasonable that if you should buy a fresh-milk cow and ship her from home down to Texas, without any care, would you expect her to continue a nice fresh cow when she arrived? Would you expect this of a nice tested queen? Yet it is not the fault of the queen-breeder? I believe that some of us are inclined to criticise queen-breeders that are doing right, and need upholding in what they are doing. We should know that a man is shipping from an infected yard; those things ought to be investigated.

Dr. Bohrer—I want to explain in regard to the mater of queens being injured through the mail. I have not found much abuse in that particular. I purchased a queen from a Texas queen-breeder, and she was one of the best that I ever saw.

#### MOST PROFITABLE RACE OF BEES.

"What is the most profitable race of bees for both comb and extracted honey?"

Mr. Stone—I think the Italian bee is the most profitable.

Mr. France—My observation from the State of Wisconsin says the Italian bee.

Mr. Victor—Yes, I think the Italian bee is the most profitable.

W. H. Laws—I would like to ask Mr. France if it is the improved or the 3-banded Italian he prefers.

Mr. France—I favor the 3-banded Italians for their honey-gathering qualities.

Pres. Dadant—In Europe there are some countries where they criticise the Italian bees. I had the opportunity of investigating bee-culture and the Italian bee. The man who writes a book is very careful of his statements. Now, I took 12 of the leading works of Europe and America, two German, one Swiss, one Italian, one English, one Irish and two French, and I think one or two American. Everyone said that the Italians were more industrious. I

believe that this is as good as can be given.

Mr. Stone—I would like to introduce the golden Italian, especially where I have any black blood in my colonies. You get good hybrids when you get the 3-banded bees.

Mr. Anderson—I stand up for the Carniolans, although I have not reared many. I have been using Italians principally until this year. I get more honey from the Carniolans.

Wm. Atchley—For 10 years I preferred the 3-banded improved Italians, but for the last 5 years the Carniolans have proven themselves superior to the Italians in my country.

#### THIRD DAY—FIRST SESSION.

After the members had assembled, they were requested to go to the City Hall, where a group photograph was taken. Then at 10 o'clock, a. m., the meeting was called to order by Pres. Dadant. The Committee on Amendments appointed last year was called upon to make a report.

Pres. Dadant—Mr. Holekamp was a member of the committee to divide the membership into districts in the different States.

Mr. Holekamp—I studied about this matter and found that the work which I had in mind for the directors was so great that it will be very difficult to find men who will undertake the work. Therefore, I think it best not to make any recommendations. I withdraw the proposition.

Pres. Dadant—You have heard the report of the committee. Under the conditions I think it will be well to accept this and discharge the committee.

On motion the report was accepted, and the committee discharged.

The Committee on Exhibits then reported as follows:

#### REPORT ON EXHIBITS.

We, your Committee on Exhibits,

beg to report a very creditable exhibit of apiarian supplies and honey. However, we consider it short in many respects.

The largest exhibitor, Udo Toepperwein, of San Antonio, Tex., shows hives of various kinds, both in the flat and nailed up; honey and wax extractors, bee-smokers, and other appliances generally listed in the catalogs, besides bottled honey and beeswax. A nice feature of Mr. Toepperwein's exhibit was the distribution of delicious candy made of honey.

A. G. Anderson, Secretary of the Emery County Bee-Keepers' Association, of Ferron, Utah, has two jars of sweet clover and alfalfa honey, of light color and good flavor.

T. F. Bingham, of Farwell, Mich., has one of his latest improved bee-smokers.

L. Werner, of Edwardsville, Ill., shows a bottle of Spanish-needle honey. This honey is rather dark in color, and strong flavored, otherwise resembling buckwheat honey.

N. E. France, of Platteville, Wis., General Manager of the National Bee-Keepers' Association, has gotten up a neat Guarantee Label or Seal, for members of the Association to be placed on packages of honey for protection. Mr. France also has samples of different kinds of honey from 34 States, labeled according to their source. One reason for the small exhibit here at the convention hall is on account of the exhibits at the Fair.

Exhibits of this kind in connection with bee-keepers' conventions should be encouraged. It draws out much interest, acts as a source of advancement in bee-culture, and adds materially to the interest of the conventions.

LOUIS H. SCHOLL,  
DAVID H. COGGSHALL,  
A. G. ANDERSON,  
Committee on Exhibits.

On motion the report was approved.  
(Continued next week.)

Send Questions either to the office of the American Bee Journal, or to  
DR. C. C. MILLER, Marengo, Ill.

Dr. Miller does not answer Questions by mail.

#### Perforated Wood Separators

I have mailed you to-day a few samples of a perforated separator which I am making, and would like your opinion on the merits or demerits of the same. As you see, it is the plain sawed separator perforated in order to secure the advantages of the slat separator at less cost. I buy them at 40 cents per hundred, and can perforate 1800 per day, so you see it has the recommendation of cheapness, at least.

As I use the T-super I can not use slat sep-

arators with bee-way sections. Have such separators ever been used?

The greatest trouble in doing work of this kind is to keep from splitting the wood, and I have overcome that, having perforated 800 without splitting one.

Would it be worth while to patent the machine, or could the separator be patented?

Provided there is enough merit in a separator of this kind, I should like to make them and sell them at a more reasonable price than the supply-dealer would.

IOWA.

ANSWER.—You do not say whether you

have used these separators, but I suspect not, for unless the perforations are narrower you will be pretty sure to have sections with ridgy surfaces. I do not believe you could secure a patent, for the same thing has been in use before. Wood separators are sold for much less than you mention, but I think they are sliced, and not sawed.

I do not quite understand why you say, "As I use the T-super I can not use slat separators with bee-way sections." I do not understand why any separator can not be used in a T-super, nor any section. Of course a fence separator will not work the very best with bee-way sections, but the two will work together just as well in a T-super as anywhere else. I have used in a T-super fences and separators of different kinds, also plain sections and bee-way sections of different sizes, and if you will explain a little more fully what you mean, perhaps I can show you the way out.

## Two Queens in a Colony

At one of the bee-exhibitions held at Vienna, a discovery was made which perhaps will change the opinion held on queens living together. Before this it was thought an uncontrollable fact that every bee-family obeys one queen, and that it was never possible that the mastery could be divided. This opinion can not be maintained after Prof. Gatter von Simmering exhibited a bee-hive whose population was governed by 2 queens, and which seemed to enjoy the innovation. And what is more remarkable, the 2 sovereigns lived together quite peacefully, and without ever getting hostile. There was never a sign of grudge, jealousy, or any attempts to get rid of a disagreeable rival; but, on the contrary, the 2 queens seemed to feel a really reciprocal inclination. They came together from time to time caressing, and separated tranquil and peacefully, followed by their devoted subjects. —Translated by HUGO BARTH, of Washington.

ANSWER.—While in general only one queen is to be found in a hive, it is not at all an uncommon thing, at the time when an old queen is superseded, to find at least for a short time mother and daughter living peacefully together. Indeed, this may be the rule rather than the exception; only hives do not happen to be opened a great deal at the usual time of superseding, which is at or near the close of the harvest. If the case in question was that of mother and daughter, it is only what may be found in the fall in almost any apiary. If the 2 queens were not mother and daughter, then the case is rare. In my own experience I never had but one such case.

## Wiring Frames and Fastening Comb Foundation

1. I engaged in bee-keeping 2 years ago, and now have 25 colonies wintering in the cellar. I hope to double this number the coming summer, and have contracted for the 1½-story dovetailed hives for new swarms. I shall work for extracted honey from these hives exclusively, and have thought to use full sheets of comb foundation in both brood-chamber and supers. Not knowing the depth of the brood-frames in the ordinary dovetailed hives, I wish to know if I can procure comb foundation sufficiently wide to fill the frames above mentioned. Also, is it best to wire said frames? If so, how many wires would be necessary?

2. Describe briefly how the wires are put on the frames and fastened.

3. How close to the bottom-bar should the foundation come? and is it necessary to fasten the foundation to the end-bars of the frame? What instrument is best for the purpose?

IOWA.

ANSWERS.—1. Yes, comb foundation of that size is kept regularly in stock, and by ordering in advance you can have foundation out any special size.

Yes, unless the foundation is heavier

than is profitable, it should be supported either by wires or foundation splints. For the deep frames 4 horizontal wires are used; and 2 for shallow frames.

2. You will probably find the end-bars of the frames pierced for wiring when you purchase them. Find out how long a wire will be necessary for each frame, and then figure on having your wire cut a little longer than necessary. Suppose you want to cut the wire 7 feet long. Cut a board half that length, 3½ feet, and wind the wire upon it. Then with wire or string tie around the wires every 6 or 8 inches, to keep it from snarling; and at the same time tie around the board so that the lot of wire will stay upon the board till all used up. Now cut the wires at one end of the board, and you can take hold of each wire at the other end and draw it out as wanted. Now run one end of a wire from the outside through the hole next to a top hole in one end-bar, then straight through the corresponding hole in the other end-bar, then back through the top hole of this last end-bar, then through the top hole of the other end-bar, and fasten the end by giving it a turn or two about a small nail driven partly in, and then drive the nail fully in. You will now see your way clearly to working downward with the other end, and fastening it in the same manner. Make a board that will just fit inside the frame, put cleats on the edges so the frame will be supported with the wires just resting on the board, lay the foundation on the board and the wires on top of it, pushing the foundation into the saw-kerf of the top-bar as you lay down the frame; run the wire-imbedder over the wires with sufficient pressure to imbed them, then lift off the frame and crowd the wedge into the top-bar good and deep.

3. Leave ¼ inch between foundation and bottom-bar. With foundation splints the foundation comes clear down, but as you have not Miller frames, you can not well use them. There is perhaps no better tool for imbedding than the spur wire-imbedder.

## T-Supers and Cleaning Sections

I have been very much interested in those discussions in the American Bee Journal about cleaning sections. I have been keeping bees in modern hives 7 years, and have now run my apiary up to nearly 100 colonies, and run mostly for comb honey. I have your "Forty Years Among the Bees," and read and studied it quite carefully in connection with a number of others, and all the bee-papers. I am using the Danzenbaker, Langstroth and Ideal super, and 10-frame hives. I adopted the plain section on account of the style and the close packing for market, and because they take less wood and are simpler and easier to make if I take a notion to make them, and a little cheaper when I buy them. But it is a hard proposition to decide whether I like the Danzenbaker better than the Ideal.

I have also been very much interested in your T-super, and I think I shall try it next summer, to see how I can make it work with my kind of section.

I noticed in one of your discussions, in replying to "Colorado," regarding the prodigious speed in which you get your sections scraped and cleaned, you seemed to place great stress on the T-super for a short cut. I fall to see the point. If I understand your "Forty Years," your sections are all out of the super before any attempt is made to clean them. Then how can the super have anything to do with the speed at cleaning? Of course, I note that you say you take your sections out in bulk, but my sections will also come out in bulk from the Langstroth and Ideal supers, and I imagine the slats would be about as easily lifted off as the T-tins; and I can not see why the fences won't come out as easily as your plain sawed separators, though I must confess it generally takes a good, stout knife all the way through to disengage the pieces, as they are so everlastingly glued together with propolis. I very seldom take them out in bulk, but one row at a time, and

it is generally done right out in the yard and among the bees. I just tip up a Langstroth super on one side, or an Ideal super on one end, as the case may be, right on the hive where it was filled, with bees and all in it, and with my right hand on the bottom of a slat, and my left hand on the top of an adjoining section and super-body, I work my fingers among the bees until I get good bearings, and begin pushing until one row of sections comes out. I then shake off the bees and set that row on top of a near-by hive, and with a knife I loosen another row and take it out, and so on until I get a load to carry in the house. I have found this the most practical way I have ever tried for the bulk of my crop. Sometimes, when bees are cross, or robber-bees are bad, I have to smoke the bees down and run inside fortifications with the super to do the work, but these are exceptional cases.

But to get back to the point: You say your honey comes out of the super in bulk. Well, I suppose all bee-keepers bulk their honey when it is taken out, anyway. What I want to know is, how the T-super makes any short cut at cleaning. My honey (what I have left of it) is now bulked on a long bench made by laying some 16-foot barn-boards on hive-bodies, and I can pick up 8, 10 or 15 at a time by simply gripping two outside sections in a row and pressing the others between like a printer does a form of type. I could set a number of them on a cleaning board in a jiffy, and throw a clamp around them and wedge them up as you say "Philo" does, but I can't see where the T-super part comes in to help me out in the matter.

My sections are protected on the bottom and sides, and the top is nearly always the hard part to clean. Now, I can not see how it will better the case to give the bees a chance to gob up the bottom. Nevertheless, I think what you say must have something in it, and I desire to test the matter the best I can, and I want all the light I can get beforehand. And now we go for the questions:

1. In what particular way does the T-super assist at cleaning sections?

2. Do you think your methods of manipulating T-supers would work as nicely with plain sections and fences as with bee-way sections and sawed separators?

3. Did you ever try the all-metal separators made of woven wire? If so, what was your experience with them?

4. Do you think it would be easier to push the super full of sections out of a T-super than it would a Langstroth super, or an Ideal super with slats?

5. Do you think it much easier to lift out the T-tins than it would be to lift off the slats?

6. Do you think it easier to lift out the sawed separators than the fences?

7. Do you not think plain sections would scrape much nicer in a clamp than the bee-way section, there being no chance for propolis to drop down between the sections?

8. How do you keep bits of propolis from flying against the faces of sections and sticking there, anyway while cleaning 2000 a day in that dexterous fashion?

9. How do you keep your scraper clean? I have always practised cleaning one section at a time with a knife; the latest is a butcher-knife, and I find a very few strokes clog it up so the edge is of no service, and so I devised a damp cloth to wipe it on. Sometimes it has to be wiped several times while cleaning a section, and the cloth fills up with propolis. I used to wipe it on my apron, which consisted of an old cotton wheat-sack ripped up and arm-holes cut in it, until I got a good portion of it well veneered with bee-glue, and I got tired of that. The knife clogs especially quick when a little honey has run out and stands on the wood with the propolis.

10. When cleaning sections, how do you manage the parts that are gummed with honey as well as with bee-glue?

11. Well, you can supply this question, as I think I have gone far enough; but I will add that I think I am getting a little above the average with the butcher-knife. I can beat "Colorado." I can clean 200 a day all

# American Bee Journal

right, and then some; but I will confess that I do not try to take off the stains. I have found that a great deal of the stains on my sections penetrate considerably into the wood, and so I content myself with making them smooth and unsticky.

MISSOURI.

ANSWERS.—I am glad of the prelude, for it gives me a better idea of just what you want answered.

1. I think you have an idea that I credit to the T-super more than I actually do give it credit for in the way of shortening the work of cleaning sections. I don't for a minute think it makes all the difference between cleaning 2000 and 500 or more. The most important particular is the opportunity of handling the sections in a block. If I think the next 9 answers do not bring that out clearly, I'll return to it in the 11th question.

2. Yes, and no. Depends upon what you mean by the question. One of the beauties of a T-super is that it adapts itself to a section of any kind. Indeed, you can use sections of 6 different widths in the same T-super at the same time. Can you do that with any other kind of super? I have used in the same T-super at the same time plain sections and bee-way sections, plain sawed separators and fences. If that's what you mean by the question, then my answer is yes; and I may say that the T-super used with plain sections and fences gives the same advantage over other supers, as when used with the bee-way sections and plain separators. But if you mean to ask whether I can work as rapidly with a T-super filled with plain as with bee-way sections, my answer is no. I can't say about others, but in this locality it's slower work taking out fences than plain separators, and slower work cleaning plain sections than bee-way sections.

3. I tried them when they first came out, many years ago, and at this distance I can not give particulars, but I did not find advantage enough in them to adopt them.

4. It is not easy to answer without the opportunity to try the two side by side; but it may be said in general that there ought to be very little difference in emptying two supers if the entire contents of each super comes out in a mass.

5. Yes. Even if a T-tin were no more easily removed, there are only 3 in a super.

6. Yes. A knife will slice right through at one stroke between the sections and the sawed separators. With fences you must hesitate at each post or you'll cut into the post. Whether you have plain separators or fences, it's easier to get them out of sections from a T-super than from any other super that allows the sections to be close together endwise. For in the T-super the sections are about  $\frac{1}{2}$  inch apart endwise, and when at the proper temperature you can strike with the ball of each hand at the two ends of a row of 4 sections, and the single stroke will loosen all 4 sections from the fence. That trick is in constant use in this locality, and I think it's possible only with a T-super.

7. One ought to scrape about as well as the other, provided there be a perfect adjustment. But in clamping together a superful, it would be nothing strange to find a good many places where one section was 1-16 inch or more higher than its next neighbor where the two joined; this would make more trouble with the plain than with the bee-space sections. Bee-glue has the better chance to fall through the bee-spaces, but in this locality that is not a serious trouble.

8. It doesn't stick, because it isn't sticky. It's merely dry powder or larger pieces of entirely unsticky glue.

9. We don't have any trouble of that sort. The secret of it is that we don't work with sticky propolis, and I don't believe you need to either, if you wait till it's cool enough to be brittle.

10. If there be honey on a section it will be on the top. If there is any considerable quantity it is first lifted off by sliding under it a case-knife and scraping the honey from the knife into a dish. Where there isn't enough to scrape up thus, or after it has been

scraped up, a cloth quite wet mops off the honey, and a drier cloth wipes it off.

11. This is the hardest of all to answer, but I'll not attempt to answer *all* I can think of. I feel like first asking *you* a question: Don't you think you ought to be a bit ashamed to shirk off upon the other fellow the task of asking all your questions heretofore? Never mind about that, but let's go back to the first question. You may possibly not have caught the idea from what has been said that when a superful of sections is emptied out, all you have to do is to lift off 3 T-tins, and you have full chance at the whole top and bottom of the superful, and when you have the tops and bottoms of the sections cleaned you have the job pretty much done. If there is any other super with which that can be done, it does not now occur to me. You are quite right that you can assemble in the same way the sections from any super; but you must first take them apart and then put them together again. The T-super saves this.

When you say you take out 4 sections at a time and then get the bees off, I can't help wondering whether you would not get along a good deal faster to take off the whole super, and after piling up 10 or 12 supers allow the bees to get out of their own accord.

I don't know whether there may be anything in your circumstances to oblige you to clean sections while the glue is soft, but I feel pretty sure you would get along twice as fast if you would do the work when the glue is brittle. The soft glue falling on the face of a section and sticking there is a thing that never occurs here, and it's ever so much easier to scrape off dry, brittle glue than the sticky stuff.

Now after all I've said in favor of the T-super, I advise you to go slow and try it on a small scale before you think of investing much in that direction.

with 5 small holes, so small that a bee can not get its head through. In putting the bees into winter quarters a couple of years ago, I missed taking one of the tins out, and they were closed up 5 months. When I came to take them out I found the tin there. I thought surely they would be dead, but when I opened them I found they had wintered the best of any in the yard. So much for ventilation. I may say that they had a little upward ventilation, as had all the rest.

Clarksburg, Ont.

EDWARD KNOLL.

## First Spring Pollen Record

The weather is warm. I have some losses of bees, but not heavy except in 2 groups numbering 14 colonies, which I let go into the winter in a quite unusual way.

The first pollen was brought in yesterday. The following is the first pollen-gathering record for 28 springs:

1880....	March 30	1894....	March 17
1881....	April 14	1895....	April 5
1882....	March 2	1896....	April 11
1883....	April 10	1897....	April 18
1884....	March 27	1898....	March 21
1885....	April 20	1899....	April 12
1886....	April 12	1900....	April 7
1887....	April 9	1901....	(?)
1888....	April 5	1902....	March 23
1889....	March 22	1903....	March 17
1890....	April 8	1904....	(?)
1891....	April 2	1905....	March 26
1892....	April 3	1906....	(?)
1893....	March 31	1907....	March 26

Of the first 13 there were only 4 in March; the last 13 have 7 in March. So the notion that the springs are later now don't amount to much.

E. E. HASTY.

Toledo, Ohio, March 27.

## Rearing and Mating Queens

Last season with one colony I reared 47 queens in 90 days. This colony built all the cells, nursed all the cells till the queens were hatched, and nursed all the young queens till they were mated with the drones. I tested a good many queens and I made an increase of 3 colonies from this colony, and this spring the colony is one of my best. I am getting this colony ready now to rear queens this season.

If I would have the time in August and September to rear queens, I could rear 100 queens with a single colony in only one season, and the colony would do all the work. With my method I need not make nucleus colonies, nor break up a colony. With this method of rearing queens you can find out how many queens will meet more than one drone. The last lot of queens I reared last season I watched closely to see how many queens would meet more than one drone, and out of 11 queens 6 queens met 2 drones each. I had one queen that met 3 drones.

The 3 queens I received as premiums last July are fine queens, and are better than I expected to get. The 3 queens breed nice bees. I am so well pleased with one of the queens that I will use her as a breeder this season. She is leather-colored, and her bees are the same, and are uniform in bands.

JACOB F. HERSHEY.

Lancaster Co., Pa., April 8.

## Alsike for Bee-Pasturage

I wish to answer a question asked last spring about this time in Gleanings. The questioner lived in Iowa, and asked the question: "What shall we plant or sow for bee-pasturage?" The same answer that would be true then is true now. There is nothing better than alsike or Swedish clover. It makes as fine honey as white clover or as sweet clover. And no other clover makes as fine hay for any kind of stock as alsike. All kinds of stock like it, and will eat all of the stems up. Then the second crop comes in good play for fall honey.

We sow nothing in the clover family but

## Good Prospects for Honey

My bees have wintered very well and are at present very busy gathering pollen and maple sap, but no flowers are yet to be seen. The thermometer was up to 80 degrees above zero in the shade for nearly 4 days in March, when a sudden change came and the thermometer went down to nearly zero. April started in pretty cool, but it is getting warmer every day, with a little rain. Everything is getting green up here, and prospects are for a good honey-year.

B. F. SCHMIDT.

North Buena Vista, Iowa, April 4.

## Unfavorable Weather

I took my bees out of the cellar April 3, after a confinement of 4 months. I found 3 colonies dead out of 55. The weather since then has been quite cold, cloudy and windy. Today it is freezing, with a high northwest wind, and "spitting" some snow. It is rather unfavorable weather for bees or farm work.

Riceville, Iowa, April 8. A. F. FOOTE.

## Ventilation in Wintering Bees

My bees swarmed very little last year, and gave me very little surplus. As it was cold and wet the bees did not build up in time for the clover. They used most of the honey for brood-rearing, but they went into winter-quarters in good condition. I dug them out of 4 feet of snow on March 13, and they had a good flight, so I think they will come out all right.

I read a good deal in the American Bee Journal about ventilation in out-door wintering. In moving my bees into the winter boxes, I close the entrance with a piece of tin

alsike. Some people get the impression that alsike and alfalfa are the same thing, but this is a mistake. Alsike must be sown with timothy, as the stems of the alsike are so lumber it can not stand alone. It can be sown in the sprang with the small-grain crop.

I have just received the March numbers of the American Bee Journal, and it seems as if an old friend has come to see me. The heading on the outside says 47th year. Forty-one years ago last fall I traded my old musket, that I brought home with me, for my first colony of bees, and it was up and down with me (down most of the time) until Thomas Chantry recommended me to take some good bee-paper. So I took the American Bee Journal, and from that time on I made better success, but I had a great many failures. I always tried to do better next time.

Menlo, Iowa. O. P. MILLER.

**Bees and Honey in Montana**

Bees are doing fine here. I have 35 colonies which I run for comb honey. I got 100 pounds of honey from each of some colonies, and the queens I got from you did better yet. I rear my own queens now and want nothing better.

I get 25 and 30 cents per pound for comb honey, and \$10 to \$15 per colony for bees. I winter them outdoors. I have 4 colonies in one tenement house, but do not like it as well as a single chaff hive. My main honey-flow is from wild roses.

I clipped my queens March 23 and found one dead out of 35. For experiment I left 2 supers of honey on. The honey was extra-fine, but the bees are dead.

FRED HOFFMAN.  
Lewistown, Mont., March 26.

**Queens** By uniting swarms **Supplies** from 1000 colonies

I sell queens at—1 queen, 25c; doz., \$3. Also following supplies at 1/2 Root's prices: 1000 P. & I. fences; 1000 plain section-holders; 1000 4 1/4 x 4 1/4 plain sections; Daisy foundation fastener; 10-inch foundation mill; 200 10-frame wood-zincs; 2 doz. Porter escapes; 500 Hoffman frames. **R. M. SPENCER,**  
4A16t Nordhoff, Cal.

**TAYLOR'S STRAIN OF ITALIANS IS THE BEST**

Long Tongues and Golden are best of honey-gatherers; 18 yrs. a specialty, breeding for best honey-gatherers. Untested, 75c, or \$4 a doz.; Tested, \$1, or \$10 a doz.; Select Tested, \$1.50. Breeders, very best, from \$3 to \$5. Carniolans same price. Try them. We also sell Nuclei and full colonies. Bees in separate yards. Safe arrival guaranteed.

J. W. TAYLOR & SON  
13A10t BEEVILLE, Bee Co., TEXAS.

**70 Colonies of Bees For Sale Cheap**

In large quantities, \$3.00 per colony, and \$3.50 in small lots. The bees are in 10-frame Langstroth hives, and in excellent condition.

13A4t G. PROGNOW, Mayville, Wis.

Samples of Honey analyzed. Correspondence solicited.

**Something New=The Ideal Hive=Tool**

Bee-keepers have long needed a special Tool to work among the hives during the bee-season. The one shown here was invented by Wm. Muench, a Minnesota bee-keeper, some years ago, but it was not on the market before. We have lately bought this Tool, and all rights, from Mr. Muench's widow, and have had the first lot made. They are ready for delivery now.

Best Hive-Tool

Only 30c, by mail

(This picture is exactly one-half the size.)

DESCRIPTION.—The Ideal Hive-Tool is made of high-grade malleable iron, much like wrought iron, 3 1/2 inches long. The middle part is 1 1/16 inches wide and 7-32 thick. The smaller end is 1 1/2 inches long, 1/2 inch wide, and 7-32 thick, ending like a screw-driver. The larger end is wedge-shaped, having a sharp semi-circular edge, making it almost perfect for prying up covers, supers, etc., as it does not mar the wood.

**What Dr. Miller and Miss Wilson Say of It:**

In the first edition (1903) of Dr. Miller's "Forty Years Among the Bees," page 58, he says: "Of all the hive-tools I have tried, I like best the Muench tool." On Jan. 7, 1907, he wrote us saying he thought "just as much of the tool as ever."

Miss Wilson, Dr. Miller's assistant, says this of the Ideal Hive-Tool: "It is an ideal tool. In fact, I don't see how it could be improved upon. I am sure we would feel utterly lost in the apary without it. . . . You will have to try one yourself if you want to know its worth."

**The "Ideal Hive-Tool" Free as a Premium.**

We will mail an Ideal Hive-Tool FREE as a premium to any present paid-in-advance subscriber to the American Bee Journal, for sending us ONE NEW subscription for a year at \$1.00; or we will send the American Bee Journal one year and the Ideal Hive-Tool—both for \$1.20. Price of the Ideal Hive-Tool alone, postpaid, 30 cents. Address,

GEORGE W. YORK & CO., 334 Dearborn Street, CHICAGO, ILL.

# American Bee Journal

## Standard-Bred Italian FREE PREMIUM QUEENS

We are booking orders now for those Fine Untested Italian Queens that we offer every year FREE to paid-in-advance subscribers as premiums for getting NEW subscribers for the Weekly American Bee Journal. These orders are taken for May or June delivery.

### What Some Say of our Standard-Bred Italian Queens:

*George W. York & Co.*:—The two queens received of you some time ago are fine. They are good breeders, and the workers are showing up fine. I introduced them among black bees, and the bees are nearly yellow now, and are doing good work. A. W. SWAN.  
Nemaha Co., Kan., July 15.

*George W. York & Co.*:—After importing queens for 15 years you have sent me the best. She keeps  $9\frac{1}{2}$  Langstroth frames fully occupied to date, and, although I kept the hive well contracted to force them to swarm, they have never built a queen-cell, and will put up 100 pounds of honey if the flow lasts this week. CHAS. MITCHELL.  
Ontario, Canada, July 22.

*George W. York & Co.*:—The queen I bought of you has proven a good one, and has given me some of my best colonies. N. P. OGLESBY.  
Washington Co., Va., July 22

*George W. York & Co.*:—The queen I received of you a few days ago came through O.K., and I want to say that she is a beauty. I immediately introduced her into a colony which had been queenless for 20 days. She was accepted by them, and has gone to work nicely. I am highly pleased with her and your promptness in filling my order. My father, who is an old bee-keeper, pronounced her very fine. You will hear from me again when I am in need of something in the bee-line. E. E. MCCOLM.  
Marion Co., Ill., July 13.

### How to Get these Queens Free

To any one whose own subscription to the Weekly American Bee Journal is paid in advance, we will mail a Fine Standard-Bred Untested Italian Queen next May or June, for each new name and address sent to us with \$1.00 for the Bee Journal a year. No one can get for himself the Bee Journal a year and the Queen for \$1.00. The Queen is offered as a premium for the work of getting some one else to take the Bee Journal a year. If you, yourself, want the Bee Journal a year and the Queen, send \$1.50 for the two, and we will book your order for a Queen. Queen orders will be filled in rotation—"first come, first served."

Address,  
**GEORGE W. YORK & CO.**  
334 Dearborn Street, CHICAGO, ILL.

## Millions of Dollars

are made every year in the book business. Every family, rich or poor, must have books. During the last few years, \$7,500,000.00 have been expended for Modern Eloquence, \$12,000,000.00 for Stoddard's Lectures, \$21,000,000.00 for the Century Dictionary, and the tremendous sum of \$4,000,000.00, covering over half a million sets of the Encyclopedia Britannica. These books were sold by subscription in American homes and sales are still going on.

We have a subscription publication which sells more readily than any of the above. The demand is already so tremendous that more capital is required to swing it, or get behind on orders. Profits are enormous, several times savings bank interest.

### We have arranged a plan whereby Any Progressive Man or Woman Can Share These Profits

becoming stockholders in a profitable business, based on twenty years' experience. Remember, the success of this publication is not away off in the future—it is not prospective, but it is a success at the present time and growing in demand every hour. Sales of this publication at the time of publishing this advertisement

### Often Exceed \$2000 a Day

This is an exceptional opportunity for those of small means to get in on the ground floor in a business which legitimately pays large dividends and is as solid as the Rock of Gibraltar. It cannot be held open for long as the response is certain to be so great that we shall have all the capital we need to increase the number of our presses and secure stock to be turned out in completed books, which are selling like wildfire.

You owe it to yourself to investigate this opportunity. You will never have a chance like this again to become

### Part Owner in a Mammoth Publishing House

which is already in successful operation, already earning big dividends, and which is led to sell a small amount of its stock simply because the business is already so tremendous as to exhaust the working capital. But if you would grasp this opportunity you must

CONVENTION NOTICE.

Minnesota.—The Minnesota Bee-Keepers' Association will hold its spring meeting on Saturday, April 20, 1907, at the Old State Capitol in St. Paul. The afternoon session will commence at 1 o'clock, and the evening session at 6 o'clock. Free refreshments will be served from 5 to 6 o'clock, by the lady members of the Association. A leading feature of the afternoon session will be a practical demonstration of the modern method of queen-rearing, by Chas. Mondeng; and at the evening session the simplest way to cure foul brood. Papers will also be given on, "Spring Management," by Wm. McEwen; "Production of Comb Honey," by Chas. Blomquist; "Shipping Bees and Honey," by Mr. Gent; "Bee-Keeping in Connection with Farming," by Pres. II. V. Poore; "Bee-Keeping for the Beginner," by W. R. Ansell; and a paper by Mrs. E. E. Merrill. Questions on bee-keeping by any one interested will be fully discussed and answered. Lay everything aside and attend this meeting; you will never regret it. We want every one to come, whether a member or not. Brother and sister bee-keepers are all cordially invited. The membership dues are \$1.00 a year, including membership in the National Bee-Keepers' Association.

CHAS. MONDENO, Sec.

Minneapolis, Minn.

## YOUR MONEY IS GOOD

You know that. We know that. Every one knows that. If it were not, every one would not be ready to take it. You and you alone must insist on returns, real returns for the good money you spend for bee-supplies. If you don't see to it that you get your money's worth no one will.

## NOW WE WANT TO ASK YOU A QUESTION

Do you know that you are losing money—real, hard-earned money—every time you put a colony of bees into a cheap, poorly fitting hive? You are, for the good reason that the bees are spending most of their time building over the hive when they ought to be making honey.

## HONEY MEANS MONEY

Thus more than the money that you think you are saving when you buy a cheap hive the bees are losing for you "hand over fist," and you don't know it. It's the fault of the hive.

That's why some bee-keepers get a whole lot more honey than others. That's why the man using the best goods makes the most money when it comes to cashing in at the end of the season. We can prove that. Men can build hives cheaper and better than bees. Then why not have everything just right to begin with?

## Honey and Beeswax

CHICAGO, April 4.—Market is quite bare of best grades of comb honey. When sales are made it is on a basis of 15@17c, with very little outlet for the off-grades. Extracted, 7@8c; off grades, 6@6½c. Beeswax in good demand at 30@32c. R. A. BURNETT & CO.

PHILADELPHIA, April 10.—Owing to the cold weather, there has been quite a demand for comb honey in the last 10 days; quite a number of odd lots have been moved in this market, with not so many arrivals as heretofore. We quote: Fancy white comb honey, 15@16c; No. 1, 14@15c; amber, 12@14c. Fancy white extracted, 7@8c; light amber, 6@7c. Beeswax, very firm, 32c.

We are producers of honey and do not handle on commission. WM. A. SELSER.

NEW YORK, Jan. 15 — The stock of white comb honey is pretty well exhausted, and we do not expect any more arrivals of large lots from now on. Prices are firm, and we quote from 15@16c for fancy white; 13@14c for No. 1; 12c for light amber. There is quite a little dark and buckwheat on the market, but no over-stock, and we think that all of it will be disposed of before long at present prices, which we quote from 10@12c, according to quality. Extracted honey very firm, with sufficient supply to meet demand. California white sage is bringing from 8@8½c; light amber, 7½c; amber, 6½@7c; buckwheat extracted in fairly good demand at 6@6½c. Southern in barrels finds ready sale at from 55@70c per gallon, according to quality. Beeswax firm and steady at 31c. HILDRETH & SROELKEN

DENVER, Feb. 14.—Producers in this State are practically closed out of both comb and extracted honey. We have not sufficient good comb honey to supply our local trade, but have a good supply of white extracted of excellent quality. We quote strictly No. 1 white comb honey, per case of 24 sections, at \$3.20; No. 1, light amber, \$3; and good No. 2, \$2.80. White extracted, 8@8½c per pound; light amber, 7½@8c. Clean, yellow beeswax, 27@28c, delivered here.

THE COLO. HONEY-PRODUCERS' ASSN.

CINCINNATI, Mar. 11—There is very little demand for extracted honey at this writing, which is only natural, owing to the unsettled

Office and Salesrooms, 2146-48 Central Ave. Warehouses: Freeman and Central Aves.

weather at this time of the year. However, we are looking forward with interest to a revival of trade, as soon as the warm spring days are here. We quote amber extracted honey in barrels at 6½@7½c, the price depending upon the quantity purchased. Fancy table honey in crates of two 60-lb. cans each, at 8@9c. There is little demand for comb honey owing to the lateness of the season. Choice yellow beeswax, 32@35c, delivered here.

THE FRED W. MUTH CO.

INDIANAPOLIS, April 12.—comb honey is not plentiful, but demand is slack. Fancy white comb brings 16@17c; No. 1 white, 14c; amber, 12@13c. Best grades of extracted honey bring 8@9c; amber, 6@7c. Good average beeswax sells here at \$35 per 100 pounds.

WALTER S. POWDER.

TOLEDO, Nov. 30—The market on comb honey remains about the same as last quotations, but has been coming in much more freely, as beekeepers seem to be very anxious to get rid of their stock. Fancy brings in a retail way 16c; extra fancy, 17c; No. 1, 15c; buckwheat, 15c. Extracted white clover in barrels brings 7@7½c; cans the same. Beeswax, 26@28c.

THE GRIGGS BROS. & NICHOLS CO.

KANSAS CITY, Mar. 30—The demand for comb honey is light, as also are the receipts. The market is about bare of extracted. We quote: No. 1 white comb, 24 sec. cases, \$3 10 to \$3.25; No. 2, \$2.50 to \$2.75. Extracted, white, 8@9c; amber, 7@8c. Beeswax, 28c.

C. C. CLEMONS & CO.

CINCINNATI, April 3.—The market on honey is entirely bare of fancy comb honey; No. 2 selling at 12½c, and slow sales. Light amber extracted sells in barrels at 5½@6c. Beeswax, 32c, delivered here. C. H. W. WEBER.

# My Rapid-Fire Business Methods

By the Bee-Crank.

Quick action on the comb-foundation proposition. I will pay 33c in trade for beeswax, and ship you IMMEDIATELY whatever supplies you may order in exchange, including foundation, without delaying to have your wax worked over.

The advantage of this plan is that it saves time, and gives you the same results exactly that you would have if your own beeswax were worked over and returned to you.

Here's a recent letter from another customer who appreciates quick service and good treatment :

VINCENNES, IND.

WALTER S. POWDER, Indianapolis, Ind.

Dear Sir:—The goods came with usual promptness—fact is, they came so quick that I thought they must have been sent by "Dyna Mite" instead of "Pouder." Thanking you for your more than fair treatment of me in the past, and assuring you that when I "want goods quick" I will send to "Pouder," I remain,  
Yours truly, JAY SMITH.

I carry ready for immediate shipment Metal-Spaced Hoffman Frames, Danzenbaker Hives, Dove-tailed Hives, Section Honey-Boxes, Weed Process Comb Foundation, Honey and Wax Extractors, Bee-Smokers, Bee-Veils, Pouder Honey-Jars, and a host of other standard supplies that are sold about more fully in my new catalog, which is yours for the asking. I sell Root's goods at Root's prices, and save you time and freight charges.

NOTE.—When you send beeswax, attach your name to the package. Send by freight or express, according to amount.

GEORGE W. YORK, Editor

CHICAGO, ILL., APRIL 25, 1907

Vol. XLVII—No. 17

## Editorial Notes and Comments

### Caring for Empty Combs

Various methods of caring for empty combs when not in use by the bees have been mentioned. Recently it was advised to wrap them in paper. Regarding this, Mr. E. V. Pagan writes:

MR. EDITOR:—On page 286, "Michigan" is advised to wrap his combs in paper to protect them from wax-worms. If the combs are free from the eggs or larvæ of the bee-moth when thus protected, the plan will be successful, for the moth that lays the eggs will be kept out. But the chances are 9 out of 10, if not 99 out of 100, that at least some of "Michigan's" combs already had eggs or larvæ in them, and these would go on with their work just as cheerfully wrapped up as unwrapped. Almost always, when combs are to be taken care of, they are combs from colonies that have died in winter. Such combs are pretty sure to have larvæ or eggs in them when left by the bees, and wrapping up would be no protection. E. V. PAGAN.

### Abbott Plan of Queen-Introduction

Dr. Miller calls attention to the fact that the Abbott method of introducing queens has been mentioned several times in the American Bee Journal, though some seem not to have remembered seeing it, among them being Wm. M. Whitney. Here is what Dr. M. says:

MR. EDITOR:—On page 280, my good friend Wm. M. Whitney speaks of the Abbott plan of introducing queens, and says: "I have never observed it in any work on bee-keeping, nor in any paper, if I'm not mistaken." Are you not in the habit, Mr. Whitney, of skipping anything you find on the introduction of queens? Look at the American Bee Journal for 1906, page 449, 3d answer to Minnesota, where you will find, "There is probably greater safety in the Abbott plan of putting the caged queen into the hive 2 or 3 days before," etc. See also page 738, 1906, last sentence of reply to Massachusetts. Possibly, however, you don't spend time reading such

elementary things as are to be found in the Question-Box—and I don't blame you for that—but surely you ought not to have omitted the editorial page 798 of the same volume, where the 3d sentence on the page reads, "Mr. E. T. Abbott advises this imprisonment without losing the time of the old laying queen," and then particulars of the plan are given. I am pretty sure mention of the plan can be found in other places, but the ones mentioned are enough to free the American Bee Journal from the charge of neglecting to mention what you esteem an important item. C. C. MILLER.

### Loose-Hanging versus Self-Spaced Frames

The editor of the Bee-Keepers' Review valiantly champions loose-hanging frames. He says:

"The American Bee Journal says that I make it appear that the self-spacing is most valuable for holding the frames in place when moving bees, when the greatest value is in the rapid handling that may be done with self-spaced frames—no time used in spacing them. Let's see about this rapid handling. With self-spaced frames some sort of a wedge or spring must be pried out. Then a dummy must come out—and oh, how it does stick, sometimes."

Isn't that something new that a wedge or spring must first be pried out? Has it ever appeared in print before? Perhaps his is an unfortunate locality, for with the right kind of self-spacing frames there is no more need of wedges than with loose-hanging frames, and they are just as objectionable in one case as the other.

"Then a dummy.....and oh, how it does stick, sometimes." Yes, sometimes. And how a loose-hanging frame does stick, sometimes. But with the right frames and dummy, what need of a dummy sticking? Of course it is possible to have a dummy so

made and so used that "how it does stick" applies; but there is no need to have it so made and used, ever.

Mr. Hutchinson says further:

"Then the frames must be pried apart. Sometimes it is possible to pry the brood-nest apart in the middle, but oftener the frames are stuck fast so tightly that it is necessary to commence at one side and pry the frames loose one at a time until the middle of the brood nest is reached, when, at last, we are ready to remove a comb. All this does not strike me as very rapid handling. With loose-hanging frames it is necessary only to pry loose a comb each side of the one to be removed, press them over a little to one side, when the comb between can be lifted out."

It is to be feared that the bad cases have made so strong an impression on Mr. Hutchinson's mind that the good cases are too little considered. Possibly, too, the good cases are greatly in the minority. Later he speaks of Hoffman frames as especially objectionable. There are self-spacing frames and self-spacing frames, and there is a material difference between frames with the end-bars partly or wholly in contact and those with the small point of contact of nails or staples. He says, "Sometimes it is possible to pry the brood-nest apart in the middle," and he might well have added, "and with the right frames it is always possible." Also, he might well have added a "sometimes" to the statement that to get out a loose-hanging frame it is necessary to move only 2 other frames; at least he has been extremely fortunate if he has not met cases where it was necessary to move 3 or 4 other frames.

It must be admitted that self-spacing frames may be so bad that to get out the first frame is harder than to get it out of nicely managed loose frames, and if Mr. Hutchinson insists that the worst case of loose frames he ever met was not to be compared with some cases of self-spacers, no one "in this locality" is inclined to quarrel with him. But when there is so much difference in self-spacers, it is hardly fair to condemn all because some are at fault.

Again, Mr. H. says:

"In the matter of getting the combs back, one kind can be put back as rapidly as the other. After they are in the hive, the loose-hanging frames will probably need some spacing with the fingers, but this won't take so very much longer than it does to put in

the dummy and get it into place with wedges or springs."

"Loose frames will probably need some spacing." Some of the veterans who handled loose frames for years will smile at that "probably." If Mr. Hutchinson has a gift that allows him to put loose frames in proper place instantaneously, or even to space them afterward correctly in less time than he can return self-spacers, he is an expert in that direction, and it is hardly fair to decide the case by his performance. It is probably a moderate statement to say that the average bee-keeper will put in the dummy (for he has no need of "wedges or springs") in one-

fourth the time he will take to space the loose frames satisfactorily; and when it comes to exactness of spacing, he will in 2 seconds space the self-spacers more exactly than he can the loose frames in a whole day with only eyes and fingers. Mr. Hutchinson says:

"I have used the 2 kinds of frames, side by side, in our own apiaries the last season, and my choice comes from actual practise, not theory nor prejudice."

Undoubtedly, Mr. Hutchinson; but have you not been unfortunate in the kind of self-spacers? Try a better kind, and see if you will not change your verdict.

The Apiary of Samuel Dysart, on the first page, was thus described by its owner when sending us the photograph:

"The Pines Apiary" of 30 colonies is shown in winter quarters. I use 8-frame Langstroth hives as improved by myself. Each, as shown by the picture, is enclosed in a separate box, also made by myself. I think I have perfectly mastered the wintering of bees on the summer stands, by protection from cold and keeping them perfectly dry. I keep bees for both pleasure and profit. My plan is more expensive than most bee-keepers, but it gives me pleasure to see them thus protected.

The picture shows the apiary from the southeast, with the pine trees and the rear portion of my residence to the northwest.

I am now in my 73d year, and all my life since infancy I have been used to bees. I met Father Langstroth and Moses Quinby during their lives, and nearly all the time since the days of Samuel Wagner, as publisher of the American Bee Journal, I have been one of its subscribers.  
SAMUEL DYSART.

### A Home Song

I turned an ancient poet's book,  
And found upon the page:  
"Stone walls do not a prison make,  
Nor iron bars a cage."

Yes, that is true; and something more:  
You'll find, where e'er you roam,  
That marble floors and gilded walls  
Can never make a home.

But every house where Love abides,  
And Friendship is a guest,  
Is surely home—and home, sweet home—  
For there the heart can rest.

HENRY VAN DYKE,  
in *Country Life in America*.

**Central Tennessee Association.**—The bee-keepers of Davidson and adjoining counties in Tennessee met March 30, and organized the Central Tennessee Bee-Keepers' Association. The election of officers resulted as follows: President, John M. Davis, of Spring Hill; Vice-President, W. M. Joseph; and Secretary, J. M. Buchanan, of Franklin.

It was a very enthusiastic meeting, and the Association starts off with 15 members, representing Davidson, Wilson, and Williamson counties. The members of the Association believe that the bee-keeping industry can be made a much more important business in Tennessee than it is at present, although the interest in it has been increasing during the recent past. The time of the next meeting will be Saturday, April 27, at 10:30 a.m., in Nashville, in the building occupied by the local Board of Trade.

**A Correction.**—On page 317, 3d paragraph in the article, "How to Clip a Queen," it says, "In the left hand is held a fine pair of curved-pointed surgical scissors." This should be right hand.

**The Apiary of John P. Coburn,** of Woburn, Mass., is pictured on the first page this week. When sending it, he wrote as follows:

I enclose a picture of my apiary. There are 74 hives in the yard in 4 rows, only 2 of them showing in the picture. Forty of the hives have outside winter-cases, allowing 1½ inches of corkdust packing at the sides, 2 inches at the back, and one inch at the front. Twelve colonies are in Dadant hives with Jumbo frames; these are without winter-cases, but have corkdust dummies on their sides and the same cushions on top. There are also 2 tenement winter-cases with 4 hives each, which have leaves for packing at the sides. Several hives have 2-ply roofing-paper for winter protection around them.

Until 10 years ago I had my bees in box-hives with drawers in them for surplus honey.

There are in this apiary 5 different styles of frames. Seven of the colonies are on Danzen-

baker frames, and 4 on 6-inch double extracting frames, thus making a sectional hive.

I make my own hives, principally—that is, the bodies; I buy the inside fixtures in the flat. I am not a carpenter, nor the son of a carpenter, but I think I could give something that would be of interest to bee-keepers about making hives and winter-cases.

My granddaughter, who is in the High School, took the picture.

JOHN P. COBURN.

Conducted by J. L. BYER, Mount Joy, Ont.

### Stealing Foul Brood

While present at the Victoria County Bee-Keepers' convention, held on Good Friday at Little Britain, Ont., Mr. Burton, of Lindsay, told me of an amusing incident that happened while he was learning bee-keeping with Mr. D. A. Jones, once so prominent in apicultural circles.

As many will remember, during the latter years of Mr. Jones' extensive bee-keeping operations, his apiaries became very badly affected with foul brood; indeed, I have heard some say that this was one of the main reasons he quit the business. Be that as it may, one of Mr. Jones' out-apiaries was particularly bad with foul brood, and only a mile or so away from this yard was a gentleman of none too good reputation who had upwards of 100 colonies of bees in the spring, in grand condition and free of foul brood. Along

about the latter end of May, Mr. Burton and another gentleman visited the out-yard in question, and found that some one had been there before them and had taken a lot of the brood combs out of the hives. Suspicion at once fell upon the neighboring bee-keeper, but they decided to keep quiet and await developments.

About 6 weeks after this, the man who was suspected of the theft, came to the factory of Mr. Jones, and, meeting Mr. Burton, in the course of the conversation remarked, "Say, what does this foul brood look like that we are hearing so much about these days?"

Mr. Burton explained things as best he could, and the bee-keeper remarked, "I have it among my bees, sure."

At this juncture the foreman of the factory came in, and hearing this assertion, he, without hesitation, boldly accused him of the theft, and said it

served him right if he lost all his bees. The man was so taken back at this that he never denied the accusation, and left the factory at once.

It seems he had gone through the Jones apiary and taken out all the fullest combs of brood he could find; they were then taken home and given to his colonies to strengthen (?) them. As he lost his entire apiary, this certainly was a case of "taking fire into his bosom" with a vengeance, and about on a par with the case of a thief going along the road one night and stealing the bed-quilts on which a smallpox patient had died, the quilts having been hung outdoors that evening for an airing.

### Cement Hive-Stands

This is an age of cement construction, so it is not to be wondered at that bee-keepers are turning to this durable and inexpensive material for making hive-stands and other things connected with the apiary.

While at the Brantford convention R. H. Smith, President of the Ontario Association, was telling me that they are this winter making a number of these hive-stands for their own use. If I remember correctly, they make them in the form of a cross in molds made for the purpose. While it is not possible to make them very rapidly, unless one has a number of molds, yet if the work is done in the winter, or other time when the bee-keeper is not busy, this is no serious objection. Of course, if the work is done in the winter, it will be necessary to have some place to do the work where the frost does not bother.

The thing that struck me most forcibly was the extreme cheapness of such stands, Mr. Smith assuring me that the cement required for each stand did not cost over 2 cents each. As to cost of sand required, with most of us that is simply a matter of the labor required for hauling.

With the rapidly advancing prices of lumber, we need not be surprised if within 10 years the most of the present wood-stands will be superseded by cement; indeed, some have already used cement *bottoms* for their hives, but this departure at present is but in the experimental stage.

### Comb or Extracted Honey for Beginners?

At the recent Brantford convention, the question as to whether a beginner should produce comb or extracted honey, was provocative of more discussion than almost any other topic presented. In the Canadian Bee Journal Mr. E. G. Hand, who conducts a "page for beginners," has the following to say on the subject:

A question that presents itself to every beginner is whether he shall run his bees for the production of comb honey or extracted honey. He often decides in favor of comb honey, because he figures that the outlay for supplies will not be so large—no extractor, uncapping-knife, tin cans, or anything of that kind to buy. The production of first-class comb honey at a profit is a thing, how-

ever, that can be accomplished only by a person who thoroughly understands the banding of bees, and the money spent for section supers, sections, foundation, cases, crates, etc., and the time required to put these things together (breaking probably half the sections the first time it is tried) will come to nearly as much as would start in the plant necessary for the securing of extracted honey.

Another thing: When you have a stock of extracting combs and a good extractor, you have them for all time if properly cared for; and if you ever want to sell out, these combs are worth money—a lot of it. In the production of comb honey, everything except the supers must be bought and put together every year, and is sold with the honey. It is also much more difficult to control swarming when rearing for comb honey, and without control of swarming comb honey can not be produced successfully.

There are plenty of other reasons, too, but these will suffice for the present. After you have been running the bees a year or two and have become acquainted with them and with your locality, if you feel like having a "try" at comb honey, by all means have it. You will be far more likely to succeed than if you tried it first go off.

### Quilts Over Frames

As to what percentage of bee-keepers on this side of the Atlantic use quilts over the frames, I would not have the slightest idea if asked the question. Editor Hutchinson has never used a quilt, and he says in a late issue of the Review, "If any one thinks I ought to use quilts, I wish he would write me." Commenting on this in the British Bee Journal, D. M. Macdonald says:

"I don't suppose many American apiarists will trouble to communicate with Mr. Hutchinson, and I know 999 out of every 1000 active bee-keepers on this side think he ought to use quilts." Moreover, they would give him the most convincing argument men could produce by unanimously voting that they are the best and most natural covering for frame tops. The ease of manipulation with these coverings is an important point well worth consideration. The pleasure in bandling frames thus wrapped up is one of the delights of opening up a powerful colony, because they lend themselves to a gentle, expeditious, and effective examination of the contents of a hive without unduly exposing or agitating the bees."

While I personally would use nothing but quilts, yet I am aware that a large number of extensive apiarists have no use for them. If for no other reason I would use them because they allow, as Mr. Macdonald points out, an examination of the colony without unduly exposing or agitating them at times when the weather is none too warm.

My bees are all packed on the summer stands, and during the first week in April I pushed the top packing forward and lifted up the quilt at the back of the hive, and formed a good idea as to the condition of every colony in the yard. Not more than 2 hours were required to examine 100 colonies, and the majority of them were hardly aware that they had been molested. Had boards been on instead of quilts, I would have hesitated to open the hives so early in the season, as when bees are agitated so early in the spring there is great danger of some colonies balling their queens.

Conducted by LOUIS H. SCHOLL, New Braunfels, Tex.

### Long Distance Bee-Keeping and Swarming

With 10 bee-yards to look after all by myself, with one horse and rig, I have been having my hands full. The mesquite-trees have surprised many of us by coming into bloom just about 4 weeks ahead of time, and then they opened up with such a rush that it required our attention at several yards all at one time. Since my nearest apiary is only 10 miles from home, and the farthest 180 miles, with the others scattered very much, it means a good deal of "humping" to get around. But with short cuts and systematic management I believe I am able to handle from 500 to 600 colonies, *all by myself*, except during the time of harvesting the honey—taking it off the hives.

Swarming—how to control it—is one of the much-discussed problems with

out-apiaries. By leaving shallow extracting supers on all the colonies all the time to prevent crowding in the brood-chamber, and keeping the bees at work when there is something for them to do, giving freer ventilation by enlarging the entrances, and, if necessary, breaking up the solid brood-nest of sealed brood and providing laying room for the queen, it has been possible to curtail swarming until the honey-flow came on; and this is all that is necessary in our localities here in the South. As soon as the honey-flow begins, and the swarming fever does not already exist in the colony, the bees bend their whole energies toward storing honey, and swarming is entirely forgotten, it seems. Then the thing to do is to provide super-room and not let the bees become crowded. In this way I have kept down swarming to 2 percent for 7 years.

## More Texas Honey-Bloom

I have been asked to continue giving a list of Southern honey-plants, together with a description of each and their blooming period each month, but space forbids doing so in a satisfactory manner. A list will be given, therefore, of the rest of our March and April bloomers without the description, and these, if desired, can be looked up in some work on botany:

*Populus monilifera*, Ait. Our common Cottonwood or Necklace Poplar. Much pollen and honey. Extends into west Texas.

*Citrus trifoliata*, L. Hardy orange. Cultivated. Planted for hedges. Not abundant.

*Spirea virginica*, Britt. Bridal Wreath. Cultivated. Not important.

*Asparagus officinalis*, L. Cultivated asparagus. Bright colored pollen; little honey. Naturalized from Europe.

*Phacelia globosa*, Nutt. "Phacelia." Ranges from Arkansas into eastern Texas.

*Ricinus communis*, L. Castor-oil plant. Cultivated and escaped. Pollen and honey; nectar-glands at base of leaves.

*Celtis mississippiensis*, Bosc., and *C. occidentalis*, L. "Hackberry" trees are most extensively planted for shade-trees. Valuable for pollen and some honey.

*Cornus asperifolia*, Mx. Dogwood; extends from Southern States into central Texas. Bees fairly roar on the blossoms.

*Lupinus subcarneus*, Hook. Blue Lupine, or Blue Bonnet, is our State flower in Texas, and covers the ground with a blue mantle on fertile slopes and open places in woodlands; intermixed with *L. texensis*, not so plentiful. Honey-yield fair; much pollen of bright red and orange colors. Blooms into April.

*Pisum sativum*, L., cultivated garden pea; unimportant, but pollen sometimes.

*Malus malus* (L.), Britt. Apple, with fruit-bloom. Blooms into April.

*Robinia pseudoacacia*, L. Black Locust; ranges from Pennsylvania into Texas. Honey-yield good if not hurt by cold weather, which affects it easily.

*Cercis canadensis*, L. Red-bud or Judas-tree. From Ontario to Texas; yields honey early, and aids in brood-rearing. March into April.

*Ilex decidua*, Walt. Passinu Haw. Bearberry or Yonpon of the Southern States, into west Texas. Short honey-yield; sometimes very early and valuable for stimulating early brood-rearing. *S. caroliniana*, Irel., Yonpon; not so important.

*Eysenhardtia amorphoides*, H. B. K., commonly called Eysenhardtia, or Kock Brush, of southern and western Texas. Honey-yield abundant and of good quality; blooms several times during good seasons with much rain. In March, April, and May, and sometimes in June, July, and August.

It is difficult to give exactly the time these plants bloom, as an early or a late season influences plants very much, so that any of these may, in some years, bloom a month later, or even earlier, than during the average years.

## Cause of Supersedure of Queens

There is something about bees superseding their queens that I have never been fully able to understand. You may take a poorly-reared queen—one that will not keep more than 3 or 4 Langstroth frames filled with brood in the height of the breeding season, and so long as she is young the bees, as a rule, will not offer to replace her with a better one. Take this poor young queen away, and introduce one that is 2 or 3 years old—one that her colony has been trying to supersede but is lay-

ing, and will lay more than double the amount of eggs than the young, poorly-reared queen—and the bees will persist in superseding this old queen. So I conclude it's not altogether the amount of eggs a queen lays that causes her supersedure, but more her age.

When any colony of bees in this State (Texas) on Feb. 1st has as much as a quart of good, healthy bees, and a queen that fails to bring her colony up to the swarming point by the middle of April, provided they are not allowed to run short of stores—you might as well pinch that queen's head off now as later, for such queens are not worth keeping. Let me illustrate:

Last fall, when I reared my last batch of queen-cells, I noticed that one of the queens that hatched from this lot of cells was small, and showed all signs of being worthless; but as I needed her I concluded to use her anyway until I could replace her with a better one. So I put her and a full sister (but well developed) each in a

small colony of bees as near the same strength as I could tell, but both well supplied with stores. To-day (April 6) the large, well-developed queen has brood in 13 Langstroth frames, and the one with the small queen has brood in only 4 frames. Neither has had any help, only to give room as needed.

Let me say, it pays, and pays *big*, too, to have good queens.  
Rescue, Tex. L. B. SMITH.

Yes, sir, it pays! It is an unknown quantity of honey that would have been secured year after year if the queens were better looked after. Nothing disgusts me more than to have colonies in the apiary that come up with empty supers, while others are "chucked full." And why? Just because the queen below these supers was not a good one. It makes a big difference whether the product from an average apiary is only 6000, or 10,000 pounds.

The "Old Reliable" as seen through New and Unreliable Glasses,  
By E. E. HASTY, Sta. B. Rural, Toledo, Ohio.

## MAKING FENCES CARRY THE SECTIONS.

Peter Bohm's scheme of making the fences carry the sections, and so dispense with the T-tins altogether, is quite ingenious, at least. Whether a great many will thoroughly like the arrangement is another matter. Possibly some will find it difficult to get the right kind of tacks. Possibly some will find the tacks pull out too easily. The old advice, "Try a few, and go deeper if you like them," seems sage. Page 147.

## NON-SWARMING EXPERIMENTS.

Whoever can run a series of experiments in non-swarming and *have them succeed* is a public benefactor. Had a senate of experts voted on the theory propounded by E. W. Diefendorf, I doubt if a majority would have made a favorable forecast. But the results reached by trying this "off-side" theory are rather startling. First, in a year when nearly all swarmed the 2 experimental colonies did not. Next year—a year when more than half swarmed—24 experimental colonies gave but 2 swarms. One of these seemed not normal, but due to a quarrel over queen-cells that had to be built on account of the death of the queen. But sad was the result last year. Forty colonies were experimented with; not one swarmed—all right so far—but neither did the rest to any extent. Doubtless Mr. D. will go on until he makes assurance still more sure. Well,

the results already attained entitle the theory to a respectful consideration. It may be stated in this shape: One great reason why colonies swarm is that they *overwork their queens*. Remove that cause and they will swarm less, or not at all. The theory seems to have some power to account for things. Old queen more easily overworked than one in her first prime—hence, colonies with old queens swarm worse.

Perhaps I can use its explanatory power in my own case. I have many rather weak colonies in spring. They squeak along making little headway for a long time. At last circumstances get favorable—warm weather, lots of pollen, some nectar (not enough to turn their heads), and the bees, now no longer weak, are most of them young. The way they come forward when they do get started once is a caution; and my, oh my, the swarms! Long since I came to suspect that this sudden forward rush was somehow or other part cause of the unusually swarming record of my yard. If I thought to look into the why of it I stopped at saying, too many nurse-bees with no larva to feed. I see that this else might be said: Because in this vehement rush queens just then get awfully overworked. In either case my first labor in the non-swarming effort might profitably be to winter my colonies better. Then they would come forward more steadily, and queens would stand it better. Between

this and the other saying—that nurses would be worried less carrying un-called for larval food—there need be no clash.

But we decidedly need to remember that what proves the practise does not necessarily prove the theory. Practise may succeed from some other cause not discovered. The practise is taking away the lower half of a sectional brood-chamber just at the proper time. Taking away half the frames of an ordinary brood-chamber obviously might not do so well. Perhaps even that would be worth trying by those of us who have no sectional hives. Page 197.

## HONEY AND SUGAR FOR CONSUMPTIVES.

Remarkable if consumptive patients can take with profit 17½ ounces of sugar per day. As suggested, it's worth trying if with honey they could not take still more, or rather, more of them take the large amounts. My additional suggestion is that half sugar and half honey may prove better than wholly of either. Try just a little of some strongly nitrogenous food, some milk, and all the rest sugar and honey. Should sugar and honey become the standard treatment for consumptives it would make quite a difference in the honey market. The advertisement and fame which honey would get would

count more than what the patients would consume. I'm pretty well qualified at this point to be an experimenter myself. Have had for some 60 years a sort of chronic bronchitis—mild, only manifest by a little abnormal "ahemming," but always there. Liable to change to the worse disease some time, one might fear. And also for years I have dosed myself heavily with sweets. Have rung the changes pretty thoroughly on honey, dates, raisins, candy, and sugar. Simple granulated sugar seemed to argue itself into victory in the long run. But just now I'm back on honey again—mainly because the sugar I happen to have does not please me as to flavor and smell. There's a sort of "six o' one, half a dozen o' tother" in the shortcomings of honey and sugar, medically considered. The naughty sugar-men put in things invalids would better not eat, to color and condition their product. The naughty bees mix in aphid secretions. Also the naughty foundation-man puts in soap in tastable quantities—doubtless a serious bar to the eating of large quantities when the appetite is skittish, as invalid appetites are pretty sure to be. 'Pears like I could easily tell what would be the best curative sweet for invalid use—or, at least, for my use; but I will forbear to say. The dynamite might go off. Page 205.

gratulate ourselves on the safe arrival thereof.

Of course we have some trouble with any kind of honey put up in any form, unless we except that which is carried on a straw-bedded spring-wagon to a near destination, and handled alone by the producer.

The dread of handling was not alone responsible for my conversion to the use of 60-pound cans. Honey in barrels must be sold in a more wholesale way than if in smaller packages, and it usually landed in a commission house or wholesale bakery establishment. One commission firm held my honey, or money, almost a year, leading me to think that they would eventually get a better price, and when the returns finally came in, the selling price was the same as could have been obtained on its arrival—the wonder was that it was not less. Other firms, to whom I sold by sample, for a stated price, claimed, after the honey was in their possession, that it was not as good as the sample and proposed to let the deal drop, *unless I would take a reduced price.*

Again, in my rambles around a certain city, I stumbled on some honey being offered for sale and represented as coming from my yards, which in no way resembled my honey, and I positively failed to recognize it as anything I had ever handled. No comb honey from my yards had been placed on that market that season, yet here were nice glass cans filled with a clear liquid in which floated a nice, tempting piece of comb honey, all purporting to have been of my production! Had I not been satisfied that it was a glucose mixture, posing for extracted honey, it would have been a fine advertisement, but, as it was, I saw that if I sustained the reputation of my honey, I was compelled to get as close to the consumer as possible. Thus ended my barrel experience, and of all the packages since tried the 60-pound can comes nearer filling the bill than any other.

Gallon and half-gallon buckets are nice for a home retail trade, but let them be of the friction-top variety else there's trouble ahead for one.

Time was when I imagined it economy to use second-hand cans, but this illusion was short-lived, dying in its inception. One trip over the roads was all that was probably expected of them, by their makers, and the damage sustained by them on their initial trip runs all the way from a slight rupture to almost complete destruction, they sometimes being so battered as to bear very slight semblance to a can.

The crates are of light material and should be bound by scrap sheet-iron, or tin, at the corners, for most probably they will form the acquaintance of the freight-smasher before they reach the other end of the line, as their forlorn and battered appearance frequently tells the tale of a head-on collision somewhere *en route*. Distance does not always count, as we have had honey packages damaged as badly in an 80-mile transit, or perhaps more badly damaged, than in an 800-mile trip.

Nor are the railroad men altogether to blame, the condition of the cans and crates figuring largely in such mishaps.

Conducted by EMMA M. WILSON, Marengo, Ill.

## Shipping Extracted Honey

I shouldn't wonder if many of the sisters were not better equipped than myself to treat us to some interesting chat connected with their actual experience in shipping and selling honey. Formerly we used barrels and sold to commission houses. The excessive weight of a barrel of honey constitutes one of the main objections to their use. When it comes to the loading of a barrel of honey two or more men are in demand, even when the use of skids, levers, etc., is taken into consideration. If not hunting for a blacksmith bill one must ever be on the alert as to the condition of every part of the wagon which is being pressed into service. Say you cheerfully pay a blacksmith bill—possibly mostly due to actual carelessness of others than yourself; after a wagon or two have been broken down, the handling of your barreled honey seems to have grown *decidedly unpopular* among teamsters, they taking no cognizance of the prior condition of said dilapidated wagons.

It is barely possible the back-breaking

lifting has more to do with their disinclination to take hold than wagon-breakage. Self-respect is a most meritorious attribute, but when it begins to meddle with a man or woman in the way of turning an honest penny to enable them to maintain an existence, it seems, in these days, not particularly in need of encouragement.

In the days of the barrel we were frequently forced to resort to the second-hand ones, and oh, the cleaning of them! There was much scraping, scouring, rinsing, and finally draining, to clear them of excessive moisture; then they must not get too dry for fear of shrinkage; and just about the time they were filled, pop! would go a hoop, and the chances were extremely good for having to change to another—a shameful waste of honey and time. Did the barrel stand the test until on the road, we saw it depart with a certain degree of apprehension as to the slipping and bursting of hoops because of inferior cooperage or second-hand material. After exercising every known caution to secure safe transportation we considered it *good luck* if permitted to con-

After being emptied of their contents cans and crates find storage-room in some city back-yard, with the sky for a roof, subject to the action of the elements aided by coal-dust and all other kinds of dust and filth of our cities; and granted that it does not affect the inside of the can, it mars the outside, and ever after the appearance of the whole is not conducive to either safe shipping or ready sales.

It might seem to some that an old, decrepit, scarcely-able-to-hold-together-package should command the more tender care, but the reverse is quite true. The freight-handler regards it more or less as worthless rubbish, and scorns its owner, in his mind; while things which appear to have had a friend at some time of their existence, command greater respect. Perhaps it strikes him that the man who has taken care as to the make-up of his packages would also the sooner make him trouble, on the discovery of mishandling.

Arrived at market the buyer eyes them suspiciously; reasons that they have come from some careless person or persons who would, most probably, take no more care of the inside and the contents, and thus such packages go a-begging, while bright, new cans, and clean, not weather-beaten crates, move off lively.

Many times second-hand cans have not been properly cleaned, and the time consumed in that is of more value than the difference of price between them and new cans. Oh, yes, I am aware there are plenty of people who have never learned to put a value on time, but are they found among live bee-keepers?

The injury sustained by exposure is not always confined to the crate and outside of the can—it sometimes is found inside, in shape of rust, than which honey has no greater enemy. Bee-keepers are careful to keep their wax from contact with iron, and users of second hand cans will soon learn it is of vastly more importance to shield their honey from iron rust.

New cans must frequently make a visit to the tinshop before they will hold, owing to punctures with nails in crating, and places which have been slighted in soldering. Old cans are as frequently punctured, and *more often* fissures are found caused from rust or having been crushed.

Again, does it not seem passing strange that bee-keepers will on the one hand fight for protection in the way of a foul-brood law, and on the other hand will ship the germs of foul brood into their apiaries in the second-hand can? "Oh, consistency, thou art a jewel." All the foul brood I have ever heard of in Missouri was shipped in. Of what avail are foul brood laws if we continue the shipping in and use of cans which are liable to carry the germs of this dreaded enemy?

It is of no use to agree to pay so much for the return of your cans, because you are certain of but one thing, that is, the number you claim as yours; it never occurs to the sender, that substitution is the least objectionable to you.

I wouldn't be surprised if the pure food law should step in and serve to

sever that partnership between the bee-keeper and second-hand cans. If honey is found to be impure from contact with deleterious matter, will that not about settle the question?

We are almost frantic in our demand for pure white and unsullied sections for our comb honey; then we spend long tiresome hours in another frantic endeavor to remove the last vestige of stain in clean, new shipping-cases ornamented with paper lace to hide even the edges of the sections; and turn right around and put the same grade of honey, minus the bees-wax, in begrimed and otherwise repulsive looking cans. Is it because of a superior respect for the wonderful formation of the cells and beautiful cappings? Even so, why should we cultivate our taste to the extreme in the case of comb honey, and insult that very same inborn taste by slovenliness in connection with extracted honey?

By unthinkingly or willfully placing extracted honey in bad company do we not give it a black eye, and injure its reputation in more ways than in the mere selling of the same? By our being careless and less painstaking in the presentation of our extracted honey to the market can we blame the public for coming to the conclusion that bee-keep-

ers themselves prefer comb to extracted honey?

Sisters, how would we rate a house-keeper who in setting the table would place either kind of honey in any but a pretty, clean and attractive dish? Were she to use a besmeared, untidy-looking receptacle, amazement would get the best of us, and we would shortly conclude that she had certainly gone daff.

Again as to canned goods in general, what house-keeper will buy a can that has the appearance of being anything but fresh? Is a can in the least bulged, battered, soiled or otherwise forbidding, it is disdainfully left to rest on the grocer's shelves. In fact, the dread of ptomaine poisoning deters many from using tinned goods of any sort. Water in honey will set up a fermentation, while honey in contact with rust will as surely set up a putrefaction.

In conclusion perhaps it would be the correct thing to assure the sisterhood that I am in no way connected or interested in any can manufactory or supply house. I simply offer that which experience has taught me, and it is scarcely necessary to add I have paid well for the lessons.

Miami, Mo.

MARY E. NULL.

## Government Aid to Apiculture

BY PROF. A. J. COOK.

I do not think that any Government in the entire Globe can compare at all with our own, in the valuable aid that is given to us by experts in the line of valuable scientific research. Our Department of Agriculture has a band of trained men, eminent in every line of scientific discovery, and these men keep their ears to the ground and are ever alert to come to the assistance of the practical man, whatever may be the difficulties that confront him. Our splendid "Pure Food Law" which is destined to be of such signal benefit, not only to producers but to every one that eats and drinks would, no doubt, have been withheld much longer, but for the grand work and influence of Secretary Wilson and his able assistants. This is only one of a long and brilliant array of services that we owe to this excellent department of government work.

### FOUL BROOD.

The bee-keepers of the country are not left out in this round of benefit. We who have had occasion to examine and study this disease that attacks our pets of the hives, know full well that there

are two well-marked forms of the disease that destroys the brood, and so is a fatal obstacle to success. The one is copy, and as it strings out from the cell when drawn by a pin or toothpick, flies back with a snap, as it lets go the pin. This, too, is very odorous, and is easily detected by the smell. The other differs in both respects. The former is more serious than the other, but both are quite destructive, and much to be dreaded. The Department of Agriculture has solved the riddle, and has shown that there are two distinct diseases, caused by two specific germs. The first one named above, is the old, best known foul brood, and it is called "American Foul Brood," while the other, often called "black brood" in the United States, and in New York, where it has prevailed, perhaps more generally than elsewhere, is now dominated "European Foul Brood." This is the one described in Europe some years ago, and is caused by the well-known *Bacillus alvei*. The other is our better-known form in most of the States of the Union, is more virulent, more pertinacious, and is caused by another micro-organism, *Bacillus larvæ*. It is fortunate that both forms of disease succumb to the same treatment.

### TREATING FOUL BROOD.

There is no doubt but that this dis-

ease can be quickly banished from any apiary, by the well-known method, so long and successfully employed in Canada and many of the States. This is to change the bees from the old hive into new, clean hives with no honey, and to be sure that the honey that they carry from the old hive is all consumed before they have place to store it. There are two cautions that must ever be observed in all such work. If we shake the bees we must never scatter any honey, as it may carry the disease to other bees that sip up this sweet from ground or grass. We must also be equally cautious that no robber-bees gain access to the hive of the diseased bees, as the honey that they pilfer and carry off will very likely carry the disease-germs and so spread the disease. It is probably in these two ways that bees become attacked. By use of the bee-tent and a good sheet of canvas we may steer clear of spreading the mischief in manipulating bees that have the disease. Of course it is always best to work with the bees when they are actively engaged in gathering. At such times they are not likely to rob, and they are less likely to get any honey that, perchance, may be scattered about the bee-yard.

#### PEAR-BLIGHT.

I have before called attention to the fact that this disease is doing great harm in some parts of our State. As the pear industry was very remunerative in some sections, and as the fruit was very superior, and was produced in great quantities, this evil is very disturbing. The disease has, as I am told, entirely wiped out pear-culture in the rich County of Fresno. It has now threatened the same disaster in Tulare, Sacramento and Yolo Counties, and in many other sections of the more northern parts of the State. It is found that it does not need the bees, as it spreads where bees are rare as well as where they are numerous. I have called attention before to the fact that very few insects were sufficient to carry this disease, or to inoculate the trees, and so it would spread perhaps as fast were there no bees at all in the orchard. This statement is sustained, if I am rightly informed, by the actual experience of the pear-growers in the State.

The remedy that is found most effective so far is to practice very severe pruning with sterilized knives, cutting away every twig or branch as soon as any sign of the blight is seen. Of course, in all such cases it is well to burn the prunings as soon as possible. It is believed that the germs must be conveyed in a fluid, and so that the germs must generally be carried from tree in either nectar or in the bee-glue. In this last case bees, either wild or the honey-bee, may sow the seeds of the mischief. It is true that many wild bees do not gather the propolis or bee-glue, which the bees get in almost all cases from the buds of plants.

#### ACACIAS.

As is well known we get our beautiful Acacias from Australia. There are many species, as they run up into the hundreds. They interest us much, as

they are very beautiful, both as to bloom and foliage—yes, and habit as well. and the wealth of yellow is wonderful to behold. One of the trees is peculiarly admirable; it is *Acacia baileyana*. The bloom and the foliage are alike attractive. I know of no more beautiful tree anywhere. But what interests us most, is the fact that the bees are very partial to these trees. I have noticed the bees thick on the bloom, and also visiting extra-floral glands as well. These are good for stimulative feeding as they come in February, and so will stimulate the bees to breed rapidly, and so the hives will be replete with bees as the orange-trees fling out their bloom and perfume a little later. We may well plant many of these Acacias. We are doing so in Claremont.

Claremont, Calif., March 14.

## Bees Robbing in the Spring

BY G. M. DOOLITTLE.

A correspondent writes thus: "Will you please tell through the columns of the American Bee Journal, something about bees robbing colonies in the spring, how we can tell when colonies are being robbed, and what can be done to prevent it? I had nearly one-fourth of my colonies robbed out last spring in spite of all I could do."

After setting the bees from the cellar it sometimes happens, especially if the weather is very warm, that the first set out will commence to rob or carry off the stores of those set out last, which are so busy with their cleansing flight that they do not seem to notice the robbers. Robbing is not always confined to such colonies, but all weak colonies, whether wintered in the cellar or otherwise, and especially queenless colonies, are subject to attack in early spring, and I know of no one thing more vexatious to the apiarist than robbing. But how are we to tell when a colony is being robbed? is the question nearly always asked by the novice, and the answering of that question has often puzzled the bee-keeper of several years' experience, when he has almost been ready to decide that a colony from which the bees are seen running out and in with much commotion at the entrance, are robbing or being robbed, while later on he was obliged to admit that what he saw was nothing more than the colony having a general play-spell.

While to the experienced eye, robber-bees are generally quite easily distinguished, yet those just starting in bee-keeping are often perplexed to know whether the bees are being robbed or not, as young bees at play often resemble robbers. Robber-bees are generally so filled with honey that they are conspicuous for their size when leaving the hive; but a young bee taking its first flight is often just as conspicuous from the load of excrement it is anxious to void. Robber-bees often run up the sides of the hive or a long way out on the alighting-board before taking wing, and a young bee when taking its first flight, more often than otherwise, does the same thing.

Robber-bees turn with the head toward the entrance of the hive when taking wing, so as to mark where to come back for another load of honey, and the young bee on its first flight always turns thus with its head toward the entrance so as to mark its location, so it may always thereafter know just where home is. Thus we find robber-bees, and young bees on their first flight or play-spell, acting almost exactly alike. But if we look closely we shall see that these young bees are much lighter-colored than are the robber-bees, very many of which are dark and often shiny by having the fine hairs on the back of the abdomen all scraped or worn off by their many encounters in trying to enter other hives.

However, I know of but one sure way for inexperienced persons to tell when a colony of bees are being robbed, and that is by killing two or three of the mistrusted bees and dissecting them so as to expose the honey-sac. If this sac is empty there is nothing wrong, but if you find a bee leaving a hive with its sac full of honey, rest assured that robbing is going on, for bees in a normal condition should always be conveying honey to the hive, not from it.

Then another way of telling is to keep the entrance of any hive suspected of being robbed closed so that only a few bees can go in and out at a time, so that if robbing is going on, no large amount can be carried off in 4 or 5 hours; then look after such hives toward sunset, and if the commotion is still kept up about the entrance of these hives while the bees have quite generally settled down to where there are only a few flying, you can rest assured that such hives as have bees rushing in and out of the entrance thus late in the day, while the most of the rest of the colonies are becoming quiet, are being robbed, or are robbing other colonies. It is now quite easy to tell whether they are robbing or being robbed, for if robbing, as the air begins to get cool and heavy, the loaded bees will drop short of the entrance; while the hive that is being robbed will show many bees that are unable to take wing with their heavy loads on first trials.

Having found out that any colony is being robbed, what is to be done to save such a colony? This question has received very many answers which I will not attempt to give here. If you mistrust that only one or two colonies are at the work of robbing, sprinkle a little flour on the robber-bees as they go out from the colony being robbed with their loads of honey, having an assistant stand at the hives you suspect are doing the robbing, and if the returning bees are covered with flour, you are positively sure that you have found at least one of the colonies which is doing the stealing. If more than one is at work at this robbing, mark the strongest one, and as soon as darkness has stopped the flying of all bees, carry the colony that was being robbed and put it on the stand of the marked strong colony, and put this strong colony on the stand just occupied by the colony which was being robbed. Do this in the evening as soon as the bees stop flying. Don't allow yourself to think that you

can do it in the morning just as well, for it often happens that the bees are out and at their work of stealing at the first signs of day, before you are up. Where it is so an exchange can thus be made, it is generally the means of stopping the whole trouble.

It is often very laughable to see the look of disgust that comes on the robber-bee after he has sallied out the next morning, leaving his hive without noting that it is not where it was, and then hurrying back into it with an air of "I'll soon be home with a load," only to find that she has gone back to the "wrong" hive; then come out again, look the whole situation over, and finally go and make her home with the colony she had been robbing all of the day before, because it is now where her old home was. Then where more than one hive had been doing the robbing, and a robber from the other hive comes after a load, she is seized so quickly by this strong colony that she shows a feeling of "good luck" when she gets away and returns home, satisfied not to try the thing again.

But it is not always that we are so fortunate as to find that only one colony is being robbed, for it is often our neighbors' bees that are concerned in this work, or we have a general mix-up of many colonies in the apiary. Where this is the case I know of no better way than, at nightfall, to carry the robbed colony or colonies into the cellar, and

leave them there for a few days till pollen becomes plenty, or the bees mainly forget about this stealing affair, when, near sunset of some nice day they are to be set back on their own stand again, examined as to their strength in bees and stores, adjusting the entrance to suit the size of the colony, and reducing their stores by taking away combs of the same till they have only what you think they can reasonably protect, and shutting them on the combs you have allowed them by means of a dummy. In this way any colony that is of any value (alone) can be saved, and if too small as to numbers of bees to hold its own, then it should be united with another colony, doing this at this time, so that the bees when they have their flight the next day may mark their location anew, as they will always do after being a week in the cellar.

In closing, allow me to say that if we are careful to adjust the entrances to suit the size of all colonies just after their first flight in the spring, and take away all surplus of stores from all colonies which are few in bees, shutting them on the combs left, as I have above advised, we shall have very little trouble with robbing. Here, as elsewhere, in bee-keeping, "an ounce of prevention is worth a pound of cure." I especially recommend this prevention part to the correspondent, and all others who are not entirely familiar with this part of bee-keeping.

vised keeping the bees contented in the early spring by cooling them. He also advised spring manipulation to begin about April 20. He then spoke upon his methods of rearing queens.

A. H. ESTABROOK, Sec.

### Report of the 37th Annual Convention of the National Bee-Keepers' Association, held in San Antonio, Tex., Nov. 8-10, '06

Pres. Dadant—We will now have the paper by Dr. E. F. Phillips, of Washington, D. C., on

#### WHAT SCIENCE CAN DO FOR BEE-KEEPING

Science is classified knowledge. In Apiculture observations can be made in infinite number, but until the facts discovered are systemized and classified very little advance can be made, and only with this classification does apiculture become an exact science.

By the majority of people science is looked on as something entirely apart from the practical. By most people a scientist is supposed to be a man who works on subjects which are of no practical use whatever. The criticism is heard on all sides that "book farming" is a failure, and that scientific men who attempt to write on practical industries do not know what they are talking about. In the first place we may as well admit that there is entirely too much truth in such criticism, but the fault lies not with science but with the men. Unless a scientist is willing and anxious to listen to what the practical man has to say, he can hardly expect to arrive at proper conclusions.

On the other hand, it is, to my mind, a serious mistake for the practical man to disregard what the scientist has to say. Scientific training fits a man to "put two and two together" and arrive at a conclusion. When a host of observations are made, not every one is qualified to study them and get at the bottom of the subject.

But for the fear of misunderstanding, let us confine ourselves to Apiculture, and see who are the scientists in that work.

In Apiculture the scientist is generally looked on as one who studies the anatomy of the bee, the effects of color on flight, or similar subjects of no practical importance. This is entirely and unqualifiedly an error. The man who analyzes the results of different methods of wintering, or the different ways of producing comb honey, is engaged in scientific work just as much as the man who works on anatomy, although he may not realize it.

Assuming then that scientific work is nothing but the systematizing of numerous observations, there can be no doubt in the mind of any one that Apiculture is sorely in need of more such work.

It must be admitted, however, that in speaking of scientific work in Apiculture the more or less theoretical problems are generally the ones to which reference is made. I shall, therefore, not speak so much of the need of scientific

#### Report of the Worcester (Mass.) County Bee-Keepers' Convention

The March meeting of the Worcester County Bee-Keepers' Association was held at Horticultural Hall, in Worcester, on March 9, at 2 p. m. Dr. James P. Porter, of Clark University, gave an illustrated lecture on "The Bee: Its Nervous System and Sense Organs; Its Origin and Life." He spoke of the evolution of the bee from the solitary bee, through the one that lays its eggs and stays with the young till the eggs are hatched. The next advance is in a bee that makes provision in its underground nest for the draining off of moisture. The next higher in the group is that where the male and female pass the winter together in the same nest. The bumble-bee has irregular structure in the cells of its honey-comb, and then gradations up to the nest of the honey-bee in which every cell is regular, and there is a distinctness of order, care, and regularity about the hive. Division of labor in the hive now becomes prominent and necessary, not for the individual life and rights of the bee, but for the general benefit of the hive and

the generations to come; and at this stage the hive has become somewhat of a machine.

Dr. Porter then went into the details of the nervous system, illustrating here especially with lantern slides, and comparing the large brain of the worker with its many duties; the medium one of the queen with the mere machine and purely animal function of egg-laying; while the drone with a very small brain, as after the fertilization of the queen the drone has nothing to do but die.

The next speaker was Mr. H. F. Cary, who spoke on wintering and spring increase of bees. He said that the optimum temperature for wintering in the cellar is 45 degrees, with a stove-pipe for ventilation, but not large enough to cause a draft into the hive. He advised an entrance to the hive  $\frac{3}{8}$  of an inch by 3 inches. Comparing those wintered inside with those left outside and carefully packed, he stated that those wintered in the house seemed to start in with more vigor than those left out, and got their brood started first; but he finds that on comparing them June 1st, that those left outside are stronger, and working better than the others. When wintering inside he ad-

# American Bee Journal

methods on problems conceded to be practical, as to discuss the practical import of questions now considered as merely theoretical by most bee-keepers.

At the Chicago meeting of this Association, I spoke at some length of the need of better bees. Here is one place where science can work untold wonders for Apiculture. Of recent years breeding has become a subject of very general discussion, and much scientific work has been done on variation and heredity, the ground-work of breeding. By continually selecting first-class breeding material a bee-keeper may improve his stock until he really has a superior line of bees. He cannot expect, however, to make progress which will be lasting unless he knows something about the hereditary transmission of characters, and the variations according to the laws of chance of all characters. The only way for a bee-keeper to become a breeder is by studying scientific works, and doing some work himself, and I regret to say that very few of our queen-rearers are doing this. Breeders in other lines of work are studying and working on these problems, and their results can be read by breeders of queens. Here science can help Apiculture.

As an example of what science can do for bee-keeping, take the work on bee-diseases. We know the causes of our two worst bee-diseases, and by comparisons (scientific method) we know what to do to destroy disease. Without scientific work on this subject the practical bee-keeper would be absolutely ignorant as to the nature of the different diseases, and cures would be mere accidents. As an example of the ineffectiveness of efforts of practical men in the face of a lack of scientific investigation we have only to cite the discussions of bee-paralysis, as it is called. A number of practical men, thoroughly competent from a practical standpoint, have undertaken to write on paralysis, and several cures have been advocated for this particular disease. No one can doubt, however, that we are still in ignorance of a universal cure and I am inclined to the opinion that we will remain in this state until the cause of the disease is determined by some one thoroughly trained in methods of scientific observation. In his book, "Bees and Bee-Keeping," Cheshire mentions a bacterium, *Bacillus gaytoni*, which he says causes the workers to become shiny; but this is no proof that *Bacillus gaytoni* causes paralysis.

Bee-Keeping would be benefited by work in various branches of science. Take, for example, work in chemistry. Those who have had anything to do with having samples of honey analyzed cannot fail to conclude that the work that has been done so far is entirely unsatisfactory, and that there is great need of better methods of honey analysis. The polariscope method is not reliable enough so that adulteration can be determined with certainty, because honeys from different sources differ so greatly in their polarization. The same condition is true to almost as great an extent, of wax-analysis.

While the bee-keeper must depend largely upon natural forage, the fact

still remains that the industry would be greatly benefited by a careful study of honey-producing floras. We need to know the exact climatic and soil conditions necessary to the growth of all our honey-plants so that they produce nectar, for with such knowledge we would be able to make plantings of value. The exact geographical distribution of the honey-producing plants, and the marking out of the areas in which given plants secrete nectar, would help greatly.

The bee-keeper would be greatly benefited by better information as to the function of the bee in fertilizing flowers. At present it often happens that there are times when bees are looked on as very detrimental, but if the apiarist has an array of actual facts to present in place of the generalities now indulged in by the journals, it would have more weight with municipalities which try to banish bees, and in similar cases.

And now as to scientific work on the bees themselves: Those present may remember the bootless discussion in the bee-journals some time back as to whether bees pack pollen into cells with their heads. In the face of such discussions the question might well be asked why some one did not look. It was argued that the head of the bee is hard, and that it could pack pollen if it wished to; but the writers were content to argue, and not investigate, reminding one very forcibly of the academic discussions of the middle ages.

Properly constructed observation hives are of some value in such a case. Fortunately or otherwise, we have a few writers for apicultural papers who feel fully competent to cope with any subject connected with bees, but just how much weight we may give to their expressed opinions can be determined only when we find out how much observation they have made. Random discussions based on compilation of obsolete work are of meager value.

There are numerous facts concerning the habits of bees inside the hive which are highly important from a purely practical standpoint, which can be determined only by scientific observation. In spite of the fact that the bee-keepers have for years made observations concerning the swarming of bees, we still do not know just what it is that causes a swarm to issue. This is of paramount importance. Possibly some of these problems will forever foil the investigator, but it does not pay to be pessimistic.

We know that under certain conditions queen-cells are started, and we also know that there are some conditions under which the workers feed the royal larvæ better than others. By the use of the swarm-box we are able to produce these conditions of superior feeding so that the larvæ are fed as well as during preparation for swarming, but we still do not know why it is that this confinement produces the effect of the "swarming fever." If we could but analyze the swarming impulse we would, beyond all doubt, be able to devise vastly superior methods of queen-rearing. It need scarcely be pointed out, also, that a knowledge of swarming would enable us to devise methods to prevent

that bane to the bee-keeper, and this would benefit many more bee-keepers than better methods of queen-rearing.

We need also but mention the desirability of knowing the methods used by bees in storing surplus honey. This is important. If honey is first deposited in the brood-chamber and then carried to the surplus chamber, then it is important that care be exercised in feeding sugar syrup, for under such circumstances any sugar syrup left from the feeding for winter or spring stimulation could possibly reach the super, and the bee-keeper be open to the charge of adulteration. If such is not the case sugar-feeding before supers are put on is justifiable; but this can be determined only by scientific investigation. The care of larvæ is an unknown factor in bee-life, as well as many other points which may have an exceedingly important bearing on practical work.

As far as the hearing of bees is concerned, we may be safe in saying that it matters little to the bee-keeper whether bees hear or not, but, still, almost every bee-man wants to know. No organ of hearing has yet been discovered, and the evidence that bees hear is extremely meager. In spite of this fact the majority of persons familiar with bees believe that bees do hear. The arguments generally advanced as proof of this are absolutely valueless, and we await impatiently a scientific investigation.

Not only will Apiculture be benefited by new scientific work on subjects relating directly to bees, but comparisons with results obtained in other fields will yield results of great value. Bee-keeping is not a science entirely apart from all others, but is most intimately connected with many sciences. For example, if we look at bee-keeping from the standpoint of breeding it becomes evident that it is not necessary that all the principles of bee-breeding be worked out on bees. From multitudes of results in such work it is evident that a few underlying principles are concerned in the improvement of a species, race, or variety, by selection; it matters not in the least to the bee-breeder whether these principles are discovered by work on bees. There are already scores and hundreds of papers detailing the methods used by the breeders of other species, and these papers await the persons who are to take up the one great problem of Apiculture. Improved appliances and manipulations are valuable, but their importance becomes infinitesimal when considered with the improvement of the bees themselves. The problem is so great that it is not to be wondered that it has not been undertaken systematically, but the day will come when it is begun, and then the results of other scientific breeders will be of inestimable value.

The second great problem which confronts American bee-keepers is the diseases to which bee-flesh is heir. Perhaps no one factor is so great a drawback to advance in Apiculture. The two virulent diseases of the brood are spreading through the States of the Union at a rate which is truly appalling, and heroic measures are necessary. I do not wish to become an alarmist, but

during the past year I have traveled several thousand miles studying conditions of diseases and the rapidity of their spread, and I cannot refrain from saying that conditions are serious. The scientific work which has already been done on the subject is of very great value. We know that these two diseases—European foul brood and American foul brood—are of bacterial origin, and we know from scientific work on other bacteria that certain methods of treatment are necessary. The result is that with this work we now have reliable methods of treatment.

The control of diseases of animals and plants by inspection methods has been the object of a great deal of thought on the part of very competent men, and inspection is really a science. Horticultural and veterinarian inspection methods are well worth study by those interested in the extermination or control of brood-diseases, and for this purpose there will be a meeting of bee-disease inspectors in this city next Monday. How much good will result from such a meeting remains to be seen, but it is certainly a worthy object. Bee-keeping must be up-to-date in its methods of disease control, and to accomplish the maximum good our inspectors must work in the greatest harmony.

In addition to the direct good resulting from scientific work, great good results from the publication of scientific results in the stimulating effect which such work has on practical methods and discussions. As an example of this I need only refer once more to the work on bee-diseases. The recent work on this subject has given us a better insight into the causes of the two forms of foul brood, yet it must be confessed that these results are of minor value, since methods of control are not changed in the least. In spite of this the announcement of results and public discussions have stimulated the persons interested in disease work, and we now are in a better position to take up the practical question of ridding ourselves of these plagues.

Over and above all this, scientific work makes better bee-keepers, in that the more a man knows about bees the better bee-keeper he is, and the better man he is. We must not lose sight of the fact that a bee-keeper has some mission in life besides honey-production or queen-rearing, and increased knowledge adds infinitely to the pleasure of living. To add to the sum of human knowledge and to interest others in some new line of thought is fully as commendable as the production of something to tickle the palate. Let us, therefore, hail with delight any advance in our knowledge of bees.

E. F. PHILLIPS.

(Continued next week.)

**Our Wood Binder** (or Holder) is made to take all the copies of the American Bee Journal for a year. It is sent by mail for 20 cents. Full directions accompany. The Bee Journals can be inserted as soon as they are received, and thus preserved for future reference. Or we will send it with the American Bee Journal a year—both for \$1.10. Address office of the American Bee Journal.

Send Questions either to the office of the American Bee Journal, or to  
 DR. C. C. MILLER, Marengo, Ill.  
 Dr. Miller does not answer Questions by mail.

### Clipped Queens—Swarming—Yellowest Bees

1. I bought a queen last year and her wings were clipped. This spring they seemed to be grown out. Will they grow out, or was it a young queen?

2. Will bees swarm before any young queen is hatched?

3. Which strain of bees is most golden yellow?  
 SUBSCRIBER.

ANSWERS.—1. No, a wing that is clipped never grows out again. One advantage of having a queen clipped, is that, as in the present case, you can tell when a young queen has taken her place.

2. A first swarm issues about 8 days before the first queen emerges. When an after-swarm issues, a young queen has already emerged, ready to go with the swarm, while one or more young queens still remain in the cell.

3. Probably Italians; although it may be that some Carniolans are equally yellow.

### Management for Chunk Honey

I have a few colonies of bees that I wish to run for chunk honey; i. e., use extracting frames and supers and cut the comb honey out instead of extracting. Will it be necessary for me to use queen-excluders if I use full sheets of comb foundation in my frames?

OHIO.

ANSWER.—That depends. With a small brood-chamber the queen is likely to go up; with a large brood-chamber she is not likely to trouble much in that way. In any case she is less likely to go up into an apartment filled with foundation than into one filled with old combs.

### Management to Prevent Swarming—Transferring

1. I would like to put 2 old colonies of bees on one stand with space between for one young colony. Now, if I should take the 2 old colonies with old queens away to another stand a distance of 4 rods, will the field-force of worker-bees unite with the young queen left on the old stand, and work, or will they loaf?

2. Will this plan keep the old colonies from swarming?

3. When the old colonies are heavy with bees, by bringing them back to the

old stand will it do to use the same plan again with another young colony?

4. Can I transfer a colony of bees by waiting until they swarm and putting the young swarm close beside the old colony, and then setting the old colony on the opposite side of the young colony every 6 or 7 days until the old colony is run out? or will the bees stay with the old colony when moved such a short distance?  
 MICHIGAN.

ANSWERS.—They will unite and work.

2. Yes, at least for a time; but when they get strong enough they will be likely, if undisturbed, to swarm later.

3. Yes, if you remove the 2 colonies to a new place at any time, you may count on the field-force uniting with any colony left in their place.

4. It will probably not work as well as you expect. Each time you make the proposed change you will throw the field-force from the old hive to the new one; but at the same time you are likely to throw some of the field-force of the new hive into the old one. It will work better when making the second shift to set the old hive on top of the new one. But either plan will work fairly well, and 21 days after the issuing of the swarm you can drive out, or shake out, all the bees from the old hive and add them to the swarm.

### Saving Bees from Spray-Poison—Honey-Adulteration—Super-seding Old Queens

1. How can I best save my bees from being poisoned? I have an apple orchard of 30 acres. I spray for codling-moth as the blossoms are about to close and fall. I use arsenate of lead. Would you advise feeding for a few days with sugar syrup?

2. Will the pure-food laws prevent to a great extent the adulteration of honey with glucose?

3. Will a good colony supersede its worn-out queen, or is it not best to introduce a new queen at least every 3 years?  
 OREGON.

ANSWERS.—1. Feeding with syrup would probably have little effect, for the bees prefer the blossoms. The easy way out is not to spray till the blossoms have fallen. That's the wiser course, anyhow, even if there were no bees in the case. The best authorities will tell you that it is an injury to the blossoms to spray while the stamens and pistils are still active. Neither is it at all neces-

sary for the earlier portion of the blossoms. The codling-moth doesn't do any work on the blossoms, nor for some time after the blossom has fallen, depositing its eggs in the calyx end of the young fruit after the fruit is large enough for that purpose. No, don't spray fruit while in bloom.

2. Undoubtedly, if faithfully carried out.

3. Opinions are divided. It is possible that locality may have something to do in the case, as it has in so many other cases. In this locality it is as well to leave the matter to the bees generally, although it pays any time to supplant a poor queen with a good one, even if the poor one is only a month old.

**Dividing Colonies for the Buckwheat Flow**

I commenced bee-keeping five years ago, and through ignorance lost all but 2 colonies in the spring of 1905. I had 10 colonies last fall; lost one the past winter. I now have 9 of as strong, healthy colonies as I ever saw. They are literally running over with bees and have been busy bringing in pollen the last 2 days, which is remarkable for this latitude. We get our surplus from buckwheat August 1 to 20. When should I divide so as to have strong colonies for the buckwheat flow? PENNSYLVANIA.

ANSWER.—A phenomenally warm spell was on about the time of your writing, and if that had continued straight along, swarming and dividing would have come unusually early. But as it is, quite likely matters may be little if any earlier than usual. A very strong colony might be divided in fruit-bloom, but the general-ity will probably as well wait till the beginning of clover.

**Removing Bees from Dwelling—Re-queening**

1. I have 2 colonies of bees to take out of 2 different houses (dwellings). When is the best time to take them out, and what is the best way?

2. I wish to put a new queen with one how should I do this? ILLINOIS.

ANSWERS.—1. During fruit-bloom is a good time. Places are so different that one can tell the very best way only by seeing the place. In general, you can cut away enough of the wall to expose the combs, cut out the combs, fasten enough of them into frames to give the bees a good lodging-place, as you would in transferring, of course using smoke as needed, get all the bees into the hive, and unless you are going to take them a mile or more away it will be well to shut them in a dark cellar for 3 or 4 days so they will not get to the old place when they fly out.

2. You are not likely to be able to get a young queen before about the first of June, and printed instructions for introducing always come with the queen. If you want to pay the extra price for a tested queen, a good time to get it will be in fruit-bloom.

**Standard-Bred Queens**

Reared from Imported and Home-Bred Caucasian, Carniolan, Hall's Superior Goldens, and Leather-Colored Italian Breeders. Their bees are honey-getters. Untested Queens, \$1; 6, \$5; 12, \$9. Select untested, \$1.25; 6, \$6; 12, \$10. Tested, \$1.50; select \$2.50; best, \$5. List free.

The Oldest Supply-house in the East, and only Reliable Goods sold.

10 cents brings sample jar by mail.

Mention Bee Journal when writing.

**Langstroth on the Honey-Bee**

Revised by Dadant—Latest Edition.

This is one of the standard books on bee-culture, and ought to be in the library of every bee-keeper. It is bound substantially in cloth, and contains nearly 600 pages, being revised by that large, practical bee-keeper, so well-known to all the readers of the American Bee Journal—Mr. C. P. Dadant. Each subject is clearly and thoroughly explained, so that by following the instructions of this book one cannot fail to be wonderfully helped on the way to success with bees.

The book we mail for \$1.20, or club it with the American Bee Journal for one year—both for \$2.00; or, we will mail it as a premium for sending us **THREE NEW** subscribers to the Bee Journal for one year, with \$3.00.

This is a splendid chance to get a grand bee-book for a very little money or work.

GEORGE W. YORK & CO.

334 Dearborn Street, CHICAGO, ILL.

**BEE-BOOKS** Sent postpaid by George W. York & Co. 331 Dearborn St., Chicago, Ill.

**Advanced Bee-Culture.** Its Methods and Management, by W. Z. Hutchinson.—The author of this work is a practical and helpful writer. You should read his book; 330 pages; bound in cloth, and beautifully illustrated. Price, \$1.20.

**A B C of Bee-Culture,** by A. I. & E. R. Root.—A cyclopedia of over 500 pages, describing everything pertaining to the care of the honey-bees. Contains about 400 engravings. It was written especially for beginners. Bound in cloth. Price, \$1.20.

**Scientific Queen-Rearing,** as Practically Applied, by G. M. Doolittle.—A method by which the very best of queen-bees are reared in perfect accord with Nature's way. Bound in cloth and illustrated. Price, \$1.00; in leatherette binding, 75 cents.

**Bee-Keeper's Guide,** or Manual of the Apiary, by Prof. A. J. Cook, of Pomona College, California. This book is not only instructive and helpful as a guide in bee-keeping, but is interesting and thoroughly practical and scientific. It contains a full delineation of the anatomy and physiology of bees. 544 pages, 295 illustrations. Bound in cloth. 19th thousand. Price, \$1.20.

**Langstroth on the Honey-Bee,** revised by Dadant.—This classic in bee-culture has been entirely re-written, and is fully illustrated. It treats of everything relating to bees and bee-keeping. No apiarian library is complete without this standard work by Rev. L. L. Langstroth—the Father of American Bee-Culture. It has 520 pages, bound in cloth. Price, \$1.20.

**Honey as a Health Food.**—This is a 16-page honey-pamphlet intended to help increase the demand for honey. The first part of it contains a short article on "Honey as Food," written by Dr. C. C. Miller. It tells where to keep honey, how to liquefy it, etc. The last part is devoted to "Honey-Cooking Recipes" and "Remedies Using Honey." It should be widely circulated by those selling honey. The more the people are educated on the value and uses of honey the more honey they will buy. Prices: Sample copy for 2-cent stamp; 50 copies for 70 cents; 100 for \$1.25; 250 for \$2.25; 500 for \$4.00; or 1000 for \$7.50. Your business card printed free at the bottom of the front page on all orders for 100 or more copies.

**Forty Years Among the Bees,** by Dr. C. C. Miller.—This book contains 328 pages, is bound in handsome cloth, with gold letters and design; it is printed on best book-paper, and illustrated with 112 beautiful original half-tone pictures, taken by Dr. Miller himself. It is unique in this regard. The first few pages are devoted to an interesting biographical sketch of Dr. Miller, telling how he happened to get into bee-keeping. About 20 years ago he wrote a small book, called "A Year Among the Bees," but that little work has been out of print for a number of years. While some of the matter used in the former book is found in the new one, it all reads like a good new story of successful bee-keeping by one of the masters, and shows in minutest detail just how Dr. Miller does things with bees. Price, \$1.00.

**"The Honey-Money Stories."**—A 64-page-and-cover booklet, 5 1/2 x 8 1/2 inches in size, printed on best quality paper. Many short, bright stories interspersed with facts and interesting items about honey and its use. The manufactured comb honey misrepresentation is contradicted in two items, each occupying a full page, but in different parts of the booklet. It has in all 33 fine illustrations, nearly all of them being of apiaries or apiarian scenes. It also contains 3 bee-songs, namely, "The Hum of the Bees in the Apple-Tree Bloom," "Buckwheat Cakes and Honey," and "The Bee-Keeper's Lullaby." This booklet should be placed in the hands of everybody not familiar with the food-value of honey, for its main object is to interest people in honey as a daily table article. Price, 25 cents, or 3 copies for 50 cents.

**TEXAS QUEENS**

**Something New = The Ideal Hive-Tool**

Bee-keepers have long needed a special Tool to work among the hives during the bee-season. The one shown here was invented by Wm. Muench, a Minnesota bee-keeper, some years ago, but it was not on the market before. We have lately bought this Tool, and all rights, from Mr. Muench's widow, and have had the first lot made. They are ready for delivery now.

Best Hive-Tool

Only 30c. by mail

(This picture is exactly one-half the size.)

**DESCRIPTION.**—The Ideal Hive-Tool is made of high-grade malleable iron, much like wrought iron, 5/8 inches long. The middle part is 1 1/16 inches wide and 7-32 thick. The smaller end is 1 1/4 inches long, 1/2 inch wide, and 7-32 thick, ending like a screw-driver. The larger end is wedge-shaped, having a sharp semi-circular edge, making it almost perfect for prying up covers, spurs, etc., as it does not mar the wood.

**What Dr. Miller and Miss Wilson Say of It:**

In the first edition (1903) of Dr. Miller's "Forty Years Among the Bees," page 58, he says: "Of all the hive-tools I have tried, I like best the Muench tool." On Jan. 7, 1907, he wrote us saying he thought "just as much of the tool as ever."

Miss Wilson, Dr. Miller's assistant, says this of the Ideal Hive-Tool: "It is an ideal tool. In fact, I don't see how it could be improved upon. I am sure we would feel utterly lost in the apiary without it. . . . You will have to try one yourself if you want to know its worth."

**The "Ideal Hive-Tool" Free as a Premium.**

We will mail an Ideal Hive-Tool FREE as a premium to any present paid-in-advance subscriber to the American Bee Journal, for sending us ONE NEW subscription for a year at \$1 00; or we will send the American Bee Journal one year and the Ideal Hive-Tool—both for \$1.20. Price of the Ideal Hive-Tool alone, postpaid, 30 cents. Address,

GEORGE W. YORK & CO., 334 Dearborn Street, CHICAGO, ILL.

# Millions of Dollars

are made every year in the book business. Every family, rich or poor, must have books. During the last few years, \$7,500,000.00 have been expended for Modern Eloquence, \$12,000,000.00 for Stoddard's Lectures, \$2,000,000.00 for the Century Dictionary, and the tremendous sum of \$41,000,000.00, covering over half a million sets of the Encyclopædia Britannica. These books were sold by subscription in American homes and sales are still going on.

We have a subscription publication which sells more readily than any of the above. The demand is already so tremendous that more capital is required to swing it, or get behind on orders. Profits are enormous, several times savings bank interest.

## Any Progressive Man or Woman Can Share These Profits

becoming stockholders in a profitable business, based on twenty years' experience. Remember, the success of this publication is not away off in the future—it is not prospective, but it is a success at the present time and growing in demand every hour. Sales of this publication at the time of publishing this advertisement

## Often Exceed \$2000 a Day

This is an exceptional opportunity for those of small means to get in on the ground floor in a business which legitimately pays large dividends and is as solid as the Rock of Gibraltar. It cannot be held open for long as the response is certain to be so great that we shall have all the capital we need to increase the number of our presses and secure stock to be turned out in completed books, which are selling like wildfire.

You owe it to yourself to investigate this opportunity. You will never have a chance like this again to become

## Part Owner in a Mammoth Publishing House

which is already in successful operation, already earning big dividends, and which is led to sell a small amount of its stock simply because the business is already so tremendous as to exhaust the working capital. But if you would grasp this opportunity you must

# BEE-SUPPLIES

PERFECT GOODS LOW PRICES  
A Customer Once, a Customer Always.

Now is the time for you to buy your Bee-Supplies. We manufacture Bee-Hives of all kinds. The Dovetail, Langstroth, Alternating, and the Massie Hives, we make all of them. Remember that half the work and worry of your apiary is removed when you use our goods. Every one knows the advantage of a good, substantial hive; the quality of material and workmanship in our hives are not excelled by any other make.

We have been in the business over 40 years, and know what is practical, and when you once give our goods a trial you will have none other. Remember that now is the time to get your order in for the season's supplies. Have you received our new 1907 Catalog? If not, write for it at once. You cannot fail to understand how to order just what you want from our Catalog, it is the easiest to understand that you ever saw.

No trouble to give estimates; tell us what you want.

# “WHAT’S IN A NAME?”

That depends whose name it is.

Did it ever occur to you that it means something to order bee-supplies with a reliable name back of the goods—a name that has stood for over 30 years for the very best in bee-goods?

When you see **LEWIS** on a hive or on a crate of sections you know what you are getting. You also know that if the goods are not just exactly what they are sold to be, back goes your money to you. The G. B. Lewis Company or its distributing houses do not want your money if you are not satisfied.

They do not want you to take any chances, either. Before you buy your bee-supplies, order a sample crate of Lewis Sections and five Lewis Hives or less, just to see what you are going to get when you do buy. If **Lewis Beware** does not win out on the trial, give some one else the order. That’s fair, isn’t it?

Lewis Beware is sold at consistent prices, and is the cheapest beware because it is the best beware. A season’s trial will convince you.

# American Bee Journal

## A GREAT IMPROVEMENT

Will be found in

### The American Bee-Keeper for 1907

It is profusely illustrated and enlarged, and contains only articles of the most practical as well as scientific nature. A special corps of the best writers has been engaged. The editors are Harry E. Hill and Arthur C. Miller, than whom there are no more practical or experienced bee-keepers in this country. We have published the American Bee-Keeper continually and regularly since 1890.

Regular subscription price, 50 cents a year. One year to new subscribers, 35 cents; three years for \$1.00.

Send for sample copy and our new illustrated price-list of BEE-SUPPLIES OF ALL KINDS.

Guaranteed highest quality at lowest price. Address,

## Honey and Beeswax

**CHICAGO, April 4.**—Market is quite bare of best grades of comb honey. When sales are made it is on a basis of 15@17c, with very little outlet for the off-grades. Extracted, 7@8c; off grades, 6@6½c. Beeswax in good demand at 30@32c. R. A. BURNETT & Co.

**CINCINNATI, April 16**—There is nothing new in the honey market, excepting that this part of the country is bare of comb honey, and it is well, for consumers will appreciate the new crop more when it arrives. We are selling extracted amber honey in barrels at from 5¼@6½c. Fancy table honey, 8¼c@9c, in crates of two 60-pound cans. For choice yellow beeswax, free from dirt, 32c delivered here. THE FRED W. MUTH CO.

**PHILADELPHIA, April 10.**—Owing to the cold weather, there has been quite a demand for comb honey in the last 10 days; quite a number of odd lots have been moved in this market, with not so many arrivals as heretofore. We quote: Fancy white comb honey, 15@16c; No. 1, 14@15c; amber, 12@14c. Fancy white extracted, 7@8c; light amber, 6@7c. Beeswax, very firm, 32c.

We are producers of honey and do not handle on commission. WM. A. SELSER.

**NEW YORK, April 12.**—COMB HONEY.—There is very little doing; stock of white honey of all grades is practically cleaned up, and small shipments which arrive from time to time, find ready sale at 14@15c for choice white stock, and 12@13c for off grades. Considerable dark comb honey is left on the market, and there does not seem to be any demand whatsoever. We quote nominally at 10@11c, but in large lots we doubt whether this price can be realized. EXTRACTED HONEY.—California stock seems to be well cleaned up, and we are informed that there is very little left on the Coast, and, before the new crop is marketed, whatever is on the market now will have been consumed. The prospects in California are very good for a large crop, but nothing definite can be said at this time, and there is no surety of a big crop until it is actually gathered. Last season the outlook was just as good, but in the height of the season, cold northern winds and generally contrary weather affected the crop to such an extent that it was as small as in previous years. With favorable

# C. H. W. WEBER CINCINNATI OHIO

Office and Salesrooms, 2146-48 Central Ave. Warehouses, Freeman and Central Aves.

weather in California for the next two months a large crop will undoubtedly be harvested, and if so prices will naturally be considerably lower than those of the past season and present prices. We quote white sage at from 7@9c, and light amber at from 7@7½c. Near-by, as well as Southern honey, is well cleaned up, and the markets are in good shape for new crop. Cuban and other West Indian honeys are arriving in large quantities, most of which are sold for export. The market is firm, at from 58@60c per gallon, duty paid according to quality. Beeswax firm and steady at from 30@31c. HILDRETH & SEGELKEN.

**INDIANAPOLIS, April 12.**—comb honey is not plentiful, but demand is slack. Fancy white comb brings 16@17c; No. 1 white, 14c; amber, 12@13c. Best grades of extracted honey bring 8@9c; amber, 6@7c. Good average beeswax sells here at \$35 per 100 pounds. WALTER S. POWDER.

**TOLEDO, Nov. 30**—The market on comb honey remains about the same as last quotations, but has been coming in much more freely, as beekeepers seem to be very anxious to get rid of their stock. Fancy brings in a retail way 16; extra fancy, 17c; No. 1, 15c; buckwheat, 15c. Extracted white clover in barrels brings 7@7½c; cans the same. Beeswax, 26@28c. THE GRIGGS BROS. & NICHOLS CO.

**KANSAS CITY, Mar. 30**—The demand for comb honey is light, as also are the receipts. The market is about bare of extracted. We quote: No. 1 white comb, 24 sec. cases, \$3.10 to \$3.25; No. 2, \$2.50 to \$2.75. Extracted, white, 8@9c; amber, 7@8c. Beeswax, 28. C. C. CLEMONS & Co.

**DENVER, Feb. 14.**—Producers in this State are practically closed out of both comb and extracted honey. We have not sufficient good comb honey to supply our local trade, but have a good supply of white extracted of excellent quality. We quote strictly No. 1 white comb honey, per case of 24 sections, at \$3.20; No. 1, light amber, \$3; and good No. 2, \$2.50. White extracted, 8@8½c per pound; light amber, 7¼@8c. Clean, yellow beeswax, 27@28c, delivered here.

THE COLO. HONEY-PRODUCERS' ASSN.

**CINCINNATI, April 3.**—The market on honey is entirely bare of fancy comb honey; No. 2, selling at 12½c, and slow sales. Light amber extracted sell in barrels at 5¼@6c. Beeswax 32c, delivered here. C. H. W. WEBER.

## Marshfield Bee-Goods

talk for themselves; having bought once, you will buy again. Our orders show that. The reason for this is that nothing is used in the making of our **BEE-GOODS** that we know is not fit to go in. Why should we when we have plenty of the best as it comes direct from the forest to our mill and factory.

**SECTIONS** are made of the basswood timber, grown here in the basswood belt of Wisconsin.

**DOVETAILED HIVES**, of lumber almost clear, made accurate and smooth.

**SHIPPING-CASES**, strong and neat—nothing flimsy about them.

### SHIPPING FACILITIES THE BEST

You will get your orders sent on very short time, as we are located on three direct railroads to Chicago, there connecting with the trunk lines for the East, South, and Southwest, and some parts of the West. The West by way of St. Paul and Minneapolis.

If you have not yet received our Catalog of **BEE-SUPPLIES** for 1907, just write for it.

**MARSHFIELD MFG. CO., Marshfield, Wis.**

**How I Get Orders from Afar**

*By the Bee-Crank.*

Distance is measured these 20th-century days not by miles and feet, but by hours and minutes.

How far, for example, is it from Indianapolis to New York?

You can walk it and see.

Or you can cover it by local freight, and it won't be one-tenth so far.

A through freight will cut it down still more.

A limited freight lops off another chunk.

And a long-distance telephone wipes out all that's left of the intervening space.

**SEE THE POINT?**

Indianapolis is not very far from anywhere.

It is less than a day's walk of the exact center of population of this country.

But then distance is only relative after all.

Indianapolis is at the hub, and there is a railroad line like a spoke that reaches to every part of the wheel.

No roundabout shipments from Indianapolis.

It is straight as the crow flies from my warehouses to you.

I take advantage of this fortunate strategic position by carrying in stock ready for immediate shipment a full line of the best Supplies, including Root goods at Root prices.

Prompt service is a great stimulant in the bee-supply business.

That's why I get so many orders from afar.

Get my new catalog. It's free.

Vol. XLVII—No. 18

### Spring Protection of Bees

The editor of the Bee-Keepers' Review is quite enthusiastic about protecting bees in spring by wrapping the hives with tarred felt. If N. E. France is correct in saying that a colony protected by tarred paper will have double as much brood as an unprotected one when warm weather comes, it may well be worth while to make trial of such protection. Although the protection should be given immediately when the bees are taken from the cellar, there are still some cold days due for many this spring.

One may make a jumbling job of fastening on the covering, and Editor Hutchinson gives what seems to be an excellent way in the following:

The usual method of putting on the felt is to fold it down over the hive and fasten it by tacking a strip of thin wood along the lower edge on each side of the hive, but I have tried a plan that I like better, viz., that of tying it on, putting a piece of wool twine, or some coarse twine, around the hive in two places and drawing it up as tightly as possible, then tying it. The only difficulty with this method of fastening on the paper, is to keep it in place while the strings are being put on and tied. Ordinarily it would require the services of two or three persons, but I hit upon a scheme whereby one man can do the act easily.

The felt is a yard wide. Cut it off in lengths just long enough to reach over the top of the hive and down each side to the bottom. Then cut out pieces just the size of the end of the hive. The piece that is to go in front of the hive should be cut on a slight circle on one edge, and this edge turned down so as to leave a place open at the bottom for an entrance. To hold the paper in place while it is being tied, I tacked a block to the side of the top-bar of a brood-frame (of course, any stick will answer) at each end. I had the blocks at such a distance apart that when the felt had been folded over the hive, as one would fold paper over a package that was being done up, these blocks would just nicely

slip over the end of the hive. Then by pressing one end of the stick up, and the other down, any amount of pressure could be brought to bear—enough so that the stick would remain in place and hold the felt in place while it was being tied.

I made two of these sticks with blocks nailed on, one for each end of the hive. Lay the large piece of felt over the top of the hive, set the end-piece up against the end of the hive, place the knee upon the top of the hive, fold down the felt around one end exactly as you would fold paper in doing up a package, put on the stick to hold it in place, turn to the other end of the hive and serve it the same. Have the strings cut off the right length, put one around, draw it up tight, tie it, then put on another string in the same way down near the bottom of the hive, remove the sticks, and the work is done.

Five cents worth of tarred felt will cover a hive, and with this method of putting it on there is not much likelihood of its being injured, and it can be piled away and saved to use another spring.

### Using Combs on Which Bees Died

"Can combs on which bees have died during winter be given to healthy bees in the spring?" is a question that arises annually, and is answered thus in Gleanings in Bee-Culture:

Every year about this time a good many inquire whether it would be safe to put live bees on combs from which bees have died. We should have no hesitation whatever if they are not badly soiled with dysentery stains; and there would be no danger even then after settled warm weather comes on. Even if the stores were so inferior as to be responsible for the death of the colony during winter, such stores would probably do no harm to bees that are permitted to have a flight one or two days in a week in early spring. Combs very badly soiled with dysentery should be set aside and not used until the bees can fly every day; and even then we would not give more than one to a colony at a time. If they are well sealed and badly

spotted with dysentery, a bee-brush dipped in water should be used to clean them up before giving them to the bees.

### Why are Bottom-Starters Necessary?

This question is raised by the editor of the Bee-Keepers' Review in the following paragraph:

Bottom-starters are favored by a few bee-keepers; and I will say this: If you can't get the combs firmly attached to the bottom-bars without the use of bottom-starters, then use them by all means. I have no use for them. As I have said before, no man by looking at my finished sections could tell which side up they "grew." I would like to visit some bee-keeper who can't succeed without bottom-starters, and see his sections before he gives them to the bees—see them as he gives them when trying to succeed without bottom-starters. If the section is not filled full, of course the comb may not be attached at the bottom—I would not expect that it would. If it is filled full *why* don't the bees attach the comb all around? They do with me and with hundreds of bee-keepers that I have visited.

In the absence of anything authoritative on the subject, it may do no harm to make a tentative answer to Mr. Hutchinson's "why." There are some who believe in having their bees somewhat crowded in supers, and bees thus crowded will, other things being equal, fill out sections more plumply, fastening them well to sides and bottoms. If you want to see outside cells next the wood filled and sealed, allow only one or two supers of sections to a strong colony in a heavy honey-flow, so that the supers will be literally crammed with bees. You may, however, overdo the business, compelling the bees to build a lot of bur-combs between the sections.

Others, however, think that the advantages gained by thus crowding are offset by disadvantages. They think there is a loss in having bees so crowded that all can not have room and to spare at their work, especially if the crowding reach the point where the bees turn part of their honey into clumps of white wax to be practically wasted. Another thing is, that some desire to have just as many colonies as possible go through the season without making any attempt to swarm, and to favor this the bees must have abundant room, and with this abundant room in the supers some sections will not be well built down without the persuasive influence of bottom-starters.

Mr. Hutchinson's advice is good: If you

can not have sections well built down without bottom-starters, by all means use them; if you don't need them, you may as well save the trouble and expense.

### Drifting or Mixing of Bees

To prevent the drifting or mixing of bees when taken from cellar, whereby a large number go to a few hives depleting others, and sometimes resulting in the death of queens in the over-populated colonies, it has been recommended to contract the hive-entrance immediately on taking the bees out of the cellar. Confirmatory of this view is the following from E. D. Townsend in the Bee-Keepers' Review:

"If the entrance is contracted so that only

a few bees can fly at a time, it helps to keep them flying at a more moderate rate. We sometimes throw a shovel full of sand into the entrance, then, with a small stick, make an opening at one corner so that only a few bees can fly at a time. This certainly helps to keep them from mixing. I am sure the whole secret lies in so managing that only a few bees fly at a time. In other words, so manage that the strong colonies are not allowed to show their extra strength in flying force, and with the entrances contracted the strong colonies can not throw out a force much, if any, stronger than the weak or moderately strong colonies. It seems that with this first mad rush for a flight the bees forget all about marking their location. They seem to get started to entering a few hives, then a great share of the bees in the air are attracted to these few hives, with the result that these few colonies get the lion's share of the flying force."

ship (or remove queens otherwise) under 4 days' laying (and usually not under 5 to 10 days), the nuclei are overstocked with brood at all times. Having Italianized fully 90 percent of the neighboring bees within 3 or 4 miles of my yard, I get pure mating with very few exceptions.

The bricks on these little nucleus hives covers not only hold the covers securely, but make exact queen-records by reversing the sides, turning lengthwise or crosswise of the nucleus, or standing on edge. With wife as my assistant (mostly in correspondence), I do the work alone. I also work 2 out-yards.

CHAS. M. DARROW.

**Maeterlinck's Bee-Foolishness.**—Not often is a new work received with higher words of praise than was Maeterlinck's work on the bee. Men thoroughly familiar with the literature of bee-keeping gave it unequalled praise, its brilliant style apparently dazzling their eyes so that they could not see the grave faults it contained. It is hardly possible, however, that brilliancy of style will be sufficient to blind the eyes of any but the utterly uninformed to the glaring errors contained in the following:

#### MAETERLINCK ON THE INTELLIGENCE OF THE BEE.

It would be easy, without appealing to any prehistoric event, to bring together a large number of facts that would show that the faculty of adaptation and intelligent progress is not reserved exclusively for the human race.

Transported to Australia or California, our black bee completely alters her habits. After one or two years, finding that summer is perpetual and flowers forever abundant, she will live from day to day, content to gather the honey and pollen indispensable for the day's consumption; and, her recent and thoughtful observation triumphing over hereditary experience, she will cease to make provision for her winter. Buchner mentions an analogous fact, which also proves the bees' adaptation to circumstances, not slow, secular, unconscious and fatal, but immediate and intelligent: in Barbados, the bees whose hives are

### Removal Notice

By the time this number of the American Bee Journal is in the hands of its readers, we will have moved into our new and larger quarters, on the 5th floor of the "Electrical Building," at 118 W. Jackson Boulevard—about a half-mile west of where we have been located the past 3 years. Our correspondents will kindly notice this change in our street address when writing us, and when in Chicago come and see us in our new place of business. GEORGE W. YORK & Co.

The National Association continues to grow, there being at this writing 2327 members. Only 173 needed to make the 2500. If not a member, why not send a dollar now to General Manager, N. E. France, Platteville, Wis.? It would be a nice thing to have a membership 2500 strong by the time of the next annual meeting, next fall. We understand the exact time and place will be decided in a few days.

The Family and Apiary of Chas. M. Darrow, of Milo, Mo., are shown this week. Mr. D. wrote as follows, April 20:

Referring to the picture of myself and family, I will say that we are all good honey-eaters. The largest boy, "Willie," was initiated into beedom when only a small baby. As myself and wife were returning home with a wagon-load of bees I had purchased, he was stung on the neck, but as soon as I removed the stinger he turned over and went to sleep. Then when he was nearly 2 years old, he and a cousin went out to the bee-yard, and he took a piece of iron and beat on the hive with it. My wife heard him cry, and carried him to the house, and we must have removed 200 stingers from him, all over his body, but mostly in his hair. It made him very sick for a few days. He has had a few stings since, but is not afraid of bees.

The little chap standing before me is "Theodore;" he has been stung only a few

times, but will probably have more experience in that line, as he is not afraid to go anywhere among the bees.

The little girl, "Myrtle," is very fond of bees. I think she will follow in her father's footsteps, and be a queen-breeder, as she always asks to see the queen. She has been stung only a few times, and she walks among the bees quite often to see what is being done there.

It was windy when the picture was taken, and so we had to strike for tall timber, as will be seen.

The other photograph represents myself and part of my home apiary and nucleus yard, looking northwest. The public road is in the background, with a cornfield still further

PARTIAL VIEW OF NUCLEUS YARD AND APIARY OF CHAS. M. DARROW.

back. The pole in the background is a telephone pole by the roadside. There were 40 or 45 colonies in this yard, used chiefly for queen-rearing, although it furnished quite a quantity of honey last May and June, which was mostly used in queen-rearing later on. We had no fall flow.

The third colony shown on the right has one of my fruit-jar feeders; this is the most convenient feeder I ever had, and can be used when others can't.

The nucleus yard contained 113 nuclei, each with 4 frames  $5\frac{3}{4} \times 8\frac{1}{2}$  inches. As I never

in the midst of the refineries, where they find sugar in plenty during the whole year, will entirely abandon their visits to the flowers.—Harper's for March.

It is the old floating fragment of folly that went the rounds of the press years ago, and has been refuted time and time again. In a matter of such remarkable change in the department of bees, why could not Maeterlinck have informed himself as to the truth or the falsity of the matter before committing t

wings of the press such an egregious blunder? There are plenty of bee-keepers in Australia and California who could have told him the truth. Indeed, the very fact that there are still bee-keepers in those countries shows the monstrosity of the statement, or else bee-keepers in Australia and California must be great fools to give their time to the care of bees which "cease to make provision for winter." No doubt some of those men who throw upon the market 50,000 to 100,000 pounds of honey in a single season will smile at the idea that their bees "live from day to day, content to gather the honey and pollen indispensable for the day's consumption."

Possibly some one may say, "But it's the black bee of which Mr. Maeterlinck speaks."

Well, there are still enough black bees left in Australia, and surely Mr. Maeterlinck does not want us to think that the Italian is more lacking in intelligence than her black sister.

Neither would it be a difficult thing for our writer of the charming manner to inform himself with regard to bees in Barbadoes, and he would probably find that even in that sugary island bees still pay some attention to flowers. And if "the bees' adaptation to circumstances" is so "immediate and intelligent," perhaps Mr. Maeterlinck will tell us why, when bees see that their visits to refineries are so fatal, their immediate and intelligent adaptation to circumstances does not lead to immediate and intelligent avoidance of such places.

see for myself what the black bees can do for one who appreciates them.

Custer Co., Nebr.

## Honey-Cakes or Honey-Ginger Bread

We read in Holy Scripture that the manna with which the Hebrew people were fed in the wilderness during 40 years, was according to the taste of everybody and was like to "flour with honey." One naturally regrets that the recipe of such a good thing should not have been handed down to us. However, the bee-keeper may easily have something similar, for flour and honey, which are the substance of the heavenly pattern, are the only necessary constituents of honey-cakes, and these the bee-keeper may always have.

It is a mistake to think that buckwheat honey is required, as has been stated in some bee-papers. I make use of best clover honey without any difficulty. Honey-cakes, if properly made, may be said also to be according to everybody's taste, and are sometimes more useful than pure honey itself, for, strange enough, there are some persons who are unable to bear the taste of honey in its natural form, whilst I have not seen any one who would not relish honey-cakes; I know even some to whom the doctor has forbidden the use of sweets, and on whom honey-cakes produce a good effect.

From personal experience I am of the opinion that honey-cakes would advantageously take the place of many drugs, and are much to be recommended to sick persons who suffer from a weak stomach, or who have but little appetite, for being so light, and at the same time so highly substantial, they are easily digested without fatiguing the patient. One never gets weary of eating them day after day, as is often the case with pure honey. These advantages are enough to wish that the way of making them should be known in every bee-keeper's home.

Honey-cakes should not be eaten hurriedly, but allowed a sufficient time to ooze away, so to say, in the mouth. When newly made they are very light and dry. Some will find them too dry, but they will improve with age, and, if left in the open, will quickly absorb moisture which will make them soft.

Now, the following is the way to proceed in making them: I generally take 40 or 50 pounds of honey at a time, and as much flour, so that they may last for many months. But for the sake of beginners I must give lower figures. Take then 3 pounds honey, 3 pounds flour,  $\frac{1}{2}$  ounce powdered ammonia, a small teaspoonful of ground cinnamon,  $\frac{1}{2}$  teaspoonful of ground cloves, and 6 ounces of orange peel cut very small. The three last-mentioned ingredients are not essential, but they improve the taste. Ammonia is necessary. To those who would object to it, I may explain that it does not remain in the cake, but evaporates during the baking process, its function being to raise the dough.

DIRECTIONS.—Pour the honey in a copper or enamelled pan, and set on a stove or quick fire. When it boils, draw it aside and remove the scum.

Conducted by EMMA M. WILSON, Marengo, Ill.

## Another Defense of Black Bees

I felt that I wanted to shake hands with Mr. Macdonald, of Banff, when I read his defense of the black bee. Partly that was from pure "clannishness," and partly it was from a fellow-feeling, which, as you all know, makes us "wondrous kind."

So your favorite bees have not been receiving, as it seems to you, justice! Neither have mine, Mr. Macdonald, and I predict that I will yet successfully wield, or else break, a lance in defense of the beautiful "gray bees of Carniola." But such is not my purpose now, but to see if I can offer you a little comfort.

You complain that American bee-keepers write as if the blacks were a useless and effete race. You should read W. Z. Hutchinson's latest "Advanced Bee Culture." Mr. Hutchinson starts one chapter of his really excellent book with the statement, "There are only two varieties of bees worthy of consideration for use in the United States; in fact, they are about the only varieties now left here for consideration, and they are the Italians and the Germans or blacks, as they are commonly called." There is much more in the chapter commendatory of the black bees, and Mr. Hutchinson is one of our leaders, Mr. Macdonald.

Further, if you read our bee-papers you will see every once in a while where some one uses the black bee as the "little leaven" that "leaventh the whole lump."

While I have quoted you Hutchinson, I would not like to leave the impression that I swallow that statement as truth. It is a matter of astonishment to me that Mr. Hutchinson could make a sweeping assertion like that. I

can hardly hold myself, here and now, from giving facts and figures in disproof of it. But the error is so manifest that there is no need. To mention just one fact: A single queen-breeder in the United States told me he sent out last season 3000 Carniolan queens, and judging of the future from the past, there would be a call for 5000 this season. Then there are the new candidates for favor—the gentle Caucasians and the "Banats." Mr. Macdonald says that while he has consistently upheld the good points he has found in blacks, he has at the same time shown charity to Carniolans and Italians. That is the right attitude, I think, and it makes me think of Mr. Benton's bulletin. When I read that I said, "Mr. Benton likes *them* all." With a climate ranging from the cold of Canada to the warmth of Florida and Mexico, I don't see why there is not room for all in North America, and it is quite within belief that the best bee for me *here* is not the best for a very different climate. I have been a bee-keeper for nearly 15 years. For 12 years I have had Carniolans as well as Italians, and they survive with me because of Nature's law—the "survival of the fittest."

Mr. Benton had this to say of the blacks, Mr. Macdonald:

"The same care and skill applied in the selection of breeding stock would result in as great improvement in this as in any of the more attractive yellow races."

Small doubt of it the black bee did not have fair play when people brimstoned the colonies that gave promise of yielding the heaviest spoils. Improve your blacks all you can, Mr. Macdonald, and I promise you that if I ever go to Banff, I will hunt you up and

Then pour the honey into the vessel in which the paste is to be made; leave it to cool; then add flour and mix it up well. This is the remote preparation, and the paste may be left in that condition for weeks and months without fear of deterioration. The proximate preparation is made on the day on which the cake is baked, and consists in adding the other ingredients, when the paste is worked thoroughly up again. The ammonia must first be placed in a cup, pour on it a few drops of cold water and stir it well, so as to form a thick paste, then mix it up with the rest. Then take a piece of the paste, roll it out into a cake not over  $\frac{1}{4}$  inch thick, and cut up into convenient sizes as desired. This done, put the cakes on a flat tin (which must be greased beforehand) and bake from 12 to 15 minutes in a hot oven.—BR. COLUMBAN, St. Mary's Abbey, Buckfast, Devon, England.

## Bees Wintered Well—Remedy for Bee-Sting Poisoning

On Nov. 20, 1906, we put 87 colonies of bees into our bee-cellar. They wintered well. On March 25, 1907, we set out one colony, the thermometer showing 70 degrees. We set out the rest by moonlight that evening. The next day they had a good flight, although the east wind was a little rough, but at 5 p.m. the thermometer showed 70. Although the last 3 days of March were very rough, cold, and windy, yesterday the bees brought in pollen. The one colony set out on the 25th brought in pollen shortly after being put out.

On page 93 is given a remedy for bee-sting poisoning. Will the writer please tell us how to use this remedy, and what quantity to use? Bee-sting poison has had at different times a severe effect on me, and caused terrible agony and distress, therefore to know a remedy would be greatly appreciated.

MARY THEILMANN.

Theilman, Minn., April 3.

assemblage when Ralph Benton (the papers got his name as Button) was called in to bring order out of chaos, and did. So great is the name of "Benton" in the "Land of Berkeley," as former Gov. Pardee used to write it in one of his parodies when he was a student at that University. Benton met the bees and smote 'em wing and sting, and no lance, sword, javelin nor sting had he. But the bees made the children scream and scamper "to see a bee at school."

## Alfilarela—A Rich Nectar Secreter

I had written somewhat at length of this plant a score of years ago. It is still one of our very best early honey-producers. Some call it "pin-weed." When the rains come early we find it in bloom rather sparingly in December. All through April and May it is abundant; I may state that it is about the most common weed we have, and makes an excellent forage for neat cattle. The flowers are rather small, and mostly of a sickly-pink color. This year I have what I believe is a new variety here on our place. It is thrifty as to growth, and the flowers are pure white. I am going to propagate it that I may have quite a showing of the plants. Mr. J. S. Harbison, in his "Bee-Keepers' Directory," page 172, states:

"This plant yields large quantities of pollen for about 3 months, commencing in March and ending in June."

Had Mr. H. pursued his investigations a little further during the pioneer days of bee-culture in California, he would have found that this plant was a rich honey-secreter, and that in moist places it grew and thrived the year around. Like the geranium, it seems to be a part of California. I believe I should have been tempted to have called it the "State Flower," if the choice had been left to me, instead of the *Escholtzia*, or golden orange California poppy—the gorgeous flower of hill and plain. Though the latter is plentiful in patches, it is not to be found everywhere about as the *alfilarela* is. Well, long may they both wave. Here, in passing, I may mention that the California poppy is visited by the bees; it is a veritable store-house for pollen. I never saw any nectar in its gorgeous chalice-like flowers.

**Honey as a Health-Food.**—This is a 16-page honey-pamphlet intended to help increase the demand for honey. The first part of it contains a short article on "Honey as Food," written by Dr. C. C. Miller. It tells where to keep honey, how to liquefy it, etc. The last part is devoted to "Honey-Cooking Recipes" and "Remedies Using Honey." It should be widely circulated by those selling honey. The more the people are educated on the value and uses of honey, the more honey they will buy.

Prices, prepaid—Sample copy for a 2-cent stamp; 50 copies for 70 cents; 100 for \$1.25; 250 for \$2.25; 500 for \$4.00; or 1000 for \$7.50. Your business card printed free at the bottom of front page on all orders for 100 or more copies. Send all orders to the office of the American Bee Journal.

## A Swarm of Bees at School

The little episode of the "thawed out" Berkeley bees reminds me of the time the principal of the Hawthorne School, San Francisco, had with a swarm of bees that came from Principal Prior's apiary. The latter's school is in South San Francisco, while his residence adjoined the Hawthorne School. One day Prof. Prior's bees swarmed and lit on a small tree in the school-yard next door. The children became frantic. They were not used to seeing "bees at school." The lady principal did not know what to do, but she thought it well to ring up some of the city officials. The Fire Department was called upon the scene to quench the fiery bees; the Health Department to allay any poison the bees might inject into the pupils; and, I believe, the Pound Department was sent for to lasso the bees and put 'em in the lock-up with the "bad dogs."

It was a comic mix-up all around, but no harm was done after all.

## The Bees at Berkeley

A big laugh has gone up about the Berkeley bees. The daily papers of Oakland and San Francisco were full of it. It came about in this way. But first let me remark that the story reminds me of the child's story of "Mary Had a Little Lamb," or especially that portion which recites that "it made

the children laugh and play to see a lamb at school."

Prof. C. W. Woodworth, the head of the entomological department, was going to tell his class "how doth the busy bee." But the hour was not a sunshiny one on this late March day—a day just after the long, wet spell. Live bees were required to elucidate the subject—I was going to remark, to enliven the subject, and that was about the way of it, anyway.

Well, the bees did not wake up to the fact that they were to be real good bees for this auspicious and educative occasion; they were required to step about a bit lively. They could kind of number them. A happy idea seemed to strike the dignified Professor; he would put some "ginger" into the observation-hive full of bees. So the hive was placed near a stove in the lecture-room.

The class was assembled, and as a merry hum passed through the lads and misses at the fount of knowledge, another hum started up in the hive. The bees began to wake up; they began to step about pretty likely; in fact, they became very animated. They got out of the hive; they were no respecters of persons; the Professor and students, it was rumored, were attacked by the bees with ginger in them. There was a hot time in the class-room. The "co-eds" screamed; the male students would have fought, but there was no general to lead 'em in the fray. The bees were getting the best of the

### No. 3—Things to Do, and Why Management During the Harvest— Value of Early Nuclei

BY R. C. AIKIN.

Having told how to manage to obtain the largest number of bees ready for the harvest, also how to control swarming to the same time, next is the management during the flow. It is one thing to handle our bees previous to the harvest, but quite a different thing during the harvest flow and in the natural-swarm season when we have the greatest number of factors to contend with.

But the management depends upon several things, as whether comb or extracted is to be produced; whether the flow comes in a pile or is strung out over a considerable period of time; whether continuous or intermittent; and whether there is a second or later harvest season. That is, there are several things to consider, but they must be taken into account, and yet I have not enumerated all the things to be remembered.

Here we have but little gathering of anything up to about June 15, when the first crop of alfalfa begins to yield; this is expected to last from 2 to 3 weeks. Following this comes sweet clover, and the second crop of alfalfa, though I seldom get much out of the latter. Sometimes there is a gap of a week or 10 days between these flows when only a dribbling flow comes in which will not do anything toward super-work, and sometimes because of varying conditions of weather and season the two flows meet, or nearly so. This second flow is likely to be the best of the two, and the one that will give us the most surplus, so I must plan to have a good force of bees to work it.

The first flow coming in during the last half of June the brood-combs will be heavily loaded with honey to the exclusion of brood. Eggs laid during this time—last half of June and first half of July—are the August workers, and as my flow from sweet clover lasts usually till August 20 to 25, I must keep the queens doing business the *full limit* during the first flow.

It often happens that the first flow is so light and tedious that the tendency is very much intensified to clog the brood-combs to the exclusion of brood, thus cutting off my supply of fielders for the sweet clover, the last of July and most of August. This late flow is likely to last from 3 to 4 weeks. A slow flow is worse to crowd out the queen than a quick one. Such also intensifies

the swarming fever. A rapid, sharp flow in which the colony will fill all empty comb in the brood-chamber and put up from one to 3, and even 4 or more supers, often so takes up the energies of the colony that they seem to forget about swarming—they are so busy, and there is such a rush of wax-work and comb-building that there is little chance for swarming. But we cannot depend upon this, for sometimes a colony will get so excited with a sudden rush of honey that they will swarm even without waiting to build cells. It's the excitement, and they rush around and do many peculiar things.

Those colonies that were made 2-story before the flow came must now immediately be reduced to one chamber for the brood, and super-room given—one, two or more supers as the strength of the colony and flow demands. If you are to have but this one flow, with a dearth to follow, then it matters little about breeding, so give your whole attention to making the most of the flow. The queen may be caged, or what is better, take her away with the chamber that has the least of brood and honey in it, and let the other chamber with its honey and brood remain on the old stand; but be sure there are no queen-cells in it. The other hive put on a new stand with the queen, being robbed of fielders will not swarm; those on the old stand cannot for lack of a queen until they have reared one. Ten days later—or between the eighth and eleventh days—go through the old colony and cut out all but one of the best cells, and in leaving a cell choose not the ripest but one less matured; the riper ones were from older larvae, and may not be so good.

The foregoing plan puts all the super-work on the old stand where you have no queen, and you can rest as easy as an old shoe, for all you have to do is to cut out those cells save one, and manipulate supers to get best results. In adding supers, unless you are confident that the fresh one will surely be filled better, put it on top of the others until they are filled. When a super is filled so that all that remains to do is some sealing and finishing, then it should be *over the fresh one*; but up to that time the colony should be made to work up through the unfinished ones to reach the new one. If you raise a super too soon the finish will be much poorer, and the weight scant; you may even fail to get anything finished.

When the young queen gets to laying in the old colony, if at this time there is still nectar coming in, even though but slowly, super-work will go on, for the honey will be moved up from the brood-

chamber to make room for the brood-nest below. If, however, your honey season is all over, you have made a hundred percent increase, and it remains for you to arrange that matter to suit your notion. If no increase is wanted, lift the old hive at the old stand, and set on the chamber that was set aside earlier, and put on top of it the old colony with the new queen, making a 2-story colony for winter, the operation to be repeated the next year. Hunt out and kill the old queen before uniting, or make whatever use of her you wish.

But some of the young queens will fail at mating time, and so there will be some of the old ones queenless; in such cases leave the old queen with her colony when uniting. If you adopt the plan of doubling back, of course you should not take the old queen far away at the time of dividing—keep her near enough to facilitate the uniting. One ought, however, to make some increase, for there are always some losses to replace. If increase is wanted, do not unite.

But suppose you have a second flow, or even a long-continued flow. In either case this management is good—I call it the most up-to-date, profitable plan. The old queen being put off aside from the old stand, and having few fielders, will get a chance to lay unmolested; she will get double, quadruple, or more, brood than if left on the old stand with a horde of fielders chucking in nectar. It will not be long until she not only has a hive full of brood, but the brood taken with her and hatching out makes a strong colony. For your late flow these old queens on the new stand can be given supers and they will surely surprise you with the amount of honey they put up, and that with little or no swarming. My estimate is that where other management will give a 50-pound surplus this will give a 75-pound one.

In the production of extracted honey these principles may be applied by other plans, as by tiering up all on the old stand; but even for extracted it is best to separate, giving the old queen a new stand *if there be a later flow*. Even if that later flow be but a light or slow one, if there is anything to be gathered a large force will get more than a small one.

I spoke in a previous article of making early nuclei where conditions were such that one could do it. If you have done so, and had queens laying with the beginning of the flow, I want to tell you that such colonies will build more comb and gather more honey in proportion to the number of bees engaged in the work than any other condition. More than this, these make the very best of colonies for winter. Then, too, if there be an August or September flow they often put up quite a little surplus, and no bother about swarming. This nucleus plan is the very best way to make one's increase, counting on these for the permanent stock, in the main; this leaves you free to make the most of the old colonies for honey. A colony worked hard for honey is not so good for winter—better depend upon the old ones for honey, sacrificing many of them entire for the crop, and replace them with these nuclei.

Many of our apiarists recommend methods of management that will do away with increase, preferring to have just so many colonies, and no more. No doubt in many cases that is a very desirable thing, in some ways, yet I doubt if it is profitable except in very few cases—that is, the most profitable. I believe a little more invested in supplies, and some increase made temporarily, will prove more profitable both in the amount of honey obtained and in facilitating management. It has always been my contention that the apiarist must be the master to the extent of controlling swarming, and making increase, when he was ready; that those who allow natural swarming are always at a disadvantage. Dividing for increase can be made just as much of a success as natural swarming, so far as the question of getting colonies is concerned; and it can be made much more satisfactory in that you do really become master, and fix things as you want them. You cannot make the seasons to insure a proper filling of the hives with stores, no matter what method of increase is used, but you can make the increase yourself, and when and how you want it, being in control yourself, and not driven about at the call of a swarm that you never know its time. The mating and time of casting young in almost every other of domestic animals we control; why not in the bee-family?

Have a few extra hives for increase. These hives do not represent any great outlay to start with, and once the investment is made it is permanent, and needs no addition for many years to come. But on the other hand, if you try to get along with just the scantiest stock of supplies, you add cost in the matter of labor which is a continual expense, year by year, until you have soon paid out the value of all necessary hives several times over.

A few bees taken from each strong colony and made into a nucleus before your main flow will not materially injure the parent colony, and this nucleus may be made into the very best colony for winter. Those old ones run hard for honey, often come to the fall in a weakened condition; that is, the brood-nest is so clogged with honey that but few bees can be reared, and the colony goes into winter with too few young bees. In natural conditions it often happens that many colonies perish in winter just because of this condition. Let me illustrate by an experience:

Once a neighbor asked me to come and see what was the matter with a colony of bees he had. The hive was heavy and yet the colony seemed weak and would not swarm. I found the hive simply full of honey, bur-combs built, and every possible place filled with honey, and just a few square inches of brood in two little spots in the 2 center combs, and this at midsummer, too. That colony had no place to breed and would have been a weak colony throughout the season so far as sufficient forces for honey-storing were concerned—could never by the most possible coaxing be induced to work in a super.

You want honey; and when you have reared the massive colonies, and the harvest time has arrived, work those bees

for honey; work them all they are worth, centralizing their efforts for that one thing—*honey*. In our factories men are made to stick to one thing, on the principle that it is more profitable to have a specialist for this and another for that, because a jack-of-all-trades is master of none. This principle is just as true of a colony of bees. The man who tries to make every colony store some surplus, and every one do its share of all the other things that bees can and are supposed to do, is making each and every one a jack-of-all and master of none, and does so at a financial loss.

Select those colonies that are to store your honey, and make that their specialty, that you may get all there is to be had in surplus, and in the best possible shape, even taking almost their entire stores for surplus by some method of contraction or other route, even to the extermination of the colony, if need be. Make other colonies work for those colonies that are to be your next year's working colonies.

Loveland, Colo.

## No. 4—Feeding and Feeders —Hive-Body Feeding

BY C. P. DADANT

Feeding *in the body* of the hive is practiced in several ways. Some apiarists lift out 2 or 3 body-frames, that contain only the dry comb, and pour liquid food into the cells. At first sight this might be considered as the easiest way of feeding, until one has given it a trial. You very quickly ascertain that this pouring of a liquid into the cells is not as practicable as might be imagined. Even clear water is put into the cells with difficulty, because of the small size of the cells. The capillary attraction that holds the drops together causes the liquid to cover the tops of the cells instead of soaking into them. But a certain quantity liquid food may be inserted in the cells with careful pouring and some jarring. This method will never be much practiced, because in addition to the trouble it gives in getting the liquid down into the cells, it necessitates the opening of the hive twice—first to get the combs, and afterwards to insert them back in the hive. During these manipulations there is loss of heat and danger of robbing. The manipulation may be reduced to a single opening of the colony if we have spare combs in sufficient quantity before the feeding is begun, for we then are enabled simply to make the exchange of a comb of feed for one dry comb removed.

The supplying of heavy combs of honey from over-fat colonies to the needy ones, by exchange, is a good practice. But as these combs of honey are usually sealed, if we wish to incite breeding, it will be well to uncap a part of the cells, for bees are very parsimonious when it becomes necessary to uncap honey. They seem unwilling to do so, and do it probably with as much regret as the provident housekeeper who finds herself compelled to remove her last jar of fruit-preserves out of the cellar for use, when several months are

yet to elapse before a supply of fresh fruit may be obtained for the table, which she has been regularly supplying.

Some European apiarists use an outside feeder which reaches the brood-chamber through a hole made opposite the center of the brood at about the middle of the height of the brood-chamber. This has the advantage over the bottom-feeder that it is in much closer proximity to the brood, and on a level with it, so that even in unpleasant weather the bees may visit it. The only objection is the hole which has to be bored through the outer wall to connect the body with this food supply.

A very good body-feeder is the Doolittle feeder. It consists of a frame made the exact size of the brood-frames, though sometimes a little wider, and enclosed on both sides by thin boards which change the frame into a deep box, with openings at the top. The feed is poured into this, and the frame is inserted at the most convenient part of the brood-chamber. The lumber used must be rough on the inside, so that the bees may readily climb in and out. Even with this help they sometimes have difficulty in climbing out, and we have found it necessary to place a float on the feed that is given, so the hurrying bees may not drown in it and find their numbers diminished by the very thing which is intended to help increase the colony.

A thin slat, or a couple of cleats, nailed together so the bees may crawl between them at will, should be dropped into this feeder. Some careful apiarists drive two tacks at each end of the underside of this float, so that it may be held off the bottom when the feeder is emptied by the bees. In this way the little workers are enabled to suck up the very last drop of liquid, from under the float.

The life of our bees is of the utmost importance at all times, but it is the more so at the time of breeding, when all the efforts of the colony are turned towards obtaining the means of rearing large quantities of brood. To be sure, the importance of warmth in the brood-nest is greater in some seasons than in others, for there are seasons when the colony comes out of winter with a strong force, while in others it has to struggle for weeks before it recuperates its winter losses. But we may set it down as a rule that food must be given in a way that will cause neither loss of bees nor loss of heat. In seasons when the colony is strong at the opening of spring, feeding is rarely necessary, and seldom practiced. Therefore, when we find it advisable to feed, the conditions of warmth and economy of life are imperative and indispensable to success.

Hamilton, Ill.

## A "Badger" Bee-Keeper in Texas

BY C. A. HATCH.

It would be presumption on my part even to say that I know much about bee-keeping in Texas, for I have spent only a few months here and have had only one colony of bees to take obser-

ventions from. But in the same way that a mariner may study the chart to learn where the rocks and shoals are before going on shipboard to put his knowledge to actual use, so I may look for the rocks and shoals of bee-keeping here in the most southern part of Uncle Sam's domain. To any one at the North as he sits before the grate of glowing coals on some zero day and reads of the flowers and 80-degree weather here, it seems as if there is the bee-man's paradisc; but the All-wise Creator gave us the law of compensation, by which no part of His children can have any great advantage over another, for what is gained in one way is made up in loss elsewhere.

As far as flora goes, this country is nearly all that could be desired—thousands of acres of mesquite, catclaw, chaparral, and prickly pear, and no bees. But this is a land of drouths and excessive rainfall; the heat of summer close onto the cold of winter; and if there is any country that can show more insects of the pestiferous kind, it has not been my lot to learn of it.

#### THE SOUTHERN SEASONS.

The seasons are so variable here that a bee-keeper would be put to his wits to know whether to encourage breeding or to withhold stimulating. When I tell you that the season this year is almost 6 weeks earlier than last year, you may appreciate the situation. Suppose an apiarist starts his bees on a last year's season, he would bring them up to full strength 6 weeks too late. And how are we to know this in advance? And how are we to prepare for one of those fierce "northers" when the thermometer falls from 80 degrees above down to almost freezing in 2 hours? How would such a change affect a hive full of young larvæ? One thing is sure, the queen has to commence operations much sooner than at North, with the mesquite in bloom in March. February 1st would not be too soon for "her majesty" to be doing her best, and I am told that February is usually the coldest month of the year here.

#### ANTS THE WORST.

Of all the insect pests I ever had any experience with, this one, lauded by Solomon, is the worst. "Take the wings of the morning" and go anywhere you will, the ant is there before you, and ready for business; not only one variety, but many—and all of them are stingers. Even little ones, almost microscopic, can pierce our tough skin and inflict a painful wound. If there is any kind of food they are not fond of from sour to sweet, salt to bitter, greasy or otherwise, it has not been shown to this dependent. The only way food can be kept from them is to put it on tables whose legs stand in cans of water, and woe unto you if a chair, a cloth, or any other thing can be turned into a bridge by them. They are seemingly always there and ready to take advantage of it. The only way one can be sure of his bees is to isolate each hive by standing it on legs surrounded by water.

The ant worst to fight is almost too small to notice, yet he is a terror. Not that he cares much for honey, although

he will take it if nothing better offers; but he goes right into the hive and drags out the young larvae. One man near here started with 5 or 6 colonies and these little fellows destroyed them all, but left the honey. What can the poor bees do with anything so small that one of their feet would cover—too small to sting and too quick to bite, and in a stinging contest I am not sure but the ant would come out the best?

Ants are the greatest menace to horticulture as well as bee-culture. One species called "trimmers" works at night, but they are easier to exterminate than the small ones, for their nests are easily found, and boiling water or "High Life" will soon fix them; whereas to exter-

minate the small ones would mean to treat the whole landscape, for their name is legion, and they are too small to fight by such an awkward animal as man.

But in spite of ants, weather, and all other adverse conditions, bees do thrive in Texas, and the wide-awake bee-keeper gets his reward, so if any reader thinks of going to a warmer country and taking his bees along, I would be only too happy to help him to locate in a good territory.

C. A. HATCH.

Nueces Co., Tex., April 4.

[Mr. Hatch spent the past winter in Texas, but is now again in his Wisconsin home.—EDITOR.]

### Report of the 37th Annual Convention of the National Bee-Keepers' Association, held in San Antonio, Tex., Nov. 8-10, '06

(Continued from page 358)

Mr. France—I dislike being the first to speak on a paper of so much value, which has covered a vast amount of ground; it is something that I hope, when you get the Report, you may study by sections. I have repeatedly asked for something of this nature to be done, as is expected to be done here on Monday, and I hope all will try to attend. The subject of bee-diseases will be nicely presented. I don't know that there is any definite part that I care to take up personally in discussing. It seems to me that Dr. Phillips has covered the ground.

Mr. Victor—I would like to ask if they have ever discovered that bees hear?

Dr. Phillips—I do know that bees are very sensitive, but I don't know absolutely if they hear.

Dr. Bohrer—I was once driving nails 5 or 6 feet from a hive of bees, and the first thing I knew I was covered with bees, and they must have gotten the vibration from the ground.

Mr. Rouse—Why does a swarm in the air attract other swarms?

Dr. Phillips—Bees secrete a light-colored fluid in swarming, and by this they attract each other; there is a very strong odor in the air, and the bees can smell it.

Mr. Rouse—Can they smell?

Dr. Phillips—There is no doubt that they smell.

Mr. Anderson—There is one point that meets with my convictions, and that is the improvement of stock we were discussing here yesterday—whether bees could be improved—and I believe they can in all the different strains.

J. Q. Smith—If bees can not hear, why do queens pipe, and upon their piping the other queens answer? The piping are of different sounds. The first queen has a clear sound, and the one about to get out of the cell has a coarser voice.

Mr. Stone—I can not be made to believe that bees can not hear. Why can't they hear as well with some of their organs as we do with our teeth?

Dr. Phillips—We don't hear with our teeth.

Mr. Stone—Some ladies and a little girl were traveling on the train with me. The little girl asked if bees could hear with their ears, and I said they had no ears. She said they hear "just the same as I do with my teeth;" and the mother of the little girl said that she knew of people that held their mouths open to hear better.

Mr. Rouse—I have worked in steam mills and if I wanted to know that the piston was working properly I would put a stick on the cylinder end, then on my teeth, and I could hear very distinctly. I don't know what caused it.

Mr. Holekamp—I don't know whether it is worth while to talk about this much more. I certainly can hear from the inside of my mouth much better than on the outside.

Dr. Bohrer—There is one thing that I wish to speak of that was mentioned last night. Dr. Phillips did not hear it; he is in charge of the Government Apiaries at Washington, and through him a number of queens were sent out to be tested. I don't think that we can recommend to him too strongly the matter of refusing to give any man a queen to test her and her progeny, unless those bees are sufficiently isolated from other bees. I would just say, "My dear sir, I will give you a queen, but you must separate your bees 12 to 15 miles, the farther the better." There is dan-

ger 12 miles, but I don't know about 15. We have had our Italian bees injured by the introduction of Cyprian blood. If these bees can be placed in the hands of careful men, that is all right. I am sorry Italian bees in different localities have not been improved. Forty years ago I found the bees better dispositioned than to-day. In the State of Indiana I could open a hive without a protection on my face, but I don't find it so in the State of Kansas where I live. I never go to a hive without my face and hands well protected. I wanted to speak of this to the Doctor, for I know there is harm being done by not having the bees sufficiently apart from each other.

Dr. Phillips—Perhaps I would better explain it, since the Doctor has taken exception. In the first place the Bureau of Entomology is the only organization that is improving bees, and we are the only people that import Caucasian queens. I do know that what we have sent out are good, reliable Caucasian queens. As to putting them in isolated places, it is absolutely impossible. Any person that has tried knows that it is absolutely impossible to find places 20 miles apart to keep queens. I was asked to do something that I can not do; neither can I go to see every man that writes for queens. We can not send to people who are good queen-rearers. The distribution of queens has been stopped, and will be for all time, if I have my say about it. I don't think the Bureau has any business giving away queens, and I have recommended that it be stopped.

W. H. Laws—I want to thank Dr. Bohrer for his painstaking advice to the queen-breeders; we need the older heads to keep us straight. The Carniolans, Holy Lands and Cyprians have been imported and spread broadcast over the country, and I think that some of these races I have named have created more injury than the Caucasian race, and in some cases they have proven very valuable.

Dr. Bohrer—I want to make one more suggestion, and that is to secure some place like Kelly's Island.

Mr. Stone—As far as I am concerned, I don't feel any danger in the introduction of this bee, or any other kind of bee. I feel toward them like I do toward my farm crops. When I introduce a particular kind of potato or grain of any kind I think of them just like my bees. If I have introduced Italian bees and they are better they will eventually run out the others that are no good; they will eventually come to the top, just like oil will come to the top of water.

Mr. Anderson—I have received queens from Dr. Phillips, and I have one queen that Dr. Phillips sent me that I would not take \$50 for today. I don't consider this stock would injure the Italians.

#### NEXT PLACE OF MEETING.

Pres. Dadant—It is customary for those, who wish to have the place of meeting selected for next year, to make a proposal of the place, which is passed on afterwards by the Executive Committee. There has already been a place

proposed, not only for next meeting, but for the following meeting, and I would like to hear from you. Our General Manager has some correspondence on the subject.

Mr. France—The bee-keepers, especially the members of our Association, feel that the cost is great, but the good they get is great, and they would like to see this convention moved about. Invitations to different places have come in. We had to drop the invitation from Minnesota and come to Texas this year. Minnesota has renewed her invitation for the future. There will be at Jamestown, Va., next summer, and continue until the early fall, an anniversary of the Jamestown Settlement, and there are here letters from the Pennsylvania bee-keepers and their neighbors, that we meet at one of those respective places. Then there is also one from Michigan; they feel that that part of the United States is entitled to the next meeting.

Pres. Dadant—I would like to hear from the bee-keepers, if they have a place selected. The meetings have been held west of the Mississippi River, and it is time we were going East.

Mr. Coggshall—I would suggest that we go to Virginia. I think that would be a good place. We have come West a number of times, and we would like to meet in the East.

Mr. Holekamp—It seems that the Jamestown people's invitation should be accepted.

Dr. Bohrer—I don't know; there are a good many bee-keepers in Virginia, and a good many in Pennsylvania, and a good many in New York, and they should be favored with a meeting of this kind. I don't think this would be a discredit to the bee-keepers there, nor we a discredit to them. I have never been in Jamestown, Va., and I think we could have a whole lot of fun there. I attend these meetings for the fun, and I have had a good deal of it here.

Mr. York—All we can do is to recom-

mend that the places be considered by the Committee.

Pres. Dadant—I want to impress upon your minds that it is important that we should go where there are bee-keepers, and if they are not in numbers it will make a poor meeting. Now the Norfolk, Va., people want us there, because they want us to see the town. If these bee-keepers want us, it is all right.

Mr. Holekamp—Would it not be better to let this be undecided, and give it a little more time? Maybe those Minneapolis people would come in and invite us there.

Mr. York—I don't think that we should consider an invitation from the West for next year; we should go East, as Mr. Coggshall says.

Mr. Coggshall—You might come to Philadelphia or Harrisburg.

Mr. France—This will finally have to be left with the Executive Board. Your suggestions are good, but, remember, we can not decide here. This meeting was to have been held here last year, but when the cry of yellow fever broke out in the South it seemed best to meet elsewhere. I doubt very much if the meeting will be held at Jamestown. On account of excursion rates some of the larger cities will obtain the meeting, but I am in favor of the meeting being held in the East.

Mr. Victor—I think this Association should meet East of the Mississippi River, and that it be left to the discretion of the Executive Committee, without recommending any special place, except to meet east of the Mississippi River.

President—Have we a second for the motion?

Mr. Coggshall—I second the motion.

Pres. Dadant—It is the sentiment of this meeting that when you vote, that we desire the meeting held east of the Mississippi River. The motion is carried.

(Continued next week.)

Send Questions either to the office of the American Bee Journal, or to  
Dr. C. C. MILLER, Marengo, Ill.

Dr. Miller does not answer Questions by mail.

### Introducing Queens—Building Up Colonies

1. I have 2 colonies that have no queens, so I am going to send for some. How shall I introduce them? I have just started in bee-keeping.

2. My colonies are very light. How can I get them strong? MINNESOTA.

ANSWERS.—1. In probably all cases,

those who ship queens send with them instructions for introducing, and you are expected to follow those instructions. Generally they are that you are to put the cage in the hive, between the frames or over the top-bars, where they will be sure to be well surrounded. The old queen is to be removed at the time the new one is to be put in, and the bees are to eat the candy to liberate the queen. Some prefer to have the new

queen in the hive 2 or 3 days before the old one is removed, according to the advising of Rev. E. T. Abbott, the bees not being allowed to get at the candy till the old queen is removed.

2. That's a good deal like saying, "My calf is very small, tell me how to make it big." Of course, you're to let the calf have all it can eat and let it grow. And you're to let a weak colony have all it can eat and let it grow. Be sure that in each hive there is all the honey the bees need—and more. In that respect the colony is different from the calf; if you feed the calf more than it can eat, the food will be wasted, and you may hurt the calf by overfeeding. The bees will not waste any extra feed given them, and they will build up faster with a good lot of honey in sight than if they have only enough to keep them going from day to day. Of course, you must not do anything to make the bees cold, such as leaving a cover loose or making too large an entrance. You might try the Alexander plan of putting a very weak colony over a very strong one, doing the work quietly so as not to stir up the bees, and having an excluder between the 2 colonies; but if you have no strong colonies you can't do that.

### Queen-Excluders and Comb Honey Production

1. Is it really necessary to put a honey-board between the brood-frames of the newly-hived swarm and the super of partly-filled sections taken from the old colony?

2. Is it usual for the queen to go up into the super to lay unless she is prevented by the use of a honey-board?

NEW YORK.

ANSWERS.—1. If the super is put over the swarm immediately after it is hived, there is danger that the queen will go up into the super unless a queen-excluder—or a honey-board, as you call it—is used. But there is no need to put the super on so soon. Let it remain on the old hive until a brood-nest has been established in the brood-chamber, and then put it on. So the general practice is to put the super over the swarm 2 or 3 days after the swarm has been hived.

2. Some have trouble with the queen going up, and some have no trouble. If sections have starters only, and there is little or no drone-comb in the brood-chamber, the bees will build drone-comb in the sections and the queen will lay in them; and when she has made a start there she will not stop with the drone-comb but will fill the sections. For many years I have produced sections without queen-excluders, and not one section in a thousand is troubled with brood; but the sections have been entirely filled with foundation.

### Curing Rheumatism with Bee-Stings

A lady in my neighborhood has had rheumatism in the ankle of her right foot for several years. She has tried many remedies, and all failed. I advised her to try bee-stings, so she has

tried it twice, each time 15 bees stinging about the ankle. The first time I applied the bees. The stings relieved her, but later she got very sick, although a week later she asked me to try again, with worse results. She thinks the bee-stings would cure her rheumatism, but is afraid they might poison her system.

I had inflammatory rheumatism for 4 months in my left leg, and after a doctor gave up, 15 bee-stings cured me with one operation. Would you advise us to keep on with only a few bees at a time?

PENNSYLVANIA.

ANSWER.—Yes, I would try it again with a smaller number, repeating the operation many times at intervals of a day or more. I don't believe she need be afraid of the poison in her system. Thousands of bee-keepers have been stung enough to show bad effects if there were any, but they're a pretty healthy lot.

### Danzenbaker Hive and System

1. Is the Danzenbaker hive as good as any for comb honey?

2. I have a small book, "The Danzenbaker Hive System." Is it safe to follow?

3. Are the Danzenbaker brood-frames deep enough for bees to winter well?

ANSWERS.—1. Some are enthusiastic over it; some condemn it severely. After a limited experience with it, I still prefer the regular 8-frame dovetailed hive.

2. If I am not mistaken, that booklet was written by the inventor of the hive, and so should be exactly adapted to it.

3. Yes, except in the colder regions of the North it is all right for outdoor wintering, and in the colder places cellars are used anyhow. Even in the coldest localities, for outdoor wintering one could use 2 stories for very strong colonies, and that would make it a deep hive.

### Questions on Topics Found in "Forty Years Among the Bees"

I have read your "Forty Years Among the Bees," and re-read parts of it several times, especially on queen-rearing, and may have to read it several times more before I become an expert. I have taken some notes as I went along and may have to ask you some questions; not however, with a view of intimating that my way is better than yours, but merely to get your opinion of mine.

1. You speak of tags on your hives. I have my hives numbered. Will not this take the place of tags? Or, do you change the tags every year?

2. In regard to depending upon clipped queens for out-apiaries, if the clipped queen is lost when she comes out, and the swarm returns, will they not swarm again when the first young queen is hatched?

3. In speaking of self-spacing frames by nails, I have used them but thought that too tinkering. You object to side frame-spacing, alleging that the frames will become so glued up that they will not occupy the same space again. I

don't care if they don't. I don't generally use a dummy the second time, and allow the frames to spread a little after the frames are built, thinking the bees will not draw out the cells any after they are once finished. Am I right?

4. You speak of wetting sections before putting them together. I never found that necessary. I keep mine in the cellar and find them damp enough.

5. On page 168, "Giving a nucleus to a swarm," etc., what advantage is there over giving a hive with frames of foundation, or starters, with its own queen?

6. You seem to take frames out of a hive and put them into another to clean my hives and lift them off the bottom-board. Is not this preferable?

7. Page 237. Having your breeding-queen in a 2-frame nucleus, you take away one of the combs and put in its place a frame with 2 small starters (Fig. 86). A week later you will have a comb built in it well filled with eggs (Fig. 88). This is then taken away and another of the same kind given, and this will furnish such an egg-filled frame once a week. Then for every such a one taken away, I must make a colony queenless. Having 2 of this kind in 2 queenless colonies, you clip off a little of the outside of these; why is this? I thought the younger the brood, the better the queens.

8. As I understand, you now place these hives back to back. How is this one frame a week older than the other? To get them back, I must lift them from their stands and take them to a new place. Won't they incline to go back to their old stands? And as they have been used to come in from the same direction, won't they go into the hive that is set in that direction? Of course they will be conscious of their queenlessness as I made them so to receive these frames. Now, am I not getting two plans mixed? When I have got my prepared comb into a queenless colony, what more do I need? It strikes me that is where you want to rear queens by the quantity.

9. I tried making nuclei in one hive, but the bees all wanted to come in from the one side.

10. In making 2 or more nuclei in one hive, is it necessary that there be no passage from one apartment to the other by the workers, either at top or bottom?

11. I have always been at a loss to know how to keep queens when I have them reared till I wanted them. If a queen is caged, is it necessary that there be worker-bees with her, or if her cage is between combs will outside bees feed her?

12. I believe you told me once that you caught the worker-bees one at a time and put them into the cage with the queen. Is there a particular way to take hold of a worker to avoid getting a sting?

13. You use splints in fastening foundation in frames. Where do you get them?

14. You give directions for making cages to protect queen-cells. Did you ever use the spiral queen-cell protec-

tors? I suppose you have seen them. Are they not a success?

15. There is a man living in this city who says he kept bees in Ohio years ago, and that he had hundreds of queens fertilized in confinement, and he told me how he did it. It is very simple. He used a barrel; took one head out of it; then had that covered with something that would not admit light. Then he made a hole in the other end about 3 inches in diameter and covered it with a glass on the inside. Then he made another hole near this large enough to introduce the queen and drones. Then he stopped this up. The queen and drones would collect at this glass. The other end was covered by glass. The covering of this glass was quickly removed and in the dash for this light the drone would meet the queen. Before the large glass was uncovered the small one was darkened. I told him fertilization in confinement was talked of 40 years ago, but was abandoned to-day as impracticable, but he claimed it had been practicable with him. He is not in the business now, but is a practising physician. IOWA.

ANSWERS.—It is perhaps not to be regretted that bee-keepers do not all think alike. If a beginner should take for his model the best bee-keeper in the world and blindly follow in his footsteps, he would not come out so well as to do some thinking for himself. Even a beginner, too, may sometimes think up something that, at least for his conditions, may be an improvement over the plans of the veterans, and I feel pretty sure that from a man of your experience I could learn something, even if it is worth while for you to ask questions.

1. It depends something upon plans whether it is better to have numbers on hives permanent or movable. If each hive is to keep the same location always, it is better to have the numbers painted on the hives. But that sort of numbering wouldn't suit my plans very well. The hive that stands at the beginning of the first row in the home apiary is No. 1. But I may, for some reason, change that hive to some other place, and then the number must be changed to fit the place. That, you will see, makes the changing of numbers a necessity. This spring, for instance, for the sake of the drones—because queen-rearing is done in the home-apiary—I kept at home any colonies which distinguished themselves in the out-apiary last year. The numbers of course had to be changed, and it is an easy thing to pull off one tin tag and put on another. If you find no necessity for changing numbers, you are rather to be congratulated. For sometimes—indeed much oftener than is pleasant—tags get lost; and sometimes when one is hurried the tags are not changed for some time when hives are changed. Indeed, at this present writing, a lot of tags on my hives have not been changed that need changing. I'm not proud of it, and I'm not advising others to be so shiftless.

2. Almost certainly, if left to themselves. It's "up to you" to see that they don't.

3. I have had a few cases in which a dummy has been left out at the side, and the bees lengthened out the cells until they came within  $\frac{1}{4}$  inch of the hive-wall. Unless your bees are better trained than mine they are likely to do the same thing.

4. Yes, I have done the same thing, and I have also received sections that needed no wetting when received. If only 2 or 3 sections in a box should break, I wouldn't wet them.

5. The plan you mention, which is the shake-swarm plan, leaves the colony constantly diminishing in numbers for 21 days, for not a young bee will emerge till the end of that time. The nucleus I give has at least 2 or 3 frames of brood, and sometimes can hardly be called a nucleus, having from 3 to 5 frames of brood. Indeed, in some cases it is about as strong as the colony removed. Possibly you may say, "If you leave the old colony in full strength, it will swarm again. Why will it not swarm if another colony of equal strength is put in its place?" I suppose the reason is that a young queen is present, and the brood is different from what it was in the colony that had been swarming. At any rate I never had one swarm. (As a postscript I may add that the new queen has no swarming fever, and the old one has.)

6. Yes, if bottoms are loose, and you want to clean off only the bottom. If you want to clean out rabbits, the other way is better. Or, if bottoms are stapled on, it may be easier to change hives than staples.

7. That "younger the brood the better the queen" business may be carried too far. No better queen can be reared from an egg just laid than from a larva a day or 2 old, and the larva has the advantage that it will be 4 or 5 days in advance of the freshly-laid egg. The bees seem to understand this, and they would not start any cells on the edge of the comb that contains only eggs, and as that part of the comb is in the way, I trim it off so the cells will be started on the edge, where the bees like it best, and where it suits me best to cut off cells.

8. Yes, you have things somewhat mixed; I hardly know why, but it doesn't matter. I wouldn't advise you to use that plan unless you are rearing queens by the hundred, and I'm sorry I didn't say so in the book. I don't use it myself when I rear queens only for my own use, which I have always done with the exception of one year. You are quite right; if you get your prepared queen into a queenless colony that's all you need, and generally some colony will be queenless in an apiary of any size. If not, you can make any colony queenless long enough to start a hatch of cells.

9. I hardly know why you should have trouble. If the nucleus-hive is put on a new stand, and the bees imprisoned for 1 to 3 days, each nucleus ought to mark its own entrance.

10. It is absolutely necessary that no bee can get through from one side to the other at top, bottom, or anywhere else except by going outdoors through the entrance.

11. Better have no workers in the cage

with her. Sometimes the bees will not find her, but you can provision the cage with candy and then the queen is independent.

12. Look for a bee with its head in a cell taking a lunch. It is partly bent so its wings project in the most convenient manner, and you can easily take the wings between thumb and finger. But unless to ship a queen, I don't know of any need ever to put workers in a cage.

13. Supply manufacturers make them to order.

14. The West cell-protectors are all right.

15. If you have any faith in it, try it, and then tell the rest of us of your success.

### Queen-Rearing and Swarming

1. Does the plan of opening a hive shortly before swarming time and destroying the queen-cells necessitate the devotion of one colony to queen-rearing, to supply the demand for young laying queens to be put back 8 days later? Or can some of the queen-cells taken from the colony be utilized? If so, how?

2. Why not, at the time of opening the hive and removing the old queen, save one of the best cells that will hatch in a few days—say 5? Would not this queen, upon arriving home from her mating trip, destroy all queen-cells in the colony? Would it prevent swarming?

MICHIGAN.

ANSWER.—Good cells obtained from anywhere may be utilized, of course keeping in view to obtain them from best stock. Even if the cells are not advanced, merely started, they may be put into an upper story over an excluder on a hive with a laying queen, and the bees will care for them. For this purpose a colony with an old queen is better; the best being a failing queen that the bees are about to supersede.

### Bulk Comb Honey

Having read an article on page 257 on the "Production of Bulk Comb Honey," I wish to give my method, as I have practised that method all my bee-keeping life—23 years. In fact, I have sold but little of any other kind of honey but bulk honey, and my customers seldom call for any other. One merchant who handles a large part of my crop told me that the honey I put up in quart and 2-quart glass jars "did not last till it was all gone!" All he had to do was to put a few jars in sight and it went quickly. I fill in about  $\frac{3}{4}$  extracted and the rest nice squares of white comb, and I get about as much for it as section honey brings. The receptacles are useful in any family and they pay as much per pound for the jars as the honey. The same is true with tin pails in which I sell a great deal of honey. I just weigh it all to the customer, and at wholesale the pails cost about 10 cents per pound, and they buy and make no complaint. There is no need to put in more than 1-3 comb honey, either. I sell all my extracted honey that way, except where extracted is wanted for medicinal or cooking purposes, or a few buy it for their table use. But those are mostly old customers who know

me, and are not afraid of getting glucose instead of honey. My honey was all sold before cold weather last year. And I had calls for several hundred pounds after all was sold, and I never shipped a pound of it. I find honest weight and honest goods build up a good local trade that stays with me. I have customers who have been buying honey from me for 15 years.

If I could only produce the honey, I would have no trouble to sell 5—yes, 10 times as much as I do. I cut out alternate combs, leaving about one inch of the comb on the top-bar for a starter. I have regular hives for comb honey, and others wired for extracted. I use only inch starters for comb honey when living new swarms, but full sheets wired for extracting hives. D. F. MARRS.

Lorena, Tex., April 2.

**Mild Winter for Bees**

The past winter was a mild one here, resulting in the bees' wintering quite well. Mine were set out as follows: 70 colonies on March 24; 50 on March 28; and 43 on April 3; making 163 colonies in all. A few days later, I took an inventory and found them in the following condition: 126 strong colonies; 28 medium; 5 weak; and 4 dead. This is the way I estimated them: a strong colony reaches from 5 to 7 and 8 spaces; a medium colony reaches from 4 to 5 spaces; a weak colony reaches from 3 to 4 spaces. The inventory was taken on cold, frosty mornings when the bees were in compact clusters.

FRANK STOFLET.

Auburndale, Wis., April 11.

**An Amateur's Success**

I am only an amateur in the bee-business, but was very successful last season, getting over 1,200 pounds of nice section comb honey from 10 colonies with only 3 swarms. All have wintered well on the summer stands, and are building up nicely now.

I am well pleased with the American Bee Journal. JAMES SOWARDS.

Pikeville, Ky., April 12.

**A Buggy-Spring Hive-Tool**

Herewith find description of a good, cheap, and practical hive-tool which can be made of a wagon or buggy spring. The broken end of a spring can generally be found at any blacksmithshop, and the thin end can be filed sharp, or you can get it sharpened for 10 or 15 cents; have it sharpened as per the illustration herewith—the thin end sharpened, and one side

6 to 10 inches long.

about 2 inches back, to be used as a scraper, screw-driver or chisel; and the thick edge could be squared on one edge to use as a hammer to drive a nail with.

Have it the above shape to scrape out the corner of a hive, with the sharp, square edges so the fingers will not strike on the bottom or side of a hive. VIRGIL P. CUTLER.

Canon City, Colo.

**Well-Bred Queens**

Will greatly increase the yield of honey. Am now taking orders for **Cook's Select-Bred Queens**—to be sent as soon as weather permits mailing. Also Caucasian Queens from imported stock.

**Cook's Square Honey-Jar** is the best, cheapest, and most sanitary package for retailing honey. Send for circular and price-list of Hives, Bees, and useful Implements.

# BEE-SUPPLIES

PERFECT GOODS LOW PRICES  
A Customer Once, a Customer Always.

Now is the time for you to buy your Bee-Supplies. We manufacture Bee-Hives of all kinds. The Dovetail, Langstroth, Alternating, and the Massie Hives, we make all of them. Remember that half the work and worry of your apiary is removed when you use our goods. Every one knows the advantage of a good, substantial hive; the quality of material and workmanship in our hives are not excelled by any other make.

We have been in the business over 40 years, and know what is practical, and when you once give our goods a trial you will have none other. Remember that now is the time to get your order in for the season's supplies. Have you received our new 1907 Catalog? If not, write for it at once. You cannot fail to understand how to order just what you want from our Catalog, it is the easiest to understand that you ever saw.

No trouble to give estimates; tell us what you want.

## HAND-MADE SMOKERS

Extracts from Catalogs—1907:

BINGHAM  
CLEAN  
BEE SMOKER  
Pat. 1878, '82, '92 & 1903

Chas. Dadant & Son, Hamilton, Ill.—This is the Smoker we recommend above all others.

G. B. Lewis Co., Watertown, Wis.—We have sold these Smokers for a good many years and never received a single complaint.

A. I. Root Co., Medina, Ohio.—The cone fits inside of the cup so that the liquid creosote runs down inside of the smoker.

All Bingham Smokers are stamped on the tin, "Patented 1878, 1892, and 1903," and have all the new improvements.

- Smoke Engine—largest smoker made.....\$1.50—4 inch stove
- Doctor—cheapest made to use ..... 1.10—3½ "
- Conqueror—right for most apiaries ..... 1.00—3 "
- Large—lasts longer than any other..... .90—2½ "
- Little Wonder—as its name implies ..... .65—2 "

The above prices deliver Smoker at your post-office free. We send circular if requested.

Original Bingham & Hetherington Uncapping-Knife.

T. F. BINGHAM, Farwell, Mich.

Patented May 20, 1879. BEST ON EARTH.

**E. A. SIMMONS, Greenville, Ala.**

17Atf Please mention the Bee Journal.

Please Mention the American Bee Journal when writing Advertisers

are made every year in the book business. Every family, rich or poor, must have books. During the last few years, \$7,500,000.00 have been expended for Modern Eloquence, \$12,000,000.00 for Stoddard's Lectures, \$1,000,000.00 for the Century Dictionary, and the tremendous sum of \$41,000,000.00, covering over half a million sets of the Encyclopaedia Britannica. These books were sold by subscription in American homes and sales are still going on.

We have a subscription publication which sells more readily than any of the above. The demand is already so tremendous that more capital is required to swing it, or get behind on orders. Profits are enormous, several times savings bank interest.

We have arranged a plan whereby **Any Progressive Man or Woman Can Share These Profits**

becoming stockholders in a profitable business, based on twenty years' experience. Remember, the success of this publication is not away off in the future—it is not prospective, but it is a success at the present time and growing in demand every hour. Sales of this publication at the time of publishing this advertisement

**Often Exceed \$2000 a Day**

This is an exceptional opportunity for those of small means to get in on the ground floor in a business which legitimately pays large dividends and is as solid as the Rock of Gibraltar. It cannot be held open for long as the response is certain to be so great that we shall have all the capital we need to increase the number of our presses and secure stock to be turned out in completed books, which are selling like wildfire.

You owe it to yourself to investigate this opportunity. You will never have a chance like this again to become

**Part Owner in a Mammoth Publishing House**

which is already in successful operation, already earning big dividends, and which is led to sell a small amount of its stock simply because the business is already so tremendous as to exhaust the working capital. But if you would grasp this opportunity you must

**Write Quick—Only a Few Can Come In**  
Address your letter to me personally, like this—

W. B. Gilbert  
Dept. G 28 Jackson Blvd., Chicago

## YOUR MONEY IS GOOD

You know that. We know that. Every one knows that. If it were not, every one would not be ready to take it. You and you alone must insist on returns, real returns for the good money you spend for bee-supplies. If you don't see to it that you get your money's worth no one will.

## NOW WE WANT TO ASK YOU A QUESTION

Do you know that you are losing money—real, hard-earned money—every time you put a colony of bees into a cheap, poorly fitting hive? You are, for the good reason that the bees are spending most of their time building over the hive when they ought to be making honey.

## HONEY MEANS MONEY

Thus more than the money that you think you are saving when you buy a cheap hive the bees are losing for you "hand over fist," and you don't know it. It's the fault of the hive.

That's why some bee-keepers get a whole lot more honey than others. That's why the man using the best goods makes the most money when it comes to cashing in at the end of the season. We can prove that. Men can build hives cheaper and better than bees. Then why not have everything just right to begin with?

JAMESTOWN, N. Y.

[Established 25 years.]

Mention *Bee Journal* when writing.

**Honey and Beeswax**

**CHICAGO, April 4.**—Market is quite bare of best grades of comb honey. When sales are made it is on a basis of 15¢@17¢, with very little outlet for the off-grades. Extracted, 7¢@8¢; off grades, 6¢@6½¢. Beeswax in good demand at 30¢@32¢. **R. A. BURNETT & CO.**

**CINCINNATI, April 16**—There is nothing new in the honey market, excepting that this part of the country is bare of comb honey, and it is well, for consumers will appreciate the new crop more when it arrives. We are selling extracted amber honey in barrels at from 5¼¢@6½¢. Fancy table honey, 8¼¢@9¢, in crates of two 60-pound cans. For choice yellow beeswax, free from dirt, 32¢ cash, delivered here. **THE FRED W. MUTH CO.**

**PHILADELPHIA, April 10.**—Owing to the cold weather, there has been quite a demand for comb honey in the last 10 days; quite a number of odd lots have been moved in this market, with not so many arrivals as heretofore. We quote: Fancy white comb honey, 15¢@16¢; No. 1, 14¢@15¢; amber, 12¢@14¢. Fancy white extracted, 7¢@8¢; light amber, 6¢@7¢. Beeswax, very firm, 32¢.

We are producers of honey and do not handle on commission. **WM. A. SELSER.**

**NEW YORK, April 12.**—**COMB HONEY.**—There is very little doing; stock of white honey of all grades is practically cleaned up, and small shipments which arrive from time to time, find ready sale at 14¢@15¢ for choice white stock, and 12¢@13¢ for off grades. Considerable dark comb honey is left on the market, and there does not seem to be any demand whatsoever. We quote nominally at 10¢@11¢, but in large lots we doubt whether this price can be realized. **EXTRACTED HONEY.**—California stock seems to be well cleaned up, and we are informed that there is very little left on the Coast, and, before the new crop is marketed, whatever is on the market now will have been consumed. The prospects in California are very good for a large crop, but nothing definite can be said at this time, and there is no surety of a big crop until it is actually gathered. Last season the outlook was just as good, but in the height of the season, cold northern winds and generally contrary weather affected the crop to such an extent that it was small as in previous years. With favorable

**Headquarters for Bee-Supplies**

**C. H. W. WEBER** CINCINNATI OHIO

Office and Salesrooms, 2146-48 Central Ave. Warehouses, Freeman and Central Aves.

weather in California for the next two months a large crop will undoubtedly be harvested, and if so prices will naturally be considerably lower than those of the past season and present prices. We quote white sage at from 7¢@9¢, and light amber at from 7¢@7½¢. Near-by, as well as Southern honey, is well cleaned up, and the markets are in good shape for new crop. Cuban and other West Indian honeys are arriving in large quantities, most of which are sold for export. The market is firm, at from 58¢@60¢ per gallon, duty paid according to quality. Beeswax firm and steady at from 30¢@31¢. **HILDRETH & SEGELKEN.**

**INDIANAPOLIS, April 12.**—comb honey is not plentiful, but demand is slack. Fancy white comb brings 16¢@17¢; No. 1 white, 14¢; amber, 12¢@13¢. Best grades of extracted honey bring 8¢@9¢; amber, 6¢@7¢. Good average beeswax sells here at \$35 per 100 pounds. **WALTER S. POWDER.**

**TOLEDO, Nov. 30**—The market on comb honey remains about the same as last quotations, but has been coming in much more freely, as bee-keepers seem to be very anxious to get rid of their stock. Fancy brings in a retail way 16¢; extra fancy, 17¢; No. 1, 15¢; buckwheat, 15¢. Extracted white clover in barrels brings 7¢@7½¢; cans the same. Beeswax, 26¢@28¢. **THE GRIGGS BROS. & NICHOLS CO.**

**KANSAS CITY, Mar. 30**—The demand for comb honey is light, as also are the receipts. The market is about bare of extracted. We quote: No. 1 white comb, 14 sec. cases, \$3.10 to \$3.25; No. 2, \$2.50 to \$2.75. Extracted, white, 8¢@9¢; amber, 7¢@8¢. Beeswax, 28¢. **C. C. CLEMONS & CO.**

**DENVER, Feb. 14.**—Producers in this State are practically closed out of both comb and extracted honey. We have not sufficient good comb honey to supply our local trade, but have a good supply of white extracted of excellent quality. We quote strictly No. 1 white comb honey, per case of 24 sections, at \$3.20; No. 1, light amber, \$3; and good No. 2, \$2.80. White extracted, 8¢@8½¢ per pound; light amber, 7¼¢@8¢. Clean, yellow beeswax, 27¢@28¢, delivered here.

**THE COLO. HONEY-PRODUCERS' ASSN.**

**CINCINNATI, April 3.**—The market on honey is entirely bare of fancy comb honey; No. 2, selling at 12½¢, and slow sales. Light amber extracted sells in barrels at 5¼¢@6¢. Beeswax 32¢, delivered here. **C. H. W. WEBER.**

# Coming On Through Freight

By the Bee-Crank.

There's a lot of talk these days about car shortage. If you are curious to experience a taste of what it means, order your next bill of Supplies shipped from some out-of-the-way point, and then sit down and await developments.

But if, like most bee-men, you haven't much time to sit in idleness—if you order your Supplies because you need them—betler cut out the experiment business and order from Pouder. There is no car shortage in Indianapolis. There never is, and in the nature of things there is no likeli-

hood of there ever being one. Indianapolis is the center point of a lot of the big trunk-line systems of the country. Cars pour in here by the thousand daily, from every quarter. When your order is received by me in the morning, by nightfall the shipment is booming along on the way by through freight, straight for your place, and it keeps moving until it reaches you.

I carry a full line of the Root goods at Root prices, and I not only save you time, but I save money in freight charges.

**BEESWAX**—send it along. I will pay the highest market price at all times. Send by freight or express, according to size of shipment.

**Walter S. Pouder** 513-515 Massachusetts Avenue  
INDIANAPOLIS, INDIANA

# Trade Notes

## The A. I. Root Company, Medina, Ohio

### GASOLINE ENGINES

A four-page article on the use of large honey-extractors with gasoline engines is found in the May 15th Gleanings. The article is fully illustrated and well worth 25 cents to any one interested in the production of extracted honey. When labor is high and help hard to find the gasoline engine and power extractor come in to help the bee-keeper out and save his crop. Send for this number of Gleanings. Price, 10 cents. Six months to new subscribers (12 copies) for only 25 cents, and your money refunded if dissatisfied in any way.

### BEEES AND QUEENS

There is sure to be a heavy demand for bees and queens for months to come, on account of the large losses all over the North during the past month, because of the continued unfavorable weather. If you want to re-queen your apiary, or get a good breeding queen, or restock your empty hives, you should send your order at once to secure delivery early. There is sure to be a large demand and consequent inability of breeders to supply promptly, so remember, "first come, first served."

### PRICE-LIST of BEEES AND QUEENS

#### HOME-BRED ITALIAN QUEENS

	Oct. to June.	June to Oct.
Untested queen.....	\$ 1.25	\$ 1.00
Select untested queen ..	1.50	1.25
Tested queen.....	2.50	2.00
Select tested queen.....	3.50	3.00
Breeding queens.....	6.00	5.00
Select breeding queens.....	9.00	7.50
Extra select breeding queens, 1 year old.....	12.00	10.00

#### IMPORTED ITALIAN QUEENS

Best imported queens.....	\$5.00
Fair imported queens.....	3.00

#### SOUTHERN-BRED ITALIAN QUEENS

For those who desire to get pure Italian stock at a moderate price, we are prepared to furnish queens direct from our breeders in the South at the following scale of prices:

	Oct. to June.	June to Oct.
Untested queens.....	\$1.00	\$ .75
Select untested queens ..	1.25	1.00
Tested queens.....	1.75	1.50
Select tested queens.....	3.00	2.50

### 5-BANDED ITALIAN, CARNIOLANS, DR CAUCASIANS

These will be furnished at the same prices as our home-bred Italian queens.

#### PRICES OF NUCLEI AND COLONIES

	Oct. to June.	June to Oct.
1-frame nucleus, without queen..	\$ 3.00	\$ 2.00
2 frame nucleus, without queen ..	4.50	3.00
3 frame nucleus, without queen ..	5.50	3.50
Colony in 8 fr. Dov'd hive, no queen.....	10.00	7.50
Colony in 10-fr. Danz. hive, no queen.....	11.00	8.00
Colony in 10 fr. Dov'd hive, no queen.....	12.00	9.00

We can supply with the nuclei any of the queens mentioned in this list. When one buys an extra-select queen, or any high-priced queen, he would do well to have her come in a nucleus. This will assure safe arrival.

Where a customer desires a queen's wings clipped a charge of 25 cents extra will be made.

### BEE-MODELS

There are a good many bee-keepers who will admit they ought to know more about the anatomy of the bee; but owing to the difficulties surrounding the subject they have thus far been unable to acquaint themselves in the least with the marvelous structure of the honey-bee. For such persons there has been constructed a *pasteboard* bee, showing all the internals of a queen and also a drone in a manner that leaves little to be desired. With the aid of the key, any intelligent person may soon become well acquainted with the anatomy of the bee and the proper name of each organ. First, there is a life-like representation of the queen and drone (separately). By lifting the outer covering the breathing apparatus and digestive system are unfolded; lifting again there will be found the reproductive system and poison glands; and by again lifting, the nervous system is clearly outlined. Everything is as clear as daylight, as each part and organ is numbered, and the key which we send gives the correct scientific name of the same. Our models of the queen measure 6½ inches, while those of the drone are 5½ inches. We can furnish either with key at 50 cts. postpaid.

### THE A B C OF BEE CULTURE

The 1907 edition (English) will be ready early in the coming fall. A complete French edition ("A B C de L'Apiculture") is ready for mailing; price of this edition \$2.00, postpaid. We are booking orders for the German edition, which is expected by Sept. 1st. The price of this is also \$2.00, postpaid.

### THE SWARTHMORE LIBRARY

A series of booklets on bee-subjects by E. L. Pratt, of Pennsylvania, known to the bee-keeping world as "Swarthmore." These books are full of the most valuable information. The Swarthmore method of queen-rearing is spoken of as the most important innovation in bee-keeping of recent years.

**INCREASE.**—The first of the series. Any one desiring to enlarge his apiary should learn the Swarthmore way. Price, postpaid, 25 cts. French edition, entitled, "Accroissement," 50 cts. postpaid.

**BABY NUCLEI.**—The using of little frames and a handful of bees for mating queens has created quite a stir in the queen-rearing business. From this booklet you get your information direct. Price, postpaid, 25 cts. French edition, entitled, "Nuclei Miniatures," 50 cts. postpaid.

**COMMERCIAL QUEEN-REARING**—A complete description of the Swarthmore methods of queen-rearing in regard to cell-getting. Price, postpaid, 25 cts.

**SIMPLIFIED QUEEN-REARING.**—Revised edition. It tells the honey-producer how to rear queens by the very simplest method ever published. Good queens for little money and little trouble, in just an effective and economical plan for the bee-keeper who works for profit. Price, 25 cts. postpaid.

(Entered at the Post-Office at Chicago as Second-Class Mail-Matter.)

## Editorial Notes and Comments

### Detecting Adulterants in Honey

A subscriber in New Zealand writes as follows:

Is there any easy method which an ordinary bee-keeper might apply to detect the presence of adulterants in honey?

In New Zealand the public buy the comb honey because they know it can not be faked. It seems to be a more sensible view than that of the United States of America public. We don't nearly meet the demand for comb honey here.

We don't know of any unless it be by the taste. It is not very difficult to detect the presence of glucose by the taste.

New Zealand is ahead of the world in a good many ways, and you are to be congratulated that your public is so intelligent that it knows comb honey can not be faked. Here, too large a proportion of the public believes not only that comb honey can be, but that it is faked. But the tide seems to be turning, and we are counting much on what will be effected by our pure-food laws.

### Brevity Sometimes Dangerous

Brevity is desirable, but it should not omit an essential part of a story. Mr. D. M. Macdonald occupies a page and a half of the British Bee Journal with what he calls gems from "Forty Years Among the Bees." The work is exceedingly well done, but the brevity of the extracts, averaging perhaps 4 lines each, may in a few cases lead to misunderstanding when such short statements are taken without the context.

The sentence, "I have found no way of securing all worker-comb except by having it built by a weak colony." Taken alone that might be understood to show that weak colonies were generally used for building comb,

and that Dr. Miller had not learned the value of comb foundation. On the contrary, it is well known that Dr. Miller is an earnest advocate of full sheets of foundation, both for brood-combs and sections, and the number of brood-combs in his hives not so produced are exceedingly few. A statement of the whole truth would be, "I have found no way of having the bees build all worker-comb without the use of foundation except by having the comb built in a very weak colony. My practise is to have combs built in strong colonies on worker-foundation."

Another extract reads: "If a colony has 9, 10, or more frames of brood, all but 8 are taken away." Somewhat vague as it stands, but some might understand a disapproval of more than 8 frames of brood to the colony at any time. On the contrary, the largest amount of brood is encouraged up to the time of putting on supers, when each colony is reduced to one story of 8 frames each.

"Increase is made by taking frames to the out-apiary, and, of course, bees stay wherever they are put, and work up into a colony." The last part of the sentence suggests the advantage of making increase in that way, but the labor of moving to the out-apiary is no small item, and as a matter of fact the plan is seldom used.

Possibly some of D. M. M.'s readers would be less puzzled if he would clear up these few points.

### Nuclei and Colonies

A nucleus is well understood to be a very weak colony of bees, but just where is the dividing line between a nucleus and a colony is not so well understood, just as it is not always easy to say when a boy becomes a man. Perhaps it might be said that anything

less than 3 Langstroth frames, fairly well covered with bees, is a nucleus, and anything more is a colony. That leaves 3 frames of brood covered with bees to be called sometimes a nucleus and sometimes a colony. The time of year may have something to do with it. Hundreds of colonies come out of winter quarters with no more than 3 frames covered with bees—yes, thousands of them; and many with less than that, and yet at that time of year they are called colonies. In the middle of summer they would hardly be called colonies, but nuclei. Then there are the "baby nuclei" about which so much has been said lately, consisting of 1, 2, or 3 very small combs, with a correspondingly small number of bees.

### Higher Postage Rate to Canada

Beginning with May 8, the postage rate on all United States periodicals mailed to Canada was quadrupled, which will compel us to raise the subscription price on the weekly American Bee Journal to all Canadian subscribers, from \$1.00 a year to \$1.50. This is made necessary from the following notice which was recently sent out by our Postmaster-General, Hon. G. v. L. Meyer, at Washington, D. C.:

"It is hereby ordered that, commencing on the 8th day of May, 1907, the postage rate applicable in the United States to 'second-class matter' addressed for delivery in Canada shall be one cent for each four (4) ounces or fraction of four (4) ounces, calculated on the weight of each package and prepaid by means of postage stamps affixed."

This will compel us to put a 1-cent stamp on each copy of the American Bee Journal mailed into Canada, beginning with this week's issue. Therefore, our Canadian readers will please take notice of the increase in price when renewing their subscriptions, which increase is not our wish at a but is made necessary, as stated, through international postal agreement.

Of course, every Canadian subscriber now on our list will receive the Bee Journal the full time for which he has paid, regardless of the heavy extra postage bill we are called on to pay. It will be quite a loss to us, but the American Bee Journal means to do as it agrees. We trust that our Canadian readers will continue their kindly support right along.

## Miscellaneous News - Items

**Working Under Difficulties**—that's what we have been doing in order to get this number of the American Bee Journal out on time. It is a rather serious matter to move a printing office, and be able to find everything again very soon. But in a week or two more we will have everything in "apple-pie order," and running as smoothly as ever. Please remember we are never so much interrupted that we can't take care of all renewals and new subscriptions for the old American Bee Journal that may be sent to us.

**Honey Conditions in Southern California.**—We have received the following from Mr. John Stewart, of Southern California, dated April 28, 1907:

AMERICAN BEE JOURNAL—

The enclosed from the Los Angeles Times for April 26, is true of the conditions of the honey-production in the fog-belt near the coast in Southern California; but more inland, in the orange-producing districts, the conditions have been better for a fair honey crop this year. The swarming season is on.

JOHN STEWART.

From the clipping sent we condense the following:

Bees are dying every day this spring, while there are flowers in abundance. In some places the bee-men have to feed their bees daily on sugar to keep them alive, while in the hills and orange groves there are millions of blossoms.

This strange condition is laid to the cool, cloudy weather which is a great hardship on the busy bee, and which has prevented the development of the honey-producing element in the flowers. A continuation of such weather as has prevailed the past week will cut down the honey-supply materially. A week of sunshine will be the means of saving many valuable colonies of bees throughout Southern California.

Such is the summary of conditions as indicated by reports received by H. J. Mercer, Secretary of the California National Honey-Producers' Association. Mr. Mercer believes that unless there is a decided change in weather conditions within a few days, the crop will fall far behind that of last year, and that also was a great disappointment to bee-keepers.

Reports come from various sections that the bees start out to gather honey, load themselves down, and then are overcome by the cool and damp weather, and fall along the way to die of exhaustion. This is a condition reported from various bee-ranches in widely scattered localities.

Then the bees will not go out on the cold and foggy mornings, and, as a result, there is a consumption of the honey already stored in the hives. In some cases colonies have eaten themselves out of honey-supply, and actually have starved before their condition was discovered, and all this has occurred within a very few days.

Yesterday a shipment of 1000 pounds of white granulated sugar was sent up to Charles Ebert, in the canyon above Azusa, to feed his bees that are on the point of starving. Other bee-keepers have been feeding for the past 2

weeks—the very period when the bees ought to be laying in large amounts of honey.

Such reports come from La Canada, Providencia and Chatsworth. Emerson brothers, near Fullerton, who have 1200 colonies of bees, report that the bees are dying of exhaustion these cool days, and that they have consumed their supplies in many cases.

Similar reports come from T. O. Andrews, at Corona, who has 400 colonies, and from J. W. George, at Perris, Riverside county, who has gone into bee-keeping on an extensive scale. A like discouraging report comes from M. H. Mendleson, of Piru, who has begun to feed his bees to keep them from starving on a ranch which has been famous for its fruit-trees, and which have been simply aglow with blossoms.

The bee-ranch of L. E. Mercer, in the Castaic Canyon, is said to be the largest in the United States. He has close to 2000 colonies in this canyon, and has them scattered about in 6 locations. The season started in with brightest prospects for a record-breaking year for honey-producers, says this veteran bee-man. There was a wealth of blossoms, brought about by the extensive wet season, but this has not availed. A few weeks ago Mr. Mercer estimated that he would have fully 100 tons of honey from this season's work. Now he has scaled this down to a crop of 50 tons, and unless there is a change very soon in weather conditions, he thinks this will still be reduced.

The bee and honey business has reached an extent in Southern California that is little realized. The report of last year made by the Los Angeles County Statistician, gives the number of colonies of bees as 40,000, and their value as \$200,000; and the amount of bees-wax marketed as 9000 pounds, with a value of \$2050.

E. A. Fischer, Inspector of Apiaries for Los Angeles county, said yesterday that he is convinced there has been an increase of fully 10,000 colonies of bees in this county since the report was made. He has been waging a constant war against the spread of "foul brood," and believes that with the co-operation of the honey-producers the pest will be kept down to the minimum.

The first honey to come into the Los Angeles markets is from the orange-growing sections, stretching from Pasadena to San Bernardino and Redlands. This orange-blossom honey is generally of fine quality, but it has the objection of granulating quickly. The first arrivals of this honey are now due; but honey merchants in Los Angeles said yesterday that there is no prospect of shipments here for at least 3 weeks.

A factor showing the extent of the honey industry is the record of sales by one firm in this city which makes a business of supplying bee-keepers. This shows that there were sent out from the place last year more than 50,000 5-gallon cans for the storage of honey.

Anticipating a shortage of crop, H. J. Mercer has been storing honey for the past 2 years, and since last July he has sold to Los Angeles merchants alone honey amounting to \$35,000. This surplus honey is now well cleaned out, and with the partial failure of the present season's crop, there is certain to be a soaring of honey-prices that will make the sweet substance taste like money.

The National pure-food law, which has affected the marketing of so many products, has also had its effect on the honey-market, and has put the producers of pure ex-

tracted honey in their proper position, where they do not have to compete with adulterated honeys.

The merchants now require wholesalers of extracted honey to give them a written guarantee of its purity, as a matter of protection to the merchants, and this is gladly done by the concerns which have heretofore had to compete with the "dope."

Surely, the foregoing is not a very encouraging report for the bee-keepers of Southern California. It is hoped, however, that for their sakes, if not for the sakes of the bee-keepers of the rest of the country, honey conditions may yet take a turn for the better, so that there may be at least a fair crop of honey harvested by the bee keepers in the region mentioned by the clipping from the Los Angeles Times.

But evidently honey is to be honey this year, as a good share of the North has had a cold, backward spring, which, in all probability, will prevent the bees from being ready for the honey crop even if it is in the flowers later on.

### Ode (Owed) to the Weather Man

Weather is cold. Bees don't get out more than 2 days in the week. Yesterday it snowed.

I don't know how the others feel  
About this horrid weather;  
I wonder if 'twould help to squeal  
If we all squealed together.

The pussy willows blossomed fine,  
The clover started growing;  
But soon the sun forgot to shine—  
'Most all the time it's snowing.

The weather man who did these things—  
Who brought this useless freeze—  
Just ought to bee-filled up with stings—  
I'd like to furnish bees.

Bellevue, Mich., May 1. C. H. BENSON.

**Rev. Robt. B. McCain, of Oswego, Ill.,** called on us in our new quarters at 118 W. Jackson Blvd. last Friday. He reports cold weather in his locality, but expects a good honey season just the same. We had quite a snow-storm in Chicago the day he was here—May 3.

**Getting New Subscribers** for the Bee Journal is something that almost any reader can do if he makes a sincere attempt. No one knows better than does he its value to every would-be successful bee-keeper. And we offer valuable premiums, to those of our present readers whose subscriptions are paid in advance, for the work of going out and getting new subscriptions. Your neighbor bee-keepers perhaps have never heard of the American Bee Journal, although it is now in its 47th year. Why not try to get them to subscribe? You may be surprised how readily they will do so upon your invitation.

**The San Antonio Convention Picture** is a good one. It shows over 100 of those in attendance. We are mailing them, unmounted, for only 60 cents. They can be mounted by a local photographer for only 10 or 15 cents more. We will mail one of these pictures with the American Bee Journal one year—both for only \$1.40. Send all orders to the Bee Journal office.

## Facts About Swarming of Bees

BY ADRIAN GETAZ

Among the different kinds of work done by the European Societies of Agriculturists is now and then a study of some subject connected with bee-keeping. A series of questions or experiments is submitted to the members with the request to observe or experiment during the ensuing summer, and report. It is not obligatory on the members, so only those who can do take part. Sometimes when the experiments requested involve a notable expense of time or money, prizes are offered to be given to those who have done the best work. Among the apiarists are found a good many who have for a number of years studied some subjects, or kept note, of whatever happened in their apiaries. It is through some arrangements of that sort that the following information on the swarming question was obtained, principally through the efforts of Mr. Thibault, Secretary of the Societe du Bassin de la Meuse.

### TIME OF SWARMING.

In the country covered by the observations (northeastern part of France), the swarming commences on an average date on May 28 and ends on June 20. The extreme dates have been from May 17 to June 13 for the beginning, and from June 6 to July 4 for the ending.

Duration: An average of 24 days. It is understood that these dates refer to the northeast part of France. Other localities differ for different seasons. For instance, in Belgium Mr. Mercier gives for the swarming period from May 20 to June 30.

A full study of the swarming period observed during 20 years in an apiary of about 80 colonies is given. I will not reproduce it here in full. Out of the 20 years 3 were quite early, 10 near the average, 5 late, and 2 very irregular so far as the dates and duration of the swarming period are concerned.

Taking all the information obtained in consideration, the average number of first swarms is put down in the following proportions: One-fifth in May;  $\frac{1}{2}$  from June 1 to June 10;  $\frac{1}{4}$  from June 10 to June 20; 1-10 after that date. Very few swarms come out before May 25, and very few after June 20, so the apiarist could go to the expense of close watching only between these dates.

### TIME OF THE DAY.

The limits observed are 8:15 a.m. and 4 p.m. in the extreme cases. On

the total number observed, 5 percent issued before 10 a.m., 22 percent between 10 and 12, 56 percent between 12 and 2 p.m., 15 percent between 2 and 3 p.m., and 2 percent after 3 p.m.

### THE WEATHER.

Needless to say that the bees will not swarm when it is raining. To what extent they may do it in cloudy but not actually rainy weather has unfortunately not been noted. The wind, when the weather is otherwise favorable, seems to have considerable influence. Evidently no swarm will issue on a stormy day. But in fair weather 82 percent of the swarms issued during no wind, or a light wind, and only 18 percent with a wind of medium strength or more.

As could be expected, the temperature has a paramount influence. Eighty-nine percent of the swarms issued when the temperature was above 68 degrees Fahr., in the shade, and 11 percent when below. One swarm issued at a temperature of 59 degrees, and the weather "nearly raining." That was the lowest observation.

It was also ascertained that by far the largest number of swarms issue when the barometer is high, but as the state of the weather as to being more or less cloudy or more or less warm was not observed in connection with it, the fact has but little value.

### POSITION OF THE HIVES.

Eighty-six percent of the swarms issue when the sun shines on the entrance. It seems by that that the number of the swarms ought to be materially decreased when the hives are in a shaded place. It is also stated that a very large proportion of the swarms issue from hives turned otherwise. Unfortunately the number of hives turned either way was not recorded. As most of them are turned toward the south, or nearly so, most of the swarms come from such hives in at least the same proportion. It would have been interesting to ascertain this point fully and find out whether the direction has any influence at all, and if it has whether it is due to a higher temperature, or to the actual shining of the sun on the entrance, or perhaps something else.

### NATURE OF THE BEES.

The disposition to swarm varies excessively with the different races, and in the same race with the different varieties, and even the different individual colonies. Nothing definite could be deducted from the reports. It is stated that in France fully 99 percent of the colonies are the common black bees.

In one of the apiaries reported (probably that of Mr. Thibault himself) everything is recorded in detail since 1883. A study of the swarming in that apiary brings out some interesting facts concerning the vitality of the different strains or varieties of bees. Suppose an apiary of 100 colonies to start with. These colonies and the swarms produced by them will swarm more or less every year. After 20 years, out of the 100 colonies 42 will have disappeared entirely, not only themselves, but the swarms that descended from them in succession. Eighteen will be represented by one colony each; 16 by 2 colonies each; 8 by 3 colonies each; 4 by 4 colonies each; 4 by from 5 to 9 colonies each; 4 by from 10 to 19; 2 by from 20 to 29; 2 by 30 or more. It is also shown by the tables given that the colonies having left the largest number of descendants are those which swarmed neither very early nor very late.

### AGE OF THE QUEEN.

Out of 301 swarms 130 were from colonies having swarmed the year before, and therefore had queens one year old; 61 from colonies having swarmed 2 years before; 44 from colonies having swarmed 3 years before; 66 from colonies having swarmed from 4 to 12 years before. These can not be taken into account. Evidently nearly all their queens had been superseded and therefore their age can not be ascertained. Some may have swarmed unobserved.

It would seem by these figures that the age of the queens has but little to do with the swarming question. This was quite a puzzle to me. I would have thought that the colonies with queens but one year old would have swarmed considerably less than those with older queens. At least that is certainly the case in my apiaries.

After considerable reflection on the subject I came to the conclusion that the discrepancy is due not exactly to the "locality," but to the hives used. In Europe most of the hives are yet the old-fashioned straw hives. The straw is all right enough, but the hives are usually entirely too small. Now when a colony is decidedly too crowded, and the space is lacking for brood and surplus, the colony will swarm if the conditions of weather and honey-flow are favorable, no matter how old or young the queen may be. And, after all, I do not know but that under such circumstances the colonies with young queens might swarm the most, since the young queens, being the best layers, would get the colonies crowded the soonest or the most.

### THE DRONES.

Fifty-four percent of the swarms observed came from colonies having a great many drones, and 46 percent from colonies having but few. Mr. Thibault adds, however, that while it does not make much difference whether there are many or few drones, no colony will swarm when there are none at all. He also says that a queen which is not defective in some way or other will not lay any drone-eggs during the year she has been reared; that means a queen less than a full year old.

# American Bee Journal

He advocates as prevention of swarming requeening just before the main honey-flow; that is, as far as that part of France is concerned.

## NEARNESS TO WATER.

Owing to the fact that the bees need a considerable quantity of water to rear their brood in the spring, it was supposed that the proximity to a suitable place to get water would increase the amount of brood reared, and the swarming would occur sooner. The reports fail to show any noticeable difference.

## SIZE OF THE HIVE.

On 722 hives observed during 7 years, it has been found that out of 100 colonies lodged in straw hives of a capacity of nearly a cubic foot, 60 to 70 will swarm. Out of 100 lodged in one-story movable-comb hives of a capacity of about 2 cubic feet, 25 to 30 will swarm. And, finally, out of 100 lodged in Dandant-Blatt hives, with enough supers to accommodate them fully, only 5 will swarm. Mr. Guillemin reported that in his own apiary with such hives, many years have passed without any swarm at all.

## AMOUNT OF HONEY.

In regard to the quantity of honey in the hive, 45 percent of the swarms observed came out of colonies having less than 20 pounds of honey; 41 percent from those having between 20 and 40 pounds. And what puzzles me most, only 14 percent from colonies having 40 to 60 pounds of honey. I would have thought that the colonies having the most honey would be those crowding the queen the worst, and therefore the most liable to swarm. The size of the hives should have been noted, but was not, so that no certain conclusion can be deducted.

## EMPTY COMBS.

If the quantity of honey present in the hive has no influence in itself, that is, no direct influence on the swarming, it may have a great influence in restricting the amount of empty comb. Eighty swarms out of 100 issued from colonies where the amount of empty comb was insufficient for both the queen and the workers. Hence, the advantage of large hives.

Concerning the straw hives, Mr. Thibault thinks the best mode of management is that which consists in adding just before the honey-flow another body under the old one. That is practically the equivalent of the Simmins method.

If I were working for extracted honey, I would certainly try putting the supers under rather than above the brood-nest. When working for comb honey it is different, because the sections would be badly travel-stained.

## HONEY-FLOW.

The first swarm of an apiary usually issues 6 or 7 days after the main flow has begun. The dates may vary some years between 4 and 13 days, not counting colonies swarming on account of some exceptional conditions. It follows that the preparations for swarming are begun before the main flow occurs; at least in that part of

France. It might not be so everywhere else, by any means.

In discussing this subject, Mr. Thibault recalls the well-known fact (in Europe) that there are but few swarms when the honey-flow is heavy and of long duration.

Knoxville, Tenn.

## Why and How to Clip Queens' Wings

BY G. M. DOOLITTLE

In a recent article I told the readers of the American Bee Journal how to find queens; giving as plain directions as possible, so that even a novice could find one. Perhaps some of the readers wondered at this, thinking that it would not be necessary to find one queen out of 20 during the season, but, according to my views, all queens should be seen at least once a year for the purpose of clipping their wings.

This clipping of queens' wings has been under discussion for many years, and while the majority of practical apiarists agree, that, to reap the best results the wings of all laying queens should be clipped, a few oppose it, claiming that swarming is conducted with more labor, and also that such a practise will tend toward the weakening of the wing-power of our bees in years to come. Without stopping to discuss these matters further just now, except to say that I believe both points raised are fallacious, I will tell the readers why I clip the wings of my queens.

In the first place, a queen with her wings all clipped short is more readily found when looked for than the one having her wings, and as in our manipulations with bees, it is often very necessary to see the queen so as to keep her when and where we desire, this finding of a queen is quite an important item. And as the average bee-keeper can find a "fully" clipped queen in less than half the time it takes to find an unclipped queen, this saving in time is often quite an important matter.

Second, in the swarming season we have complete control of the bees, so that we can compel them to do just about what we wish them to do. The first idea of clipping queens' wings was to keep the swarm from flying off to the woods, as all know that as soon as a swarm misses its queen it will come back to the old or parent hive again; but valuable as this idea is, still there are other points which I consider of far more importance than the roving of now and then a swarm which might result during the season from the apiarist not seeing them in time for their hiving, or the occasional swarm that might go off without even alighting.

My home apiary is located near a piece of woodland with tall trees near by, and by having the wings of all queens clipped I do not worry about such swarms as may cluster 40 or 50 feet up from the ground in these trees, for as soon as the bees notice their loss of queen, they will uncluster and return to the old stand hunting for their queen; so by having the queens

clipped I am complete master of this situation; never having to climb tall trees (where none but prime swarms are allowed to issue), and never having to cut off limbs of lower trees to secure the swarm, as is done many times to the mutilating of valuable trees.

Then in hiving such swarms as have their queens clipped, all that is necessary is to set the new hive in the place of the parent hive till the bees return and run in with their queen, which you will let loose at the proper time, having picked her up and caged her as soon as the swarm was on the wing. As soon as the bees are in the new hive, having hived themselves, as it were, the hive is picked up and set where we wish it to stand, and the old one put back where it was before. Or we can leave the new hive with the swarm on the old stand, and carry the old hive to a new stand, just in accord with our practise of working an apiary. Then you are sure in having the queen go into the hive just where you wish her, as you have her in the cage at your command, while if she were with the swarm she might run under the hive, or take wing and go back on the limb where the bees clustered, taking them with her, etc.; in fact, doing unthought-of things apparently just to perplex and annoy the apiarist.

Again, in an apiary containing from 10 to 100 colonies, it frequently happens that two or more swarms will come out near the same time and cluster together, when we have a perfect nuisance where the queens are enabled to fly with the bees; but where their wings are clipped these bees can be separated so as to have only one swarm in a hive as easily as any stock mixed together could be. And, lastly, if for any reason we are not ready to hive the swarm when it comes out, and therefore wish to hold the swarm on a limb or pole while we make a hive or something of the kind, we can keep them as long as we please by simply hanging the caged queen with the cluster. If they try to go off through our being slow in our part of the matter, they will come back to the limb or pole where the queen is as soon as they miss her, and stay there instead of going back to their old home, as I supposed they would till I found out differently. I have thus held swarms for nearly 2 days in trying to see what could be done.

But as this is an article written so that the novice can "catch on," I think I hear some one asking "how the clipping is done."

There are various ways, and a few devices invented for holding the queen while she is being clipped, but with me I use only two plans, and have no use for anything further. The first is the one used at all times (except where I wish to do some special clipping to make sure of the identity of a certain queen which I have reason to believe will prove very valuable), the clipping in this case being done with the jack-knife, which is always with any apiarist, for a man is "not at home" unless he carries a knife in his pocket.

Having found the queen, catch her by the wings, using the thumb and forefinger of the left hand. Now place

the sharpened blade of the knife on the wings of the queen, when both hands are lowered down within an inch or two of the tops of the frames in the hive, when the knife is lightly drawn, the wings severed, and the queen runs unharmed below. You need not be afraid of cutting the fingers, for if you stop drawing the knife as soon as the queen drops, you can not do so.

If you think you can not catch the queen "left handed," then use the right hand in catching her. Next hold her so her feet can touch the forefinger of the left hand, to which she will immediately cling. Now shut the thumb down carefully over her feet, being sure that you get all three legs on one side so she will not twist around and break a leg, as she would surely do if only one foot were held fast. Having her held thus securely, carefully lower her with her back to the top of the hive till her wings spread out on top of the same, when you can cut them off by bearing down with the knife on top of the edge of the hive.

If it is the first queen you have ever clipped, you may be a little nervous and shaky, but if you go slow and

think of nothing but the work you wish to perform, you will soon feel as much at home clipping queens as you are in removing the surplus honey from the hive.

Now for the other plan which is used to mark certain queens which you wish to keep track of. Have at the apiary a pair of small scissors, and when you wish to cut only one wing, or any definite part of the wing or wings, use these scissors instead of the knife. When doing this you will catch and hold the queen by the legs in your left hand, as told how to do above, when you will deliberately, with the points of the scissors, cut just as much, and just as little, and just where on the wings or wing as you have decided that should be done that the queen may be marked so as to distinguish the points which you wish to register in your book in which you keep the pedigree of all your best queens.

I would as soon think of going back to the old-fogy ways of our fathers, when keeping bees, as to work an apiary on the swarming plan without having the wings of all queens clipped.

Borodino, N. Y.

long-distance gathering does not appeal to me in a controversial manner, as I believe it is one that every intelligent bee-keeper can solve for himself, and, personally, I only wish I could truthfully (and thankfully) claim to have a strain or race of bees that would reach my pasturage 3 miles away, or even 10, for that matter.

### Clipping Queens' Wings

Glad to note (page 262) that so well-known an apiarist as R. C. Aikin clips his queens while they are on the combs, without touching them with his fingers. Now, if any one comes along and pokes fun at me for advocating such a method, I shall just turn him over to the mercy of Mr. Aikin, and look on and smile.

The scissors I use are by actual measurement  $4\frac{1}{2}$  inches long, and have a curved point. Most of the small scissors are manufactured for ladies' use, and, as a consequence, the handles are too small for the clumsy fingers of one of the masculine gender. The pair I am using are, as previously stated, made specially for surgeons' use, so this difficulty is overcome, and at the same time the scissors are small and light.

I might add for the benefit of some who may try the plan, and at first pronounce it a failure, that the first time I attempted to clip in this way the method was pronounced impracticable, but after exercising a little patience, my mind was changed, and to-day I can clip the queens about as fast as you have a mind to pass them along.

### Dysentery Among Bees

While at the Victoria County bee keepers' convention, a few weeks ago the subject of dysentery was under discussion. As previously stated, this trouble has been unusually prevalent during the past winter and present spring here in Ontario, and a number of the bee-keepers at the meeting referred to were telling of their losses from this cause.

Mr. J. T. Storer, of Lindsay, who is a very successful bee-winterer, stated that for more than 10 years past he had not had a single case of dysentery among his bees, and he attributed it all to the fact that he always made it a point to have every colony go into winter quarters *very heavy* with good stores. And, again, no matter how heavy a colony might be with honey in the fall, he wanted each colony to have at least 10 pounds of syrup made of best granulated sugar. Mr. Storer uses a fairly large hive, viz.: 8-frame Langstroth length, but 3 inches deeper, and he sees that each colony has at least 40 pounds of stores before putting it into the cellar. Although his cellars are about perfect, and his bees winter in ideal condition, consequently using very little stores, yet Mr. Storer finds no difficulty in turning this reserve supply of honey into his bees before the clover flow comes on.

Mr. Storer's success certainly speaks well for his methods, and while some

### The Prospects in Ontario

Reports as to how bees have wintered here in Ontario are exceedingly varied. Dysentery has been quite prevalent, and, on the whole, I am inclined to think that the loss will be above the average.

April, up to date of writing (17th), has been unusually cold; in fact, in our locality there has not been a single day that bees could fly freely. Cold north winds during the day, and freezing nights, have been the rule. As a result, *alsike*—which is our chief source of surplus here—is quite badly heaved, especially on low grounds. Taking everything into consideration, the prospects for a good crop of honey are, with us, none too flattering. However, last year prospects were good, yet the crop was almost *nil*; so with the hopefulness so characteristic of bee-keepers, we are trusting that conditions will be reversed this season.

### Distance Bees Gather Nectar

I hardly know what to think of the claims of Doolittle, Chambers, and some others, relative to bees working freely at from 3 to 5 miles from the apiary. Mr. Chambers seems to think (page 279) that the race of bees has

much to do with this long-distance working, for he says: "I have learned to despise a race of bees that are not good for a crop of honey if it is to be had only 3 miles from them. Doolittle and others pin their faith to the Italians, and claim that it is common for their bees to work at distances named."

Now I happen to be an admirer of the same race that Mr. Chambers is so enthusiastic over, viz.: the Carniolans—and while I have them as well as Italians in my apiaries, yet I am sorry to confess that, so far, pasturage 3 miles or over from the bees might just as well, so far as practical results are concerned, be 20 miles away. While bees at my out-yard were working freely on buckwheat, at the home yard hardly a bee was moving, although the nearest fields of buckwheat were little over 3 miles away.

Have an idea that there is a good deal of truth in Mr. Chambers' guess, that the "location of the apiary with regard to the surrounding country has something to do with it." No doubt if there had been some fields of buckwheat, say half way between the home yard and the buckwheat 3 miles away, the bees would have found the latter also, as I have noticed that they seem to go further when they have something to lead them on, as it were, than is the case where there is a lot of blank territory to fly over. This question of

may object to giving such a large amount of stores in the fall, personally I feel that it is wise to err on the safe side, and each year I am more and more inclined to think that *abundance* of good stores is one of the first requisites of good wintering, and also just as essential towards the rapid building of our colonies in the following spring—especially during a very backward season like we are just passing through, it is a source of comfort to know that

every colony has 20 pounds or more of honey in the hive, and that we need not worry for fear some colonies will starve.

Aside from the matter of worry, there is no question in my mind but that the feeding operations—opening up the hives during inclement weather—and other work necessitated by bees that are light in stores in early spring is anything but conducive to the welfare of the colonies.

one. Then the handling of the frames takes more time.

With the shallow extracting-super on the hive nearly full, a second one is given if needed before the flow for comb honey begins. Our object should be to have one super well filled on every colony by this time that is to store in the comb-honey supers. Just before the flow begins these supers are given *between* the full extracted honey super and the brood-chamber. Starters only are necessary in these, as the bees will be secreting, and have an excess of wax from the work done in the extracting-supers, and work will begin *at once*, so that by the time the main flow begins, the combs will be partly drawn out ready for the honey. This is an ideal condition to get fine comb honey, and built out excellently. The brood-nest will not be clogged with honey, but brood instead, and the colony will come through stronger with a lot of young bees for any subsequent honey gathering, either surplus or for winter stores.

The advantages of shallow supers are well known to many bee-keepers, even to some of the opposers of the divisible hive; but just here is where the divisible hive makes the shallow supers more valuable, in that they can be interchanged. For extracting supers I prefer them. Their first cost may be slightly more, but "I soon get that out of them." Lighter weight foundation can be used in full sheets, and without wiring. If starters are used there is not so much drone-comb. When filled the honey is removed by *cases*, in a wholesale way, in a short time. No use in trying to get around that. In uncapping I know I can uncap 2 of these faster than a deep comb, and 2 of my shallow combs hold more honey than one of the Langstroth size.

For bulk comb honey they are the best (and most extensively used). Weaker colonies will often fill one of these when they would not even have begun in a deep one, and this holds for all colonies during a short flow or in a bad year. Besides, deep frames can not be filled with full sheets of foundation light enough for comb honey, for it will be "gobby." Even shallow frames are better with starters only, especially when used under full supers of extracted honey, as already mentioned. This also answers our correspondent's question. Such supers of comb honey are also taken off in a wholesale way just like the extracted honey.

Who would think of producing section comb honey in anything but shallow supers of one tier of sections and the tiering-up system? Hence, I see no reason why the same should not be applied to extracted honey, for it is used in bulk-comb-honey production. My advice is to try a few such hives first and compare them with the others.

**Our Wood Binder** (or Holder) is made to take all the copies of the American Bee Journal for a year. It is sent by mail for 20 cents. Full directions accompany. The Bee Journals can be inserted as soon as they are received, and thus preserved for future reference. Or we will send it with the American Bee Journal a year—both for \$1.10. Address office of the American Bee Journal.

Conducted by LOUIS H. SCHOLL, New Braunsfels, Tex.

### The Langstroth or Divisible Brood-Chamber Hive—Which?

A correspondent from Germany has written me in regard to the kind of American style of hive I would advise him to adopt especially for out-apiaries, having read some of my articles on the divisible brood-chamber hives I have been using for several years. He has studied American apiculture thoroughly through several of the books and papers on bees and bee-keeping of this country, and is well acquainted with our hives, appliances, and methods of management. However, it has been a hard matter for him to decide which hive to adopt, since there is such a difference of opinion expressed in these books and papers. He had almost decided to adopt the regular standard Langstroth 10-frame hive when articles like those of Alexander were read; while, again, such articles as those by Stachelhausen, Hand, Chambers, and those by myself on the divisible brood-chamber hives and their advantages, changed his views and left him without knowing what to do.

He gives a description of the character and the conditions of the surroundings under which the honey crop is obtained, and the time of blooming of the sources from which the honey-flow comes, viz.: White clover blooming from June 15 to July 15; basswood latter part of June to end of July, and soon followed by the main source, the heather, lasting until Sept. 15. The bees are moved to the heather fields, which are from 3 to 10 kilos distant from where our correspondent resides.

The honey from white clover and basswood is extracted, and the heather honey being too thick to be extracted, is mostly sold in the comb, the combs being cut from the "skeps" or frames. Sections are unknown.

He further questions me in regard to using full sheets of comb foundation in shallow frames for bulk comb honey—whether comb honey built

from such is not found "gobby" when eaten. Examinations of the apiaries are made every 6 or 8 days, no person being with the bees between these visits. I might add that my correspondent favors a hive like the one described by me, but wishes my opinion.

Now for *my* advice: Since I have had such excellent success with the divisible brood-chamber hive, I would certainly adopt it where the conditions are like those given, but whether this kind of hive is *best* for the other fellow is better found out by first giving a few a *thorough* trial. That is the way I began, with no great visions before me to begin with, but the actual practise and the success with them *gradually* induced me to increase the number in use.

Since *both* comb and extracted honey are the products of my dozen apiaries—much like that mentioned by the enquirer—the circumstances in both cases are about the same. Here extracted honey is first obtained in this wise: As soon as the colonies begin to get crowded room is given, not on top but *between* the upper section partly full of honey and lower one of the brood-chamber. When this is done the season is already well advanced, and, if the swarming season, it prevents swarming to a surety. The middle case is soon filled with brood, and the scattering honey over that used up by the bees is carried above into the upper case, now an extracting super. With a deeper hive, or the Langstroth, room could not be given in any such way except to set a shallow super on top. But unless the crowded condition of the *brood-nest* is broken up and laying-room provided, swarming will go on just the same; or the time-taking, tedious handling of frames must be resorted to.

If full-depth supers are used, combs can be lifted up and exchanged for empty ones, but I prefer the shallow supers; besides, the large supers would be too large for our purpose unless the extracted honey-flow was a very good

The "Old Reliable" as seen through New and Unreliable Glasses, By E. E. HASTY, Sta. B. Rural, Toledo, Ohio.

QUEENING A LAYING-WORKER COLONY

It is so seldom worth while to save a colony with laying workers and try to make it accept a queen, that we might well afford to ignore the whole subject so far as direct profit is concerned. But if one brother succeeds and the rest of us mostly fail, we ought to be stirred up a little to find out the reason why. Can't afford to let our knowledge-box go empty. H. Piper, who evidently knows what he is talking about, has a method which he says succeeds every time. Queer that such simple variations should make such a difference. First, the queen must be an old one. Second, she must be as hungry as she can well be without getting weak. Third, put her on comb where she can't find any open honey to help herself to—and not in any crowd of bees. Watch and boss matters until you see her accept honey from the bees, and be sufficiently fed. Then quietly close up—they won't kill her after that. Well, what is there in this, I wonder? Puts her under slight bonds not to misbehave herself—that's good so far. Stomach well filled with food just regurgitated by citizens, makes her a little more at one with the other citizens than a meal drawn out of a cell could do. (Breathing exactly the same kind of onions that the rest breathe!) And why an old queen? Is it that young queens have a great deal more of the *ineradicable individualities* of odor? Possibly have also learned in their lives to be more *tolerant* both of manners and smells. Still, I would not have predicted success for the plan. If it's all right, something profitable to ordinary introduction ought to come out of it. He properly reminds us that the colony must have some young bees in a few days, else they can't rear brood much.

It's a sharp, and probably good, idea to use on bees united from above, to get them down at the rear rather than down over the entrance. The savage bees are down at the front. Help on this improvement by turning them end for end—so they will *incline* to go down at what seems to them to be the front, but is now really the rear. Page 319.

THAT TALLEST BEE-KEEPER.

So bee-keeper Rehorst kind o' upset the State of Wisconsin with his challenge for a taller man. Also upsets the rule that giants die young, as he is 63. Upsets my notions of how much stature goes down with age. I thought

it was but a fraction of an inch; and he has decreased 1½ inches. Only 6 feet 8 inches now. Of course, he upsets the old proverb, "Like master, like man." If his bees were like himself, they would be worth going to see. Page 319.

SCALE RECORDS.

A. E. Patton's report of his scale hive is interesting. And reporting gains by weeks instead of by days gives something of a different turn to the thing in reporting a quite moderate flow. Scale records, we have never had a surplus of, I believe. Page 319.

NEW MOUSE FOR MOTH-LARVAE—THOSE MOUSE EXPERIMENTS.

No, Mr. Pryal, we don't need to breed a new mouse to exterminate moth-larvæ. The one we now have is tip-

top, as I long ago found out. And, sometimes, as in your case, he does very little damage except in digging out the small, silk-bound nests that get formed. But I fear it won't do to assume in advance of experiment that he will do so good a job except when very hungry—which same is his normal condition when he gets into a comb closet.

I shall have to ask the forbearance of the brethren for not, even yet, repeating and verifying the important mouse experiment I gave a while ago—and for not getting to the new ones which I had in view. Be merciful to the everlasting worthlessness and do-nothingness of the invalid. But here is one experiment fresh as yesterday, that has its lesson as an experiment that went wrong: At 11 a.m. I put in the cage of two captive mice a frame taken from a starving colony. It had fresh-capped brood, and some bees scarcely dead crawled into the cells. What I expected was that the mice would eat quite a meal of the brood. What I *hoped* was that they would spend some of their leisure time pulling the bees out. Didn't do either one. What they did do was to gnaw the comb quite a bit in about five different places. Why was this thus? I had taken the comb out 6 hours after it was put in. Did they enjoy the taste of the comb as they chewed it? Or was it the simple joy of having something available to nibble? Or was it a little of both? *Hoc docet* Our theories and expectations and hopes and notions oftentimes go all to pieces the minute they run up against some simple experiment. Page 333.

Send Questions either to the office of the American Bee Journal, or to Dr. C. C. MILLER, Marengo, Ill.

Dr. Miller does not answer Questions by mail.

Transferring Bees, Etc.

1. Some time ago I discovered bees in a tree after cutting it. I cut off as close on each side of their entrance as I thought I could without cutting through the honey, and brought them to the house. Can I transfer them to a hive? If so, how?
2. Must I have foundation-starters for the brood-frames?
3. Are the bees likely to swarm if left in the log?
4. The bees are dark with 3 yellow bands. What race are they?

ANSWER.—The bees are likely to swarm unless they have too much empty room in the log. If so, better saw off the empty part. Then leave them until they swarm, hive the swarm in a movable-frame hive, set it in place of the log-hive, and set the log-hive close beside it. A week later set the log-hive on top the other—of course, no communication between the two. Three weeks after the swarming you can set the log-hive in a new place to

build up for the next year. Or, you can cut open the log-hive and transfer into a frame-hive. If you care for honey and not increase, cut open the log-hive 3 weeks after swarming, brush all the bees into the swarm and melt up the combs. In any case the swarm is the one to count on for surplus.

If you give empty frames without starters the bees may build combs crosswise, and your combs will not be movable. Small starters will give too much drone-comb; full sheets will give all worker-comb.

If all the bees have 3 yellow bands they are likely Italians. If some have less than 3 bands, they are hybrids.

Perhaps Affected Only by Bad Weather

What is the matter with my bees? I had 36 colonies to start in the winter and lost 4. The 32 did fluently in the warm spell in March, and I thought I never had had bees doing

better; but April 1st they began to dwindle, and it looks now as if I were going to lose all of them. They look all right in color, but they can not fly. The ground is strewn with them crawling around, and they can not get on the wing. I opened the strongest colony to-day, thinking it was queenless, but found the queen and some brood, but no larvae, and the queen had begun laying eggs, but not many. The strong colonies have lots of dead bees in front of them, and a great many not dead yet. They act as if they were poisoned, but it continues so long I fear it is bee-cholera. I have lost 13 colonies, and will lose several more if the weather stays bad and they keep dying as they have been doing. Their abdomens are natural in size and the color is natural. I do not see any young larvae in front of the hives.

My bees were short of stores last fall and I fed them  $1\frac{1}{2}$  barrels of granulated sugar, and so it can not be stores. INDIANA.

ANSWER.—The probability is that there is no trouble except the terrible weather. I don't remember a spring just like it in 45 years. A few days of summer in March made the bees start a lot of brood that they couldn't care for when it froze up again, and the nurses were in no condition to stand the confinement. To-day—2 days later than the date of your letter—it begins to look as if we might have spring again in place of winter, and we will hope that by the time this meets your eye in print your bees will be on the upgrade—greatly reduced, to be sure, but healthy, and hopefully building up again.

### Feeding Pollen Substitutes

Where can I get a kind of bee powder or food that is fed to bees to make them work better and produce more honey? My neighbor uses such, but refuses to tell me where he got it, or what it is. It looks something like wheat flour. Bees like it very much.

MINNESOTA.

ANSWER.—There is no sort of secret powder or food that can be given to bees to make them do more unless it be honey and pollen, and there's no secret about that. The thing probably meant in the present case is some kind of meal used in place of pollen. In the spring, when the weather is good, and yet there is no pollen to be had, set out a box or dish of any size containing some kind of meal, and the bees will take it in place of pollen. Grain of any kind ground will answer. The kind I have used more than any other is ground oats and corn—the kind that cattle and horses eat, that kind being conveniently on hand. Put a stone or block under one side of the box, and when the bees dig the meal down level, change the stone to the other side. They will dig out all the fine parts, and the coarser parts that are left can be fed to 4-legged stock. But just as soon as they can get the natural pollen they will desert the meal-boxes.

### Cold Weather for Bees—Rearing Queens—Brood Foundation—Hive-Covers

1. Is this steady cold weather liable to hurt the bees very much?

2. I also have a select breeding-queen which I bought last spring, and would like to rear all young queens from her. How would it do to build this colony up strong early, make them queenless, and after they had started queen cells divide them into about 7 nucleus colonies, and then when my other bees swarm unite each swarm with one of these nucleus colonies, letting the bees run through a queen-excluder and catch the queen and put her back into the old colony, move that to one side, cut out all queen-cells, and set the new swarm where the old one stood, and after 10 days remove the old colony to another stand? If this plan will not work, will you please give me a better one?

3. What kind of brood-foundation do you

use, and how many sheets does it run to the pound?

4. How would you have your hive-covers made if you were buying new hives? I want to increase to 12 or 14 colonies this year.

MICHIGAN.

ANSWERS.—1. Yes, in some places there has been a confinement of 3 weeks in April from continued cold weather, and there is danger that not a few colonies, reduced at this time of year to their smallest numbers, will have all stores within reach eaten, and will starve with plenty of honey in the hive.

2. If your bees don't get to swarming before you are ready for them, the plan will work. By adding combs of brood from other colonies you can have your best colony occupy 2 stories. Then you ought to be able to get your queens started in fruit-bloom, as this is supposed to be very abundant in your

region. I have worked the plan a little differently. Queens were clipped, and when the swarm issued the queen clipped was picked up, the nucleus set in place of the old colony, allowing the swarm to return and enter the nucleus of its own accord. This always succeeded, but some others have said that their queens were killed by the returning bees. If this should happen with you, you could cage the queen in a provisioned cage.

3. Medium brood, running 7 or 8 sheets to the pound.

4. "I'm not sure whether I'd get the kind I now have, or try rubberoid or something of the kind that might cost less. The ones I have are double, an upper and a lower part of  $\frac{3}{8}$  inch,  $\frac{3}{8}$  inches apart, so as to leave an air-space between, covered with tin or zinc. The only objection is that they cost about 30 cents each.

### Report of the 37th Annual Convention of the National Bee-Keepers' Association, held in San Antonio, Tex., Nov. 8-10, '06

(Continued from page 376)

#### CAUSE AND CURE OF BEE-PARALYSIS.

"What is the cause of bee-paralysis, and what is the best cure?"

Mr. Cogshall—I have been where it is. Mr. Poppleton has it in Florida. He can not cure it; the bees die about as fast as they increase, and just about keep even.

Mr. Piper—I asked that question. Of course I think I have a cure, but I would like to know the cause of it. I use sulphur as a remedy. Some recommend putting it on top of the frames. If you do you will kill the brood, though I found putting it on the bottom-board is effective, and it does not kill the brood. But of course I know there is another cure by introducing a new queen.

Pres. Dadant—I wish to say that this is an international disease; it is known in every country, although in cold countries it is less prevalent.

Mr. Anderson—I once thought that it was caused from certain flowers until I experimented with extracted honey from a few colonies. Those bees I carried through on the sugar syrup. In order to test the matter I extracted the honey late in the fall, from a few colonies, and allowed the bees to clean up the combs, and I used those combs to feed the other bees; that is, I fed the sugar syrup. I hived the bees and found them this way: Those bees that were carried through on the sugar syrup showed the disease equally as bad as the others.

Dr. Bohrer—With regard to paralysis, my opinion is that it affects the bees just as it does mankind, and I don't

know what to attribute it to. Persons are not exempt from paralysis at any age; the infant will have it, the 5 or 10 year old boy will have it, and the old man will have it, and very often when he least expects it. In fact, an old man in my settlement boasted of his good health and yet he was taken home from prayer-meeting stricken with paralysis and died the next day. Paralysis, I say, affects the nervous system, and if we can find some kind of honey that will injure the nervous system we may get at the cause. Dr. Phillips is conducting experiments along this line. I suggest that he try it. Sulphur, it is said, has cured it by being sprinkled among the bees; but I don't know whether it has.

Mr. Rankin—The last year and a half I have been in California, and most of my work has been on bee-diseases. I am not prepared to say that it is a nervous disease, but I am prepared to say that I don't know the cause, and don't know a remedy.

Wm. Atchley—I have had a little experience along that line. I don't believe that it is catching. I have tried to see if I could not affect other colonies with it, but failed. It is no doubt caused by the queen, and I have cured it by doing away with that queen.

L. Jones—I have had some experience with paralysis of the bees. Dr. Bohrer said he attributed it to the nervous system. I think it is due to the digestive system. I read an article advising the use of sulphur—just sprinkle it over the top of the frames. I had a man working for me, and we sprinkled the sulphur over the frames, and the next two or three days he said: "Look here, Jones, I believe you have killed every one of them." That was late in the fall, and the next spring the disease did not show up. Mr. Atchley says he does not believe it is catching. I don't

know whether it is catching or not, but I would have one hive affected here, and another over there, and they would die.

A Member—I would like to call your attention to the fact that Mr. Jones has said that he sprinkled sulphur, and that he killed the bees. Is it not possible you killed the bees that would have died any way?

Mr. Jones—I don't know. After that the dying ceased, and the next spring the disease did not show up on those colonies.

Mr. Anderson—I believe my bees had that disease in Utah as well as anywhere else. At one time I went into my apiary with a Southern bee-keeper of much experience, and we noticed in the front of a colony dead bees strung out for some distance. He said: "What is the matter?" We found 3 colonies in an apiary of over 100 in just that condition. He said: "I wish you would go right to town and see if anyone is spraying trees, and ascertain what it is with." I did so, and I did not find anyone spraying. I said, "I am going to get right on a horse and go to see Mr. R., who is our county inspector." He said, "It is simply a revolution going on, and when they get that conflict finished they will be all right." I went home and inspected my bees, and was convinced that there was a fight on. This may be a mistake, but I have never seen anything like it since.

Pres. Dadant—I think it will be necessary for me to say that this is out of the question. They are not fighting, the other bees are carrying them off. This has nothing to do with bee-paralysis, or "May Disease," as the Europeans call it, and I would like to hear more about it.

Mr. Stone—Is it not a settled fact that medical men can not cure paralysis? The reason I say this is that if it can not be cured, why try to cure the disease, but just prevent the spread of it? I know a case where there was a doctor who had a daughter that was paralyzed; he went to an osteopathist and said, "I have a daughter in the same condition that I lost one two years ago; you can cure her." And the osteopathist did cure here.

Pres. Dadant—Now, we are off the subject again. We called up the subject of bee-paralysis. The gentleman said it was not a nervous disease, but a disease of the digestive organs, although we call it bee-paralysis.

Mr. Parsons—I have had a little observation along the line of paralysis for more than 25 years, and a short while ago I was looking over my journal, and I found a great many instances where colonies had been affected with it. It appears in colony No. 4, and the record stated that it was not thought worth moving, and some 4 to 6 weeks later it cast a swarm; it had built up sufficiently to cast a swarm and that swarm I found was entirely clear of paralysis. I had such a case, and kept that colony built up, and I had no return of the disease during the next season. It was our custom for a number of years, that when a colony was affected with what we call paralysis, I would take the hives off and fumigate

them with sulphur, put the combs in a honey-house, distribute the brood, sometimes among the other colonies, and I would see no evil effects of it. But of late years, when I see a colony affected with it, I have to be more barbarous, so I simply cure it by fumigating the bees; but it is my opinion that it is not spread by an interchange of combs, and I know that it does get well, and remains well for one season. I have had in my yards, colonies affected with it for 3 years, and they never would build up so as to gather any surplus honey. I have tried a good many treatments—nearly everything that I read in the bee-papers—but if I have ever found anything that was good, I don't know of it.

Pres. Dadant—Mr. France has called our attention to the fact that bee-diseases would be discussed Monday, and I will now call for the next question.

Dr. Bohrer—I want to make myself better understood. It is definitely known that there is a kind of paralysis that comes from the digestive organs.

#### SMOKER-FUEL.

"Are dry rags and old bones good for smoker-fuel?"

Mr. Aten—I read in a paper that some suggest old bones and dry rags for fuel.

Mr. Holekamp—I suggested dry leaves.

#### MOTHS AND POLLENLESS COMBS.

"Will moth-worms destroy comb where there is no pollen?"

Mr. Hyde—I dropped that question in. I thought I would like to hear some of the bee-keepers talk on it. I can give my experience in a few words. Where there is no pollen there will be no moth-worm.

Dr. Phillips—I have seen it in comb foundation.

Mr. Victor—Combs with pollen are much worse than combs without pollen.

Wm. Atchley—I wish to differ from Mr. Hyde very much, as I have had them to eat up combs with no pollen in them, and have had them to destroy solid cakes of beeswax.

Mr. Hyde—In that case, was there not some comb near by, or did they degenerate?

Wm. Atchley—Why, I don't think there was any empty comb there.

Mr. Wurth—I have had the same experience as Mr. Atchley, in regard to destroying combs with no pollen in them; they will destroy them.

Mr. Stone—My experience has been like the one who asked the question. I have never known the moth to be in any of the extracting frames in my honey-house, and I have always attributed it to the fact that there was no pollen in the frames.

Mr. France—As a partial explanation of moth-worms working on wax, in many places in our State, it is the combs with apparently no pollen that are rendered into wax; and when that wax is settled, you would be surprised to see the amount of pollen in it. It is the same way with foundation. More or less pollen is in it, as in the wax. I seldom see them in new combs.

Mr. White—I want to give an experience I had last spring with the worms. During our convention in North Texas, we had a little discussion about the moth-worm. Some asked me to bring in a dry comb. As near as I could tell it was clean, smooth, nice comb, and after the convention was over I just set it back in the corner of the office, and it was left there for a few weeks; I did not move it, and I thought one day that I would put it away. The moth-worms had eaten it up, while, according to my judgment, there was no pollen in it; if any was there it was very little, and I thought then that the particles had fallen out on the floor. I had learned a lesson. I believe worms will get into combs where there is no pollen.

Pres. Dadant—I wish to correct an impression, which I consider is a mistake, given by Mr. France, that foundation contain a great deal of pollen.

Mr. France—You are mistaken: I did not say that.

Pres. Dadant—Did you not say that melted wax contained pollen?

Mr. France—I was speaking of old wax.

Mr. Jones—I have had a good deal of experience with combs and moth-worms. I have a honey-house that I put away my combs in, and I some way favor Mr. Hyde's idea. In putting away those combs I was very careful that no pollen whatever got in, but I can not say absolutely that it did not get in there. I have noticed that if there was a little brood they are just as bad to commence on it, and when I looked over my combs the moth-worm had commenced there.

#### PERFECT PACKAGES FOR SHIPPING HONEY.

"Is there a way to educate the bee-keepers to use perfect packages for shipping honey.

Mr. Muth—It was I who put that question in. The majority of bee-keepers ship their honey to market in second-hand molasses barrels, and second-hand tin cans, and it is only those perfect packages from the West that come through without loss. Imperfect packages make high rates on freight, and unpleasant business relations, and if they can get down to new packages—if honey is worth anything at all, it would be a good idea to educate them a little on this point. As it is now, most of the small shippers ship their honey in a very careless manner. The bee-papers could do a whole lot more on that subject, but they don't.

Mr. Hyde—I thought that we bee-keepers in Texas were doing pretty well along that line the last few years. In 1902 and 1903 we had a good deal of trouble in the packages for shipping—a great deal of loss in the transit—and all sized cans and packages that could be thought of; but we bee-keepers of Texas saw that we needed some packages of the proper size, and not too many of them, so at College Station in our meeting this year, we passed upon it that a certain sized package be used, and we also recommended a heavier case. We put this before the railroad companies, and they accepted our speci-

# American Bee Journal

fications. We thought that was settled in Texas. I don't know what other States are doing. We have the two 60-pounds, and ten 12-pounds; and then we have two more sizes—the ten 6-pounds, and the twenty 3-pounds.

Mr. York—I agree with Mr. Muth, that the bee-papers could do more along this line, but the dealers should write something about the proper shipping packages. I am reminded of a shipment that came from a dealer in Wisconsin lately, in second-hand glucose barrels. And the drayman made the remark that the dealer was shipping in glucose! I think that ought to be stopped.

Mr. Muth—I have had some experience in shipping honey in glucose barrels; that man that shipped the honey in glucose barrels lacked experience; that is very customary. However, if you have a clean heart and clean hands you don't care what kind of barrel honey is shipped in. I do know positively that glucose barrels are the best for honey; they have 6 hoops, and they will hold 700 pounds of honey, net. If you will have 2 more hoops placed on them, and drive them tight, they will not leak, and you can ship them anywhere throughout this world. I have shipped them to New York, New Orleans, and many places in the South, and I will guarantee that they will stand shipment in the hottest weather; they are a perfect success if it is done right. But when you buy them from a grocer and soak them up with water, and then fill them with honey, the receiver is robbing you, they say.

(Continued next week.)

## Destruction of Bees by Smelter-Smoke

After a severe struggle of over 2 years, we have finally succeeded in accomplishing a settlement by arbitration with the great smelter companies in the Salt Lake Valley for the destruction of the bee-industry by the poison of smelter fumes. Prior to the advent of these smelters the far-famed Salt Lake Valley was the banner county of Utah for the production of bees and honey. Ten years ago there were over 10,000 colonies of bees in the county. Now there are not 10 left. At first when bees began to die off, the bee-keepers, not knowing just what the trouble was, began to buy more, which died off faster than the first ones. Some of our bee-keepers, having done well with their bees, depending upon them for a living, did not like to give them up. These lost all, and in some instances these losses were very serious. While at first the bees thus purchased partly paid for themselves before they died, now they die off without producing anything, the writer having lost, all told, over 1,000 colonies, and a few others in like proportions.

While our bee-keepers have suffered an enormous loss, we finally compromised on a basis of \$1,500 from each of the 4 smelter companies, and these figures, as compared to our loss, are entirely too low. But we started into this matter for a friendly settlement with the smelter people by arbitration, and we told them that if we did not succeed it would not be the bee-keepers' fault. And if we had entered a suit, a judgment might have been the extent of our victory, which is a poor thing to live on. But a little cash has helped many of our

## Standard-Bred Italian FREE PREMIUM QUEENS

We are booking orders now for those Fine Untested Italian Queens that we offer every year FREE to paid-in-advance subscribers as premiums for getting NEW subscribers for the Weekly American Bee Journal. These orders are taken for May or June delivery.

### What Some Say of our Standard-Bred Italian Queens:

*George W. York & Co.*—The two queens received of you some time ago are fine. They are good breeders, and the workers are showing up fine. I introduced them among black bees, and the bees are nearly yellow now, and are doing good work. A. W. SWAN.  
Nemaha Co., Kan., July 15.

*George W. York & Co.*—After importing queens for 15 years you have sent me the best. She keeps 9½ Langstroth frames fully occupied to date, and, although I kept the hive well contracted to force them to swarm, they have never built a queen-cell, and will put up 100 pounds of honey if the flow lasts this week. CHAS. MITCHELL.  
Ontario, Canada, July 22.

*George W. York & Co.*—The queen I bought of you has proven a good one, and has given me some of my best colonies. N. P. OGLESBY.  
Washington Co., Va., July 22

*George W. York & Co.*—The queen I received of you a few days ago came through O.K., and I want to say that she is a beauty. I immediately introduced her into a colony which had been queenless for 20 days. She was accepted by them, and has gone to work nicely. I am highly pleased with her and your promptness in filling my order. My father, who is an old bee-keeper, pronounced her very fine. You will hear from me again when I am in need of something in the bee-line. E. E. MCCOLM.  
Marion Co., Ill., July 13.

### How to Get these Queens Free

To any one whose own subscription to the Weekly American Bee Journal is paid in advance, we will mail a Fine Standard-Bred Untested Italian Queen next May or June, for each new name and address sent to us with \$1.00 for the Bee Journal a year. No one can get for himself the Bee Journal a year and the Queen for \$1.00. The Queen is offered as a premium for the work of getting some one else to take the Bee Journal a year. If you, yourself, want the Bee Journal a year and the Queen, send \$1.50 for the two, and we will book your order for a Queen. Queen orders will be filled in rotation—"first come, first served."

Address,  
**GEORGE W. YORK & CO.**  
334 Dearborn Street, - CHICAGO, ILL.

# American Bee Journal

bee-keepers materially. Besides, there are 2 sides to every vexed question.

In this case the smelters were made welcome, as no one anticipated any trouble from their operation. Then if we take into consideration the unforeseen complications of this long-drawn-out question, our bee-keepers realize the situation we have had to cope with, and they are very well satisfied with the final settlement reached, and I feel grateful to them for the many thanks and kind expressions for my feeble efforts in this matter. Personally, it has been one of the lights of my life. I have neither time nor space to describe the voluminous correspondence of our long and persistent efforts and determination never to "give in" short of a successful issue, and while our smelter friends gave us all due credit, they thanked us for our patience and courteous good-nature, which was mutual and thus, although it was a long, tedious affair, it was pleasant throughout.

The locating of the smelters in the center of the Salt Lake Valley was a grave blunder that should not be repeated, but instead of moving them—which certainly should eventually be done—some parties are agitating the building of others under like conditions, and one was actually built last year near the agricultural center of Weber and Boxelder counties, and a protest was sent by the bee-keepers to the company before the smelter was built. If the bees were destroyed by the smoke—which is more than likely—the bee-keepers will claim full damage for their loss. There is no question but that the smelters have destroyed, and are destroying, the agricultural industry of Salt Lake county, and it certainly should be stopped. The agricultural settlers have rights which should be respected. Their homes and farms should not be destroyed. Then let the smelters be built in or near the mountains where the smoke will seek the hills or in some other location where the rights of others will not be injured. E. S. LOVESY.  
Salt Lake City, Utah, March 12.

## Covered Entrances—Grass in Front of Entrances—Solar Wax-Extractor—Caucasians

About a year ago, O. L. Hershiser in a long article described his patented bottom-board. One of its virtues was to prevent colonies becoming depopulated by many bees leaving the cluster and going out through the entrance and not returning. Now it may be that things would go differently with the Hershiser bottom, but with an ordinary one I have convinced myself that it is bad to fasten a bee-tight screen over the entrance.

Last fall I made the entrances of 18 colonies bee-tight with wire-cloth. In 3 or 4 weeks after cellaring, all colonies with closed entrances made much commotion. This also stirred up others with open entrances near by. One shut-in colony acted the same as when a hive is closed in summer. All of its bees, so it appeared, were at the entrance attempting to get out. As I could not drive them to their places and tie them, and as they did not cease their attempts at getting out voluntarily, I removed the screen. They then rushed out and many flew away, and, of course, were lost forever. This colony has been comparatively uneasy until today (February 26). As the weather permitted, I gave them a flight and now hope they will "keep their mouths shut."

Those are fine California views on the cover page of the February 21st issue, but what tall grass or weeds among the hives! Does Sir Patrick not know that Doolittle claims that the yield may be reduced one-half by such obstructed entrances? I dislike to see bees pull on a spear of grass as they will when grass grows in front of the entrances. It makes me feel as if I were attempting to pull out large trees that some one else (my superior, of course) had neglected to remove, though a great hindrance to my work.

The "Canadian Beedomer" thinks a solar wax-extractor unnecessary, as the cappings can be washed of adhering honey and then melted in water. But how about pieces of dark comb that accumulate during the busy season? If not put through a solar-extractor, the residue to be rendered by the hot-water method, I have found that they will mostly be eaten up by the wax-moth larvæ, keep them where I may.

As I think many tried Caucasian bees last season, I am surprised to see so very few reports of their accomplishments. I have had one colony for 2 seasons, and that has been one too many. I dare not "kick" them as some assert they do, for they will kick back. In other words, they are not gentle as has

been asserted. Neither are they as active workers as Italians. "Perhaps not pure," did you say? Well, I got the queen from the Government apiaries at Washington.  
Metz, Wis. P. A. STROHSCHNEIN.

## Keeping Bees in Buildings

On page 318, a Pennsylvanian asks Dr. Miller about keeping bees in a back yard, also about having them in a building. In accordance with my experience Dr. Miller's answer is right. It may be interesting to other readers of the American Bee Journal to learn what has actually been done on that line. I kept from 10 to 50 colonies of bees for 26 years in a town in Lebanon Co., Pa., about 30 yards from Main street, most of them in a building with an open front; and 41 years here in Virginia, 20 years of which were in a town here. I now have 10 colonies in my barn. I cut out an opening 3 feet high on the east gable end, set the hives inside of the building and they do better than the 60 colonies right outside on the ground in pairs, not over 6 feet from the barn, 10 in a row. During this time I had 2 colonies in my house inside at the gable-end window, raising the sash 1½ inches almost right along Main street in the town. I never had any trouble nor was annoyed with the bees at the barn or here, myself and family passing daily under and between those on the ground.

I practise Dr. Miller's advice about opening the hives and working late in the day, when I can.

I find the Italian and golden strains more gentle than any other I have, or have had. Caution must be used about the mice in the barn, as I lost 3 good colonies last winter; but in the summer I have no trouble.

WILLIAM URICH.

Herndon, Va., April 23.

## Cold April—Slow Breeding

A very cold April here thus far, and the time which bees gained in March has probably been more than lost now. Breeding has not progressed with rapidity, and colonies are to-day with less brood than they usually are at this season. But they bred early in March and young bees have very largely replaced the old bees, and you know that this means rapid work as soon as warm weather does come.

ALLEN LATHAM.

Norwich, Conn., April 21.

## Report for Last Season

I now have 7 colonies. Last year I had 5, and the year before that 2; so you see I have been going slowly, as you advise. My honey crops have been: 1905, 189 sections and 61 pounds of extracted honey from 2 colonies, and increased to 5 by natural swarming (I use the 1½-inch plain section with 8-frame dovetailed hive; 1906, 126 sections and 46 pounds extracted from 5 colonies, and increased to 6. All was buckwheat as white clover did not yield. This is the amount of honey I sold besides what we use, which is considerable. I took my bees out of the cellar March 26. They gathered some pollen in March from willows and maples, but have not had a flight this month, as it has been cold all the time.

A. OTT.

South Haven, Mich., April 17.

## Chunk Honey—Queen-Excluders

I notice in the Report of the National Convention at San Antonio, last November, that the Report has me to say that I am a comb honey producer. This is a mistake. I produced something like 16,000 pounds of honey about 20 cases of which was chunk honey.

I do not use queen-excluders, and will not have them on the place, except one or two to strain out an occasional queen that I can not find. I coax my queens to lay in any part of the hive they desire. I do this to have populous colonies, and a populous colony produces a large yield of honey. I have used queen-excluders, and my experience with

them goes to show that they not only restrict the queen in many cases, but retard the bees in transit to the upper story. The queen-excluder for me is a positive nuisance, and I would not tolerate one on a hive for any consideration.

As to section-honey producing, I am not in it. I hate sections worse than I do a serapiron pile. They are a nuisance for me from every point of view. There is at least 4 times as much work connected with their production as compared to chunk honey, saying nothing about short sections, and non-marketable sections due to a host of causes that are familiar to every bee-man of note. I took all my sections and section paraphernalia, piled it up and had a huge bonfire.

There is no trouble to sell all the extracted and chunk comb honey that you can produce, if you put it out under a positive guarantee as to its purity, etc., and back the guarantee with the money. I do not say it boastfully, but I fell short about 7000 pounds of extracted honey last season, at good prices.

Bartlett, Tex.

T. P. ROBINSON.

## A Colony That Deserted Its Hive

Day before yesterday a "swarm" of bees alighted in this town. I heard of it and could not believe it. But I went and saw the tree or bush and hunted the man that lived them, and also saw the bees. I have kept bees 50 years, more or less, and never knew of the like.

The weather is cold; no buds nor flowers have started; but a cold wind with nothing for bees to get. The man who found the bees is feeding them.

WILLARD MANN.

Buffalo, Minn., April 25.

## Mating of Bees

My bees came through the winter in fair condition, but we have had a very cold and chilly spring, and I fear much brood will be lost. I hope it may soon get warmer, and the bees make up for lost time and come out all right.

Not long ago I saw in some bee-paper that a man in England had made some experiments to get queens fertilized by attaching them to a fine thread fastened to a pole, and the writer seemed to think the plan entirely new. Now if I am not mistaken, the plan was tried some 20 years or more ago by Mr. Demaree, of Kentucky. So you see the plan was not a new one.

On page 295 (1906) Prof. Cook wrote in one of his letters from Germany, that at one time he witnessed the mating of bumble-bees, and that the act proved fatal to the male. Last summer while going through the pasture, I saw a very large bumble-bee rise up before me and fly about 50 yards and alight on some weeds. I followed it up, and, when close enough, I saw it was 2—a large female—and a smaller one on its back—I suppose a male. When I came closer they would fly some distance and alight again. They would fly away whenever I came a little too close, until finally I lost sight of them. My observations do not correspond with those of the Professor, but I did not see the finish.

FRED BECHLY.

Searsboro, Iowa, April 15.

10 cents brings sample jar by mail.

17A13t Mention the Bee Journal

"The continuous advertiser gets the bulk of the business, because others are not advertising, and he is."

## Something New = The Ideal Hive-Tool

Bee-keepers have long needed a special Tool to work among the hives during the bee-season. The one shown here was invented by Wm. Muench, a Minnesota bee-keeper, some years ago, but it was not on the market before. We have lately bought this Tool, and all rights, from Mr. Muench's widow, and have had the first lot made. They are ready for delivery now.

Best Hive-Tool

Only 30c, by mail

(This picture is exactly one-half the size.)

**DESCRIPTION.**—The Ideal Hive-Tool is made of high-grade malleable iron, much like wrought iron, 5 1/4 inches long. The middle part is 1 1/16 inches wide and 7-32 thick. The smaller end is 1 1/2 inches long, 1/2 inch wide, and 7-32 thick, ending like a screw-driver. The larger end is wedge-shaped, having a sharp semi-circular edge, making it almost perfect for prying up covers, supers, etc., as it does not mar the wood.

### What Dr. Miller and Miss Wilson Say of It:

In the first edition (1903) of Dr. Miller's "Forty Years Among the Bees," page 58, he says: "Of all the hive-tools I have tried, I like best the Muench tool." On Jan. 7, 1907, he wrote us saying he thought "just as much of the tool as ever."

Miss Wilson, Dr. Miller's assistant, says this of the Ideal Hive-Tool: "It is an ideal tool. In fact, I don't see how it could be improved upon. I am sure we would feel utterly lost in the apiary without it. . . . You will have to try one yourself if you want to know its worth."

### The "Ideal Hive-Tool" Free as a Premium.

We will mail an **Ideal Hive-Tool FREE** as a premium to any present paid-in-advance subscriber to the American Bee Journal, for sending us ONE NEW subscription for a year at \$1.00; or we will send the American Bee Journal one year and the **Ideal Hive-Tool**—both for \$1.20. Price of the **Ideal Hive-Tool** alone, postpaid, 30 cents. Address,

**GEORGE W. YORK & CO.,**

Millions of Dollars

are made every year in the book business. Every family, rich or poor, must have books. During the last few years, \$7,500,000.00 have been expended for Modern Eloquence, \$12,000,000.00 for Stoddard's Lectures, \$21,000,000.00 for the Century Dictionary, and the tremendous sum of \$44,000,000.00, covering over half a million sets of the Encyclopedia Britannica. These books were sold by subscription in American homes and sales are still going on.

We have a subscription publication which sells more readily than any of the above. The demand is already so tremendous that more capital is required to swing it, or get behind on orders. Profits are enormous, several times savings bank interest.

We have arranged a plan whereby **Any Progressive Man or Woman Can Share These Profits**

becoming stockholders in a profitable business, based on twenty years' experience. Remember, the success of this publication is not away off in the future—it is not prospective, but it is a success at the present time and growing in demand every hour. Sales of this publication at the time of publishing this advertisement

**Often Exceed \$2000 a Day**

This is an exceptional opportunity for those of small means to get in on the ground floor in a business which legitimately pays large dividends and is as solid as the Rock of Gibraltar. It cannot be held open for long as the response is certain to be so great that we shall have all the capital we need to increase the number of our presses and secure stock to be turned out in completed books, which are selling like wildfire.

You owe it to yourself to investigate this opportunity. You will never have a chance like this again to become

**Part Owner in a Mammoth Publishing House**

which is already in successful operation, already earning big dividends, and which is led to sell a small amount of its stock simply because the business is already so tremendous as to exhaust the working capital. But if you would grasp this opportunity you must

## Honey and Beeswax

**CHICAGO, April 4.**—Market is quite bare of best grades of comb honey. When sales are made it is on a basis of 15@17c, with very little outlet for the off-grades. Extracted, 7@8c; off grades, 6@6½c. Beeswax in good demand at 30@32c. **R. A. BURNETT & Co.**

**CINCINNATI, April 16**—There is nothing new in the honey market, excepting that this part of the country is bare of comb honey, and it is well, for consumers will appreciate the new crop more when it arrives. We are selling extracted amber honey in barrels at from 5¼@6¼c. Fancy table honey, 8¼c@9c, in crates of two 60-pound cans. For choice yellow beeswax, free from dirt, 32c delivered here. **THE FRED W. MUTH CO.**

**PHILADELPHIA, April 25.**—The comb honey market, on account of the lateness of the season, has grown just a little weaker in the last 10 days, although extracted honey is kept very firm. We think, however, there will be comparatively little comb honey carried over except in very small lots. We quote: Fancy comb honey, 14@15c; No. 1, 13@14c; amber, 12@13c. Fancy extracted honey, 7@8c; light amber, 6@7c. Beeswax firm, 32c. **We are producers of honey and do not handle on commission. WM. A. SELSER.**

**NEW YORK, April 12.**—**COMB HONEY.**—There is very little doing; stock of white honey of all grades is practically cleaned up, and small shipments which arrive from time to time, find ready sale at 14@15c for choice white stock, and 12@13c for off grades. Considerable dark comb honey is left on the market, and there does not seem to be any demand whatsoever. We quote nominally at 10@11c, but in large lots we doubt whether this price can be realized. **EXTRACTED HONEY.**—California stock seems to be well cleaned up, and we are informed that there is very little left on the Coast, and, before the new crop is marketed, whatever is on the market now will have been consumed. The prospects in California are very good for a large crop, but nothing definite can be said at this time, and there is no surety of a big crop until it is actually gathered. Last season the outlook was just as good, but in the height of the season, cold northern winds and generally contrary weather affected the crop to such an extent that it was small as in previous years. With favorable

# C. H. W. WEBER

CINCINNATI ... OHIO ...

Office and Salesrooms, 2146-48 Central Ave. Warehouses, Freeman and Central Aves.

weather in California for the next two months a large crop will undoubtedly be harvested, and if so prices will naturally be considerably lower than those of the past season and present prices. We quote white sage at from 7@9c, and light amber at from 7@7½c. Near-by, as well as Southern honey, is well cleaned up, and the markets are in good shape for new crop. Cuban and other West Indian honeys are arriving in large quantities, most of which are sold for export. The market is firm, at from 58@60c per gallon, duty paid according to quality. Beeswax firm and steady at from 30@31c. **HILDRETH & SEGELKEN.**

**INDIANAPOLIS, April 12.**—comb honey is not plentiful, but demand is slack. Fancy white comb brings 16@17c; No. 1 white, 14c; amber, 12@13c. Best grades of extracted honey bring 8@9c; amber, 6@7c. Good average beeswax sells here at \$35 per 100 pounds. **WALTER S. POWDER.**

**TOLEDO, May 3.**—There is very little demand for comb honey as is usually the case at this season of the year. Fancy white would bring in a retail way 16@17c; No. 1, 15@16c, with no demand for dark honey. Extracted is very scarce and none being offered for sale. Beeswax is bringing 28c. **THE GRIGGS BROS. & NICHOLS CO.**

**KANSAS CITY, Mar. 30.**—The demand for comb honey is light, as also are the receipts. The market is about bare of extracted. We quote: No. 1 white comb, 24-sec. cases, \$3.10 to \$3.25; No. 2, \$2.50 to \$2.75. Extracted, white, 8@9c; amber, 7@8c. Beeswax, 28c. **C. C. CLEMONS & Co.**

**DENVER, Feb. 14.**—Producers in this State are practically closed out of both comb and extracted honey. We have not sufficient good comb honey to supply our local trade, but have a good supply of white extracted of excellent quality. We quote strictly No. 1 white comb honey, per case of 24 sections, at \$3.20; No. 1, light amber, \$3; and good No. 2, \$2.80. White extracted, 8@8½c per pound; light amber, 7½@8c. Clean, yellow beeswax, 27@28c, delivered here.

**THE COLO. HONEY-PRODUCERS' ASSN.**

**CINCINNATI, April 3.**—The market on honey is entirely bare of fancy comb honey; No. 2, selling at 12½c, and slow sales. Light amber extracted sells in barrels at 5¼@6c. Beeswax 32c, delivered here. **C. H. W. WEBER.**

## Marshfield Bee-Goods

talk for themselves; having bought once, you will buy again. Our orders show that. The reason for this is that nothing is used in the making of our BEE-GOODS that we know is not fit to go in. Why should we when we have plenty of the best as it comes direct from the forest to our mill and factory.

SECTIONS are made of the basswood timber, grown here in the basswood belt of Wisconsin.

DOVETAILED HIVES, of lumber almost clear, made accurate and smooth.

SHIPPING-CASES, strong and neat—nothing flimsy about them.

### SHIPPING FACILITIES THE BEST

You will get your orders sent on very short time, as we are located on three direct railroads to Chicago, there connecting with the trunk lines for the East, South, and Southwest, and some parts of the West. The West by way of St. Paul and Minneapolis.

If you have not yet received our Catalog of BEE-SUPPLIES for 1907, just write for it.

**MARSHFIELD MFG. CO., Marshfield, Wis.**

# Cut Price==Anything In It?

By the Bee Crank.

Anything in it? Well, that depends. The dealer who offers to sell at cut prices is in business only for his health, and unless he happens to have a chance to make up on one article what he gives away on another, he loses out.

The other fellow—the buyer—doesn't honestly expect to get as good service and merchandise as he would at regular prices—he only thinks he does. The fact is, whether he has figured it out that way or not, he speculates on the deal, and when he gets the worst of it he is neither very much surprised nor disappointed.

No chronic bargain-chaser ever achieved much success in business. He spends more

time running after them than they are worth.

I have never offered staple goods at cut prices—and yet my business has grown enormously. Good service, prompt deliveries, square treatment and careful attention to details are worth more to my customers than the questionable advantage of a few pennies saved in the price.

## Trade Notes The A. I. Root Company, Medina, Ohio

### THE HATCH WAX-PRESS

If you have been so unfortunate as to lose some of your bees the past winter, or even this spring, save the wax in the combs by the use of some good wax-press. If you look about you will probably find a lot of old combs in your neighborhood which you can get for a song. Wax is higher now than for many years and you should hurry it to market, for the present high prices will likely continue but a few weeks, at most. Our new Hatch Press has several valuable features, viz :

- Durability.
- Ease of operation.
- Most thorough in its work.
- Superior quality of product.
- Low cost. Price is only \$6.00.

### WANTED

If you know of any one who has bees to sell this month, we can probably find a purchaser for the same—any number—5 to 100 colonies—provided we are given a brief, explicit description at once. Please state condition, hives, race, price, etc.

### BEE SWAX

We are paying at this date 31 cents cash or 33 cents in trade for pure, average beeswax, delivered at any of the following offices: Medina, Ohio; Chicago, New York, Philadelphia, or Washington. A large number of our jobbing agents make the same prices. See list of dealers in American Bee Journal for May 2.

### BEE-HIVE PAINT

We are distributing agents for the B. P. S. Paint. This is one of the best hive-paints to be found on the market. We have handled it for 10 years or more, and do not recall a complaint in all that time. Equally good for your house or any indoor or outdoor work. We ship the O. W. (Outside White) from

any of our offices; and the colors from Medina, New York, and Chicago. Send for color cards, etc.

### SPECIAL

For the next 10 days from date of this paper, to test the value of these columns, we offer a copy of the book, "How to Keep Bees," price, \$1.10, for only 60 cents, postpaid. Furthermore, we will promptly refund the money to any dissatisfied purchaser, even after you have read the entire book. You must send your order for this to Medina, and mention the American Bee Journal of this date.

### LESSONS IN BEE-KEEPING BY MAIL

There is now, and has been for years, a greater demand for experienced help than there are men ready for these places. Each winter and spring we are obliged to disappoint many large apiarists by telling them we do not know where suitable help can be found, The demand has already begun for the present season. We have found that many who take our course in bee-culture by correspondence prefer to go into business for themselves, so we still need active young men who have a fair knowledge of the subject—men whom we know something about—who can be recommended for the places frequently offered. We, therefore, offer again a limited course in

#### BEE-KEEPING BY MAIL.

We shall designate this as Course No. 2. The lessons are identical with the lessons in Course No. 1. The time, however, is limited to one year from enrollment. The course may be easily completed in 3 to 4 months. The following is the

#### OUTLINE OF COURSE NO. 2. (17 Lessons.)

- I. Definitions of Terms.
- II. Inmates of the Hive.
- III. Comb.
- IV. Handling Bees.
- V. Transferring.

- VI. Building Up Colonies.
- VII. The Honey-flow.
- VIII. Swarming.
- IX. Rendering Normal.
- X. Preparing for Winter.
- XI. Wintering.
- XII. Spring Management.
- XIII. Bee-Diseases, Symptoms.
- XIV. Enemies of Bees,
- XV. Establishing an Apiary.
- XVI. Queen-Rearing.
- XVII. General Examination.

#### TERMS OF COURSE—FULL CASH PAYMENT.

Complete course as outlined, lessons, personal answers to all questions, including the A B C of Bee Culture (500-page book), and Gleanings in Bee Culture (semi-monthly) for one year, \$5.00.

With either the A B C or Gleanings omitted in case you have one, \$4.00.

With both omitted in case you have both, \$3.00.

CHICAGO, ILL., MAY 16, 1907

Vol. XLVII—No. 20

### Don't Start Queen-Cells in Nuclei

A ripe queen-cell may do all right in a nucleus, and a virgin issuing from a nucleus may be fertilized all right, and may be all right for laying; but the beginner should be cautioned never to think of using a nucleus in which to start queen-cells. To be sure, a weak nucleus will start queen-cells, and such cells will cost very little, but they will be worth still less than they cost. A full colony is none too good to be used for starting cells. The growing larva should have all possible advantage of full warmth and full feeding. Only so can a good laying queen be counted on when it comes to maturity.

### Lebare Treatment of Foul Brood

Mr. Jas. Lebare submits the following treatment, which has been successful in his hands:

- 1st. Remove queen.
- 2d. Allow the colony to rear a queen.
- 3d. Three days old. Kill virgin queen.
- 4th. Take a small piece of brood from a choice colony containing only larvæ one or two days old, and insert same about the center of one of the worst affected combs. Now from the time of taking out the old queen till the first virgin is 3 days old, will be 15 days.
- 5th. Now you have queen-cells started. When the cells are capped over on the 8th day, take every comb from the hive, and every cell of that which contains life will be hatched, and if any cells are found still sealed up, uncapp them, as I find the bees are too slow to uncapp affected cells. Then I find that the bees will clean all germs from the comb. I have had the bees to cut the comb down to the bottom of the cell, and when their choice cell is hatched, undoubtedly the colony will be clean, for I have never failed by this treatment.

JAS. LEBARE.

If this treatment should prove successful on further trial, it would have the advantage of

saving the combs. It will be objected that the colony will be reduced, because it will be 5 weeks or more from the time the queen is removed until the new queen begins to lay; also there will be danger that in the final examination some sealed cells may be missed, to say nothing of the trouble of examination.

Of course, it remains to be seen whether others will succeed with the treatment.

### How to Start a Nucleus

Whatever may be best for the man who rears queens to sell, whether baby nuclei or what else, for the average bee-keeper who merely rears queens for his own use—and it may be said in passing that even the man with only a few colonies should have nuclei for rearing queens—for the average bee-keeper it will generally be found best to use for nuclei the same frames and the same hives that he uses for full colonies. It avoids the necessity of any separate fixtures, it is more convenient, and with hives and frames of regular size it is easy to build up into full colonies, or unite in the fall.

Starting a nucleus is not a very complicated matter. Take from any full colony 2 or 3 frames of brood with adhering bees and put in an empty hive on a new stand, and there's your nucleus. Only without any precaution it may not stay a nucleus, for when you look next day you may find nearly all the bees gone, the brood chilling, and the whole an easy prey to robbers.

So it is necessary to take steps to see that the bees stay where they are put. Fasten them in for 3 days or so, and by that time they are so accustomed to their new place and conditions that they will remain when the entrance is opened. Some close the entrance

with green leaves, grass, moss, or something of the kind. The bees will dig open the entrance in good time, with the advantage that at first only a single bee can pass at a time. If the bees are taken from a queenless colony they are more inclined to stay put.

A single frame of brood with adhering bees may answer, but it is very much better to have 2 or 3. It is well that a large proportion of the brood be sealed. The hive may be filled out with empty combs, or there may be only a single comb each side of the brood, the whole at one side of the hive, a dummy next, and the rest of the hive left vacant. Unless plenty of honey is to be found in the frames of brood, there should be some honey in one or both of the frames next to them.

It is not wise to start a nucleus generally before the time when bees begin to make preparations for swarming. The entrance should be closed down very small, allowing only a bee or two to pass at a time until they appear to be crowded.

If a sealed queen-cell be given to a colony, it may be 2 weeks before the young queen gets fairly to laying (double that time if the first virgin is lost on her wedding-flight), and it is economy to have this time spent in a nucleus rather than a full colony. Besides, it is a great convenience to have a laying queen in a nucleus, ready to be used whenever and wherever needed.

### Stock-Car for Shipping Bees

Never make the mistake of using a box-car in shipping bees on a railroad. It is too close. Use a stock-car. So advises E. D. Townsend in the Bee-Keepers' Review.

Getting New Subscribers for the Bee Journal is something that almost any reader can do if he makes a sincere attempt. No one knows better than does he its value to every would-be successful bee-keeper. And we offer valuable premiums, to those of our present readers whose subscriptions are paid in advance, for the work of going out and getting new subscriptions. Your neighbor bee-keepers perhaps have never heard of the American Bee Journal, although it is now in its 47th year. Why not try to get them to subscribe? You may be surprised how readily they will do so upon your invitation.

## Miscellaneous News - Items

**Dr. C. C. Miller and Wife** made this office a pleasant call last week, when in Chicago. The prospects for bees in his locality (66 miles northwest of Chicago) are anything but encouraging, on account of the late, cold spring. His bees wintered fairly well, but many were lost during the recent cold spring weather. Both the Doctor and his good wife were apparently in good health.

**The Apiary of E. E. Kennicott** appears on the first page this week. Mr. K. wrote as follows concerning it on April 29:

I started last fall with 28 colonies. One lost its queen, and one was robbed in March during that warm spell, so I have at present only 26 colonies in good condition.

I enclose a postal card picture of one row of hives in winter quarters, and the house in the background. I set the hives in a row about 3 inches apart, facing the south, then I cover thickly with leaves, filling each super with dry leaves, and cover over all with leaves, and set boards against the leaves to hold them in place. I have had fine success for 3 years. E. E. KENNICOTT.

**Dr. Phillips "Apicultural Investigator."**—Last week we received the following announcement from the Bureau of Entomology, at Washington, D. C.:

EDITOR AMERICAN BEE JOURNAL—

Dear Sir:—I beg to announce to you that the apicultural investigations of this Bureau are now in charge of Dr. E. F. Phillips. I would also announce to you the appointment of Dr. G. F. White as an expert in bacteriology, Mr. Franklin G. Fox as assistant in the apiary, and Mr. Burton N. Gates as co-laborator in Massachusetts.

Yours very truly,

C. L. MARLATT,  
Acting Chief of Bureau.

We believe all the appointments mentioned will give great satisfaction to bee-keepers everywhere. Dr. Phillips is already widely known among bee-keepers, having filled Mr. Benton's place in the Bureau of Entomology while the latter was traveling in foreign countries in the interest of apiarian investigation.

**"When We Meet on That Beautiful Shore."**—We have just received a copy of a very delightful and pleasing sacred song and chorus called, "When We Meet on That Beautiful Shore," composed by Samuel H. Speck. This is certainly one of the sweetest home songs ever published. It is especially suitable and adapted for the home, church and choir use, being also nicely arranged as a fine quartette for mixed voices. Retail price, 50 cents per copy. Our readers will receive a copy post-paid by sending 10 cents in silver or postage stamps to the Globe Music Co., 17 West 25th St., New York, N. Y.

**The Simplex Bee-Hive.**—A booklet setting forth the merits of the Simplex Bee-Hive, invented and patented by Carl Ludloff, of California, has been received at this office. Closed-end frames tied together with cords form the hive, protected by a straw mat, making it very close and warm. It varies no little from hives in general use.

**The Minnesota Foul Brood Law,** as recently passed, is as follows, a copy having been sent us by Chas. D. Blaker, Secretary of the Minnesota Bee-Keepers' Society:

A Bill for an Act to create the office of Inspector of Apiaries; to provide for the suppression of contagious diseases among bees and to appropriate money therefor.

*Be it enacted by the Legislature of the State of Minnesota.*

SECTION 1.—The Governor shall appoint for a term of two years a State Inspector of Apiaries. Said Inspector shall, when notified of the existence of the disease known as foul brood among apiaries, examine all reported apiaries and all others in the same locality, and ascertain whether or not such disease exists, and, if satisfied of its existence, shall give the owner or person who has charge of such apiaries full instructions as to the manner of treating them. Within a reasonable time after making such examination, the Inspector shall make another examination thereof, and if the condition is such as in his judgment renders it necessary, he may give notice to the owner or person in charge of such apiaries, prohibiting the sale, barter, or removal of any bees, honey, or appliances from such affected apiary.

SEC. 2.—After inspecting infected hives or fixtures, or handling diseased bees, the Inspector shall, before leaving the premises or proceeding to any other apiary, thoroughly disinfect any portion of his own person and clothing, and any tools or appliances used by him which have come in contact with infected material, and shall see that any assistant or assistants with him shall likewise thoroughly disinfect their persons and clothing and any tools and implements used by them.

SEC. 3.—Any bee-keeper who shall be aware of the existence of foul brood in his apiary, or who shall receive notice from the Inspector as provided in Section 1 of this Act, and who shall sell, barter, give away, or remove any such apiary or any honey, appliances or bees from such apiary, and any bee-keeper who shall refuse to allow the Inspector to examine his apiary, honey and appliances, shall be fined not less than \$10, nor more than \$50, or be imprisoned in the county jail not less than one month nor more than two months.

SEC. 4.—The Inspector of Apiaries shall make, at the close of each calendar year, report to the Governor, stating the number of apiaries visited, the number of those diseased, and treated, the effect of such treatment, and the disposition made of such apiaries.

SEC. 5.—The compensation of said Inspector of Apiaries for services and expenses is hereby fixed at one thousand dollars (\$1000) per year, and there is hereby appropriated out of money in the State treasury, not otherwise appropriated, the sum of one thousand dol-

lars (\$1000) each year for the maintenance of said Inspector of Apiaries.

SEC. 6.—This Act shall take effect immediately after its passage.

We wish to congratulate the bee-keepers of Minnesota on their success in getting this much-needed law. Now with the appointment of competent inspectors, and the right kind of co-operation with them on the part of the bee-keepers, Minnesota should be able to keep down the disease of foul brood among bees, and perhaps stamp it out altogether.

**Honey as a Health-Food.**—This is a 16-page honey-pamphlet intended to help increase the demand for honey. The first part of it contains a short article on "Honey as Food," written by Dr. C. C. Miller. It tells where to keep honey, how to liquefy it, etc. The last part is devoted to "Honey-Cooking Recipes" and "Remedies Using Honey." It should be widely circulated by those selling honey. The more the people are educated on the value and uses of honey, the more honey they will buy.

Prices, prepaid—Sample copy for a 2-cent stamp; 50 copies for 70 cents; 100 for \$1.25; 250 for \$2.25; 500 for \$4.00; or 1000 for \$7.50. Your business card printed free at the bottom of front page on all orders for 100 or more copies. Send all orders to the office of the American Bee Journal.

**"Songs of Beedom."**—This is a beautiful 16-page-and-cover pamphlet, 6x9 inches in size, containing 10 bee-songs—words and music—all the songs so far written specially for bee-keepers, we believe. It is nice, as well as convenient, to have these songs all in one binding. Every bee-keepers' organization should have copies for use at conventions. They could be sold to members after using once, or held by the secretary for use at future meetings. Of course, every bee-keeper's family will want at least one copy. It is sent, postpaid, for only 25 cents, or 3 copies for 60 cents; or, we will mail one copy with the American Bee Journal one year—both for \$1.10. Send all orders to the office of the American Bee Journal.

**Why Not Advertise?**—There are many dealers in bee-supplies, and those who have bees and queens for sale, who are not now advertising, that might increase their business by advertising in the American Bee Journal. The rates charged are very low, as will be seen by referring to the second page of this number. During the next 6 months will be done the bulk of the season's business among bee-keepers. Why not begin at once to let the readers of the American Bee Journal know that you have something to sell? Our advertising columns are open only to those who will give their patrons "a square deal." If you are in that class we will be pleased to have your advertisement in our columns.

**Our Wood Binder (or Holder)** is made to take all the copies of the American Bee Journal for a year. It is sent by mail for 20 cents. Full directions accompany. The Bee Journals can be inserted as soon as they are received, and thus preserved for future reference. Or we will send it with the American Bee Journal a year—both for \$1.10. Address office of the American Bee Journal.

**The San Antonio Convention Picture** is a good one. It shows over 100 of those in attendance. We are mailing them, unmounted, for only 60 cents. They can be mounted by a local photographer for only 10 or 15 cents more. We will mail one of these pictures with the American Bee Journal one year—both for only \$1.40. Send all orders to the Bee Journal office.

**No. 5—Feeding and Feeders  
—Top Feeders**

BY C. P. DADANT

This is the most common method of feeding. Probably the most extensively used top feeder is the Miller feeder, devised by Dr. C. C. Miller, and described by him in "Forty Years Among the Bees." The manufacturers make the Miller feeder a little different from the original used by the inventor. The Miller feeder is all in one, and the bees have access to the feed from both sides, while the copy is made in two parts, with the ascent to these in the middle, right over the brood. At first sight it looks as if this were the better way, since the ascent is where the bees can reach it from the center of the brood-nest, and better guard it against robber-bees; but Dr. Miller does not agree to this, and says:

"I thought it was an important improvement to allow the bees to go up the middle instead of up the sides, because the heat ought to be greater at the middle. After a thorough trial of the two, side by side, I am obliged to admit that the improvement is one in theory only, and that the bees go up the sides whenever they will go up the middle, and it seems a little better to have to feed all in one dish."

Feeding granulated honey over a piece of paper on top of the frames, at the back of the brood-nest, is quite practical because the quilt may be allowed to drop back on this food, and close the top as soon as the food is removed. But for stimulative feeding granulated honey is probably not so good as liquid warm food, because it is very thick and will force the bees to go in search of water. Honey in extracting-super combs may be fed to the bees when the colony is powerful, but will not do for a weak colony because it leaves the upper story open and causes loss of heat.

A very cheap and convenient feeder which brings the food right over the cluster is made of a fruit-can with a cloth tied over the mouth of it and inverted over the combs. The can must first be inverted over a dish or a pan, with two small cleats under it, to let the first flow of liquid come. It is kept in that position till laid over the frames. At first the honey comes very freely, but when the atmospheric pressure acts the liquid stops running through the cloth and is taken by the bees only as fast as needed. The pepper-box and Hill feeders are similar, only they have a perforated-tin cover which allows the feed to come through. But the ordinary tin-can feeder, made of any round tin can which has been emptied of its contents, is fully as

good as these, because when the bees have emptied it they will gnaw through the cloth and get the very last drop of liquid. It is, however, quite a little more trouble to prepare it for use. Cloth must be used which is thick enough not to let the air pass through, as otherwise the food would continue to leak through after inverting and would waste. The bees must be able to take care of it or the feeder is a nuisance. The greatest objection to the inverted tin can as a feeder is that it allows the heat to escape in the cover unless a honey-board is used in connection with it.

As honey-boards are used by us only with bee-escapes when we wish to remove the supers, and as we use the cloth and mat only, at all other times we have devised a honey-board to serve alternately with the bee-escape or with the feeders. This does away with the

enough to interrupt the taking of the food by the bees. The other, the rusty cans must be carefully avoided.

The ordinary quart can which is now so plentifully used for all kinds of preserves and canned vegetables, and which is usually thrown away after being emptied, need never be used more than once for feeding the bees.

Hamilton, Ill.

**Lyman Method of Swarm-Control**

BY W. C. LYMAN

How to get the best results from my bees in a rather poor location; how to control swarming, and to run for comb honey as easily as for extracted; how to keep the colonies strong, and at the same time contented; and to be able to do this in an out-yard as well as at home; how to do it all with only a little labor, comparatively, and without cutting or changing my hives in any way, and without many extra fixtures—to develop a system that would apply to any standard hive, has been a pretty large problem over which I have studied a good deal, and have tried in a number of ways to solve.

Also, I have made some progress, and with the help of the photographs which I have taken of the hive-parts

*Bee-Escape Board Used for Feeding Bees.*

necessity of having two sets of honey-boards in the apiary. When the feeder is used the round plug carrying the escape is temporarily removed.

In the use of tin feeders care must be taken that they be not allowed to rust. During the fall of 1906, one of our men used a lot of feeders that were rusty inside. The feeding was done late, about the last of October, and a number of colonies fed for winter left a portion of the food in the feeder for 2 or 3 weeks before it was stored in the combs. The result was a darkened syrup instead of the clear food which ought to have carried them through in good health, and a number of the colonies—perhaps every one of those which were fed out of rusty feeders—were killed by diarrhea.

Two expensive lessons were thus secured: First, that it is advisable to feed before the weather becomes cold

and fixtures which I am now using, I will try to make plain my method.

Fig. 1 shows two bottom-boards, of the kind I use and prefer, placed as shown—front end to front end, and the 7/8-inch bee-space-side up on a stand from which I have just removed the colony which I wish to manipulate. When to do this work must be left to the judgment of the bee-keeper, but I usually do it about the time when a shaken swarm should be made to prevent swarming.

Fig. 2 shows a false bottom made of galvanized iron, leaning against, or held up by, a short piece of board, and these two articles are all that are required in my plan for the manipulation of a colony. The false bottom, as I use it for the 8-frame hive, is made by cutting a sheet of galvanized iron to measure, 21 inches long by 12 inches wide, and nailing to it on the underside

# American Bee Journal

pieces of wood  $\frac{3}{8}$  inch by  $\frac{7}{8}$  inch, and 21 inches long, one piece being nailed to each of the sides of the iron, as shown in the illustration.

Across one end of the iron sheet—on what is to be the upper side—is nailed a  $\frac{3}{8}$  inch by  $\frac{7}{8}$  inch strip of wood 12 inches long, which completes the false bottom.

The short piece of board shown in Fig. 2, is used to lay on the front end of the rear bottom-board, to close the space between the two brood-chambers, when the manipulation of the hive is completed, as shown in Fig. 4. It is 2 inches by 14 inches long.

Fig. 3 shows the false bottom dropped into its place in the front bottom-board of the two shown in Fig. 1. This false bottom does not fit tight against the bottom-board at B, but is drawn a good bee-space back toward A, so that bees running under at A can emerge at B; that is, the false bottom forms a sort of bridge for bees to run under and come out at B. The strip of wood on the back end and upper side of the false bottom at A closes all exit in that direction for the bees, when a brood-chamber is set on the front bottom-board, and the space between the two is closed by dropping in the little board

Fig. 2.—False Bottom and Closing Stick.

shown in Fig. 2; all egress for the bees from the rear brood-chamber is under the false bottom in front.

Fig. 4 shows the arrangement of the hives completed.

The entrance of the hive marked 11 is in the usual place, and is the only place where bees can get into that hive. The entrance to the rear brood-chamber, marked 1, is just in front of the entrance to hive 11, and is shown by a dark line in front of the entrance to hive 11. This is also the only place where bees can get into or out of the rear brood-chamber.

Now in practical use I find that very few of the bees which come out from the rear brood-chamber locate the place where they come out, but instead locate the entrance to the front hive. In fact, the hive is "all one to them," as it is to all the bees which fly from either brood-chamber.

The idea that they would not locate the entrance to the rear brood-chamber, I took from the fact that it is more natural for bees to go up into a hive, as they are in the habit of doing through a short passage-way, than it would be to go down and under through a long one, and it works that way in practise. But to get out, they will go

Fig. 1.—Two Hive-Bottoms Facing.

3.—False Bottom in Place.

Fig. 4.—Complete Hive-Arrangement for Swarm-Control.

# American Bee Journal

in any direction *toward the light* for a considerable distance.

But to go back to the manipulation of the hive: All the work of arranging the bottom-boards which I have described is supposed to have been done on the stand of a strong colony of bees, or one about to swarm, and which has been set off its stand for the purpose. The first thing to do after arranging the bottom-boards as described, is to put on the front one a brood-chamber arranged as for the hiving of a natural swarm, with frames of foundation, or combs, as the bee-keeper may think best, and on it put the supers, bees and all from the removed hive. Back of this, on the rear bottom-board, put the brood-chamber of the removed hive, containing the brood and queen, and close up the space between with the piece of board described.

In Fig. 4 the prepared brood-chamber is marked 11, and the one containing the brood and queen is marked 1. Next remove the queen from 1 and put her (and perhaps a few of her bees for company until enough return from the field) into hive 11, put on the covers, and see that all the parts are closed up bee-tight except the entrances, and the work is done.

I still use a queen-excluding honey-board, which is shown in dark color on

the hive in Fig. 4. There are reasons for this, but I will not take up that part of the subject, nor other details of management, for that must be according to location, the size and kind of hive in use, etc., and if any one wishes to try this method he must arrange those things to suit himself.

E. F. Atwater, in the February Bee-Keepers' Review, tells of his method, which is similar to this, and speaks of putting a comb containing water into the brood-chamber containing the brood. I believe that is an excellent idea, and I will try it in the future.

So far this method is the most satisfactory of any I have tried, in meeting all the requirements of both comb and extracted honey production, and if any one thinks well enough of the plan to try it, I wish he would report result to the American Bee Journal, no matter if it is a failure, for by failures we often learn to succeed.

One thing I forgot, which is, that I think it is best to cut out the queen-cells before they hatch, that will be built in the rear brood-chamber, for the bees will agree better when they come together at the entrance; but the queen-cells can be left long enough to make use of them in the bee-yard, if required.

Downers Grove, Ill.

West queen-cell protectors, and on the upper side with a piece of queen-excluder. This, placed between 2 hives with the cell-protectors pointing downward, will allow all the bees in the upper hive to go below, and the queen-excluder prevents it becoming clogged with dronea. For transferring from hives with crooked combs to those with straight combs it is unequalled, only a new queen must be provided, or the old hive taken to pieces when the bees are all out, and the queen hunted and run in below. In which case the brood is lost.

Now my plan of management is somewhat variable, depending upon what I wish to accomplish. I hardly think the extractor-man would care for this device, but it is all right for comb honey.

We will suppose that hive No. 1 is full of brood and in need of more room. If I have plenty of time and want to save all the brood I manage this way: Set hive No. 1 off its stand on a box or wheelbarrow near at hand, and put hive No. 2, supplied with frames of foundation or starters, in its place. Now place hive No. 1 on hive No. 2, and smoke the bees until they have nearly all gone down into No. 2, and we hope the queen is with them. Remove No. 1 quickly—before the bees have time to boil up into No. 1—and place a queen-excluder on top of No. 2, replacing No. 1 on No. 2, with the excluder between. This, I believe, is Mr. Alexander's plan of saving the brood, only he shakes the bees down instead of smoking them. I have lost queens that way, and it takes more time, but it is more certain. I think Dr. Miller has somewhere suggested smoking, but if smoked down the frames must be examined in a day or two for eggs to see where the queen is; and if she is not below she must either be smoked or shaken down. If the smoking was well done, she will nearly always be found below—"in this locality."

In 5 days after the queen has been placed in the lower hive I remove the queen-excluder, replacing it with the screen above described—or "bee-sieve," as I call it—and in 3 weeks hive No. 1 is empty of brood and bees.

If you want increase, Mr. Alexander's plan is all right just as he gives it.

After the brood in No. 1 is capped remove it to a new stand, and supply it with a good queen. But if you are a comb-honey man, and your time is worth more than the brood, and if you don't care for increase, place the sieve between the 3 hives at the first operation, and either introduce a new queen to hive No. 2 in any way that recommends itself to you, or the next day or two you can easily find the queen in hive No. 1, and run her into No. 2. She will be accepted, as she has the same scent.

If the honey-flow is on place the super with sections between the two hives, with the sieve between it and hive No. 1 now on top.

If your bees get ready to swarm again just change—putting hive No. 1 below and No. 2 above, using the sieve as above.

I think I am indebted to Mr. Doolittle for the suggestions which led me to plan the bee-screen.

Please tell Mr. Aikin (page 251) that I think the rhyme he referred to, but could not remember, ran something like this:

"Some water and oil one day had a broil.  
As down in a dish they were dropping.  
They would not unite, but continued to fight  
Without any prospect of stopping.

"Mr. Pearlsh o'erheard, and as quick as a word  
He jumped in the midst of the clashing;  
And all three agreed they united with speed,  
And the soap was created for washing."

I would like to close with a stanza which bee-keepers would do well to think of in a bad year.

"The inner side of every cloud  
Is always bright and shining;  
I therefore turn my clouds about,  
And always wear them inside out.  
To show the lining."

MRS. EMILY H. HAFPOD.  
Fennville, Mich., March 31.

You have evidently been doing your

Conducted by EMMA M. WILSON, Marengo, Ill.

## Beginning Bee-Keeping—Management of Swarming

MY DEAR MISS WILSON:—I always look forward with pleasure to the arrival of my bee-paper, and enjoy very much the Sisters' department. And now I feel inclined to "speak in meetin'."

In early childhood an uncle kept bees on my father's place, and having been stung a few times, I regarded the bees with fear and terror. I well remember my feeling of relief when at last they were taken off the place.

In later years my eldest son contracted the "bee-fever" by association with a neighbor bee-keeper; and yielding to his importunities, I bought 3 colonies very much against my inclination. As we knew nothing about the management of bees, papers were subscribed for and books procured, and we read with increasing interest of the various manipulations to be performed. He would put on the veil and gloves and go out to manage the colonies, while I would look out of the window and counsel him what to do. But this did not satisfy me long, so I donned the togs, and timidly ventured out to investigate for myself; but it was with fear and trembling. It required all my self-control when I heard the bees buzzing around me, not to drop things and run, and I had frequently to reassure myself that they couldn't possibly get at me anywhere. Yes, and it was cruel the way we smoked them.

Our neighbor had said the bees were pure Italians, and we knew not differently; but after sending off for a few pure queens, and watching their bees as they hatched, we soon discovered that our first colonies were mostly blacks, with only a little Italian blood.

Our mistakes that summer were many, and considering the good instruction in our papers and books, some of them were inexcusable. My son was stung several times, and after the bees had crawled up his pant-legs, he said "two in one pair of pants was too many," and he finally gave up the whole business of bee-keeping to me.

That winter we lost all our bees—the result of our mismanagement; but my interest was aroused, and the next spring I sent off for nuclei, and started again. I am not so fearful now, and I greatly enjoy my pets.

As my bee-keeping has to be sandwiched in between household cares, poultry-raising, the care of an aged mother, and the general oversight of a large farm (I am a widow), I have little time to hunt queens, and the question of swarming has been studied by me most earnestly. I have finally settled on a plan that is a combination of the ideas of several prominent bee-men. I think I can give credit to Mr. Doolittle, Dr. Miller, and Mr. Alexander, and I have added some thoughts of my own. The main feature of my plan is a piece of wire-screen the size of a queen-excluder, with 4 holes (one in each corner) large enough for one or two bees to pass through. These are covered on the lower side with

# American Bee Journal

share of thinking and planning, and isn't there a lot of fun in it?

You seem to prefer smoking to brushing or shaking in getting the bees from the upper to the lower story, with the chance that you may have to operate the second time to get the queen down. As the queen is the only member of the family you are very particular about, unless you have an antipathy to finding queens, it might be easier to find the queen and run her into the entrance below. This would avoid the possibility of a second operation, and there would be no need to look in 2 or 3 days to learn the location of the queen.

You put supers under hive No. 1, allowing the bees from above to go down into the supers of sections. Please tell us what effect that has on the sections. When we tried it the capping of the sections was considerably darkened. Of course, if the combs in No. 1 were quite new it would make a difference. Ours were old and black.

Thanks for helping out Mr. Aikin's memory.

## Miller Frames—Anti-Swarming and Extracting Management

I am making some Miller frames as described in "Forty Years Among the Bees," page 82, and filling them with foundation just as Dr. Miller says he does. The foundation is  $8\frac{1}{2}$  inches wide, but instead of using splints I mean to use medium-sized broom-wire, first taking the temper out. The bees will rear brood over this wire, and there is no ridge over it as shown over Dr. Miller's splints. I will then stretch 3 No. 30 wires lengthwise of the frame. This is an experiment with me, and I would like to know any objections there may be to it.

Then when the honey-flow comes for good, and the bees are at their best before swarming, I plan on filling an empty hive with these frames, placing it on the old stand, the old hive in front of it with entrances together. Then I put excluder-zinc over the new hive, and a hive-body on that. Then brush the bees from the brood down in the old hive, allowing them to go into the new hive on the foundation, and put the brood above, but keeping out one frame, and spacing the rest equal distance apart by guess so as to fill up the hive. After 8 days cut out the queen-cells.

My idea is that this will start the bees to carrying their honey above and building the combs thicker for extracting as fast as the brood hatches out, but the Miller frames are thicker at the bottom than the Hoffman. There is only  $\frac{1}{4}$ -inch space for the bees to go up through, and the air-space under them will be  $\frac{3}{8}$ -inch. Would this be ventilation enough for that kind of frames? Would it not be good to put a  $\frac{1}{4}$ -inch piece around under the top-story, giving entrance across one end? Of course, I could put pieces on the bottom-board and enlarge their entrance.

I would be glad to read the criticism on this subject. I have 30 colonies, and am thinking of treating all this way.

LAURA E. RUDY.

Fairmount, Ill., April 27.

Very evidently you have a wrong idea of the ridges over the splints in the Miller frame. I think you must have gotten your idea from the picture given on page 97 in "Forty Years Among the Bees." That picture is one of the frame filled with foundation before given to the bees at all, and what you call ridges are the splints themselves. It is possible that once in a while a ridge may be seen, but surely

not often, as I do not now remember ever seeing one, and usually the only way that the presence of the splint is discernible is by holding the comb up to the sun and looking through it. If you will look at pictures on pages 87, 101, 105, 261, you will see that there are no ridges from the splints to be seen.

Wire in place of splints will work, but hardly so satisfactorily, as the wire may bend, and the splints are always perfectly straight. The addition of horizontal wires will, of course, add strength for extracting-combs, but are hardly necessary.

Your plan during the honey-flow will work all right, but I would not advise

you to give any more space under the frames, as one experiment along that line would be enough. The bees would surely fill that space chuck-full of comb and honey, and a sticky mess you would have of it. If you wish to give more ventilation, just shove the upper story forward enough for bees to pass, and that will give a free circulation of air without the dire results of the other plan.

That  $\frac{1}{4}$ -inch space between bottom-bars is all right.

You do not mention that your plan of operation is to prevent swarming, but it is nothing more nor less than the Demaree plan to prevent swarming.

BY W. A. PRYAL, Alden Station, Oakland, Calif.

## "Our Youthful Bee-Expert"

Ralph Benton, to whom I referred recently as being connected with the bee-department of the University of California, is making a greater stir in the bee-world in these parts than his distinguished father did 30 years ago, when he (the latter) commenced to attract attention in the bee-papers by his writings. Perhaps at the University a new broom may sweep clean—I hope it will always do so. At any rate, I notice that the "youthful bee-expert," as one of the daily papers calls him, is to make a tour of the Southern California apiaries as soon as class-work is over at the University, and get material for a bee-bulletin. Bully for the "Varsity;" bully for Benton!

## Hunting for Bee-Fixings

Did you ever have to hunt for bee-appliances? I don't mean hunting about your apiary, but in your town or the next one. I've had a time of it this week getting some things I found I was short of. Before the big fire that destroyed San Francisco a year ago, there were a couple of places where one could easily procure almost anything in the bee-line. Well, the other day I sought those places, but I must say I did so sorrowing. The day was hot, and it is no easy job to get around in the "ashen city" these days, though order and beauty are fast being brought out of chaos. One of the houses that represented a well known Eastern bee-supply manufacturer, resumed business in a big shack near the former location of its fire-swept store. In answer to my inquiry, I found that they did not handle bee-supplies now; that they did not have sufficient room to do so. Neither could they tell me where I

could find any. I tried to see if there was anything to be had a few blocks further up, where I knew there had been a dealer in dairy and bee fixings. There was nothing on the block but old bricks and other debris. Some excavators were at work on some of the lots, as they were on nearly every block—they and the builders.

The next day I found that a firm from an outside city, which had faith in San Francisco's future greatness, had opened a big store and carries bee-ware as well as a fine stock of garden-supplies. But they don't advertise! Printer's ink is as essential in greasing the path of the bee-man and his allies as it is for the man who sells Fillyourstomach goods and Feathers-andfrills for Maria.

## An Honored Professor Retired

I learn that Prof. E. J. Wickson, for many years Dean of the Agricultural College of the State University of California, at Berkeley, is to be succeeded by a man from one of the Eastern colleges. This is rather unfortunate for the California University, as Prof. Wickson has been connected with that institution for a little over 30 years, and it may be said that he has done more than any other person in the State to give the University the high standing it has won among the agricultural colleges of the world. In his earlier connection with the college he held the Chair of Dairying, and at the same time was editor-in-chief of the Pacific Rural Press. Later, he was the horticultural expert of the college, and had general supervision of the agricultural grounds, and at the same time filled the position of Horticultural editor of the paper named. His work, "The Fruits of California," is the rec-

# American Bee Journal

ognized authority on the subject in this State. While he may be transferred to another sphere of the institution, I hardly think the Regents will allow so valuable and worthy a professor to sever his connection with the college altogether.

I first made the acquaintance of Prof. Wickson in the fall of 1876, I believe, when I was a student of the University. I think I wrote an article for the Rural Press, showing that some alleged moth-proof bee-hive, extolled by one of the paper's correspondents, was not what it was claimed to be, and it could not be. Later, I disproved (or think I did) that a certain variety of eucalyptus near Los Angeles killed honey-bees wholesale when they quaffed of the nectar contained in the flowers thereof. Since then, nothing has been heard of the alleged honey-bee-killing eucalyptus. The story came through one of the Los Angeles dailies, and was copied by the Rural Press.

Prof. Wickson, though not a practical apiarist, has always taken quite an interest in bee-matters, and had quite an apiarian department in his weekly. I believe it was in 1875, when he was connected with the Utica (N. Y.) Herald, that he was appointed on a committee of the American Bee-Keepers' Society, which met, if I remember correctly, in the city just named, for the purpose of investigating the alleged adulteration of honey. One of the other members of the committee was the great American bee-keeper, Moses Quinby. The Professor tells an amusing story of his visit to the veteran apiarist's home.

A more unassuming, yet agreeable, gentleman than Prof. Wickson, never lived. He was held in such high esteem in his home city, Berkeley, that he was retained as a member of the School Board for over 20 years, and he would probably be looking after the interests of the children yet if he did not insist upon having his name withdrawn from further elections of the position.

## Where All is Golden

The Golden State! Golden in its most precious metal; golden in the color of its countless acres of wild flowers! In a short trip down the county recently I noticed vast fields of yellow flowers—a cloak of gold seemed to be spread over a large section of the earth within the reach of one's vision. There was the thrifty mustard, and there were turnips. The last-named seemed to vie extermination, for grain-field, truck-garden and pasture were all taken possession of, as it were, by this earliest blooming of flowers. Then there were some rape and radish—all yellow as the gold of Ophir, except the latter. These all grow in a wild state in luxuriant profusion—so much so at times that they are a sore annoyance to the cultivator of the soil. This season they seem more numerous than ever; I suppose the long, wet winter and spring was the cause. But to the apiarist they are more of a joy than a sorrow—they all yield richly in nectar, and, I believe, of a very fine flavor. I know that in years when these flowers

are most abundant, we get the most delicious honey of the year. This is the latter part of April and during the first half of May, when the weather is warm.

## Advertise, Ye Bee-Caterers

The closing lines in another paragraph impel me to add a few more words upon the subject of advertising. No merchant nowadays hopes to make a success of his business unless he devotes a portion of his profits or capital to advertising. As proof, just look at the vast acres of advertising space used in the papers—daily, weekly, and monthly—and to the broadsides printed

or painted upon dead walls, fences, etc. If your business is young and your capital small, advertise moderately; if well established, advertise generously. Big ads sell little biscuits for the greatest baking concern in the world; heavy advertising built up the most pernicious tobacco trust known to English speaking people. The queen-breeder, the hive-maker, the honey-seller, may all find their several businesses expand under the magic of the impress of cold type and printer's ink. Try it in the "Old Reliable," if you are not doing so; thousands of bee-keepers are in need of what you have to sell; perhaps I, myself, may be in need of the very article you are hiding in the dark.

The "Old Reliable" as seen through New and Unreliable Glasses, By E. E. HASTY, Sta. B. Rural, Toledo, Ohio.

## WINTER HIVE-ENTRANCES—CLIPPING QUEENS' WINGS.

Thanks to Mr. Byer for evidence that entrances contracted for winter all on one side do not always prove disastrous.

And he is setting a record when he gets his bees to roar at night in maple-sugar time. (A sleet had torn maple branches everywhere, and then it came warm.)

And the Byer method of clipping queens is likely to prove very catching among spry-fingered operators who delight in doing something other folks can't do. (Curved surgical scissors, which can be had for about 60 cents a pair. And deftly whisk up the wing and clip it without touching the queen elsewhere.) "No use o' talkin'," the scent of human fingers does sometimes cause queens to be attacked and killed. Thus the improved way is a life-saver. One heavy objection to the usual way is that the queen at once throws a foot upon one of the blades in the effort to push it away, and loses a foot in the process. The Doolittle way with a keen pen-knife is vastly safer, as well as being a good way otherwise. Whether the Byer method is splendid or bad depends partly upon whether the queen is, or is not, going to notice the thing enough to "put her foot in it." I hope she will not; but it needs lots of watching—and lots of examination of queens afterward—to be sure of it. Very desirable to obviate the scent of fingers which the Doolittle way puts on. I don't clip. If I did I think I should use wire forceps—made of such fine wire as frames are wired with. Loop on each tip sized and shaped like a bean. This wire, when doubled and twisted, is just stiff enough to hold the

queen, and just flexible enough that you can't pinch to injure her. Once in the forceps, you can focus her in your specs and proceed so deliberately that the danger of amputating feet and legs is minimized. Alas, she is so quick, and the human nerve-telegraph so slow, that the foot *may* go in just as the blades close by any scissors method—unless, possibly, by the method which uses a West cage and pulls a wing through the wires before cutting. Page 317.

## THE SAD MIX UP OF NAMES OF PLANTS.

Yes, Mr. Scholl, it's a sad nuisance that in the popular names of plants it so often happens that totally different plants have the same name in different localities. The sage of Texas is not, by a mile, the sage of California. The poplar of the South is about as different as you can well get from the poplar of the North—and so on around. Use the botanical names? Ah, yes—if only our jaw-bones would not break in the process—and if only the angels were white, and didn't have such big black spots on them! Botanical names pretty badly mixed, too. From the sheer vastness of Nature, the same plant innocently got two or more botanical names. Competent botanists worked, and worked hard and wide, and didn't always see each other's work in time. But mending the trouble, and getting down to one name, was a tedious affair not yet fully over. Also some duplicates were given *on purpose*. The big trees of California had to fight it out between Wellingtonia (biggest British general) and Washingtonia (biggest American president), and Sequoia (biggest Indian thinker), the last finally

winning because the other two stirred bad blood and killed each other off. And now an awful squabble seems coming on between those who want to keep the established genera about as they are, and those who want to split them up, and lug in a great lot of new names. We bee-folks have a right to speak feelingly (to pass from plants to creatures higher), for our bee is called both *Apis mellifera* and *Apis mellifica*; and the great bee is called both *Apis dorsala* and *Megapis dorsala*. Let us wait with patience. Millennium will get here finally. And meantime it does help *some* to use botanical names. Page 299.

#### BREEDING FOR NON-SWARMING BEES.

The San Antonio convention tried to get its eye on the non-swarming bee. Hardly had conspicuous success at it. Sad to relate, the bee that swarms more than usual is a great deal easier to obtain than the one that swarms less than usual. And where certain bees

seem to be non-swarming, it transpires that it was all in the conditions, not in the bees. Change the conditions and directly the bees swarm as badly as others. Still the rooster crows that some time in the geological ages of the future there will be a non-swarming bee. But complete control of drone-parentage will come first, I think, to help the thing along. I sometimes suspect that Nature's present bee is about as good at gathering honey as it ever will be, or ever *can* be. But non-swarming will give the breeders of the future something valuable to breed for. Page 309.

#### AGAINST SULPHURIC ACID FOR CLEANSING BEESWAX.

Certainly C. P. Dadant is qualified to protest against anything that injures beeswax—has used beeswax enough. We notice that he protests against the use of sulphuric acid as a dirt starter when rendering it. Page 306.

sections are sold with the honey, and you have more to buy each year, and new separators every 2 or 3 years. And the shipping-cases cost more than for bulk comb. It is much more trouble and time to pack it than to pack bulk comb, and much more apt to get broken up in shipping than bulk comb. And it takes double first-class freight-rate. Bulk comb honey takes fourth-class rate, less than one-half what it takes to ship section honey. Another great advantage in producing bulk comb honey is that we can get the bees to work in the supers much earlier than we can in sections, and they can get in larger clusters to get up heat sufficient to produce wax much better and faster than when they are cut up into so many departments. All bee-keepers that have tried both kinds will readily testify that they can produce from one-half to twice as much bulk comb as they can section honey.

The convention then adjourned to meet again at 1:30 p. m.

#### THIRD DAY—AFTERNOON SESSION.

Pres. Dadant—As the Resolutions Committee are not yet ready, we will proceed with the Question-Box.

#### WAGES OF APIARIAN HIRED HELP.

“What should we pay experienced hired help in the apiary?”

Dr. Bohrer—Let Dr. Phillips answer that question.

Dr. Phillips—We never hire help except by the year, and the work is entirely different from ordinary apiaries.

Mr. Jones—In our district it is hard to get competent help, and we pay all the way from \$15 to \$30 and \$35 per month, but it is mostly at these prices; but we don't get experienced labor.

Mr. Hyde—I think the part of the country in which we live has a good deal to do with that. I could not tell you what you should pay in Colorado or any State in the North, but I hire from 2 to 4 men each year during the summer season, and I have generally paid about \$30 down to \$18 for the best experienced men; but this would not apply in North Texas, as labor is worth twice as much as it is in this part of the State; but since I have been down here I have been paying \$30 for the best labor I get.

Mr. Victor—I have paid as high as \$40 per month for some of my help, and I don't know but that the \$40 help paid me as much as 2 men that did not know much about it. The balance of my help, I had rather they did not know much about it; but I want one experienced man, and I would like to have one man in charge of each apiary that knows what is to be done, and pay from 75 cents to \$1.00 a day for the labor, and from \$30 to \$40 for a man that knows how to do something.

Mr. Hyde—I aimed to make that explanation. The others I call helpers, and the apiaries are under the charge of that man.

Mr. France—I am a good ways from home, but experienced bee-keepers, I would infer from that; and it is a hard question, indeed, in our part of the country to get men that will work for some

#### Report of the 37th Annual Convention of the National Bee-Keepers' Association, held in San Antonio, Tex., Nov. 8-10, '06

(Continued from page 398)

#### HONEY FOR TEXAS PRODUCERS.

“What is the most profitable kind of honey for Texas bee-keepers to produce, bulk comb, section honey, or extracted?”

Mr. Hyde—Mr. President, I put that question in there. I want to hear the discussion of bulk comb honey before the Northern bee-keepers, not that we are expecting you to produce bulk comb honey because you have a *shorter* honey-flow, and it is quite different in this part of the country. We have long seasons, and the seasons are such that we don't find it profitable to produce section-honey. A few years ago, bulk comb honey was practically unknown. But today there is scarcely a bee-keeper in the United States that has not heard of it and how it is produced. It is now the principal product of South-west Texas, and is gaining foothold further North. The demand of the consumer for this article is rapidly growing, and is keeping far ahead of the production. There are many reasons why it is rapidly growing. The buyer feels sure that he is getting just as pure honey as if he were buying section honey; and that he is getting full weight; also that he has bought it at a less price than he could section honey. Then, he has it in a nice vessel where there is no waste nor leak-

age, and, when the honey is used up, he has a nice pail left that is handy in any kitchen. The above will apply to the majority of buyers. Of course, there are some that will always buy section honey because it looks nicer to them. The most delightful sight to nine-tenths of the buyers, is a nice pail of bulk comb honey, with just enough clear, sweet, extracted honey poured over it to cover it and to make it juicy. Bulk comb honey is mostly produced in the Ideal super. There are some bee-keepers that still use the full bodies for bulk comb, but we feel sure it is because they have never used the Ideal, which is lighter to handle; nearer the right amount of room to give a colony at one time; and last, but not least, easier to get rid of the bees. Take off the cover, give them a few puffs of smoke, pry up the super, bounce it on the hive lightly, and most of the bees will fall off. Then pile them up in a pile, smoke them at the bottom, and in a few minutes all of the remaining bees will leave. In that way you have no handling nor brushing of bees. The Ideal frames are handier for extracted, and if you will use a No. 17 Cowan Extractor, you can extract 4 frames at once. We pack bulk comb honey by cutting it out of the frame; then place it nicely in cans and fill the can full. Then pour in extracted honey to fill the crevices. In this way about one-third is extracted honey. Now as to the relative cost of bulk and comb honey. You buy supers and frames for bulk comb once for all time to come. When you buy supers for sections, the

# American Bee Journal

one else. Most of them want to work for themselves in our country, and I have to take the other side of it, and use their hands and my ability. We can not get experienced bee-keepers—they all want to work for themselves.

Dr. Bohrer—Well, you have to pay for such as you do get, don't you?

Mr. France—I have had students for several years, who attend our State Normal School, and during the vacation I can get them at reduced prices, paying about 80 cents to \$1.00 a day and their board; but if I have to go outside

of that class of labor I have to pay more. The man who is living across the road from me has charge of the extracting and casing. He goes with me from one apiary to the other; he does the handling of the machinery, etc. I give him \$2.00 a day and his dinner; but he extracts about 4,000 pounds a day, and rides 6 or 8 miles a day. It has been suggested that the Information Bureau ask for such bee-keepers, so if you know of any, let it be known.

Pres. Dadant—We will now hear from the Committee on Resolutions.

(Continued next week.)

same time, if there is a strong prejudice among your neighbors against having sweet clover on the roadside—a prejudice which is by no means uncommon—I think I would not sow any seed except on my own land. After your neighbors learn that you can utilize sweet clover for pasture and hay, their prejudice may be overcome.

3. As generally used, the word "bee-keeper" applies to any one who owns bees, whether a single colony or a thousand. It would perhaps be better to limit the word to designate one who takes care of bees with some degree of skill, the number of colonies having little or nothing to do in the case. An amateur bee-keeper is one who keeps bees largely for the pleasure of it, no matter how many colonies he has.

## Rearing Queens for Home Use

1. I will probably need 10 to 20 queens this summer. To buy them is rather expensive, and to wait for the bees to swarm is too late; besides, I don't want them to swarm if I can help it. Some think good queens can not be reared in a queenless colony. What is your opinion?

2. Would the following plan be profitable? Divide a colony according to the Alexander plan, put the queen in the lower and the brood in the upper story, then place a honey-board between to get cells started.

3. How long would it be necessary to let the honey-board remain to get cells started?

4. Is it likely that the bees would destroy the cells after the honey-board was removed if a queen-excluder were put on?

5. Is there danger that the bees would swarm if the cells were left until sealed?

6. Wouldn't the cells be as well off in a 2 or 3 frame nucleus after they were sealed as in a full colony? IOWA.

ANSWERS.—1. Rightly managed, I believe as good queens as any in the world can be reared in a queenless colony.

2. Your plan will work if there is a strong force of bees in the upper story, but it isn't the best way. If I understand you correctly, a board cuts off all communication between the lower and upper story, and, with no nectar coming in, the bees will be to some extent in a discouraged condition. Better take a little more trouble and have the very best queens obtainable.

3. Probably 2 days will be long enough.

4. Sometimes they would. There is more danger of it with an energetic young queen than with an older one. The best is to have in the hive below a queen that the bees are about to supersede.

5. No, cells in the upper story over an excluder will not cause the colony below to swarm.

6. Probably they generally would; but if a cold spell should come they would be better off in a full colony. There is no particular object in putting them in nuclei as soon as they are sealed, for any number can be put in an upper story over an excluder, and they are quite safe there until about 10 days after the colony was made queenless in which the cells were started, and having the cells in the upper story doesn't hinder the working of the colony below, unless they are working in sections. Better keep the cells in a full colony just as long as you can. The matter of good queens is so important that it pays to give them the best chance possible. About the only place in which it pays to economize is in the place where the young queen has to wait to be fertilized and to begin laying. A nucleus will do for that perhaps just as well as a full colony.

## Amerikanische Bienenzucht,

by Hans Buschbauer, is a bee-keeper's handbook of 138 pages, which is just what our German friends will want. It is fully illustrated, and neatly bound in cloth. Price, postpaid, \$1.00; or with the American Bee Journal one year—both for \$1.75. Address all orders to this office.

Send Questions either to the office of the American Bee Journal, or to  
DR. C. C. MILLER, Marengo, Ill.  
Dr. Miller does not answer Questions by mail.

## Wintering Bees in Danzenbaker Hives, Etc.

I use the Danzenbaker hive and winter my bees on the summer stands. I expect to get some shallow Danzenbaker frames filled with buckwheat honey. Then when I pack the bees for winter I want to give each colony some of these frames in a super.

1. Would I have to give them a full super, or could I just as well hang 3 or 4 frames in the center and leave the rest of the super empty?

2. Would that extra space to keep warm be more of a detriment than the honey would be a help?

3. Would I still have to put a super of packing on top of all, or could I pack on each side of the 3 or 4 frames of honey?

4. If so, how should I do it?

5. Would it be better to put the super of filled shallow frames, whether 3 or 4 or a full super, under the brood chamber, and let the bees take it up as needed?

6. If I did this, should my outer winter-case come clear to the bottom of all, or just to the bottom of brood-body?

7. To make it still better, if they were your bees, what would you do different from any of these suggestions?

8. I am giving my bottom-boards, super-covers and escape-boards 2 heavy coats of paint all over top and bottom. Is this a good plan?

9. What is the best foundation-fastener one can get for full sheets or for full sheets and bottom-starters in sections?

10. How high from the ground is it best to have the hives? We have quite a bit of wind here, but not strong enough to blow a hive over.  
PENNSYLVANIA.

ANSWERS.—1. You can do either way.

2. That depends. With a colony none too strong and abundant honey in the brood-chamber, it might be more of a detriment. With a rousing colony and a bare possibility that the stores in the brood chamber might run out, it would be an excellent precautionary measure.

3. You could pack on each side.

4. On each side of the frames of honey put a dummy, having spacers either on the frames or on the dummies so that there would be no danger in packing a dummy might be crowded up too close to the honey; and then

pack each side just as you would pack an empty super.

5. I don't know. I'm not sure but it would; only in that case you must be careful you don't start robbing when the under story is first given.

6. Not very material; but it would be a little better to come clear down.

7. I'm not sure I've anything better to suggest, unless it would be to have the honey stored in frames the same size as those in the brood chamber, and then have all the honey in the brood-chamber.

8. Yes.

9. I suppose you mean for fastening foundation in sections. Perhaps you can have nothing better than the Daisy fastener.

10. That depends somewhat upon location. In some places in the South, hives must be stilted up to keep ants out. In this locality, and probably in your locality, no such necessity exists, and it is better to have the hives merely raised enough so they will not suffer from the moisture of the ground, the bottom of the hive being 3 to 6 inches above the ground. That makes it more convenient for any returning bees that drop on the ground in front of the hive, and it is also more convenient for the bee-keeper to sit beside the hive.

## Taxing Bees—Sowing Sweet Clover Seed—Number of Colonies to be a Bee-Keeper

1. Are bees assessable? Does a man have to pay taxes on them after he gets a certain number of colonies? A man here said they were taxable, and I seem to remember seeing in the American Bee Journal that they were not.

2. Can one be prosecuted for sowing sweet clover along the country road?

3. About how many colonies of bees must one have to be a bee-keeper—not an amateur bee-keeper?  
MISSOURI.

ANSWERS.—1. In Illinois they are assessable the same as any other property, whether one has 1000 colonies or only a single colony. Why should it not be so? I don't know whether the law is any different in Missouri.

2. I never heard of any law that would make such sowing a criminal offense. At the

## Reports and Experiences

### Bees Doing Well

I have 68 colonies of bees, spring count, doing well. Our honey comes from alfalfa and sweet clover. I run my apiary for extracted honey, which sells at 6 cents per pound here.

I could not get along without the American Bee Journal. JOHN MILLS.  
Hagerman, Ida., April 25.

### Baby Nuclei for Queen Mating

On page 329, the subject of baby nuclei is spoken of which prompts me to give my experience in trying to get young queens fertilized in such quarters.

In 1905 I made a number of baby nuclei, each to hold 3 one-pound sections, making them double, with entrance at opposite ends. But one season's use satisfied me that they were entirely useless for the purpose intended. Even virgin queens seemed to realize that such cramped quarters were no place to build a strong colony, and the few that did become fertilized, unless removed at once, would fill the empty cells with eggs, and the little colony would desert their contemptible quarters.

One in particular gave me considerable trouble. A large swarm issued that had a clipped queen, and a fertilized queen from a baby nucleus came out at the same time and took the swarm to the top of a tall apple-tree. It does not matter how high a swarm settles if they have no queen, for like Crockett's coon, they have to "come down."

I am not afraid of virgin queens with a first swarm, for the bees will ball them, and it is an easy matter to find the young queen in a

cluster of angry bees on the ground directly under the clustered swarm.

My present plan is to use not less than 3 of my standard brood-combs (which have a 14-inch top-bar) to each nucleus. My nucleus hives hold from 4 to 6 such frames, and if at any time orders for queens are slack, I remove the division-board and add such comb or combs as may be needed, and keep my queens at work.

W. J. DAVIS, 1st.  
Warren Co., Pa., April 23.

### Not An Encouraging Prospect

My bees have not wintered so well as usual. I lost one colony out of 27; two I found queenless, and thieves entered my yard and carried off one. The prospect for bees this spring is very poor. Frost has killed nearly all fruit-buds, and high winds and cold waves are common this spring. Snow—yes, we are getting some of that, too. April 18 we had about 3 inches on the level, and this morning about 1½ inches, so you see the prospects are not what they might be. Well, it's no use to grumble over spilled milk. My bees are well provided with honey yet, and I have about 200 pounds of sealed honey in brood-frames to build them up for the honey-harvest, which, as a general thing, starts the latter part of June.

HENRY HANSEN.  
Ashton, Nebr., April 25.

### "The Judgment" as Seen In a Bee-Keeper's Dream

I had a strange dream last night. I thought I stood by the gate which St. Peter is supposed to guard, watching the throng passing through. It seemed to be "Bee-keepers' Day," for I recognized many of them by the pictures that have become so familiar to readers of the bee-papers. Occasionally one was "turned down," but the most of them went through without question.

Soon my attention was attracted to a rather important-looking shade who was pushing and crowding his way rapidly along. He

crowded in front of A. I. Root, who meekly stepped to one side, pushed in between Dr. Miller and Doolittle, and was slipping through in the wake of big, good-natured Scholl, when St. Peter stopped him. He looked surprised, and haughtily said, "I'm a bee-keeper!"

"Yes, yes," said St. Peter, "that's all right; but there is something more needed here. What have you ever done to entitle you to a seat inside?"

"Why," replied the important one, "I have been the means of saving thousands of bee-keepers from perdition."

"So! so! In what way?" asked St. Peter. "Well, I discovered a secret that, if published, would have made millionaires of all the bee-keepers that knew of it; and you know it is almost impossible for a rich man to enter into the Kingdom of Heaven."

"Strange," said St. Peter. "I never heard of this. What might be your name?"

"My name is Davenport!"

Just at this juncture I awoke, but not before I saw a frown gather on St. Peter's brow that I imagined hoded no good for our secretive friend.

E. J. GILLETT.  
Mexico, N. Y.

### Winter and Spring Hard on Bees

A friend whose bees I had charge of last spring would not put any expense on them, so he did not feed them last fall. They were very light in honey. The open winter we have had in Iowa was hard on bees wintered on the summer-stands. Out of 35 or 40 colonies, fall count, only 10 were alive this spring. The 3 colonies I had in the cellar were all right in January, but my wife has been very sick with typhoid fever, and I could not take the bees out in March as I should have done, so all 3 are dead, although they had plenty of stores. The cellar was quite damp and the air foul, which I think was the principal cause of their dying.

I will not give up bee-keeping because I am out of bees, for I now have 10 empty hives and enough supplies to last a year. I expect to use them the coming season. I have taken 4 colonies on shares about 2 miles from where I live, and have had 2 colonies given me that I will keep here.

This month has been a hard one on bees. Last month was so warm that brood-rearing was pretty well started, and this month has been so very cold, with extreme changes.

(REV.) J. W. STINE.  
Durham, Iowa, April 15.

### Managing Weak Colonies—Last Year's Crop

Alexander's plan for weak colonies was a complete success with me in 3 cases last spring. I think the best plan in dividing them when they become strong is to move the bottom hive just half its width to one side, and set the top hive close up to the side. This really makes one hive of them with a wide entrance, and each one catches its share of bees. After a day or two they can be moved apart.

I got about \$40 worth of honey from 18 colonies, last season, and increased to 23 colonies.

E. J. GILLETT.  
Mexico, N. Y.

### Lost 4 Out of 6 Colonies

I put 6 colonies of bees into the cellar last fall, and have had rather bad luck as I took only 2 colonies out alive this spring.

I must have the American Bee Journal as long as I have a single colony.

M. O. ROCKWOOD.  
Osage, Iowa, April 16.

## THE AMERICAN FOOD LABORATORY

E. N. EATON, M.Sc., Chemist.  
4 years State Chemist, Minnesota.

# HOW TO PAINT

Buggies, farm wagons, farming tools, barns, outbuildings and houses often need painting. "Everybody's Paint Book," written by a thoroughly practical painter, will be found a complete guide to the art of outdoor and indoor painting. It is designed for the special use of those who wish to do their own painting. It gives practical lessons in plain painting, varnishing, polishing, staining, paper hanging, kalsomining, etc.

It also tells how to renovate furniture and gives many hints on artistic work for decorating a home. Precise directions are given for mixing paints for all purposes.

If farming tools and farm vehicles are kept painted, they will last twice as long, and anybody can do the work with the aid of this book. It is handsomely and substantially bound in cloth. A copy will be sent postage prepaid on receipt of price, **\$1.00**

## SPECIAL OFFERS

For \$1.60 we will send the above book and the Weekly American Bee Journal one year; or for \$1.40 we will send the Paint book and a Standard-Bred Untested Italian Queen. Address

GEORGE W. YORK & CO., 118 W. Jackson Blvd., Chicago, Ill.

## Bee-Hives, Sections

### WHY BUY OF US?

Remus, Mich., Feb. 25, 1907.

A. G. Woodman, Grand Rapids, Mich.

Dear Sir:—I use Lewis Sections exclusively; there are none better—the only perfect "V"-cut section that has come to my notice. They fold without moistening.

E. D. TOWNSEND.

Remus, Mich., Feb. 18, 1907.

The Lewis Hive-Bodies are far superior, both in material and workmanship, to any I ever bought.

As ever yours,  
E. D. TOWNSEND.

Beeswax Wanted. Advanced Bee-Veil, cord arrangement. Silk face, 50 cents, postpaid.

**A. G. WOODMAN CO.** Grand Rapids Mich.

**American Bee Journal  
Novelty Pocket-Knife  
Gold Fountain Pen**

All for **\$3.00**

(This cut is the full size of the Knife.)

**NOVELTY POCKET-KNIFE**

(Name and Address on one side—Three Bees on the other side.)

Your Name on the Knife.—When ordering, be sure to say just what name and address you wish put on the Knife.

The Novelty Knife is indeed a novelty. The novelty lies in the handle. It is made beautifully of indestructible celluloid, which is as transparent as glass. Underneath the celluloid, on one side of the handle is placed the name and residence of the owner, and on the other side pictures of a Queen, Drone, and Worker, as shown here.

The Material entering into this celebrated knife is of the very best quality; the blades are hand-forged out of the very finest English razor-steel, and we warrant every blade. It will last a life-time, with proper usage.

Why Own the Novelty Knife?—In case a good knife is lost, the chances are the owner will never recover it; but if the "Novelty" is lost, having name and address of owner, the finder will return it. If traveling, and you meet with a serious accident, and are so fortunate as to have one of the "Novelties," your POCKET-KNIFE will serve as an identifier; and, in case of death, your relatives will at once be notified of the accident.

How to Get this Valuable Knife.—We send it postpaid for \$1.25, or club the Novelty Knife and the American Bee Journal for one year—both for \$2.00. (Allow two weeks for Knife order to be filled.)

**SOLID GOLD FOUNTAIN PEN**

Finally we have found a good Fountain Pen that is reasonable in price. The manufacturers of this pen say that if you pay more than \$1.25 for other fountain pens, it's for the name.

This pen is absolutely guaranteed to work perfectly, and give satisfaction. The Gold Nibs are 14 kt., pointed with selected Iridium. The Holders are Para Rubber, handsomely finished. The simple feeder gives a uniform flow of ink. Each pen is packed in a neat box, with directions and Filler.

Worker

Queen

Drone

$\frac{3}{8}$  size

We mail this Gold Fountain Pen for only \$1.25, or for \$2.00 we will mail it and the weekly American Bee Journal for a whole year.

Sample copy of the American Bee Journal free; trial trip of three months (13 copies) for 20c; regular yearly price, \$1.00. Address all orders to

"The continuous advertiser gets the bulk of the business, because others are not advertising, and he is."

## Something New = The Ideal Hive-Tool

Bee-keepers have long needed a special Tool to work among the hives during the bee-season. The one shown here was invented by Wm. Muench, a Minnesota bee-keeper, some years ago, but it was not on the market before. We have lately bought this Tool, and all rights, from Mr. Muench's widow, and have had the first lot made. They are ready for delivery now.

Best Hive-Tool

Only 30c, by mail

(This picture is exactly one-half the size.)

DESCRIPTION.—The Ideal Hive-Tool is made of high-grade malleable iron, much like wrought iron, 8¼ inches long. The middle part is 1 1-16 inches wide and 7-32 thick. The smaller end is 1¼ inches long, ½ inch wide, and 7-32 thick, ending like a screw-driver. The larger end is wedge-shaped, having a sharp semi-circular edge, making it almost perfect for prying up covers, supers, etc., as it does not mar the wood.

What Dr. Miller and Miss Wilson Say of It:

In the first edition (1903) of Dr. Miller's "Forty Years Among the Bees," page 58, he says: "Of all the hive-tools I have tried, I like best the Muench tool." On Jan. 7, 1907, he wrote us saying he thought "just as much of the tool as ever."

Miss Wilson, Dr. Miller's assistant, says this of the Ideal Hive-Tool: "It is an ideal tool. In fact, I don't see how it could be improved upon. I am sure we would feel utterly lost in the apiary without it. . . . You will have to try one yourself if you want to know its worth."

**The "Ideal Hive-Tool" Free as a Premium.**

We will mail an **Ideal Hive-Tool FREE** as a premium to any present paid-in-advance subscriber to the American Bee Journal, for sending us **ONE NEW** subscription for a year at \$1.00; or we will send the American Bee Journal one year and the **Ideal Hive-Tool**—both for \$1.20. Price of the **Ideal Hive-Tool** alone, postpaid, 30 cents. Address,

GEORGE W. YORK & CO.,

CHICAGO, ILL.

# BEE-SUPPLIES

PERFECT GOODS LOW PRICES  
A Customer Once, a Customer Always.

Now is the time for you to buy your Bee-Supplies. We manufacture Bee-Hives of all kinds. The Dovetail, Langstroth, Alternating, and the Massie Hives, we make all of them. Remember that half the work and worry of your apiary is removed when you use our goods. Every one knows the advantage of a good, substantial hive; the quality of material and workmanship in our hives are not excelled by any other make.

We have been in the business over 40 years, and know what is practical, and when you once give our goods a trial you will have none other. Remember that now is the time to get your order in for the season's supplies. Have you received our new 1907 Catalog? If not, write for it at once. You cannot fail to understand how to order just what you want from our Catalog, it is the easiest to understand that you ever saw.

No trouble to give estimates; tell us what you want.

are made every year in the book business. Every family, rich or poor, must have books. During the last few years, \$7,500,000.00 have been expended for Modern Elegance, \$12,000,000.00 for Stoddard's Lectures, \$21,000,000.00 for the Century Dictionary, and the tremendous sum of \$41,000,000.00, covering over half a million sets of the Encyclopaedia Britannica. These books were sold by subscription in American homes and sales are still going on.

We have a subscription publication which sells more readily than any of the above. The demand is already so tremendous that more capital is required to swing it, or get behind on orders. Profits are enormous, several times savings bank interest.

We have arranged a plan whereby **Any Progressive Man or Woman Can Share These Profits**

becoming stockholders in a profitable business, based on twenty years' experience. Remember, the success of this publication is not away off in the future—it is not prospective, but it is a success at the present time and growing in demand every hour. Sales of this publication at the time of publishing this advertisement

**Often Exceed \$2000 a Day**

This is an exceptional opportunity for those of small means to get in on the ground floor in a business which legitimately pays large dividends and is as solid as the Rock of Gibraltar. It cannot be held open for long as the response is certain to be so great that we shall have all the capital we need to increase the number of our presses and secure stock to be turned out in completed books, which are selling like wildfire.

You owe it to yourself to investigate this opportunity. You will never have a chance like this again to become

**Part Owner in a Mammoth Publishing House**

which is already in successful operation, already earning big dividends, and which is led to sell a small amount of its stock simply because the business is already so tremendous as to exhaust the working capital. But if you would grasp this opportunity you must

**Write Quick—Only a Few Can Come In**

Carloads of the famous Lewis Beeware now ready for you at Indianapolis, one of the greatest shipping centers in the United States.

Can be shipped you at the drop of the hat.

10 different counties voice the sentiment of the State.

## Promptness! Quality! Reliability!

THE C. M. SCOTT CO., Indianapolis, Ind.

*Gentlemen:*—I have bought Lewis Company's bee-supplies for the last 25 years. In the last 7 years, since you had an agency for them, I have bought them from you and have found you honest to the cent. Your sections can't be beat.  
White Co. Yours truly,  
W. H. WHITCHER.

THE C. M. SCOTT CO., Indianapolis, Ind.

*Gentlemen:*—All bee-keepers' supplies I ordered from you in past years were all first-class goods, nicely packed, and promptly shipped. I am yours for future patronage.  
Green Co. W. M. DAUBENSPECK.

THE C. M. SCOTT CO., Indianapolis, Ind.

*Gentlemen:*—Having done business with you some time, I can not say anything but good words in regard to your plan of doing business. I will look upon it as my duty, also an honor, to do all I can to advance your interests.  
Vigo Co. Yours truly,  
E. E. REED.

THE C. M. SCOTT CO., Indianapolis, Ind.

*Gentlemen:*—I have always found supplies from you to be perfect in every respect, and as good as can be bought. My orders have always been promptly filled, goods well packed and in first-class condition.  
White Co. Yours truly,  
IRA CLAPPER.

THE C. M. SCOTT CO., Indianapolis, Ind.

*Gentlemen:*—For the last three years I have used your bee-supplies, and find them as you recommend them. I never had dealings with a fairer firm for prompt shipments and honesty.  
Sullivan Co. Yours truly,  
JOEL C. BARNES.

THE C. M. SCOTT CO., Indianapolis, Ind.

*Gentlemen:*—Upon dealing with you I have always found you prompt in shipping, and the goods are just as you recommend them to be. I never have had a mistake to rectify in my dealings with you.  
Fulton Co. Yours truly,  
WM. BAUMANN.

THE C. M. SCOTT CO., Indianapolis, Ind.

*Gentlemen:*—Having purchased bee-supplies from you for three or four years, would say that I have found the goods as advertised. Everything full count, boxed and shipped promptly.  
Park Co. Yours truly,  
DEMPSEY SEYBOLD

THE C. M. SCOTT CO., Indianapolis, Ind.

*Gentlemen:*—The orders for bee-keepers' supplies I have placed with you have been given prompt attention. Goods came securely and carefully packed and in good condition. The goods are durable and have given perfect satisfaction in every way. I can cheerfully recommend you to any one wishing anything in your line. Wishing you continued success, I am  
Posey Co. Yours truly,  
W. O. KLOTZ.

THE C. M. SCOTT CO., Indianapolis, Ind.

*Gentlemen:*—I have been using G. B. Lewis Co. bee hives and fixtures for the past 20 years, and have always found their goods very satisfactory. I have been dealing with you ever since you commenced selling Lewis Goods, and have always found you honest and upright.  
Montgomery Co. Yours truly,  
J. E. COEN.

THE C. M. SCOTT CO., Indianapolis, Ind.

*Gentlemen:*—I have had dealings with the C. M. Scott Co., jobbers and dealers in bee-keepers' supplies, for several years. I find them prompt, and in packing and shipping my orders they surely have my thanks.  
Wishing them good success, I am  
Tippecanoe Co. Yours truly,  
ISAAC E. WINDLE.

THE C. M. SCOTT CO., Indianapolis, Ind.

*Gentlemen:*—I will say that the sections and bee-supplies I got from you are the best I ever received, and when you make an error you will correct it. I am in the business forty-five years, and got supplies from different firms and none compare with yourselves.  
Allen Co. Yours truly,  
M. J. KISTLER.

**A GREAT IMPROVEMENT**

Will be found in

The  
**American Bee- Keeper  
for 1907**

It is profusely illustrated and enlarged, and contains only articles of the most practical as well as scientific nature. A special corps of the best writers has been engaged. The editors are Harry E. Hill and Arthur C. Miller, than whom there are no more practical or experienced bee-keepers in this country. We have published the American Bee-Keeper continually and regularly since 1890.

Regular subscription price, 50 cents a year. One year to new subscribers, 35 cents; three years for \$1.00.

Send for sample copy and our new illustrated price-list of **BEE-SUPPLIES OF ALL KINDS.**

Guaranteed highest quality at lowest price. Address,

**THE W. T. FALCONER MFG. CO.**  
JAMESTOWN, N. Y.

[Established 25 years.]

**Honey and  
Beeswax**

CHICAGO, May 9.—Very little honey on the market of any kind. Prices are therefore nominal. A little choice white clover comb sold at 17c, and would bring that at present, but supply seems to be exhausted; even with this scarcity there is no demand for No. 2 grades. Extracted, white, 7@8c; amber, 6@7c. Beeswax in good demand at 32c. R. A. BURNETT & CO.

CINCINNATI, April 16.—There is nothing new in the honey market, excepting that this part of the country is bare of comb honey, and it is well, for consumers will appreciate the new crop more when it arrives. We are selling extracted amber honey in barrels at 5 1/2 @ 6 1/2c. Fancy table honey, 8 1/2c @ 9c, in crates of two 60-pound cans. For choice yellow beeswax, free from dirt, 32c cash, delivered here.  
THE FRED W. MUTH CO.

PHILADELPHIA, April 25.—The comb honey market, on account of the lateness of the season, has grown just a little weaker in the last 10 days, although extracted honey is kept very firm. We think, however, there will be comparatively little comb honey carried over except in very small lots. We quote: Fancy comb honey, 14@15c; No. 1, 13@14c; amber, 12@13c. Fancy extracted honey, 7@8c; light amber, 6@7c. Beeswax firm, 32c.  
We are producers of honey and do not handle on commission. W. M. A. SELSER.

NEW YORK, April 12.—COMB HONEY.—There is very little doing; stock of white honey of all grades is practically cleaned up, and small shipments which arrive from time to time, find ready sale at 14@15c for choice white stock, and 12@13c for off grades. Considerable dark comb honey is left on the market, and there does not seem to be any demand whatsoever. We quote nominally at 10@11c, but in large lots we doubt whether this price can be realized. EXTRACTED HONEY.—California stock seems to be well cleaned up, and we are informed that there is very little left on the Coast, and, before the new crop is marketed, whatever is on the market now will have been consumed. The prospects in California are very good for a large crop, but nothing definite can be said at this time, and there is no surety of a big crop until it is actually gathered. Last season the outlook was just as good, but in the height of the season, cold northern winds and generally contrary weather affected the crop to such an extent that it was small as in previous years. With favorable

Office and Salesrooms, 2146-48 Central Ave. Warehouses, Freeman and Central Aves.

weather in California for the next two months a large crop will undoubtedly be harvested, and if so prices will naturally be considerably lower than those of the past season and present prices. We quote white sage at from 7@9c, and light amber at from 7@7 1/2c. Near-by, as well as Southern honey, is well cleaned up, and the markets are in good shape for new crop. Cuban and other West Indian honeys are arriving in large quantities, most of which are sold for export. The market is firm, at from 58@60c per gallon, duty paid according to quality. Beeswax firm and steady at from 30@31c.  
HILDRETH & SEGELKEN.

INDIANAPOLIS, April 12.—comb honey is not plentiful, but demand is slack. Fancy white comb brings 16@17c; No. 1 white, 14c; amber, 12@13c. Best grades of extracted honey bring 8@9c; amber, 6@7c. Good average beeswax sells here at \$35 per 100 pounds.  
WALTER S. POWDER.

TOLEDO, May 3.—There is very little demand for comb honey as is usually the case at this season of the year. Fancy white would bring in a retail way 16@17c; No. 1, 15@16c, with no demand for dark honey. Extracted is very scarce and none being offered for sale. Beeswax is bringing 28c.  
THE GRIGGS BROS. & NICHOLS CO.

KANSAS CITY, May 4.—Receipts of comb and extracted honey are light; in fact, the market is almost bare. The demand for comb honey is good, but for extracted is rather light. We quote: No. 1 white comb, 24 sections, \$3.25; No. 2, \$2.75; No. 2 amber, \$2.50 to \$2.75. Extracted, white, 8@9c; amber, 7@8c. Beeswax, 50c.  
C. C. CLEMONS & CO.

DENVER, Feb. 14.—Producers in this State are practically closed out of both comb and extracted honey. We have not sufficient good comb honey to supply our local trade, but have a good supply of white extracted of excellent quality. We quote strictly No. 1 white comb honey, per case of 24 sections, at \$3.20; No. 1, light amber, \$3; and good No. 2, \$2.80. White extracted, 8@8 1/2c per pound; light amber, 7 1/2@8c. Clean, yellow beeswax, 27@28c, delivered here.  
THE COLO. HONEY-PRODUCERS' ASSN.

CINCINNATI, April 3.—The market on honey is entirely bare of fancy comb honey; No. 2, selling at 12 1/2c, and slow sales. Light amber extracted sells in barrels at 5 1/2@6c. Beeswax 32c, delivered here.  
C. H. W. WEBER.

# DADANT'S FOUNDATION

## IT EXCELS

Ask any dealer who handles our make along with any other and he will say, "Of course, Dadant's is the best."

Ask a bee-keeper who has used our make and he will tell you the same thing. WHY? Because we make the manufacture of foundation OUR SPECIALTY. We devote our time and energies to making **THE VERY BEST COMB FOUNDATION THAT CAN BE MADE.**

For 27 years we have led in the manufacture of this article. Don't experiment with a new make. Insist on Dadant's—get Dadant's and you will have the best. It will cost you no more than any other.

### WORKING BEESWAX

We work beeswax into Comb Foundation for the bee-keeper direct. Send for our prices and Catalog. Remember you take **NO CHANCES** when you get our foundation. We absolutely **GUARANTEE SATISFACTION IN EVERY WAY.** Agents for our foundation everywhere.

Early order discounts on all kinds of goods for the bee-keeper.

**DADANT & SONS, Hamilton, Ill.**

# Marshfield Bee-Goods

talk for themselves; having bought once, you will buy again. Our orders show that. The reason for this is that nothing is used in the making of our **BEE-GOODS** that we know is not fit to go in. Why should we when we have plenty of the best as it comes direct from the forest to our mill and factory.

**SECTIONS** are made of the basswood timber, grown here in the basswood belt of Wisconsin.

**DOVETAILED HIVES**, of lumber almost clear, made accurate and smooth.

**SHIPPING-CASES**, strong and neat—nothing flimsy about them.

### SHIPPING FACILITIES THE BEST

You will get your orders sent on very short time, as we are located on three direct railroads to Chicago there connecting with the trunk lines for the East, South, and Southwest, and some parts of the West. The West by way of St. Paul and Minneapolis.

If you have not yet received our Catalog of **BEE-SUPPLIES** for 1907, just write for it.

**National Bee-Keepers' Association**  
Objects of the Association.

- 1st.—To promote the interests of its members.
- 2d.—To protect and defend its members in their awful rights.
- 3d.—To enforce laws against the adulteration of honey.

Annual Membership Dues, \$1.00.

General Manager and Treasurer—  
N. E. FRANCE, Platteville, Wis.

If more convenient, Dues may be sent to the publishers of the American Bee Journal.

**Bee-Keepers' Souvenir Cards**  
are just the thing.  
**We send them by Return Mail**

As most of our readers know, we have got tenout a Souvenir Postal Card for bee-keepers. The cuts herewith show the card in reduced size, and but one color, while the real card is printed in 4 colors. It could also be sent to honey-customers, to remind them that it is time to buy more honey, etc. There are many uses to which this Card can be put.

Prices—postpaid: 3 cards for 10c (stamps 2 silver), or 5 FREE with the American Bee Journal one year at \$1.00; 10 for 25c. There is a blank space on the card about 2x2 1/2 inches in size for writing. Send all orders to

**GEORGE W. YORK & CO.**

## Trade Notes The A. I. Root Company, Medina, Ohio

### THE HATCH WAX-PRESS

If you have been so unfortunate as to lose some of your bees the past winter, or even this spring, save the wax in the combs by the use of some good wax-press. If you look about you will probably find a lot of old combs in your neighborhood which you can get for a song. Wax is higher now than for many years and you should hurry it to market, for the present high prices will likely continue but a few weeks, at most. Our new Hatch Press has several valuable features, viz :

- Durability.
- Ease of operation.
- Most thorough in its work.
- Superior quality of product.
- Low cost. Price is only \$6.00.

### WANTED

If you know of any one who has bees to sell this month, we can probably find a purchaser for the same—any number—5 to 100 colonies—provided we are given a brief, explicit description at once. Please state condition, hives, race, price, etc.

### BEE SWAX

We are paying at this date 31 cents cash or 33 cents in trade for pure, average beeswax, delivered at any of the following offices: Medina, Ohio; Chicago, New York, Philadelphia, or Washington. A large number of our jobbing agents make the same prices. See list of dealers in American Bee Journal for May 2.

### BEE-HIVE PAINT

We are distributing agents for the B. P. S. Paint. This is one of the best hive-paints to be found on the market. We have handled it for 10 years or more, and do not recall a complaint in all that time. Equally good for your house or any indoor or outdoor work. Weship the O. W. (Outside White) from

any of our offices; and the colors from Medina, New York, and Chicago. Send for color cards, etc.

### SPECIAL

For the next 10 days from date of this paper, to test the value of these columns, we offer a copy of the book, "How to Keep Bees," price, \$1.10, for only 60 cents, postpaid. Furthermore, we will promptly refund the money to any dissatisfied purchaser, even after you have read the entire book. You must send your order for this to Medina, and mention the American Bee Journal of this date.

### LESSONS IN BEE-KEEPING BY MAIL

There is now, and has been for years, a greater demand for experienced bee-help than there are men ready for these places. Each winter and spring we are obliged to disappoint many large apiarists by telling them we do not know where suitable help can be found. The demand has already begun for the present season. We have found that many who take our course in bee-culture by correspondence prefer to go into business for themselves, so we still need active young men who have a fair knowledge of the subject—men whom we know something about—who can be recommended for the places frequently offered. We, therefore, offer again a limited course in

#### BEE-KEEPING BY MAIL.

We shall designate this as Course No. 2. The lessons are identical with the lessons in Course No. 1. The time, however, is limited to one year from enrollment. The course may be easily completed in 3 to 4 months. The following is the

#### OUTLINE OF COURSE No. 2. (17 Lessons.)

- I. Definitions of Terms.
- II. Inmates of the Hive.
- III. Comb.
- IV. Handling Bees.
- V. Transferring.

- VI. Building Up Colonies.
- VII. The Honey-flow.
- VIII. Swarming.
- IX. Rendering Normal.
- X. Preparing for Winter.
- XI. Wintering.
- XII. Spring Management.
- XIII. Bee-Diseases, Symptoms.
- XIV. Enemies of Bees.
- XV. Establishing an Apiary.
- XVI. Queen-Rearing.
- XVII. General Examination.

#### TERMS OF COURSE—FULL CASH PAYMENT.

Complete course as outlined, lessons, personal answers to all questions, including the A B C of Bee Culture (500-page book), and Gleanings in Bee Culture (semi-monthly) for one year, \$5.00.

With either the A B C or Gleanings omitted in case you have one, \$4.00.

With both omitted in case you have both, \$3.00.

#### USE THIS FORM IN ORDERING.

Vol. XLVII—No. 21

### The Banat Bee

The editor of the Far-Western Bee-Keeper had a Banat queen sent him by Prof. Frank Benton. He reports Banatians as gentle as Caucasians, extremely prolific, but falling far behind other bees as storers.

### Composition of Pollen

An Illinois reader asks: "What is the average composition of pollen?"

We don't remember ever to have seen an analysis of pollen, and a search in some of the books in which we thought it might be found has not been successful. The likelihood is that if an exact analysis were made of pollen from different sources there would be found no little difference. The word "pollen," too, is used for two different things—pollen as it is found in the flowers, and also as it is found in the hive. The latter consists of the former mixed with some honey, if we are not mistaken.

### Ventilation of Bees

The generally accepted belief is that there is a systematic ventilation of the hive by the bees in hot weather, a regular detail acting in concert for that purpose. In a somewhat lengthy article in the British Bee Journal, Col. H. J. O. Walker combats this idea, saying in closing:

To sum up, I believe that although the air in the hive must be gradually renewed, and the bees sometimes assist towards the desired result by fanning, there is much less inlet and outlet than is generally supposed, and most of what takes place is automatic. Although I am well aware that a bee can produce, in proportion to its size, a strong backward or forward air motion in its immediate neighborhood, enough, perhaps, to extinguish

a candle, I do not think that the action of the fanners always, if even generally, sets up an exhaust current.

This view will not be readily accepted by one who has held his hand at the entrance of a hive on a hot day. Yet Col. Walker is a man whose word has weight, and no doubt careful observations will be made the coming summer, that will give us more exact knowledge on the subject.

### Worms in Combs

Combs that have been out all winter, subject to freezing, will need no immediate attention. Freezing has killed eggs and larvae, and there is no further danger until moths have laid eggs in them afresh. If bees have died in the cellar, or outdoors any time after, say February, it is pretty safe to say that they are more or less infested with the pests. If kept in a cool cellar slow progress will be made by them, but outdoors, as soon as weather warms up, the worms will make rapid progress in riddling the combs.

### "An Old Wives' Fable?"

Under the above heading appears under the signature of D. M. Macdonald, in the British Bee Journal, the following paragraph:

Certain statements once uttered become stereotyped, and, from oft repetition, are very liable to get established as so-called "facts." Here, on page 861 of the American Bee Journal, is one: "Not only some, but all honey light or dark that is put into sections is carried there from the brood-nest," and Mr. Doolittle is quoted as affirming that "when a fielder brings in a load of nectar she does not go with it into the super, but deposits it in some cell of the brood-chamber, whence it is afterwards carried into the surplus apartment." If true, let us go on believing it, but if even doubtful let us revise our ideas.

First, I would say that such heavy labor of gurgitating, regurgitating, charging and discharging into cells and carrying upstairs would be an *absurd* proceeding for any intelligent creature, and certainly so for one gifted with the brain powers of *Apis mellifica*. Second, I see no necessity for it. It would be a case of "Love's labor lost." Third, I have never seen any evidence of it. Fourth, and lastly, and including all the others, it is *impossible*. C'est impossible! shuts the door at once if true—which it is. With a heavy flow on, every brood-cell is crammed full of eggs, larvae, young and old, sealed and unsealed, just emerging bees, or a percentage of cells being cleared dry for "Her Majesty's" use, along with a small percentage with unsealed honey and pollen ready for the nurse-bees to manipulate. Where, then, are the spare cells for just-gathered nectar to be even temporarily stored? No, like "Tom Bowling," it goes to the right place—"aloft!"

Of the four arguments used, it is hardly necessary to discuss any, if the last of them is true. And our Scotch friend asserts most positively that it is true, that it is *impossible* for bees upon returning from the field to deposit nectar in the brood-chamber. Well, if it is impossible, of course there's no room for argument; but there is probably no sin in asking Mr. Macdonald a question.

Will he kindly tell us what it is that one shakes out of brood-combs any day when bees are storing, when the combs are shaken hard enough to shake the bees off? However it may be in Scotland, "in this locality" it is the regular and orthodox thing for some kind of liquid to be shaken thus out of the combs—not merely a few drops, but spoonfuls and spoonfuls of it, so that one may collect from the different frames a gill or more of a liquid which looks like nectar and tastes like nectar, but which of course can not be nectar, as it is *impossible* for the bees to deposit nectar in the brood-combs!

We are all attention, awaiting Mr. Macdonald's reply.

### Poultry or More Bees

A symposium in the Australasian Bee-Keeper seems to show a division of opinion as to whether it is better for a bee-keeper to be a specialist and keep more bees, or to run some other business in connection with bee-keeping; and of those who take the latter view the majority favor keeping poultry as a companion occupation.

## Carbon Bisulphide for Eggs and Larvæ of Wax-Moth

J. L. Byer, in the Canadian Bee Journal, expresses increasing confidence in this remedy, and has proved to his satisfaction that a box or room does not necessarily have to be nearly air-tight for the drug to do its work effectively. He says:

Formerly our local druggists charged me 5 cents per ounce, but now I buy all I want

from them at 25 cents a pound, and I surmise that at that figure they have a "reasonable" profit. If you have many hives full of combs to treat, carry them into a building and stack them up 5 or 6 stories high, put the bisulphide on top of all and cover securely, and you will be surprised and pleased to see how little of the drug is required to treat a large number of combs. Sulphur may be a trifle cheaper, but it does not destroy the moth-eggs, consequently it has to be used more than once; and it is, besides, a very disagreeable article to handle.

It is fortunate that America has been more ready to accept the improvements of the progressive. We have made long strides in practical bee-keeping. But our results are not those of systematic investigation. They are rather summation or collective benefits from a large number of individuals. They are trials and errors. What we need (and it is coming if the Department of Agriculture is permitted to carry out the work outlined by Dr. Phillips, referred to below) is a "long-headed," systematic research in apiculture characteristic of German science.

The old world has led in most scientific lines by Germany, by German investigation and invention. As American scientists we have always looked to Germany for much of our inspiration and encouragement. The American is ever in a hurry; he is after immediate results, and seeks them at hazards in the quickest possible way. Doubtless for this reason American investigation has been hampered; Germany has held the lead. The German investigator—scientist—has the peculiar persistence, "stick-to-itiveness," earnestness, and firmness of purposes, who, having conceived a problem, solves it with such full detail that it is seldom necessary to re-work or prove his findings. Such work, of course, has been done in America, particularly in recent days; but it has not been characteristic of American research. This is particularly true of biological investigation. We have but few American works in biology, which are the results of a lifetime's observations. Charles Darwin's admirable volume on the Earthworm, published after 40 years of study, or, as Darwin says, for that time "has been to me a hobby-horse, and I have perhaps treated it in foolish detail," it is a noble example of the German spirit in American research. Whether the labor was fruitless or not may be judged from the fact that within 3 years of its publication 8500 copies of the work were sold. Even to-day it is a masterpiece and model of dynamic biology.

But you question what bearing this has upon apiculture? It is most pertinent, and has a most direct bearing, to-day especially, here in America where the industry is growing so fast, and where the possibilities are so vast; refer to Dr. Phillips' paper read before the National Bee-Keepers' convention in November, 1906 (page 356). He has not overstated the case one grain; but distinctly outlines work which must be immediately undertaken.

If some one could do for bees what Darwin has done for the earthworm, the returns would be inconceivable, not alone, nor chiefly, in the moneyed sense, but rather in view of results upon the world as a whole. It may be difficult to see what benefit it would be to human health; but what do we know of the hygiene and physiology of honey-eating? It is difficult to conceive of the possibilities of such investigation on the fruit-growing industry, on the production and uses of wax; in fact, no one knows the possible benefit and the ultimate outcome of such work on apiculture itself. Our view of apiculture to-day is but a distant and fogged glimpse of a vast ocean of possibilities. **BURTON N. GATES.**

## Southern California Prospects.—

The following letter by M. H. Mendelson to G. F. Merriam, both of Southern California, was sent to Mr. C. P. Dadant, of Hamilton, Ill., who thought it of sufficient interest for publication in the American Bee Journal in connection with Mr. Merriam's letter and his own reply:

**FRIEND MERRIAM:**—Yesterday was the first clear day, and bees seemed to be busy. To-day is clear also. The scale hive showed the first gain. I also have been feeding considerably. Colonies were dormant until fed. I have better hopes now, although the bees are in a weak condition. But if we have clear, warm weather from now on we might have a partial crop. Worms com-

The Weather at Dr. Miller's is described as follows in a letter sent us May 16:

Weather for bees beastly. For one good day there are 2 to 4 bad ones. Dandelions enough to keep bees busy, and fruit is in bloom; but blossoms are no good without weather. No matter how good the season, it will hardly be possible for colonies to build up in time to do good work on clover.  
Marengo, Ill. C. C. MILLER.

**Apiary of G. L. Sauer in Winter.**—This appears on the first page this week. When sending the photograph on March 2, 1907, Mr. Sauer wrote as follows:

The picture of my apiary shows how I have the hives packed for the winter on the summer stands. I have 53 colonies, 45 of which are strong and in good shape; 8 were late swarms, and weak, but I fed them some last fall, and put a super with some honey in it on each, so I think they will pull through.

In preparing my bees for winter, I put wire screen on the bottom of the top box, then on the inside I put a piece of gunny-sack, and filled the top box half full of rye straw. Then I gave the bees a few puffs of smoke, pulled the cloth off, and set the top box on. After I had them all fixed in this way I boarded them up with ship-lap lumber, packing second-growth hay all around the hives. The hives face to the south, and the bees can get out when the weather is fit. They had a number of good flights this winter. I use the "Eclipse" hive.

If any one else has bees packed as I have described, and has any objections to it, I will be pleased to read about them in the Bee Journal. G. L. SAUER.

**Disappointed Hopes** seem to be the bee-keeper's lot in Southern California this spring. Prof. Cook, writing us from Claremont, Los Angeles county, on May 10, had this to say concerning the season and prospects for honey in that part of the State:

Owing to the generous and timely rains of the past winter, bee-keepers had good reason to expect an exceptional honey-year in California. And so we would have had except for the cold, foggy weeks of April and May. We had the same kind of a season a year ago. This cold weather acts in double way to lessen the honey crop. It tends to keep the bees from the field, and so closes the nectar-glands of the flowers that there is little or no nectar to gather. There is, however, room for hope even yet. The sages, both white

and ball, are vigorous, and with warm, genial sunshine, which I think we must have soon, we may yet get a bountiful crop. I never saw more, and more vigorous, bloom, even in this land of sunshine and flowers.

A. J. COOK.

**The New Canadian Postal Ruling** is thus looked upon by Mr. R. B. Ross, Jr., one of our subscribers at Montreal:

**EDITOR AMERICAN BEE JOURNAL:**—Your issue of the American Bee Journal for May 9 has just come to hand, and before tearing off the wrapper I noticed that the changed postal laws had commenced operating on one of my favorite papers. It is with pleasure that I enclose herewith 50 cents to cover the extra charge—and which I believe is uncalled for—but that the American Bee Journal would be just as much appreciated at \$1.50 as at \$1.00. While from your standpoint the new arrangement may appear serious, I don't think many Canadian readers will be so short-sighted as to fail to renew on account of the higher cost. Yours sincerely,

R. B. ROSS, JR.

We believe Mr. Ross is right, that very few Canadians will stop reading United States papers because of the increased postage rate.

**Apicultural Progress.**—Prof. Burton N. Gates, of Clark University, Worcester, Mass., sent us the following with the picture of straw-skeps shown on the first page:

I have often questioned just where England stands to-day in the apicultural world. Surely there is many a master of the profession there; yet there is a trace of the antique, of "the way that father used to do," in most of their bee-keeping. It is hard to get out of the ruts worn by generations.

The query was once more brought to my mind, as, at one of the recent meetings of the Worcester County Bee-Keepers' Association, two hives, pictured in the accompanying illustration, were exhibited side by side. The larger of the two is one which was brought from Vermont, having been used there over a century ago, and long since abandoned for the more serviceable wooden hive. The smaller is one recently imported to this country from England, as a type largely used in that land to-day. Why the advantages of the American and the Continental types of hive—the improved methods of these lands—have not influenced the English people and satisfied them that there is no longer need for this skep is a problem. It is evidence of the proverbial dogmatism.

menced in the sage, but good, warm weather will soon eradicate them.

Yours sincerely, M. H. MENDLESON.

Piru, Calif., May 2.

C. P. DADANT, Esq.—

*My Dear Sir:*—I think it very strange that the editors of the bee-papers have not heard that we are likely to have almost if not quite a total failure of our honey crop. We had abundant rains up to April 1, and every one looked for a record crop. Then the rains cut off short, and we have not had any since. All the time we had cold, cloudy weather and no honey. Bees by the million go out, get chilled and die, so that all colonies are weak, and have very little brood. Then the paralysis began April 4, and is killing off the bees. I find 2 colonies this morning entirely gone—the first instance I have seen. I am just returned from sweeping dead bees with a broom away from in front of the hives. I am feeding all colonies.

G. F. MERRIAM.

San Marcos, Calif., May 9.

DEAR MR. MERRIAM:—Yours of the 9th to hand. Misery loves company, so we hasten to tell you we are having the worst spring for bees that I have ever seen, and I have been in the business for about 40 years. Rain, snow, frost, and no bloom. Had a frost on the 11th. The fruits are about all killed.

I see the May disease is still giving you trouble. You will remember I wrote to you about it a year or two ago. I take it that the cold, wet weather causes it in some way, and it strengthens my opinion that something in the condition of the honey, either the old or the new, causes the start of the malady. Some have said it was spoiled pollen, but this ought not to make the adult bees sick as much as the brood, and it is the adult bees which suffer. If you see anything in that May disease that interests you I would like to know about it.

Honey is going to be a good price if things continue as they are. I hope the prospect may change soon.

The same conditions also exist in Europe. I received a letter from Switzerland, and they say that the weather is bad and the bees very much behind.

Our grapes have been touched by the frost, while the buds were yet small. We thought them all right till the few warm days came, when we found the buds dried up. There will be a few peaches yet.

Yours fraternally,

Hamilton, Ill., May 14. C. P. DADANT.

Surely the outlook is discouraging for bee-keepers in both the far west and also in the Mississippi Valley. The past has been perhaps the coldest spring known in many years; in fact, it has made a very long winter for the bees, and unless we can have reasonable weather very soon the honey crop will likely be a very short one.

We think there is no doubt about honey bringing a good price hereafter, and for several reasons. The pure-food law will prove a great help; and if the honey crop is short, whatever is produced should bring a fair price.

It is to be hoped that settled warm weather will come very soon to help out the bee-keepers as well as farmers generally. Fruit will also be high, in all probability. So much depends upon the weather.

**Our Wood Binder** (or Holder) is made to take all the copies of the American Bee Journal for a year. It is sent by mail for 20 cents. Full directions accompany. The Bee Journals can be inserted as soon as they are received, and thus preserved for future reference. Or we will send it with the American Bee Journal a year—both for \$1.10. Address office of the American Bee Journal.

## Working for Section Honey

BY G. M. DOOLITTLE

Having the wings of queens clipped, and all colonies looked after so they will be in the best possible condition to take advantage of the honey harvest when it arrives, our next thing to do is to see that the supers of sections are all ready to put on the hives at a moment's notice, when the right time for doing this arrives. The time for putting the supers in readiness is during the winter months, but if it has been neglected, it should be done now. Do not put this off till the harvest arrives, for if this is done we are often caught by having the best part of the season past while we are getting ready. Always have the "dish right side up to catch the honey." A few days' neglect of this will often turn what might be a splendid success into poor returns or an entire failure.

Having the supers all ready we should ever be on the alert to know just when to put them on the hives. They should not be put on until the colony which is to receive them is strong enough in numbers to fill the hive with bees and brood, for if put on sooner they only tend to retard the process of building up, which is the main thing we are aiming at in the early part of the season.

Again, no matter how populous the colonies, it is little use to put on the sections when no honey is coming in from the fields, for the bees will do no work in them, while with some colonies the bees will insist on tearing down the thin foundation put in the sections to help them start, where they cluster in the sections before any honey is coming in from the fields. Keep watch of the bees each day from the entrance, and when you see many bees coming in which strike heavily on the alighting-board; or the bees which are just outside of the entrance fanning look as if transparent about the locality of the honey-sac, then you may begin to think the time has arrived. If you wait until about 4 o'clock in the afternoon, and then put your head near the ground so that the sun will strike the bee as it runs into the hive, having the bee between your gaze and the sun, only so the sun does not shine in your eyes, you can tell on any day as to the amount of nectar the bees are bringing in. The bee with no load of nectar will look dark or opaque, while the one with a sac full of nectar will look translucent, especially thus with the yellow races of bees. Then this will vary all the way from opaqueness to the most translucent, just according to the size of the

load the bee carries. In this way I can tell almost to a half pound what a colony on the scales is bringing in.

Do not be deceived by now and then a bee dropping on the alighting-board being fully translucent, while all the rest are opaque. These occasionally translucent bees are carrying water into the hive; but where nectar is coming in to any amount, at least two-thirds of the bees coming in at this time of the day will show the light through their abdomens to an extent that you may know that they are getting more than a living from the fields. When you see this, open the hive occasionally, and when the bees begin to build little bits of comb here and there about the hive, and the cells along the tops of the frames are being lengthened with new white wax, the time is ripe for putting on the sections.

If the super is supplied with "bait" sections—which means from 4 to 12 sections partly filled with comb left over from the season previous—you will find that such baits will be pretty well filled with honey within a week, and the comb foundation in the rest well under way. It is then time to put on another super. And where shall this next super be placed? Under or over the one already on the hive? Ten years ago I should have answered, as did nearly every one then, and the majority of bee-keepers do so to-day—put this next super under by raising the first one up and putting the last super between the one the bees are working in and the hive. But after a practise of 10 years' trying the matter both ways, I now say put this empty super, except starters in the sections, over every time. In fact, for the past 4 years I have always put the empty super over the one the bees are at work in with the most gratifying results, as I not only secure larger yields of section honey in this way, but the sections are universally better filled.

With the old way of tiering up, I have come to the end of the season with thousands of sections worked in, not half of which were finished enough to be salable; but with putting the empty super on top when tiering up, nineteenth-twentieths of the whole worked in by the bees were salable, even in the poorest of seasons. In the old way of tiering up, as soon as the first super was from half to two-thirds full, it was to be raised up and the empty one put under it, and next to the hive. This was said to cause the bees to work with redoubled energy to fill up this space between their brood-nest and the room they were at work in above, thus securing much more honey than would otherwise result. But after having the flow of nectar slacken many times soon

after tiering up in this way, and in a few days cease altogether, this leaving me with double the number of sections worked in, with not one, or very few, completed; while when the empty super was put on top at the same time, I would have nearly every section in the lower super completed, with a few worked in sufficiently for baits the next year, I concluded that the old way was a delusion and a snare.

With the empty super on top the bees will go into it as soon as more room is really needed, and, as far as I can see, work to fully as good advantage as they will the other way, and that when a good yield of nectar continues right along for several weeks.

As soon as the first super put on is finished take it off, when enough work will be done in the second one put on to hold the bees right at work therein, the same now being set down on the hive and an empty super set on top of it to catch any overflow of bees which may come about. If this overflow amounts to filling this now third super (on top of the second), set the fourth super of the season on top of the last one put on, thus making the hive 3 supers high, which is generally enough to satisfy any colony.

As any full super is taken from the colony, lower the others down on the hive, putting all empty ones supplied at the top, and so on to the end of the season; and if you are anything like myself, you will be abundantly satisfied with the results.

When I used the old way, if I averaged 150 sections to the hive which the bees had worked in, I would have from 50 to 75 unfinished or unsalable sections out of every 150 worked in; but with the new way my proportion of unfinished sections has grown less and less, so that in the fall of 1905 the total of unfinished sections was only about 8 out of every 100 completed; while in the fall of 1906 there were scarcely 4 unsalable sections out of every 100 that were marketed, or hardly enough for "baits" for this year.

Borodino, N. Y.

## Making Cement Hive-Stands

BY DR. G. BOHRER

Having made a number of cement hive-stands, it may be a matter of some interest to such bee-keepers as may think of making them, to know in what proportion to mix Portland cement and sand, and how to wet the same for use.

Take 6 gallons of good sand and one gallon of cement. Put them on a tight board floor. (I put mine on a common tongued-and-grooved door that is not otherwise in use.) Mix them thoroughly, dry. Then sprinkle the mass freely with water and stir well with a rake, shovel, or hoe. Then sprinkle again, repeating this process until the whole batch is sufficiently wet to adhere when pressed into a body.

Then put it into a box 16 inches wide and 20 inches long and 4 inches deep, inside measurement. The side pieces may be cut 26 inches long, sloping the ends beyond the end of the hive-body down to a point. Five inches back

from where the slope begins put in a partition-board and one 6 inches from the rear end. This leaves a 6 inch space across the hive-stand not filled with cement. Set the box up where the hive is to sit, and level it. Do not nail the box together, but drive stakes on the outside to hold the boards in position. Then put in the cement mixed as directed, and with a piece of 2x4 or 4x4 scantling, say 3 feet long, stamp the mass of cement down so as to pack it into a solid body. When the mold or box is level full, smooth the top with a trowel or anything that will leave the surface smooth. Then, without waiting one moment, the stakes may be taken up and the boards removed, and the stand is completed. This must be done when there is no freezing, and in a few hours the cement will have set. The stand should be sprinkled 2 or 3 times per day for several days, so as to have the mass harden gradually, as it will be much harder than if permitted to dry out quickly.

The front end should be filled out down to the bottom of the slope at the ends of the side-boards with cement. This will serve as a landing for the bees in front of the hive. The dimensions of this stand fit the 10-frame Langstroth hive, and the amount of material used is sufficient for one stand, and not much more. There should not be more mixed for use than is required for one stand, as it is quite sure to set if permitted to stand only a few moments; and after once set it is never so good, as its cohesive power is destroyed.

One gallon of cement (the amount I use in making one stand) will cost from 10 to 12 cents. I pay 80 cents per sack, weighing 95 pounds. Not having weighed one gallon of cement, nor learned just how many gallons there are in one 95-pound sack, I can not state definitely the cost of a gallon, but think I have not put the cost per stand far from the correct price.

Lyons, Kans.

## The Hershiser Hive-Stands, Etc.

BY F. L. DAY

It was with much interest that I read in the April 15th number of *Gleanings* Editor Root's account of their test of the Hershiser hive-stand in wintering a portion of their bees. I have the more interest in this matter because a neighbor of mine has used a similar stand for some years, and has often urged me to try it. His stand is ventilated at one end only, but this has a sliding screen, easily removed. When prepared for winter each hive has a large sheet of pasteboard, obtained from cracker-boxes, put on the floor of the stand to catch the dead bees or other waste matter. Several times during the winter these pasteboards are removed from each stand and carefully cleaned. Then there is no accumulation of dead bees to rot and mold.

I should consider the stand an improvement over the Hershiser, in having ventilation on only one side, were

it not for the fact that my hives are left wide open on the bottom, and my bees winter finely. I have lost only 3 colonies in the cellar in 5 years. To be sure, I do have one thickness of burlap under the hive to help keep the bees confined when putting them into the cellar. But once in the cellar this burlap is loosened so as to fall away from the hive at the ends, so as to leave them open.

This neighbor's bees winter quite well, especially so considering that he never knows in the fall whether a colony has a queen or not. He winters only 10 colonies. Each season he increases by natural swarming to about 30 colonies. Then in the fall he selects the 10 that appear best on the outside, and sulphurs the balance. One year he secured 1000 pounds of surplus honey.

My colonies, as wintered with the hives open at the bottom, come out in good shape; the larger portion with bees enough to cover from 6 to 10 frames of brood. Very few weaklings that need to be helped. This spring, of 43 full colonies put into the cellar 2 were dead, 2 weak, and the other 39 in excellent condition. Each one of the 41, as well as the 4 nuclei, has a laying queen and plenty of stores. Taking it altogether, I am unable to see how it would pay me to invest in a hive-stand to shut my bees in during the winter when they do well without it.

### TAKING BEES FROM THE CELLAR.

It was with some degree of amusement that I read of G. M. Doolittle having a wheelbarrow with springs, and then putting on quilts to ease any possible jars to his bees at the time of taking out the cellar. Now I use just the opposite course with, I believe, even better success. I take a common railroad barrow, and put a few gunny-sacks in the bottom to fill up the hollow. Then I set a hive over these, the same having no bottom-boards, the hive having its 4 corners bearing on the sloping sides of the barrow, and wheel as fast as I can go over the rough ground about 25 rods from the cellar to the summer stands. When I lift the hive from the barrow and set it on its stand scarcely a bee comes out. In 10 minutes they commence to fly out slowly, and in 20 minutes they are in full flight.

This spring I used no smoke or other device, but put them all out as fast as possible. When about half through the wind turned to the north, the sky clouded over, and the temperature fell from 70 to 40 degrees. The last colonies put out did not fly much, but waited a day or two later, when the weather was warmer. I must say, though, that my bees have been quieter than usual this spring, and the cellar quite cool, which may have helped.

This spring I contracted the entrance of each hive as soon as on its summer stand, but did not see that it made any particular difference about the bees flying out. They came out just the same as in other years when I left the entrances wide open until near night. I contract the entrance of strong colonies to  $\frac{3}{8}$  x 1 inch, and the weak ones much less. I never have any chilled brood, no matter how cold

the weather, and my best colonies usually swarm about June 1st.

Last fall Dr. Miller told a questioner that he would expect a colony fed on thin sugar syrup as late as Sept. 1, to die from dysentery before spring. Now, Doctor, my bees are *always* fed all the sugar syrup they need—half sugar and half water, mind you—after Sept. 20. Last fall I finished feeding Oct. 1, and there is no trace of dysentery in any of my hives this spring. Is this a matter of locality?

We are having a late, cold spring,

snowstorms and freezing weather right along. It is now May 1, and the ice is still in the lakes. I took my bees out of the cellar on April 18. We had several warm days so that I could examine all colonies, but since then it has been very cold. Bees are shut in their hives as in winter. I do not expect that they will get any pollen for 10 days yet. Most years they bring both pollen and honey from the willows before this time. But a bee-keeper must live in hopes.

Detroit, Minn., May 1.

## Melilotus—Annual and Biennial

E. E. Hasty asks, "Am I right that the genus *Melilotus* (like *Trifolium*) has both biennial and annual members?"

Yes; we have them here in Texas! There are only a few of them, however, but enough to answer our question. *Melilotus Indica*, All., is an annual, quite abundant hereabouts, and with yellow blossoms resembling very much the cultivated yellow sweet clover, *M. officinalis*, which latter, however, differs from the first named, in that it grows somewhat larger and longer (both ways); that is, it is a biennial.

We also have *M. alba*; escaped and sparsely planted here and there, mostly by bee-keepers, on waste land and along fences. The climate, which, with its long, dry summers, seems not to suit the *mellilotus* very well, is one cause why it is not more abundant.

There is considerable of white sweet clover in North Texas. Bees are in some seasons busy only on *M. Indica*, but always visit the other two—white and yellow.

## The Texas Foul-Brood Law

Since the many discussions on foul-brood legislation and foul-brood laws, of which quite a number have been in print of other States, I have been requested to give our State law in the *American Bee Journal*. One reason for the request is that many bee-keepers are not acquainted with our foul-brood law, never having obtained a copy of it; and, secondly, to answer several questions in regard to "the workings" of our law.

There seems to be a question existing in the minds of quite a few who know of it, or suspect foul brood in some apiary, whether such knowledge must be reported to the State Entomologist.

There are some apiarists who have had foul brood in their apiaries, but who kept it a secret with the intention of eradicating it themselves, only to have to report some time later, and often a great "mess" had been made of the whole apiary. In my inspection work several such cases came under my notice. The pride of the owner or possessor of the bees seems to be the cause of such procedure. It should not be done!

The first step should be to inform the State Entomologist if there be any trouble or any suspicion. Such reports are strictly private matters, and kept on file as such in his office. If the apiarist is not certain whether it is foul brood or not, a sample of the diseased brood should be sent to the State Entomologist, but directions for sending such sample should *always* first be obtained from the State Entomologist, who will give these in all cases, and send proper mailing packages.

Never try to treat infected colonies unless you have had experience in such work, and then report the case to the Entomologist at College Station, Tex., before doing so. If without this experience, let "the inspector" do the work for you. He will know how, and will save you much trouble, worry, and bees.

The common notion that an inspector should be feared instead of trusted, should be out of existence by this time, for the inspector is there to look after your interests, hence should be given all assistance necessary.

The following rules and regulations have been formulated by the State Entomologist for operating the Texas foul-brood law, and should be observed:

1. If any owner of, or any person having control of, honey-bees in the State of Texas knows or suspects that any bees so owned or controlled are affected by foul brood or any other contagious bee-disease, he shall report said fact to the State Entomologist in writing, stating the number of apiaries involved, the number of colonies in each apiary, and

the number of colonies that are known or suspected to be infested with foul brood or other contagious bee-diseases.

2. Any owner or person having control of bees reporting infection, shall state the number of movable-frame hives in each apiary, also the number of box-hives, or such hives as will not admit of ready examination.

3. If any bees are kept in box-hives, or such other hives as will not admit of ready examination, the owner or person in charge will be notified by the State Entomologist to transfer all bees in the apiary to movable-frame hives, or such as will admit of a ready examination as any good modern frame hive, before a specified time. If for any good reason such a time is detrimental to the apiarist involved, the reason should be transmitted in writing to the State Entomologist, whereupon a date more agreeable to the owner or person in charge may be arranged for. In default of such transfer as above provided for, the case will be treated according to Sections 1 and 2 of the Texas Foul Brood Law.

4. When, upon inspection, an apiary is found to be infested, instructions for treatment will be prescribed by the State Entomologist. If the owner or person in charge fails to carry out such instructions, the State Entomologist, or his assistant, will give the necessary treatment at the expense of the owner, as provided for in Section 3 of the Texas Foul Brood Law. Every person who intends to barter, give way or receive bees, honey or appliances, should make certain that no infection is carried in such transactions or shipments. Where any doubt exists application should be made to the State Entomologist for inspecting the apiaries involved. Persons violating the provisions of this rule are deemed guilty of a misdemeanor, and upon conviction thereof shall be fined in any sum not exceeding \$200, as provided for in Section 4 of the Texas Foul Brood Law.

The following is the text of the

### TEXAS FOUL BROOD LAW.

An Act to provide for the protection of honey-bees against foul brood and other contagious diseases, and providing that all bee-keepers report to the State Entomologist when infectious diseases exist; providing for collecting the expense of eradicating the disease, and fixing the charges upon the owner of the bees; providing for the extermination of all contagious diseases, and providing penalties for the violation of this Act.

Be it enacted by the Legislature of the State of Texas:

SECTION 1.—If any owner of, or any person having control or possession of any honey-bees in this State, knows that any bees so owned or controlled are affected with foul brood, or any other contagious disease, it shall be and hereby is made his duty to at once report said fact to the State Entomologist, setting out in his report all the facts known with reference to said infection. The State Entomologist shall have full power in his discretion to order any owner or possessor of bees not dwelling in hives with movable frames, or not permitting of ready examination, to transfer such bees to a movable-frame hive within a specified time. In default of such transfer, the State Entomologist may destroy, or order destroyed, such hives, together with the honey, combs, frames and bees contained therein without recompense to the owner, lessee or agent thereof.

Sec. 2.—The State Entomologist shall prescribe such rules and regulations as may in his judgment seem necessary for the eradication of all contagious diseases of bees, and if at any time the Entomologist finds, or has reason to believe, that the owner or keeper of any bees, or the owner of any apiary has refused, or is refusing to comply with all or part of any such regulations, then and in that event the State Entomologist is hereby authorized to inspect said bees, and if necessary burn diseased colonies, appliances and honey, and do any and all things necessary in the premises to eradicate foul brood or any other infectious disease of bees.

Sec. 3.—When any owner or possessor of

bees shall fail to carry out the instructions of the State Entomologist, as set forth in Sections 1 and 2 of this Act, the State Entomologist shall carry out such instruction or treatment, and shall present to the owner of said bees a bill for the actual cost of such destruction or treatment. In the failure of the owner or possessor of such bees to pay said bill within thirty days after the delivery of same to himself, tenant or agent, or within thirty days after mailing same to his usual postoffice address, the State Entomologist shall certify to the County Attorney of the county wherein such bees are located, the amount and items of said bill, and the County Attorney shall file suit for the recovery of said account. All moneys recovered by the County Attorney for such destruction or treatment shall be paid into the hands of the County Treasurer, to become a part of the fund for the carrying out of the provisions of this Act.

SEC. 4.—If any owner or keeper of any diseased colonies of bees shall barter or give away any infected bees, honey or appliances, or shall expose any other bees to the danger of infection of the disease, or shall refuse or neglect to make report as provided in Section 1 of this Act, he shall be deemed guilty of a misdemeanor, and, upon conviction thereof, shall be fined in any sum not exceeding two hundred dollars.

SEC. 5.—The fact that the season when young colonies of bees will leave the mother colonies is near at hand, that there is no existing law properly governing colonies affected with foul brood, create an emergency and an imperative public necessity, requiring the suspension of the constitutional rule which requires bills to be read on three several days, and the same is so suspended, and this Act shall take effect and be in force from and after its passage; and it is so enacted.

sionally a colony, seemingly in normal condition, will leave the hive.

Since I have been keeping bees only twice have I had these unseasonable "swarms." Six years ago, during a very warm day near the last of April, a strong colony left the hive and settled on the limb of a small cedar-tree in the yard. On examination the hive was found to be sweet and clean, with abundance of honey and pollen, and brood in all stages. What induced them to leave I know not, but the bees, on being returned, remained there and gave a good account of themselves that season.

My second case occurred only a few days ago, but this time there was a reason, as the colony was very weak, having suffered with dysentery, and spring dwindled badly. They settled on the corner of a hive in a small cluster; the queen, being clipped, was lost in the grass, and the bees scattered and went into other hives.

Reports of "swarming out" in the early spring are always more plentiful after a severe winter, and, as a rule, there is more of it with bees wintered in the cellar than among those wintered outdoors. I remember, some years ago, of a bee-keeper who lives some distance from here, who had a lot of this trouble the day he put his bees out of the cellar. Some 90 colonies were put on the stands, and inside of an hour over 20 had swarmed out. To say there was a "mix-up" would be putting it mildly. A number of queens were killed, and over a dozen colonies were lost. As the bees seemed to be in fair condition, just why they acted so is hard to say, and, fortunately, an occurrence of this kind is not very frequent.

### Bees Enticed Out in Cold Spring Weather

Speaking of bees being enticed out of the hives by the sun on cool, windy days, reminds me of what Mr. J. F. Davison was telling me a few days ago. Mr. Davison is one of our prominent comb-honey men, and has an apiary of 175 colonies, of which 80 were wintered in the cellar and the balance outdoors. While walking through his yard last week, he called my attention to the fact that when he put out his cellar-wintered bees, half of them were put with entrances facing south, and the other half facing north. Without exception the colonies facing north are at this date *much stronger* than those facing south. Mr. Davison has experimented along this line before, and results have always favored the ones facing north.

The day I visited him the sun was shining brightly, but the wind was blowing cold from the north—in fact, it was a typical "dwindler," and it was quite noticeable that while the bees in hives facing south were flying quite freely, in the hives facing north scarcely a bee was moving.

Mr. Davison is so thoroughly convinced that, for early spring, hives are better faced north, that, in the future, if I mistake not, he will place all that way when taken from the cellar. It is

Conducted by J. L. BYER, Mount Joy, Ont.

### Coldest April on Record

The first pollen was gathered here on April 28. By all odds one of the coldest Aprils on record has just drawn to a close. Bees, as a consequence, are very backward, but as all honey and pollen bearing flora are also late to a certain degree, conditions may be somewhat equalized. A heavy rain followed by somewhat milder weather has improved the clover somewhat, but quite a large percentage of the alsike, and most of the red clover, has been damaged so much by "heaving" that the farmers have to plow it under.

### Tarred-Paper for Hive-Protection in Spring

As mentioned on page 369, Mr. Hutchinson and others are quite enthusiastic over the use of tarred-paper for spring protection of the bees. Naturally when a man like N. E. France makes such sweeping assertions as claiming that bees so protected will have double the brood of unprotected colonies, many amateurs, as well as "old-timers," will be giving the plan a trial this spring. I venture to predict that the large majority of these experimenters will come to the conclusion that more is claimed for the plan than it is entitled to.

With all due respect for Mr. France and other advocates of tarred-paper, I feel pretty sure that, other conditions being equal, in order to get double the brood in one hive of what there is in another, some more factors than simply tarred-paper will have to be taken into consideration. As the most of my hives are packed on the summer stands

till fruit-bloom, I have been able to try the paper only on a limited scale; but the results from said trials were not a "howling success" with me, and, personally, unless hives were very open at the joints, I would not be bothered with the paper at all. Hives that are fairly well made, entrance contracted, and a tray over the top of the hive filled with some dry material that fits snugly on the frames are, in my estimation, of far more value than paper.

One objection I found in regard to the paper, was that hives so wrapped would warm up too much during early spring days when the sun was shining; but with cold wind blowing, as a result the bees would be coming out of these hives when other colonies were quiet.

### Colonies "Swarming Out" in Early Spring

The bees came out of 2 hives to day, acting as if they wanted to swarm. After flying a little they returned to their hives. What is the cause of such a performance at this season of the year, in Canada?  
Elgin, Ont.

H. S. DAVISON.

Unfortunately quite a number of bee-keepers have had some of this "swarming" during the present backward season. When bees swarm out of the hives in the early spring, there is something not right, yet the reason is not always easy to find out. One of the commonest causes is starvation, and when stores are all consumed and a warm day comes, if the bees have not perished they are very apt to leave the hives—indeed, they will do this during the summer time, too. Sometimes weak colonies affected with dysentery will act the same way, and *occa-*

only fair to say that his yard is very much protected by buildings, etc., and,

with a contracted entrance, very little wind blows directly into the hive.

**Report of the 37th Annual Convention of the National Bee-Keepers' Association, held in San Antonio, Tex., Nov. 8-10, '06**

(Continued from page 417.)

The Secretary read the report as follows:

**REPORT ON RESOLUTIONS.**

*Whereas*, The National Bee-Keepers' Association, in convention assembled, has been royally received by the bee-keepers of Texas and the citizens of San Antonio, and have been shown great favors; therefore, be it

*Resolved*, That the National Bee-Keepers' Association extend its thanks to the Texas Bee-Keepers' Association, and the members of the Arrangement Committee, Messrs. W. O. Victor, Udo Toepferwein, Louis H. Scholl, F. L. Aten, and W. H. Laws, for the kind reception given to the members of the National Bee-Keepers' Association; for the many favors shown them; for the splendid arrangements made; and for the Mexican Banquet which they spread so lavishly for us, the participation in which will long be remembered as a token of the generous hospitality of the bee-keepers of Texas, which we recognize as the hospitable and kind-hearted spirit which the Texans have always shown to the people coming from all parts of the world, and for which the people of this great State of Texas are known.

*Resolved*, That we thank Mr. Bryan Callahan, the Mayor of San Antonio, for kindly giving us the privilege of the City Hall, at the front of which he joined the Association in a picture, giving us a lasting remembrance of San Antonio and its whole-hearted Mayor.

*Resolved*, That we extend our thanks to the press of San Antonio, and especially to the Daily Express for sending reporters to our meeting and giving the space of its paper so generously to the interest of our Association.

*Resolved*, That we thank the City of San Antonio for its hospitality and the free use of the Market Hall granted to us; that we thank the Business Men's Club of San Antonio and the Traction Company for kindly offering us a trolley-car ride through the City of San Antonio and its surroundings, showing our members the sights of this ancient and historic city.

*Resolved*, That we thank the San Antonio International Fair Association for setting aside last Thursday as National Bee-Keepers' Day, thus honoring

the vocation of bee-keeping and bringing our convention prominently before the people of this State; That we thank Messrs. Goggan Bros., for kindly lending, for the use at our hall, a fine piano and organ; That we thank Mr. J. W. A. Hansens for his beautiful piano entertainments at the intervals between our sessions; That we thank Judge T. M. Paschal for his speech, and for the kindness towards bee-keepers shown by helping to invite us to this beautiful city.

*Resolved*, That we especially thank our worthy President, Mr. C. P. Dadant, for his able and just presiding over the meetings of our Association. That we renew our thanks to the General Manager of the Association, Mr. N. E. France, for the efficient work he has done in conducting the business of the Association, and for the great efforts he has made to further the interests of the members of our Association.

We also thank the Grand Central Hotel for our entertainment.

R. A. HOLEKAMP,  
JAS. A. STONE,  
C. C. PARSONS,

Committee on Resolutions.

Dr. Bohrer—I move that the Resolutions be adopted as read.

Mr. York—I second the motion. I might say that as the President is very modest, and his name is mentioned in the resolutions, I will put the motion. It is carried unanimously.

**MAKING CERTAIN MEMBERS INELIGIBLE TO OFFICE.**

Pres. Dadant—I have but little more business to perform. The National Bee-keepers' Association was organized a great many years ago by bee-keepers who were queen-breeders, dealers in bee-keepers' supplies, and editors—the men who were mostly interested in the progress of this Association. The Association has grown from 40 to 50 to several thousand; the conditions are different, the feelings are different. We find to-day that some members in the East are dissatisfied with the conditions as they are; they think that men interested in the sale of bee-supplies or the publication of journals should not be entrusted with the management of the Association. I feel that it is well to give all a chance to express themselves on the subject. We are only about 125 here, and we can not dictate, but we can, according to the Constitution, ask the membership to express themselves

and amend the Constitution if they see fit. I have gone to the Committees on Resolutions and on Amendments, and we prepared some joint resolutions. We will propose them to you only to present these matters for vote. If they are approved by the whole membership they will exclude bee-supply dealers, queen-breeders and editors. I want to make you all feel entirely at liberty to vote on the subject, and I think it best to announce that I have decided to decline any further offer as President of the Association, so that you can feel that you are not voting against your President when you act upon the matter. I wish to say that Mr. H. H. Root, who is here, and his brother, E. R. Root, are entirely in accord with my views. We will give the membership a chance to amend the Constitution if they so desire.

A copy of the Resolutions prepared by the Committee on Amendments were read by Mr. J. Q. Smith, as follows:

**REPORT ON AMENDMENTS.**

*Resolved*, That the General Manager be instructed to place before the members of the National Association, the following propositions to be voted upon according to Section V., and Article 9, of the Constitution of the National Bee-Keepers' Association, concerning amendments, each proposition to be voted upon separately:

1st. Shall manufacturers, dealers, directly or indirectly interested in the sale of bee-supplies, and patentees of apianian implements, be considered eligible to office?

2d. Shall queen-breeders, or importers of queens for sale, be considered eligible to office?

3d. Shall apianian editors, associate or department editors, authors or publishers of works on bees, be considered eligible to office?

J. Q. SMITH,  
W. O. VICTOR,  
ROBT. A. HOLEKAMP,  
C. C. PARSONS,  
JAS. A. STONE,

Submitted by request. *Committee.*

Pres. Dadant—You have heard the report of the Committee, what will you do with it?

Dr. Bohrer—I object to the resolutions in their present form. I want another resolution offered, then vote against the whole thing. It is, that all men selling bees shall not hold office, and any man that deals in bees and honey shall not vote. It is not justice to ourselves and our officers and I am opposed to the whole thing.

Pres. Dadant—I fear that Dr. Bohrer does not understand. We are not asking you to vote, we are asking you to permit the matter to go before the members of the Association. We do not anticipate that each one of these sections will be adopted, but I think two of them, at least, will be adopted; but I want to give each of the members a chance to vote. We want harmony, and this is the only way to get harmony. We have things our way, and the East is not satisfied; give them a chance, which they could not have without an opportunity to vote on these

# American Bee Journal

resolutions. It takes a notice of 45 days, in order to act upon this next year; and then leave it to their fairness as to what shall be done.

Mr. Holekamp—If I ever have been sorry since I am a member I am sorry now. It seems there is a great dissatisfaction in the East about nothing. If we exclude these men we will be left. Now, I am in the Association and get letters from our members in Missouri. All of our members either have a few dollars worth of supplies or honey to sell, or they are queen-breeders, and if these resolutions would be passed I would recommend our Association to withdraw from the National, because if we lose all of those men, who are acting under the head of dealers, they will pay little attention to our Association, and those who do the work will be left out. If these resolutions should pass I would withdraw.

Pres. Dadant—I will call on Dr. Phillips to state to us what he thinks about the matter.

Dr. Phillips—What I have to say is not to be considered my attitude in the matter. I have attended meetings in several of the Eastern States. Perhaps those who are present do not know that in several parts of the East resolutions have been passed to withdraw from the National Bee-Keepers' Association, on the ground that the body is controlled by the bee-supply dealers, editors, etc. This dissatisfaction is manifested by the withdrawal of several State associations in a body from the National Bee-Keepers' Association, so there is no doubt of it. Now, in order that this division may have an opportunity to express themselves, they should be allowed to vote upon these propositions. Especially, to be explicit in this thing, the New York Association withdrew in December, last year, from the National Bee-Keepers' Association; several states have followed New York. Some of the individual men, who belong to the National, still retain themselves in the Association, and several of the members have withdrawn. These men have been members of the National, and many of them will become members as soon as this thing is to be voted upon and they have a chance to vote. Therefore, I am in favor of passing these resolutions in order to give them an opportunity. I think that these men should be allowed to have their say. The claim is made that these various interests that are specified control the National Bee-Keepers' Association for their own interests. These resolutions, if carried, will exclude from office the persons mentioned. At any rate, if these resolutions are approved, and it is put to a vote by the General Manager, we will have an opportunity to know what the people think about it. Pennsylvania passed a resolution to withdraw, but can not do so consistently. Pennsylvania is growing at a very rapid rate in bee-keeping affairs. If these resolutions are passed, I feel sure that this Association will not withdraw. New Jersey has withdrawn. Massachusetts is represented by a few members, but they have two societies that will join as soon as it is passed.

Pres. Dadant—According to the rules, it will be necessary for them to be passed upon and approved. It seems to me that if these people are as weak as they are represented to be, they should give in; if they are strong, we should give in. We are in a country where the minority give in to the majority, and that is what makes us great.

Dr. Bohrer—That being the case, I shall not object to their going before the National Association. I want to be at the next National meeting, and help kill the resolutions so dead that they will never be brought to the front any more.

Mr. Stone—I don't see where the fight is; I don't see anything they have to fight. Who are the directors, are they all dealers or editors?

Dr. Bohrer—They would be practically disfranchised.

Mr. Stone—I know of several, and I don't know of any that are supply dealers or editors; but I don't see anything for us to fight, and as far as that is concerned, I would feel about it like voting out all the agricultural papers and all the implement dealers; if I voted them out I would quit farming. If the bee-supply dealers, editors, etc., were voted out I would quit bee-keeping.

Mr. Rankin—I have been through the West a good deal, in California especially, and this dissatisfaction exists there to a certain extent. There are some who think an injustice has been done, and by giving them this opportunity this will square them. If you give in and do this, the next year they will deny that they ever said it. It seems to me that it is a safe proposition, that the National can not help but win out on. I don't want this Association to divide the States, I want to help the National, because it can not win any other way. For instance, the Fruit Association is composed of fruit-growers; a dealer would not have a voice in these matters. I call attention to the fact that the members in these dissatisfied States do not represent the bee-keepers of those States, nor do they represent the bee-keepers' associations.

Mr. York—I notice in the list of officers of this Association that there are some supply-dealers. It is too bad they are in, but how did they get in? Mr. Dadant did not do any political work to get in—he was simply elected by the membership of the Association. There are only a few that are dealers or editors. I have been in office myself, but I never did anything to get in, and I certainly did not vote for myself. Of course, it is too bad I am the Acting Secretary now. Really I don't see any sense in the opposition.

Mr. Kimmey—Will the next annual meeting have a chance to pass upon it?

Pres. Dadant—The Constitution calls for a 45 days' notice. Therefore, if we do not pass this, that would be putting off a chance for these people to get a hearing, while if we put it before them to-day, they can still have another chance to vote upon it at the election. We are giving you a chance to vote upon the amendment to our

Constitution. One thing I think the members are forgetting, that we are not supposed to exclude anybody from membership. I expect to remain a member, but I expect to keep out of office. I would be much disappointed if you did not favor these resolutions to-day; it would look as if we were afraid to let them go before the Association.

Mr. Kimmey—I think that I am alone, and I don't want this amendment to the Constitution, but you want somebody to vote upon it. Now, if I understand, it gives us a chance now to approve to-day what we are to vote upon at the next annual election. I am opposed to the amendment; I don't propose to vote and approve it. I don't propose to say that I attended this meeting and approved of it. You are asking me to approve of them at this meeting. I don't believe in that kind of organization. Of course I am right. We are saying that a majority approved of it; you can not change this, the rule on Amendments in the Constitution here.

Mr. Stone—I can understand it only as Mr. Kimmey says. The Constitution says that it has to be approved at a previous meeting.

Dr. Phillips—As I understand, the whole thing is this: This Convention is not approving these things at all. The resolution says the next meeting will have an opportunity to approve this if they wish to do so. You are simply specifying business that is to come up at the next meeting. I am not approving of it. I want the membership to have an opportunity of a say. This will be held some time next year; if they approve of it, a notice will be given, and 45 days after the next Convention will be time to take this up.

Mr. Kimmey—Suppose that the next meeting occurs like this one—in November—the month of the election in 1907?

Mr. Holekamp—Very few of those here to-day will be present at this convention, if it is held in the East next year; and part of the bee-keepers will think that we approve of these amendments. Very few will understand it.

Mr. York—This, of course, is not in proper form for an amendment. To amend the Constitution we should form a new article. It has got to be put in proper form, and then the question is, Do we approve of this amendment?

Dr. Phillips—I think the President is right.

Mr. York—We are supposed to approve them at this previous meeting, else they can't go to the membership for voting.

Mr. Kimmey—We have no right to approve them.

Pres. Dadant—We have the right to instruct the General Manager to send it out to the whole membership.

Mr. Holekamp—I move that this whole thing be put on the table.

Dr. Bohrer—I second the motion.

Pres. Dadant—All in favor of this motion, say "Aye." The motion is carried.

(Continued next week.)

### Section Supers with Empty Comb

My bees did not store any honey in the supers last year, but put some comb in the sections. Will it be all right to put the supers on (as I took them off last fall), or do I have to clean the comb out and put in foundation or starters again? IOWA.

ANSWER.—If there's nothing but comb in the sections, and that comb is nice and clean, by all means give them back just as they are. If the bees have plastered bee-glue all over the comb, as they sometimes do when sections are left on late in the fall, such comb must not be used. The bees are very loth to accept it.

### Strength of Colonies—Bee-Glue

I started with 2 colonies of bees 4 years ago, and I now have 25 colonies, all in good shape, I think.

1. My bees cover from 5 to 7 combs in a 8-frame hive. Do you call that strong, fair, or weak? I use Hoffman frames.

2. Can I feed sugar syrup so that the bees will put honey from fruit-bloom into sections?

3. Is there any wax in bee-glue? IOWA.

ANSWERS.—1. For April 22, especially this year, you may call them strong.

2. Not at all likely, and hardly advisable to try it.

3. No and yes. In pure propolis of course there is no wax; but in propolis scraped from sections or frames—indeed as bees use it in general—there is more or less wax, as you will find out if you melt it.

### Would It Prevent Swarming?

Why not at the time of opening the hive and removing the old queen, save one of the best cells that will hatch in a few days—say 5? Would not this queen, upon arriving home from her mating trip, destroy all queen-cells in the colony? Would it prevent swarming? MICHIGAN.

ANSWER.—This question appeared on page 378, and by what means it happened that it wasn't answered I do not know. I am not sure that I understand just what is meant, unless it be that when queen cells are found in a hive the old queen is removed to prevent swarming, all queen-cells being removed at the same time except one, and from that one a virgin is expected in about 5 days. The bees would be sure to start other queen-cells, and the question is whether the young queen would not destroy them on returning from her mating-trip, and whether it would prevent swarming. I must frankly say I don't know, and I wish some one who has actually tried it would tell us. If the cells were old enough it would be practically certain that the oldest virgin would issue with a swarm. But if no cell is left but one, and that one is old enough to send out a virgin in 5 days, then no subsequently started cells will allow

other virgins to emerge until a week later—possibly 6 days later. The question is: Would the young queen swarm without waiting for any of the later queens to mature? Would she swarm as soon as one or more of them had matured? Or, would she remain without swarming, the later cells being destroyed? Who will tell us?

### Wood Strips or Splints for Fastening Brood-Foundation

I have been interested in wood-strips as foundation-supports, and would like to have you tell me just the size of wood you would use for this purpose. I should think that strips  $\frac{1}{2}$ -inch wide and quite a little less than 1-10-inch thick would do better than thicker ones. I suppose you have tried different sizes. What would you advise? MICHIGAN.

ANSWER.—You are quite right that the size of splints you mention will be better than larger. And it is equally true that something still smaller is better. The size I use altogether is 1-16x1-16. I am not sure that I ever tried any different size, and as this size gives entire satisfaction, I hardly think it worth while to try other sizes. This size holds the foundation perfectly straight, so there is no object in trying a larger size; and as a splint of this size appears not the least bit in the way, there is no object in having a smaller size. I never knew a single cell that was not occupied by the queen on account of the splint being in the way, and generally you can not tell by the surface of the comb where a splint is.

### What Caused the Commotion?

On April 9 I hived a swarm in a 10-frame hive and contracted the entrance to about half its usual size. On the 27th, in the morning, I noticed quite a commotion at this hive. The air in front was full of bees, around the entrance it was black with them, and some boards I have laid in front to keep the grass down also had a lot of bees on them. I thought they were swarming. Some time later they quieted down (they did not swarm) and I noticed the bees on the boards in front were dead. There must have been 200 of them. There were also a good many drones among them. The day before I had put a super on this hive. When I found there had been trouble I closed the entrance more. What was the trouble? CALIFORNIA.

ANSWER.—No telling for certain. It might have been that a weak swarm tried to enter and was killed.

### A Troublesome Neighbor

I live in a town of about 100 inhabitants, and have 70 colonies of bees on the back of my lot, where they molest no one. One neighbor, however, claims that the bees are a nuisance, and told me to take care of them

or he would kill them all. All the rest of my neighbors stand by me, and say they are not bothered by the bees. What would you advise me to do, for the opposing neighbor is a very bad man? I treat him as well as I can, but it seems to do no good. WISCONSIN.

ANSWER.—There is nothing in the case specially different from what it would be if your unkind neighbor should threaten to injure any other property. So long as there are only threats, it is hardly worth while to pay any attention to them, although it is well to keep in mind always the saying of the wise man: "A soft answer turneth away wrath." If the threats should materialize into action, there is the same remedy at law that there would be if he should injure your horse or cow. In any case, if you are not already a member of the National Bee-Keepers' Association, you would be wise to send at once a dollar either to the office of the American Bee Journal, or to General Manager N. E. France, Platteville, Wis., to become a member. The very fact that you were a member of such a powerful organization would have its effect in deterring from a conflict.

### Fastening Brood-Foundation—Entrance-Guards and Swarming—Number of Colonies to Average \$600

1. What is the best way to fasten foundation in Daanzenbaker brood-frames?

2. Why couldn't I use bee-entrance guards to keep down swarming when running for comb honey?

3. How many colonies would it take to average \$600 a year, if run properly? MINNESOTA.

ANSWERS.—1. By means of the saw-kerf and wedge that are sent with most top-bars nowadays. A saw-kerf receives the foundation, and the wedge is pushed into the other saw-kerf by its side. Be sure to drive the wedge down as deep as you can.

2. How do you suppose that would keep down swarming? Likely you will say the queen can not get out. Yes, but the bees will swarm just the same, and after they have swarmed often enough the queen will be killed and a young queen will take her place, and the bees will swarm worse than ever with the young queen, and if you don't take away the guard the queen will be a drone-layer.

3. It varies so much that it's hard to give any kind of an answer. In some localities it would take twice as many colonies as others. In some years it would take 10 times as many as in others. It might be any where from 100 to 250 colonies.

### Moldy Combs with Sour Honey—Spacing Combs, Etc.

I put 5 colonies of bees, one little better than a nucleus, into a good bee-cellar of a neighbor who has the habit of running things to extremes. The two previous winters his bees wintered on 7 or 8 pounds of honey, weighed in and out of the cellar. Last winter was so very mild that many of his bees were lost in the cellar and so this winter he often opened the windows and doors from another room and kept the place so cold that they ate 17 pounds of honey per colony. That is, they averaged that. Many mice also got among them and worked in the planer-shavings with which they were packed. They were set on 4-inch scantling without bottom-boards, 3 tiers high.

I put my hives on bottoms 5 inches deep, with strips of perforated  $\frac{1}{8}$ -inch zinc, about  $2\frac{1}{2}$  inches wide and nearly as long as the hives on two opposite sides. The bees were entirely closed in, something on the Hershiser plan, but I doubt if I shall do it again. The nucleus had, I think, nearly 3 frames of bee and a young vigorous queen put in very late. She was laying Nov. 2, and 3 days ago (May

# American Bee Journal

3), she had laid eggs with only half a teacupful of bees. Another hive had only a pint of bees and I put them with her on Friday without any precautions, they having been queenless, and on Saturday, May 4, there fell from 4 to 6 inches of snow, and sleighs were running, though much of the snow had gone with the sun that came out towards noon, but it was freezing hard again at night. Some of the snow still remains (Monday morning the 6th), and although the thermometer is up to 36 degrees, it is chilly enough for Greenland, and this is some 10 miles north of Port Hope on the north shore of Lake Ontario. So on account of the cold, I have not been able to tell whether the pint of bees have killed the young queen or not. Another colony has perhaps 3 frames of bees and a queen, with eggs and larvae. Another has perhaps 4 frames of bees, and, I think, no queen. These frames were all of the Danzenbaker type, only 9 inches deep and 13 1/4 inches long, set crosswise in the hive. The only colony that came out reasonably was in the same style of hive with frames 11 inches deep. They had probably a pint of dead bees and they were put out of the cellar on Wednesday, May 1, the soft maples just coming out on the previous Saturday. On Friday there were lots of eggs in this hive from a 2-year old queen, and the bees were carrying yellow pollen. This might have been a big colony had I not kept robbing it to build up the lesser ones. After this much of history, that will certainly interest some of your bee-keeping beginners, I want to ask you some questions.

1. The bees being dead, some of the beautiful white combs are moldy, and I have read somewhere that cleaning moldy combs by the bees causes bee-paralysis amongst them. But what troubles me most is that in nearly every comb are some 50 or more cells of uncapped honey that has fermented or has bubbles in it. I set one of them in the house near the stove, and the fermentation went on so lively that the bubbles overflowed the cells in a few hours. Many of these frames are from a third to half full of good capped honey, but spotted by excrement. Shall I have to throw away these beautiful combs on account of fermented honey in them? This same man in whose cellar I wintered my bees, spoiled hundreds of pounds of honey by uncapping just such bubbled cells as these last summer. I would rather melt them down for wax than run such a risk. What shall I do with them and the moldy ones that I think less dangerous? Not knowing what to do with them the moth may get into them if not otherwise disposed of.

2. There have been tons of ink and paper wasted over spacing combs. I saw, last summer, simply a strip of hard-maple wood 1/4-inch thick and the length of the hive, with notches 1/4-inch deep cut in one edge at equal distances apart, to slip down over the ends of the frames. I think hard-maple is about the only wood strong enough for these frame-spacing strips. The hive in which I saw them was at the time perfectly clean of bee-glue. Whether the strips had been greased or not I can not say, as I did not ask. They looked as if recently cleaned.

3. On page 553 (1906), the last letter is signed by Julius Happel, and the last sentence reads thus: "Later on I will give a plan by which 20 colonies can be formed from 2, and still produce a surplus of honey." Has he ever fulfilled his promise? or, if he did, where can I find it? If he did not, stir him up to do so.

4 I criticise the American Bee Journal for these half-told stories more than for anything else, and only last week I wrote Mr. York under my full name to that effect. The worst article I have seen was headed, "Rearing and Mating Queens," page 338, by Jacob F. Hershey. "With my method I need not make any nucleus colony," and so he goes on, only boasting, boasting, boasting, and nothing else.

ONTARIO.

ANSWERS.—1. Don't be in any fret about those combs. They're good stock yet. All the mold that gathers in one winter can soon be cleaned off by the bees. And the souring

honey will all be cleaned up by them, too. But don't be in too much hurry about the matter. The worms will make little headway till it gets pretty warm, and if put in the cellar will do little damage till June. As soon as bees are flying every day, and that ought to be as soon as this gets into print, give a comb at a time to the stronger colonies, giving another every day or two. An easier way is to give a whole hiveful at a time, giving to the strongest colonies. Set the hive of combs to be cleaned under the colony, so they will have to go through this lower story when going out or in. Better do this about the time when bees stop flying in the evening, for if given earlier in the day it is barely possible that the smell of the fermenting honey might attract robbers. I don't know of any case on record where moldy combs or fermenting honey gave any disease to the bees if given thus early in the year, although such honey would be sure to give them diarrhea if given as winter stores. But paralysis will not come

from moldy combs nor from fermenting honey at any time of the year.

2. This plan of spacing combs is very old, but it is too troublesome and time-consuming to be in general use. If you try the two ways side by side, you will probably much prefer to have the spacers on the frames.

3. On page 723 will be found what he probably refers to.

4. Please don't blame the American Bee Journal too much, for I don't think it often happens that mention is made of some improved plan only to keep such improved plan a secret. But I quite agree with you that said Journal might better omit all such advertising of people that possess secrets unless published at regular advertising rates. What's the good of advertising a secret unless its possessor is ready to sell it, in which case he should pay for the advertisement just as other advertisers do.—[Mr. Hershey has promised to describe his methods later.—EDITOR.]

## American Bee Journal Novelty Pocket-Knife Gold Fountain Pen

All for **\$3.00**

(This cut is the full size of the Knife.)

### NOVELTY POCKET-KNIFE

(Name and Address on one side—Three Bees on the other side.)

Your Name on the Knife.—When ordering, be sure to say just what name and address you wish put on the Knife.

The Novelty Knife is indeed a novelty. The novelty lies in the handle. It is made beautifully of indestructible celluloid, which is as transparent as glass. Underneath the celluloid, on one side of the handle is placed the name and residence of the owner, and on the other side pictures of a Queen, Drone, and Worker, as shown here.

The Material entering into this celebrated knife is of the very best quality; the blades are hand-forged out of the very finest English razor-steel, and we warrant every blade. It will last a life-time, with proper usage.

Why Own the Novelty Knife?—In case a good knife is lost, the chances are the owner will never recover it; but if the "Novelty" is lost, having name and address of owner, the finder will return it. If traveling, and you meet with a serious accident, and are so fortunate as to have one of the "Novelties," your POCKET-KNIFE will serve as an identifier; and, in case of death, your relatives will at once be notified of the accident.

How to Get this Valuable Knife.—We send it postpaid for \$1.25, or club the Novelty Knife and the American Bee Journal for one year—both for \$2.00. (Allow two weeks for Knife order to be filled.)

### SOLID GOLD FOUNTAIN PEN

Finally we have found a good Fountain Pen that is reasonable in price. The manufacturers of this pen say that if you pay more than \$1.25 for other fountain pens, it's for the name.

This pen is absolutely guaranteed to work perfectly, and give satisfaction. The Gold Nibs are 14 kt., pointed with selected Iridium. The Holders are Para Rubber, handsomely finished. The simple feeder gives a uniform flow of ink. Each pen is packed in a neat box, with directions and Filler.

Worker

Queen

Drone

3/8 size

We mail this Gold Fountain Pen for only \$1.25, or for \$2.00 we will mail it and the weekly American Bee Journal for a whole year.

Sample copy of the American Bee Journal free; trial trip of three months (13 copies) for 20c; regular yearly price, \$1.00. Address all orders to

**GEORGE W. YORK & CO., 334 Dearborn St., Chicago, Ill.**

## Standard-Bred Italian FREE PREMIUM QUEENS

We are booking orders now for those Fine Untested Italian Queens that we offer every year FREE to paid-in-advance subscribers as premiums for getting NEW subscribers for the Weekly American Bee Journal. These orders are taken for May or June delivery.

### What Some Say of our Standard-Bred Italian Queens:

*George W. York & Co.*:—The two queens received of you some time ago are fine. They are good breeders, and the workers are showing up fine. I introduced them among black bees, and the bees are nearly yellow now, and are doing good work. A. W. SWAN.  
Nemaha Co., Kan., July 15.

*George W. York & Co.*:—After importing queens for 15 years you have sent me the best. She keeps 9/10 Langstroth frames fully occupied to date, and, although I kept the hive well contracted to force them to swarm, they have never built a queen-cell, and will put up 100 pounds of honey if the flow lasts this week. CHAS. MITCHELL.  
Ontario, Canada, July 22.

*George W. York & Co.*:—The queen I bought of you has proven a good one, and has given me some of my best colonies. N. P. OGLESBY.  
Washington Co., Va., July 22

*George W. York & Co.*:—The queen I received of you a few days ago came through O.K., and I want to say that she is a beauty. I immediately introduced her into a colony which had been queenless for 20 days. She was accepted by them, and has gone to work nicely. I am highly pleased with her and your promptness in filling my order. My father, who is an old bee-keeper, pronounced her very fine. You will hear from me again when I am in need of something in the bee-line. E. E. McCOLM.  
Marion Co., Ill., July 13.

### How to Get these Queens Free

To any one whose own subscription to the Weekly American Bee Journal is paid in advance, we will mail a Fine Standard-Bred Untested Italian Queen next May or June, for each new name and address sent to us with \$1.00 for the Bee Journal a year. No one can get for himself the Bee Journal a year and the Queen for \$1.00. The Queen is offered as a premium for the work of getting some one else to take the Bee Journal a year. If you, yourself, want the Bee Journal a year and the Queen, send \$1.50 for the two, and we will book your order for a Queen. Queen orders will be filled in rotation—"first come, first served." Address,

**GEORGE W. YORK & CO.**

## Langstroth on the \*\*\* Honey-Bee

Revised by Dadant—Latest Edition.

This is one of the standard books on bee-culture, and ought to be in the library of every bee-keeper. It is bound substantially in cloth, and contains nearly 600 pages, being revised by that large, practical bee-keeper, so well-known to all the readers of the American Bee Journal—Mr. C. P. Dadant. Each subject is clearly and thoroughly

explained, so that by following the instructions of this book one cannot fail to be wonderfully helped on the way to success with bees.

The book we mail for \$1.20, or club it with the American Bee Journal for one year—both for \$2.00; or, we will mail it as a premium for sending us THREE NEW subscribers to the Bee Journal for one year, with \$3.00.

This is a splendid chance to get a grand bee-book for a very little money or work.

**GEORGE W. YORK & CO.**  
118 W. Jackson Blvd., CHICAGO, ILL.

## DOOLITTLE & CLARK

Have some fine Italian Queens of last fall's rearing that are ready to be sent out, by return mail, at \$2.50 and \$5.00 each.

**Borodino, Onondaga Co., N. Y.**  
21D1f Please mention the Bee Journal.

17A13t Mention the Bee Journal

"The continuous advertiser gets the bulk of the business, because others are not advertising, and he is."

**Something New = The Ideal Hive-Tool**

Bee-keepers have long needed a special Tool to work among the hives during the bee-season. The one shown here was invented by Wm. Muench, a Minnesota bee-keeper, some years ago, but it was not on the market before. We have lately bought this Tool, and all rights, from Mr. Muench's widow, and have had the first lot made. They are ready for delivery now.

Best Hive-Tool

Only 30c, by mail

(This picture is exactly one-half the size.)

DESCRIPTION.—The Ideal Hive-Tool is made of high-grade malleable iron, much like wrought iron, 8½ inches long. The middle part is 1 1-16 inches wide and 7-32 thick. The smaller end is 1¼ inches long, ½ inch wide, and 7-32 thick, ending like a screw-driver. The larger end is wedge-shaped, having a sharp semi-circular edge, making it almost perfect for prying up covers, supers, etc., as it does not mar the wood.

**What Dr. Miller and Miss Wilson Say of It:**

In the first edition (1903) of Dr. Miller's "Forty Years Among the Bees," page 58, he says: "Of all the hive-tools I have tried, I like best the Muench tool." On Jan. 7, 1907, he wrote us saying he thought "just as much of the tool as ever."

Miss Wilson, Dr. Miller's assistant, says this of the Ideal Hive-Tool: "It is an ideal tool. In fact, I don't see how it could be improved upon. I am sure we would feel utterly lost in the apiary without it. . . . You will have to try one yourself if you want to know its worth."

**The "Ideal Hive-Tool" Free as a Premium.**

We will mail an **Ideal Hive-Tool FREE** as a premium to any present paid-in-advance subscriber to the American Bee Journal, for sending us **ONE NEW** subscription for a year at \$1.00; or we will send the American Bee Journal one year and the **Ideal Hive-Tool**—both for \$1.20. Price of the **Ideal Hive-Tool** alone, postpaid, 30 cents. Address,

GEORGE W. YORK & CO.,

CHICAGO, ILL.

are made every year in the book business. Every family, rich or poor, must have books. During the last few years, \$7,500,000.00 have been expended for Modern Eloquence, \$12,000,000.00 for Stoddard's Lectures, \$21,000,000.00 for the Century Dictionary, and the tremendous sum of \$44,000,000.00, covering over half a million sets of the Encyclopaedia Britannica. These books were sold by subscription in American homes and sales are still going on.

We have a subscription publication which sells more readily than any of the above. The demand is already so tremendous that more capital is required to swing it, or get behind on orders. Profits are enormous, several times savings bank interest.

We have arranged a plan whereby

**Any Progressive Man or Woman Can Share These Profits**

becoming stockholders in a profitable business, based on twenty years' experience. Remember, the success of this publication is not away off in the future—it is not prospective, but it is a success at the present time and growing in demand every hour. Sales of this publication at the time of publishing this advertisement

**Often Exceed \$2000 a Day**

This is an exceptional opportunity for those of small means to get in on the ground floor in a business which legitimately pays large dividends and is as solid as the Rock of Gibraltar. It cannot be held open for long as the response is certain to be so great that we shall have all the capital we need to increase the number of our presses and secure stock to be turned out in completed books, which are selling like wildfire.

You owe it to yourself to investigate this opportunity. You will never have a chance like this again to become

**Part Owner in a Mammoth Publishing House**

which is already in successful operation, already earning big dividends, and which is led to sell a small amount of its stock simply because the business is already so tremendous as to exhaust the working capital. But if you would grasp this opportunity you must

99 Percent of your Wax can now be saved  
by using the

## HERSHISER WAX-PRESS

Manufactured Exclusively by

G. B. LEWIS COMPANY, Watertown, Wis.

"NOT IN ANY TRUST."

We are offering to our customers this year for the first time the Hershiser Wax-Press, a cut of which is herewith given. It has just been invented, and consequently has never before been offered for sale.

The Hershiser Wax-Press is not only the best wax-press ever put on the market, but it is an almost perfect device for extracting wax. WE WILL GUARANTEE IT WILL EXTRACT WITHIN 1 PERCENT OF ALL THE WAX CONTAINED IN THE SLUMGUM PLACED IN IT, IF PROPERLY OPERATED. All the other wax-presses now in common use will necessarily leave in the slumgum a large amount of wax, the quantity varying from 8 to 25 percent; in other words, the Hershiser Press is able to get about 7 percent of wax out of slumgum after the very best of all other wax-extractors has obtained the greatest possible amount of wax from it.

For Sale Everywhere.

Ask Your Dealer About It.

Read what One of the First Users, who is an Experienced Bee-Keeper, says of the Hershiser Wax-Press :

Mr. O. L. Hershiser, Buffalo, N. Y.

*My Dear Sir:*—I have had one of your wax-presses for about 30 days, have used it about one-half of the time and got about 700 pounds of nice wax from the slumgum and refuse that accumulated in 18 months from the kettle and boiling process of getting out wax that I have used for years and thought I got out all the wax. The machine more than paid for itself in 5 days. Mr. Hershiser, I think I am safe in saying that I have thrown out in the field \$100 to \$150 worth of wax each year for the last 10 or 15 years. You surely have them all stopped on wax-presses.  
W. L. COGSHALL.

## A GREAT IMPROVEMENT

Will be found in

## The American Bee-Keeper for 1907

It is profusely illustrated and enlarged, and contains only articles of the most practical as well as scientific nature. A special corps of the best writers has been engaged. The editors are Harry E. Hill and Arthur C. Miller, than whom there are no more practical or experienced bee-keepers in this country. We have published the American Bee-Keeper continually and regularly since 1890.

Regular subscription price, 50 cents a year. One year to new subscribers, 35 cents; three years for \$1.00.

Send for sample copy and our new illustrated price-list of **BEE-SUPPLIES OF ALL KINDS.**

Guaranteed highest quality at lowest price. Address,

**THE W. T. FALCONER MFG. CO.**  
JAMESTOWN, N. Y.

[Established 25 years.]

## Honey and Beeswax

**CHICAGO, May 9.**—Very little honey on the market of any kind. Prices are therefore nominal. A little choice white clover comb sold at 17c, and would bring that at present, but supply seems to be exhausted; even with this scarcity there is no demand for No. 2 grades. Extracted, white, 7@8c; amber, 6@7c. Beeswax in good demand at 32c. **R. A. BURNETT & CO.**

**CINCINNATI, April 16.**—There is nothing new in the honey market, excepting that this part of the country is bare of comb honey, and it is well, for consumers will appreciate the new crop more when it arrives. We are selling extracted amber honey in barrels at from 5½@6½c. Fancy table honey, 8½c@9c, in crates of two 60-pound cans. For choice yellow beeswax, free from dirt, 32c cash, delivered here.  
**THE FRED W. MUTH CO.**

**PHILADELPHIA, May 11.**—The continued cold weather has made the sales in the comb honey market hold out much later than usual. Quite a good many sales have been reported in the last 10 days. Prices have been steady and at the present time show a little tendency to weaken. We quote: Fancy comb, 14@15c; No. 1, 13@14c; amber, 12@13c. Fancy white extracted, 7@8c; light amber, 6@7c. Beeswax firm at 32c.

We are producers of honey and do not handle on commission. **WM. A. SELSER.**

**NEW YORK, April 12.**—**COMB HONEY.**—There is very little doing; stock of white honey of all grades is practically cleaned up, and small shipments which arrive from time to time, find ready sale at 14@15c for choice white stock, and 12@13c for off grades. Considerable dark comb honey is left on the market, and there does not seem to be any demand whatsoever. We quote nominally at 10@11c, but in large lots we doubt whether this price can be realized. **EXTRACTED HONEY.**—California stock seems to be well cleaned up, and we are informed that there is very little left on the Coast, and, before the new crop is marketed, whatever is on the market now will have been consumed. The prospects in California are very good for a large crop, but nothing definite can be said at this time, and there is no surety of a big crop until it is actually gathered. Last season the outlook was just as good, but in the height of the season, cold northern winds and generally contrary weather affected the crop to such an extent that it was small as in previous years. With favorable

# C. H. W. WEBER

CINCINNATI ... OHIO ...

Office and Salesrooms, 2146-48 Central Ave. Warehouses, Freeman and Central Aves.

weather in California for the next two months a large crop will undoubtedly be harvested, and if so prices will naturally be considerably lower than those of the past season and present prices. We quote white sage at from 7@9c, and light amber at from 7@7½c. Near-by, as well as Southern honey, is well cleaned up, and the markets are in good shape for new crop. Cuban and other West Indian honeys are arriving in large quantities, most of which are sold for export. The market is firm, at from 58@60c per gallon, duty paid according to quality. Beeswax firm and steady at from 30@31c.  
**HILDRETH & SEGELKEN.**

**INDIANAPOLIS, April 12.**—Comb honey is not plentiful, but demand is slack. Fancy white comb brings 16@17c; No. 1 white, 14c; amber, 12@13c. Best grades of extracted honey bring 8@9c; amber, 6@7c. Good average beeswax sells here at \$35 per 100 pounds.  
**WALTER S. POWDER.**

**TOLEDO, May 3.**—There is very little demand for comb honey as is usually the case at this season of the year. Fancy white would bring in a retail way 16@17c; No. 1, 15@16c, with no demand for dark honey. Extracted is very scarce and none being offered for sale. Beeswax is bringing 28c.  
**THE GRIGGS BROS. & NICHOLS CO.**

**KANSAS CITY, May 4.**—Receipts of comb and extracted honey are light; in fact, the market is almost bare. The demand for comb honey is good, but for extracted is rather light. We quote: No. 1 white comb, 24 sections, \$3.25; No. 2, \$2.75; No. 2 amber, \$2.50 to \$2.75. Extracted, white, 8@9c; amber, 7@8c. Beeswax, 50c.  
**C. C. CLEMONS & CO.**

**DENVER, Feb. 14.**—Producers in this State are practically closed out of both comb and extracted honey. We have not sufficient good comb honey to supply our local trade, but have a good supply of white extracted of excellent quality. We quote strictly No. 1 white comb honey, per case of 24 sections, at \$3.20; No. 1, light amber, \$3; and good No. 2, \$2.80. White extracted, 8@8½c per pound; light amber, 7½@8c. Clean, yellow beeswax, 27@28c, delivered here.

**THE COLO. HONEY-PRODUCERS' ASSN.**

**CINCINNATI, April 3.**—The market on honey is entirely bare of fancy comb honey; No. 2, selling at 12½c, and slow sales. Light amber extracted sells in barrels at 5½@6c. Beeswax 32c, delivered here.  
**C. H. W. WEBER.**

# AMERICAN BEE JOURNAL

## Cover Them Over

BY WILL CARLETON

Cover them over with beautiful flowers;  
Deck them with garlands, those brothers of ours;  
Lying so silent, by night and by day,  
Sleeping the years of their manhood away;  
Years they had marked for the joys of the brave;  
Years they must waste in the sloth of the grave.  
All the bright laurels they fought to make bloom  
Fell to the earth when they went to the tomb.  
Give them the meed they have won in the past;  
Give them the honors their merits forecast;  
Give them the chaplets they won in the strife;  
Give them the laurels they lost with their life.  
Cover them over—yes, cover them over—  
Parent, and husband, and brother, and lover;  
Crown in your heart these dead heroes of ours,  
And cover them over with beautiful flowers.

\* \* \* \* \*

Cover the thousands who sleep far away—  
Sleep where their friends can not find them to-day;  
They who in mountain and hill-side and dell  
Rest where they wearied, and lie where they fell.  
Softly the grass-blade creeps round their repose;  
Sweetly above them the wild flow'ret blows;  
Zephyrs of freedom fly gently o'erhead,  
Whispering names for the patriot dead.  
So in our minds we will name them once more,  
So in our hearts we will cover them o'er;  
Roses and lilies and violets blue  
Bloom in our souls for the brave and true.  
Cover them over—yes, cover them over—  
Parent, and husband, and brother, and lover;  
Think of those far-away heroes of ours,  
And cover them over with beautiful flowers.

When the long years have crept slowly away,  
E'en to the dawn of Earth's funeral day;  
When, at the Archangel's trumpet and tread,  
Rise up the faces and forms of the dead;  
When the great world its last judgment awaits;  
When the blue sky shall swing open its gates,  
And our long columns march silently through,  
Past the Great Captain, for final review;  
Then for the blood that has flown for the right,  
Crowns shall be given, untarnished and bright;  
Then the glad ear of each war-martyred son  
Proudly shall hear the good judgment, "Well done."  
Blessings for garlands shall cover them over—  
Parent, and husband, and brother, and lover;  
God will reward those dead heroes of ours,  
And cover them over with beautiful flowers.

**National Bee-Keepers' Association**  
Objects of the Association.

- 1st.—To promote the interests of its members.
- 2d.—To protect and defend its members in their lawful rights.
- 3d.—To enforce laws against the adulteration of honey.

Annual Membership Dues, \$1.00.

General Manager and Treasurer—  
N. E. FRANCE, Platteville, Wis.

If more convenient, Dues may be sent to the publishers of the American Bee Journal.

**Bee-Keepers' Souvenir Cards**  
are just the thing.

We send them by Return Mail

O WONT YOU BEE MY HONEY,  
AND CHEER THIS LONELY HEART?  
FOR I WOULD HUG YOU ALL THE TIME,  
AND WE WOULD NEVER PART

As most of our readers know, we have got tenout a Souvenir Postal Card for bee-keepers. The cuts herewith show the card in reduced size, and but one color, while the real card is printed in 4 colors. It could also be sent to honey-customers, to remind them that it is time to buy more honey, etc. There are many uses to which this Card can be put.

Prices—postpaid: 3 cards for 10c (stamps c. silver), or 5 FREE with the American Bee Journal one year at \$1.00; 10 for 25c. There is a blank space on the card about 2x2 1/2 inches in size for writing. Send all orders to

**GEORGE W. YORK & CO.**

JOHN DOLL & SON, Proprietors,

Nicollet Island, No. 33,

MINNEAPOLIS, MINN.

Mention Bee Journal when writing.

# HOW TO PAINT

Buggies, farm wagons, farming tools, barns, outbuildings and houses often need painting. "Everybody's Paint Book," written by a thoroughly practical painter, will be found a complete guide to the art of outdoor and indoor painting. It is designed for the special use of those who wish to do their own painting. It gives practical lessons in plain painting, varnishing, polishing, staining, paper hanging, kalsomining, etc.

It also tells how to renovate furniture and gives many hints on artistic work for decorating a home. Precise directions are given for mixing paints for all purposes.

If farming tools and farm vehicles are kept painted, they will last twice as long, and anybody can do the work with the aid of this book. It is handsomely and substantially bound in cloth. A copy will be sent postage prepaid on receipt of price, **\$1.00**

## SPECIAL OFFERS

For \$1.60 we will send the above book and the Weekly American Bee Journal one year; or for \$1.40 we will send the Paint book and a Standard-Bred Untested Italian Queen. Address  
**GEORGE W. YORK & CO., 118 W. Jackson Blvd., Chicago, Ill.**

# Dittmer's Gomb Foundation

Why do thousands of bee-keepers prefer it to other makes?  
Because the bees like it best and accept it more readily.

## Dittmer's Process is Dittmer's

It stands on its OWN NAME and its OWN FOUNDATION, to which alone it owes its reputation and merits.

We are now ready to make prices for next season for WORKING WAX for CASH and for full line of Supplies. Wholesale and Retail. Free Catalog and Samples.

## GUS DITTMER, Augusta, Wis.

# The Business End of the Bee

By the Bee-Crank

A genius has been defined as one with an infinite capacity for details. This puts the bee in the genius class. He goes after the first promising prospect, cleans that up and hunts up another. He doesn't spend his time waiting for a streak of luck. He just gathers the honey wherever he can find it.

Now, the bee-supply business is a good deal the same way. I believe one customer on the book is worth a flock in the open. I take care of him first, and do my prospecting afterwards if I have time. I treat him in such a way that he will come back without coaxing.

How I do it is another story. But it means an infinite attention to details for one thing, and the best way to get a taste of it is to send me your next order, and let me show you.

**BEESWAX**—I pay 33 cents in trade. Will ship any Supplies you may need in exchange for your wax. Send by freight or express according to size of package, and put your name upon it.

My new Catalog—Have you seen it? It's free. Send a postal for it to-day.

Arthur, Ill., May 9, 1907.  
Walter S. Pouder, Indianapolis.  
Dear Sir:—Draft for beeswax arrived promptly; the amount was for more than I had expected.

Yours truly, Ed Cox.

## Walter S. Pouder

513-515 Massachusetts Av., INDIANAPOLIS, IND.

# American Bee Journal

## Trade Notes The A. I. Root Company, Medina, Ohio

### THE HATCH WAX-PRESS

If you have been so unfortunate as to lose some of your bees the past winter, or even this spring, save the wax in the combs by the use of some good wax-press. If you look about you will probably find a lot of old combs in your neighborhood which you can get for a song. Wax is higher now than for many years and you should hurry it to market, for the present high prices will likely continue but a few weeks, at most. Our new Hatch Press has several valuable features, viz :

- Durability.
- Ease of operation.
- Most thorough in its work.
- Superior quality of product.
- Low cost. Price is only \$6.00.

### WANTED

If you know of any one who has bees to sell this month, we can probably find a purchaser for the same—any number—5 to 100 colonies—provided we are given a brief, explicit description at once. Please state condition, hives, race, price, etc.

### BEE SWAX

We are paying at this date 31 cents cash or 33 cents in trade for pure, average beeswax, delivered at any of the following offices: Medina, Ohio; Chicago, New York, Philadelphia, or Washington. A large number of our jobbing agents make the same prices. See list of dealers in American Bee Journal for May 2.

### BEE-HIVE PAINT

We are distributing agents for the B. P. S. Paint. This is one of the best hive-paints to be found on the market. We have handled it for 10 years or more, and do not recall a complaint in all that time. Equally good for your house or any indoor or outdoor work. We ship the O. W. (Outside White) from

any of our offices; and the colors from Medina, New York, and Chicago. Send for color cards, etc.

### SPECIAL

For the next 10 days from date of this paper, to test the value of these columns, we offer a copy of the book, "How to Keep Bees," price, \$1.10, for only 60 cents, postpaid. Furthermore, we will promptly refund the money to any dissatisfied purchaser, even after you have read the entire book. You must send your order for this to Medina, and mention the American Bee Journal of this date.

### LESSONS IN BEE-KEEPING BY MAIL

There is now, and has been for years, a greater demand for experienced bee-help than there are men ready for these places. Each winter and spring we are obliged to disappoint many large apiarists by telling them we do not know where suitable help can be found. The demand has already begun for the present season. We have found that many who take our course in bee-culture by correspondence prefer to go into business for themselves, so we still need active young men who have a fair knowledge of the subject—men whom we know something about—who can be recommended for the places frequently offered. We, therefore, offer again a limited course in

#### BEE-KEEPING BY MAIL.

We shall designate this as Course No. 2. The lessons are identical with the lessons in Course No. 1. The time, however, is limited to one year from enrollment. The course may be easily completed in 3 to 4 months. The following is the

#### OUTLINE OF COURSE NO. 2. (17 Lessons.)

- I. Definitions of Terms.
- II. Inmates of the Hive.
- III. Comb.
- IV. Handling Bees.
- V. Transferring.

- VI. Building Up Colonies.
- VII. The Honey-flow.
- VIII. Swarming.
- IX. Rendering Normal.
- X. Preparing for Winter.
- XI. Wintering.
- XII. Spring Management.
- XIII. Bee-Diseases, Symptoms.
- XIV. Enemies of Bees.
- XV. Establishing an Apiary.
- XVI. Queen-Rearing.
- XVII. General Examination.

#### TERMS OF COURSE—FULL CASH PAYMENT.

Complete course as outlined, lessons, personal answers to all questions, including the A B C of Bee-Culture (500-page book), and Gleanings in Bee Culture (semi-monthly) for one year, \$5.00.

With either the A B C or Gleanings omitted in case you have one, \$4.00.

With both omitted in case you have both, \$3.00.

#### USE THIS FORM IN ORDERING.

Vol. XLVII—No. 22

## Editorial Notes and Comments

### The Alexander Weak-Colony Plan

Some have met failure in trying the method of strengthening weak colonies in spring by placing them over strong colonies, and excluder between; but others are so enthusiastic over their success that it may be worth while for those who have not succeeded to make further trial with perhaps some precaution added. It has been suggested that if greater care were used, even hybrids would be all right. None but a *very* strong colony should be used for the lower one, and if it be very much stirred up at the time the weak colony is placed over, it may proceed at once to massacre the intruders. So the work should be very quietly done, so that the bees be not aroused.

A. A. Ashley gives in *Gleanings in Bee Culture* a plan worth trying. He says:

"I tried it on 3 colonies, and it proved a success with me. I think the reason some fail is because they fuss with the strong colony till they get them too thoroughly roused up. I put on the excluder, then put screen wire over that, and I set the weak colony on; 24 hours later I lifted off the weak colony, and quickly and gently removed the screen, then very gently set the weak colony back, and I never had a bee killed. After 30 days I separated them, leaving the weak colony on the old stand, moving the strong one to one side. This gives the weak colony the most of the flying bees. I can't tell any difference in the strength of them."

A correspondent suggests a little different plan: Put over the strong colony a sheet of newspaper. At the central part punch a hole large enough for a bee to pass through. Put over this an excluder, and over this the weak colony. No matter how much the bees are stirred up, they will have plenty of time to quiet down before any considerable number can get through the paper. The hole is made

in the paper, not to make a passage immediately for the bees, but to make a ready starting point for the bees to gnaw through. If this proves upon trial to work all right, it has the double advantage over the wire-cloth plan that it saves the trouble of removing the wire-cloth, and it also saves any possible danger of stirring up the bees at the time of removing the wire-cloth.

The season is so late, and the number of very weak colonies so unusually large that there are no doubt still many colonies that are mere nuclei, and there may be no small gain in trying the plan of Mr. E. W. Alexander.

### Destroying Foul-Brood Spores

Samuel Simmins says this in the *British Bee Journal*:

"The conclusion I have arrived at is, that while a short period of heat at boiling point may fail to destroy the spores of foul brood, there is no reason whatever why a more protracted term at blood temperature should not bring about the end of their existence where further propagation is out of the question."

### Dwarf Bees in Old Combs (?)

In *Prak. Wegweiser* it is reported that undersized workers appeared in a colony, and inspection showed combs with cells not a centimeter (about 2-5 inch) deep, because these combs had never been exchanged, and were now 10 years old. One wonders whether closer investigation might not have led to a different conclusion. Thousands of combs in this country can probably be found that are 10 years old and older, some of them 20 or 30 years old, and none of them are found with cells less than the usual depth. Indeed, a little thought ought to make one expect that

bees would keep their brood-cells of normal depth unless such a thing were impossible. Cut away the walls of a cell, either in whole or in part, and the bees will build them again, so as to make the cell the proper depth; why should they not build them out to the proper depth if they are made too shallow by cocoons filling up the bottom? Exactly that is what they do. Measure a brood-comb from which its first set of brood has emerged, and it measures  $\frac{3}{8}$  of an inch. Take a comb that is old enough, and it measures a full inch. The septum has become  $\frac{1}{8}$  inch thick, and the mouth of the cell has been built out to correspond, leaving the cells just as deep as when first built.

### Tearing Down Worker Foundation to Build Drone-Comb

Dadant's denial of this, except in case of imperfect foundation, calls forth this remark in *Prak. Wegweiser*:

"Many bee-keepers, who observe with open eyes, will shake the head incredulously at this assertion: noted leaders are not infallible."

It might not be a safe thing to assert that a thing never happened just because one has not seen it, but after hundreds of swarms or colonies had been given hives entirely filled with foundation, if not one of them had torn down any part of the foundation in order to fill its place with drone-comb, it would seem pretty safe to conclude that bees were not in the habit of thus tearing down. Certainly a great many in this country make a practise of giving full sheets of foundation; has any one had it torn down to be replaced with drone-comb?

### Thickness of Hive-Walls

D. M. M. says in the *British Bee Journal*:

"Should the walls of a hive be thick or thin? Fifty years ago it was advised that wood one inch up to an inch and a half thick should be used. Gradually a change came, till now we rarely find factory-made hives with wood thicker than half an inch. I am not aware that bees have suffered in any way from the innovation."

In this country  $\frac{3}{8}$  is perhaps the universal thickness. If  $\frac{1}{2}$  inch does as well across the water, perhaps it might also answer here. Certainly there would be some advantage in

# American Bee Journal

the matter of cost, and in the matter of lightness.

## Planting for Honey

This is a subject that has been discussed among bee-keepers for many years, the conclusion arrived at being that unless the plant grown for honey has other special values it will not pay to grow it. Touching this matter, Prof. A. J. Cook has this to say in *Gleanings in Bee-Culture*:

Another thing that we have determined once for all, is that it will not pay to plant exclusively for honey. Plants like clover and alfalfa, that will pay for other purposes than honey, will pay well. It may, and often will, pay well to furnish seed to a farmer who

lives near our apiary, if he will grow alsike clover, alfalfa, or any other useful plant that has a double use in that it also furnishes honey; it will also pay well to secure the planting of valuable honey-trees along the highway, such as linden, tulip, acacia, catalpa, and eucalyptus, when they are among the best of trees for roadside adornment. It is wise to plant sweet clover, motherwort, and other good honey-plants in all waste places near the apiary. It is better to have such space occupied by plants that have value, and not grow weeds that are a sore disfigurement, and, besides, furnish seeds to scatter to become a nuisance to our neighbor as well. I once heard Mr. Harbison, the distinguished bee-keeper, say that he had planted the wild sage in waste places to great advantage in our State; but to grow any plant on valuable land that has no use other than the nectar it yields is a mistake. This has been demonstrated beyond question.

of the National. The exact time and place have not yet been decided, but doubtless will be very soon.

Mr. France had letters on his desk from the following States, which referred to the condition of the bees and weather:

California, where they were feeding the bees.

Texas, where they have had two extractings with a cold wave following.

Tennessee, with weather too cold for brood-rearing.

Louisiana, where the cold weather was still continuing.

It seems that reports indicate quite general cool weather over the country during the past few weeks.

Mr. France had been away from home for about 3 weeks in Wisconsin, and reports cold weather for the past 6 weeks, which injured Wisconsin bees as much as had all the past winter.

Mr. J. J. Shearer, of Plymouth, Mich., when renewing his subscription recently, wrote as follows:

I am now taking 52 papers and journals every month, but can't think of dropping the American Bee Journal. All of them are worth more than they cost. I am 75 years "young" to-day, and get time to look them all over. I would like to send you some subscribers if I could, but there are only 3 colonies of bees within 4 miles of me.

J. J. SHEARER.

Mr. Shearer certainly takes his share of current literature. He was one of the "young fellows" who made up the carload of bee-keepers that went to the Los Angeles convention in 1903. Dr. Miller was another. So was A. I. Root. They will probably never forget that memorable trip, nor will 25 or 30 others who were permitted to enjoy it.

**Worst Outlook for Bees.**—Mr. C. P. Dadant, of Hamilton, Ill., wrote us on May 21st as follows:

FRIEND YORK:—The outlook is the very worst for bees that I have seen in 40 years. There is no white clover here, and we can not see anything to help them out, unless we have an exceedingly wet year.

C. P. DADANT.

Surely, the above seems discouraging, but let us all hope that the season may yet be all right for the bees.

**The Sixth Annual Report** of the Illinois State Bee-Keepers' Association has just been issued, containing 176 pages. Its contents, besides considerable miscellaneous matter, are the 1906 reports of the Illinois State Bee-Keepers' Association, the National, and the Chicago-Northwestern. There are a number of very fine engravings of apiaries, the Illinois State Capitol, etc. Cloth-bound copies were issued for the members of the Association only, and will be sent out as long as they last to any who become members on the payment of \$1.00 to the Secretary, which not only secures a cloth-bound copy, but membership in the State Association one year, and the same in the National Association. A paper-covered copy of the Report will be mailed to any one who sends 15 cents to the Secretary to pay postage and wrapping. We think the Sixth Annual Report is as attractive and instructive as any we have ever issued. General Manager N. E. France says concerning this Report: "It is a credit to all concerned in getting it out."

JAS. A. STONE, Sec.

Route 4, Springfield, Ill.

**Quitting the Strenuous Life** is the subject of an article in the Saturday Evening Post of May 25, written by that interesting author, Mr. Forrest Crissey. In it he recommends bee-keeping as a work to be taken up by those who have tired of the stress of life in the city and wish to get back to Nature and country life. He quotes largely from the experiences of those who have succeeded with bees, among them being Dr. C. C. Miller.

It may seem strange, but the article referred to was prepared about 2 years ago, and only now appears in print. This fact will account for some statements in it, among which is this one: "In March of this year there was organized, in Chicago, The Honey-Producers' League, which can scarcely fail greatly to extend the honey market." Most of our readers know that last year the League was discontinued, and its funds turned over to the National Bee-Keepers' Association, to be used as originally intended by the League. So its good intentions will be carried out.

Mr. Crissey has done bee-keepers a good service, in that he has placed before perhaps a million readers the fact that there is not, and never was, any such thing as manufactured comb honey; and also that honey is of such great value as a daily food.

We may say further that Mr. Crissey has been a reader of the American Bee Journal for several years, and takes great interest in the bees he keeps for experimental purposes.

**Dr. Bigelow and the Agassiz Association.**—The Daily Advocate, of Stamford, Conn., of recent date contains a lengthy account of the Agassiz Association and its new president, Dr. Edward F. Bigelow, who was elected at a meeting of the trustees of the Association in Pittsfield, Mass. Dr. Bigelow is greatly interested in bees as a nature study, so doubtless he will help to promote the gen-

eral interest in them through the organization of which he is now the honored head.

*Gleanings in Bee Culture* gives this notice, which, though brief, covers the case very nicely:

Our esteemed friend, Prof. Edward F. Bigelow, has just been elected to the presidential chair of the Agassiz Association, a world-wide organization, having for its object the popularization of nature study and outdoor science. In connection with the election of Dr. Bigelow, it has been decided to erect a building for a permanent headquarters for the society, and in addition a museum, library, and a model school of nature study, all to be located in Stamford, Conn.

It ought to be stated that the Agassiz Association is not a combination of scientists, but, rather, a collection of people who are endeavoring to extend their knowledge of animated nature; and it rather aims to interest ordinary every-day people who wish to educate themselves along such lines. The work is particularly interesting to teachers.

We are certain of one thing, Dr. Bigelow will not neglect the study of bees in connection with the work he has undertaken, and an apiary will surely form a prominent part of any nature-study enterprise with which he has to do. For this reason, and the fact we are well acquainted with the Doctor personally, we wish the Association every success.

Those who may be interested in this kind of work, and who desire more information, should apply to Dr. Bigelow, Stamford, Conn., for all particulars.

We congratulate both the Agassiz Association and Dr. Bigelow. It is a great combination. And Pres. B. will now have a wider opportunity for his abounding enthusiasm along the line of nature study.

**General Manager N. E. France** (Platteville, Wis.), of the National Bee-Keepers' Association, writing us May 18, 1907, reported that there were 2346 members of the Association at that date. It would seem that it might be an easy matter to have a membership of 2500 by the time of the next meeting

Conducted by EMMA M. WILSON, Marengo, Ill.

### A Sister's Experience With Bees

MY DEAR MISS WILSON:—About 10 years ago a friend gave me a swarm of bees in a box-hive, and told me this was too poor a honey-producing region to make bee-keeping profitable, but that I could hive the swarms that came off each year, and in the fall kill off the old colonies and use their honey.

For the first 2 or 3 years I paid little attention to the bees. If we chanced to be about when they swarmed we put them in a box, but got little honey, as I could not make up my mind to kill them. Finally I was persuaded to get a frame hive, and the way we *mis*-managed the swarm that we put into it would take too long to tell. All the family, and some of the neighbors, assisted; and the stings we got! I was stung on the face and head, and in about an hour my eyes were closed, and for a day or so I could not see, and was very sick. The "other half" wanted to shoot the bees, and not have one on the place, but for my part I rather admired them for resenting our treatment, and next year I got 5 hives, and that season I sold \$9 worth of section honey, at 20 cents a section. The bees in the boxes (except the old one) died. I now have the old box and 25 colonies in frame hives, though I have lost quite a number some winters.

Most of the hives are under an open shed, and part of them out in the open, and only one colony died last winter. Some seasons there is too much rain, and they store very little honey, while in others they store a good crop.

Some years I have sold \$35 worth of section honey at 15 cents. I take it to our little town and peddle it out among my neighbors. Often I could ask 25 cents, but believe it better to take less and have a steady cash custom.

Last year I put a new swarm into a hive where the bees had died during the preceding winter, and in about 4 weeks they had filled the 24 sections (also the body).

As the stings poison me so I do not handle my bees as they should be handled for profit; that is, I could divide and double up colonies, and do much more with them according to the bee-books.

I do not know what kind of bees they are, but unless abused they are easy to work with. Often, when I am working with them, I get interested and handle them quite freely, and am not nervous with them at any time, yet I think it best to wear a veil and be on the safe side. A number of times,

when trying to saw off a limb high up in a tree, I have had the swarm fall on my head, and down to the ground in a shower, but they would at once go back to the limb, and never seem to know I was there.

The bother about swarming time is, there are so many trees, and tall ones, too, in which the bees cluster. I find that if they seem inclined to go too high or not settle, a shower with the spray-pump settles them—just a mist so they think it is raining. Sometimes I put on a trap when I think a swarm will be coming out, and that way I have less trouble; but as I am quite hard of hearing (not deaf, but unable to hear low sounds), I can not hear the queen, nor have I ever been able to see her, though I often have looked for her so I could put her into the hive, as sometimes a swarm seems so contrary about going in, though maybe the next swarm that I have will go into the same hive at once.

Two years ago I was alone when a swarm issued and clustered high up in a young oak-tree. I could get to them all right by using a long ladder, but I could not bring down the swarm—it was so very large. I disliked asking a neighbor to help me, so this is how I managed:

After cutting away all brush below the cluster, I carried a small rope up and put it over a crotch above the bees, then tied it to the limb holding the swarm. Then I went down and fastened the other end of the rope; went up the tree and sawed the limb off, and descended and lowered the cluster till it almost touched the table holding the hive. As they made no move toward going in, I gently brushed them down on the cloth, and in 15 minutes there was no sign of a bee out of the hive, but they scampered in at once.

It amuses me to read about the possibility of sisters handling bees, doing the rough or heavy work, with the exception of moving the hive when full of comb, etc. I have done everything required myself, when no one is here to help. When I tell you I am in my 56th year, you will agree with me that climbing trees and all that is no easy work, but a great many times I do it.

Taking off the supers used to be the hardest for me, as I almost always got stung, but I got a bee-escape, which every bee-keeper should use. I put it in a board as directed, but when it was put under the super I found that the honey was so heavy it had sagged in the center, and that left a space around the edge where the bees went back and forth; and, besides, I did not like so

much handling the bees, so I set my wits to work and this is the result:

Make a box 8 inches deep, of proper inside measure to set a super into. On the inside, half way down, fasten the board in which is the escape. Early in the morning—it is cool then and the bees are more quiet, I find—set the prepared box near the hive. Have ready another super with a cover on. Take off the super full of honey, and set it inside the prepared box; put on the other super, and there you are. If you have some one to help it is easier, but I do not mind in the least doing the job alone—and you can have your honey for dinner. Of course, you understand that the ends of the box below the escape are to be open to allow the bees to get out, and there is to be a cleat on the upper side of the board so as not to crush the bees.

Another improvement, in my opinion, would be to have the metal strips holding section-holders wide enough to be seen at the outside of the hive. A number of times when they are glued down tight, I have run the knife *above* the tin strip and lifted the super-frame off empty.

The bees are now working well. I looked in a few times this morning and they are filling sections. Some are almost full, but I do not like to take off too soon.

Regarding light and dark honey, a good many prefer the dark, saying it has a better flavor than the white. I can not eat honey myself, as it makes me sick. I try it once in a while, though, and now and then, if it is *old* and dark, it does not hurt me.

MRS. GERTRUDE L. GOODWIN.

Roy, Wash., May 1.

As a help against having swarms settle in high trees, you might try a plan that some have reported as successful. Take 4 poles 6 feet long, or longer, tie them together near the top, and then set up the 4 wigwam fashion, with a small bundle of branches with leaves upon them fastened at the top, and also a piece of old comb. Of course, the leaves will wither, but that may be all the better.

If one swarm settles on it, others will be more likely to settle in the same place.

No matter how sharp your hearing, you would not hear a queen in a swarm. When flying she makes no noise different from other bees.

Always glad to hear from you.

### Management for Extracted Honey— "Catty" Molasses vs. Foul- Broody Honey

If I should run my bees for extracted honey till they have the benefit of the honey-flow, which ends about July 15, I think, up to this time I would start nuclei, having each on top of a hive with a laying-queen, with wire-cloth under it to keep the bees from going down and carrying up honey from the lower ones, and to give them the same scent. At the end of the flow I will set the old colony off by itself, put the nucleus down to receive the flying bees, with an excluder over them, and the honey over them to finish ripening. What would be your opinion of the results?

When I was a girl I lived with the family of a man who made sorghum molasses for the

public. He always had lots of molasses to sell. Being short of barrels he filled one  $\frac{3}{4}$  full which had no head in one end, and left it in an outhouse with a cloth over it to keep out the dirt. A cat jumped out of the loft down on the cover and settled down in the molasses till only its head was above the surface. He pulled it out and washed it off, and said, "We will use from another barrel and sell the one the cat was in," and forbade my saying anything about it. Knowing the penalty, I obeyed. How would "cat molasses" do to compare with foul-broody honey on the table of the foul-broody honey-man, and he knowing the condition?

MRS. LAURA E. RUDY.

Fairmount, Ill., April 7.

I think your plan will work all right provided your season is long enough for the new colonies to build up for winter with plenty of stores. It may be necessary for you to feed in order that the bees have enough. You did

not mention it, but, of course, you give your nuclei an outside entrance so they can fly.

Another thing you will need to look after, that is, to give your colonies plenty of room to store during the harvest, or they will surely swarm. It will be a great help in preventing swarming if you give plenty of ventilation also. Just slide each upper story forward, leaving a space large enough so bees can pass through; that will give a good circulation of air, which aids a good deal in the prevention of swarming.

If obliged to eat either, I would prefer the foul-broody honey to "catty" molasses. Surplus honey stored by foul-broody colonies is entirely wholesome for the human stomach, but I must say I prefer not to eat it.

fact, we have to hoe out many of them each year. They grow very freely from self-sown seed, and are perfectly hardy. I had been thinking of saving the seed and scattering it by the roadsides and through the hills whenever I should chance to stroll off for a walk. But I have been a little wary about doing so, as I find that the "A B C of Bee Culture" has dropped the article on this plant from the last edition of that work.

Prof. Cook, in his "Guide," speaks well of the plant as a honey-producer. G. M. Doolittle praises it very highly in one of the early volumes of *Gleanings in Bee Culture*. Why it has been dropped from an encyclopædia on bees and honey I do not pretend to know, unless the compiler was convinced that it was of insufficient importance as a honey-secreting plant. If this were so, the caption should have been retained and a few lines made to follow, stating that the plant is no longer worthy of the consideration of bee-keepers. As a honey-plant I believe it is all right; I should be afraid, though, that it might become a troublesome weed. Who in this State knows all about its honey-value? The spinous fruit-heads are no longer of value in the preparation of woolen cloth, as machinery has taken its place, so Prof. Cook says.

By W. A. PRYAL, Alden Station, Oakland, Calif.

### Indigo Plant

I never knew this was a honey-producer until I saw the bees working upon its blooms in early April at the University of California. In fact, it was not the true indigo-tree that I saw, but the species known as *Indigofera Australis*—a plant bearing rather showy red flowers in early April. It is a native of Australia, and seems to be a good bee-plant. I judge that the true indigo plants, *I. anil* and *I. tinctoria*, yield honey. Plants of each were introduced into the Southern States a century and a half ago.

### The Acacias

This is a flower that I have long recognized as being of benefit to the bees, at least for pollen during the latter part of winter and during spring. I notice that Prof. Cook writes (page 355) in praise of these trees. I endorse what he states in commendation of the tree, but I do not think it is of much value as a nectar-secreting flower. The tree is grown in greater numbers in this portion of California than it is in any other portion of the State that I ever visited. This reminds me that some 10 years ago, when some bee-keepers from the southern counties of the State visited me, they complimented me upon the beautiful appearance of our orange-trees; they were nicer looking trees than they had in the south. I did not understand at first, and so stated. They pointed to some stately specimens of *Acacia latifolia*. There was some resemblance on casual observation—otherwise there

was none. Of these trees I may make mention later, and use some photographs I have made of them during the past couple of years.

### The Teasel

Some teasels found their way into our garden several years ago and became quite a curiosity, for this plant is a rarity in this portion of California. The women-folk at our home soon appropriated the tops with a long stem attached for ornamental and decora-

TEASEL.

tive purposes. Even their friends would carry away some of these "ornaments." The plants became interesting to me, as I found bees always working on the peculiar flowers. From a small beginning the plants have become quite numerous on our place; in

### Judas-Tree and Red-Bud

I never knew how pretty a sight this tree could make until I saw a couple of good-sized specimens in bloom the first week in April. Though not the most showy, *Cercis siliquastrum* seems to be the most thrifty and a profuse bloomer. Its nodding pink pea-shaped flowers are as attractive to humans on account of their prettiness as they are to the bees on account of the nectar they contain. The flowers appear before the leaves, and this adds to the plant's attractiveness. This variety is called "Judas-Tree," and is a native of Southern Europe and Western Asia.

*C. occidentalis*, also called *C. Californica* (red-bud), is found in a wild state in the Sierra Nevada Mountains in the Golden State. Every garden should contain at least a specimen each of these trees.

"Songs of Beedom."—This is a beautiful 16-page-and-cover pamphlet, 6x9 inches in size, containing 10 bee-songs—words and music—all the songs so far written specially for bee-keepers, we believe. It is nice, as well as convenient, to have these songs all in one binding. Every bee-keepers' organization should have copies for use at conventions. They could be sold to members after using once, or held by the secretary for use at future meetings. Of course, every bee-keeper's family will want at least one copy. It is sent, postpaid, for only 25 cents, or 3 copies for 60 cents; or, we will mail one copy with the *American Bee Journal* one year—both for \$1.10. Send all orders to the office of the *American Bee Journal*.

**Amerikanische Bienenzucht**, by Hans Buschbauer, is a bee-keeper's handbook of 138 pages, which is just what our German friends will want. It is fully illustrated, and neatly bound in cloth. Price, postpaid, \$1.00; or with the *American Bee Journal* one year—both for \$1.75. Address all orders to this office.

## Bees as Blossom Fertilizers

BY C. P. DADANT

Since the publication in the American Bee Journal of my articles concerning spraying of fruit-blossoms, and the usefulness of the bees in the fertilization of flowers, I have had letters from a number of bee-keepers and fruit-growers. The sentiment is now very clearly on all sides in favor of waiting to spray until the bloom has disappeared. Even one of the dealers in sprayers, who, until lately has recommended to spray trees during bloom, has changed his advice to "spraying when the bloom is beginning to drop." The very strong assertion made by Senator Dunlap, that "no intelligent horticulturist will hereafter spray during bloom" is bearing its fruits and helping our cause.

Allow me to add another testimony to that already gathered on this subject. W. T. Cary, of Wakenda, Mo., requested one of his bee-friends to inform me of his experience with bloom spraying, and I received the following terse letter which is the more weighty for its conciseness:

CHILLICOTHE, Mo., March 23, 1907.

MR. C. P. DADANT:—There is a man in the neighborhood who sprayed his apple-trees in full bloom; consequently he destroyed his apple crop and killed a great many of my bees.

Yours truly, G. W. BABB.

However, it is necessary to state that spraying must not be long delayed after the bloom, in the case of the apple, for the destruction of the codling-moth, and we find in Bulletin No. 114, of the Agricultural Experiment Station of the University of Illinois, the following remark:

"Taking into consideration the variation in the different clusters on the same tree, and the fact that the calyx cavities can be more readily reached by the spray if the calyx is entirely open, rather than partially closed, it is probable that the entire orchard should be sprayed within 7 days from the time that most petals have fallen."

They add that in a mixed orchard spraying may be commenced upon the earlier blossoming varieties before the others are ready.

But I did not sit at my desk to talk spraying; what I meant to do was to give another evidence of the usefulness of the honey-bee in bloom fertilization.

I have an orchard of 2 acres, one-third in Kieffer pears, the other two-thirds in Duchess. Every orchardist knows that the Kieffer pear is a very bad self-fertilizer, and that it is necessary to have other trees among the Kieffers to help fertilize the bloom. Nurserymen usually recommend the Garber pear for this purpose. It is very

similar to the Kieffer, and a very strong grower—in most respects a pear like the Kieffer. In our case, the Duchess being only a short distance away, has always proven sufficient to help the Kieffers out, and our crops have been large, even too large for the good of the trees.

This spring the trees opened into bloom at the beginning of the cold April weather, and remained in bloom for nearly 2 weeks with hardly an hour of sunshine sufficient for the bees to work on the blossom. The result is, that even with the best fertilizers the Duchess trees have less than a third of the fruit on that they usually have. But the Kieffers, which have been left to their own resources for pollen-fertilization, have only a fruit here and there, evidently produced in the very short time during which the bees came to them. A neighbor who has none other than the Kieffer in one orchard, has not a single fruit on the trees. The other varieties of pears were evidently too far away for any bees to visit both in the exceedingly short time allowed them by the weather.

It has been stated, time and again, that there are varieties of strawberries which require the agency of insects for fertilization, as they are deprived of stamens and must be fertilized by the pollen of other varieties; but very few people have stopped to think that when any tree or plant which has been domesticated becomes an ineffectual self-fertilizer, the bees are imperatively needed to help them out.

The honey-bee has been accused of carrying the blight from one tree to another among the pear trees, as if there was no other method by which the fungus of this disease could be carried from tree to tree in an orchard. The same people who are so prompt to call the bee to account for imaginary damages, fail to bear in mind that in many cases they would have no fruit at all were it not for the pollen-bearers, which, unconsciously, do the work that no other agency could do as well as they.

So we may rejoice in the little honey-bee, for the more we investigate the better we see its usefulness in more ways than one.

Hamilton, Ill.

## Clipping Queens' Wings, Etc.

BY PROF. A. J. COOK

I am requested to give the reasons, pro and con, for clipping the wings of the queen-bee. I am glad to do this, as it is to my mind a well-established fact that it is always advisable to do this, and in some cases it is a tremen-

dous advantage. We know of a certainty that the bees will never swarm and go off unless the queen goes with them. They may come forth from the hive, and often will do so, and will also often cluster with no queen following them, but unless the queen joins the bees they will in all and every case go back and not go off to start a new home. Of course, it would not do them any good to go forth without a queen, as with no queen and no eggs to rear one they would soon dwindle away and come to nothing. The purpose of the clipping, then, is obvious. We may lose our queen, as she may wander out and fail to return to the hive and be lost, but the colony can not be lost, at least not till a new queen is reared in the old colony.

In case a farmer keeps bees, and does not wish to remain about the apiary all day at the swarming season, he can have his wife or some child keep watch, and as the bees swarm out the watcher marks the hive and catches and cages the queen, which is easily and quickly done, and as the farmer comes to the house at noontide or later, he can divide the colony or proceed as his plan dictates, and so arrange for the safety of his bees with no loss, and in the cheapest way possible.

My brother has kept bees for years, and with marked success, and at the same time runs a stock and berry farm. He told me last summer, as he has often told me before, that he finds his bees by no means the least profitable part of his ranch or farm, and he would be slow to part with them. He manages the swarming as just suggested. He would not feel that he could give time to remain with the bees, and he would be even more slow to have his wife bothered with the hiving, but she makes no objection at all to watching and caging the queens, and so the whole matter of swarming is easily and cheaply managed.

I have never heard but three objections urged to the practise of clipping queens. The first is that it injures the queens, and so is unwise. I do not believe that it is an injury to the queen at all. I have practised this plan for years, and so far as I could see the clipped queens were no whit behind the others in performance. Indeed, the ants do this very thing themselves; that is, the worker ants bite off the wings of the queens, and surely the queen-ants seem to lose no potency or virility by this pruning. No, the queens are not made any the less prolific, and are in every way as good.

It has also been claimed that the bees are more likely to supersede the queen if her wings were clipped. Long experience and close observation make me very sure that this is not true. The third point urged is that it somewhat injures the appearance of the queen. This may be so, but as we see the queen so seldom I should hardly think that this could be urged very seriously.

### HOW TO CLIP.

Some claim to be nimble enough to clip the queen as she walks on the comb. I could never succeed this way. I catch the queen by the wings with my right hand, then grasp her by the

thorax gently with the left hand, and, with delicate scissors held in the right, I clip the right front wing about one-half distance from the tip. Some claim to keep the age of the queen by clipping one-half of the other right wing the second year, the left front one the third year, and the last one the fourth year. This may be done if desired, but I do not think it will usually be any signal advantage.

I always clip my young queens as soon as I am sure that they are laying. I must see eggs in the cells before I clip, as in case we clip before the queen has met the drone we ruin her, as they fly forth to mate; and in case the queen has been clipped she can not fly forth, and so will always be a drone-layer; hence of no use at all.

#### BEES AND POLLINATION.

Our fruit-men are coming more and more to recognize the importance of bees in cross-pollinating the fruit. They are generally recognizing—at least the best informed fruit-growers—that unless we have warm days during fruit-bloom the crop will usually set only a partial crop. I have just had a trip among the big fruit-men of the Sacramento Valley, and was pleased to find that they very generally consent to the view that good weather is very desirable during the blooming season. Many are sure that there must be bees to visit the bloom or the crop in many cases will be light. As our fruit-men become better informed, there will be much less complaint regarding the injury of fruit by bees, but much more contention that the bees are necessary to full crops. One of the most intelligent and prosperous fruit-growers that I know in California, makes it a point to induce a large bee-keeper to keep his bees in his orchard. As there are large alfalfa fields close by, and as the orchardist has a large planting of all kinds of deciduous fruits, they find this plan mutually beneficial.

#### PEAR-BLIGHT AND BEES.

I find also that the bees are not coming in for so much complaint from the pear-growers. Indeed it is found as I predicted it would be, that there are always enough insects to scatter the pear-blight, and would be even were there no bees at all. It is found that by extreme thoroughness and vigilance the blight can be held in control. It is also demonstrated that unless the utmost caution is practised the blight will conquer. It is a case where it pays well to be vigilant and tremendously energetic, for pears are a very profitable fruit, and will become more and more so, as so many will not go to the fight with sleeves rolled up.

It seems more than likely that those who fight to the knife will be amply rewarded. Had I a fine orchard I would go at this enemy full tilt, and would win, and would reap a splendid reward. I would do one thing more: I would get all my neighbors to fight with me, as all must fight to bring the full success. In case some would not fight it would be well, if one could do so, to rent the trees of such an one, as trees not watched and pruned become a center of infection of all surround-

ing trees, and so with each blossoming season the inoculating germs are sown broadcast.

It is splendid that our scientists have discovered that this malady is controllable, but it is unfortunate that the cure is so expensive, and also that the cure must be universally applied or it will be unsatisfactory. It seems that the disease is spread through the propolis or gum as readily as through the nectar.

Claremont, Calif.

## Shallow Hives and Short Cuts in Bee-Keeping

BY J. E. CHAMBERS.

On page 304 I see an article by Dr. Bohrer, entitled, "The Construction and Manipulation of Hives." In this article the good Doctor falls into the common error of supposing that the shallow hive means necessarily a shallow brood-chamber. In this connection I wish to say that I do not here desire to offer any argument against the claim he advances, that bees winter-kill more in shallow hives than they do in deep ones. This kind of stuff has been refuted too often to need any notice here; besides, while I do not live in quite as cold a climate as Dr. Bohrer, we do have some quite cold weather here, and I have known bees to become frost-bound and perish in deep hives, but never in shallow ones.

But Dr. Bohrer's hole bored through the center of the combs to enable the bees to pass from side to side is the explanation of the whole thing. This very movement is secured by the space through the center, and between the top and bottom bars of the divisible hive.

But the main points on which the venerable Doctor is wrong, according to my experience, which covers a period of some 15 years' use of shallow hives, is where he says that he does not see how we find the queen-cells. Why, bless your soul, Doctor, that is the easiest, the quickest, and the surest of all the manipulations capable of being performed with the shallow hive. With my hive the frames are clamped together by a knob that yields to pressure, and when examining for cells I can divide the hive through the center and tilt the upper case on end, allowing it to rest on the upper part of the bottom chamber, and with thumb and forefinger turn the combs apart an inch or two, and see every square inch of comb-surface in the hive, and without removing even one comb.

Regarding the finding of queens, I will say that I have lately been much pleased with a few words contained in an article by Mr. Alexander, which lately appeared in *Gleanings*, in which he says that the young honey-producers of the future can not long remain in the ruts that we older men have made, but must with renewed perseverance push forward until they have made great improvement in the methods now in use. I fully indorse all this and go still further, that the everlasting hunting of queens and continual tearing up of the brood-nest is the prolific cause of more harm than is any

other one thing. A man who can not tell the condition of a queen by the work she is doing, has, to say the least, missed his calling, and is struggling in one of Alexander's ruts.

Another splendid thing I heard at the San Antonio convention was contained in the paper of Mr. Townsend, where he said, Don't do the things with the bees that they can do just as well as you can; and don't handle brood-frames. These few words were worth the cost of the trip to me, and compensated for the other disappointing features of that noted convention; not that it was new to me, but there is always to the mind of a dullard, like myself, at least some satisfaction in knowing that he is in good company in some of his beliefs. I have just mentioned these things in order to illustrate how I have been for years trying to cut out every unnecessary manipulation.

I keep good stock, and as long as a queen keeps her colony strong she is in every way satisfactory to me. When one fails I immediately know it by the decreasing strength of the colony, and at once slip one of my requeening boards between the upper and lower section of the brood-chamber, and without removing the old queen introduce a young one at one and the same operation.

In this connection I may mention that I requeen all colonies that make preparations to swarm by the use of my non-swarmer board. This makes it unnecessary to watch those bees that have young queens. However, I will say for Dr. Bohrer's information, that I find queens whenever by chance I need to do so by the use of a simple mechanical device which I call a queen-trap. You are aware of the fact that a queen when trying to escape from the fumes of smoke will run into any crack or crevice. This device consists of a thin board with 4 transverse openings in it, arranged so as to allow the bees a free passage through by means of escapes of wire, but when it is in operation the queen, after passing through with the rest of the bees, is caught and automatically caged, so the apiarist can give her attention when and how he pleases. The whole operation takes but a minute or two.

These are but a few of the ways and short cuts by which I manage to do the things easily that others complain so much of. I do not write much for publication or otherwise court notoriety, but I am following the course mentioned by Mr. Alexander; that is, trying to find out improved methods, and in a way at least I have succeeded. In many things I am not orthodox, but I always did hate that word; it means to me the throttling of individuality and the strangling of every higher aspiration. I don't intend to follow in the same ruts that others do, even though my way is not so good as theirs. In my methods I have shortened the time required to enable me to accomplish most of the manipulations necessary in the managing of my business, and that suits me exactly, though it may not give the same measure of satisfaction to others.

Vigo, Tex.

[We would be pleased to have Mr.

Chambers describe more fully his re-queening and non-swarming boards, and their use. Perhaps he has some pictures of them that could be used to make everything plainer.—EDITOR.]

## The American Bee-Keepers Criticised, With Side-Lights of German Bee-Keeping

BY F. GREINER

Dr. Bruennich, of Zurich, accuses the American bee-keeper (in Leips. Bztg.) of esteeming no one higher than himself; that he regards himself smarter, as we often say, than the bee-keeper of any other country; that he is a long way ahead of all, and that all nations have a reason to look up to him. In the line of practical results the Doctor may make some concessions, but he says bee-keeping on the large American scale is an absolute impossibility in Europe. In the line of breeding we have not even learned the a b c. In breeding fowls he thinks we have made achievements, but in breeding bees we can show nothing. As a characteristic proof he cites from Gleanings: The \$200 red clover queen that did not reproduce herself in her daughter—nay, that she did not produce even one daughter her equal; and that Root is now willing to give \$500 for a queen as good as the one spoken about. Dr. Bruennich holds that this lack of stableness has no other cause than our crazy passion for new races of bees, and the constant crossing which has resulted in a cross without any fixedness. He censures us for importing all sorts of bees—Italians, Carniolans, Punics, Cyprians, and now the Caucasians—and possibly some other races that Prof. Benton may have hunted out on his trip around the world. We dream of the ideal bee, but are very far from it. A similar craze was raging in Europe some years ago, he says, but they have freed themselves from it, and they have found that by keeping a race pure they can attain that stableness desired, which makes their "Switzer Bee" reproduce itself. The purer their bees the surer they transmit their qualities to their offspring; we know that particularly in breeding bees it is a most dangerous sport to keep crossing our bees, mixing in new blood. Just as long as the bee-keeping masses are not enlightened by their press, so long there will be no stable American bee, but simply hybrids. The Doctor is apparently pretty well posted, for he says: The black bee is constantly being run down, although such a bee in its pureness does not exist any more in America.

How nearly right Dr. B. is in his analysis and criticism I can not say, but it may do us good to see ourselves once as others see us. If the Americans have been guilty of looking down upon their European brothers in the past, it is my impression the Americans have been treated similarly by the Europeans. It, however, seems to me that of late years we have become better acquainted with each other, and

that superior feeling is fast giving away to esteem. Conditions are so totally different on the different continents that it is difficult for one to set himself up as a judge. If the reader will bear with me I will give him an example of a practise that would perhaps not appeal to him as one to follow in America, and yet in Europe it is all right:

Generally speaking, bee-keeping is not carried on in Germany as a profession as is the case in America; still in certain parts of Germany it is. The "heath bee-keepers" have a great reputation. Their hives are straw-skeps; their heath-bee is much like the Carniolan bee, inasmuch as they are great on swarming. The swarms are all hived, and the heavy colonies are brimstoned in the fall, also driven, and the bees sold. There exists a regular trade in these bees in the fall, many less fortunate bee-keepers purchasing them to strengthen their weak colonies. The hives full of comb and honey are an article of commerce. Some of these bee-keepers go to a large city like Hamburg, Berlin, Bremen, etc., and take a hundred or more of the beelless hives with them. They rent a little room in an out-of-the-way corner of the city, where they do their work. Evenings the combs are cut out of the hives and assorted in trays.

During the day they peddle the honey

on the street; they are neatly dressed, white apron and cap, carrying the honey in a neat, clean, wooden tray with nickel trimmings. It can not be denied that such honey, presented in this fashion, attracts, often more than our beautiful honey in sections. It is certainly much cheaper to produce such honey than such as we produce, and still it brings twice as much as we are realizing. There are no complicated honey-cases or supers with cleft separators, no sections to buy; no work with frame hives, wiring frames, buying comb foundation, etc. When the honey is cut out of the straw-skeps the empty shells are shipped back home and are ready again to accept new swarms. It is a simple method, with few expenses. What American, up-to-date comb-honey producer would want to advise these men to adopt American hives and American methods as long as the dear public is willing to pay good prices for these honeys of the Lueneburg-heath bee-keeper?

Some of us may have looked down upon these bee-keepers who have practised such methods for many, many years, and do not seem to advance. But when we look into the matter we will find redeeming features even in such bee-keeping, and we will also find many a "bee-master" in the ranks of these men.

Naples, N. Y.

### Report of the 37th Annual Convention of the National Bee-Keepers' Association, held in San Antonio, Tex., Nov. 8-10, '06

(Continued from page 436.)

#### GETTING A LARGER CONVENTION ATTENDANCE.

"While endeavoring to increase the membership to the National Bee-Keepers' Association, would it not be well to try to touch the tariff on passenger transportation, whereby more members might be enabled to attend the National Bee-Keepers' Convention, and see new flowers bloom, bees' tongues grow longer, and, indeed, see honey grow sweeter? I believe such a move would bring many into the National, who to-day are non-members."

Mr. Holekamp—A cheaper rate can easily be obtained if there are enough bee-keepers attending a meeting.

Mr. Kimmey—You can always obtain a special rate by going before the proper authorities, and by getting 100 members.

Mr. Anderson—Now, then, right there is the point. Some of us can not even get a return ticket, while some got great

reductions. I believe this thing should be taken up in the proper way, and we will all be treated right. There are a great many sorrowful-looking faces back our way, just simply because the railroad companies said they knew nothing about our convention. Some of them got so disgusted that they thought that if the Association would not look out for us so as to get rates, we were not wanted, and we will drop out; but if you swell a fellow's pocket a little, and they see they are going to get a reduced rate, it will be an inducement to bring them in.

Mr. Kimmey—I move that the General Manager be instructed to make arrangements with the different Passenger Associations for reduced rates to and from all annual meetings hereafter.

Dr. Bohrer—I second the motion.

The motion as put was unanimously carried.

Mr. France—I have tried to secure these rates so far as my influence would go. I believe that the rates from the different places should be considered. What rate can we secure if we go there, and it is almost depends upon the rate. Now we would not have met in St.

# American Bee Journal

Louis two years ago if it had not been for the World's Fair and the cheap rates; and then we promised to come here last year, and the railroads granted a special rate, but the yellow fever broke out. Then the question was, Where can we go? and the nearest to it was the Chicago International Live Stock Show, in December; then we came here this year. I have been trying to do what I could for you in that line.

Mr. Stone—I would ask Mr. France if these rates can not be gotten every two weeks. We can secure these rates the first and third Tuesdays every month, just as we did this time.

Mr. France—Yes, sir; there was a definite promise in favor of Texas, and they had been put off, and were getting tired of that.

Mr. Anderson—I was angry about this, but I came on, anyhow, and I was going to find out if other bee-keepers were treated the same way. The first thing I went into the Santa Fe office and asked if there were any reduced rates to Texas, and the agent said he did not know of any just now. He said, "What part of Texas do you want to go to?" and I said, "San Antonio." He looked at his book and said, "Beginning on the 4th the National Bee-Keepers' Association is there, and I will give you the single round-trip plus 50 cents, good until the 15th." Now, see, the National Bee-Keepers' Association had something to do with it there. I believe that Mr. France has done all that he could; but let's better it.

Mr. Holekamp—There is a blank on which these people can secure rates. If we have enough to go, there is no trouble about securing rates.

Pres. Dadant—I think I can throw a little light upon this. I received several letters from railroad companies. All the meetings of the associations are announced in a special sheet published specially to give notice of all the association meetings in the United States. Ours was published in that sheet, and I received two letters from them; all they wanted were the delegates' names. I have tried this in getting rates. Rates are promised if you have 100 delegates; if you have 99 you can not get them. So you see the railroads do know something about us. The superintendent wrote to me asking the names of our members, but they wanted a large crowd to go; they are not giving these rates out of kindness, it is simply to make money. If you can assure them a profit they will give us rates; otherwise they will not.

Pres. Dadant—There are two papers which have not been received, one by Mr. R. F. Holtermann, of Ontario, Canada, on "The Difference Between Ripening and Evaporating Nectar;" and one by Mr. C. A. Hatch, of Wisconsin, who says he would prefer to re-prepare his paper and then send it in for publication, if admissible. Now, if there is no objection we will insert them in the published report. Under those conditions I think we are through with the business. I have been asked to state that the Bee-Disease Inspectors meet here on Monday, and I hope that every member will attend. Dr. Phil-

lips and Dr. White will both be present.

Mr. France—Some have asked me if there will be anything except lectures in regard to diseases. Yes, there will be demonstrations and samples of foul brood. It is important that you stay.

Dr. Phillips—I wish to say that the inspectors have been meeting together, and have been studying up on these matters. It therefore behooves the inspectors to get together and learn all they can. For that reason, Mr. France, Mr. Hutchinson, and myself, met in Milwaukee to talk over this subject, and we decided to call a meeting of all the inspectors we could reach, and the place we finally decided upon was San Antonio. We are going to have quite a number of inspectors here, and the main thing is, the proceedings will be published, and the papers that are read will be available for the persons that are unable to attend. Dr. White, who has done the best work, will be here Monday for the meeting, prepared to give a demonstration of the work that has been done. My part will be that of reviewing or pointing out where mistakes have been made. I have in my possession papers from two or three inspectors. I will also have present copies of the Foul Brood Laws of the United States and the members will inspect them and pass resolutions; and many things will come up for discussion.

Pres. Dadant—The Secretary says there are two questions left. We will hear them.

## AMERICAN BREEDERS' ASSOCIATION.

"Should not the National Bee-Keepers' Association become a member of the American Breeders' Association?"

Dr. Phillips—I suggested this for this reason: Last year we had something to say about the American Breeders' Association. That Association is composed of men in all lines of breeding work, and the object is to discuss the methods that they employ in improving the plant or animal on which they are working. The laws that are behind breeding are perhaps few in number; there are certain underlying principles to be considered. For that reason I am very anxious that the bee-keepers, who are interested in the breeder's side of the industry, should become more interested. The bee-keepers can aid in this way, or express their approval, by becoming a member, by paying the annual dues of \$1.00 per year, for the whole National Bee-Keepers' Association.

Mr. Kimmey—I move that the General Manager be instructed to apply for membership.

Pres. Dadant—It is moved and seconded that the General Manager be instructed to apply for membership in the American Breeders' Association by paying the fee. All in favor of this say, "Aye."

The motion was carried.

## EFFECT OF THE NATIONAL PURE FOOD BILL.

"What effect has the passage of Hepburn Pure Food Bill on the sale of adulterated honey?"

Pres. Dadant—I have had some par-

ticular experience along that line. We have several wholesale grocers, and they have been selling adulterated honey. I went to one dealer and told him that we wanted pure honey handled. He said, "I have had to handle adulterated honey, because everybody does it, but I don't like to do it. We are glad of that law and we will be glad to handle your honey."

## MISCELLANEOUS.

Mr. York—I want to refer again to the amendment proposed this afternoon. I was Secretary of the Los Angeles Convention, and Mr. W. F. Marks was then Chairman of the Committee on Amendments. I remember at that time that the convention approved of the amendment, so I think that we have done the proper thing with this amendment this afternoon, because I am sure that a majority of those present would not approve of the amendment proposed. The Constitution is very plain, and that was the way it was proposed to amend it in Los Angeles, which was perfectly proper.

A Member—Before we adjourn, there is one other business proposition. With the kindness of the Department of Apiculture to come here and hold an Inspectors' Meeting, there is no provision for the publication and report of what is said and done next Monday, so that we could all get copies of the same. There is no provision, as I understand, for a reporter to take the proceedings. It will therefore be necessary for us to furnish a reporter. The reporter we have engaged for the National Bee-Keepers' Association, if I mistake not, is willing to stay over and report for this meeting, but that is independent of this Convention, and if we could raise the amount by subscription I would gladly see that done; because the information we will obtain on bee-diseases next Monday is worth a big contribution.

Mr. Victor—I wish to say that the Texas Bee-Keepers' Association will donate the necessary amount. I wish also to state this about the bouquet that has been presented to Dr. Bohrer: At the first session he said he would like to shake hands with him, if there were a Confederate soldier here. This bouquet was given as a token of regard from the South for the sentiments expressed by Dr. Bohrer.

Dr. Bohrer—The language of the flowers is peculiar, and no one has ever been able to express them fully. At funerals, when our friends lie down and die and leave us, we put a bouquet in their hands; at the wedding feast the women and the bride are decorated with flowers. Flowers carry with them everything that speaks of refinement, of sympathy, and of purity. Nothing perhaps of the three kingdoms carry with them such loud expressions as flowers. We have made it a custom up North, when we decorate the graves of the Federal Soldiers, not to forget the Confederates. I don't want to say any more. [Dr. Bohrer as well as many others were almost in tears at this point.]

Pres. Dadant—If there is no more business, I wish to thank the members

for their kindness and attention during the sessions of this Convention.

Dr. Bohrer—I move that we adjourn.

Mr. Parsons—I second the motion.

The motion was put, and carried, thus adjourning to meet at the call of the Executive Committee in 1907.

The following paper by C. A. Hatch, of Richland Center, Wis., was not read at the convention, as Mr. Hatch was not then fully prepared on it, hence there was no discussion:

#### WHAT CAN THE NATIONAL DO FOR ITS MEMBERS?

I am not among the number who think the National Bee-Keepers' Association should take up the bee-supply business, neither do I think it should go into the direct selling and handling of honey; this is too large a country for that, the interests of each section are so varied, the grades of honey are so various, that mountains of difficulty loom up at all points; while they may not be insurmountable, the difficulties are too many to think of with comfort. So let us look at things yet undone which are less complicated.

To reach the highest success there must be the best feeling and greatest confidence among members. Loyalty should be the watchword of the membership—this breeds confidence, and confidence gives self-respect. There is no place for jealousy or suspicion in a successful society.

It should be a sort of "clearing-house" for its members, of ideas as well

should be able at any time to furnish to members or dealers the exact amount of bee-products held by each member, and at what price it could be put on the cars. If a dealer ordered a certain amount of honey of the General Manager, he should be able to fill it from the nearest member having that grade of goods to sell, to the mutual benefit of both producer and dealer.

He who thinks the National can dictate prices and "hold up" the consumer for an advance, is harboring a delusion, besides fostering a principle that has given us over to the power of the trusts.

That the producer does not get all he is entitled to is self-evident, but he has, as a rule, no one to blame but himself; for no sooner does a large crop come to him, and his neighbors, than they all rush it into the nearest market, with the result that they each compete with the other, and the market goes to smash, and freight and commission consume what ought to have been a fair compensation.

The sooner we learn that the interests of dealer and producer require that each should be fully informed as to crop of each year, the better; and do not for a moment imagine you can get ahead of the dealer and get inside information before he does; he has correspondents in every neighborhood that keep him informed, and it remains to inform ourselves as well, and be prepared to act intelligently, thereby will we be able to ask for our crop what it is worth, with the certainty that we will get it. The mere fact that you are a member of the great National Bee-Keepers' Association is not going to help you the least; help can come only from facts and statistics which it can furnish, and if you would get benefit from these you must be prompt to do your share toward making them full and complete; give and you shall receive, withhold, and what you seem to have shall be taken away.

Some seem to think that the mere fact that you are a member is going to give you an advantage in the market for supplies that others have not. If you have that kind of a bee in your hat, get it out quickly, for nothing is further from the facts. No can company or supply dealer cares one cent how many societies you belong to; all he cares is how many cans you want and your ability to pay for them. I know that something to rather disprove this last assertion has been sent to members, yet I am willing to stand by it, for there are facts to back it up.

If you and your neighbors can jointly use a carload of supplies of any kind, then, and then only, can you demand reduction from the dealer; and you are working against your own interest if you do not avail yourselves of the discount on price and saving on freight-rates. If you think some supply dealer is building up a trust, deal with some other one; there are plenty of factories in this broad land of ours, and the supply dealer can not live without patronage; on the other hand, neither can we as producers get along without supply dealers. Do not let us waste strength kicking one another, for each is dependent on the other.

Another way in which members can

be helped is by furnishing them information as to reliability of commission men and dealers in the cities. One correspondent at each distributing center could easily do this, and save much loss and trouble. With fair knowledge as to amount of honey produced each year, and a knowledge as to whom to deal with, producers can stand some show of getting reasonable prices.

C. A. HATCH.

The following paper, by Mr. R. F. Holtermann, of Brantford, Ont., was received too late to be read at the Convention.

#### THE DIFFERENCE BETWEEN RIPENING NECTAR IN THE HIVE AND EVAPORATING IT ARTIFICIALLY

The subject which has been assigned to me has, I am sure, much about it as yet unknown, and yet probably of much practical value to the bee-keeper in making him put a better article upon the market, and assisting him in the sale of it; and to the consumer in showing him wherein lies, in part at least, the superiority of honey to all other sweets, fats and starchy products, as a food.

The apiarian body will contradict itself in the value of honey as long as some of its members claim what has been proven as to the nature of honey, and other members claim that honey or nectar taken from the hive freshly gathered and evaporated outside of the hive is the equal of that which has gone through all the stages in the hive until capped and fully evaporated to the consistency of well-ripened honey.

The obvious superiority of honey over many other products as a food, lies in part in its source—fragrant blossoms. It is gathered by the most fastidious and cleanly insect known; this insect storing the honey, and in the process of ripening the nectar, in the combs and moving it about from cell to cell, inverting the saccharine substance and making in reality a predigested food. Such foods are highly prized, and in other lines very high prices must be paid for them. Nor is this all. Honey is not only a sweet, but it contains an essential oil, imparting to it an aroma peculiar to the source from which it springs; this with our commercial honey, pleasing the palate and bringing into beneficial action the organs of digestion and assimilation. That the honey in the process of production before explained, is inverted, has been proven, the latest evidence being by Prof. Phillips, of the Washington Apiarian Experimental Station.

We know that during the process of evaporating nectar outside of the hive, no honey will be inverted. We can therefore not contend that the product of this artificial ripening is as valuable as that of the more natural process. Some may not be willing—more, I know some are not willing—to recognize this inversion by the bee. The question of the fact is not dependent upon such a recognition any more than that the fact that my friend

C. A. HATCH.

as actual products. Not that the products of the membership should be actually handled, but members should be placed in such close touch with each other that each would know what all are doing in the way of producing and selling honey and wax; this leaves no place for secrets.

The Secretary or General Manager

# American Bee Journal

will not recognize me proves that I am non-existent.

## FORMIC ACID.

That the percentage of formic acid varies in various honeys, we know. Some 8 years ago, when conducting a series of experiments for the Ontario Government, I discovered this, and the experiment has since been verified in Europe. Finding that when bees worked on buckwheat the sting was more painful, I thought that the percentage of formic acid in buckwheat honey might be greater than in white honey. A sample of clover and also of buckwheat honey was analyzed, and it was found in the sample sent that buckwheat had about twice as much formic acid as clover honey. I have since realized that this experiment was very crude, and in this direction (formic acid) there is still open a wide field for research. We do not yet know if the percentage of formic acid in honey varies in varieties of bees. That is, do Italian, black, Cyprian, Caucasian, etc., show a marked difference in this respect? If not, do individual colonies show the difference? Does honey gathered early have less formic acid than honey gathered late, irrespective of the source? If so, may it be because honey gathered early has longer time and more favorable conditions under which it can thicken and be less liable to ferment than that gathered later? At what stage, or stages, of ripening is the formic acid put in by the bees, and how? Is it added to as are the secretions which invert the honey, or is it added through the organ of defence? I am not afraid to uphold or condemn the "sting trowel theory." In part it may be correct. Is this formic acid valuable, and do the bees keep adding it as it is being ripened? If so, nectar evaporated outside of the hive will vary in this respect. I would guess that formic acid is added to the nectar in its early stages of evaporation, to prevent fermentation, for without the formic acid in warm and muggy weather, the condition would be favorable to start fermentation, the temperature of the hive never being high enough to destroy the germs of fermentation floating in the atmosphere passed through the hive.

The formic acid may also be there to disinfect the honey to be fed to the larvæ, to prevent the spread of diseases peculiar to bees. The constitutional strength of the bee, the vigor of the bacillus, and the percentage of formic acid in the honey, may all have a bearing upon the spread of disease in the hive, and may be a factor in the degree of immunity from diseases of certain strains of bees. When the above points are answered, we can better answer what is the difference between ripening nectar in the hive and evaporating it artificially.

## AROMA.

As to the difference in the aroma or flavor, it may be that the formic acid in combination with the essential oil, causes the flavor or aroma to undergo a change. This I do not know. The milder honey, however, changes its

flavor less than more pronounced flavors in the process of ripening. It may be that if there is no essential oil, the formic acid would not have an oil to combine with, and so the change would not take place. We know that the odor in the apiary, especially marked at night, during the gathering season must be at the sacrifice of something. Is this odor not a combination of the peculiar odor of the hive in union with the odor from the nectar? If so, no similar artificial condition can be created. This odor is certainly not similar to that from a ripening tank of nectar.

To illustrate the change: The past summer we had 240 colonies located in an apiary in the neighborhood of a

gratulated upon the work begun at Washington, D. C. Let us do everything to encourage good work, and condemn in all these positions the appointment of inefficient men. Let us be careful not to demand definite results too rapidly. In research work I rather admire the methods of the best European countries, where they study, and study, and work, upon a question, confirming results again and again before much is given to the public. I would also suggest that these experimental stations, as far as possible, seek the co-operation and corroboration of our best practical bee-keepers' in their own individual apiaries. A committee even (advisedly) to advise as to work, and discuss

R. F. HOLTERMANN.

species of mint. I tasted a peculiarly strong flavored honey in the hive, but could not discover its source, until I traced through, first capped and then uncapped honey, back until I tasted the nectar shaken from the comb, and then the smell of the mint blossom. All formed a perfect chain when there appeared to be no connection in flavor between the ripe honey and its fresh nectar. Several of my apicultural students remarked the same thing.

In closing, let me say that we as bee-keepers' do not realize how much there is yet to learn in our profession. We do not realize how great the practical need of learning is, and how little we unitedly are doing to have this work done. The United States is to be con-

all the points or conditions which must be alike, in order to compare the merits of points not alike, should be of very great value, and such a suggestion from the National Association would surely have its weight, and might—in fact, should—aid the work greatly.

R. F. HOLTERMANN.

---

**Our Wood Binder** (or Holder) is made to take all the copies of the American Bee Journal for a year. It is sent by mail for 20 cents. Full directions accompany. The Bee Journals can be inserted as soon as they are received, and thus preserved for future reference. Or we will send it with the American Bee Journal a year—both for \$1.10. Address office of the American Bee Journal.

# American Bee Journal

## Report of the Chicago-Northwestern Bee-Keepers' Association, held in Chicago, Wednesday and Thursday, Dec. 5 and 6, 1906

The sixteenth annual meeting of the Chicago-Northwestern Bee-Keepers' Association was held in Chicago Dec. 5 and 6, 1906, with President George W. York in the chair.

The convention was called to order at 10:30 a. m., and R. L. Taylor, of Michigan offered the following prayer:

Our Heavenly Father, we thank Thee for the blessings which Thou hast given us to enjoy. We thank Thee that Thou hast preserved our lives for another year; that Thou hast given us a good measure of health and strength. We thank Thee for all the wonderful blessings which Thou hast showered upon us. And now we pray Thy blessing upon us as we are met together to discuss one of the subjects which Thou hast given us to employ our thoughts and our labors. We pray that Thou wilt bless us as an association; that Thou wilt direct us aright; that Thou wilt keep us from wrong; that Thou wilt cultivate among us a friendly, brotherly feeling. We pray Thee to guide us in all our doings while we are here together at these sessions; that Thou wilt direct our thoughts; that Thou wilt enable us to walk aright; and we pray that Thou wilt continue to be with us during our lives; that Thou wilt bless us and keep us from wrong and make us like Thy Son, Jesus Christ, in whose name we ask it. Amen.

As usual at the opening of the session of this convention, the President introduced all present by calling their names and requesting them to rise, so that all might the more easily become known.

The minutes of the previous meeting were read and approved.

The Treasurer read his report, showing a balance on hand of \$22.88.

On motion, the chairman was directed to appoint a committee of three to audit the Treasurer's books, and Messrs. Kimmey, Chapman and Wheeler were appointed.

Pres. York—We will now have a recess for a few minutes for the payment of dues.

After the call to order again, the question-box was taken up, as follows:

### EXPERIENCE WITH CAUCASIAN BEES.

"Will any person having Caucasian bees give his experience?"

E. T. Abbott—A man sent me a queen, and she died on the hive before we got her in.

A. A. Clarke—I have had some little experience, perhaps not worth mentioning, but as I did not hear anybody else reply I thought I would speak. I had 2 Caucasian queens the past season, and I have bred nearly 300 queens from them and probably sent out 150 of those queens to different States, on their own merits. I could not recommend them, because I had not had any experience with them; but I found out that they were excessive swarmers, and not better honey-gatherers than a very poor Italian. It would probably be safe to say that they showed great tendency to

start queen-cells when they had sufficient room for all the storage capacity. I found that they were excellent comb-honey-builders, as far as they went, but the record in amount of pounds was away behind the common German bee and the Italian, and a number of bee-keepers could not distinguish them from the common bee. But I do not think I have really had them long enough to say whether that is the natural tendency or not. I think it is hardly a fair estimate. I am wintering 75 of them, selected ones, and I intend to try them.

W. G. Reynolds—I haven't had experience myself, but a neighbor of mine has. A year ago last summer he bought some. He was away one day and a swarm got out, and his wife attempted to live them, or to get them in, and they got under her veil and she was laid up for a week; and during the time she was in bed, between life and death, her sister attempted to live another swarm, and she had the same experience.

Wm. M. Whitney—I have one colony of Caucasian bees, but have not had them long enough to form any definite opinion as to what they may be worth. I have handled them a good deal and they seem very gentle. They are what are called a "grey Caucasian." I have handled them perhaps a half-dozen times without smoke and without veil. They go over the frames with their wings about half raised, as if they were going to fly, but still they are very gentle and easy to control. I have been told by some individuals, who had had considerable experience, that they would almost close up the entrance with propolis—they just daub everything up—but that has not been my observation. I don't know what they might do. I simply got mine for the purpose of experimenting a little, to know for myself what to make of them.

### CAUSE OF SWARMING IMPULSE.

"What is the chief cause of the swarming impulse?"

F. Wilcox—I venture the opinion that that question is prompted by the statement made that Caucasians show a tendency to swarming, to building queen-cells, and the question naturally arises, Is that tendency a hereditary tendency? Is one race or strain of bees more inclined to swarm than another, or is it other conditions, such as atmosphere, or differences of the season? There are various influences that tend to promote swarming, but the question is, What is the chief influence? And I wonder whether the tendency to swarming is anything against the Caucasians or not, whether it is hereditary or not.

H. F. Moore—It occurs to me that the chief cause here is the instinct implanted in man, and all animal creation from man down, to multiply and people the earth. That is the reason why bees swarm, and it is absolutely hopeless to attempt ever to get rid of it. The question is, Is it desirable to get rid of it?

Mr. Wilcox—The question is, Is it greater in one race than another?

Dr. C. C. Miller—If it is not getting away from the subject, I would like to reply to Mr. Moore's remarks, that however undesirable it may be for him to

try to get rid of the swarming impulse, there are a whole lot of us that would give just about half our lives if we could get rid of the swarming impulse. It would take off half of the trouble we have in bee-keeping. I, for one, have been trying to find out for a good many years what is down at the bottom of it, that is, the answer to that question. I don't know what it is, by any means. I think possibly there may be a good deal of reason in the answer that is given by some, that the prime cause of swarming, or the basic cause, at least, is the accumulation in the nurse-bees of a certain amount of the chyle food they have prepared, and they become, as you might term it, in that way clogged with that, and then comes the swarming fever. Now if Mr. Moore is correct, of course we don't care anything about that. I am sure that Mr. Moore is "away off." In my case, I would give a whole lot to know what makes bees swarm, and put a percent on top of that to know how to stop the swarming.

Mr. Moore—Produce extracted honey.

E. K. Meredith—I suppose that the impulse of swarming is in the relation, to a certain extent, of birds laying eggs. It is just simply a matter of nature propagating or keeping up the race of bees, just the same as any other bird or animal does. That is my answer to the question of why bees swarm.

Mr. Abbott—I think about 15 or 20 years ago I wrote some articles for the American Bee Journal, that seemed to have a good deal of heresy in them, in the minds of some of our brethren, among them Dr. Miller; and I think I stated in one of those articles that it was just as natural to swarm as it was to live, and the swarming impulse was what made bees valuable. I have never gotten away from that idea yet.

Dr. Miller—Never ceased to be a heretic!

Mr. Abbott—The bees that swarm are the bees that do the work. They have the energy and vigor and enthusiasm of all young life. They have the enthusiasm of a couple that is just founding a new home, and planting shrubs and flowers and things about it, endeavoring to develop and make it what a home ought to be. Now bees do the same thing, and are influenced by the same impulses, divine in their nature, planted in their being when the Almighty gave them existence, and it is just as futile for a man to attempt to breed it out as it would be to attempt to stop the sun in its course. It lies in the very foundation of life itself. The first germ of life that existed had in it the impulse of development and division, separation, and so it has gone on amplifying and increasing until we have today the endless germs that people this earth, and the planets that "people" the heavens above, and that will go on forever. It is all right to make the best of swarming, but bees will always swarm in spite of you.

Mr. Whitney—The question is, What is the chief cause of swarming?

Mr. Abbott—The swarming impulse.

Mr. Whitney—I think Mr. Abbott has hit the nail pretty nearly on the head; but we notice that in some seasons the

# American Bee Journal

swarming impulse is a great deal stronger than it is in others, and it seems to me one of the chief reasons for that has been a close, damp atmosphere, with not quite room enough, or ventilation enough, in the hive. Now I think that if one can anticipate the weather, and will give the bees sufficient room, and good ventilation, one can very often break up swarming.

W. C. Lyman—I have experimented more or less along this line, and I find that if you could eliminate from the colony of bees, that is, from the hive of bees, the young bees—those just hatching, and so on,—the remainder of the colony will seldom swarm, and there are ways that that can be done. Perhaps I will show some of the ways tomorrow—ways in which I have done that.

Dr. Miller—If it be true that the swarming fever is a thing that gives life—maybe I don't quote exactly—but if it is the grand opportunity, that there is where you get the bees that will do the work, the ones that swarm the most, then we want to encourage swarming, and we want to have a whole lot of other swarms and all such things as that. Now I don't believe a word of it, that it is an instinct that is in all of them, and they will all swarm anyhow, and you can't do anything about it. That is all nonsense. There are plenty of men here today that know that there are certain bees that will swarm more than others. Take the Carniolan and compare them with other bees, and there is a difference, and in any kind of bees, whether Italians or blacks or what they are, there are certain strains that will swarm more than others. I have tried for a good many years to do a little in the line of breeding from those least inclined to swarm. It may be entirely true, and I am not sure but it is. I am a little afraid Mr. Abbott is right when he says you never can get the instinct out entirely, but I believe you can get a whole lot of it out. I know that the past summer—it was a year of failure with me, but I think all will bear me witness that in years of failure there is often as much swarming as in good years—sometimes in good years, when the bees get thoroughly interested in storing honey, we have very little swarming. This year I know of but one colony amongst my bees that made any preparation whatever for swarming. I am just as sincere as I can be in the belief that my attempting to breed from those least inclined to swarm made a difference. I don't know how much difference. I believe, though, that it has made a real difference, and that I have less swarming today because I have tried to breed from those bees that did not swarm. If any of the rest of you want swarming, it is all right. I don't want swarming; none of it in mine, if I can get along without it. I know it used to be, and is today, customary to talk about the enthusiasm there is in seeing the bees flying around, and all that sort of thing. It makes me sick when I see them come out.

R. L. Taylor—How poor a season, I would like to ask, did you have?

Dr. Miller—It was so poor a season that I think I did not get more than

2 pounds of surplus honey and it was not so bad as it might have been, because the last of the season the bees got a good amount of fall honey for the winter stores.

Mr. Taylor—Would you really like to have us believe that your bees did not swarm because you have been breeding for non-swarming, rather than they did not swarm because there was no honey coming in?

Dr. Miller—I doesn't matter so much what I believe about that—

Mr. Taylor—No; I don't ask you what *you* believe, but I ask you what you would have *us* believe.

Dr. Miller—You asked me what I think. I am going to give you one or two facts, and you can believe just what you like. I spoke of what was the fact this year. Now years ago I had just the same kind of season that I had this, and I had ten times as much swarming as I had this year.

Mr. Taylor—Yes. Do bees ever do anything twice alike?

Dr. Miller—No; not mine.

Mr. Taylor—Well!

Mr. Lyman—Dr. Miller referred. I think, to the nurse-bees. I would like to ask, when a swarm issues naturally, where will you find the majority of the nurse-bees—going with the swarm or remaining in the hive?

Dr. Miller—I have been taught that it is a mixture, that all sorts go and all sorts stay. I think I have seen the statement that young bees go, and sometimes the statement that old bees go. I think that the general consensus of opinion is that it is a mixed lot. There are field-bees that go with the swarm, and there are nurse-bees that go with the swarm—all sorts.

Mr. Taylor—I have seen a good deal of swarming, and I think that pretty much all the bees that can fly in the hive—a large portion of them, that can fly and get out in time to go with the swarm—go, and often bees come out that can not fly, and try to get away and can not, because they are too young. If the nurse-bees can fly, then the nurse-bees go with the swarm, and if they can not—if they are too young to fly—of course they have to stay behind.

Mr. Meredith—From 103 colonies of bees last spring I had 2 swarms. Three years ago from 48 colonies I had possibly 60 swarms, and I have come to the conclusion that bees look a little farther ahead for what they expect to be than possibly other animals, and I should judge, from what I have seen, that unless the conditions are favorable for a honey-flow, the bees will proceed to swarm.

J. C. Wheeler—I was just recalling a thing that happened, and wondering how long ago I remembered the subject and these very same arguments used. I believe it was 15 or 16 years ago, in this very same convention, the very same question came up, and the very same answers were made. I believe Dr. Miller made very nearly the same speech and I was wondering, in 15 years how much advancement had been made. Probably every year we have discussed this question, and I doubt if we have any of us advanced one step along the line of keeping bees from swarming, or

eliminating the swarming instinct. I may be mistaken.

F. L. Kimmey—I am young in the business, and I would like to have you continue repeating the things that were said before I was here. While it is true, as Mr. Wheeler says, we do not gain fast—we sometimes say there is nothing new under the sun—yet what we do gain comes in this way, and I, for one, vote to keep it up. Two years ago—and when I mention this I hope we won't fall into the error of thinking that Dr. Miller has produced bees that do not swarm because they did not swarm this year. The year preceding this there were few swarms; then they swarmed oftener than I had colonies, that is, some of them swarmed twice and some three times. I did all I could to prevent it. This year I did not see a single swarm, with double the number of colonies, until I stopped watching for them. There seemed to be something in the season. I did not see a single swarm until away along in the month of August I discovered one hanging on a tree, and after that I found another, and away late, about Oct. 5, I found a swarm hanging on a tree. I mention this fact to show that there must have been something in the season rather than in the bees, for I had done nothing whatever to produce a race of bees that would be non-swarming. Yet I believe, and I sincerely hope, that Dr. Miller is right, that you can produce a strain of bees that will be non-swarming; and I think from the success that has been achieved in other lines of race-breeding, that we can do something in that direction.

W. B. Chapman—I would like to say in relation to the subject under discussion, that I have kept bees for 17 years. I started with one colony; never have gotten any outside blood in my apiary, and from that one colony I now have, of the original strain, 11 colonies of bees. I have never had an afterswarm. I have been in a location where we always had plenty of honey. The least amount of honey that I ever had was 30 pounds to the colony; the most was 70 pounds; and right here in Cook County. I believe that I have a strain of bees that are considerably non-swarming. From what I have heard of afterswarms and such matters here in convention, I have always considered that I must have been very fortunate to have had a non-swarming strain of bees to start with.

Mr. Wilcox—I asked that question, because I wanted to know, and not because I knew as much as the rest; but I have studied it for 20 years. I know something about it, and I agree pretty nearly with Dr. Miller, that there is a little in the hereditary tendency, but not enough to rely upon it altogether; that it is possible that the Caucasians may be more inclined to swarm than some other races or strains, but, after all, there is evidence on both sides. I have noticed, some seasons, when I produced comb honey, in examining my hives, that the colonies all started queen-cells at about the same date. I have gone through my apiary and found almost every colony preparing to swarm at the same time. Now the question was, whether they contemplated the sea-

# American Bee Journal

son and what was coming, and prepared for it, or what would cause them all to take that notion at the same time. I then reached the conclusion it was the hatching period, and the prospect of a honey-flow, or something of that kind. There is a good deal there worth considering. I have, however, had some colonies that did not swarm, never swarmed, and I don't know whether I could make them swarm or not. I never tried to. But they didn't. They were prolific and good honey-producers. I followed the queen up in one particular case. I had an excellent crop of honey and the bees never swarmed, and her progeny—as I reared queens from them—was not inclined to swarm. So there is something in that hereditary tendency, but how much I would not care to say. I want to know more about it. I know that I can prevent an apiary from excessive swarming, in comb or extracted honey, by giving them surplus room and good ventilation a little before they are ready for that—a little too soon rather than too late—and giving them shade, plenty of it, will check the swarming impulse very much.

Mr. Meredith—While bees may be bred to a certain extent non-swarmling, possibly the same relation may apply to bees as does to poultry. The Mediterranean class, including Leghorns, as we usually keep them, are non-sitters, but if they have their own way, where they can go out into the brush and lay their eggs, I think that they will have the sitting fever the same as any other breed of chickens; and I think, possibly, that same rule might apply to bees that if they get back to their natural rock cavities, or logs, they will swarm just the same as ever.

## USING QUILTS OVER FRAMES.

"Are quilts worth enough to bother with?"

Mr. Wilcox—What do they mean by "quilts?"

Mr. Chapman—Covering for the frames in the hive.

Mr. Wilcox—An enameled cloth is not a quilt for covering the frames. That is used for another purpose. A quilt is used to prevent the heat from escaping at the top, and an enameled cloth is used to prevent the cover from sticking. I used to use the enameled cloth, and I have tried a good many times to use a board, but it causes me more trouble than it is worth, so I continue to use the enameled cloth.

Dr. Miller—Allow me to suggest that there are three alternatives in that. One is the quilt, another is the enameled cloth, the other is to use the naked frames; and it might be worth while, instead of discussing the matter, just to take a vote on that, how many prefer the naked frame.

Pres. York—How many prefer the enameled cloth, just raise your hands? 5. How many prefer quilts, raise your hands? None. How many the naked frames, without anything over them? 12.

Mr. Whitney—It would depend upon what that quilt is used for. I would prefer a quilt for certain purposes. I do not know the difference between the enameled cloth and the board, because

I use the enameled cloth and I know nothing about the other. But I use a quilt sometimes over the section-cases to keep them warm.

Mr. Abbott—Do I understand they are used without any covering at all—any board, or anything?

Dr. Miller—Let me explain, Mr. Abbott, that this is a body of bee-keepers, and that they have their little ways of talking about things without using a lot of words!

Mr. Abbott—They should use good English. The best thing I ever saw to put over the top is a board.

Dr. Miller—That is a good thing too! (Laughter).

Mr. Abbott—Mr. Wilcox says they stick fast to the boards. In most hives they only touch in two sections, and I do not see how they stick as much as the cloth. When we used to use a cloth in Missouri the top would stick fast.

Mr. Wheeler—How about the bees?

Mr. Abbott—That is the way they do, and there is a row of propolis right around, just the shape of the section. I never saw any in Missouri that did not do that.

Mr. Wilcox—I am surprised, for I have used them for 40 years and never saw a single instance of sticking to the enameled cloth. I am sure that won't happen in Wisconsin. They of course build new combs to them, so that the enameled cloth is stuck a little, but you can take hold of one corner and turn it back without disturbing or alarming a single bee, and for that reason I much prefer to use such an arrangement and to scrape the frame down, often, because they will build up to it, and sometimes push it up and fill up the space; but when you have only the board, if you leave it long enough the bees will stick it down and close the cracks airtight, and if you do not it will stick in places and the wind will blow right through under it from one side to the other. The heat must escape. It certainly cools off the top of the frames more than it does where there is an enameled cloth over it; and for that reason I prefer the inconvenience of the enameled cloth rather than the board with its perfect fitting on the upper edges of the hive.

Dr. Miller—May I ask, Mr. Wilcox, whether you ever knew your bees to carry the black material from the oil-cloth down and use it in the section-combs?

Mr. Wilcox—I have known several such instances. It is not a common occurrence. If there should be any ragged edges the bees could get at they would tear it out, and they might carry it down and attach it to the cappings of the combs in some cases.

Mr. Abbott—Will they cut holes through them?

Mr. Wilcox—No; I never knew of it. A worm will do it, and do it quickly, if there are any moths in it, but the bees do not do it unless the enamel is cracked from being handled when cold.

IS HONEY VEGETABLE OR ANIMAL?

"Is honey a vegetable or an animal product?"

Dr. Miller—Yes.

Mr. Abbott—I think some that I have

seen in our market was purely animal, and two-legged animal. The ordinary honey I think is vegetable.

Mr. Taylor—Is a boiled potato an animal or a vegetable production?

Dr. Miller—I believe that is really a serious question, after all. I am sure I don't know what the answer is.

Mr. Moore—About a boiled potato?

Dr. Miller—Mr. Taylor's question is entirely applicable, and yet the question would come, Where is the line to be drawn? I should say a boiled potato was a vegetable without any question, because it has not ceased to be a vegetable, and yet the thing gets mixed up and in the case of the bee here is a vegetable material that is afterward worked up by an animal and there is animal matter in it. I confess I don't know. I wish I did know. If Mr. Taylor has an answer to it, I wish he would give it to us.

H. M. Arnd—I asked that question. I knew it would cause a good deal of laughter, but one of my customers met me on the street the other day, and I told him that honey is vegetable, and he argued and argued with me that it is animal. I told him there was going to be a bee-keepers' convention, and I would bring it up.

Mr. Wilcox—In my opinion it is a vegetable product. There is nothing animal about it. Sugar is not an animal product. Sugar syrup isn't animal; has nothing to do with it. It is derived from a vegetable in the first place, and it is boiled down—as it were, somewhat digested, perhaps—I am not sure about that—but at any rate, it is derived from a vegetable and retains a vegetable character, and there is no animal character injected in it, although it might be digested and assimilated and converted into animal, but I do not think it has reached that stage.

Dr. Miller—We do know that there is injected into the honey something by the bee. Come back to milk. Is milk a vegetable or an animal product? If you are going to rule honey out, and say there is nothing animal about it, by the same token we can rule milk out. There were those who said that honey was gathered from the flowers—bees do not make honey. There were those who said, the bee makes honey. I think nowadays we are pretty nearly all agreed that the bee has something to do with making honey. If it has, look at it and see if there is something animal in it.

Mr. Moore—Maybe this will throw some light on the question, the illustration of the maple tree. A man taps the maple and carries the sap to the sugar camp and boils it down. There might one of his finger-nails drop in it, or even a lock of his hair; there might be some slight mixture of animal with the vegetable. Here a bee carries the sweet from the flower just the same as a man carries sweet from the tree.

The Members—No, sir! No, sir! Not a bit of it!

Mr. Moore—There is no chance for argument, I believe. They are both vegetable absolutely, all the time.

Mr. Taylor—If the bee should carry the nectar, put it into the cell and leave.

# American Bee Journal

it there, what would it be? Would it be good honey?

Mr. Moore—Bad honey is honey, just the same.

Mr. Taylor—No; it is nectar.

Dr. Miller—Mr. President, wouldn't it be of advantage to talk about something we know something about?

Pres. York—*Sure!*

Mr. Kimmey—If we are going to talk about something we know all about, there is no use of talking. We might as well go home.

Pres. York—I think a convention of bee-keepers ought to know something about honey.

Mr. Kimmey—Perhaps you will remember a few years ago we were talking about the same question, and I asked Dr. Eaton, the Illinois State chemist, if it were possible for a chemist to produce a single drop of honey, and he said no. We may talk about bees gathering nectar from the flowers; it is not honey. I once at a table said to a lady, "Why do you put cream in your coffee? Why not put in butter? It is the same thing." "Yes," she said, "Why not put grass in your coffee? It is the same thing." It isn't the same. You can't make a drop of honey unless you let the bee go out and gather the nectar and put it in its organism. I have tried to find out exactly what they do. You honey-dealers just keep quiet a little and try to look wise. I have seen some of your product and, unbeknown to you, I have had some of it analyzed. You do not get honey until the bees work it over. I think you can say they make honey just as surely as the cow makes milk, and in that sense I think it is an animal product, from the matter of working over a vegetable product, just as lard is an animal product; perhaps not exactly work on it, but there is a change made which makes it animal instead of vegetable. It is not simply gathering nectar.

On motion, an adjournment was taken until 1:30 p. m.

## FIRST DAY—SECOND SESSION.

The convention met at 1:30 p. m.

Pres. York—Is there anything to come before the convention before we take up the questions? Under the heading of Miscellaneous Business there is the question of joining the National Bee-keepers' Association in a body. What shall we do about it?

### JOINING THE NATIONAL IN A BODY.

Mr. Wilcox—I move that we join the National in a body.

The motion was seconded.

Pres York—Are there any remarks on the motion?

Mr. Moore—Not to obtrude my own views on this assembly, but to get the subject before you, I want to object to joining the National in a body. My objections are nothing new. Our income is rather small. The Treasurer's report shows about \$22 in the treasury before this meeting, and when we join the National and pay them 50 cents, and join the Illinois State State Association and pay them 25 cents, that leaves us 25 cents for our income, which is hardly sufficient to pay our expenses; and if this Association wants to continue join-

ing both these associations in a body, I want them to do it with their eyes open to the facts in the matter. Do what seems best.

Dr. Miller—Across the ocean they are a long way ahead of ours. Only this past week I noticed the Austrians were congratulating themselves that they had reached the number of 10,000. Then here is the united organization of pretty much all of those that use the German language, in which I think there are perhaps 30,000. They do it largely by the fact that the smaller societies unite, and if we consider it important to have the National Association what it ought to be—if it grows to what it ought to be—I believe it will be more than anything else by associations like this joining in a body. If we do not do it, the National is going to remain always a great deal smaller than it will if we do; and so for the sake of having the National encouraged and increased as it ought to be, I should even vote to increase the amount of money we pay into the treasury here rather than to withdraw from uniting with the National in a body—if that is the only question—the question of money—and it is necessary to have a larger amount of money. I consider it of very, very great importance, that we do that very thing—unite in a body.

The motion was put and carried.

On motion, it was voted not to join the Illinois State Bee-keepers' Association in a body, a very influential reason being that if we join one State association we ought to join several, as different States are represented in the membership of the Chicago-Northwestern.

### HOW TO CONSTRUCT LANGSTROTH HIVES.

"How should the Langstroth hive be constructed for general convenience and durability among American bee-keepers?"

Mr. Taylor—A plain box, without any cleats.

Dr. Bohrer—I wrote that question. I began the use of the Langstroth bee-hive more than 40 years ago. I think in 1864 I used it first, and Mr. Langstroth himself used it at that time. I have seen a good many changes, some very valuable improvements, and some so-called improvements that in my opinion are not valuable improvements at all; at least, they would not work well with me, and in bringing up this question I have no war to make with the gentlemen who manufacture bee-hives. I believe it to be the duty of bee-keepers, not only as individuals but as an organization, to make known to the manufacturers what their actual wants are, and ask them to make their hives in accordance therewith; and I believe they will do it. As long as we stand off and they go to work and make a hive of this idea and that and the other, you will have a whole lot of different patterns, and no one will suit but a few bee-keepers. I have never seen a hive that pleased me any better, that is, the construction of the frame, than Mr. Langstroth's frame as he used it 40 odd years ago. The bees in Kansas would not glue the frames together, as they do with what is known as the Hoffman frame. There are two valuable features about the Hoffman frame—the

heavy top-bar and grooves. The frames as constructed by Mr. Langstroth I liked as well as anything at that day and time, but the grooved frame and heavy top-bar were certainly improvements. The Hoffman frame did not suit me at all. I killed too many bees, even if there wasn't too much propolis carried in. I object to that, and I object to the so-called improvement of the bottom-board being made out of lumber hardly  $\frac{1}{4}$  inch thick, so that it will shrink and the bees crawl out of the bottom. It is too thin to ship bees in, and not safe to handle bees in to move them from one apiary to another, or even about the farm. I say to manufacturers, Don't make them that way. You are not benefiting us as you might do with another follower or division-board. I want it made out of something not less than  $\frac{1}{2}$  inch thick. I would not undertake to ship a colony of bees with that kind of a bottom-board. I have to go to work and make new bottom-boards for those hives. They are absolutely next to worthless. I want to repeat that I am not making war upon any manufacturer, but when you manufacture a hive of that kind you are not manufacturing what the bee-keeper really wants—what he stands in need of.

And now on the production of comb honey. I am not handling bees much for comb honey. Men who do would know more how to dispose of that feature of the subject than I do. My idea is and has been for years, that I can produce more honey and cheaper and can sell it for less money, and in the long run make more money, than the man can who produces comb honey alone, that is, by the use of an extractor.

Mr. Sewell—The hive I use myself I can make for about 25 cents. I mean I can get it cut out at the mill for about that price, and it is a good hive. But perhaps it could be improved quite a little. While I had a Langstroth hive when I was about 10 years old, yet I have not had very many hives since, for the last few years not over 5, and it seems to me I could learn a great deal about hives. The hive that we have is a dovetailed; that is a little more expensive than necessary, it seems to me, but I don't know. Perhaps 20 years is long enough without painting, but if they last 20 years without painting, they ought to last considerably longer if they are painted; but it is a question that I think all of us are very much interested in. Personally, I like the halved corner better than the dovetailed corner.

A Member—Can you get that for 25 cents?

Mr. Sewell—I mean just the brood-chamber. The hive I use is a very plain hive. I don't know that I need to describe it, but I would like to hear more said about this matter. A great many of us want more hives. We want them as cheap as we can get them. We want them as plain and as easily operated as possible, and we want them to last just as long as possible.

Mr. Taylor—I have had considerable experience in using hives and in making them. Some here have had more experience than I have, but I should say that if a person wishes to use a Langstroth hive, to make it just as plain as he

# American Bee Journal

possibly can. If he wants anything over and above the boards sawn square across at the ends of the hive, he can make it a little firmer at the corners, but I do not think that is necessary. If made out of good, fair lumber, what we used to call "cull lumber"—they don't call it cull lumber now (lumber with some occasional "shakes" in it, or a worm-hole)—and nailed together at the corners, it will last 30 or 40 years, with reasonable care. All it wants is a plain bevel at the ends inside, and it does not want any cleats around the outside; it wants handholds, and that is all I should put in a hive. There is no need of paying \$1.50 or \$2.00 for a hive, when you can make one from which you can get just as much honey for 25 cents.

W. Z. Hutchinson—For the bottom-board I would just have a plain board. Some make a board with a cleat at the end to keep it from warping, and a rim on each side. I agree with Mr. Taylor about the sides—just plain boards nailed together.

Dr. Bohrer—How thick do you make your bottom-board?

Mr. Hutchinson— $\frac{7}{8}$  inch. Plain handles to lift it by; cover and plain end; plain rabbets at each end to hang the frames in; and all-wood frames.

Mr. Abbott—I am interested in where these brethren live, that they can buy lumber enough to make a box as big as a hive frame for 25 years. Take any hive-frame, make it 12 inches long, where can you buy that amount of lumber?

Mr. Taylor—How many feet are in it?

Mr. Abbott—You can figure it yourself. They charge down in our country for the cheapest kind of ship-lap that you can get—that is, so full of knots you can't put your finger down where there isn't a knot—\$2.50 a hundred.

Mr. Taylor—Move into Michigan.

Mr. Abbott—And for any kind of lumber such as used in a modern beehive you have to pay from \$3.50 to \$4.50 for the lumber. We could go back and wear homespun jeans, if we wanted to; we could go back to the long-horned Texas steer; we could go back to a great many things; we could go back to homely men and women if we wanted to; but in these modern days we want a good looking woman, a well-dressed man; a fat, sleek cow; a fine house and an automobile; and I do not see why a bee-keeper is not entitled to just as good things as other people. Thirty years ago they said that cheap clothes made a cheap man. There is a good deal of truth in that. And cheap beehives make a kind of cheap bees and a Cheap John affair all around.

Mr. Taylor—We are not proposing to go back. We are proposing to go ahead. These men who are making supplies are inviting purchases, and they are asking big prices, and men who have not very much experience—who have not the ability to make their own hives—are buying them. When they get those hives and put bees in them and look after their crop, where are they going to get the money, after paying for all this stuff, to buy their fine Jersey cows and their automobiles and their fine houses? I tell you, we are in the business to make something out of it, and we can't make

anything out of it if we go to these men and buy the stuff that they offer at their prices. That is the way I look at it.

Mr. Stuebing—I think every bee-keeper will pay a little higher price if he gets a good bottom-board and a good cover. I think they are the important things.

Mr. Wheeler—I am a friend of the bee-keeper, and a friend of low prices as far as you can get a good article for a low price, but at the same time on this bee-hive body, I think the dovetailed corner is a great improvement. I have had hives side by side and have tried them for 15 or 20 years—one with corners simply nailed together, and another lot where I dipped the dovetailed corners into a good strong paint, drove them together, and they have stood the weather nearly 20 years without being warped or twisted. I believe the dovetailed-corner beehive is far and away ahead of the other, in which the nails will rust and they will begin to twist, and they won't either fit the cover or fit the bottom-board, but they will twist out of shape, out of square. The dovetailed-corner hives, if they are put up right and driven together, with new paint, will last indefinitely. They will never lose their shape, and no matter if the nail rusts off they will keep their shape. They have great trouble nowadays with the nails rusting off. It is surprising how well those hives will keep their shape even after the nails are gone. I am in favor of the dovetailed corners.

Dr. Miller—There are so many different points of this question we hardly know where to grab on. One thing that has been neglected is the cover. That has not been tackled, and the thing I am most anxious about is the cover. We haven't a good cover yet that I know of—a satisfactory cover. Some of these good people that have learned how to make hives, let them tell us how to make the cover.

Pres. York—Mr. Hutchinson says a  $\frac{3}{4}$  cover.

Dr. Miller—Plain board, with a cleat on each end. I have had lots of them. They will warp so that a bee will crawl out from underneath, "in my locality." It makes a very satisfactory cover; if it would stay always new and always straight I would like a plain board cover, I wouldn't want any thing better. Another objection to them is that they do not protect enough. They don't keep warmth enough. A cover with an air-space is very much better than that. They are very expensive; but if we could get one that was reasonably inexpensive, I should like that kind better.

Dr. Bohrer—Dr. Miller, do you use covers made in 3 pieces, that is, the cover itself, with the cleat on the end? How do you like them?

Dr. Miller—I have used them with 3 pieces, with 2 pieces, and with one piece. The one piece is the most satisfactory for me, and yet it has that objection. I can not keep it square, and no amount of cleating will keep it square, either.

Mr. Taylor—What kind of lumber do you use?

Dr. Miller—I never tried basswood. That might twist worse.

Mr. Taylor—What kind of pine?

Dr. Miller—A white pine.

Mr. Taylor—Your locality must be very bad.

Dr. Miller—It is.

Mr. Wilcox—I shall have to agree with Dr. Miller about the covers. I have them in use and have for many years, and as they get older they will warp and sometimes crack. I have never been able to make any that would stay good, year after year, for any great length of time. We have fine yellow pine up in our country. If it were not for the cost I would want a gable roof, and I would really think I would do better if I had a little cleat around the outside of the hive, and had that set over on that. I rather object to the wind blowing straight through it under the cover—in at one side and out at the other. It ought not to do that. I would have room for covers if I wished to use them. I believe the cover is quite an important matter for the beehive. There is just one more point in regard to the dovetailed corners. If you are going to buy your hives made in a factory, they are a nice thing, and I would buy them. If you are going to make them yourself, don't, because you make them up pretty quick and they are liable to shrink, some pieces more than others, and the dovetailing does not fit. Another reason why: I can make a very good hive and one that will stay good by rabbeting the end pieces  $\frac{7}{8}$  inch deep half way through the board. That is equal to 7-16 inch deep on the three sides. The top and the two ends and the side of the hive are nailed into them, and they are also nailed the other way. They are nailed both ways, and they hold together just as well as the dovetailed. I have had them in use side by side for the last 10 or 15 years, and can see no difference; and it is easy enough to make them that way.

Mr. Taylor—I want to say a word about the cover. I have a great many covers. Of course, once in a while one will warp a little, but I would not use a  $\frac{7}{8}$  inch board. I would use a  $\frac{5}{8}$ , and you see at once the reason for it. It has not the strength in warping to draw the cleats out of shape. I would use a  $\frac{5}{8}$  inch board, and instead of using a single cleat at the end I would have a flat piece nailed on to the end of the cover even with the upper surface of the board, and then another flat piece up on the top covering the first cleat and part of the board. In that way you will likely get those two parts of the cleat so that they will not both want to go in the same direction if the cover wants to warp. If you use that thickness of board,  $\frac{5}{8}$ , and cleat them in that way (I can't give the size now of the cleats I use, but not very heavy), there will be very few of them that will warp to do any damage.

Mr. Wheeler—I have one idea on this subject. It is not my idea; it is the idea of James Heddon. The first cover he put out gave a space all around and under the cover. We tack a strip on the outside edge of the cover on the side and a cleat on the edge—I presume you have seen them described in the American Bee Journal—so that the cover sits on the rim and does not crush any bees; and if the board in the center warps, the outside rim sits square

# American Bee Journal

because it is fastened to the ends. The 4 pieces around the hive are fastened together, and if the center board warps or twists a little bit it does not allow the cover to change so that the bees can escape. The warping of the main cover does not affect the warping of the rim outside, which will maintain its shape, because the ends of the 4 pieces around are nailed together, and rest down on the square hive. I like it very much, and I do not have any trouble at all with the cover warping enough to let the bees get out or the cold weather to get in.

Mr. Hutchinson—When a board warps, it is the heart side, that is, the convex; and in nailing up the hive turn that side up. It is at the corner of the hive, and not in the center—it is always at each end. Nail them up with the heart side out, and then the tendency is to warp to the center, and that is almost impossible. If the corner will stay the board will last.

Dr. Bohrer—I want to sanction what Mr. Hutchinson said in regard to the manner in which boards ought to be put together, whether top, bottom or side. With regard to the roof of a hive, I think, as Dr. Miller said, that it is one of the most important things connected with the hive, to have a roof that will not leak, and one that will be the least trouble. The roof that has given me the most satisfaction is made of two boards, coming together in the center, and the outer edges being dressed down, beveled with almost a feather edge, or  $\frac{1}{2}$  inch, maybe, at the outer edge, and  $\frac{3}{8}$  in the center, and then a saddle-board on top of that. In putting them together they won't come down square on the roof, and I make it a rule to put a weight on them—a brickbat. That will usually weight them down, and I do not find that kind of cover to warp very much. There is the cover made of two boards, in the center a piece of tin, and as long as the tin is well painted it will last 15, 20, maybe 25 years. In calling this question up, understand it is not the price of hives that I wanted to bring up a discussion in regard to, but for convenience and durability—that is what we want. The price is one thing, and the question of durability and practicability is another.

#### NATIONAL FOOD LAW AND HONEY.

"Will the National Pure Food Law, enacted by Congress, increase the sale of either or both comb and extracted honey?"

Mr. Taylor—No.

Mr. Nau—Yes.

Mr. Arnd—I think it will. At least I have found it so in the grocery trade in Chicago. We used to have to send a wagon to sell our honey, and now they come to our place and get it. Those people that have been putting up bogus honey are out of business today. I think it will increase the sale of pure honey.

Mr. Wilcox—I think the more pure food laws we have the better. It does increase the sale of honey. The pure food law increases the sale of almost everything that has been adulterated. It restores confidence in the product, and the people will buy. I think it is a good thing in that way.

Mr. Wheeler—I would like to ask what is going to be done about the honey-dew that happens to get in the honey. How are we going to meet that?

Mr. Moore—I think the answer to this is that this law, as drawn, includes honey-dew—a small amount. It is not illegal to have a small amount of honey-dew in the honey. That is my understanding of it.

Mr. Wheeler—That is rather indefinite, isn't it, a small amount? What does that mean? One inspector might say it was a small amount and another, a large amount.

Mrs. Glessner—Isn't the adulteration to be by man instead of the bees?

Mr. Taylor—Not according to the law. If there is too much water in it it is adulterated, even if the bees do it, as I understand it.

Pres. York—I would like to hear from Mr. Burnett on this question. He has a little (?) experience in honey, and probably can tell whether this law is going to have any effect upon the sale of either comb or extracted honey.

Mr. Burnett—It has not been in force long enough for me to give an opinion on it!

Mr. Abbott—There seems to be a misunderstanding about the law, and bee-keepers ought to understand it thoroughly. The lady is correct as to the adulteration—the statement of the law; but the Board of Agricultural Chemists have made some rulings in their application of the law as they understand it, and those rulings become law, and among the rulings the last circular that was sent out by Dr. Wiley's department, who has charge of that, it is said a small portion of honey-dew could be included and it would not be considered adulterated; but they specify how much water may be in; in other words, they describe what pure honey is, and if it does not come up to their tests, no matter where it came from, it is impure. If you get it out of a bee-hive, and never put anything in it, if it won't stand the test of the law, it is impure. The same thing occurs in milk. The regulations, I presume of Chicago, make it 3 percent, butter-fat; they do in Kansas City, I know. It is a fact that Holstein cows, and some very good ones, give milk that tests but  $2\frac{1}{2}$  percent, and a man was arrested in Kansas City for selling Holstein milk that he milked from his cow. It was a gross injustice, of course, and the law ought not to be administered, in my opinion, in that way. Bee-keepers ought to take that matter up and agitate the question until there is some relief along that line. No man should be prosecuted for selling the natural product for what it is. A man who sells the milk from a Holstein cow that has  $2\frac{1}{2}$  percent, or even 2 percent, of butter-fat, ought not to have to go to jail for it, if he milks it from the cow, and does not put any water in it. Any law that condemns him is wrong. Any law that would condemn a man for selling what his bees gathered is radically wrong, in my opinion, and he ought not to have to go to jail for anything of that kind. But as a bee-keeper he ought to avoid putting anything on the market that would injure his trade. I would not do that,

not because I am afraid of going to jail, but because I do not want to injure the trade. Any honey that does not come up to the standard ought to go into manufactures, or into the sewer. That is the way it looks to me.

Mr. Wilcox—I think a man that would produce milk testing less than 3 percent should be punished for it—not for the injury done to others, but for the injury done himself. A man who produces honey testing more than 25 percent water is producing honey that won't keep. If it is exposed to a warm temperature it will sour. I think the rules and regulations are right as they are.

Mr. Wheeler—Now don't you think that we are up against a hard proposition? We can't follow the bees and find out where they gather their honey. What in the world are you going to do? Are you going to have it tested every time you sell a gallon of honey? One colony may gather honey-dew, and another one clover honey. Who is going to tell? You put that honey on the market in good faith, and if it doesn't stand the test, what are you going to do? There was a committee appointed at the National Convention to meet with the chemists and formulate some kind of a formula for honey, and what did they do? They eliminated honey-dew—anything gathered in the shape of honey-dew was eliminated from pure honey. Of course, they say now a little of it will not do any harm—we will overlook a little of it—but that leaves the leverage with the man who tests it—with the chemist. He can put his finger on one man and not on another—do just as he pleases. It seems to me that the only straight way to do is to make honey pure when it comes from the bee—the only way that any man can safely sell honey—as long as he can not follow the bee up, and he is not a chemist himself.

Mr. Moore—I do not think in his dissertation that Mr. Abbott quite covered this case fully. You must go back to the origin. Honey is the nectar of flowers gathered by the bees and stored in the combs. I believe that is where they start. But in order to protect an innocent party whose bees might have gone to the leaves of trees and gotten honey-dew and mixed a small amount with the honey, this small amount is allowed. But I think that there will be no trouble about this matter in the minds of any one who acts in good faith. Honey-dew tastes different, and the only trouble comes if you sell honey-dew and label it honey. You can sell all the honey-dew you please and label it honey-dew, or you can say, "Honey with a small amount of honey-dew;" and if you, as experts—bee-keepers, honey-dealers, if you please—can not tell the difference between honey-dew and honey, if you do not distinguish anything about it, don't you believe that your customers will. If you conscientiously taste that honey and decide that it is all right, your customers will be pleased with it. You won't have any trouble along that line. This law is all right as it stands, for one who inadvertently has a small amount of honey-dew in his honey, but not so as

to be distinguished by the taste. I take it that that is the point of the whole matter. If it is so thin, if it is so disagreeable, if it is so strange, that any of us bee-keepers or honey-dealers can distinguish it by the taste, you must not sell it as honey. The labeling of this honey-dew as honey is the danger-point. If there is any question in your mind you must put a label on it, "Honey with Honey-Dew." It seems to me that the pure food law has a whole lot of effects. I am not so sure that it increases the sale of honey. I don't know but it increases skepticism. When you call on wholesale grocers they say, "Is that pure honey?" and even about comb honey, "Your honey is pure, is it?" If you have honey-dew, I would advocate labeling it honey-dew, or not selling it. Sell it if you can, of course, but don't label it as edible honey.

Mr. Wheeler—I think this is a vital point. I have something right in mind that bears on that point very closely too. There is a town near Chicago that I watched closely this summer and the trees were just covered—once in June and once in August—with this honey-dew. It was on the leaves of the maples, and the bees worked on that, morning, noon and night; all day they stored that, and I know of a person that is putting the honey up and selling it. He is a *bona-fide* bee-keeper, and undoubtedly he thinks that the honey is clover honey. I will wager any amount of money that that honey hasn't a particle of clover honey in it. I think those bees gathered that honey entirely from the leaves of the soft maple. I tasted it and it is not bad honey at all. It is dark. I was in a town this year where there was no clover honey or anything else except that secretion off the trees, and this man put that up and put it on the market. It makes a very passable honey. It is not as light as some, has a peculiar taste to me, because I have tasted a good deal; but supposing that honey is tested, I would wager that 97 percent of it would not pass the test. What is the man going to do? He put it up in good faith, put it on the market in good faith. It suits his trade. He is selling quite a lot. We bee-keepers ought not to favor a law of that kind. Supposing it is flavored a little with basswood and so on. You can't tell. People's tastes fool them. It seems to me it is favoring something we ought not to favor as a convention or as a lot of bee-keepers.

Dr. Miller—Just one point that Mr. Wheeler raises: If we look at the law of the State of Illinois, the honey definition is "material that the bees gather from plants." That will cover honey-dew. You will not get into any trouble with the amount of honey-dew you get in your honey, without specifying the amount, and I do not believe there is much trouble about adulteration. I take the ground Mrs. Glessner does. What the bees do without any adulteration on the part of man would not be called adulteration. There, of course, might be such a thing as their getting something that is not fit. I have tasted here in Chicago honey taken from the nectar of plants that I considered much worse than any honey-dew. I do not remem-

ber now what it was from, but it produced the effect on the mouth that eating Indian turnip does. The question before us is whether this law is a benefit to us or not. A fundamental question upon which that rests is, Did the putting on the market of all this adulterated stuff hurt us as bee-keepers? I think we have pretty well settled that Karo corn syrup, and corn syrup of all sorts, was a damage to us; and when it has come that they must put on the label that it is so much glucose—you don't see it printed glucose, because the people would not stand glucose, but they will stand "corn syrup"—but if on the label there is such a percent corn syrup, the people won't take that. But I would give more for five words of testimony from a man like Mr. Arnd, who knows what has been done, than for all the theories.

Mr. Arnd—In selling honey to the grocery trade, especially to the wholesale grocery trade, we are compelled to sign an agreement that the honey that we sell to them, that we bottle, is put up according to the pure food law. How are we dealers going to protect ourselves so that we can sign these agreements without testing? Don't you think that the bee-keepers that supply us with the honey ought to furnish us with the same agreement, that the honey that they send to us will stand the pure-food test, and so right along the line, so that the dealers, grocery men, the retail men, and every one all along the line, can go back to the original bee-keeper if there is any trouble? I think the dealers ought to have some protection, because we have to sign an agreement that the honey that we furnish the wholesale grocery houses is up to the pure food test, and they have to furnish the same thing to the retail grocery trade.

Dr. Bohrer—I wrote the question, and what induced me to write it was, there has been quite an effort among bee-keepers (and I feel a deep interest myself in it) as to how to dispose of our product, and I have become convinced that one thing that caused slow sale of honey was that the people were suspicious that both comb and extracted honey were impure, and were an artificial product. All the advertising that the bee-keepers have been able to do up to the present time has been ineffectual. An organization sprang into existence in this city, I think it was, and some money was paid in. I did not take stock in it, did not become a member, for the reason that I was not an extensive producer of honey, having but few colonies; yet I felt an interest in the matter, and hoped that something would come of it; but I will be honest, I did not have any faith in any good results growing out of it. I then believed, and I believe now, that what the people wanted was a pure food law, and when the people understand that no man dare to put a label "Pure Honey" upon any package, and put it upon the market and sell it, when it is other than pure honey—that, I think, will undoubtedly increase the sale of both comb and extracted honey. The people today believe that 4-5 of everything that goes on to the market in the shape of honey is bogus; that it is

adulterated; that glucose is largely fed to bees, and that they store it in the combs. No longer ago than last winter at our State bee-keepers' convention in Kansas, I offered \$500 to any man who would bring 2 sections of comb honey that was made of artificial comb and filled with artificial honey. One man said he had it at home, and brought in 2 sections. I appointed a committee immediately, being President, and I asked him to aid me in the selection of the committee, so that no injustice should be done and that he would get his \$500. The committee said: "These two sections are not alike at all, and if they were manufactured by a machine they would be just alike; they would have to be." Well, he thought they were both artificial, but one had been made by one set of molds and the other in another set! Then the question naturally arose, How many molds would have to be obtained in order to make each section different? It can't be done. It is an impossibility. When the people come to understand this law, they will say: "Here, it is more than any man dare do to combine glucose with honey, perhaps put  $\frac{1}{4}$  honey or 1-5 honey and the balance glucose, and label it honey and put it on the market." If he labels it honey and glucose, then that is another matter; but people want pure honey, both comb and extracted. These side-issues and questions as to what the Government may ultimately define as honey and a legitimate article to put on the market, are not fully determined, but when people learn the effect of this law, that glucose cannot enter into a package of honey, whether comb honey or put up in sealed packages, buckets, jars or anything; that they can buy honey and know it is honey; that there will be a United States officer to test it, and if it is not pure, the man's brand being on the package lays him liable to arrest and prosecution, you will find that the men who have been counterfeiting honey heretofore will not want Uncle Sam to handle them, because he does it without gloves. I remember, a good many years ago, I think in 1871 or 1872, at the Michigan State bee-keepers' convention, a Mr. Perrine was at that convention and said that a great deal of honey was now being prepared and made salable by getting the bees' comb honey and putting it into a jar and then filling it up. He said it was not always honey. In your agricultural papers and in your country papers it says the sale of bogus honey is shut down on by Uncle Sam, that it is more than any man can do to put an impure preparation on the market and label it honey.

Mr. Taylor—What was the fact last year, Mr. Arnd, in regard to the crop of honey? Wasn't it all sold?

Mr. Arnd—Of course I don't know; but I think the honey was pretty much all sold.

Mr. Taylor—You understand it was pretty well cleared up before the present crop came on?

Mr. Arnd—I think so. Mr. Burnett could tell you more.

Mr. Taylor—How about this year? Will it be cleared up?

Mr. Arnd—I think so. I am not sure.

Mr. Taylor—How can the law help

you if you sell it all any way?

Mr. Arnd—I don't handle all the honey there is.

Mr. Taylor—I am talking about the people who deal in honey. You are talking for the lot.

Mr. Arnd—I am talking of my own orders. If my orders come in faster this year than last I will sell more honey. Another thing, too, when orders come to you without your solicitation it shows it is being helped along.

Mr. Abbott—I want to suggest that the law could not do anything, for it is not in force until the first of January, and, besides, it has no relation to any honey except that which enters into interstate commerce. There is no pure food law in Missouri or in Kansas. I believe but few States have a pure food law corresponding with the National law, and you can adulterate all you please in the other States, provided you never send it out of them. Illinois has one, and it is the Illinois State law that is operating here, and every State in the Union ought to have one like the National law. Let us keep that in mind, and go home and besiege our legislatures, if we want it to benefit us, to make a law in accordance with the National law.

Dr. Miller—We can vote on it.

Pres. York—All who think the National law will be a benefit, raise your hands. All who think it is not a benefit raise your hands. It seems to be all one way; those who voted, any way. Practically all think the law will help. The law is not in effect yet, and probably will be amended if there are any weak points in it, after a while.

#### REMEDY FOR BEE-PARALYSIS.

"What remedy, if any, have we for the disease known as bee-paralysis?"

Mr. Taylor—In my experience, a simple change of queens is all that is necessary.

Mr. Whitney—I asked that question. I had a colony of bees in June that developed what I supposed to be bee-paralysis; that is, they exhibited all the symptoms such as I have read about in the bee-papers; it was growing worse rapidly for about a week, and I thought it was being communicated to an adjoining colony, from the appearance of bees on the alighting-board. I got some sulphur and decided to experiment a little, even if I killed a colony of bees. I sprinkled sulphur all over the alighting-board, all over the bees, on the top-bars of the frames of both hives, and in 2 or 3 days I gave them another dose; inside of 6 or 8 days there was not a bit of the disease left. I did not know but what I had discovered something.

Dr. Miller—I have had paralysis among my bees; I painted my shop red and the disease disappeared. I do not know that there is any other disease, unless it be the disease of bee-stings, that has had so many remedies as bee-paralysis. One man says he has done so and so, and the disease disappeared. In this part of the country, as far north as this. I think it will generally disappear of itself, no matter what you do, or don't do; and I doubt very much

whether anything in the way of medication or treatment will do any good, unless it be sulphur treatment. And I may say that is the only one that I have known of, that has been mentioned, that a number of people have not mentioned as having failed. I think so far no one has reported that the sulphur treatment has failed; but it is not original up in this part of the country. Mr. Poppleton, of Florida, is the one who has used the sulphur cure, and really I have a great deal of faith in it. I think so far no one has reported who has faithfully tried the sulphur cure and it has failed; and until some one tries that faithfully and says it is a failure I shall have some faith in the sulphur cure. I do not know anything else that has been reported but what has been a failure. A number have reported the change of queens and a cure resulting, but a number of others say that they changed queens and it did not cure.

Mr. Taylor—I had a colony that was very badly affected with paralysis. It was early in the season, and I got a queen from another colony and took out the queen that belonged to the affected colony and put in the new one. I put her in a cage, and soon after I did the exchanging a bee-keeper from the neighborhood called on me and wanted to know if I could not let him have a queen. I told him that I hadn't any queens to spare, but I had just taken one out of a hive that I did not consider of any value, and if he wanted to take her and try her he might. Accordingly he took her. In 3 or 4 weeks he was back again, and I inquired how the queen had done, and he said that the young bees were shaking terribly, while mine were steady and all right. I thought that was pretty good proof, at least in that case, that the changing of the queen had completed a cure, and that the difficulty was with the queen.

Mr. Wilcox—Transferred the disease, you mean?

Mr. Taylor—Transferred the disease to another colony.

Mr. Whitney—Doesn't that prove that the sulphur remedy is of value?

Mr. Taylor—I do not think it has any bearing on it.

Mr. Whitney—I did not change queens, but I gave them a dose of sulphur.

Mr. Taylor—I don't know what else happens in the hive. We guess too much about these things.

Mr. Hobbles—I have one or two colonies every year that have what I suppose to be paralysis, and when I had the first one I knew nothing about treating them in any way, and I gave them a good dose of salty water. They got well all right. I have continued that from that time to this, and I have never lost a colony, and they have always come out all right.

Mr. Kimmey—How do you administer the dose?

Mr. Hobbles—I put the salty water in a little pepper-box; take the hive cover off, and then shake it all over the hive, letting it run right down over the frames.

Pres. York—You sprinkle or spray it on the frames and bees.

Mr. Hobbles—I have never lost a colony yet, and they always got well in the course of about a week.

#### ELECTION OF OFFICERS.

After an intermission, election of officers was taken up, and resulted as follows: President, George W. York; Vice-President, Miss Emma M. Wilson; of Marengo, Ill.; and Secretary-Treasurer, Herman F. Moore, of Park Ridge, Ill.

Pres. York—I hope every person who is here now will remain for the evening session. We have invited some singers, and expect to have quite a little musical program to begin with, both instrumental and vocal.

In accordance with what had been the custom for several years, Secretary Moore was allowed \$20 for the past year for his services.

#### AGE OF LARVAE FOR QUEEN-REARING.

"What is the age of larvæ chosen by a queenless colony from which to rear queens?"

Mr. Taylor—My answer probably would not be agreeable to all. My experience is that they use larvæ from 2 to 5 days old. I used sometimes to experiment in rearing queens, and of course in those days I was very curious, and observed closely with regard to what they did choose—what sort of larvæ they did use for rearing the queens—and I found that they chose larvæ of different sizes, so much so that I was in the habit, when I wanted queens from those reared in that fashion, of looking through the hives in the course of 5 or 6 days after the colony was made queenless, and examining the cells and removing from the cells those larvæ which appeared to be too large. I found proof of that fact in the time required for the hatching of the queens. The queens with me begin to emerge in 10 days from the time the colony is made queenless. If the bees chose larvæ two days old it would not be possible for the queens to emerge in 10 days. It would take at least a day or two longer, because until the larvæ are chosen for the purpose of rearing queens, their progress is slower. It takes a worker to mature say 20 percent or more longer than it does a queen, so that the larva of a queen would have advanced as far in 5 days as a worker in 4 days; so I will say that the choosing of a larva first devoted to the rearing of a worker must take a little longer than one devoted from the first to the purpose of rearing a queen. Dr. Miller will not agree with me. He made an experiment several years ago—and I wish I had it here—quite an extensive experiment on that very point, to prove, as he claimed, that the bees never choose larvæ that were more than 3 days old. But as I looked at his experiment, which was very elaborate, and which was thoroughly discussed both by himself and myself, I thought the experiment showed conclusively that larvæ more than 3 days old were chosen. Of course now, after the lapse of time, I can not enter into the particulars, but that has been my experience.

Dr. Miller—I do not understand part

# American Bee Journal

of what Mr. Taylor said, that the relative worker and queen time is 4 days and 5. I don't know what that means, but I do know that he says that he had queens emerge 10 days after the time that the bees selected the larvæ. Do I understand that, Mr. Taylor?

Mr. Taylor—After they were made queenless.

Dr. Miller—Now if they chose the larva immediately upon being made queenless—I do not think they do; I think they must take a little time, but they do not take a great deal of time to find out that they are queenless; but if they do, there is 10 days that is taken from the time. I don't know how many days Mr. Taylor will say that the queen takes from the time of the laying of the egg.

Mr. Taylor—It varies from 15 to 17 days.

Dr. Miller—It was 17 days when I was a boy; it was 16 days some 20 years later, and now the latest authority gives it 15, although it varies, as Mr. Taylor says. I think 15 is what Mr. Cowan says. I saw that very thing last week in the British Bee Journal. Take 10 from 15 leaves 5; and take 3 days in the egg state, leaves us 2 days for the larva state. But I don't think it will figure down as close as that. Now I will give you some experiences on that same line: For a number of years I have been rearing queens by allowing a colony of best stock to start a frame of brood, and then I would take that frame having eggs and larvæ of all ages up to that which is nearly ready to be sealed over, or perhaps ready to be sealed over, and put it into a colony which I had made queenless. I reared hundreds of queens in that way, and I never had one of them emerge until 12 days after the colony was made queenless and that frame put in there. That is the way it is in my locality, and that same rule holds over in Germany, I find by the authorities over there. In cases where bees are allowed to select for themselves the larvæ they want, they in every case select what will be 12 days in hatching out. I don't know just how Mr. Taylor's and my experience have been so different. One thing I think has helped to create the impression that the bees select larvæ too old: Make a colony queenless, and if you just take the pains to lift out a frame and look at it—Mr. Hutchinson says that the bees will select larvæ too old. I will ask him to say what they do nowadays. Bees have improved. They may have done other things when he was young, but what do they do nowadays? Have you tried that, Mr. Hutchinson?

Mr. Hutchinson—No; I have been too busy.

Dr. Miller—You will always be too busy.

Mr. Hutchinson—I tried it years ago.

Dr. Miller—They didn't do it years ago.

Mr. Hutchinson—They did just the same with you years ago.

Dr. Miller—You refer to the first volume of the American Bee Journal, and you will find that the time for rearing a queen is 17 days. Now it is 15 days.

Mr. Hutchinson—Not always.

Dr. Miller—To go back: I said to make a colony queenless, and lift out the frame and look at the size of the larvæ—and I don't believe there is a man here, or woman either, that would say that the larvæ were older than 2 days, if they are at all familiar with the size of larvæ at certain ages; let that colony go on for a week or so, and they are not satisfied with the queens they start; they will keep on starting them, and after the time comes that there are no larvæ young enough to make proper queens they will still keep on starting, and will then start queens from larvæ that are too old.

Mr. Taylor—That is all I claim. [Laughter].

Dr. Miller—Will you put in words what you claim?

Mr. Taylor—I claim simply that they do not always use larvæ young enough.

Dr. Miller—Then we are exactly together.

Mr. Taylor.—Yes.

Dr. Miller—They don't always, because they don't always have the stuff before them. When they have their choice of the right and wrong kind of material they will always use the young, never the old.

Mr. Taylor—That is not material at all. I have got the queens from too old larvæ. You admit that now.

Dr. Miller—No, not necessarily. If you take all the cells that they will start, old and young, then you will get some that are too old. Leave them to themselves to rear the queens and they will never have any that are wrong, because the ones they first start will mature ahead of the bad ones. But you meddle with it, and take out all the cells, and you will get the bad cells as well as the others. The point is this: Bees allowed to select, given free choice of brood of all ages, will never select a larva that is too old for a good queen; and if they did do that, then some of those should have matured and emerged before the period of 12 days, and they never do.

Mr. Hutchinson—When I take away a queen from a colony and leave the brood of all ages, I almost invariably get some poor queens; but if I allow all that brood in the hive to mature, and then give them a frame of just hatching brood—just put in a comb filled with eggs nearly all of the same age—I don't know that I ever got any poor queens. Where they had larvæ of different ages to choose from, sometimes they chose too old larvæ, but when they had nothing except the young larvæ to choose from, had no larvæ that were too old, then the queens were always good. I have found in rearing thousands of queens that it is not safe to allow a colony more than 10 days for the hatching of the queen. If you wait more than 10 days, when you go to the hive you will quite likely find some of the larvæ hatched.

Mr. Taylor—It is so invariably in Michigan.

Mr. Wheeler—At one time I lived about 50 miles south of where Dr. Miller lives, and my experience was the same as in Michigan—10 days from the

larva. It may be different now. I have not tried it for a few years.

Dr. Miller—I tried it last year.

## DISCRIMINATING AGAINST CERTAIN MEMBERS FOR OFFICERS.

"Should the constitution of any bee-keepers' association bar any of its members from holding an official position in the association?"

Mr. Taylor—Using the words of a noted author, "I don't know."

Mr. Wilcox—I do not think any of us know the constitutions of all the various bee-keepers' associations. That question was evidently asked in reference to some association other than this.

Pres. York—No. The question is: Should the constitution bar any of its members from holding an official position—should the constitution be made in that way?

Mr. Wilcox—Whoever wrote that question was thinking of some other association than this, probably the National.

Pres. York—Not necessarily.

Dr. Miller—He might be thinking of this association, whether the constitution ought to be changed in that way for this association. You can't tell what the questioner was thinking about. If you will allow me to say so, I think he was thinking of the National, and what was done at San Antonio.

Dr. Bohrer—I wrote the question, and I will tell you what I was getting at. I know there was proposed an amendment to the constitution of the National, to bar certain members of that Association from holding official positions because they were dealers in bee-keepers' supplies, or editors of bee-papers. There was an effort of that kind made, it is true, at San Antonio. I opposed it and declared then that if that kind of an amendment were added to the National Association I would not be a member of it any longer. I took the position, and Mr. Kimmey here took the same, and the constitution of the United States takes the same view of it, and all the States of the United States, that there is only one class of people barred from being eligible to the presidency of the United States, and that is foreign born; and the constitution of any organization must apply to all its members. If not, it is un-American and unjust. It places the members in a state of alienship before that association, and I was opposed to it, and I believe it is our duty to discuss that question here. I am a member of the Kansas State Bee-keepers' Association—President of that organization—and a member of the National, and I do not want an amendment so un-American as that, and so unjust as that, to become a part of the organic law of our National organization or of any State organization. I took the broad stand, and made the sweeping declaration, and I repeat it, that if it became a part of our organic law I would not be a member of the organization any longer. While it may not be at all times policy upon the part of the members of the organization to elect a dealer in bee-supplies to an official position in that organization, it is simply the duty of every individual

# American Bee Journal

member, if he does not want a man to serve in an official position, to vote against him, and so get rid of him; but place the membership on a common equality before the law, and if the members for any cause see proper to elect a man that is a dealer in bee-keepers' supplies, they have a right to do so. If they find when they put him in office that he warps and twists his position for selfish purposes, they do not have to re-elect him; but know how to "sit down" on him in the future. Some of the best and most worthy members of the bee-keepers' associations in the United States have certainly been dealers in bee-keepers' supplies. Among them was the great Langstroth himself. A purer-minded man never lived, in my opinion. I speak from having known personally the man, having been in his apiary and talked with him on different topics, and he was a pure-minded man, first, last and all the time. He never would accept an office. I do not believe he was ever an officer. He may have presided at one meeting in Cincinnati, but it was against his inclination and his will. An amendment of that kind would bar the great Langstroth. Our worthy friend Dadant (I give him all praise that is due him; I would not take a laurel from his brow) seemed to favor an amendment of that kind to our constitution, stating that some of our Eastern bee-keepers, notably the State associations of Pennsylvania and New York, would withdraw from the National if it did not become a part of the organic law of that Association. I do not believe that the bee-keepers of New York and Pennsylvania feel that way; and I do not believe, if they are fairly dealt with, and that question is fairly discussed before them, that they will vote in favor of that kind of an amendment to the constitution. I hope they will take the broad view of it, that all the members are on a common ground. If you do not want a man who deals in supplies to be an officer, do not elect him; and any other person who is not fit for the position—sit down on him likewise. It is our duty as American citizens, and members of a growing institution, to select the very best men and women that we have for our official positions—persons who have energy, and will put some push and life into the pursuit in which they are engaged and that which they represent. If I were the Secretary of the National Bee-Keepers' Association I would feel it a duty to push the interests of the Association everywhere possible; and if I were President I should do the same thing; but I am not electioneering. I would not have an office in the Association.

Mr. France—I want to say just a word of explanation to Dr. Bohrer, and for the benefit of some others, as I was at the San Antonio convention. The disturbance in the East is a good deal like some church choirs that I have been in before now. Some wanted to be heard, and because they couldn't be heard just as they wanted to, they made a little disturbance; but the choir kept right on singing; and since the San Antonio meeting, 88 from New York State, and 104 from Pennsylvania, have voted,

and sent their dues direct to the National. [Applause]. And in the election of the National officers, of which I have received returns it is quite nicely divided up—the election of Mr. L. A. Aspinwall, for President; Vice-President, Geo. E. Hilton; Secretary, Jas. A. Green; General Manager, N. E. France; Directors, G. M. Doolittle, Jas. A. Stone and R. A. Holekamp. You will notice if you are going to draw the line on bee-supply men, the majority of these have handled supplies, more or less.

Pres. York—Mr. Aspinwall and Mr. Hilton are from Michigan; Mr. Green is from Colorado; Mr. France from Wisconsin; Mr. Stone from Illinois; Mr. Doolittle from New York; and Mr. Holekamp from Missouri.

Dr. Bohrer—If they don't supply anything else, they supply honey.

Mr. Abbott—There has been a good deal of agitation, and a good deal said in certain bee-papers concerning various fraudulent dealers. There are only 6 or 8 bee-supply manufacturing establishments in the United States, and probably 300 or 400 bee-supply dealers. I think these gentlemen who make such charges owe it to the bee-keepers as a whole to mention names. If Mr. Root is a fraud we ought to know it. We all know him pretty well, and we don't think you can tell us anything new about him. If Mr. Lewis is a fraud we ought to know it. If the Falconer Manufacturing Company is a fraud we ought to know it, and so on around. We know them personally, and think they are all right. We think they are honest. We think they are honorable. We think they are engaged in an honorable, conservative, upright business, offering wares that the bee-keepers seem to want, for they are making their factories bigger and bigger all the time every year, and if it were not for the support of the bee-keepers of the United States they could not afford to do it. Now, if it is a crime to furnish people something they want, why, then, these people ought to be ostracized and excluded from associating with bee-keepers. If it is not a crime, let us stop all this nonsense about classes. The more we talk about classes, the more we divide humanity up into classes; the more we magnify the differences, the more strife and contention we make. I know a few of those New Yorkers will leave the National Association, but it reminds me of a remark that Ralph Waldo Emerson made once when an Adventist was talking with him very earnestly and enthusiastically to convince him that his philosophy was wrong, and that the world would surely come to an end. Emerson in his quiet, quaint way—and if you ever saw him you know he was very quiet and very mild-spoken—smiled, and said, "Well, what if it does? It won't trouble me very much. Somehow I think I can get along without it." Somehow I think the National Association can get along without about a half a dozen of those fellows, and if they do not want to come in, why, the world is as big outside as it is inside—let them stay out. It seems from the report of Mr. France that the majority of them want to come in. There are

only a few of them in New York, and if they can get along without the National Association, and would rather not be in it, the National Association isn't going to die to accommodate them. It is going to live right on, and not stop breathing.

Dr. Miller—It is not because these men are rascals, as mentioned by Mr. Abbott—it is not necessary to take any such view as that. The resolution, if I remember rightly, was that supply-manufacturers, supply-dealers, editors and department editors, should not be allowed to hold office; they are to be allowed membership. You will perhaps see the reason for that is that these supply manufacturers and supply-dealers are working in antagonism to bee-keepers; they are getting their money! And so are the editors, and so they should not be allowed to have office; and the department editors are aiding them, and on that account they should not be allowed to hold office; and those who assist them—the members in helping to get subscriptions for these papers are aiding these same editors—they should not be allowed to hold office; and the men who subscribe for those papers are helping the editors, and they should not be allowed to hold office. Well, I don't know just how far that thing is going. [Laughter].

Dr. Bohrer—Doctor, I suggest one more alteration or amendment to the suggested change in the constitution—that they include everybody that purchases or handles bees and honey, and then they would have the thing just right.

(Continued next week.)

**Honey as a Health-Food.**—This is a 16-page honey-pamphlet intended to help increase the demand for honey. The first part of it contains a short article on "Honey as Food," written by Dr. C. C. Miller. It tells where to keep honey, how to liquefy it, etc. The last part is devoted to "Honey-Cooking Recipes" and "Remedies Using Honey." It should be widely circulated by those selling honey. The more the people are educated on the value and uses of honey, the more honey they will buy.

Prices, prepaid—Sample copy for a 2-cent stamp; 50 copies for 70 cents; 100 for \$1.25; 250 for \$2.25; 500 for \$4.00; or 1000 for \$7.50. Your business card printed free at the bottom of front page on all orders for 100 or more copies. Send all orders to the office of the American Bee Journal.

**Getting New Subscribers** for the Bee Journal is something that almost any reader can do if he makes a sincere attempt. No one knows better than does he its value to every would-be successful bee-keeper. And we offer valuable premiums, to those of our present readers whose subscriptions are paid in advance, for the work of going out and getting new subscriptions. Your neighbor bee-keepers perhaps have never heard of the American Bee Journal, although it is now in its 47th year. Why not try to get them to subscribe? You may be surprised how readily they will do so upon your invitation.

**Amerikanische Bienenzucht,** by Hans Buschbauer, is a bee-keeper's handbook of 138 pages, which is just what our German friends will want. It is fully illustrated, and neatly bound in cloth. Price, postpaid, \$1.00; or with the American Bee Journal one year—both for \$1.75. Address all orders to this office.

Send Questions either to the office of the American Bee Journal, or to  
Dr. C. C. MILLER, Marengo, Ill.  
Dr. Miller does not answer Questions by mail.

### Comb Probably Not Diseased

The pieces of comb I am sending you were taken from a colony of bees that died during the warm spring weather that we had here in March. Three out of five colonies died within a few days of each other. All had an abundance of stores. The frame from which this was cut had considerable honey. Any information you can give me will be appreciated.

NEBRASKA.

ANSWER.—I'm not an expert in brood-diseases, and I'm not the one to whom to send samples, but I think there is no disease in your case. The number of dead bees in the comb makes it pretty certainly a simple case of starvation, even although there may have been plenty of honey in the hive. See answer to "New York." If you want to make sure in any case of suspected disease, send sample to General Manager N. E. Francee, Platteville, Wis., provided you are a member of the National Association. If not, it will cost only a dollar to become a member.

### Transferring Bees—Baiting Wild Bees

1. I have subscribed for the American Bee Journal and like it very much. I am thinking of going into the bee-business on a small scale at first. I have 2 colonies in box-hives. They have not swarmed yet. I bought 2 patent hives quite awhile ago, but never have been able to get them home. I wanted to transfer my bees into the patent hives. Is it too late now? I have been trying to buy a few colonies here, but can not. As there are a good many wild bees here, I thought probably I might find some trees and save the bees. That is the way I got those I have.

2. Is there any kind of bait for wild bees? I have tried honey, but they will not touch it.

TEXAS.

ANSWERS.—1. It is perhaps just as well, and many prefer, to do no transferring before swarming. When a colony swarms, hive the swarm in a movable-frame hive, and 21 days later transfer the contents of the old hive.

2. Some scent the thinned honey with essence or oil of anise; others make a smudge by burning old comb, the smell of which attracts the bees, and helps them to find the honey present.

No need to send stamp for reply. As a subscriber to this paper you are entitled to have answered in this department all the questions you like, free of all charge; and questions are not answered by mail.

### Keeping Bees Out of the House

I am a subscriber to the American Bee Journal and appreciate it very highly. I have 20 colonies of bees, and I wish an answer to a question which, to my mind, is a "corker."

For 2 years my bees have insisted on coming into the house, hovering over the roof day after day, and working themselves into

the house in different parts. The windows are well screened, but that does not stop them. Last year I reshingled, thinking there might be some crevices in the roof through which they might come. I carefully puttied up every crack where I thought a bee could come in, but all to no purpose. To-day is the first day that has been warm since I brought them from winter quarters, and the roof is covered like a swarm. They tried to get into the chimneys, but a little fire stopped that. Now, if you can tell me any way to stop that I will be happy, because my wife has cleaned house!

IOWA.

ANSWER.—Well, that is a "corker," for sure. Makes me feel discouraged. Just when I begin to think I do know a little something about bees, along comes some one like you with a question to which I can find no answer in the whole pile of answers I've been laying up for years. What under the sun should induce your bees to take on that particular form of insanity is beyond me. If it were later in the season, I might make a bluff at an answer by saying the bees on the roof were scouts finding a place for a swarm to enter; but that answer won't fit when they first leave winter quarters. If any one else wants to answer he may; I'm not going to. Won't even try to puzzle over it, for I don't want to go as crazy as your bees. Sorry for your wife, though.

### Starved Bees—Foul Brood

I bought 2 colonies of bees about the middle of March. During peach-bloom in this section I set them in the north edge of a 75-acre peach-orchard. They began to work to "beat the Dutch." They were rather light of stores when I bought them, but as fruit-bloom was plentiful, I thought they would make it all right. Then with the disappearance of fruit-bloom came cool, rainy weather which lasted about 3 weeks. In the meantime a great deal of brood had been hatched out, consuming all the stores. They began to dwindle and the bees died by the hundred. As soon as I discovered what the trouble was, I lifted the frames and brushed the bees away, and poured warm sugar syrup along next to the top-bar of every frame. Before I did this, the bees were crawling around all over the ground and could not fly (like "Indiana," page 395). Perhaps if "Indiana" had fed  $1\frac{1}{2}$  barrels more of sugar during the warm spell in March, he would not have lost 13 colonies of his bees.

My bees are doing fine now, and storing in the super from white clover in one colony. The other I have divided for increase, having ordered one tested golden queen, and I think I got a 3-band. I make my own hives with dovetailed corners, which makes the most substantial hive I ever saw. One bee-keeper who saw my hives, said: "They are nice; but that is work." So it is, but I think it is the best in the long run.

Where can I get the book, "Foul Brood and Its Causes?" I have seen many questions in regard to cause of foul brood, but have never seen a satisfactory answer.

ARKANSAS.

ANSWERS.—1. You were wise in looking out for starvation. There is many a case of starvation that is not suspected. Beginners do not realize how rapidly stores disappear when brood-rearing is going on rapidly. There's probably many a case of starving even when white clover is in full bloom. Plenty of bloom, but the bees are getting nothing from it; first the beginner notices is that the bees are dragging out the sucked-out skins of the larvae, and he wonders what disease has attacked his bees, when it's a plain case of starvation.

2. I think the U. S. Department of Agriculture has issued the pamphlet about foul brood you inquire about. As to the cause of foul brood, for years the answer has been that it is *Bacillus alvei*, but of late that is disputed by some and asserted by others. Let us hope the question will be definitely settled before long. In actual practise, however, exact knowledge as to the real culprit will hardly make any difference. The McEvoy treatment is the same whatever the cause.

### Wonderful Spring—Early Drones—Killing Off Drones

1. This has been a wonderful spring. The weather during March was so warm that bees were out and hard at work nearly every day. Fruit-bloom of all kinds came out and bees were almost frantic in their effort to gather the rich harvest contained therein. But spring had not really come, as about April 1 the weather changed, and kept steadily cold all through the month; only an occasional warm day when the bees could come out. But the bloom and blossoms were all killed as it had been as cold as 26 degrees above zero, and froze ice regularly nearly every night, and is still cold at night; froze some 2 nights ago. I have been feeding my bees of late, and they appear unusually strong in numbers, and are working some on dandelion blossoms. Is it not unusual for drones to appear this early in the season? Some of my colonies have had as many as at any time in July or August, and have had for 2 or 3 weeks. Every warm day they are out flying thick and the bees have been killing them.

2. Is it necessary to kill them off? How should I go about it?

KANSAS.

ANSWERS.—1. A drone may be seen here and there occasionally at any time of the year, but it is unusual to see them in appreciable numbers as early as during dandelion blossoms. The same thing occurs here this year. Is it not because the unusual warm weather in March caused the queens to lay in drone-cells?

2. Unless in very great numbers, it's hardly worth while to do anything about killing them. If you think best you can put drone-traps at the entrances.

### No Disease—Probably Starvation

To learn apiculture evidently takes time and experience. Some time ago I found one hive robbed of all the honey. The bees had also departed. An examination of all the frames revealed no sign of eggs or brood. On one comb I found cells with what I call "dead brood." I sent you a sample. What do you think of it? Do you think it was a queenless colony? I have read about foul brood and pickled brood, but never saw a case of the disease. To a beginner it is very confusing to read so many different opinions, theories and practices in bee-culture. But I suppose after a few years' experience, even the timid novice will get the necessary confidence in this pleasant hobby. What shall I do with the combs?

NEW YORK.

ANSWER.—My good friend, your eyes or your spectacles are not so good as mine. You say no eggs were present. In the sample of comb you sent me there were at least 2 dozen. You are quite right in saying there was dead brood, and all of it was sealed. No appear-

## Langstroth on the \*\*\* Honey-Bee

Revised by Dadant—Latest Edition.

This is one of the standard books on bee-culture, and ought to be in the library of every bee-keeper. It is bound substantially in cloth, and contains nearly 600 pages, being revised by that large, practical bee-keeper, so well-known to all the readers of the American Bee Journal—Mr. C. P. Dadant. Each subject is clearly and thoroughly explained, so that by following the instructions of this book one cannot fail to be wonderfully helped on the way to success with bees.

The book we mail for \$1.20, or club it with the American Bee Journal for one year—both for \$2.00; or, we will mail it as a premium for sending us **THREE NEW** subscribers to the Bee Journal for one year, with \$3.00.

This is a splendid chance to get a grand bee-book for a very little money or work.

**GEORGE W. YORK & CO.**

118 W. Jackson Blvd., CHICAGO, ILL.

**Western Bee-Keepers** **You Will Show Us** how to save money. Send for our new catalog of the best Bee-ware made.

THE COLORADO HONEY-PRODUCERS' ASS'N. Denver, Colo.  
9Atf Please mention the Bee Journal.

ance of disease whatever. In the absence of fuller information I can only guess what was the trouble, and my leading guess is that it was a case of starvation. Quite possibly you may say, "Oh, there was plenty of honey left in the hive." Very likely, but in this very unusual spring there have, doubtless been many cases of starvation with plenty of honey in the hive. Those warm days in March set the bees to breeding and consuming more rapidly, and then came many days when it was so cold that it meant death for any bee to leave the cluster, and after all the honey was consumed that was within reach there was nothing for the bees to do but to starve, although there may have been abundance of honey just out of reach. The queen was probably all right. Again, it may have been a case of desertion.

Keep the combs to use later. In the last few numbers of the American Bee Journal, both in the editorial department and in this department, you will find instructions about keeping and using them, and if anything is not fully understood don't hesitate to ask all the questions you like.

Getting New Subscribers for the Bee Journal is something that almost any reader can do if he makes a sincere attempt. No one knows better than does he its value to every would-be successful bee-keeper. And we offer valuable premiums, to those of our present readers whose subscriptions are paid in advance, for the work of going out and getting new subscriptions. Your neighbor bee-keepers perhaps have never heard of the American Bee Journal, although it is now in its 47th year. Why not try to get them to subscribe? You may be surprised how readily they will do so upon your invitation.

## 29 Years Means QUEEN Quality

100 pounds to the colony in a poor year, like last, and 250 to the colony the year before. My Italians are non-swarmers. Every queen purely mated or money back. Circular tells of Italian and Caucasian.

SElf A. D. D. WOOD, Lansing, Mich

Please mention Bee Journal when writing advertisers.

While the Present Stock of these **BEE-HIVE CLOCKS** lasts, we will sell them at only **\$1.50 each**, by express; or \$2.00 for the Clock and the Weekly American Bee Journal one year. **Better order at once**, before all are gone.

# The Bee-Hive Clock

A \$4.00 CLOCK FOR \$2.50 ... With the American Bee Journal 1 Year—Both for Only \$3.00

We have originated and had made specially for our readers, a bronzed-metal Clock, called "The Bee-Hive Clock." It is 10¼ inches wide at the base, 9¾ inches high, and deep enough at the base to stand firmly on a mantel or elsewhere. It is a beautiful piece of work, and would be both ornamental and very useful in any house, and particularly in a bee-keeper's home.

The Clock part itself is warranted for 3 years to keep good time. So it is no plaything, but a beautiful and needful article for everyday use.

Clocks like "The Bee-Hive Clock" usually sell in the stores at from \$4.00 to \$5.00 each, but having them made for us in quantities enables us to offer them at \$2.50 each by express, or with the American Bee Journal a year—both for only \$3.00. Either Clock or Journal would make an ideal gift.

## How to get "The Bee-Hive Clock" FREE

Send us **5 New Subscribers** to the Weekly American Bee Journal for one year, at \$1.00 each, and we will send you this beautiful "Bee-Hive Clock" FREE (excepting express charges). Or, send us **4 New Subscribers** (at \$1.00 each) and 50 cents—\$4.50 in all. Or, **3 New Subscribers** (at \$1.00 each) and \$1.00—\$4.00 in all. Or, **2 New Subscribers** (at \$1.00 each) and \$1.50—\$3.50 in all.

Address all orders to **GEORGE W. YORK & CO.,**

Only \$2.50, f.o.b. Chicago, by Express.  
Weight, with packing, about 4 pounds.

## What Dr. Miller Thinks of the Bee-Hive Clock

Busily ticking away, in the room where I am sitting, stands a genuine bee-keeper's clock (please understand that the word "genuine" belongs to the clock and not to the bee-keeper) or, as the legend upon the clock has it, "The Bee-Hive Clock." I don't know

whether the idea of getting up such a clock was conceived in the brain of the Editor of the American Bee Journal, or whether he got it elsewhere, but the wonder is that such a thing was not thought of long before.

Setting aside all idea of its association with the business of a bee-keeper, there is a peculiar appropriateness in having the minutes and the hours "told off" in a case representing the home of the busy little workers. The glance at the clock, with its ceaseless tick, tick, tick, can not fail to remind one that the flying moments must be improved now or be forever lost, and that suggestion is reinforced by the thought of the never ceasing activity of the little denizens of the hive, always busy, busy, busy, working from morn till night and from night till morn, working unselfishly for the generations to come, and literally dying in the harness.

Let us be thankful that the form of the old-fashioned straw hive or skep was adopted, and not that of any modern affair, patented or unpatented. The latter smacks of commercialism, but the former of solid comfort, for no other form of hive has ever been devised that contributes so fully to the comfort and welfare of a colony of bees as does the old-fashioned straw-hive. It appeals, too, to one's artistic sense as can no angular affair of more modern times. As an emblem of industry, artists have always used—probably always will use—the old straw skep.

Thanks, Mr. Editor, for furnishing us a time-keeper so appropriate for all, and especially for bee-keepers. C. C. MILLER.

**Something New = The Ideal Hive-Tool**

Bee-keepers have long needed a special Tool to work among the hives during the bee-season. The one shown here was invented by Wm. Muench, a Minnesota bee-keeper, some years ago, but it was not on the market before. We have lately bought this Tool, and all rights, from Mr. Muench's widow, and have had the first lot made. They are ready for delivery now.

Best Hive-Tool

Only 30c, by mail

(This picture is exactly one-half the size.)

**DESCRIPTION.**—The Ideal Hive-Tool is made of high-grade malleable iron, much like wrought iron, 8 1/4 inches long. The middle part is 1 1/16 inches wide and 7/32 thick. The smaller end is 1 1/4 inches long, 3/4 inch wide, and 7/32 thick, ending like a screw-driver. The larger end is wedge-shaped, having a sharp semi-circular edge, making it almost perfect for prying up covers, supers, etc., as it does not mar the wood.

**What Dr. Miller and Miss Wilson Say of It:**

In the first edition (1903) of Dr. Miller's "Forty Years Among the Bees," page 58, he says: "Of all the hive-tools I have tried, I like best the Muench tool." On Jan. 7, 1907, he wrote us saying he thought "just as much of the tool as ever."

Miss Wilson, Dr. Miller's assistant, says this of the Ideal Hive-Tool: "It is an ideal tool. In fact, I don't see how it could be improved upon. I am sure we would feel utterly lost in the apiary without it. . . . You will have to try one yourself if you want to know its worth."

**The "Ideal Hive-Tool" Free as a Premium.**

We will mail an **Ideal Hive-Tool FREE** as a premium to any present paid-in-advance subscriber to the American Bee Journal, for sending us **ONE NEW** subscription for a year at \$1.00; or we will send the American Bee Journal one year and the **Ideal Hive-Tool**—both for \$1.20. Price of the **Ideal Hive-Tool** alone, postpaid, 30 cents. Address,

**GEORGE W. YORK & CO.,**

**CHICAGO, ILL.**

**BEE BOOKS** Sent postpaid by  
 GEORGE W. YORK & Co.,  
 118 W. Jackson Blvd., Chicago, Ill.

**Advanced Bee-Culture.** Its Methods and Management, by W. Z. Hutchinson.—The author of this work is a practical and helpful writer. You should read his book; 330 pages; bound in cloth, and beautifully illustrated. Price, \$1.20.

**A B C of Bee-Culture,** by A. I. & E. R. Root.—A cyclopedia of over 500 pages, describing everything pertaining to the care of the honey-bees. Contains about 400 engravings. It was written especially for beginners. Bound in cloth. Price, \$1.20.

**Scientific Queen-Rearing,** as Practically Applied, by G. M. Doolittle.—A method by which the very best of queen-bees are reared in perfect accord with Nature's way. Bound in cloth and illustrated. Price, \$1.00; in leatherette binding, 75 cents.

**Bee-Keeper's Guide,** or Manual of the Apiary, by Prof. A. J. Cook, of Pomona College, California. This book is not only instructive and helpful as a guide in bee-keeping, but is interesting and thoroughly practical and scientific. It contains a full delineation of the anatomy and physiology of bees. 544 pages. 295 illustrations. Bound in cloth. 19th thousand. Price, \$1.20.

**Langstroth on the Honey-Bee,** revised by Dadant.—This classic in bee-culture has been entirely re-written, and is fully illustrated. It treats of everything relating to bees and bee-keeping. No apiarian library is complete without this standard work by Rev. L. L. Langstroth—the Father of American Bee-Culture. It has 520 pages, bound in cloth. Price, \$1.20.

**Honey as a Health Food.**—This is a 16-page honey-pamphlet intended to help increase the demand for honey. The first part of it contains a short article on "Honey as Food," written by Dr. C. C. Miller. It tells where to keep honey, how to liquefy it, etc. The last part is devoted to "Honey-Cooking Recipes" and "Remedies Using Honey." It should be widely circulated by those selling honey. The more the people are educated on the value and uses of honey the more honey they will buy. Prices: Sample copy for 2-cent stamp; 50 copies for 70 cents; 100 for \$1.25; 250 for \$2.25; 500 for \$4.00; or 1000 for \$7.50. Your business card printed free at the bottom of the front page on all orders for 100 or more copies.

**Forty Years Among the Bees,** by Dr. C. C. Miller.—This book contains 328 pages, is bound in handsome cloth, with gold letters and design; it is printed on best book-paper, and illustrated with 112 beautiful original half-tone pictures, taken by Dr. Miller himself. It is unique in this regard. The first few pages are devoted to an interesting biographical sketch of Dr. Miller, telling how he happened to get into bee-keeping. About 20 years ago he wrote a small book, called "A Year Among the Bees," but that little work has been out of print for a number of years. While some of the matter used in the former book is found in the new one, it all reads like a good new story of successful bee-keeping by one of the masters, and shows in minutest detail just how Dr. Miller does things with bees. Price, \$1.00.

**"The Honey-Money Stories."**—A 64-page-and-cover booklet, 5 3/4 x 8 1/2 inches in size, printed on best quality paper. Many short, bright stories interspersed with facts and interesting items about honey and its use. The manufactured comb honey misrepresentation is contradicted in two items, each occupying a full page, but in different parts of the booklet. It has in all 33 fine illustrations, nearly all of them being of apiaries or apiarian scenes. It also contains 3 bee-songs, namely, "The Hum of the Bees in the Apple-Tree Bloom," "Buckwheat Cakes and Honey," and "The Bee-Keeper's Lullaby." This booklet should be placed in the hands of everybody not familiar with the food-value of honey, for its main object is to interest people in honey as a daily table article. Price, 25 cents, or 3 copies for 50 cents.

**Standard-Bred Italian**  
**FREE**  
**PREMIUM QUEENS**

We are booking orders now for those **Fine Untested Italian Queens** that we offer every year **FREE** to paid-in-advance subscribers as premiums for getting **NEW** subscribers for the **Weekly American Bee Journal**. These orders are taken for May or June delivery.

**What Some Say of our Standard-Bred Italian Queens:**

*George W. York & Co.*—The two queens received of you some time ago are fine. They are good breeders, and the workers are showing up fine. I introduced them among black bees, and the bees are nearly yellow now, and are doing good work. A. W. SWAN.  
 Nemaha Co., Kan., July 15.

*George W. York & Co.*—After importing queens for 15 years you have sent me the best. She keeps 9 1/2 Langstroth frames fully occupied to date, and, although I kept the hive well contracted to force them to swarm, they have never built a queen-cell, and will put up 100 pounds of honey if the flow lasts this week. CHAS. MITCHELL.  
 Ontario, Canada, July 22.

*George W. York & Co.*—The queen I bought of you has proven a good one, and has given me some of my best colonies. N. P. OGLESBY.  
 Washington Co., Va., July 22

*George W. York & Co.*—The queen I received of you a few days ago came through O.K., and I want to say that she is a beauty. I immediately introduced her into a colony which had been queenless for 20 days. She was accepted by them, and has gone to work nicely. I am highly pleased with her and your promptness in filling my order. My father, who is an old bee-keeper, pronounced her very fine. You will hear from me again when I am in need of something in the bee-line. E. E. MCCOYM.  
 Marion Co., Ill., July 13.

**How to Get these Queens Free**

To any one whose own subscription to the **Weekly American Bee Journal** is paid in advance, we will mail a **Fine Standard-Bred Untested Italian Queen** next May or June, for each new name and address sent to us with \$1.00 for the **Bee Journal** a year. No one can get for himself the **Bee Journal** a year and the **Queen** for \$1.00. The **Queen** is offered as a premium for the work of getting some one else to take the **Bee Journal** a year. If you, yourself, want the **Bee Journal** a year and the **Queen**, send \$1.50 for the two, and we will book your order for a **Queen**. **Queen** orders will be filled in rotation—"first come, first served." Address,

**GEORGE W. YORK & CO.**  
 118 W. Jackson Blvd., CHICAGO, ILL.

# Millions of Dollars

are made every year in the book business. Every family, rich or poor, must have books. During the last few years, \$7,500,000.00 have been expended for Modern Eloquence, \$12,000,000.00 for Standard's Lectures, \$1,000,000.00 for the Century Dictionary, and the tremendous sum of \$4,000,000.00, covering over half a million sets of the Encyclopedia Britannica. These books were sold by subscription in American homes and sales are still going on.

We have a subscription publication which sells more readily than any of the above. The demand is already so tremendous that more capital is required to swing it, or get behind on orders. Profits are enormous, several times savings bank interest.

## Any Progressive Man or Woman Can Share These Profits

becoming stockholders in a profitable business, based on twenty years' experience. Remember, the success of this publication is not away off in the future—it is not prospective, but it is a success at the present time and growing in demand every hour. Sales of this publication at the time of publishing this advertisement

## Often Exceed \$2000 a Day

This is an exceptional opportunity for those of small means to get in on the ground floor in a business which legitimately pays large dividends and is as solid as the Rock of Gibraltar. It cannot be held open for long as the response is certain to be so great that we shall have all the capital we need to increase the number of our presses and secure stock to be turned out in completed books, which are selling like wildfire.

You owe it to yourself to investigate this opportunity. You will never have a chance like this again to become

## Part Owner in a Mammoth Publishing House

which is already in successful operation, already earning big dividends, and which is led to sell a small amount of its stock simply because the business is already so tremendous as to exhaust the working capital. But if you would grasp this opportunity you must

**Honey and  
Beeswax**

CHICAGO, May 9.—Very little honey on the market of any kind. Prices are therefore nominal. A little choice white clover comb sold at 17c, and would bring that at present, but supply seems to be exhausted; even with this scarcity there is no demand for No. 2 grades. Extracted, white, 7@8c; amber, 6@7c. Beeswax in good demand at 32c. R. A. BURNETT & CO.

CINCINNATI, May 23.—There is no material change in the honey market at this writing. Extracted honey is not moving so rapidly as it could, owing to the cool weather. We quote amber in barrels at 5½@6½c; fancy table honey in crates of two 60-pound cans at 8@9c. For choice, yellow beeswax, free from dirt, we are paying 31c cash, delivered here.  
THE FRED W. MUTH CO.

PHILADELPHIA, May 25.—The honey market has been quite brisk for this time of the year. The continued cold weather has made both the comb and extracted honey sell much higher than usual. A number of odd lots have been cleaned out of the market. We quote: Fancy comb, 14@15c; No. 1, 13@14c; amber, 12@13c. Fancy white extracted, 7@8c; light amber, 6@7c. Beeswax firm at 32c.  
We are producers of honey and do not handle on commission. WM. A. SELSER.

NEW YORK, May 21.—White comb honey is practically cleaned up, and there is very little demand at this time. There is some dark and mixed comb on the market, but no demand to speak of, and some of this will have to be carried over until next season, or sold at a sacrifice. Therefore we cannot encourage shipments of off-grades or dark honey at this time. Extracted honey is in fair demand and prices are ruling firm. There is very little new crop arriving as yet from the South, and while it is rather early, we doubt whether we will have any large shipments from the Southern States this season, as we fear there will be a short crop, judging from the reports we are receiving. There is quite a good stock of last year's crop still on the market, sufficient to last until the new crop from various states arrives. There is no change in price as to extracted honey since our last. Beeswax firm and likely to remain so for the next 2 months.  
HILDRETH & SEGELKEN.

**C. H. W. WEBER** CINCINNATI OHIO

Office and Salesrooms, 2146-48 Central Ave. Warehouses, Freeman and Central Aves.

INDIANAPOLIS, April 12.—comb honey is not plentiful, but demand is slack. Fancy white comb brings 16@17c; No. 1 white, 14c; amber, 12@13c. Best grades of extracted honey bring 8@9c; amber, 6@7c. Good average beeswax sells here at \$35 per 100 pounds.  
WALTER S. POWDER.

TOLEDO, May 3.—There is very little demand for comb honey as is usually the case at this season of the year. Fancy white would bring in a retail way 16@17c; No. 1, 15@16c, with no demand for dark honey. Extracted is very scarce and none being offered for sale. Beeswax is bringing 28c.  
THE GRIGGS BROS. & NICHOLS CO.

KANSAS CITY, May 4.—Receipts of comb and extracted honey are light; in fact, the market is almost bare. The demand for comb honey is good, but for extracted is rather light. We quote: No. 1 white comb, 24 sections, \$3.25; No. 2, \$2.75; No. 2 amber, \$2.50 to \$2.75. Extracted, white, 8@9c; amber, 7@8c. Beeswax, 50c.  
C. C. CLEMONS & CO.

DENVER, Feb. 14.—Producers in this State are practically closed out of both comb and extracted honey. We have not sufficient good comb honey to supply our local trade, but have a good supply of white extracted of excellent quality. We quote strictly No. 1 white comb honey, per case of 24 sections, at \$3.20; No. 1, light amber, \$3; and good No. 2, \$2.80. White extracted, 8@8½c per pound; light amber, 7½@8c. Clean, yellow beeswax, 27@28c, delivered here.  
THE COLO. HONEY-PRODUCERS' ASSN.

CINCINNATI, May 21.—The market on fancy white comb honey is entirely bare. No. 2 is selling slowly at 12c. Extracted, light amber, brings 5½@6c. Beeswax is selling here at \$35 per 100 pounds.  
C. H. W. WEBER.

# HOW TO PAINT

Buggies, farm wagons, farming tools, barns, outbuildings and houses often need painting. "Everybody's Paint Book," written by a thoroughly practical painter, will be found a complete guide to the art of outdoor and indoor painting. It is designed for the special use of those who wish to do their own painting. It gives practical lessons in plain painting, varnishing, polishing, staining, paper hanging, kalsomining, etc.

It also tells how to renovate furniture and gives many hints on artistic work for decorating a home. Precise directions are given for mixing paints for all purposes.

If farming tools and farm vehicles are kept painted, they will last twice as long, and anybody can do the work with the aid of this book. It is handsomely and substantially bound in cloth. A copy will be sent postage prepaid on receipt of price, **\$1.00**

## SPECIAL OFFERS

For \$1.60 we will send the above book and the Weekly American Bee Journal one year; or for \$1.40 we will send the Paint book and a Standard-Bred Untested Italian Queen. Address  
**GEORGE W. YORK & CO., 118 W. Jackson Blvd., Chicago, Ill.**

# Dittmer's Gomb Foundation

Why do thousands of bee-keepers prefer it to other makes?  
Because the bees like it best and accept it more readily.

## Dittmer's Process is Dittmer's

It stands on its OWN NAME and its OWN FOUNDATION, to which alone it owes its reputation and merits.

We are now ready to make prices for next season for WORKING WAX for CASH and for full line of Supplies. Wholesale and Retail. Free Catalog and Samples.

"If goods are wanted quick, send to Pouder."

Established 1889

# "GOING SOME."

By the Bee-Crank

A writer in the Philadelphia Record says that a pound of honey represents the product of 62,000 clover blossoms, and that it requires 2,750,000 trips of the bee to collect it. If every round-trip averaged one and one-tenth miles, it would mean that in collecting it a single bee would travel 3,000,000 miles, or 120 times the distance.

These are good figures to bear in mind the next time you order supplies. They will help you to be patient while you are waiting for them—unless you order of Pouder, and then you won't need them. Indianapolis is like a great bee-hive. It is a

bee-line to Indianapolis and back again from every point in the country. The splendid shipping facilities here have had as much to do with my success in establishing a reputation for prompt shipments as my determination to do it has had. The next time you conclude that your supplies have started on a circuit of the earth to reach you, give me a trial.

I sell Root's goods at Root prices, and carry a full line of bee-supplies, which are told about in my catalog that you have for the asking.

Send me your beeswax and I will pay you the best market rates for it.

WALTER S. POUDEr, Indianapolis, Ind.  
Dear Sir:—The Pouder Honey-Jars just received. Not a broken jar in the lot.  
Truly Yours,

### ROOT OBSERVATION HIVE

In recent years there has been an ever-increasing interest in bees as a subject for nature study in the schools, and a corresponding demand for observation hives to facilitate the study of bees at work, without exposing the student directly to them, as is necessary with ordinary hives. To meet this demand we offer several styles and sizes of observation hives. These are made with skeleton frame, with glass in sides and ends of the brood-chamber, and in sides only of the super. Shutters are provided to cover the glass. These shutters have brass rings to handle them by and brass buttons to hold them in place. Brass hooks are also provided to hold the several sections of the hive together. The hives are finished in the natural wood, oiled and varnished, and altogether they are very attractive in appearance. We furnish them regularly in 8-frame, Langstroth depth. The super is fitted for the 4x5x1 $\frac{3}{8}$  plain section. Hives are usually furnished put together and finished. We can supply material in the flat, but it is work for a cabinet-maker who understands his business to put them up, and we do not care to furnish them in flat unless you order one complete as a model.

The bottom is no longer than the hive, and a covered extension is provided to lead the bees out-doors under the window-sash or other opening provided. In the full-sized hive a colony of bees can be kept by a window the year round, or for only a part of the season, as may be desired. The work of the hive, including the building of comb in the sections, can be watched

*Observation Hive Inside a Room with Entrance under the Raised Sash.*

at intervals without opening the hive or disturbing the bees. For work in the school-room before a class we recommend the one-frame hive. With the one-frame observation hive it is necessary to remove the frame of bees and put in a fresh one about once a week at least, for the best results. As a rule, arrangements may be made with a local bee-keeper to provide a frame of bees each Monday morning, returning at end of week.

We make one-frame observation hives for L. frames or for Danz. frames and a row of sections above, or the L. frame with a row of sections above. These are provided with a wood case to slip over to shut out the light when you are not watching the bees. We show this one-frame hive and the case in accompanying illustration. This consists of turned-wood corners with glass inserted in grooves in ends as well as the sides.

*Observation Hive with Panels Removed.*

### PRICE-LIST OF OBSERVATION HIVES

**Improvement of Bee-Stock**

Considerable has been said in these columns in this regard, and more is likely to be said so long as the need is so urgent. Reinforcement of the views given may be found in an earnest article in the British Bee Journal, not written by any radical hot-head, but by that canny Scotchman, D. M. Macdonald. His closing paragraph contains the following summing up:

Now this I say without fear of contradiction: While we have men who rear so few queens that they have to keep customers waiting we shall never have selection! Every queen of every batch goes out, no matter what defects she may possess, if they are not over-patent. That it may not be supposed that I am a voice "crying in the wilderness" on this subject, I should like to quote a few authorities showing that improvement is urgently desired by others:

Mr. McEvoy, of Canada, says: "Ninety percent of the queens on the American Continent want killing."

Mr. Green considers "too much of our breeding has been done haphazard, and without any intelligent direction. My own experience with superior stock has been very disappointing."

Mr. Scholl's opinion regarding our queens is: "The best of them is none too good. Too little attention is given this subject, and if more were given better strains would be found than the run-down strains that are not yielding the profit that could be obtained."

Mr. Hutchinson's opinion is that "well-directed efforts at improving stock will prove the most profitable of any which a bee-keeper can pursue. The wonder is that it is so greatly neglected."

The American Bee Journal has again and again quite recently devoted short editorials to the subject of improvement of stock, and has emphasized the pressing need there is for securing better queens. It has even the gravest doubts whether the belauded "tested queens" really conform to the guarantee given by queen-breeders.

In addition to what I have quoted, a very

large bulk of further evidence could be produced from both sides of the Atlantic, to show that the subject deserves the gravest consideration if bee-keeping is to take the prominent position which is its due.

**Self-Spacing Frames—and Fairness**

On page 349 appears a review of the Review's view of self-spacing frames. While thinking that the arguments in reply were the best possible in the case, Editor Hutchinson deems it unfair that the last paragraph of his article was utterly ignored, which paragraph reads as follows:

When it comes to the production of extracted honey, the frames with staples and projections, "excrescences," I call them, are simply not "in it." For several reasons it is better to space the combs wide apart in the supers, when the self-spacing arrangements come to naught. The same can't be said of them, however, when it comes to using the honey-knife.

Editor Hutchinson admits that he read the arguments through with just the shade of a twinkle in his eye as he wondered what would be said in reply to that last paragraph. Which is much the same as saying that in the said paragraph he felt he held an impregnable position, and was enjoying in advance the discomfiture of the enemy in attempting to attack it. Well, now, when a military commander comes up against something that he knows to be utterly impregnable, what is the use of his wasting good shot by firing at it? But that Mr. Hutchinson may not feel too much aggrieved at the neglect of his pet paragraph, it shall have, here and now, the benefit of the best shot in the locker.

First, it may be well to note the limitations of the argument. Evidently it can not apply in any way to that class of bee-keepers who

produce comb honey exclusively; not such a very small class. Neither can it apply to the brood-chambers of those who never use brood-combs and extracting-combs interchangeably. Indeed, from the wording of the paragraph it was intended to apply only to those frames which, with "excrescences" which space them properly for the brood-chamber are still used in the extracting-super.

When thus used "the spacing arrangements come to naught." Correct; they are a negative quantity, doing no good, and equally doing no harm.

"The same can't be said of them, however, when it comes to using the honey-knife." Let us see about that. Self-spacing frames may be divided into two classes. The first class, as the Hoffman, has the projections for spacing on each side of the end-bar. Bees seal their combs with a space of 1/4 inch or more between two opposing surfaces. Move the frames apart 1/4 inch more than in the brood-chamber, and the comb will be flush with the projections. That would be spacing 1 1/8 from center to center, and as "it is better to space the combs wide apart in the supers," 1 1/8 is probably none too much. Indeed, it is less than many use. Even if the knife should occasionally strike a spacer, the knife would be little hurt by striking wood.

The second class embraces those which have a spacer that projects at one side of the end-bar, such as the Miller frame or those spaced with staples. To have such spacers on a level with the surface of the comb, the spacing must be 1 1/8 from center to center. Even with such wide spacing, unless the bees built their combs with the utmost exactness, the knife would sometimes strike a spacer, and as spacers in this class are mostly of metal, there would be trouble. Even so, one need not despair, for self-spacing frames of the second class have the spacers at only one end on each side, and if one always begins with the knife at that end there ought to be little chance for trouble. Besides, if intended for extracting, spacers in this second class need not be such as will hurt the knife. Very satisfactory ones have been made of wood, and only lately C. S. Lord has brought out a spacer with a head of type-metal which should answer excellently.

There, Mr. Hutchinson, that is the best, the

# American Bee Journal

very best on hand in this locality to meet the case, and you will please remember that others beside yourself may feel aggrieved if their best paragraphs are ignored; so we will look with interest, even if with no shade of a twinkle in the eye, to see what you will do with us in the near future.

## British Bee-Keepers' Insurance

Details of this are given in the British Bee Journal. The British Bee-Keepers' Association has arranged with insurance companies to issue a policy to an intending insurer after

he has sent to the Association "a premium of 2 cents per colony on the maximum number of colonies kept; minimum premium 18 cents."

The policy is to indemnify the owners of bee-hives insuring under the British Bee-Keepers' scheme against their liability to third parties for damages to persons or property occasioned by bees from the insured apiary outside such apiary, such claim in any one year not to exceed the sum of \$150 in the aggregate, and not to include any claim for injury to the assured, or persons, or live stock under his control. The policy covers the period from March 25, 1907, to March 25, 1908, only.

for Wisconsin, completed his 10th year as inspector, on May 28—about a week ago. Wisconsin bee-keepers are to be congratulated on their being able to retain Mr. France as inspector for so long a time.

**Prof. A. J. Cook**, of Claremont, Calif., made this office a brief call on Monday of last week, when on his way East to meet his wife and daughter on their way home from Germany, where they have been the past two years. The "Professor" is looking fine, and seems to be as youthful as ever, although he's around 65 years now.

## Bread and Honey

Of all the meals you can buy for money,  
Give me a meal of bread and honey!  
A table of grass in the open air,  
A green bank for an easy chair.  
The table-cloth inwrought with flowers,  
And a grasshopper clock to tick the hours.  
Between the courses birds to sing  
To many a hidden shining string.  
And neither man nor maid be seen,  
But a great company of green,  
Upon a hundred thousand stalks,  
Talk to us its great green talks.  
And when the merry meal is done,  
To loiter westward with the sun,  
Dipping fingers ere we go  
In the stream that runs below.  
Of all the meals you can buy for money,  
Give me a meal of bread and honey.

RICHARD LE GALLIENNE.

## National Convention at Harrisburg.

—The Executive Committee of the National Bee-Keepers' Association has selected Harrisburg, Pa., as the place for the 1907 meeting. The exact date at this time has not yet been agreed upon. No doubt it will be settled very soon, when we will be pleased to make further announcement. We congratulate Pennsylvania bee-keepers, and all others of the East, on the decision of the committee to hold the next National convention at Harrisburg. It ought to be a well attended meeting, and doubtless will be.

scheme of decoration will be carried out. Running all around the building an aisle 15 feet wide will carry the main crowd of spectators. Along the outside of this aisle will be acenic reproductions of shops of all nations and time, making the aisle a veritable promenade of all nations. In the center of the building the booths will be uniform in design and color—a White City of pure foods and food products.

Managing Director Thos. T. Hoyne has already received hundreds of letters in regard to space and inquiring for information, diagram, etc.

The first allotment of space was not to be made to exhibitors before June 1. Owing to the fact that an enormous amount of space has been devoted to aisles—more than in any previous exposition at the Coliseum—the actual space to be sold for exhibition purposes seems ludicrously small in comparison with the floor area of the big building.

It is the purpose of the management to make the annual World's Pure Food Show the most attractive exposition held in Chicago, and with this idea plenty of space has been given up to handle a crowd of 20,000 spectators daily.

It seems to us this will be a fine opportunity for bee-keepers to make an exhibit of honey that would simply surprise the public. We do not now recall just where we saw it, but some one suggested that the National Bee-Keepers' Association would be the proper organization to take charge of the honey exhibit. Why not use some of the money received from the Honey-Producers' League, for the purpose mentioned? Surely, it would be good advertising for all bee-keepers, for this World's Pure Food Show will be advertised everywhere, and the various exhibits will be described and illustrated in countless numbers of papers and magazines.

**Mr. N. E. France**, of Platteville, Wis., General Manager of the National Bee-Keepers' Association, and also Inspector of Apiaries

## "To Bee or Not to Bee?"

"To bee or not to bee?"—when that old fellow Sprung that conundrum on us long ago,  
He probably (when springtime should be mellow,

And all the earth with warmth and heat aglow)

Stood by his snow-lad bee-hives wondering  
If time had struck and there would be no spring,

As we this year in Michigan; and he,  
Disgusted, wondered if it paid to Bee.

It is warmer now; maybe we'll get some honey yet.  
C. H. BENSON.  
Bellevue, Mich., May 18.

**A World's Pure Food Show.**—Chicago's first annual World's Pure Food Show, which will be held at the Coliseum, Nov. 19 to 25, 1907, has already enlisted the hearty support and co-operation of manufacturers and dealers in all parts of the country. The names of the members of the various commissions are a guaranty to exhibitors of the great commercial, industrial and educational value of the exposition.

Seventy-five awards will be made in as many classifications. All of them will be granted under the direct supervision of the commissions, which are honorary bodies.

Enthusiasm over the exposition is widespread. For the first time in the history of food-product expositions, the exhibitor will be furnished with his booth. An elaborate

**Amerikanische Bienenzucht**, by Hans Buschbauer, is a bee-keeper's handbook of 138 pages, which is just what our German friends will want. It is fully illustrated, and neatly bound in cloth. Price, postpaid, \$1.00; or with the American Bee Journal one year—both for \$1.75. Address all orders to this office.

"Songs of Beedom."—This is a beautiful 16-page-and-cover pamphlet, 6x9 inches in size, containing 10 bee-songs—words and music—all the songs so far written specially for bee-keepers, we believe. It is nice, as well as convenient, to have these songs all in one binding. Every bee-keepers' organization should have copies for use at conventions. They could be sold to members after using once, or held by the secretary for use at future meetings. Of course, every bee-keeper's family will want at least one copy. It is sent, postpaid, for only 25 cents, or 3 copies for 60 cents; or, we will mail one copy with the American Bee Journal one year—both for \$1.10. Send all orders to the office of the American Bee Journal.

**The Sixth Annual Report** of the Illinois State Bee-Keepers' Association has just been issued, containing 176 pages. Its contents, besides considerable miscellaneous matter, are the 1906 reports of the Illinois State Bee-Keepers' Association, the National, and the Chicago-Northwestern. There are a number of very fine engravings of apiaries, the Illinois State Capitol, etc. Cloth-bound copies were issued for the members of the Association only, and will be sent out as long as they last to any who become members on the payment of \$1.00 to the Secretary, which not only secures a cloth-bound copy, but membership in the State Association one year, and the same in the National Association. A paper-covered copy of the Report will be mailed to any one who sends 15 cents to the Secretary to pay postage and wrapping. We think the Sixth Annual Report is as attractive and instructive as any we have ever issued. General Manager N. E. France says concerning this Report: "It is a credit to all concerned in getting it out."

### Something About Queens in the Spring

BY G. M. DOOLITTLE

When settled warm weather comes in the spring, it is necessary that each colony contains a good, prolific queen, for if the queen in any colony should be old and failing, that colony could not be gotten in the best shape to take advantage of the honey harvest.

As the queen is mother of all of the bees in a hive, she must be able to lay rapidly so as to increase the population of the colony, and if such an one is not in the hive, she should be superseded with a better queen.

It often happens that the queen dies of old age during the winter or early spring, and in that case it is absolutely necessary that the apiarist knows it, else the colony will dwindle away till it is overpowered with robber-bees and the stores carried off, when the combs will be devoured by the larvæ of the wax-moth. Old bees rapidly die off with the work that now devolves upon them, for old age is brought about very much in accord with the labor done; hence at this time of activity it is very necessary that all colonies contain good queens from whose brood many young bees will be emerging, more than to make good those dying of old age. There is no other way of knowing for a certainty just what is going on inside of a hive, except by opening it and inspecting the combs. To know if there is a queen in the hive, inspect the combs, and if no eggs or small larvæ are found in the bottom of the cells at this season of the year, you can reasonably expect that they are queenless, while, if the eggs are few and scattered about in different cells without regularity, the queen is unprolific.

To be absolutely sure that a colony is queenless, take a frame of comb having eggs and little larvæ in it and put it in the center of the supposed queenless colony, leaving it there for 3 or 4 days. If queenless, queen-cells will be formed over some of the little larvæ, while, if no such cells are started, rest assured that the bees have something they are cherishing as a queen, which makes it unsafe to try to introduce another until the thing they are cherishing is disposed of. To find such a queen carefully look over this frame of brood, for in nine cases out of ten she will be on this frame. In fact, if I wish to find any queen that is not laying, I always put a frame of young brood into the hive containing such, leaving the hive further undisturbed for 3 or 4 hours, when, upon opening it

again, this frame of brood is immediately lifted out, when, in nine cases out of ten, anything which the bees are keeping as a queen (and said queen is not laying) will be found on this frame of brood. This is the way to find out whether a colony has a queen. The started queen-cells will tell us that the colony is absolutely queenless, and if no cells are started, whatever they have and are keeping as a queen, can be found on this frame of brood we have given.

To the accustomed eye of the practical apiarist, prolific queens are easily found, especially if the bees are of the Italian race, but a virgin queen, or an apology for a queen, is often hard to find by an expert, and was, to me, a very worrying affair until I learned this "giving of brood trick."

From the middle of April to the middle of June a prolific queen can usually be found between the hours of 9 a.m. and 4 p.m., on one of the 2 outside combs of the brood-nest, for most queens seem to have a certain route which they go over every 24 hours during the time of enlarging the brood-nest preparatory for the swarming season, she being in the center of the brood-nest at midnight, and from there traveling in her egg-laying toward the outside of the brood till noon, when she commences to return, reaching the center again at midnight. The next day she does the same thing again, only going in the opposite direction, or toward the opposite side of the brood-nest, which brings her on one of the 2 outside combs between the hours mentioned.

As more eggs are laid in these outside combs than in any others at the time of the brood being spread from comb to comb, the queen is on these outside combs longer in proportion than she is on those which already have their centers full of brood; and that she does not go clear across the brood-nest during the daylight of one day, I have proven by finding the queen hundreds of times on the east side of the brood-nest one day and on the west side the next day; the east side the next day, and so on for days in succession. Of course, I have never opened the hives at midnight, but the finding of the queen one or 2 combs out from the center at sunset on a June evening, and one or 2 combs out from the center in an opposite direction at sunrise the next morning makes me conclude that she is at the center at midnight. All queens do not show this regularity, and all persons do not open a hive carefully enough so that the queen is not stampeded from her work; but a careful examination during a week's time will convince any

apiarist that most of the queens do have a certain route in which they travel in egg-laying, where the brood-nest is not spread or materially interfered with by the apiarist.

From this, in looking for a queen during the period of time spoken of above, I take out the frame in which is the first brood in the hive next to me, and if the queen is not on the comb I next take the comb at the outside of the opposite side of the brood-nest, and in nine cases out of ten I find the queen on one of these 2 combs at this time of the year and at the time of day spoken of.

In all of these operations, when looking for queens, the operator should always stand with the back to the sun, so that the eyes may be in the shade while the rays of the sun strike the bees and the "face" side of the comb, when, if the eyes are at all sharp at queen-hunting, she will be quickly seen. No person can expect to find a queen readily with the sun shining in his or her eyes, when the face side of the comb on which we expect the queen will be in the shade; yet I have seen many would-be bee-keepers looking for queens in just that way, and wondering why they could not find them. If the directions here given are followed out it should not be a great job to find any queen, whether fertile or unfertile.

Borodino, N. Y.

### Experience With Caucasian Bees

BY E. A. MORGAN

So many enquiries are coming in in regard to the Caucasian race of bees, that we think it our duty to give our (Morgan Bros.) experience with them.

I notice most writers caution beginners not to try Caucasians—not yet. Some say they are still on probation in this country; others, that they are vicious; and others, that they are away behind Italians in honey-gathering qualities, are great propolizers, etc.

Now, to all of these I wish to say they either have not tried them, are prejudiced against them, or have not the true Caucasians.

Our experience is that they are away ahead of the best Italians, both in honey-gathering and in hardness, and are non-stingers, perfectly gentle, so much so that veil and smoker can be laid away forever with them.

We were furnished 9 queens by the Department at Washington in April, 1906, for experimental purposes—to test them. We put them through a series of tests alongside of 100 colonies of the finest Italians.

It will be remembered that Morgan Bros. have been extensive bee-keepers and queen-breeders for 35 years, and we tested these Caucasians intelligently and carefully; and we must say for them this: First, they are perfectly gentle—no amount of rough handling will cause them to sting, and we operated them in cold weather on rainy, and on muggy, hot days, when Italians would sting viciously, and never received a sting. Second, with the same strength of colony they gave one-

fourth more surplus than the best Italians. Third, they are more prolific, therefore more profitable to keep. Fourth, they are far the best winterers—more quiet—both wintered outside and in the cellar; consume less honey, and do not spring dwindle. They work all day on cold, spring days when Italians do not fly at all during the day.

In regard to propolis, they plaster most of that near their entrance, but carry none whatever to the sections. Their section honey is whiter, cleaner and better-finished than any Italians ever did for us.

To beginners and ladies wishing to start in bee-keeping, we consider them the best of all, and we predict that as soon as the veteran bee-keepers test a pure strain of Caucasians, they will very soon weed out their Italians and keep none but the former.

South Dakota.

## Bee-Keeping in Carniola

BY F. GREINER

The home of the Carniolan honey-bee (Carniola, Austria,) is also a country in Europe where bee-keeping is carried on by professionals, and where bees are reared for sale and to stock up the empty hives of less fortunate bee-keepers. There must be a good honey-flora in those mountainous sections, for very large apiaries are kept. I hope some time to see them myself, but at present I only write from what I learn through the press.

Ambrozic was the owner of one of the largest and oldest bee-establishments in that part of the country, and a circular of Strgar is coming to me now. Bees and queens are reared here for sale in large quantities. The apiaries are kept in the mountains, and it is a common sight to see men and women following the mountain-paths with hives containing bees strapped on their backs, for it is probably impractical to reach these high points with any vehicle. In America a business could not be carried on this way on account of high wages. It would hardly pay here to move bees on the backs of men and women carrying them many miles.

The hives used in Carniola are rather peculiar on account of their shape. They are about 27 or 28 inches long, and 12 inches wide; in height they are only about 7 inches. A hive with bees like the illustration is sold for about \$3 in Carniola. The fact that such a hive can winter bees in the cold, exposed regions in Carniola speaks well for the bees, and perhaps is also a proof against the so often advanced theory that bees ought to have their winter stores above rather than at the side of the cluster. However, it must not be lost sight of that the method of keeping the bees in Carniola differs from our own very materially. Such hives are never placed singly; on the contrary, they are corded up as we would cord-wood, the whole lot of bees in one huge pile, and under one common roof. This manner of wintering leaves only the ends of the hives exposed, and if the combs run crosswise

and not lengthwise of the hive, there are no frames in the hives producing a draft around the cluster, and the combs at the ends act as division-boards, thus giving a very good protection.

The hives are made of thin lumber, the ends being the heaviest. Prof.

Benton exhibited one of these ends or fronts of such a hive, which he had brought from Carniola some years ago. It was decorated nicely with some Bible scene—a habit these Carniolans have of proving again that time is not worth much with them.

## Early Manipulation of Bees

In Gleanings of May 1st, R. F. Holtermann tells of having "examined colonies for queens, brood and honey, clipped queens—something unusual for us in March." While I am, as a rule, pretty much in accord with Mr. Holtermann's teachings, yet in this case I would decidedly take issue with him as to the advisability of such early manipulations in our climate. I am quite certain that tearing the brood-nest apart early in the season, especially when no pollen or nectar is coming in, is responsible for a whole lot of queens "turning up missing" later on.

Aside from a little time gained by having the queens clipped before a busier time comes, I fail to see any good reason for lifting the frames out, in order to diagnose the condition of a colony. Where a quilt is used, all that is necessary is to turn the same up slowly, and gently puff in a little smoke to drive the bees down; nine times out of ten a single glance among the frames will reveal the general condition of the colony.

## Removing Pollen by Cutting Down Combs

Commenting on a question asked by a bee-keeper in England, as to whether any British bee-keepers had tried the "Canadian system" of cutting away the comb to the base or mid-rib to remove pollen clog, Mr. Holtermann says that it is news to him that this plan is a Canadian system. While I do not know that the idea is of Canadian origin, yet I *do know* of a number of good

bee-keepers, among them Messrs. McEvoy and Storer, who follow this plan every year with their super-combs. While I personally have followed the plan advised by Mr. H.—cutting out the pollen-filled parts and melting into wax—yet, after seeing Mr. Storer at work scraping the pollen off, I am bound to say that he made a neat job of the matter.

## Propolized Fingers for Clipping Queens

Speaking of clipped queens, Mr. H. says: "If bee-keepers would thoroughly rub propolis over their fingers before touching a queen, no evil results would occur from foreign odors." Dear me! the problem with a number of us has been how to keep the propolis off our fingers; in fact, the propolis item was one of the factors that led me to adopt the *sensible* plan of clipping the queen without touching her with my fingers at all.

## Early Stimulating of Bees

Mr. House, in his address, had considerable to say in favor of early stimulating, yet he admitted that stimulating was impracticable for out-yards. To quote his own words:

"It is too much trouble to feed out-apiaries. I stimulate them by giving them a queen so prolific that she will lay all the time. I depend upon my queens for stimulating out-yards."

While it pleases me to agree with Mr. House, yet it appears quite logical to ask why he doesn't apply the same less

troublesome system to his home apiary. From remarks dropped by Mr. House, I feel quite sure that in the near future he will dispense with early stimulating altogether, as I feel sure that with the right strain of bees colonies can be in the very best of condition for the honey-flow without the bee-keeper having to feed an ounce of food in the early spring.

My home apiary, and the one at Cashel, 4 miles away, have both wintered poorly, the loss all being caused by dysentery, for which we blame a small amount of honey-dew, coupled with a very severe winter. At the Altona yard, 8 miles away, every colony wintered, and although the spring has been *very* backward, pollen having only been brought in 4 or 5 days to date (May 13), yet 90 percent of the yard require top stories inside of a week or 10 days, if the weather is fine.

In fact, we found one colony with queen-cells with eggs in, every available cell in the hive being occupied with brood, pollen, or honey. Be it remembered that the hives at this yard are all equal in capacity to a trifle more than a 12-frame Langstroth, and May 13 this year means, with us, previous to any sugar-maple, dandelion, golden willow or fruit-bloom. The surprising difference in favor of this yard has been laid to absence of honey-dew, yet I find all around this apiary, at least 50 percent of other people's bees are dead.

I have no explanation to offer, but I will simply say that at this yard there is not a single Italian queen—the bees being all Carniolan and blacks, and their crosses. The hives were heavy last fall with buckwheat honey, and this spring, regardless of steady bad weather, this honey was turned into one great host of young bees. To use Mr. House's statement, "the queens were so prolific that they laid all the time."

### Sectional Hives Non-Starvers

Speaking of the sectional hive, Mr. House, in his address at the Brantford convention, said: "I never saw a colony starve to death with honey in the hive in a sectional brood-chamber." Pretty strong claims, and enough almost to induce some bee-keepers, after a winter like the last, to adopt a hive of that style. Yet with a frame considerably deeper than the Langstroth, with ordinary precautions, there need be little loss from the foregoing cause, even if the divisible feature is lacking.

**Why Not Advertise?**—There are many dealers in bee-supplies, and those who have bees and queens for sale, who are not now advertising, that might increase their business by advertising in the American Bee Journal. The rates charged are very low, as will be seen by referring to the second page of this number. During the next 6 months will be done the bulk of the season's business among bee-keepers. Why not begin at once to let the readers of the American Bee Journal know that you have something to sell? Our advertising columns are open only to those who will give their patrons "a square deal." If you are in that class we will be pleased to have your advertisement in our columns.

Conducted by LOUIS H. SCHOLL, New Braunsfels, Tex.

### Those Texas Ants

It seems that it always takes some "tenderfoot" to come to the wild and woolly (?) West and "hatch" out some wonderful tale that most of *we'uns*, who have been "bred in old Texas," know very little of. We knew that there were ants in Texas—yes, lots of them—but we did not know that "the only way one can be sure of his bees is to isolate each hive by standing it on legs surrounded by water." My, my! what would the bee-keepers of Texas say who have hundreds of thousands of colonies *right down on the*

to call the attention of bee-keepers to the danger of letting their apiaries "run down," as it is commonly called; letting hives and combs from which bees have died become exposed to others or healthy bees. The picture herewith shows just such a dilapidated apiary.

Besides exposing these dangers, "it is strictly against the law" to expose any infected honey, comb, hive or appliances as per the foul-brood law, hence it will be well to guard against any such negligence, or else become liable for a misdemeanor.

It may be well to remark again that

APIARY DEVASTATED BY FOUL BROOD.

ground, and are not bothered by ants? The writer is only one of these, with hundreds of colonies. There are ants here, too, but never have they done harm to my bees. Hence, "in spite of ants, weather, and all other adverse conditions, bees do thrive in Texas, and the wide-awake bee-keeper gets his reward —."

I will admit that there may be some isolated locations where ants may be troublesome to some extent, but the wide-awake bee-keeper would soon have the upper hand. It is true that some of the smaller ants make trouble for the bee-keeper, and for the house-keeper, too, by getting into the honey and other things, if not in tight vessels; and the easiest and surest remedy is the "legs-in-pans-of-water." A little careful study of these interesting little creatures will help much toward getting along with them, however.

### Ravages of Foul Brood

Right along the matter of foul-brood laws and inspection of apiaries, I wish

it is to your interest to report any trouble of suspected diseases of your bees as soon as discovered to the State Entomologist, College Station, Tex., and have the bees inspected, if need be, rather than let your apiary get into such condition as here presented.

### Good Home-Made Hive-Covers

There is no part in the make-up of a bee-hive that we prize more than a good, serviceable, and durable cover, and here in the South, where our hives are exposed to all kinds of weather all the time, it is very essential that we have the best covers obtainable, for it often happens that a cover gives way, and, before we are aware of it, a leak has done considerable damage, especially if it happens in the winter when we are not often around. So we are constantly culling them out for various reasons.

We do not advocate home-made hives, but we do say that a mechanical bee-keeper can make his hive covers and bottoms, and, perhaps, it would be best

for him to do so, for he might run out, some time, and need a few before he could get them from the factory or dealer. But caution should be taken in selecting the material, and it would be best if it were seasoned in the open air, and mostly heart, and soft; also, it should not be warped, and should be free from knots and other defects. Lumber from goods-boxes makes very good covers, as it is soft and not easy to split, but it should be painted well, for if it is very thin it will let the water through.

In putting the covers together, great precaution should be used to turn to the weather the side of the board which grew nearer the center of the tree, and nail well with small flat-headed nails (not finishing nails). Then paint them well and keep a few extra at each yard.

I have tried several styles of covers, but the two illustrated have given me the best satisfaction, and they are simple, durable, and cheap.

Where hives are exposed to the sun, Fig. 1 is the best cover, for it has an air-space and needs no shade. I have

lost some colonies, many combs, and no small amount of honey from the heat of the sun, but I have never lost any combs under these covers. Figure 2 is a still cheaper cover, and is used

where the hives are not exposed to the sun. Most of the nails in these covers can be driven through and clinched, and will not give way and work out.

Crisp Co., Ga. J. J. WILDER.

#### ROBBER-BEES AND POLLEN.

T. P. Otis, on page 267, contributes a very interesting observation. Robber-bees gathered up pollen on the alighting-board and carried it off. Quite rare, I think. With wires, or zinc, or too closely contracted entrance, there is often quite a pile of lost pellets at the door; and I never could see that the home-bees would ever take pains to save them—though, perhaps, they do sometimes. Cow will eat what she wouldn't eat otherwise, provided she can steal it; and I suppose these robbers found their souls similarly moved. Willing to gather lost pollen provided they could consider it plunder.

#### CEMENT HIVE STANDS AND BOTTOMS.

Yes, Mr. Byer, cement hive-stands and cement bottom-boards are taking words. If the latter prove too cold for winter, how would it do to use a thin thickness of wood and the cement under it? I am specially attracted because at my apiary termites do lots of damage. I am quite sure a projecting cement bottom would keep them down; as they would not be able to carry forward their mud-works unless they had a passage to moist earth to get the material. Page 351.

#### CANADA AND U. S. POSTAL WAR.

The Koran has a proverb to the effect that, "When nations go to war the people must suffer from the soldiers." Bluntly and brutally just so! And just so now, it seems, even in this twentieth century. Canada and the U. S., having had postal annexation for a spell, now want to have postal war for a spell. Does seem that (with all the peace agitation and Hague Tribunals of the day) they might have given a little longer notice of hostilities. Peaceful publishers certainly ought to have time to get out from under the wheels of the war Juggernauts. How easy it is to show spunk when somebody else has to take the suffering part of the consequences! Page 389.

#### OBSERVE AND REPORT.

"Observe during the ensuing summer and report," eh? There! That sounds more like science. We've had, "Give us off hand your impressions"—about everything under the crazy moon—until we have about played out that kind of Question-Box. Why not *we* take a lesson from France, and have some questions tested by actual and fresh observations by a company of competent men? Page 391.

Getting New Subscribers for the Bee Journal is something that almost any reader can do if he makes a sincere attempt. No one knows better than does he its value to every would-be successful bee-keeper. And we offer valuable premiums, to those of our present readers whose subscriptions are paid in advance, for the work of going out and getting new subscriptions. Your neighbor bee-keepers perhaps have never heard of the American Bee Journal, although it is now in its 47th year. Why not try to get them to subscribe? You may be surprised how readily they will do so upon your invitation.

The "Old Reliable" as seen through New and Unreliable Glasses,  
By E. E. HASTY, Sta. B. Rural, Toledo, Ohio.

#### THE DEER-MOUSE AS A HONEY-EATER.

I have a live deer-mouse. He's a beautiful fellow, fawn-colored above and pure white below. His eyes are large, dark, shining and projecting, like they were beads set on his head. He's a peach. Likewise he is (at least my specimen is) surprisingly tame, or audacious, or something, for a creature with no previous contact with human beings. Did not even scamper a little when first let out of the trap. Walked to a cracker and smelt of it; walked to the water-fount and took a long, hearty drink of it; took a little turn around the limits of his quarters; and then got to business by beginning to eat. From the first hour he would let me almost poke him with my finger before he would move away. And 48 hours later, in response to one of my finger pokes, he bit me—but not sharply enough to hurt much. Deer-mice mostly keep to the fields; but this one was caught in the house upstairs. They are one-half larger than house-mice—14 drams—while the normal weight of the house-mouse is 9 drams. But though larger, mine, so far, seems not so ravenous to eat as the little chaps.

Well, this is the fellow I accused of eating the honey of out-apiaries, and getting it laid off on the house-mice.

Wishing to have his normal performance, before any pampering or other influence from captivity, I gave him honey the first night, a partly-built section, mostly empty comb, but some honey on one side, all sealed. My theory seemed to get a backset at first. He nibbled most of the dry comb into powder, and in the process started the honey to running somewhat; but it lay on the bottom of the big can which served as cage. To the best of my observation he had not eaten any of it. Possibly I was slightly in error there; but that's what I decided at the time. In this experiment I gave no other food; but he had been eating all the cracker he wanted just before. During the next day he ate some honey, and some more the next night. Then I put in a piece of bread and an ordinary section of honey, which has been his regimen ever since. Soon came to eat more honey than bread. For the last 2 days I can't see as he has taken any off his piece of bread—getting to an exclusive honey-diet, 'pears like. Weighing the section as accurately as I can, I find he has taken 12 drams 16 grains in 5 days, or 2 drams 14 grains per day. That's over one-seventh of his own weight. It will do—although a long way behind the eating exploits of the house-mice when they let loose once.

**Report of the Connecticut Convention**

The 16th annual convention of the Connecticut Bee-Keepers' Association was held in the Capitol at Hartford, April 6, 1907. That the Association has grown during the past year was evidenced by the fact that the room in which the meetings have been held for more than 15 years was too small on this occasion, and an adjournment was taken to the Supreme Court room.

Officers for the ensuing year were elected as follows: Allen Latham, of Norwich, President; Rev. D. D. Marsh, of West Hartford, Vice-President; and J. Arthur Smith, of Hartford, Secretary and Treasurer. Executive Committee, Edwin D. Barton, Stephen J. Griffen, and George W. Smith.

Dr. E. F. Phillips, of Washington, D. C., spoke in the morning concerning American and European foul brood, and referred to the enormous losses caused throughout the United States, and some of the good work done by inspectors. He said that either disease can be handled easily if one knows how to do it; that if you teach a man and treat the disease you don't have to visit him again.

In the afternoon he took for his subject the inspector, and stated that the bee-disease inspectors throughout the country are doing fine work; that they are reliable, hard-working and a much maligned class. A high tribute was paid to Charles Stewart, of New York State, as an inspector, whose tact in handling bee-keepers is remarkable. A. G. Edmondson was referred to as one who knows bee-diseases, who makes no mistake in a diagnosis, and who, when sued, has taken honey into court to prove that the disease actually existed. Dr. Phillips said it is harder to handle the bee-keeper than the disease, and although there is no opposition from honest bee-keepers, yet it is necessary that the inspector have a strong law back of him; that although there is only one case in 500 that the inspector has to call in his power as a police officer, nevertheless he should be given a weapon that is strong.

Dr. Phillips strongly favors legislation, and said that if Connecticut gets a law passed, and the right man for an inspector, all will be right. He believes that the honey industry has decreased in the State in the last 25 years because of the prevalence of foul brood.

On May 2 the Committee on Agriculture of the Connecticut Legislature reported favorably on the Foul Brood Bill. It is hoped that it will finally become a law.

Dr. E. H. Jenkins, of the Connecticut Agricultural Experiment Station, New Haven, was present and extended a cordial invitation to the Association to hold a meeting at the Station. It was voted to accept the invitation, and a field-meeting is to be held there the coming summer.

A list of questions was taken up for discussion, which had been suggested by members.

The question, "What is the best outfit and methods for a beginner," was answered by Mr. Latham, "A hive of bees, a smoker, spunk, brains and time."

The best way to teach the box-hive bee-keeper to use a frame-hive was, "Let him alone."

The question as to why bees stop gathering nectar and build drone-comb received two answers: "Bees build drone-comb when the honey-flow ceases and the wax supply doesn't." "Sometimes bees build drone-comb for no apparent reason."

No one present had experimented with Caucasian bees except Dr. Phillips. He said that they hardly proved themselves equal to the Italians and Carniolans, yet they capped their honey all right. Since they had been under observation they had not exhibited swarming tendencies, but might later on. Their extreme gentleness was emphasized.

The bee-moth was discussed, and Mr. Latham said he thought it was present in all colonies, strong and weak, but that the former kept it in subjection. Mr. Griffen believed that there were none in his hives. The method of placing a moth-infected colony over a strong colony, which would rid the former of moths and grubs, was advocated.

It was the opinion of Henry L. Jeffrey that alsike clover yields poor honey.

The best way of feeding in the fall was said to be the Townsend method, which Mr. Latham explained.

The question as to the best method of producing wax annually without sacrifice of the honey crop, seemed to be best answered by the remark that every bit of wax should be carefully saved. One member said that in that way he was able to make all his own comb foundation.

The question of stimulating bees in the spring by feeding, led Dr. Phillips to say that honey from any locality where disease is known to exist should not be fed.

To prevent honey granulation the rule was given to heat to 140 degrees.

E. D. Barton said that snow should

be cleaned away from the entrance of the hive in 5 weeks.

It was the general verdict that bees had wintered well under all methods.  
J. ARTHUR SMITH, Sec.

**Report of the Chicago-Northwestern Bee-Keepers' Association, held in Chicago, Wednesday and Thursday, Dec. 5 and 6, 1906**

(Continued from page 468.)

**CHARGING DIFFERENT PRICES FOR SAME KIND OF HONEY.**

"Is it policy to charge different prices to different parties for honey that is alike?"

Mr. Hutchinson—Same quality of honey?

Mr. Meredith—The meaning of the question is this: Is it policy to sell honey of the same kind to 3 different parties, charging one say 10 cents, another 12 and another 15. I asked that question for the reason that I found there were some customers that concluded that they wanted honey that cost more than a shilling a pound, because somebody else had honey that was selling for 15 cents a pound while my price might have been 13 or 14 cents. I asked if it was policy to sell honey in that way.

Pres. York—That reminds me of something I heard about an Evanston family—you have all heard of Evanston, I suppose! They discharged their cook because she did not run up big enough grocery bills. Their neighbors spent a good deal more money on their table than she had been doing, so they discharged her—to keep the grocery bills up to the same height as their neighbors. They thought they ought to pay more. Some people think that unless they pay a large price they are not getting a good article. They feel better when they pay more. I don't think that applies to bee-keepers, though!

Mr. Taylor—It might turn out to be a bad policy, if they found out it was the same honey.

Mr. Moore—I have sold honey for 20 years. I think it is really an individual matter in which the customer is not very much interested. The customer wants to buy fine honey, and he wants to pay the price agreed upon; but you, as an honest man, must treat them all alike. You may sell the same grade of honey at different prices. A man who buys one pound pays 25 cents. A man who buys a 60-pound can—you will make more money by selling at a lower figure; and a man who buys a ton, you will make money by selling at a still lower figure. The only thing that grieves me in my honey-trade—mostly a family trade—is that the millionaires can not be charged enough so that they will feel that they are getting something. I would like to see the poor man that has to look after the pennies charged the small price; but I would like to charge the millionaires enough to make them feel they were getting something good.

Mr. Baldrige—I have sold some honey, but I never had but one price to white or black, rich or poor.

# American Bee Journal

Mr. Moore—Wholesale or retail?

Mr. Baldridge—Retail. I never had but one price in my existence, and I do not see the necessity of having more than one price.

Mr. Arnd—In selling honey, I think, in order to protect the people that re-sell it—to the private trade you ought to charge more than you do to a man who expects to sell it again. I charge two prices for honey, and I charge three prices for honey—to the man that buys in large quantities by the ton; to the man that buys a few cans at a time, to the man that buys it to eat on his own table. To the man that buys it for his own table I sell at such a price that another man could buy honey of me and sell it to that same man at the same price I sell, and yet make money.

Mr. Wilcox—My trade is a wholesale trade. We sell none to families nor to jobbers to sell again to groceries, of any consequence. I have one price for everybody, and if the prices change I charge each man the same thing; even though they may have agreed upon a higher price, I give them the same price that I charge others; and I know from several years' experience that it will be best in the long run to do so. They will sooner or later discover it, if you are charging them more than you are charging others, and it will surely injure you in the end. It is not fair, it is not honest, it is not good policy—and that is the question—to have different prices for customers of the same class, for the same class and kind of honey.

Mr. Moore—That is the point.

Mr. Wilcox—But, of course, there is one trifling exception. If you have a customer that you are a little in doubt about, whether he will ever pay or not, you can charge him a little more, and perhaps he will go somewhere else.

Mr. Arnd—That remark of Mr. Wilcox's is, I think, well put. He says "the class." Now the man who buys a gallon of honey to eat on his own table ought to pay more than Mr. Wilcox or any other bee-keeper that wants several cases; and in order to protect the man who buys the honey and sells it again, we have to charge the retail man more.

Mr. Wilcox—The difference is, you class the customer and I class the honey. I spoke of the same class of honey.

Pres. York—While we are on that question, here is one that touches it a little bit: "Should not the bee-keeper be compelled to guarantee to the broker or buyer that his honey will stand the pure food law test?" How many think he ought to be compelled to guarantee it raise your hands. None. All who think the producer ought to be compelled to guarantee. About 15. It looks as if we all did, who care to vote.

Mr. Taylor—The question in my mind is, What good would it do if they guaranteed it?

Mr. Wilcox—In Minnesota they are forbidden to sell it without it is marked as the producer's honey, and that is a guarantee without anything more on it.

Mr. Thompson—This question I believe was discussed here once before, as

to what constituted honey that would stand the pure-food law test. That is the question I had in mind—how the producer is going to be able to guarantee his honey other than that it is gathered from natural sources. If honey-dew brings it into the class where it could not be guaranteed, how is he at all times going to be able to guarantee his honey?

Mr. Taylor—He guarantees it and runs the risk.

Mr. Meredith—I would like to have Mr. France give us some suggestion in regard to how to tell honey when it is pure, or any other information on that subject that he can give.

Mr. France—That is part of the constitution of the National Association; one of the planks in the platform is to prosecute adulterators of honey. I began investigating that side of our platform, and I found that honey varies greatly in different localities; it varied greatly in the same locality, according to the conditions in which it was gathered. Then I began to try chemistry to know where to get a basis to work on. I am sorry we have not yet attained satisfaction in that line. I went down to the Eastern States to see the chemists at the time of the United States Chemist Bureau meeting, as to the definition of honey. They were going to throw out entirely all forms of honey-dew, and it was on my pleading that that part was put therein. I can imagine a bee-keeper might be honest in the belief that he was selling a good grade of clover honey, and it would not all of it stand up to the test, the way they were giving it. So the definition has been modified. The only thing I know that we can do at the present time under the new food law, which will go into effect January 1st, is to keep our bees as near as we can where they will store the sweet that they get from the field; and if we find that they are gathering honey-dew, save it by itself and sell it for what it is. We will have to do the grading more than any one else. If we know our bees are gathering honey-dew, let it go as honey-dew, and sell it as such. There are always people in my locality who want to buy poor or cheap or dark grades of honey. They like to buy the "lasses" for the children, while they have something better for the older folks. They will buy honey-dew if you tell them what it is; but sell it for what it is. Then as a help to our National Association members, especially, how can we then protect ourselves under this point which Mr. Arnd brings up? When I send him honey, he, as a dealer, has to put up a guarantee to sell my honey. How is he going to be safe in his guarantee? He ought to have a right to fall back upon the producer, and the producer simply guarantees it as the product of the bee. When they go beyond that as to proof that it is from flowers, I question if we have anything yet that is satisfactory; chemistry is weak on that point.

A Member—Do the chemists know it?

Mr. France—Yes, sir; the chemists are aware that they are weak on the point of a positive proof of strictly pure honey from the nectar of flowers

or exudation of plants gathered and stored by the bee.

Mr. Meredith—What is the definition of the word "honey-dew" from a bee-keeper's standpoint?

Mr. France—As a bee-keeper understands it, it will be the exudation of insects gathered by and stored by the bee in the combs. Some one was speaking about the little white aphids upon the soft maple. We found a good deal of that in Wisconsin, in the last 2 or 3 years. The little white aphid is destroying the maple-tree. The bees are working upon the leaves, and it was in places, too, where clover was coming in enormously, and it was in many places mixed in the extracted honey. We can not separate it, but must sell it for what it is.

Dr. Miller—Mr. President, will you read the question again?

Pres. York—"Should not the bee-keeper be compelled to guarantee to the broker or buyer that his honey will stand the pure-food law test?"

Dr. Miller—I suppose that depends upon circumstances. In some cases the buyer would require it. If I were a buyer and wanted the bee-keeper to stand back of me, I would expect him to do it. In some cases I do not think I would want it. For instance, here is a dealer that wants to put out honey under his own brand, and he receives his honey, puts it up in packages himself. He can not keep the bee-keeper's guarantee upon the packages, but the bee-keeper's guarantee can stay on a package that comes from that bee-keeper only, and when that seal is broken his guarantee does not amount to anything upon it. If the dealer wants to sell it with that original guarantee on it, then he would want the bee-keeper to guarantee it. The thing, you see, will be complicated; but I think I can see that there might be some advantage in that, too. There is the disadvantage of the objection the dealer would make to it. He would say, "I want to sell my honey—I don't want any other man's name upon it, because I want the advantage of all the reputation I get from it." On the other hand, there might be this advantage. There are people who would buy honey more readily with the guarantee of the bee-keeper upon it, just because they knew who the bee-keeper was that it came from. Then, again, there are others that would buy from the dealer because they would know the dealer, and would depend upon him. So you see the thing has a good many different bearings. I would say, in answer to that question, that any honest bee-keeper would be willing to guarantee his honey. He might guarantee it to the dealer, even if the dealer chose to break it up and put it in packages of his own. I do not believe that I would ever sell honey to any man that I would not guarantee was all right.

Mr. Arnd—I asked that question, so that a dealer could trace back, and if he is "held up" he can go back to the next man, if he buys it from a dealer, and so on to the bee-keeper.

Mr. Abbott—I would like to say that the producer could not ship it unless he

guaranteed it to the railroad, under the interstate commerce law.

Mr. Arnd—As being pure honey?

Mr. Abbott—Yes.

Dr. Bohrer—I voted in favor of requiring the bee-keeper to guarantee the purity of the honey. I will do that, and I have now ordered labels, and as long as the package upon which I place the label is unbroken, I will guarantee it to be absolutely pure as the bees stored it in the combs; but if the dealer that purchases it from me breaks that package and repacks it, I won't agree to be responsible any farther.

Mr. Moore—I have been making quite a number of calls on the grocery trade, and in every grocery I am met by the question, "How do you know this is

pure?" And it was suggested here that we voluntarily offer to guarantee our honey. That is good business sense. You must not wait until they come with a club and make trouble for you, but you must meet them more than half way about these matters. For my own special trade I have gotten this up; at the top is my heading, you see: "I hereby guarantee my honey to be pure at all times, in all sized packages, and to comply with all new and old pure food laws." I sign this and hand it to my customers, saying, "There is your guarantee," and it satisfies every one. In the absence of anything better, I shall continue to use that, and I am inclined to think that it covers the ground.

Continued next week

disturbed at all, and you can now take from it 2 frames of mostly sealed brood and give to colony No. 1. If it has any more brood to spare you can give a frame apiece to as many nuclei as you can; but don't reduce No. 1 nor No. 2 at any time to less than 4 frames of brood. You see you must keep them fairly strong all the time, drawing from them as you can to strengthen the nuclei. Indeed it may be best not to take more than the 2 frames from No. 2 to give to No. 1, for in a little while you will want to treat No. 2 just as you did No. 1, making it queenless and starting more nuclei. If the season is good enough and long enough, some of your nuclei will become strong enough to yield help to the later nuclei, and just how far you can go will depend on circumstances. But don't make the mistake of trying to go too fast and then being caught in the fall with a lot of weaklings that will die in winter.

### Italianizing—Working for Increase

Having made up my mind to get rid of my hybrid bees, I have bought 3 Italian queens.

1. Can I, by having 3 pure queens, increase my 3 hybrid colonies, and at the same time have all pure stock next fall?

2. If possible, I would like to increase to 10. What are some of your plans? I don't care if I do not get much surplus honey this season. I am more for increase. MICHIGAN.

ANSWERS.—1. When we say "all pure stock," that means that the queens are not only of pure descent but purely mated. So if there are any but pure drones for some distance from you, you can not be sure of "all pure stock," for although you may make sure that all your young queens are of pure descent, you can not make sure that they are purely mated.

2. If I understand correctly, you want to increase the 3 to 10 colonies. If the season is sufficiently good and also sufficiently long there ought to be no trouble in doing that. The easiest way will be to let each colony swarm naturally, putting the swarm on a new stand and leaving the old colony without being disturbed on the old stand. In something like 8 days, each old colony may send out a second swarm, and a day or two later a third swarm. Even if only one colony sends out a third swarm, that will make 10.

3. If you do not wish to trust to their swarming enough, you can take the matter into your own hands. A week after the first swarm has issued, divide each old colony into 2 or 3 parts, making sure that each has a good queen-cell centrally located.

### Feeding Pollen Substitutes in Empty Combs

I have just begun to overhaul my bees to note their condition, etc.; have examined, this afternoon (April 22), 19 colonies, and while but few need feeding, I do not find a single cell of pollen in any of the hives, nor a single cell of brood in any stage of development; in fact, I have not discovered an egg in all my search so far. Now, I have thought it might be a good plan to take dry combs which I have, sprinkle rye or other flour in the cells, and hang them in the hives next to those of honey. What do you think of the plan? Would it be better to put it outside where the bees could get it for themselves? WISCONSIN.

ANSWER.—It would be a nice thing if you could have what the Germans call "stamp-honey"—combs of honey and bee-bread all smashed up. If any of your neighbors had colonies die in the winter, you might get from them combs containing pollen; although conditions that brought about such a remarkably unusual thing as colonies utterly without pollen may have left theirs in the same condition. Unless there is no weather for bees to fly, better give the meal outside, although it will do no harm to try it inside at the same

### Tested and Untested Queens— 2-Frame Nucleus

1. What is a tested queen?  
2. What is an untested queen?  
3. What is a 2 frame nucleus? If I were to buy a 2-frame nucleus, how many swarms could I get in one season from it?

INDIANA.

ANSWERS.—1. A tested queen is one which has been laying more than 3 weeks, and whose worker progeny all show 3 yellow bands; thus showing that she is purely mated. Since the days of 5-banders this test is not so reliable as it formerly was, for it is possible now to have 3 yellow bands with some black blood.

2. An untested queen is one which has not been laying long enough to show the character of its progeny.

3. A 2-frame nucleus is nothing more nor less than 2 frames of brood and bees taken from any colony and put into a separate hive. It may do no more than to build up into a full colony for winter without any increase; or it may make 2, 3, or more, according to the season and the management. Left to itself in a poor season it might hardly hold its own. In a good season, something depending upon how early the nucleus is obtained, it may make the increase mentioned. In a poor season feeding may help out, but no feeding is quite so good as a heavy flow from the flowers.

### Management for Increase

I am a beginner in the bee-business. Last year I came into possession of about 25 colonies of bees, and about 17 more hives and bee-fixtures. The hives are 8-frame, made in our local "Novelty Works." I have lost all but 5 colonies since I set them out this spring, and will probably lose all but 2. These 2 seem to be strong and all right. These bees had never been cared for, so the comb in the brood-chamber is built in every shape. I want to cut out the old comb, put any new swarms on straight foundation, and attend to

them as they ought to be attended to. How shall I handle these 2 colonies to get the most increase? Of course it will be almost impossible to remove the frames without tearing the combs all to pieces. The bees are Italians.

IOWA.

ANSWER.—It is not an easy thing to say just what will be the best way for you to increase, as what is best for one may not be always best for another. In the first place, don't condemn too hastily all those old combs, even if at first sight they do not appear usable. Every old comb you can save will help just so much in increasing, as it will save the bees work. Take a saw and cut down at each side of a hive, so as to sever all attachments, then turn the hive upside down and jar out its entire contents. Now see if there are not some combs that are straight enough to be used, the same being of good worker-comb. If they are a little dirty or mouldy, the bees can clean them up; only you should brush off the dead bees. If a comb is nearly all in one frame, cut away its attachment to the next frame, straighten it into place, and fasten it in place with strings or otherwise. The comb should be quite warm when this is done, so it will not break instead of bending. If some combs are too much out of place, perhaps running straight across the frames, of course they must be cut out; but some of them may be fastened in frames after they are cut out.

In making increase, the most rapid way will be to start nuclei, giving to each nucleus a laying queen that you will buy. If you want to save the expense of buying, you may still like the nucleus plan. You will lose rather than gain by beginning too early. Wait till the colonies build up strong; then from one of them take the queen with 2 frames of brood and adhering bees, and put in another hive as a nucleus. In 8 or 10 days put this nucleus with the old queen back on the old stand, and out of the old colony make as many 2-frame nuclei as you can, putting one of them in the place from which you have just taken the old queen. Of course each nucleus must have at least one good cell centrally located where it will be in no danger of being chilled. Colony No. 2 you have not

time. A paste of flour and honey smeared on the combs might be worth trying. For outside meal-feeding ground corn and oats is sometimes used here. Most likely it will make little difference whether you feed any substitute for pollen or not, for the receipt of your letter finds dandelions opening here, and they are likely the same with you.

It is just possible that your lack of pollen may be an advantage in the long run. During the dreadful weather in April, your bees remained quietly doing nothing for 3 weeks or more, while others with brood were suffering.

### L Super and T-Super

1. On page 337, you quote me as saying "Langstroth" super. Please note that I never used the expression "Langstroth super" in my correspondence with you, but I said the "L" super. Now, I do not know what the letter L stands for, but I had reference to a certain kind of super designated as the "L super" in the catalog, which is a plain super for an 8-frame hive with slats and fences running crosswise of the super-body and designated to hold 30 plain sections 4x5x1 $\frac{3}{8}$ , called "Danzenbaker sections." Your answers to my questions seem to be very clear, but I can not tell how it will pan out with me until I try it. Some 2 or 3 points look sticky to me yet.

2. First, in regard to that bee-glue. I have cleaned sections at all times of the year; in fact, I never did clean my whole crop at one sitting, but just cleaned up small batches as I would sell them all through the winter, and I have yet to find the time when the propolis won't stick more or less, and more or less honey stand on the wood in the way to gum up my knife and make a messy job at best.

3. Second, in regard to pushing out the whole superful of sections at once. I have done it with the L super, also with the Ideal and Danzenbaker, but I never could see where I gained anything by it, because when I went taking off the slats and taking out the fences I had an awful time of it just the same. In fact, I rather appreciated having them back in the super to hold a portion of them steady while I pried another portion loose, and that is just the reason I adopted the plan of taking them out while on the hive and among the bees. When the super is first tilted and the bees are still in it, the glue is warm and soft, and the sections will come out one row at a time without so much difficulty, and then the fences are all separated and out of the way. Perhaps if I had the T-super I would find the case different; but I can hardly believe the bee-glue would be any less abundant or sticky. I think I will try a few this summer. MISSOURI.

ANSWERS.—1. Upon first reading your letter, throwing upon my shoulders the burden of having changed "L super" to "Langstroth super," I promptly prepared to make an abject apology, but on turning to page 337, I found that in my answers I had made use of neither term, so I slid the burden off my shoulders to let it fall on those of the Editor, "the intelligent compositor," or the printer's devil, whichever one it was who took liberties with your copy. In pity for the delinquent in the case, however, I may say that it is a very common thing to find, in manuscript sent in, the contraction "L" used for "Langstroth," and after having for a few hundred times changed "L hive" to "Langstroth hive," and "L frame" to "Langstroth frame," one would almost unconsciously change "L super" to "Langstroth super."—[We had entirely forgotten the "L" super, as it was never used extensively. Dr. Miller was not the culprit in this case. It was—THE EDITOR.]

2. There may be some peculiarity about your bee-glue with which I have no acquaintance, but I was under the impression that all bee-glue becomes brittle when sufficiently cold. I wonder if it can really be that your bee-glue is entirely different from mine when the thermometer stands at zero. With re-

gard to honey standing on the wood, that is not a matter affected in the same way by cold. When there is any honey on the top-bars of the sections, we don't attempt to scrape the glue off until the honey is removed. First a knife is slipped under the honey to scrape it off, if there is enough honey to make it worth while, and a wet rag removes the rest.

3. Of course, the kind of super makes no difference in the character of the glue, but the kind of super has much to do with the matter of cleaning a whole superful of sections at a time. At least it has "in this locality."

### Having a Fine Honey-Flow.

I have 11 colonies of bees in 10-frame hives. We have a fine honey-flow now from blackberry and white clover. Our principal flow is from sourwood, which blooms in July. G. F. JONES.  
Elkin, N. C., May 24.

### Tough Weather for Bees.

We are having tough weather for bees. They have been getting out about one day in a week, on an average, since March. We are still hopeful and look for better weather ere long. F. A. SNELL.  
Milledgeville, Ill., May 25.

### First Honey "Chunk Honey."

I took my first honey of the season today. I sell in buckets—chunk honey. It is a much better way than to be fussing with sections. More honey, more money, more rest. J. H. COLLINS.  
Bardwell, Ky., May 23.

### Cold and Backward Spring.

The American Bee Journal is "just fine," and I believe it is the only bee-paper issued in this country which is not biased in favor of the supply dealers. The article by Allen Latham on hive-making I consider valuable to any bee-keeper who feels inclined to make his own hives. I have tried a number of them and find them much superior to any single-walled hive I can buy or make, even when protected in the spring; and for comb honey, when the outside case is used to protect the supers, they are *par excellence* in this cold northern country. Unless the honey-flow is late this year there will be but a very light honey crop in this locality, as the unusual cold and backward spring has caused much spring dwindling, and there are but few colonies in this neighborhood which can be brought to a first-class condition in time for the white clover. My apiary consists of 31 colonies this spring, in fair condition, considering the season. N. P. ANDERSON.  
Minneapolis, Minn., May 18.

### Sowing Alsike Clover.

MR. O. P. MILLER: In the American Bee Journal of April 18 you say alsike clover may be sown in the spring with small grain. I have never seen any of it, but I want to try a little this spring. I know nothing about it, and your statement seems to indicate that it is an annual, needing to be sown every spring. Will you please tell me if that is so? If not, does it bloom the first year, and how long does the plant live? How do you spread the seed and what time is best to sow it?  
Monument, Colo. O. H. WHITTIER.

MR. O. H. WHITTIER: Alsike clover does not need to be sown (in this country) every spring; on the contrary, one sowing will do indefinitely. But the plant dies every other year, but seeds itself; in other words, it

blooms the first year. Sown about Aug. 1, from that until fall, then the next year it makes a seed crop, and the seed is on the first crop, and enough of the seed falls off to reseed the ground. The old plant dies in the fall after growing the second crop, but comes on the next spring without missing a crop.

Alsike does the best on damp, moist land, but will grow a good crop on clay land, or, in fact, any land but land that is real sandy. The seed is about half the size of the red clover seed, and can be sowed either by hand or with a seeder drill.

Another fact I have learned this year is, that while all the red clover is dead this spring the alsike sown last year looks fine, although it has been very dry and cold all spring. And with all these facts before us, it seems to me to be the most desirable clover to sow.

Any further questions will be cheerfully answered. O. P. MILLER.  
Menlo, Iowa, May 14.

### Heavy With Honey and Bees.

I never took bees out of winter quarters in better condition. They are heavy with honey and booming with bees. I expected them to be swarming by this time. I thought they had more honey than necessary, but they have it pretty well used up. I had some 40 or 50 pounds of brood-combs kept over from last year, and some extracted from unsealed combs, which I have fed them. Owing to the late cold and dry weather the future is an unsolved problem. J. C. ARMSTRONG.  
Marshalltown, Iowa, May 11.

### Early Swarm—Feeding Bees.

We had a swarm on May 9. It was a small swarm with a virgin queen, resulting from superseding. We have been feeding sugar liberally since the warm weather in March. A good rain came day before yesterday, for which we are thankful. There is a little honey-dew on box-elder this morning. J. L. STRONG.  
Clarinda, Iowa, May 23.

### Honey Famine in the Southeast.

We are having a honey famine in the Southeast, and bees are on the point of starvation. The blooms have come and gone, and no honey; and many barrels of sugar have been fed. Many bee-keepers are disheartened and will pull up and leave or quit the industry. The honey-plants were in bloom about 60 days. My bees got to them part of 2 days, and are now in winter quarters. J. J. WILDER.  
Crisp Co., Ga., May 14.

### Freezing Temperature — Fruit-Bloom Damaged.

As I write this morning the mercury in the thermometer stands at 25 degrees, about 4 feet above the surface of the ground on a hill. On the low ground it is 8 to 10 degrees colder. It is a surprise to me that the few blooms on the fruit trees seem to be filled with nectar, and the bees are carrying loads of it when the temperature is moderate enough for them to fly. The apple-bloom is just beginning to open, but I am afraid that last night damaged the opening buds seriously. No prospect of its warming up to-day. E. H. URSON.  
Cromwell, Ind., May 11.

### Solving the Swarming Question.

R. C. Aikin writes on page 374: "It has always been my contention that the apiarist must be the master to the extent of controlling swarming, and making increase, when he was ready: that those who allow natural swarming are always at a disadvantage."

Yes, this gentleman speaks out loudly and clearly his contention that the apiarist must be master to control swarming, etc. And yet we are at a disadvantage. Yes, but that problem must be solved, and can be, if we look at the bee as one creation in the animal kingdom, and not idealize it, but look at it just in its reality; just as

## Do You Like to be Stung?

What's the use wearing an old style net bee-veil that blows in your eyes, sticks to your face, and gives the bees a chance to hand you a hot one?

### The Muth Ideal Bee-Veil

(75 cents, postpaid)

keeps the bees at a distance because it is made of light indestructible wire and strong cloth. You can see through this wire as if it wasn't there; and you can smoke inside the veil all you want. It can't catch fire.

If you buy the has-been kind of veils

### You Certainly ARE "Stung!"

You get dollars of satisfaction out of it. No doubt about this—it's the best-ever veil on the market.

an animal with its own notions and tricks, and able to make its master work, run and sweat, only to be fooled and outwitted after all. At a disadvantage—yes, that's so. But the writer thinks it is not absolutely necessary but that this little creature can be domesticated just as well by man as the rest of the animal kingdom. But how, is the question that we are asked. I may not be ready yet to give an answer, but wait until I can do it in a practical, sure and safe way.  
P. J. ECKMAN.  
Butterfield, Minn.

### Discouraging Spring for Bees.

This has been a cold, hard spring for bees. May 20 we had a very hard frost for this time of year. In the morning there was a thick crust of ice on water, with a cold, piercing wind. To-day is cold and rainy. There have been very few days this spring that bees could gather pollen. This will undoubtedly prove a serious setback to bees when they should be building up rapidly. Yesterday I found a choice queen in a hive with a few scattered bees, possibly a dozen or two. The queen was wandering alone in a corner. There were plenty of stores. It is a sad condition that sort of makes a bee-keeper feel helpless. Other colonies have dwindled to a nucleus condition. Of course, colonies that were strong this spring with plenty of stores are all right. On these our hopes rely, and we hope for a better day with more favorable "elements." (A bee-keeper must always live in brighter hopes.) The cold weather this spring has rendered a bee-keeper helpless and at the mercy of the elements, as it has been too cold to open hives, and partly rendered work among the bees impossible thus far.  
H. H. MOE.  
Woodford, Wis., May 22.

### Fine Prospect for Honey.

I have 275 colonies of bees, and can not do without the American Bee Journal. There is a fine prospect for honey this year.  
W. J. DAVINSON.  
Diouba, Cal., April 25.

"It is continuous advertising that impresses the public with the stability of a firm."

are made every year in the book business. Every family, rich or poor, must have books. During the last few years, \$7,500,000.00 have been expended for Modern Eloquence, \$12,000,000.00 for Stoddard's Lectures, \$21,000,000.00 for the Century Dictionary, and the tremendous sum of \$4,000,000.00, covering over half a million sets of the Encyclopaedia Britannica. These books were sold by subscription in American homes and sales are still going on.

We have a subscription publication which sells more readily than any of the above. The demand is already so tremendous that more capital is required to swing it, or get behind on orders. Profits are enormous, several times savings bank interest.

We have arranged a plan whereby

**Any Progressive Man or Woman Can Share These Profits**

becoming stockholders in a profitable business, based on twenty years' experience. Remember, the success of this publication is not away off in the future—it is not prospective, but it is a success at the present time and growing in demand every hour. Sales of this publication at the time of publishing this advertisement

**Often Exceed \$2000 a Day**

This is an exceptional opportunity for those of small means to get in on the ground floor in a business which legitimately pays large dividends and is as solid as the Rock of Gibraltar. It cannot be held open for long as the response is certain to be so great that we shall have all the capital we need to increase the number of our presses and secure stock to be turned out in completed books, which are selling like wildfire.

You owe it to yourself to investigate this opportunity. You will never have a chance like this again to become

**Part Owner in a Mammoth Publishing House**

which is already in successful operation, already earning big dividends, and which is led to sell a small amount of its stock simply because the business is already so tremendous as to exhaust the working capital. But if you would grasp this opportunity you must

# BE GOOD TO YOUR BEES

Suppose a man should build a house for you with low roofs, so low you would have to stoop to walk around, the stairs steep and rickety, the windows small, the doors so narrow you could not walk through them without being squeezed, bumps and bruises right and left, nothing fitting, nothing right. WOULD YOU LIVE IN A HOUSE LIKE THAT? Well, I guess not.

And yet some bee-keepers expect their bees to do good work in hives that are made wrongly at the outset, constructed of poor material with incorrect bee-spaces, the lumber rough, encouraging comb-building and propolizing. What do the bees do under such circumstances? Why, they do the next best thing which is to set about to make over the hive—just what you would do in the case of the poorly constructed house. They try to correct the human mistakes made in the building of the hive. The men who have constructed the hive have made a botch of it, and the bees instinctively try to improve upon their work. Bees cannot make hives and honey, too. Lewis hives are made scientifically right from the time the first board is planed until the last nail is driven. Give your bees Lewis hives made of good, clean, smooth lumber, the parts fitting like a watch, every bee-space just right. This insures returns, real returns for your money invested in bee-goods.

Thousands of Lewis Hives, Millions of Lewis Sections now on hand in the warehouses of the Lewis Company and their distributing houses as given below.

**A GREAT IMPROVEMENT**

Will be found in

The  
**American Bee- Keeper  
for 1907**

It is profusely illustrated and enlarged, and contains only articles of the most practical as well as scientific nature. A special corps of the best writers has been engaged. The editors are Harry E. Hill and Arthur C. Miller, than whom there are no more practical or experienced bee-keepers in this country. We have published the American Bee-Keeper continually and regularly since 1890.

Regular subscription price, 50 cents a year. One year to new subscribers, 35 cents; three years for \$1.00.

Send for sample copy and our new illustrated price-list of **BEE-SUPPLIES OF ALL KINDS.**

Guaranteed highest quality at lowest price. Address,

**THE W. T. FALCONER MFG. CO.**  
Dept. B. JAMESTOWN, N. Y.

[Established 25 years.]

Mention Bee Journal when writing.

**Honey and  
Beeswax**

CHICAGO, May 9.—Very little honey on the market of any kind. Prices are therefore nominal. A little choice white clover comb sold at 17c, and would bring that at present, but supply seems to be exhausted; even with this scarcity there is no demand for No. 2 grades. Extracted, white, 7@8c; amber, 6@7c. Beeswax in good demand at 32c. R. A. BURNETT & Co.

CINCINNATI, May 23.—There is no material change in the honey market at this writing. Extracted honey is not moving so rapidly as it could, owing to the cool weather. We quote amber in barrels at 5½@6¼c; fancy table honey in crates of two 60-pound cans at 8@9c. For choice, yellow beeswax, free from dirt, we are paying 31c cash, delivered here.  
THE FRED W. MUTH CO.

PHILADELPHIA, May 25.—The honey market has been quite brisk for this time of the year. The continued cold weather has made both the comb and extracted honey sell much higher than usual. A number of odd lots have been cleaned out of the market. We quote: Fancy comb, 14@15c; No. 1, 13@14c; amber, 12@13c. Fancy white extracted, 7@8c; light amber, 6@7c. Beeswax firm at 32c.

We are producers of honey and do not handle on commission. WM. A. SELSER.

NEW YORK, May 21.—White comb honey is practically cleaned up, and there is very little demand at this time. There is some dark and mixed comb on the market, but no demand to speak of, and some of this will have to be carried over until next season, or sold at a sacrifice. Therefore we cannot encourage shipments of off-grades or dark honey at this time. Extracted honey is in fair demand and prices are ruling firm. There is very little new crop arriving as yet from the South, and while it is rather early, we doubt whether we will have any large shipments from the Southern States this season, as we fear there will be a short crop, judging from the reports we are receiving. There is quite a good stock of last year's crop still on the market, sufficient to last until the new crop from various states arrives. There is no change in price as to extracted honey since our last. Beeswax firm and likely to remain so for the next 2 months.  
HILDKRETH & SEGELKEN.

**Headquarters for Bee-Supplies**

For prices, refer to my catalog, page 29.

**C. H. W. WEBER** CINCINNATI OHIO

Office and Salesrooms, 2146-48 Central Ave. Warehouses, Freeman and Central Aves.

INDIANAPOLIS, April 12.—comb honey is not plentiful, but demand is slack. Fancy white comb brings 16@17c; No. 1 white, 14c; amber, 12@13c. Best grades of extracted honey bring 8@9c; amber, 6@7c. Good average beeswax sells here at \$35 per 100 pounds.  
WALTER S. POWDER.

TOLEDO, May 3.—There is very little demand for comb honey as is usually the case at this season of the year. Fancy white would bring in a retail way 16@17c; No. 1, 15@16c, with no demand for dark honey. Extracted is very scarce and none being offered for sale. Beeswax is bringing 28c.  
THE GRIGGS BROS. & NICHOLS CO.

KANSAS CITY, May 4.—Receipts of comb and extracted honey are light; in fact, the market is almost bare. The demand for comb honey is good, but for extracted is rather light. We quote: No. 1 white comb, 24 sections, \$3.25; No. 2, \$2.75; No. 2 amber, \$2.50 to \$2.75. Extracted, white, 8@9c; amber, 7@8c. Beeswax, 50c.  
C. C. CLEMONS & Co.

DENVER, Feb. 14.—Producers in this State are practically closed out of both comb and extracted honey. We have not sufficient good comb honey to supply our local trade, but have a good supply of white extracted of excellent quality. We quote strictly No. 1 white comb honey, per case of 24 sections, at \$3.20; No. 1, light amber, \$3; and good No. 2, \$2.80. White extracted, 8@8½c per pound; light amber, 7½@8c. Clean, yellow beeswax, 27@28c, delivered here.  
THE COLO. HONEY-PRODUCERS' ASSN.

CINCINNATI, May 21.—The market on fancy white comb honey is entirely bare. No. 2 is selling slowly at 12c. Extracted, light amber, brings 5½@6c. Beeswax is selling here at \$35 per 100 pounds.  
C. H. W. WEBER.

# BEE SWAX

We are always in the market to buy Beeswax, and pay the highest market prices. We want Beeswax from the bee-keepers direct.

## DADANT'S FOUNDATION

### IT EXCELS

Wherever you are you can get our goods. Write us and we will either make you prices or will tell you where you can get our Foundation nearer to you. We have Agents everywhere.

## BEE = SUPPLIES

We handle every kind of Bee-Keepers' Supplies, and only the **very best**. Write us before selling your Beeswax or buying your season's Supplies. Send for our Catalog.

**DADANT & SONS, Hamilton, Ill.**

# Marshfield Bee-Goods

talk for themselves; having bought once, you will buy again. Our orders show that. The reason for this is that nothing is used in the making of our BEE-GOODS that we know is not fit to go in. Why should we when we have plenty of the best as it comes direct from the forest to our mill and factory.

**SECTIONS** are made of the basswood timber, grown here in the basswood belt of Wisconsin.

**DOVETAILED HIVES**, of lumber almost clear, made accurate and smooth.

**SHIPPING-CASES**, strong and neat—nothing flimsy about them.

### SHIPPING FACILITIES THE BEST

You will get your orders sent on very short time, as we are located on three direct railroads to Chicago there connecting with the trunk lines for the East, South, and Southwest, and some parts of the West. The West by way of St. Paul and Minneapolis.

If you have not yet received our Catalog of BEE-SUPPLIES for 1907, just write for it.

MINNEAPOLIS, MINN.

Mention Bee Journal when writing.

## HOW TO PAINT

Buggies, farm wagons, farming tools, barns, outbuildings and houses often need painting. "Everybody's Paint Book," written by a thoroughly practical painter, will be found a complete guide to the art of outdoor and indoor painting. It is designed for the special use of those who wish to do their own painting. It gives practical lessons in plain painting, varnishing, polishing, staining, paper hanging, kalsomining, etc.

It also tells how to renovate furniture and gives many hints on artistic work for decorating a home. Precise directions are given for mixing paints for all purposes.

If farming tools and farm vehicles are kept painted, they will last twice as long, and anybody can do the work with the aid of this book. It is handsomely and substantially bound in cloth. A copy will be sent postage prepaid on receipt of price, **\$1.00**

### SPECIAL OFFERS

For \$1.60 we will send the above book and the Weekly American Bee Journal one year; or for \$1.40 we will send the Paint book and a Standard-Bred Untested Italian Queen. Address **GEORGE W. YORK & CO., 118 W. Jackson Blvd., Chicago, Ill.**

## Dittmer's Gomb Foundation

Why do thousands of bee-keepers prefer it to other makes?  
Because the bees like it best and accept it more readily.

## Queen-Clipping Device Free!

The **MONETTE** Queen-Clipping Device is a fine thing for use in catching and clipping Queens' wings. It is used by many beekeepers. Full printed directions sent with each one. We mail it for 25 cents; or will send it FREE as a premium for sending us One New subscriber to the Bee Journal for a year at \$1.00; or for \$1.10 we will mail the Bee Journal one year and the Clipping Device. Address,  
**GEORGE W. YORK & CO.,**  
CHICAGO, ILL.

"If goods are wanted quick, send to Poudier."

Established 1889

# When the Shipment Arrives

By the Bee-Crank

When your goods come to hand and you open them up and find the things that you wanted most are missing, and in their place a nice letter from the dealer, telling you that they "will follow soon," what can you do? Wait until they come. It is only a small matter, of course, but it is the small things that get on the nerves.

I make a specialty of not only prompt shipments, but complete ones. I keep the goods ahead, and it is a very rare thing indeed when I am not able to ship an order in full the day it is received. And it is very carefully packed to eliminate possibility of damage in transit.

A bee-keeper is not very much impressed with

points of this kind, until he has had some experience with the other kind of service, and then they cut a lot of ice.

These goods are never out of stock—Hoffman's Frames, Danzenbaker Hives, Dovetailed Hives, Section Honey-Boxes, Weed-Process Comb Foundation, Honey and Wax Extractors, Bee Veils, Poudier's Honey-Jars and a full line of Root's goods at Root prices. Send for free catalog telling all about them.

**Beeswax Wanted.**—The best market price paid on all shipments sent to me. Send by freight if large, and express if small package, and attach your name and address.

**Walter S. Poudier** 513-515 Massachusetts Avenue  
INDIANAPOLIS, INDIANA

## The A. I. Root Company, Medina, Ohio

### ROOT OBSERVATION HIVE

In recent years there has been an ever-increasing interest in bees as a subject for nature study in the schools, and a corresponding demand for observation hives to facilitate the study of bees at work, without exposing the student directly to them, as is necessary with ordinary hives. To meet this demand we offer several styles and sizes of observation hives. These are made with skeleton frame, with glass in sides and ends of the brood-chamber, and in sides only of the super. Shutters are provided to cover the glass. These shutters have brass rings to handle them by and brass buttons to hold them in place. Brass hooks are also provided to hold the several sections of the hive together. The hives are finished in the natural wood, oiled and varnished, and altogether they are very attractive in appearance. We furnish them regularly in 8-frame, Langstroth depth. The super is fitted for the 4x5x1 $\frac{3}{8}$  plain section. Hives are usually furnished put together and finished. We can supply material in the flat, but it is work for a cabinet-maker who understands his business to put them up, and we do not care to furnish them in flat unless you order one complete as a model.

The bottom is no longer than the hive, and a covered extension is provided to lead the bees out-doors under the window-sash or other opening provided. In the full-sized hive a colony of bees can be kept by a window the year round, or for only a part of the season, as may be desired. The work of the hive, including the building of comb in the sections, can be watched at intervals without opening the hive or disturbing the bees.

*Observation Hive Inside a Room with Entrance under the Raised Sash.*

For work in the school-room before a class we recommend the one-frame hive. With the one-frame observation hive it is necessary to remove the frame of bees and put in a fresh one about once a week at least, for the best results. As a rule, arrangements may be made with a local bee-keeper to provide a frame of bees each Monday morning, returning at end of week.

We make one-frame observation hives for L. frames or for Danz. frames and a row of sections above, or the L. frame with a row of sections above. These are provided with a wood case to slip over to shut out the light when you are not watching the bees. We show this one-frame hive and the case in accompanying illustration. This consists of turned-wood corners with glass inserted in grooves in ends as well as the sides.

*Observation Hive with Panels Removed.*

### PRICE-LIST OF OBSERVATION HIVES

Observation Hive (8-frame), complete with super, including frames, sections, glass—and bees with queen .....	\$15.00
Observation Hive (8-frame), complete with super, including frames, sections, glass—no bees .....	7.50
Observation Hive (8-frame), without frames .....	7.00
“ Super “ complete, with sections .....	2.50
“ Hive “ without super .....	5.00
“ Brood-chamber, complete, with frames—no cover or bottom .....	3.75
Observation brood-chamber without frames .....	3.25
One-frame Observation Hive for Danz. frame, no super, with case .....	2.50
One-frame Observation Hive for Hoffman L. frames, no super, with case .....	2.50
One-frame Observation Hive for Danz. frames, with super, with case .....	3.00
One-frame Observation Hive for Hoffman L. frames, with super, with case .....	3.00

(For bees and queen in one-frame hive, add \$3.00.)

## Miscellaneous News - Items

**Mr. J. L. Byer**, of Mount Joy, Ont., has been appointed Inspector for the district east of Toronto as far as Belleville and north, including Peterboro and Victoria counties. The other inspectors for Ontario are as follows:

Wm. McEvoy, of Woodburn; Jacob Alpaugh, of Dobbinton; James Armstrong, of Cheapside; H. G. Sibbald, of Claude; and M. B. Holmes, of Athens.

We congratulate Mr. Byer upon his new position, and also the bee-keepers in his district upon the appointment of so capable a bee-keeper to inspect their apiaries.

**Darwin's Nationality.**—We have received the following referring to the nationality of Charles Darwin:

MR. EDITOR:—On page 430, Burton N. Gates says that Charles Darwin's volume on the earthworm "is a noble example of the German spirit in American research." Does that mean that Darwin was an American?  
E. J.

It is not safe to say exactly what may have been meant, but at any rate Charles Darwin was an Englishman.

**A Traitor to Bee-Keepers.**—We have received a communication from Mr. Jas. A. Stone, Secretary of the Illinois State Bee-Keepers' Association, and also a member of that Association's Legislative Committee. It seems that a discovery was made while attempting to secure the passage of certain Bills in the interest of bee-keepers, and the following tells about it:

**BEE-KEEPERS, TAKE WARNING!**

What shall we name him when we find a "traitor in the camp of Israel?" For what can we call him but a traitor to bee-keepers, when he has done his very best to prevent legislation in their favor? He says in quite

a lengthy letter to the chairman of the committee in the Senate—before whom our Foul Brood Bill was to pass—that he is "the largest bee-keeper in the State of Illinois," and he "does not want a foul brood law." He "can see after his bees himself." Also says, "It is a combine that are asking for the law, that will permit them to burn a man's beehives so they can sell him more," etc.

When the Foul Brood Bill was to come before the Agricultural Committee in the Senate, the committees representing the Illinois State Bee-Keepers' Association were there. When the Bill was read before the Senate Committee, and the chairman allowed our members to be heard, he said: "We will postpone action on this Bill one week, till this committee has heard a letter from a bee-keeper, that I have at the hotel."

That afternoon we had an opportunity to read the letter. We surprised the senator who held the letter, by telling him the author of it before he named him to us.

That evening we sent out a few letters to our friends, telling them the condition, and how anxious some of the Senate were to hear from them, and it resulted as follows:

One week from that day we were at the Senate again, with a stenographer in readiness to get a verbatim copy of that letter.

When we told the chairman of the Senate Committee we wanted to be present at its meeting, he answered, "We can not meet today; but that letter will not be read, and we will report your Bill out favorably."

We heard no more from that letter either in the Senate or House. The Bill passed the Senate, but was defeated in the House on its passage; the same old objection—"Don't like to create a new office."

The warning, we think, ought to be given to bee-keepers in this: Be careful what you buy of a bee-keeper who is afraid of the foul-brood law as we offered it in the last session of the Legislature (see page 17 of our 6th Annual Report.)

"No rogue e'er felt the halter draw,  
With good opinion of the law."

We have mentioned no names, but any member of our Legislative Committee, or of the committee to draft our Bills, can name this party if asked to do so. But our advice

is to treat him as the Legislature learned to do, viz.: As an adulterator who did not want a law that prevented him from selling his goods.

JAS. A. STONE,  
Sec. Ill. State Bee-Keepers' Association,  
and one of the Legislative Committee.

We thought at first that we might make an extended comment on the foregoing, but perhaps it is unnecessary, as Mr. Stone has made it very plain. It is almost unthinkable that there could be, in the ranks of bee-keepers, one who would do what the "traitor" did, to whom Mr. Stone refers. Surely, he should be denied membership in any bee-keepers' organization, for he has clearly shown that he is not in sympathy with the objects of such organization, but, on the contrary, is an enemy.

We suppose Mr. Traitor *thinks* he has succeeded in preventing legislation, but his day of reckoning will certainly come. In fact, it seems that already some people are "getting onto him" as an "adulterator." Such have been discovered before, among bee-keepers, and then their "days were numbered" as bee-keepers.

It is to be hoped that at the next session of the Illinois Legislature bee-keepers may get all they ask for, and thus be in line with those of other States where needed laws are being enacted to prevent the spread of disease among bees.

**Worcester Co., Mass., Association.**—

There are in Massachusetts two bee-keeper's associations, of which the Worcester County Association claims the lead in activity. It is the older of the two, and has an active membership of nearly 100. The meetings are held once in each winter month, on the second Saturday, in Horticultural Hall. All proceedings are open to the public and are largely in the interest of the general welfare. Once each year, they hold, with the State Board of Agriculture, an Institute and all-day session—an occasion of the gathering from over New England of the prominent bee-keepers. The Institute for this year was held in February as reported on another page of this issue.

Membership of the Association is not limited to those of Worcester County nor the State, but any one interested in New England is eligible to membership. One fee, 50 cents,

# American Bee Journal

paid at the time of joining is all that has been required of all who have joined thus far. This low fee maintains the high standard through the courtesy of the Worcester County Horticultural Society, to whom is due many a thank for the free and unconditional use of their building. If interested, and you desire to join this society, to insure that you are kept posted on all matters apicultural in that section of the country—to insure getting all notices, and to have the benefits of a progressive group of bee-men—write to the Secretary, Mr. Arthur H. Estabrook, care Clark University, Worcester, Mass.

The meeting held last September, in the above-mentioned hall, was a 3 days' "Bee-Show"—an exclusively bee-keepers' affair, not for the benefit of the supply-men nor for the honey-market controllers, but a purely educational show, for the direct edification of the public and the producer—the source and the demand. It was a success; it drew the attention of the best bee-keepers and those interested in progression, from all parts of the country. Another will be held next fall. All interested can gain information through the press or direct from the Secretary. They are anxious to reach all interested in the Association and its aims. If you wish to become a member, or if you want the announcements, notify the Secretary. It is believed that the Association can help you to promote yourself. Ask what they can do for you.

The following are brief sketches of the officers of the Association:

## PRES. BURTON N. GATES.

Mr. Gates was born and brought up in Worcester, Mass., and went through the public schools there, entering Cornell, Class of 1905. Left Cornell to enter Clark University, from which he graduated in 1905 with degree of A.B., taking in 1906 his degree of M.A. During the past year he has been an assistant teacher in biology in Clark University.

He has kept bees for some 17 years, keeping them more for study and the pleasure of working with them than for pecuniary profit.

Mr. Gates is of a modest, kindly nature, and enjoys the blessings of a delightful home in a pleasant part of Worcester. He is an indefatigable worker, and since he is a young man we can confidently look for important work along apianian lines from him in years to come.

## 1ST VICE-PRESIDENT F. H. DRAKE.

Mr. F. H. Drake, President for the year of 1905, and Vice-President the succeeding years, is one of the progressive members of the Society. Mr. Drake lives in a good honey-country—East Brookfield—where he produces an A No. 1 quality of comb honey. The demand is greater than the product of his apiary of from 25 to 30 colonies.

Mr. Drake writes that he first became interested in bees from the time he saw a row of box-hives in a neighbor's yard when a boy. In 1900 he traded a home-made hive for a swarm, from which he made immediate increase. The lowest average of 23 pounds per colony in a poor year is more than outweighed by the best average of 86 pounds per colony. These figures are an indication of the possibilities in Massachusetts.

Mr. Drake is profiting by some of the things recommended in the meetings of the Association, which he says is the source of the latest and best information in bee-keeping. For instance, he was one of the earliest to recognize the advantage of the black-paper method of wintering bees. While the bee-keeping on the Drake farm is but a side factor in the big business, the owner finds that it pays both from the bee-keeper's standpoint, and from the market gardener's standpoint. Bees are

infinitely valuable, yea, quite indispensable to the fruit-producer and to the cucumber man, we all know. The combination is most profitable.

## 2D VICE-PRESIDENT CHAS. H. GOODELL.

Mr. Goodell is one of the oldest bee-keepers of the Association, and has had bees since a boy. His purpose has not been to keep bees for the profit as much as for the things which he can learn; he has therefore been an experimenter and investigator, has tried the various races of bees as they have been imported, has examined the new theories and inventions as they have appeared, and has given freely to the Association the things which he has learned. He cannot be without a colony or two of bees, although he has tried it at times.

The older readers of the bee-press will remember the writings of Mr. Goodell, which appeared in the years previous to 1890.

Besides being one of the charter members of the Worcester County Bee-keepers' Association, and its first president, Mr. Goodell has been president in succeeding years. On several occasions he has read papers before the Association. At the last institute meeting his subject was on the "Relations of Flowers and Bees."

At present Mr. Goodell has at his home a number of fine colonies of choice bees. He is prominent in the City Council, was secretary to the late Senator Hoar, and has been a member of Congressional Committees. He is a member of the Bar.

## SECRETARY A. H. ESTABROOK.

Arthur H. Estabrook, the Secretary and

Treasurer of the Association, is one of the newer of the bee-keepers, but is an ardent student of biology. For several years he has been connected with Clark University; he graduated in 1905 with the first class from the Collegiate Department; in 1906 he took his degree of M.A. from the University, in Biology, and is now working for the degree of Doctor of Philosophy.

Mr. Estabrook lives in Leicester, where the pasturage is similar to that of Mr. Drake's country, before mentioned. It is Mr. E.'s intention this summer to carry on some investigations on bees, which, if significant, will be published. He has just published a paper on "The English Sparrow Problem, and its Status in America."

**Northern California Bee-Keepers** will meet in convention in Sacramento, on June 24. The organization was formed in January, and a 2 days' convention held. We received no report of it, hence no mention was made in the American Bee Journal.

Mr. B. B. Hogaboom, of Elk Grove, Sacramento Co., Calif., is the Secretary of the Northern California Association. Any other information desired by bee-keepers in that section of the State can be had by addressing Mr. Hogaboom.

We would be pleased if convention secretaries would send us not only notices of future meetings, but also at least brief reports of conventions held.

Conducted by EMMA M. WILSON, Marengo, Ill.

## A Successful Sister

Massachusetts sisters are probably proud of one of their number of whom it is reported in the American Bee-Keeper:

Mrs. Richardson, secretary of the Massachusetts Society of Bee-Keepers, told of her trials in getting a start in apiculture, and gave her hearers frequent occasion for merriment. Her remarks were the more entertaining in that she had surmounted the difficulties and has made a financial success of bee-keeping.

## An Original Swarm-Shaker

MY DEAR MISS WILSON:—Since you so kindly invited me to come again, here I am, and I have spent much time the past months reading the back numbers of both the American Bee Journal and Gleanings. I found lots of good things in both, but the controversy over "shook swarms" amused me, for I feel that I have the honor to be the original "shook swarmer" or "swarm shaker." Of course, those men haven't followed my method exactly, or adopted my way, but still I feel that the honor belongs right here. You see, I used to be terribly afraid of bees—no wonder when a "dead" bee fixed me the way it did. But that is another story. And so when papa left me in full charge of his api-

ary one day, with careful instructions how to proceed in case of a swarm, I just hoped and prayed that those bees would behave themselves.

In order to discourage any swarming ideas, I attached the hose and gave the hives a good wetting. Then I decided to bake a cake. So after a delay in deciding what kind to make, I started in and was putting it in the pan when I heard the awfullest roar; and glancing through the window I saw the air full of bees. They were swarming all right. Well, I shoved that cake into the oven and shut the door. Say, it was a devil cake, and really I felt devilish right then, for I was half scared to death at the prospect of plenty of stings. But it couldn't be helped; I was in for it.

So I went out and looked for the bees. There they were, nicely clustered in a little plum tree about 7 feet from the ground. There must have been a bushel. So I put on a hat and veil, lit the smoker, got the hive and an old sheet ready, put on rubber gloves, and I was ready. No I wasn't, either, for how was I to keep those bees from crawling up my, my sh—well, my hose? I gave up that problem, for the bees were getting restless, so I carried out the sheet and spread it under the tree. Buzz in my ear, and I ran for the house. Then I carried out the hive and set it under the cluster. "Buzz" said a bee, and away I flew. Again mustering my courage, I went back and arranged the frames and hive nicely, but I had to fly again—that awful buzz made me nervous.

Now about 6 feet from the tree where the

# American Bee Journal

swarm clustered was another low, bushy tree—a dandy place to hide from an angry bee, because you could bury yourself in the green branches. So I got our long-handled rake, and hiding myself in this bushy tree, I reached over until I could hook the rake over the limb where the bees clustered, then I shook, and down went the bees kerflop, right in front of the hive. I shook a few more times for luck, then dislodging the rake I tapped the hive gently with it. After a while they all crawled in and made themselves at home. That was my first attempt to hive bees, and after explaining my method to papa, he said it certainly should be successful, and he guessed they would be willing to stay almost anywhere after that bump. Seems to me my efforts are not appreciated as they might be, here at home. Of course, I don't hive that way any more, but don't you think I was one of the very first shakers?

St. Clair Co., Ill. SISTER ESPERANZA.

Yes, you certainly are a "shaker," or, perhaps, to use the more fashionable form of the word, a "shooker." Let us hope that the time occupied in "shaking" or "shooking" did not result in too dark complexion for that case.

## Our British Expert Sisters

In 1906 there were in England 128 examinations for experts' certificates, and we are told in the British Bee Journal the 87 successful candidates were principally ladies. The British lady bee-keepers seem to be getting the start of their Yankee sisters.

## Lessons from Losses of Bees

I have been comparing notes with a few fellow bee-keepers in my own State and elsewhere, and when I find how others have fared, my own loss—20 percent which includes the dead, the queenless, and the very weak colonies—seems small in comparison.

I have had 2 reports from Lincoln, Nebr., which show heavy loss. One is from an extensive bee-keeper who handles pure Italians only. He reports a loss of two-thirds of all colonies. My own loss was mostly amongst the Italians. Carniolans and Carni-Italians are without doubt better able to withstand severe conditions.

A party writing from Kansas City reports the loss of all but 2 out of 9, and these 2 are weak. So it goes.

One of my correspondents is in the northeast part of the country. He is not a small bee-keeper, having more than 500 colonies of different kinds of bees in separate yards. He says: "Fifty percent of the golden Italians are dead, and the balance are weak; 25 percent of the leather-colored Italians are in the same condition; 10 percent of the Carniolans are weak, but the rest are all right."

I see the A. I. Root Co. also testify to the greater hardiness of the dark races of bees. Practical honey-pro-

ducers will draw their own conclusions and act accordingly.

I have quite a variety of hives in my bee-yard, and I did not find that bees in small or medium-sized hives came out worse than those in the big ones. Some of the lost colonies were in large hives, with abundance of honey. Per contra: I wintered a few colonies on 5-inch frames with candy cakes on top, and there was *no loss* amongst these, although I had removed the remains of the candy and given frames early in April, which I surely would not have done if I had foreseen such a "spell of weather" as we were to have through April and much of May. Therefore one lesson for me is to be *very slow about changing the winter arrangement for that of summer*. I had supposed that lesson learned.

As to forage for the bees, there has been very little here so far. Fruit-bloom was a failure. Much of it was "nipped in the bud," and did not open at all. There are very few dandelions here. The first real support the bees are to have is likely to be yellow sweet clover, which is a little behind time, but is looking nice since the heavy rains we have had for the last week. A few of the earliest blossoms are likely to open within a week.

I am going to feed the bees some and "bide my time," with good courage.

(MRS.) A. L. AMOS.

Comstock, Nebr., June 1.

## Cleaning Sections of Honey in a Warm Climate

On page 337, "Missouri" asks a number of questions on the subject of cleaning sections. No. 9 is a serious one with some of us, and as Dr. Miller answers it only by telling him to clean in cold weather, which is not always feasible, may I give him another answer through your column?

A damp cloth is not much good as it smears the knife. I always keep a little pot of lard on the table, and slightly grease my fingers and knives before I begin to clean; this keeps the propolis from sticking badly. Then I always use 2 knives—a butcher-knife with a curved point to clean the sections, and a common kitchen-knife to clean this knife with. A sharp stroke will clean the propolis from the greased knife much more easily than a cloth.

For taking off honey that has run out, I always use a cloth and cold water, as Dr. Miller does.

MISS COLORADO.

Many thanks for your experience. Truth is, what is especially needed is such experiences in warmer latitudes where cold weather can not always be had to order. (In this locality we can always have weather so cool that propolis will be brittle, if we wait for it.) I have used the butcher-knife with the case-knife to clean it, but much prefer the cabinet scraper, as it takes hold so much better than a knife will, and does so much better work. Just try for yourself and see if you don't find it better.

It must be admitted, however, that my experience is in weather when the propolis is generally brittle. If very warm, it might not be so easy to clean off the scraper.

It might be well to caution those who use grease on the fingers to use it *very sparingly* else the wood of the sections may be marred by grease-spots.

BY W. A. PRYAL, Alden Station, Oakland, Calif.

## New Use for the Auto-Bike

I was out to see my friend Otto Byke the other day. He was in the back yard overhauling what he called his "flying-dutchman." I asked him where he was going, and he replied, "Down south."

"And going to take that auto-bike with you?" I ventured to question him.

"No, not exactly; it will take me."

"And what do you expect to do down there?"

"Well, Bill Beeman has asked me to come down and run his honey-extractor this season. I have planned to harness the auto-bike gas-engine to the extractor, and between us we shall have a sweet old time making the honey fly."

"You don't say!" And I wondered if some other fellow would steal his idea and get it patented.

## Bee-Glue

Bees must be insane at times. Just look at the crazy manner in which

they will daub the inside of their hive all up with nasty, sticky propolis. If the stuff were used intelligently, I would not mind it a bit. But when it comes to shoving the dauby article in hunks in unnecessary places on hive and frames, I simply give up and pronounce the bees "crazy." And there is so much of it. May be it is my location; perhaps the poor little pets get it stuck to their feet and use the inside portions of the hive as a door-mat to wipe it off. But the trouble of getting the propolis off one's hands—that's what *slicks* me: the nasty, sticky stuff! I've pulled, and I've scraped, and perspired; the gum has flown in my eyes, got into my pockets; I breathed it all day and dreamed of it by night, as the odor of it haunted my wakeful as well as my sleeping hours. And it has smeared my hands so that it would not come off even when I tried grease, oil and soap of fine and coarse degree. My hands are not beauties. 'tis too true, but, then, who wants to go to a select affair in the social line with hands stained and daubed with a disagreeable yellow? Why, people would think

# American Bee Journal

that—but never mind what they might think I got on them.

There is a big blessing coming to the man who will discover an infallible and quick propolis-eradicator. Perhaps it might be better to produce a strain of bees that have not the propolis-instinct as a predominant feature.

## Commercial Letter-Writers

I received two bee-papers to-day; they are good papers and true. One was Gleanings in Bee-Culture; the other the "Old Reliable." I could not help observing letters reproduced from the files of the business or honey department of the A. I. Root Co. that were printed in the former paper; and all about honey that seemed to have mysteriously changed its character while being shipped between two points. Queer, but rather uninteresting to the average reader. The other paper had a lot more about honey—a lengthy correspondence from honey-merchants. This batch was interesting to all. And there are others, too, in both the reading and advertising columns. But I was going to state that these two numbers would make a good "Ready Letter-Writer" to give to the children as models of business letters.

## The Hoffman Frames

I like the Hoffman frames very well, especially when I am able to manipulate them once or more during the year, but woe is he who has to tackle a lot of them in hives that have not been opened for several years! The amount of good, "healthy" propolis the bees will pile on and about these frames is a caution. I have recently been using some of these frames that have the "square" edge, and I like them much better than I do when one edge is beveled—that is, when one edge on each side of a frame is so made. At first I believed that when the flat or square edges would come together, the bees would be needlessly killed. I now find that one does not have to be much more careful in handling these frames than when he is manipulating the other kind. But I have been thinking, will we always use the Hoffman frame? I rather think not. Like lots of other things introduced into our apiaries in times gone by, we came to discard them in the end, for good and sufficient reasons.

I am just in receipt of a letter from Mr. R. M. Spencer, Ventura County (this State), wherein he says that he is transferring his combs from the Hoffman frames into plain frames of his own. More than this he saith not. Still, per contra, last week I heard of a bee-keeper up the Sacramento river who ordered 3000 of these frames from a San Francisco bee-ware house. I wonder if he, too, will be discarding them, after a while.

**"It is continuous advertising that impresses the public with the stability of a firm"**

## SWARMING IN FRANCE AND HERE.

The carefully observed and collated facts about swarming which Adrian Getaz copies from the French ought to be of decided interest. Different flavor, for one thing, from what we get this side. Several years and a number of apiaries drawn on. When our folks can get around to do the like, it will be in order to note how things in France differ from things in our country. Meantime we can make luminous guesses about our conditions and compare conjecture with fact. For part of the work I have records which will parallel theirs—if it were not so great a task to collate them. Have just run over my first 3 years as to the dates of swarms. Both earlier and later than theirs, and, of course, more days in the swarming period. Their extremes are from May 17 to July 4, or 49 days for the swarming period. My extremes (taking in only 1880, 1881 and 1882) are from May 12 to Sept. 5, or 117 days—much more than twice as long, not to mention their *average* duration of only 24 days. My commencement for 1881 was not normal, as I was dividing, for needed increase, everything I thought would bear dividing. But after a bit the bees struck in and would swarm some notwithstanding the dividing. Collating 1880 and 1882 together, I had 3 swarms in May, 120 in June, 126 in July, 38 in August, and 1 in September. Total, 288. Number of colonies was 56 the former year and 68 the latter. Some of my later years have been much less swarmy than these. Collating the whole great mass would reduce the proportion of August swarms. Also, if a number of other apiaries were collated with mine, the joint result would be less swarms per hundred colonies, I take it.

Only for the year 1900 and since have I marked down the time of day. Was moved thereto by what seemed to me to be the absurdity of things I saw in print about it. Sometimes the time of day didn't get put down. Sometimes a cluster is found hanging, and no one knows how long ago it came out. But I have the records of a sufficiently jolly big lot spread over 7 years. The total is 666. Queer that it should be just the number of the Beast in Revelation, but that is what it footed up. Considering our extreme climate, we might expect swarms both earlier in the day and later in the day than in France, and so it is. In the French records 8:15 a.m. is the earliest. In my records I have one at 5:05 a.m., and 2 more before 7. The latest for France

is 4 p.m. My latest is 5:17 p.m.—with a doubt in favor of another colony which was hanging on the front of their hive at 5 p.m., and swarmed un-seen later. Both these extra-late ones were prime swarms. About the 3 extra-early ones it was either unknown or unrecorded whether prime swarms or not. Let us now make way for the table:

Between	5 and 6 a.m.	1
"	6 and 7 "	2
"	7 and 8 "	45
"	8 and 9 "	75
"	9 and 10 "	129
"	10 and 11 "	99
"	11 and 12 m.	76
"	12 and 1 p.m.	81
"	1 and 2 "	63
"	2 and 3 "	45
"	3 and 4 "	36
"	4 and 5 "	12
"	5 and 6 "	2

Total.....666

I think that seeming decline between 11 and 12 is not an eccentricity, but comprehensibly all right; and 76 the true normal for the hour and temperature. All previous figures swollen by colonies that got ready to swarm during the night, and had to postpone till day. Practically all of these would be out at 11 a.m.

The French apiaries had only 5 percent before 10 a.m. Mine had 252, which is 38 percent. They had 22 percent between 10 and 12. I had 175, which is 26 percent. They had 56 percent between 12 and 2 p.m. I had 144, which is only 21½ percent. (This is a very striking divergence between France and the United States. Swarms in the early hours of afternoon are not superlatively plenty with us.) They had 15 percent between 2 and 3 p.m.; I had 45, which is 7 percent. They had 2 percent later than 3 p.m.; I had 50, which is 7½ percent.

Swarms naturally divide themselves into primes, afterwarms, and deserters. Some little differences of time of day would very likely appear if they were tabulated separately; but I think the difference would not be very material.

**Amerikanische Bienenzucht**, by Hans Buschbauer, is a bee-keeper's handbook of 138 pages, which is just what our German friends will want. It is fully illustrated, and neatly bound in cloth. Price, postpaid, \$1.00; or with the American Bee Journal one year—both for \$1.75. Address all orders to this office.

**No. 4.—Uniting Colonies and Forming Nuclei**

BY R. C. AIKIN

I have spoken of a system of management that calls for the uniting of bees, dividing and making of nuclei, and of comb-building, etc. I think it will be well to give some more minute directions as to how these things may be best accomplished.

**UNITING COLONIES.**

Under some conditions to unite strange bees is a very easy thing; under other conditions it is almost impossible without having a general row and many bees killed. During a flow, and when every bee has its sac full, all you have to do is to unite, and it may be done by setting one hive on top of another, by mixing combs or putting them together, so mixed that there can not possibly be any two crowds.

In any process of uniting the presence of robber-bees is one of the worst things that can happen; and, perhaps, the very next worst thing is empty sacs. When a flow is on, and the day is far enough advanced that both fielders and nurses are loaded with nectar, and particularly the old bees and fielders, they can be put together in almost any way that comes handy; but if sacs are not full they should be made to fill, and the less fielding and the more scarce nectar is the more pains should be used to get them all full. If there be but little or no unsealed stores, a good way is to take, say 1 to 3 or 4 tablespoonfuls of honey or sugar and make some sweetened water, thin like fresh nectar, and with this thoroughly sprinkle them.

The directions used to say, put peppermint or something in to scent the bees alike, but that is altogether unnecessary; it is of far more importance to get the sacs full—full bees do not attack anything, neither man nor each other. A podded abdomen can do little in combat; stuffed bees seem to think of nothing but to get to where they can unload, and by the time that is done the odor and acquaintance is completed. I have made thousands of unions when bees were full, and with uniform success. In my early experience I lost many bees and queens because I did not see to the full-sac part of the matter; but when properly filled all went well.

Sprinkling with cold water until they want to cluster close, to get warm, will also make them forget to fight. Exposure to cold wind until they are ready to hunt a warm place is also effective.

Just so sure as you put them together without full sacs, or chilling, or a thorough smoking, there will be almost certain war. Do not forget the matter of robber-bees. If robber-bees are dipping in, the bees that belong there do not know one stranger from another—they tackle any and all.

When uniting two lots of bees, where one hive is to be set on another the work may be done very quickly and safely by putting a wire-cloth between for a day or two, or a cloth with a small hole through which they can unite very slowly, and most of it done after they have become settled after the excitement of handling is over. Outside of a time of nectar-gathering unite late in the day or evening; or, if early, do it when cool or rainy, or at a time they will not fly until they have become settled. When all are well loaded, I unite in any kind of way.

**FORMING NUCLEI.**

When one wants to make a nucleus colony, and get about so many bees in a hive to stay, that is not so easy if the work be done in one yard. Then much depends upon whether a queen or queen-cell be taken with the nucleus. If a cell, it also makes a difference whether it be ripe, or one not so far advanced. A cell that is so far advanced that the queen is moving about in it, and about to proceed to cut out, the bees will stick by it much better than a less-developed one.

Then there is the question of the number of very young bees. Young will stay where old ones will not. I try to select combs with a large number of very young bees on it, and also take the brood that is to be with the nucleus of that well-ripened, and many bees hatching and about to hatch, and then shake in about twice as many bees as desired.

If you have a colony that has young queens just hatching, you have one of the very best conditions for making nuclei; such a colony can be divided into from 4 to 8 if they have much brood and bees. They seem to stay by their hatching queen; but care must be taken to have them remain in the hive until they are aware that they have a queen. Sometimes when put into a new (strange) hive they may rush out before they realize that a queen is with them. They will act very much as a swarm that has been hived without the queen; the knowledge that a queen is with them goes far to making them contented. In this matter full sacs also do much to help.

If you have more than one yard, the making of nuclei is a very easy matter. Suppose you go to an out-yard to work, and can get the bees necessary for the

nuclei and bring them home; if so, here is the best way I have ever found:

Make some little boxes or cages as follows: Out of 1/2 inch or 3/8 stuff cut 2 pieces about 4x8 inches, and one piece 4x4. About 1/4 inch from one end of each of the 4x8 pieces make a saw-kerf about half through the board, using a thin-bladed saw. Nail the 4x8 pieces on the ends of the 4x4, as though you were making a box, but turn the saw-kerfs in and away from the 4x4 end.

Cut 2 pieces of wire-cloth 4 1/2 x 3, and fold over each end so they will be about 7 1/2 inches long; then nail these on the 2 open sides of the box, using thin strips of wood over the wire instead of putting them on with tacks; and put a piece of wood 1/2 x 1 inch, and

NUCLEUS BOX OR CAGE.

as long as the outside measure of the box across each end over the wire-cloth, to stiffen them at the open end, nailing one flush with the ends of the side pieces, and the other dropped down until its upper or outer edge is just even with the inside of the saw-kerfs. With some small tacks, or by putting on a cleat of tin or a strip split from a broken section, nail the wire-cloth snug to the inside of these 2 cross cleats.

You now have a box 4x8 inches, with 2 wooden and 2 wire sides, a wooden end and an open end. Cut a piece of tin just wide enough to slip into the saw-kerfs in the open end of the box, and long enough so that when it is shoved clear through snug against the cleat on the opposite side, it will stick out about a half inch; then roll or bend at right angles this extra half-

inch, which stiffens the tin and gives a finger-hold.

There are other ways of making these cages, but it will pay you to make as directed, except you may vary the size to suit your notion; but do not make it too small, for you may want to put a good many bees in sometimes. You can put a few bees into a big cage, but can not put many into a little one. Then, too, always make 2 sides of wire, and have these opposite, for then you can see what you have inside, and particularly look for a queen.

Another thing, always have that tin slide put in as directed, *full-width* of the cage, made so it is easier to get bees either in or out; they can be scooped up or shaken out. If you have a rim around the end of the box at the opening, and projecting inward, you are at a disadvantage, both going and coming.

It is a wise thing to have some of these cages always on hand and ready for use. When doing regular work occasionally you find a batch of hatching queens, and you may want to save some of them. You may have queens that you wish to save for various reasons, possibly some specially reared. You may be working a colony that can very easily spare a pint or quart of bees and not miss them; just have the cage by you and shove in as many bees as you may wish to take from the colony, and set the cage in the shade or in the sun, if not too hot. In this way, as the day's work progresses, collect bees in the cages, taking them from wherever it suits your notion as you work. A swarm may be divided in this way to populate your cages.

In a few minutes your caged bees, queenless and broodless, will get on the anxious seat. If they have not gone in with full sacs, see that they are made full—every one of them—by giving thin honey or sweet water—fill them full. Now when you find a queen you want to save, just get one of the cages and dump the bees all to the bottom, away from the tin slide; open the slide and drop the queen in. You can make more sure by dipping the queen in honey; this will fix her so she can not run, and so by the time she is licked dry the odor is all right. Do not cuddle the caged bees too much; make them think they are in hard straights, sure; and if cold enough that they want to snuggle up to each other, all the better. This is the slickest way to make nuclei you ever struck. Just take these cages to another yard and hive the contents as you would a little swarm, or dump them right into the hive. I think probably this is about the best way to form nuclei in the same yard; they can be made any time during the day, and hived late in the evening, so they get settled over night and start out in the morning to mark their new home; but the hive should have a board or special marking at the entrance.

As to how many bees to use, that depends upon the time, and what you want to accomplish. If it is just to get a queen mated to be used elsewhere later, a pint to a quart of bees will do it in warm weather. And, too, if you can put into the hive a very little patch of brood it will help to make them con-

tented. I would recommend caging the bees at any time during the day when it is convenient, but hive them just about sundown, or, at least, late in the evening when they will not fly before morning. I have brought home these cages from out-yards and hived them after dark by dumping them in on top of the frames. I have also hived in the morning. It is little trouble, and will rarely fail to succeed, done at any time, if they are gathering nectar freely; but if nectar is scarce, so that they will be bothered by robber-bees, hive only after done flying for the day.

One thing that should always be looked after in hiving bees, whether big or little swarms, is to make them comfortable, and protected from heat and from robbers. And for little swarms or bunches I prefer to give a little brood; a patch of drone is all right, or even a small bit of any kind of brood cut from a comb and grafted into one of their combs. In making small nuclei always give them more or less comb, and also some honey.

If you wish to make small nuclei early in the summer, with a view of their building up during the season to full colonies, they should be given well-nigh a quart of bees, though in favorable seasons a pint will make a full colony by fall. For queens to supply these always have them matured in full or normal colonies, but they can be mated all right in the small colony. Never have these little colonies build cells—they will not get one good queen in 25.

Loveland, Colo.

## Swarming and Section Honey

BY G. M. DOOLITTLE

A correspondent wishes me to tell, in the American Bee Journal, the best plan of working for section honey and allow natural swarming. First, I wish to say that I doubt about natural swarming being the best plan when working for section honey, as I believe that what is known as the "shook" plan of swarming is better for section honey than natural swarming. But it will do no harm to tell the readers of the American Bee Journal how I managed swarming for years, which gave me good results during my former years of bee-keeping. For years I used a plan which seemed to me to give the best results of anything known during the years when honey brought from 20 to 28 cents a pound, which was as follows:

I used every effort to bring all colonies in the apiary up to where they were in readiness for the sections about 15 days before the harvest from white clover was at its height, and, where this is the main dependence for white honey, all swarming should be finished during the next 7 days; and where basswood is the source that gives us our honey-flow, swarming should be done within 10 days before the yield from that source commences.

At that time I did not practise artificial swarming, only so far as it was necessary to have all swarming done in accord with the above. All swarms issuing previous to the 7 days before

the clover bloomed, and 10 days before the basswood, were hived singly in hives containing frames of empty combs, and in 2 or 3 days from the time of hiving the sections were put on. Those issuing during the next 5 days were hived 2 swarms in a hive, where it was possible to do so, and the sections put on at once. Where this could be done, the new swarm was set on the stand occupied by another colony which had not swarmed, and such colony carried to a new stand, thus securing to the new swarm all the field-bees from the colony moved. Each swarm thus hived was given a hive full of empty comb, if I had them, and if not the frames were filled with comb foundation, and the sections put on at once.

From this it will be seen that all of the new swarms were in splendid condition to take advantage of the flow of nectar when it came. Where 2 swarms were put together, the queen belonging to one of the old colonies was put back in her old hive, when the same was moved to a new location, and the double swarm set in its place. The old colony losing its queen by its going with the swarm, was allowed to rear its own queen. Eight days after a swarm with its queen had gone from any hive the same was opened, and having ascertained that a young queen had emerged from a queen-cell, by finding one open at the end, I cut off all the rest, and thus stopped all second or after swarming.

By waiting till the first queen had emerged from her cell, I had a certain thing, when the queen-cells were all off, which is not always the case where all but one queen-cell is cut off from 4 to 6 days after the prime swarm issues, as is so often recommended in our bee-literature.

After the time had arrived when I thought all swarming should be done, I proceeded as follows with all which had not so far swarmed:

A hive was filled with frames of empty comb or foundation, and then placed on the stand of any colony which had not yet swarmed, or had been carried to a new stand as spoken of above, the colony being set close by after the new hive was so placed. All the sections were then taken off and placed on the new hive, when all of the bees were shaken off their combs and out of the old hive in front of the new one, into which they would run as fast as they were shaken down. Thus I had a colony that was ready for business as soon as the harvest commenced, as they had the queen, the bees and the partly-filled sections all in readiness for work. Previous to this nuclei had been formed so that I might have plenty of laying queens to use whenever an occasion might require.

I now took all the combs of brood from which the bees were shaken except one, arranging them in the hive the bees were shaken out of and carried them to the stand of another colony which had not swarmed. Next, I took the frame of brood which was left out and went to one of the nuclei, taking out the frame having the laying queen on it and put the frame of brood in its place. I then took the frame—bees, queen and all—and set it in the

place made vacant for it while arranging the frames of brood. Next I put on the sections, and, having all complete, the colony was moved to a new stand and this prepared hive set in its place. Thus I had a laying queen and enough of her own bees to protect her, together with a hive filled with combs of brood and all the field-bees from the removed colony.

In a few days this colony would be entering the sections, and such generally made fully as good colonies for storing section honey as any I had in the whole apiary. The loss of bees to the removed colony put a stop to all ideas of swarming, and in about a week they had so regained their loss that they were ready to continue work in the sections again.

It will be seen that my aim was, in using these several plans, to get all the colonies strong enough to work in the sections during the best of the harvest to advantage, and still have none of them desire to swarm right in the height of the best flow of nectar. And I doubt if there is a much better way of working for section honey to-day, where the bee-keeper has only his one home yard, and the time to attend to the natural swarms which may issue up to the time he has decided that further swarming will result in a reduced yield of section honey. But where a person is running one or more out-apiaries, then some plan of artificial swarming must be adopted, or loss by swarming will occur.

Borodino, N. Y.

the right view, and, in accordance with that view, I move that the foul brood committee of this society be discharged, with thanks.

The motion was seconded and carried.

It was moved, seconded and carried, that the President appoint a committee of three on resolutions.

Pres. York—I appoint Mr. Hutchinson, Mr. Abbott and Mr. Whitney as a Committee on Resolutions, to report tomorrow.

#### FOUL BROOD.

"If foul brood is not foul brood, then what is it?"

Mr. Taylor—Something else. [Laughter.]

Mr. France—I imagine what conflicts here is the fact that the Department of Agriculture at Washington has come against this proposition. What has been known out here as foul brood is entirely a different disease from that which has been commonly known as black brood in New York State, and those two have conflicted, and the Government has been taking this matter up and decided to call both "foul brood," but to add an adjective to it, so that what is known through our country here largely as foul brood will be called "American foul brood," and the so-called New York black brood will be called "European foul brood." Unless this change was made, the laws now in existence in nearly all the States that we have upon foul brood would have to be modified; we have gone through with hard work enough to get it, and to have to do it over again would mean a good deal. So the Department has arranged it in that way. We have the two distinct diseases. If any of you have not read carefully Bulletin 79 from the Department on "Brood-Diseases"—on both European and American foul brood—I have asked that it be put in this year's Annual Report of the National, where you will have it on file and can read it.

Mr. Moore—That is my question. If foul brood is not foul brood, then what is it? If I can read correctly, it says that the *Bacillus alvei* is not found in foul brood, or American foul brood, to use this nomenclature. If that is true, what becomes of Howard and other scientists who say that the *Bacillus alvei* was the characteristic? We have not heard from them. We have not heard the last word. Have they all been mistaken? and what has become of the American foul brood, or the old-fashioned foul brood, as we know it?

Mr. France—In the demonstrations that Dr. White, from Washington made, there was this marked difference: Our American foul brood would not develop on the same cultures as the European foul brood, showing a decided difference between the two. The New York black brood or European would develop nicely upon beef as a basis, whereas our other will die—make no attempt to live.

Mr. Moore—We have been accustomed to thinking of *Bacillus alvei* as the germ of foul brood. Shall we think of *Bacillus alvei* as the basis of black brood?

A Member—Exactly.

Mr. Moore—What takes the place in

### Report of the Chicago-Northwestern Bee-Keepers' Association, held in Chicago, Wednesday and Thursday, Dec. 5 and 6, 1906

(Continued from page 481)

#### FOUL BROOD LAW.

"Is there a foul brood law framed to send to the legislature this term?"

Pres. York—I suppose that means the Illinois legislature, or it may perhaps mean any other State that has a meeting of the legislature the coming winter.

Mr. Moore—The President of the Illinois State Bee-Keepers' Association, Secretary and the Treasurer, are an executive committee who have charge of this, and they, in conjunction with some of their friends who are in close touch with politicians at Springfield, get up the foul brood law—or the bee-keepers' law, more correctly speaking—and have it introduced by some of their friends in both the House and the Senate. I don't know definitely what has been done.

Pres. York—I don't think that is an answer to the question, Mr. Moore. The question is: Is there a foul brood law now framed to present to the legislature?

Mr. Moore—I do not know of anything being done, but I know that Messrs. Smith, Stone and Becker have attended to it heretofore and probably will attend to it in the future.

Pres. York—The committee of this Association is Mr. Dadant, Mr. Wilcox, and Mr. McCain.

Mr. Wilcox—No member of the committee has said anything to me about it. I have not heard anything about it from any other source, or done anything about it myself, and I rather doubt the propriety, myself, of making any application to the Illinois legislature. I

might join with the Illinois members, but I do not think the legislature of one State is in the habit of listening very much to people from other States, unless concerning some matter in which they are particularly interested.

A Member—You will remember, at the last meeting, we came to the conclusion that this matter better be done by the Illinois State Association, and this committee was appointed to work with them.

Pres. York—I think we ought always to remember that this organization covers a number of States, and that we ought not to help one State more than another represented here. Perhaps hereafter it will not be necessary for us to have a foul brood committee. We decided not to join the Illinois State as a body, and of course all of us will not be members hereafter; but there will be individual members that live in Illinois. So unless this body moves to have a committee appointed, or continues the present foul brood committee, I suppose it will not be continued. Whatever a majority of this Association says, of course, will be done, because we decide things by a majority vote. Now is there anything else on the question?

Mr. Moore—I believe it is best to take some action on the foul brood committee. I think the committee would better make a report and be discharged. I do not think any good can come of its further continuance. I would advocate, however, that as individuals we write letters, every one of us, to the members of the legislature in favor of the law that is introduced, because it is no doubt better to have a half loaf than nothing, and the thousand dollars the legislature gives the bee-keepers in this State will do them good.

Dr. Miller—I believe Mr. Moore has

# American Bee Journal

American foul brood that was occupied by *Bacillus alvei*?

Mr. France—*Bacillus larvae*.

Dr. Miller—I am not sure whether I understand this thing or not. It looks to me a little as if you were mixing two different questions. The first is in regard to European and American foul brood, and then there is another different question in regard to *Bacillus alvei*.

Pres. York—*Bacillus alvei* is the same as the New York black brood or European foul brood—all the same thing.

Dr. Miller—It seems to me I understand that it was decided that *Bacillus alvei* was an entirely innocent party, and had nothing to do with either of them.

Pres. York—I think that is wrong.

Dr. Miller—*Bacillus alvei* is the European foul brood?

Mr. France—Yes.

Pres. York—And *Bacillus larvae* is the American foul brood.

Mr. Moore—I want to press this right home. If in the past all of these scientists have been mistaken, who have held up *Bacillus alvei* as being the germ of foul brood, and we believed them, and then somebody comes along and says we are mistaken, is our authority good enough to make us throw away all we had in the past and say *Bacillus alvei* is not in it at all?

Mr. Taylor—I think there is no doubt that they are right as far as they have gone. The trouble with Howard and those other fellows is that they relied on a single test—I suppose on a microscopic test—and I judge that the two *Bacilli* are alike in appearance; but now these men at the head of our interests in the Government have applied a new test. They have applied the test of different kinds of culture to these microbes, and they find that the beef culture will enable the *Bacillus alvei* to propagate and to increase, while if used with other *Bacilli* they perish, showing conclusively by this new test that they are two different *Bacilli*.

Mr. Kimmey—If I understood what Dr. White and Dr. Phillips were trying to explain to us at the Bee-Inspectors' convention at San Antonio, it was something like this: The European foul brood was examined and they believed that the cause of the disease was the *Bacillus alvei*, and traced it to that. When we got a disease, without making any examination we called that "foul brood." Then another disease sprang up which we called "black brood." Upon making the scientific investigations which these men directed, they failed to find *Bacillus alvei* in our foul brood, but they did find it in black brood, so they came to the conclusion that what we had always called black brood was really the European foul brood. In order not to confuse the names, they then decided to call our foul brood "American foul brood," and the black brood "European foul brood"—the one having the germ *Bacillus alvei*, the European foul brood; and the American foul brood having the *Bacillus larvae*. In order not to rob the European people of their honor of discovering that, they called that the European foul brood

which was formerly our black brood, making two distinct diseases.

Pres. York—Our foul brood they call "American foul brood," but the European foul brood happens to be the same as the black brood they have in New York and a number of other States.

Mr. Kimmey—So we will drop the name "black brood" entirely.

Mr. France—I got quite interested in this subject the past summer, and I asked Dr. Phillips upon his return from California to come to my place. I wanted to investigate this subject of black brood or European foul brood, as I understood it was approaching. I was attending a meeting of some of the inspectors at Milwaukee, and decided to take a train and go to Michigan, where we could find the European foul brood. We had no microscope, but from the appearance of the brood itself—the dead larvæ—it looked decidedly different, so that the naked eye could tell, after once seen, the difference. With the black brood, if there are larvæ at an earlier stage they turn dark, almost black, and flatten right down on the bottom of the cells, whereas the American foul brood becomes a brown, ropy, putrid matter, and lies upon the side of the cell, and becomes stringy in its nature. The European never does that. As for the odor, there was a marked difference again. Our common foul brood has what we call a glue-pot smell, the other had not; not much of any odor, but what there was, as near as I can remember, was more like sour pomace from a cider-mill.

Mr. Kimmey—Allow me to ask Mr. France these questions: Is the American foul brood prevalent in Europe? Do they have the two diseases there?

Mr. France—They have them both.

Mr. Kimmey—What do they call them there, do you know?

Mr. France—As far as I know they call them foul brood. That is why there has been this trouble. We found, by referring to scientific researches in Europe, that they had made scientific cultures of them, and examined them, and got conflicting results, examining one and then another, and were misled by the name.

Dr. Miller—If you will allow me to answer Mr. Kimmey's question, I think they distinguish them as the mild and severe.

Mr. Thompson—I would like to ask if the treatment of both is the same.

Mr. France—Not exactly, although the thorough treatment as has been described, taking away the infected combs, will cure either one.

Dr. Bohrer—Speaking about the odor of the foul brood as we find it in this country, it has been compared to the smell of dissolved glue. I want to say, from my experience, it is that way, only more so.

## INSPECTING APIARIES IN COOK COUNTY.

"Was there a foul brood inspector around this summer to inspect the apiaries of Cook County?"

Mr. Moore—I believe there was not. I acted as foul brood inspector for only one season, and I think Pres. Smith, of the Illinois State Association, is the only one who has acted as in-

spector of apiaries since then; and Mr. Smith has had the work of eight men on his hands to cover this State, so naturally, he could not cover it all. As far as I know, he has not been in Cook County at all.

Mr. Thompson—He was in Kane County.

Pres. York—He generally goes when he is sent for.

Mr. France—There have been sent to me samples of diseased brood and dead brood from almost every State, and there have been some samples from Cook County sent me and some sharp criticisms because I did not say it was foul brood; but it was not.

Pres. York—What was it—pickled brood?

Mr. France—Some of it was. Some was starved brood, and some had indications foreign to all of us as yet.

Mr. Moore—Was there any black brood, Mr. France?

Mr. France—No, sir; but I was surprised to learn from Dr. Phillips that he had found cases of black brood in Illinois, Ohio, Michigan and California. European black brood is spreading.

Pres. York—And of course in the East, besides?

Mr. France—Yes.

Dr. Bohrer—Has Illinois no foul brood law at all?

Pres. York—It has a foul brood law, but not a compulsory law. It is at the option of the bee-keepers whether they will let the inspectors in their apiaries or not.

## DISTANCE OF APIARY FROM HIGHWAY.

"How far should an apiary be from the highway?"

Mr. Meredith—Just far enough not to interfere with the public.

Mr. Taylor—That reminds me of a story. There was a gentleman in England who desired to hire a coachman, and so he advertised for one. He wished any candidates there might be to appear at a certain time. Several appeared and he began to question them, and wanted to know how near they could drive to the edge of a cliff there was upon his estate. The first one said he could drive within a yard of it; another one said he thought he could drive within a foot of it safely; and the next one thought he could drive within an inch of the edge. The last man, an Irishman, said, "Faith and be jabers, I would keep as far away from it as I could."

Dr. Bohrer—There should be a high fence, 6 or 7 feet. I remember having an apiary of about 100 colonies in Indiana, and I had them just over a fence from a public highway and the bees never annoyed people passing on the road, with a fence some 6½ feet high. They would go over that fence and go over the heads of persons in buggies and on horseback; I never knew any one molested.

Mr. Arnd—Mr. Duff, who is here, has 150 colonies right in the city of Chicago. He can probably tell you.

Mr. Duff—I can keep bees within about 10 feet of the street; but I have a 6-foot fence so the bees rise up and go right over.

# American Bee Journal

A Member—My bees are within 50 feet of the sidewalk and I have no complaints. I have only 3 colonies, but I notice they rise very quickly. They are up 10 or 15 feet in the air in 20 feet of flight. The sidewalk is running north and south, and my hives face the east, but the bees go to a marsh straight west from me, and simply make a little curve.

Mr. Moore—I know Mr. Horstmann so well, and I know he won't take any offense when I say he has had some experience. The Health Department ordered him to "get off the earth."

Mr. Horstmann—The bees that the city got after were not at my home apiary; they were in another apiary. They had a little trouble with the family there. I had my bees on a man's lot, and it seems this man and his neighbor had a little trouble, and the only way they could get satisfaction was to get after the bees, so I got notice from the Health Department to move the bees out of there; but I had that all fixed up, and left the bees there until I got ready to put them away. I wrote to Mr. Moore, and I believe I wrote to Mr. France at that time, too, for some literature. I thought I might have to bluff the city, but I didn't have to do that. I had a friend look after it, and we left the bees there until I got ready to put them away. The bees are not dangerous. Where I live I have bees on the corner, and people passing on the sidewalk every day, and they are never molested. The women-folks hang up their clothes and the children play all around the hives, and they hardly ever get stung. It is not so much the distance as it is the kind of bees you have. If I find a cross colony of bees I do away with that queen and get a more gentle strain of bees. I admit that among the bees I had at my out-apiary were some pretty cross ones, and, of course, not being on the place, I did not know where the cross bees came from; but at home I can tell, and pick them out. I think everybody should look after the bees, and then there will be no trouble.

Mr. Taylor—I think we can not be too careful with our bees in this respect. It is not altogether safe to rely upon a high fence. Bees do not always sting intentionally, often unintentionally. I know of one instance. I had started to go down town, and I had some bees some distance back from the highway. The bees flew across the highway to a pasture beyond. I suppose they went high enough when they went away, but when they came back heavily laden it was quite different; and as I was driving down a bee came and touched me on the eye, and of course eyes have a habit of winking in such cases, and the bee stung me. Now it is easily imaginable great damage might be done just from stings received in that way. Bees might get into a horse's mane, or about his eyes, and cause a runaway. You can not be too careful. There is no need of playing with bees and putting them as near the road as we can. We better be like the Irishman and get them as far away as possible.

Mr. Thompson—I had about 75 colonies behind a fence right near the street, as Mr. Duff speaks of, and I want to

ask him if he ever experienced a nervous feeling when he heard a child cry when he was not right on the ground?

Mr. Duff—I never heard them cry.

Mr. Moore—Mr. Pease has had charge of an apiary opposite a public school in Ravenswood, and I have heard people say that their families are being stung to death by those bees!

Mr. Pease—I have had charge of 100 colonies of bees, and about 85 feet across the street is the school. When I first located the apiary at this place I had some little difficulty, not so much with individuals as with an organization that had the idea that we were to establish a manufacturing plant at that point, and they did not propose to take any chances. A committee was appointed and waited on me, and I was notified to cease erecting a fence and apiary house which was being constructed; that I was going to needless expense, and that it would only have to be torn down. I disregarded that and went on with my work, and after the first week or 10 days the school children seemed to get accustomed to the bees. Nobody was stung that I knew about at that time, but a gentleman who lived some 2 blocks away had been very greatly annoyed with them, and he complained to the Department of Health. An officer came out. I showed him through the apiary, answered all the questions he asked, and possibly volunteered some information for his benefit. He said, "I will have to send in a report, but it will be one that won't hurt you."

Mr. Moore—Did he have a veil on in this inspection?

Mr. Pease—No, sir; he did not. He went through the yard with me, neither of us with a veil. I opened several hives for him. I heard nothing more from that source, and the only serious case of stinging that I heard anything about was from a little girl who was stung through the sole of her shoe! [Laughter.]

Mr. France—I see in looking over the work of the National for the year just closing that there are 18 different places where bees in cities have been attempted to be declared a nuisance and ordered removed, and 2 which were ordered removed. Now there is a cause for all this. One team was stung to death quite a distance away. The road was 225 feet from where 150 colonies were. The man that operated the bees had extracted them, and they were unusually cross. It was out of the honey-flow season and they had become so cross that he was compelled to put protection on his hands as well as his face to finish the work of the day. There was an irrigating ditch by the side of this road; the banks began to give way, and men were sent out to repair the ditch. They had to leave on account of the cross bees. The consequence was the water broke the banks, ran over the land, and the laws of the State make the irrigating company liable for all damages of the water when it is out of its channel. The next morning a team loaded with grain, passing this road, was met by a quantity of cross bees about 300 feet away. By the time they reached where the water run across the highway, mak-

ing a mudhole, there were a good many bees on hand, and the team was unable to pull the load out of the mud; before they could get them away both horses were stung to death. The man was compelled to get into the mud and besmear himself over, to save his own life. The team cost \$225 and the harness \$25, and the case came up. Should they carry it into the court or settle it? I am a compromise man—believe in settling every time and keeping out of the courts; the further you carry it the worse it becomes, as a rule, and I advised them, by all means, to settle in some way. I got a letter last night that upon receipt of my letter he had taken it over, at my request, to the party losing the team, and had read him the letter, and rather than go into court, he had agreed upon a compromise settlement of \$195. There is also a counsel fee of \$2.50, making \$197.50 as a settlement. Now he wants the National to pay the whole bill. We have a great many so-called city bee-keepers that are keeping bees. A few colonies will bother no one, but when you come to develop that into a good-sized bee-yard it is a different condition of affairs, and I have had some pretty trying times to get excuses and help some of our members when the bees—although there might be a high board fence—made trouble. The individual lay of the ground at each place cuts a great figure. There may be a high board fence, and if the lay of the land is such on beyond that the bees drop over the fence, and soon get to the ground again, the fence is of little protection. I think it is a case for each individual bee-keeper, if he learns the bees are making an annoyance, to make amends at once to those who have grievances. Let us exchange our position with the one who has the grievance, and would we like to have the bees spoiling the clothes in the spring, and so on, as they do in the cities? Would we like to be compelled to hitch up our teams early in the morning and shy around because a neighbor has bees? I stopped at a hotel not long ago, where the landlady said, "I would gladly give you your board if you would tell my neighbor how to keep the bees out of the pump." I said, "That is easy enough. A piece of cheesecloth will keep the bees from going in, and it will strain the water and make it cleaner."

Mr. Moore—I want to say that carbolic acid smeared around the edges of troughs where bees congregate is very disgusting to them, and has been used to good effect.

Mr. Kimmey—I tried it and it did not work.

Mr. Moore—Probably you did not have it strong enough; 95 percent solution—what they call pure?

Mr. Kimmey—Yes. I got over the difficulty by putting a barrel of salt in their place. We laugh, of course, at stories of stinging through the shoe and all that, and wondered on second thought whether that really occurred or not, whether anybody was so foolish as to make the complaint. But, after all, it seems to me no one should put colonies of bees 85 feet from a school and expect to keep out of trouble. I

# American Bee Journal

know, as this gentleman says, there are times of season when you can go into your bee-yard, and have children play around the bees, and everything is lovely; but I also know, as far as my experience goes, that I never have seen an apiary of 12 or 15 colonies but what a child at some time of year was stung and went about yelling, "I hurt myself on a bee!" and the mother ran with arnica, and there was trouble. I shouldn't want to set myself down with 100 colonies of bees within 80 feet of a school-house or a highway. It seems to me, as bee-keepers, we ought to be more careful, and put ourselves in the place of the other fellow, and see if we would like to be treated that way. Where I have my bees, although I am at least 100 feet from anybody, surrounded by a green-house on one side and a grove on the other, and at least 150 feet from the street, yet I am in fear every day that I may have some trouble. A year ago last spring, when I put my bees out, a neighbor said, "Mrs. Turner has had trouble with her water. Her clothes are turned and she thinks it is iron rust." I walked over, and I said, "Mrs. Turner, I know what is the matter with your clothes." She said, "I wish you would tell me." I said, "I put my bees out. If you will take those clothes and put them in water and wait until tomorrow to hang them out, and send me the bill, I shall be glad to pay the bill." "O, that is it?" "Yes," I said "that is it." "O, it is nothing at all. It only makes me a little trouble, and perhaps they will be the better for a second rinsing, any way." I only say this because I do not wish you to think that I acquiesce that you can set bees down near a school-house or where people hang their washing out. I think if you have 150 colonies in the city you would better move into the country.

Mr. Moore—I was brought up in Evanston with bees. In the eyes of bee-keepers it is a kind of joke for anybody to get stung. At our house we have two boys, and I take a frame out and say to the boys, "Look here. Run for your life!" They get stung 3 or 4 times a week and they take it as a joke. I was out at my brother's the past summer, and he and I went in and took the honey out and we got stung 10 or 15 times around our ankles. We did not mind it because it did not affect our blood at all. It did not poison us. But I want to tell you I have inspected bees around Chicago a good deal. The public think they are like snakes; they are deadly afraid of them; and although it is a joke with us it is serious to those folks. I want to bear down hard on this: A pound of honey will smooth over a whole lot of bee-stings, and whenever anybody complains, you want to do the right thing, and do it quick. Then you won't get unpopular in the cities. Otherwise you will, and they will put you out of the cities if they get after you really in earnest. You may say you have the Supreme Court of Arkansas, and all that, to show that you can not put bees out of the cities, but I say they will put you out quick if they set their minds on it.

Give them a pound of honey; keep

them good-natured. Use your judgment. Some places you must be 80 rods away from the highway. Other places you can have them close to the highway. Have their flight the other way. Some bee-keepers are foolish enough to have their flight towards the road.

Dr. Miller—One point Mr. France made, I am afraid possibly might be misunderstood, and might be misused. As I remember, he said with a few colonies it is one thing, but with many colonies it is a different matter. Some one might take from that, that as long as he had one, two or a half-dozen he might put the bees up close. I remember one year my bees seemed to be very cross—stung a great deal. A very close watch discovered to me that it was one particular colony in the apiary, and only that one, and of course Mr. France knows that as well as I do. When I changed the queen of that colony the cross bees disappeared in a little while. Suppose I had only had one colony and it had happened to be that cross one, I would have been as bad off with one colony as with a hundred. So don't count too much on it that you are safe because you have only a small number.

Mr. Pease—I wish to answer one question of Mr. Kimmey's in regard to the apiary I spoke of a few minutes ago being across the street from a school-house. That particular yard is not run for comb honey. It is run for the production of bees, the colonies being, you might say, weak. I do not suppose there are over a half-dozen colonies containing the full number of frames (8) in the whole yard. Another thing, I do not tolerate a cross colony. I simply pull off the head of the queen, and re-queen, and I find that eliminates the trouble. I find also, or I verily believe, that 100 colonies of bees can be taken care of in a manner which will be a far less nuisance to a locality than under some conditions a half-dozen colonies improperly treated. In regard to the school, and in regard to the present locality, the very best friends I have in that neighborhood are the scholars and the teachers, and there are no complaints, and have not been, from the immediate neighbors, who, I might say, are a half a block away.

I have trouble sometimes by bees being made cross by boys. Boys like to shy stones at the bees, and very often that makes them very ugly, and I think you have an ugly colony of bees when stones have been thrown at the hive, just as they would throw at bumble-bees' or hornets' nests—just throw quick and then run.

Mr. Thompson—I would like to ask Dr. Miller how he is able to locate a cross swarm in a yard of 150, for instance.

Dr. Miller—I never had 150 in one yard, but I owned one yard of 125. When I go along and come close in front of a particular hive and 15 or 20 bees come out full blast at me, I think they are cross with me; and when I find that the same thing occurs every time I go by that hive for a week or two, I settle down that that is the one, and that queen suffers.

Mr. Kimmey—I bought 5 nuclei and

I put them in the yard. They were the first I had, I think, and the next day I went to examine them. You don't know how proud I was to handle them without smoke or bee-veil. The next day I undertook to show some one how nicely I could take them out without the bee-veil or smoke. I didn't take them out. I went and got the smoke and bee-veil. That has been my experience ever since. Sometimes I can do anything; sometimes they can do anything. I have been thinking of your having bees in a small lot where your neighbors are around. Don't your bees ever act like that, especially in the fall of the year? Don't they get ugly as mine do, so that it is not safe to go within 40 or 50 feet without danger of being stung? I am like Mr. Moore. I don't mind a couple of thousand stings. I would not like to be stung to death, of course. But I have a son-in-law who was stung once, and he says he would not keep the blamed things around. I imagine there are lots of other men, and lots of women and children who feel that same way. I do not know but what you can rear bees for breeding purposes; never let them get strong; keep them always weak; and not have them sting. I do not know but what you can, but I should awfully hate to try it, and I don't want to back anybody else up. My voice is for being careful, and, if you have trouble, put yourself in the other fellow's place.

Mr. Taylor—I just want to make one suggestion, and that is this: I think that we ought, just as soon as we possibly can, to learn to know when we can handle bees with impunity. A bee-keeper after he has had considerable experience will learn, as Mr. Kimmey has done, that he can at one time handle his bees with no appearance of anger on their part, and at another time they are full of vengeance. One can learn with a little thought and care just what to do in his apiary, and to get along without ever angering them. I have not for years had any trouble in my apiary in any way. Of course, it would be a little more difficult, perhaps, if I were producing extracted honey, but with comb honey there is no necessity at all of stirring up your bees. If you only use good common judgment in handling them, and the time when to do it, there is no necessity to do it.

Mr. Kimmey—I was talking of my early experiences. I think I have now learned those things. I think on opening a hive I can tell whether they are going to fight or not. I know I can tell by the smell when they begin. But while I may know, how are the neighbors and the children to know?

Dr. Miller—There is another point. Suppose I know enough to know exactly how the bees are going to act, by their way they behave, by the odor or something like that. Suppose I go off 5 miles to do some work? The only thing is to have the bees off where they won't bother anybody. City bee-keeping is one thing, and country another. If I were in the city with the bees I have now I would not keep them except in the center of the block, and I would have blocks consolidated into one. One

point should be emphasized for the city bee-keeper: Gentleness of character is of first importance; if they will gather only half as much honey, to have bees that are gentle. If we are away off in the country it doesn't matter so much.

Mr. Wheeler—I would like to make one other point; that is, a good smoker. It is worth more than all your breed of bees. Do not fool around with a cheap smoker which many people get. They buy a smoker that costs very little—a quarter, or something of that kind. It will go out and bother them. They would better spend a little money for a good smoker, and go at the bees and frighten them well, and they won't sting.

#### WOMEN AS BEE-KEEPERS.

"Would you advise a woman to keep bees? Would she be equal to it?"

Mr. Taylor—It would depend upon the woman.

Pres. York—I think perhaps Miss Wilson can answer that.

Miss Wilson—That would be my answer. It would depend upon the woman.

Mr. Wilcox—It might be proper to say that because she is a woman is no reason why she should not keep bees. If she has the strength and the inclination, she can keep them just as well as a man.

Mr. Whitney—I have had a little experience in giving women some instructions in handling bees. There are quite a number in Lake Geneva and they are quite successful. They have no trouble in handling them at all, and I think they are more gentle in handling bees than men are. Although they may be of a nervous temper they handle the bees very carefully, without any trouble at all. We know from what we read in our journals that there are very successful bee-keepers among women all over the country.

Mr. Abbott—I think there is no reason why she would not do anything because she is a woman, if she knows how, and wants to. She can keep bees or run a farm, or a livery stable, or a barber shop, or anything she wants to. Some women could not keep bees at all. I don't think my wife could keep them long. If she had a colony she might keep it a good while, because she would not go near it. I do not think there is money enough to hire her to examine a colony of bees. She is timid about it, though she will run my business when I am gone, look after 5 or 6 head of stock, and do anything else, though she can't keep bees. A woman like that would better let them alone. But it seems to me it is an industry peculiarly adapted to women who want to pick up a few dollars for spending money to use as they will. There are only a few husbands who seem to think women need any money except what they dole out to them. But on the farm, if some girl in her teens takes up the study of bee-keeping and studies it with great patience, she can soon have an income coming in and be independent of her father and her folks. It is quite easily done, especially on a farm. Of course it can be done in the city if you have room enough. I know a number of girls who get all the spend-

ing money they want. I know one lady—a widow, who for years had just 12 colonies. She would let her bees swarm, and then she would double them back and in the spring she always had 12 colonies. She has been getting all her spending money for all these years; bought her own clothes, and had whatever she wanted and was independent; notwithstanding she inherited a good deal from her mother, she didn't have to ask her brothers for anything; made it all out of the bees and a little poultry. I know a number of such ladies, and I don't know any reason why more should not do it.

A Member—I think a lady bee-keeper is just as good as a man. I know a lady whose husband was a cripple, who made \$150 a year, and it was quite handy to her. I think she handles them better than I do.

Mr. Taylor—An old gentleman used to come to my place and get pointers on bee-keeping. He complained that his eyesight began to fail him, and it was hard to deal with his bees, look them over, find queens, and so on. One day I came there and he said, "I have been getting married. My eyesight was so poor that I thought that I would get some one to find queens for me; but she can't find them any better than I can."

Pres. York—I think we ought to hear from Mrs. Meredith before Mr. Meredith on this question.

Mr. Meredith—She probably can give you some information. She had 100 colonies the past summer.

Mrs. Meredith—I am not much of a speaker in public. I can tell you that I like handling the bees very much, and I think I could do it quite successfully.

Pres. York—Miss Meredith, I think, looks as if she wanted to be independent, as Mr. Abbott was saying.

Miss Meredith—I haven't any bees, though! [Laughter.]

Dr. Bohrer—My observation is that the ladies are a good deal like men. If they are adapted to the business, and have a taste for it, they become just as expert as men. I used to be a bee-keeper in Indiana and had quite a correspondence with both ladies and gentlemen who kept bees. I found the women eminently successful. They couple them with poultry, perhaps, or some one who took in sewing or washing owned a house and an acre or two of ground kept a few colonies of bees, and the bees coupled with poultry and other labor, made an excellent living, a very nice little income, and there are thousands of ladies that I am satisfied if they were encouraged to take hold of the industry would be successful. Francis Huber's wife was his principal helper in his discoveries. I have some daughters that are married now, not at home; they do not keep bees at all. But I have one that does a whole lot harder work. Her husband is not a strong man. She will order him to stay at the house and do something in the shade, and she will go out and drive a 4-horse plow, and do that and help him raise 4000 or 5000 bushels of wheat in a year. I think with proper surroundings she would take to bee-keeping. As a child she could pick out the queens as

quickly as I could; help carry the frames from the extractor and back again; and could have been a manager of an apiary if it had been necessary and a duty that fell to her. I believe it to be the duty of every bee-keeper throughout the country to encourage the ladies in every way to engage in the business. Not to buy up a large number of colonies to begin with, but take one colony, study their habits carefully, read a bee-paper and some of the standard works on bee-keeping. Women are just as apt at taking up information of that kind as men are, and there is no reason why hundreds and thousands of women that have not a fair income could not add materially to the little income that they have in engaging in this industry. I am sometimes asked by ladies, "Can I engage in bee-keeping and make a living out of it?" My reply would be, "It depends upon circumstances. If you study the habits of the bee, their stings are not poisonous to you, you keep enough of them—many farmers I think would furnish the ground and allow you to keep a good many colonies of bees there—I think you could not only make a living out of it but make money besides." A great many people can not engage in the industry of bee-keeping, and cannot make money out of it, but almost every farmer through the country can if he will; but they won't do it. They have no taste for it. They do not like bees, do not like their stings—they are susceptible to the influence of their poison; that class of people I advise to let it alone, both men and women. But there are many who can learn it; the stings do not hurt them, and a good many of them can make money out of it if they will keep bees enough. Almost any farmer whom bee-stings do not poison can keep a few colonies and produce all the honey he needs at home.

#### DEFENDING AGAINST TROUBLESOME NEIGHBORS.

"Should *this* Association defend its members against troublesome neighbors?"

Mr. Wilcox—I should say absolutely no, under any circumstances.

Pres. York—I might say that there are no funds to do it with, any way; and every bee-keeper ought to become a member of the National. That is part of its business.

Mr. Horstmann—I asked that question. This question has been pretty well discussed this afternoon, not exactly talking on that question, but we have been talking on those lines. I say this Association should defend the members. If the Association does not want to defend its members against troublesome neighbors, I say what good is the Association? What is the use in belonging to it, if the Association is not going to be of some benefit to you? I think that in a case similar to the one that I spoke of here this afternoon, it should be investigated by the executive committee of this Association, and if they find, after investigation, that the bee-keeper is at fault he should have no defense; and if they find that the neighbors have been quarreling, and they are only making trouble for the

# American Bee Journal

bee-keeper for a little satisfaction, then I say the Association should defend that member.

Mr. Wilcox—I want to say that we have another association—the National—and that is a part of its work, a leading portion of its business—and he should apply to that, and this Association, as an association, should not meddle with that work at all. If we attempted it we should have to levy a tax upon every member sufficient to provide an income for that purpose. It would be quite a tax.

Mr. Horstmann—Most of the members of this Association are citizens of Chicago, and I say that we should stick together. If we could put it on the National Association, all right; but what is the use of our having an Association unless we can be of some use to each other? I say there is no use of it. It is all well enough to come down here and have these talks on different questions. We, of course, are benefited by them. Some are benefited more than others. But we should defend our members in cases of the kind I have spoken of here, I think.

Pres. York—I would like to ask Mr. Horstmann what he means by defending them, if we have no money in the treasury to do it with?

Mr. Horstmann—I did not ask the Association to defend me. I fixed the thing all up; or I didn't myself, but had a good friend that did it. The city would have "fired" my bees off there if it had not been for a good friend.

Dr. Bohrer—If I may give a little experience I had about 35 years ago, I settled it very quickly. A man near me had grape-vines. The juice was running out of the grapes and my bees were around there. He said I must remove my bees; they were destroying his grapes, puncturing them and taking the juice. I said, "I think you are mistaken. Bees can not possibly do that. Their jaws are not so constructed that they can cut the skin of a grape." He said, "They are doing it." I said, "Have you seen an individual bee do anything of that kind?" "Why," he said, "there are hundreds of them doing it all through my vineyard. You have got to take them away." I said, "If you can demonstrate that they are actually injuring your grapes, it will be right for me to take them away, but unless you can establish that fact I will not take my bees away. I have got the affidavit of Mr. Quinby." I sent all the way to New York for it. "I will get Mr. Langstroth and have him testify in court that not a man of you knows what you are talking about; that it is utterly impossible for a bee to puncture the skin of a grape." Then he consulted an attorney, who called on me in my office, and I showed him the bee through a microscope that magnified about 100 diameters. I said, "Look at it, and if you think it will puncture a grape I will remove my bees." He was a reasonable man. You will find some reasonable men who are attorneys! He said, "Bohrer's statement is true. Your grapes are bursting or being punctured from some other cause. The bees are carrying off the juice." And the matter dropped.

Mr. Wheeler—The drift of the convention sounds to me as if we were not members of the National any longer. Is that the fact?

Pres. York—We are members of the National because we joined in a body, and if we get into trouble we can call on the National to help us out.

Mr. Moore—Mr. France, in this connection, will you say how much the National Association has spent?

Mr. France—In the ordinance line from \$200 to \$300, one year \$400. As a rule, with these ordinance difficulties the bees are not at the bottom of the trouble, but that the neighbors to the bees get in trouble, and complaints and grievances arise, and finally the bees are complained about and an ordinance passed declaring them a nuisance and ordering their removal. That is about the way those things are led up to. There are many cities in the United States enforcing such an ordinance, and you can not keep bees in those cities, but we haven't it here. As I say, most of these things come from some personal grievance. I recall where two neighbors got to quarreling in that way. The bee-keeper killed the neighbor's chickens, and then he turned around and killed the bee-keeper's cat, and it was back and forth, and a swarm of bees came out and clustered on the neighbor's land on a shade tree, and before they had time to get them out this neighbor took a torch and burned them on the tree. After a while they asked the city to declare those bees a nuisance.

Mr. Wilcox—There is one thing we all ought to understand—perhaps we do—the National Association was not originally intended to defend everybody that was threatened. It was intended only to protect those where it should involve something of general interest to all bee-keepers or to the bee-keeping industry, as in the case of Mr. Freeborn, the first case that ever arose, where the question was as to whether the clover was damaged by having the nectar extracted by the bees. That is a question that affects the industry generally. I have had complaints made that buckwheat was injured in its yielding by the bees depriving it of its nectar. If a lawsuit were brought to collect damages for nectar taken from buckwheat you can see at once that almost every bee-keeper in the United States would be willing to contribute, because they are all interested; but where it is a personal quarrel they ought not. If the National Association goes farther than its rules require, as it may sometimes, it will be in a case of that character, where the general welfare of the bee-keepers demands it, not where it is was a personal quarrel.

On motion, an adjournment was taken until 7 p. m.

## FIRST DAY—EVENING SESSION.

For about a half hour before the opening of the session a quartette composed of Mr. and Mrs. Roscoe M. Stryker, Miss Ruby W. Stryker and Pres. York, accompanied on the piano by Miss Kathryn Kletzing, entertained the audience with bee-songs. Dr. Miller sang also.

## CROSS BEES.

"How far from their hives are cross bees likely to volunteer an attack?"

Mr. Wilcox—If you change that word "likely" to "liable," I will say 20 rods.

Dr. Miller—I think it is a variable point. It depends a great deal upon the bees. If I understand the question it is, How far from the hives will the bees volunteer an attack? You may go to a hive and the bees will run after you a great deal farther away from the hive than that point where they would volunteer an attack, supposing they are coming towards the hives; but I understand the question is how far you are safe from a volunteer attack. If you had asked me 20 years ago I would have said that 2 rods away you would be quite safe. If you had asked me last year I would have told you 20 or 25 rods, and I don't know how much farther the thing is going. Really, that is my question, and I am asking for information. I want to know how much that thing will increase.

Mr. Taylor—An old bee-keeper was telling me what an experience he had in the neighborhood of Lapeer, Mich. He had been hunting bees, and he finally found a colony in a hollow elm standing among other trees, and he cut down the tree, intending, of course, to have it fall free from the other trees and gently; but, as luck would have it, it fell with a crash and struck against another tree and splintered it all to pieces, scattering it all over. He said the road was about half a mile off, but you could not go past on that highway without the bees getting after you.

Mr. Duby—I think it depends a great deal upon how you attend to them. The more rough you are with those cross bees, the more cross they are. I believe it is the method of attending to them; the more gentle we are with cross bees, the more gentle they will be.

Dr. Bohrer—My experience is that something depends upon the kind of bees you have.

Mr. Wilcox—Cross bees, the question calls for.

Dr. Bohrer—Some bees are crosser than others, so it depends upon the kind of bees, at last, that you have. If you have the pure Cyprian bee I think it will come for you in defense as far as it can see you in making the attack. I had a colony of them, but I got rid of it as soon as possible. If you have that kind of bees you may look out. They are on the war-path. When I opened a hive of those Cyprians I had trouble. I could not do with smoke or anything else; nothing short of killing them outright would answer the purpose. Then I took their queen away and gave them another queen, and as they died out, naturally I got rid of them. But the ordinary Italian bee or the black bee, or the hybrid, I have never known to attack horses. I have my farm horses passing up and down the lane within possibly 20 feet of where the bees are. Bees are flying on both sides, but they can not see the horses from the hives, and they do not attack them.

## KEEPING DUCKS IN A BEE-YARD.

"Is it safe to keep ducks in the beeyard?"

# American Bee Journal

The Members—Yes.

Mr. Todd—Safe for which, the ducks or the bees?

Mr. Abbott—I do not think it is. My neighbors have some ducks and I have some. My ducks are well behaved, and they do not interfere, but I noticed a big drake from the neighbor's the other morning went in front of a strong colony of Italians and the bees were disappearing very fast. I don't know how long he would have kept it up, but he kept it up until I drove him away. At that rate it wouldn't have taken long to have the bees all eaten up.

Mr. Arnd—I once had neighbors who said that my bees killed the ducks. They happened to find a bee in the neck of a dead duck and they said it killed the duck.

Mr. Kimmey—If I were going to answer that question I should inquire whom the bees belonged to, and whom the ducks belonged to. If the bees belonged to the man who asked the question I would say no; the ducks will kill the bees.

## HOW FAR BEES GO FOR HONEY.

"If honey is scarce, how far will bees travel to gather it?"

Dr. Miller—Before we get into a long discussion, I would suggest, if we stick right to the question and those who know, who have some definite testimony as to the distance they have known bees to go will tell us, we will get information.

Mr. Arnd—I have known bees to go 6 miles.

Dr. Miller—How did you know?

Mr. Arnd—Because they gathered buckwheat honey, and there wasn't any buckwheat within 6 miles.

Mr. Whitney—I can not give any evidence from personal observation, but I remember reading in one of the newspapers of bees going 9 miles. [Laughter.] Hold on! Don't laugh! Let me tell my story. You will believe it. During the time of the big fire in Chicago there was also a fire in northern New York, in a black-ash swamp, and it swept off the whole swamp. It was 5 miles long. The next year it grew up to fireweed. A gentleman living south of that swamp 4 miles owning the only Italian bees in all that region, found his bees very busily at work. He hitched up his team and drove north along the road. He could see his bees going and coming, and he drove to the south end of that swamp, and he said he never saw such a sight in his life as he saw there. His bees were busily at work on that fireweed. He drove to the extreme north end and he said they were just as thick there as they were at the south end. He knew they were his bees, because he saw them going and coming and they were the Italian bees, and the only Italian bees in that region he owned at that time. It seems almost incredible but I saw the man's picture in the journal that published the statement and he looked like an honest man.

Pres. York—Was it Ira Barber?

Mr. Whitney—That is the name.

A Member—If Ira Barber told it, it is so.

Mr. Wilcox—I have some knowledge of it, because I used to be a bee-hunter,

and as a bee-hunter we always know how far it is from where we start to where we find the bees. We followed them up and we found bees 5 miles from home, but exceedingly rarely; more commonly 4 miles. Yet I never knew bees to work profitably—to carry honey profitably to store a surplus—at a distance greater than 2½ miles.

Pres. York—Bearing on that last point, perhaps Mr. Arnd will tell as to the result of the working 6 miles away. How much did they do?

Mr. Arnd—They did not do very much. In fact, it took me about 6 months to find where they did get the honey; and I found afterwards that the buckwheat was 6 miles away.

Pres. York—The honey was all gone by that time!

Mr. Arnd—The honey was all gone.

Mr. Wheeler—I had a pretty good experience along that line. Some 20 years ago I lived in Iowa. I went into a country where there were no bees at all. The nearest colony was 15 or 20 miles. I watched those very closely, and I watched the fielders to see how far the bees went, and it was very, very seldom that I found a bee farther than a mile away from its home; and out there there was no chance of being mistaken about the distance, because the country was all measured off in section miles, mile by mile, and hardly any of those bees traveled more than a mile.

Mr. Wilcox—What season of the year?

Mr. Wheeler—At all times, all through the working season. They did not appear to go much beyond the mile limit. They were thick within that mile.

Mr. Todd—Nectar must have been plentiful.

Mr. Wheeler—No, that was the peculiar thing about it; they hardly made a living. It was a very poor country at that time. Since then white clover has come in, and it is a fine country for bees now; but at that time they had to skirmish to get a living, and they very seldom got away more than a mile.

Mr. Clarke—I think the last speaker and I come from the same locality.

Pres. York—The same State, any way.

Mr. Clarke—I don't know whether the bees we have at the present time are better fliers or honey-gatherers, but my apiary is at Plymouth Creek, half way between Le Mars and Merrill, and my apiary is situated upon the northeast corner of the section. One mile to the farthest end of it I have a pasture of 40 acres, and it was about as white as a white tablecloth this year with white clover. We had a considerable crop of honey there this year, and my bees all through the season never worked on my farm. They went almost to Merrill to gather the honey; and what could be the reason of that? Mr. Arnd says he could not see the surplus. I have forgotten just exactly what the average is, but one colony stored 630 pounds, and a number of them over 300; some of them up to 400 pounds of honey. Whether I have the long fliers, or whether the country is changed, I can not say, but that is my experience.

Mr. France—As to how far bees work from the home yard, I may say my bees had an abundance of basswood years

ago right at their door, but it has been cut away, so that the nearest basswood now to the home yard is 3 miles, and I notice that when that basswood is in bloom, although it is near one of my apiaries, the home yard works on it. One time I was out on a lake 6 miles across. There was an island, and while out there upon that island bees lit upon my shoulder and excited my curiosity. There was no bec-tree on the island, and I went across to the other side and found bees there working, and they went clear across that 6-mile lake to some hives on the other side. They had one chance to alight if they chose to, in their flight, upon this island; but they certainly were working across the lake 6 miles from home.

Mr. Wheeler—Within the last 2 or 3 years I have known apiaries within 2 or 2½ miles of each other, and as far as I know the bees are exactly alike; where one would gather a good crop, the other gathered scarcely any. That proves to me they do not fly far.

Dr. Miller—That does not prove the point Mr. Wheeler makes. How far did you say?

Mr. Wheeler—2 miles.

Dr. Miller—Here may be something off here, and this yard is gathering upon it—this one nearest to it; it is within its range, but about as far as it will go. This other yard, having 2 miles farther to go, will get nothing. (I don't know whether the stenographer can get all my motions.) The point is this; No matter how much the difference is, there is a difference in the distance, and yet it is very difficult to decide on any sort of reason why there is this difference between two apiaries. For instance, I have two. Take one year with another and the northern apiary will do a good deal better than the southern one. I can not tell any reason why. Sometimes the southern one will do the better. I do not know any reason for that either; and when you come right down to it, to find out the reasons why bees do things, there are a whole lot of things we don't know.

Mr. Duby—Maybe we could tell better if somebody could give us the average speed of bees. I wonder if anybody knows that.

Dr. Miller—For want of any rate of speed, I give 60 miles per hour.

Mr. Moore—This may be inductive, although it is not accurate at all. I feel sure I read somewhere that an engineer in his cab saw a bee quite close up to his engine when they were going at a rate of 60 miles an hour, and the bee kept up with the train. If that is true, it throws some light on the flight of the bee.

## TOADS AND SNAKES EATING BEES.

"Do toads, as a rule, destroy bees, when permitted to stay about the apiary?"

Mr. France—There are occasions when I think a toad will destroy a good many bees if allowed to stay about; but while it is destroying those bees, it there are any moth-millers around, he goes for those, also. I think he "pays his keep" if you let him alone.

Mr. Wheeler—May I amend the question so far as to include snakes? Do

# American Bee Journal

snakes eat bees?

Dr. Bohrer—I do not know whether snakes do or not. I do not like them about the apiary, though. I do not like their looks.

Pres. York—I doubt if many beekeepers drink enough to see "snakes" around the hives!

Dr. Bohrer—I saw one, a blow-snake, 6 feet long. But speaking about toads, I have heard them accused of destroying bees to quite an extent. I saw one, I think nearly as large as my fist, sitting on the alighting-board of a hive, and I concluded I would watch and see what he was up to. He was looking indifferently at nothing, as far as I could tell, but after a while a bee came in reach and it disappeared a whole lot quicker than it could have gone into the hive if it had done its best. I watched him for a while, and he destroyed a number of bees, and I destroyed the toad. He was the finest one I ever saw, the finest one I ever raised in Kansas, and it is a good place for toads. They do well. They may catch some millers, but I think my bees are strong enough so that they will attend to the millers; and I believe we ought to expel the toads from the apiary, as a rule, from what I saw there. Mr. Quinby, in his book, claims they are very destructive. They may be kept out by putting a board around.

Mr. Kimmey—I have seen a toad catch a few bees, but it did not seem to be very serious. I have seen the toad near the entrance and the bee was gone. There is no question the toad got it.

Mr. Wheeler—When I asked if snakes eat bees I was going to suggest that they eat the toads.

Pres. York—The snake may eat the toad full of bees, I suppose!

## DANGER OF OVERHEATING BUCKWHEAT HONEY.

"Why will not buckwheat honey bear heating so hot as clover honey?"

Mr. Arnd—Won't it?

Pres. York—Without destroying the flavor, I suppose it means.

Mr. France—I do not know the nature of the answer required, but when I was in New York there was some buckwheat honey brought in for me to suggest whether it was suitable to feed bees. I said, "No; not that wild honey." "But that is New York State buckwheat," they said; I replied, "I can't help it; I would not want to feed my bees on it, because that honey is full of pollen. You can feel it on your fingers—the grain in the honey of the pollen." One of our most extensive beekeepers lost 90 percent of his bees that winter. I think for the same reason of the pollen in it, if you heat it too much in liquifying, you will darken it, and also increase the flavor of it.

Dr. Miller—The question implies that the heating of buckwheat honey injures it more than heating clover honey. Has any one testimony that that is a fact?

Mr. Wilcox—I have very positively proved that it is a fact. I have been melting buckwheat honey for 20 years, and I have been melting clover about as long, and I know certainly I can not heat buckwheat hotter than 140 degrees without impairing its flavor, or

changing its flavor so that I can discover that it is what we call "boiled honey;" and I heat clover honey or basswood honey easily to 160. I have tried it with a thermometer, again and again. I will say further that it is almost impossible, with ordinary care, to reliquify buckwheat honey without impairing its flavor. I can not fully restore its former flavor. I am anxious to know if there is any other explanation than that given by Mr. France.

Mr. Moore—How do you tell how hot you have your honey?

Mr. Wilcox—Put a thermometer in it.

Mr. Moore—Do you use a thermometer at all times in heating honey over the fire?

Mr. Wilcox—Not at all times, but frequently; use it both in the water around the honey, and in the honey.

Mr. Moore—Can you overheat the honey while there is a candied portion in it?

Mr. Wilcox—I shovel the honey into the clothes-boiler, and when it is about melted I have a thermometer and drop it into it, and also in the water.

Mr. Moore—The question is, Can you overheat the honey while there is a candied portion in it?

Mr. Wilcox—Yes. If there is no more than one pound melted, and that is heated too hot, that will flavor the whole body. The rest may be candied, meanwhile.

## GROUND-MOLES IN THE APIARY.

"How can ground moles be destroyed in the apiary?"

A Member—Catch them and choke them!

Another Member—The same way as they can anywhere else.

Mr. France—Use bisulphide of carbon.

Dr. Miller—Plenty of cats.

A Member—A good dog.

Mr. Taylor—A cat won't catch one.

Pres. York—Mr. Taylor says a cat won't catch one "in his locality."

Dr. Miller—They will in mine.

Mr. Taylor—They won't in any locality.

Dr. Miller—I would like to ask what his evidence is that a cat won't catch them in his locality.

Mr. Taylor—A cat won't dig for them.

Dr. Miller—I don't know how they got there, but I see them in the cat's mouth in my locality.

Mr. Taylor—You mean the meadow-mole, don't you?

Dr. Miller—They are short, and they look as if they were blind.

Mr. Taylor—They both look as if they were blind.

Mr. Kimmey—At one time on my lawn I would get up in the morning and would find where something had gone under the ground quite a distance; and sometimes I would see it working, and dig down with a spade and get it. I thought that was a mole. That is what you are speaking about, isn't it?

Mr. Taylor—Yes.

Mr. Kimmey—That is the kind I have seen with the cat. I don't know whether she dug down, or how she got it, but I have seen it repeatedly. She

got them until she exterminated them all.

Mr. Wheeler—I have done it by digging down in the hole and putting a piece of parsnip or carrot with a little piece of strychnine in it.

Mr. Kimmey—Do your moles travel the same path?

Mr. Wheeler—They went back and forth.

Mr. Kimmey—Mine did not.

Mr. Duby—Another good way of destroying moles is a common castor-oil bean. You see the track of the mole. It is never deep. Just make a hole with a stick and drop a castor oil bean in it.

Dr. Miller—Do the moles hurt the bees?

Mr. Taylor—No, but they dig up the ground and kill the sod.

Dr. Miller—Then what do we care about moles?

Mr. Wheeler—Does the castor-oil bean kill the mole or scare him away?

Mr. Duby—Kills him. The next morning he will be on top of the ground.

Mr. Wilcox—I want to get rid of the moles. They are eating my wife's flowers. They do not hurt the bees, but they are destroying the flowers.

Pres. York—Here is a question for Dr. Miller to answer. Are you ready?

Dr. Miller—Ready.

## HOW TO SUCCEED WITH BEES.

Pres. York—"How can I succeed in bee-culture?"

Dr. Miller—I had the same question asked me a number of years ago. A lady in the State of Wisconsin wrote to me, "Will you please give me your system of bee-culture?" When I have it written out for her I will pass it on to you.

Pres. York—Dr. Miller wants more time, but he has had over 40 years now.

## DISTANCE BETWEEN QUEEN-BREEDING APIARIES.

"How far apart should queen-breeding apiaries be situated in order to prevent amalgamation?"

Mr. Horstmann—6 miles.

Mr. Wheeler—According to Mr. France, it should be 12 miles—6 miles each way.

Dr. Miller—If I am not mistaken, Father Langstroth said a distance of half a mile; and others will make it 6 miles. If there is any definite information on that point it will be important to get it. If not, we would better not spend much time on it.

Mr. Hudson—When I started rearing Italian bees for sale there were black bees around me—no Italians—and I commenced to Italianize all the bees, until I got all Italians within the 3-mile limit, and that eliminated the trouble.

Mr. Abbott—When I first started in St. Joseph I had, about  $\frac{3}{4}$  of a mile out, 150 colonies. My brother lived in the city and we had in his yard in the city 10 or 15 colonies of pure Italians. Those out in the large apiary of 150 colonies were not all pure Italians, but we kept drone-traps on them and caught all the drones except the Italian drones. We had one of those Cyprian queens, and we wanted to get all the queens mated, if possible, and the colony pro-

duced about 100 queen-cells. We saved the virgin queens and put them on the hives according to my method, having 5 or 6 on the hive—some of them in the city and some of them out at my place, where the other bees were. More than half of those out where the 150 colonies were, were impurely mated. There were no drones flying in our yard, however, except the Italian ones. Those in my brother's hives were every one of them mated with Italian drones. There was not a single queen mated there except the pure ones. They were yellow. I concluded the condition of being hemmed in in the city had something to do with that. The apiaries were not to exceed  $\frac{3}{4}$  of a mile apart. We tried that repeatedly, and we had the same experience every time. We could get them purely mated in the city without any trouble, but if we undertook to mate them out where the other colonies were, at least half of them would be impurely mated.

Dr. Bohrer—I wrote that question, because I believe it is one of considerable interest. I stated, I think, once before here today, that I bred queens as early as 1864, and I made it a point in the years 1864 to 1866 to get control of all the black bees within 6 or 8 miles of me, and of course out beyond that there were hybrid bees, because they were mixing constantly. I dropped out in 1873, moving to Kansas, where the country at that time was not adapted to bee-keeping at all, and since I have come back into line again I find there has not been very much improvement, if any, in the Italian bee brought to this country. The bees that I got in an early day, I got some from Mr. Arthur Gray, of Butler County, Ohio, and some from Mr. Langstroth. I got one queen from Mr. Langstroth that duplicated herself oftener than any I ever reared, and yet after rearing about 100 queens one hatched out that was the blackest insect I ever saw in my life, of any kind, showing that there was some foreign blood. There came the question, then, whether there was a distinct race of bees that were Italian; whether they were pure and distinct, not amalgamated with any other race of bees, and while this question was up, and I was studying about it, and I don't know but writing about it, I met Mr. Langstroth in Cincinnati and we had a talk on the subject. I told Mr. Langstroth about this queen I purchased, and having so many duplicates—about 100—and then having an insect as black as any I ever saw, and that I had some doubts as to there being a distinct Italian bee, whether they are a distinct race. He said, "I know they are not, but what their make-up consists of I can not tell." I have done a good deal of investigating for many years, and I do not believe by importing the various types of bees, Cyprians and Caucasians and different breeds, that we are going to improve our bees very rapidly. I said down in San Antonio, to Dr. Phillips that I was opposed to the Government sending out Caucasian queens to breeders unless they would pledge them to breed 12 to 15 miles from other apiaries, so that amalgamation would be impossible. Keep them separate and

see if they are really worthy to be introduced in the United States, or not. The Italian bees as we had them in their highest degree of purity along in the '60's were undoubtedly an improvement on the common black bee. I never had a colony of Italian bees destroyed by the moth-miller. They were better-natured. Then I handled my bees many and many a time without any protection whatever, either on my hands or over my face. I can't do it in Kansas with the bees I have now; only occasionally when there is quite a flow of honey the bees are better-natured. We are all better-natured when we have a full stomach, and the bees are pretty good-natured at a time like that. You can open up a colony of hybrids—not Cyprians, they do not ask any odds for a flight at any time, but they are good-natured at a time like that, but at any other time I won't venture. Sometimes they appear to be as innocent and harmless as flies, and at other times they will come out at me, thousands of them. The reason I put in that question was to argue that very point, and to show what amalgamation is doing for us, and that from 10 to 15 miles is as close as I would advise their being bred, the different races of bees.

#### TAKING BEES OUT IN SPRING.

"How soon in the spring should bees be taken from the repository?"

Dr. Miller—Take them out when the soft maple is in bloom, unless the weather is such that you feel pretty sure you will have cold weather after that; but not earlier than that.

Mr. Moore—When the oak leaf is as large as a squirrel's ear.

Mr. Horstmann—What time does the soft maple bloom?

Dr. Miller—If you haven't any soft maple you must take some other rule, but the soft maple is a very common tree, and I have no doubt Mr. Horstmann can find it without going very far from his home, unless they are scarcer than I think.

Mr. Horstmann—Can you give us about the time of the month?

Mr. Taylor—First to the 10th of April.

Mr. Moore—I think the box-elder takes the place of the soft maple in this part of the country.

Dr. Miller—That is much later.

Mr. Moore—I mean as to prevalence of the wood.

Dr. Bohrer—Any pleasant day when it is warm enough for the bees to fly.

Mr. Wilcox—When the soft maple blooms.

Mr. Wheeler—When the thermometer is from 55 to 60 degrees, without any wind, is my view.

Dr. Miller—That might occur in February.

Mr. Wheeler—Month of April, then.

Mr. Taylor—About my latitude, (Lapeer Co., Mich.,) take them out the last days of March, when it is too cold for them to fly.

Mr. Hutchinson—Suppose the bees are uneasy and would force themselves out, would you take them out then when it was cold?

Mr. Taylor—I do not think they would be uneasy, so uneasy as to force

them out, if you took them out when cold.

Mr. Hutchinson—I agree with you, if the bees are healthy.

#### SIZE OF HIVES.

"Which is better, an 8 or a 10 frame hive?"

Mr. Wilcox—I would say an 8-frame for comb honey, and a 10 for extracting.

Mr. Hutchinson—I second that.

Mr. Clarke—I prefer the 8-frame to the 10-frame, for the simple reason, if you know how to manipulate the 8-frame properly you can produce one-half more honey than you can with the same process and use the 10-frame hive. I do not claim to know as much as many of the older bee-keepers that are here, but I use both kinds together, and I have tried them on an equal footing, with the colonies of equal strength, and the queens in the colonies bred from the same queen-mother and equally prolific, sitting in the same yard, and I have set them on scales alongside one another. That is my result in 15 years.

Dr. Bohrer—Did you succeed in wintering them as well in the 8-frames?

Mr. Clarke—Yes, sir. I have never lost a colony in 15 years, wintered in the cellar.

Mr. Abbott—I suppose I ought to say that when I wrote those heretical articles some years ago, I said I would not have anything but an 8-frame hive for comb honey. I am just of the same opinion now. If I were starting in business again, I would not have anything but a 10-frame hive. I am sure I am right now. I was just as sure I was right the other time. That is the result of getting older, and getting your hair a little grayer.

Mr. Horstmann—I would like to have Mr. Abbott tell us why he knows he is right. We want some reason for it.

Mr. Abbott—There is not room enough in an 8-frame hive for an ordinary man to keep bees successfully. You won't give the bees the room they need as rapidly as they need it. In a 10-frame hive they have the room to start on, and you give them more surplus room when you put on one super, and when you put on two of course you give them still more in proportion; and you are more likely to give them room when they ought to have it. The reason why so many people fail in bee-keeping is because they do not give the bees room at the right time, and plenty of it. There is more honey wasted in the State of Missouri from ignorance as to when bees need the room than there is gathered in all the hives of Missouri every year. I am confident of that; and I am confident that if we could take out the 8-frame hives that are now in the State of Missouri, and replace them with 10-frame hives, we would not only increase the hive four sections more, but we would increase the crop nearly double. I feel confident of it. I have watched the matter very closely, and I do not think, for the farmers especially, that anything smaller than the capacity of a 10-frame hive ought ever to be used. I did not believe that when I was writing those articles, but if I were starting tomorrow, and for those reasons, I would start with a 10-frame

# American Bee Journal

hive, and give every colony from 3 to 4 supers every season. Taken one season with another, in the state of Missouri—Missouri is not a good State for honey, because the clover crop is not sure—I can get more honey out of the 10-frame hive.

Pres. York—You mean the 10-frame Langstroth?

Mr. Abbott—Yes.

Mr. Horstmann—There is no reason why the bees should not have all the room they want in an 8-frame hive. I did not write this question, but I am glad it has come up. I use a good many 8-frame hives. I can bring them out of the repository in the spring and just as soon as the colonies get strong enough I can raise the frame up and give them 16 frames to work in, and I am sure that is all they need; and when the time of flow begins I can take the hive-body off and put on supers just as they need them. When one is pretty nearly full I raise that up and put another one under it; and when the top one is full I put another one on the top, and I keep the colonies working with 3 supers. I do not see where you can get anything that will beat the 8-frame hive for comb honey. I am so well pleased with the 8-frame that I am going to use it altogether for both comb and extracted honey. I can use 8-frame bodies, put up 3 or 4 of them, build them up as high as I see fit, and give the queen all the room she wants to lay. The hive-bodies will be just as easily handled as the 10-frame.

Dr. Miller—I would like to enquire whether any of Mr. Horstmann's neighbors like a large hive.

Mr. Abbott—Mr. Horstmann does not believe in a 10-frame hive, but in a 16-frame hive. He goes me a good deal better.

Mr. Horstmann—Speaking of my neighbors, I honestly believe that there is not a bee-keeper in this hall this evening that has better neighbors than I have. I have never had the least bit of trouble with my neighbors. Speaking of the bees, I have the school teachers bring classes over almost every year to see the bees—classes of children. I have a colony of my bees over in the University now. There is no danger of any stings. I have them "educated."

Mr. Moore—I am for the 10-frame hive, first, last and all the time, for extracted honey or comb honey. The manipulation Mr. Horstmann is talking about is absolutely out of the question for most bee-keepers, I take it; it is too much bother; and, just as Mr. Abbott says, he is getting 16-frame hives instead of 8. That is not the point at all. Most bee-keepers, when they give the bees 8 frames, think they will beat the bees out of just 2 frames. When you talk of bees you are not talking of one year; you are talking of 5 years. The great question is wintering the bees. The question is, Does the queen have plenty of room? A good, young queen will fill 2 of those hives in favorable circumstances. When you move them, as Mr. Horstmann says, you upset their arrangements. They know where they want the brood, and where they want the honey. You give them the 10-

frame hive and the queen fills a large portion of it with eggs, and they put their honey in there, and they fill that as full as they dare to before you put on the sections. It is a mighty poor year when they don't have enough honey. They come out in the spring with plenty of honey, and they won't be economical as they will with the 8-frame hive, and they will be a going concern. It is not one year alone, but it is a series of years, for 5 years, that finally gets the money; and I believe for the everyday bee-keeper who can not do so much manipulation, that the 10-frame hive is the thing.

The Members—Hear!

A Member—Did I understand Mr. Moore to say that a good queen will fill 2 of those bodies?

Mr. Moore—Under favorable circumstances she will fill 3. It is only a question of unlimited honey; that is all.

Dr. Bohrer—I get more honey from 10-frame colonies than I do from the 8, and I have tried both. One thing that induced me to adopt 10 in preference to 8 was that one of the first Langstroth hives was 18 frames. A good queen would populate all of them, and we got our honey from sections. We did not use extractors at that time. Now I get more honey keeping the combs cleaned up, and keeping the bees constantly at work, from my 10-frame hive. You can get more than from the 8-frame.

Dr. Miller—There is a point that has not been touched upon, that is, convenience in handling. With some people that makes a great deal of difference. A strong man does not care whether he has 8 or 10 frames, though even to a strong man it is a matter of convenience to have the 8 frames. As to the care of them, I am sure there is a good point there. Mr. Abbott is right in saying that the farmer is better off with the 10-frame. That is not saying anything detrimental to farmers, but when we speak of farmers as bee-keepers we speak of them as those who do not make a speciality of it, and do not expect to spend a great deal of the time at it. I am sure that the average farmer is very much safer with the 10-frame hive than he is with the 8-frame; and yet, with sufficient care and attention, I am a little afraid that more comb honey can be obtained through the 8-frame hive than through the 10. For years I used the 10, and, I hardly know why, I think there was a fashion for the 8-frame, and I changed over to 8-frame hives. I have the 8-frame hives yet, but I do not know that I have got any better crops since, but I am a little afraid I have. I am afraid that it would not be so safe for me to use 10-frame hives, and yet there is a little more work required with the 8-frame hives. I do not think Mr. Moore's objection would hold, that using two stories involves so much work that it is not easily done. Really, the amount of work required using two stories during the breeding season in the spring is not a great deal, and if you will take the pains to have surplus combs you can get along through the spring and through the winter just as well with the 8 as you can with the 10; but the

man who does not give his bees particular attention will be pretty sure to lose a whole lot more bees in the winter in the smaller hives than he will in the larger hives. But there may be a difference also as to locality. We laugh about the matter of locality, and yet that comes in nearly every place you touch a bee-hive, and touch bee-work, and it may make a difference in that. But I rather suspect—I am not sure about it—I rather suspect that if you give the work to it, that you get more honey with the 8 frames, and enough more to more than pay you for the extra amount of work you give.

Mr. Taylor—There is another point I think ought to be considered in this, especially by those who are treating a good many bees. Of course it is a question of interest as to how many bees we ought to keep in one place. Now suppose my location would profitably sustain 100 colonies in 10-frame hives. According to the idea of Dr. Miller, if I kept 100 colonies in 8-frame hives in that location I would get as much, or more—probably more—honey from the 8-frame 100 colonies than from the 10-frame ones. It is claimed—and with some truth, no doubt—that the colonies in the 10-frame hives, will average considerably more brood than those in the 8-frame hives. Supposing that they have one-fifth more brood, that is, brood in proportion to the number of frames in the hive. Well, if that is so, then if the location will sustain 100 colonies in 10-frame hives, it will sustain 120 colonies in 8-frame hives. That is self-evident. Now there is a greater advantage. Dr. Miller, if his ideas are sound, would get at least one-fifth more honey; instead of 8000 pounds he would get 10,000 pounds, and probably considerably more. That is a point that we ought to have in mind. There is not so much advantage in having a great quantity of bees in large hives if we can get the honey from a few more hives that are smaller and more easily handled, even if we have to have more queens. Queen-bees do not cost much to a bee-keeper.

Mr. Moore—Dr. Miller would grant you that if you winter your bees in the cellar the question of how much honey there is in the brood-chamber is not so material. I take it that a very large number of people who keep bees in an ordinary rough way winter them out-of-doors; but I would like to ask if there is any one here who has had large experience in producing comb honey in 16-frame hives?

Dr. Miller—I am one. What is it you want to know?

Mr. Moore—We want to know whether you have made such experiments as you can say that you can not produce more honey in 100 10-frame hives than you can in 100 8-frame hives, other things being equal.

Mr. Taylor—In 5 years.

Dr. Miller—In answering this whole question, there is one point brought up by Mr. Taylor that I am afraid will not hold. He is taking the ground that a 10-frame hive will have more bees in it than an 8-frame hive. Not necessarily. Because when we are talking about 8-frame hives we are talking of

# American Bee Journal

having two stories to rear brood in, and having just as strong colonies as the 10-frames. To come now to answering the question directly: It is not an easy thing, unless you have a lot of 10-frames side by side with 8-frame hives. I had a good many years' experience with 10-frame hives, and then I had a good many years' experience with the 8-frame hives, but you see you can not compare them. It is not an easy thing. The fact that I have had much experience with each of them does not help me to any positive answer as to what they will do in the same year. The trouble with me is, when I make an experiment I go head over heels and change everything, and sometimes lose a whole lot by it, but I have an impression, by giving the right kind of care, I can get a little more honey out of the same amount of the 8 than of the 10—in comb honey—and allow them to use the two stories.

Mr. Moore—Dr. Miller, you are getting clear off the question. You are running in harness with Mr. Horstmann. You people are not talking about an 8-frame hive—you are talking about a 16-frame hive, and you are telling this convention that you can get more honey from a 16-frame hive than from a 10-frame hive, and you ought to. The question is, Will you get more honey, or as much, from an 8-frame hive as a 10-frame hive, as the ordinary person manipulates them, not the way you skilled people handle it?

Dr. Miller—Begging the Secretary's pardon, the question is not the way of manipulating. The question is, Which shall I take? and the manner of using is a question that comes afterward. The question is whether I shall take an 8-frame or a 10-frame hive, and then I may use one or both of them 2 stories. Don't let us get away from the question. If you want to go back to that, if you confine yourselves to the 8 frames—if Mr. Moore wants that question answered, I will answer it. Confine yourself to 8-frames, or confine yourself to 10 frames, and which will you get the most from? Ten frames, every time, if you are going to hold me down to 10 frames; but that was not the question, as I understand.

Mr. Moore—That is the way I understood it.

Mr. Abbott—Here is a point Dr. Miller does not seem to take into consideration. The bees that are in a 10-frame colony, separated and put into 2 8-frame colonies, will not gather as much honey in proportion as they will if left all together. They can not do it. The greater bulk of bees that you can get in one body, working in one hive, the greater quantity of honey you will get, and you can not take those 2 8-frame hives, using double bodies, and get the same amount of bees in the 2 8-frame hives, working in that way, as would be in one 10-frame hive, and get as good results as you could if the bees were all in that 10-frame hive, and working as one colony.

Mr. Wilcox—My answers were based entirely upon the suppositions that have been explained by Dr. Miller, and I am exactly agreed with him and Mr. Horstmann, and my system is exactly

the same as that described by him without the slightest variation, and consequently I still adhere to the statement. My understanding of that question was that we were to use the hives as we pleased, which is better to adopt? Of course, if we were confined to a single story, and use the same size all the season through, the 10-frame would be the better undoubtedly. Another point I want to give: I do not know that it is of any importance except that it is interesting. I tried an experiment once. I put a few colonies in 4-frame hives, a few in 6-frame, a few in 8-frame, and a few in 10-frame, and set them all in a row close together, with young queens all the same age, and kept them 2 years, and the result was just about in proportion to the size of the hives, except that the bees in the smaller ones nearly all died the first winter.

Dr. Miller—Allow me to explain, as Mr. Wilcox suggests, I did not mean to suggest by any means that the 2 stories are used all the year round, only in building up the colonies; when they have got so strong in the spring that they need the 2 stories until the time of the harvest. They do not always need the 2 stories, but I want the privilege of using the 2 stories when they get strong enough to need it.

Dr. Bohrer—Dr. Miller answered the question categorically. He says he gets more honey from the 10-frame hive, and then he stated the chief objection there is to a 10-frame hive, and I find the same objection to it, and that is, that the 8-frame hive is decidedly preferable when you come to handle it, especially to a man afflicted with lumbago. That is the principal thing. The Doctor says he gets more honey from the 10-frame hive.

Dr. Miller—No. It is the other way; at least I am afraid I get more from the 8-frame hive.

Mr. Sewell—It has come to a rather interesting point. I would like to ask a question of Dr. Miller. Does he not get some gain, or perhaps a great gain, in taking away those 8 frames just at that time? In taking them away, or shutting the queen down to an 8-frame, you cramp her to a great extent, so that she does not produce a great lot of useless workers that are going to go on and be consumers, rather than useless workers, just at that time.

Dr. Miller—I am not sure it is safe to say anything against that generally accepted theory about rearing useless workers; but if I dared say it, I would say I don't believe in it at all. I want to rear all the bees I can at all times of the year. That thing of rearing useless workers I am not afraid of—I do not bother myself about it at all. But the question he asks is an entirely pertinent one. The taking away of those frames at that time still leaves, I think, that 8-frame hive, as much room as the queen will be likely to use during the harvest time; and even if she were in a 10-frame hive, I do not believe she would use more. You know the queen begins to limit her laying as the harvest begins to come in. I think, as a rule, they will have plenty of honey in the 8-frames. And then, please remember this: In limiting the amount in the

lower story we are really not limiting the room for the bees. It is simply giving room in a different place. We give the room above, and we are giving them all the room that they need.

Mr. Moore—The importance of this discussion, from my standpoint, is this: There has been a fashion, a saying gone abroad, that to produce comb honey you should use the 8-frame hive. It is a question of what we are recommending to the bee-keepers. What are Dr. Miller and the other scientific gentlemen recommending to the bee-keepers as the best thing for comb honey? I do not believe for a moment that all these people who are not professionals, who have been using the 8-frame, have been using the 2 stories. I take it that they have been using a single 8-frame hive, and they think they have been making a profit over the 10-frame, which I think is a grievous error.

Mr. Horstmann—Mr. Moore speaks of a 16-frame hive. According to his idea, I have had 50-frame hives. I have had my hives stacked up 5 bodies of 10 frames each. According to his idea I had 50-frame hives. I say what is meant by an 8-frame hive is an 8-frame hive-body, one body that will contain 8 frames. You can pile them up as high as you please.

The meeting then adjourned till 9 o'clock the next day.

## SECOND DAY—MORNING SESSION.

The convention met 9:30 a. m., with Pres. York in the chair. Dr. Miller offered the following invocation:

Our Father, who art in Heaven, we thank Thee that Thou carest for us. We thank Thee that Thou hast the interest of bee-keepers before Thee, even with all the infinite cares that Thou hast. We thank Thee for this meeting together for conference; for the good feeling that existed in the session yesterday. We pray that this good feeling may continue, and we ask Thee that all that is done and said to-day may be useful, that the time may be well spent. We pray, dear Father, that Thy blessing may be upon us. We know that it we have Thy blessing it will be a good deal to us. We ask it in Jesus' name. Amen.

## AUDITING COMMITTEE'S REPORT.

Pres. York—We will now listen to the report of the Auditing Committee. Mr. Kimmey, I believe, is chairman.

Mr. Kimmey—We have the following report to offer:  
*To the Chicago-Northwestern Bee-Keepers' Association:*

Your committee appointed to examine the books and accounts of the Secretary-Treasurer respectfully report that they have carefully examined his books and vouchers, and find the same correct.

FRED L. KIMMEY  
W. B. CHAPMAN  
J. C. WHEELER  
*Committee.*

Mr. Kimmey—I would like to move that the report of the committee be adopted.

Dr. Miller—Second the motion. The motion was put and carried.

# American Bee Journal

## BREEDING THE BEST QUEENS.

"Under what conditions or by what manipulations are the best queens produced?"

Mr. Taylor—The swarming impulse.

Dr. Miller—I believe that the same conditions that are likely to produce the swarming impulse will perhaps be as well without the swarming impulse. That is, a good flow of honey, a strong colony, and all things in an encouraging condition.

Mr. Whitney—I asked that question. From what we read in the bee-papers there are all sorts of manipulations in breeding queens by queen-breeders. I buy a good many queens, and I would like to know where I can get the best queens, or under what sort of manipulation I can get them. But what few queens I rear for myself, I find the best ones are those that are reared, as Dr. Miller says, in a full colony of bees and under the swarming impulse. I believe we get the best queens in that way.

Dr. Bohrer—I find Dr. Miller's statement is substantially correct. There is no question about that. But the same conditions will exist if a strong colony is rendered queenless, and then given fresh-laid eggs. I have slipped a frame full of eggs the night before into a colony which built the queen-cells, and then have taken them out and distributed them among nuclei, when they were finished and sealed over. I think those conditions are similar to the swarming impulse, because they will respond to the same method, give the same kind of care until the egg is matured, as they would under the ordinary swarming impulse. Now as to the best of queens, aside from that, we might differ as to the different varieties of bees, that is, different races. I have always found the highest grade of Italian bee was the most satisfactory.

## BEST RESULTS IN COMB HONEY.

"How should 10-frame hives be manipulated for best results in comb honey?"

Dr. Bohrer—There are two ways of doing it. One is to cut it in sections, and the other—some one will take exception to the position if I should say to use another body on top, and raise the combs up and put the bees to work above. I think you would get a little more honey that way than you would to use sections, by using a two-story hive.

## MANAGEMENT OF GOLDEN ITALIANS.

"Should golden Italians be managed differently from the darker varieties?"

Mr. Taylor—Yes. Kill them.

Pres. York—Who would rather manage them alive?

Dr. Miller—I think Mr. Taylor's answer is right for some of them, and it is very wrong for some of them, too. I think there is a great deal of difference. I believe there are golden Italians that are good bees, and I think there are some not worth the powder to blow them up. I do not know any difference, so I am not answering the question. I was rather wanting to limit Mr. Taylor's very sweeping statement. At the time of the World's Fair Mr.

Doolittle had some of the golden bees here, and two of the best queens were left with me over winter to be taken care of before being returned to New York State, and from those I reared some queens, and those were good bees. I would not say that they were not up to the other, and I am not so sure at all that they were very much better. The main thing, I think, about the golden bees is the looks. They are beautiful bees, and there is a great pleasure in looking at them. As to the real value, as I said before, there are golden queens and golden queens. Some are good and some are very poor.

Dr. Bohrer—I want to corroborate what Dr. Miller has said, having a queen now that is one of the most prolific queens I ever owned, and her bees produced more honey last year than any other in my apiary. I do not think they are corrupted any by Cyprian blood, but I have had some corrupted, and to say they were cross is not expressing it.

Pres. York—Another question, right along in connection with that: "How do the golden Italians compare with the leather-colored varieties?"

Mr. Kimmey—I would like to hear from Mr. Taylor, the reasons for his remark that he would kill the golden Italians.

Mr. Taylor—I never saw any of them that were good for anything. Of course, I have no doubt but what sometimes you will get a queen that will produce bees that may be passably good, but, take them together, I think they are very gentle and very good to look at, but they are not very good for gathering honey. Now, to get right down to it, I would not have an Italian bee. I would rather have a hybrid. It is very much more difficult to get the Italians into the section-boxes than it is hybrids, and when you want to get them out, it is very much more difficult to get them out; and I don't know that they are any better for gathering honey than good hybrids in the matter of temper. It is true that you can go to a colony of bees and by being careful, handle them without veil or smoke. But it is not because their temper is better; it is because they are less disposed to take wing. You get out in a swarm of Italian bees when they are flying, and I think they are a good deal more likely to sting than the black bees are. I think that accounts for the difference in apparent irascibility of black bees. Several of my hybrids—they are all hybrids—I do not call irascible at all. There is very little stinging. I very seldom get stung. Get a stranger in there, sometimes, who is a little nervous, and he gets stung sometimes; but I do not call my bees any more liable to sting than the Italians I have had, when handling them.

Dr. Miller—Before Mr. Taylor sits down, may I ask him whether he thinks his bees are about like the average hybrid bees?

Mr. Taylor—Well, I do not know that I can say as to that. They are about like the average I have seen. There are some colonies that show quite a little yellow, and some colonies that show a good many bees that you would

take to be black bees; but every colony shows more or less of the yellow color. But I do not know that I have a colony in the yard that any one would call pure Italians from their coloring.

Mr. Whitney—Mr. Taylor's experience has been very different from mine. I have been working all the time that I have kept bees to make them as pure 3-banders as I could possibly get. I have had quite a mixture of black bees at times, and they have always troubled me—cross, run like cockroaches. I never had any trouble with 3-banded Italians to get them off the sections when I wanted to get the honey out or have the combs free. Take a frame of honey and hold it right over the end of the hive and take them off at once. Mine are very gentle. I can go into the yard almost any time. I think I showed Mr. France once, at 5 o'clock in the afternoon, without a veil, without smoke, a number of my bees, and I think in a recent copy of American Bee Journal you will find a picture of a little girl holding a frame. It was late in the day, she was without a veil over her face, and she held a frame of those bees. They were 3-banded Italians. When you come to workers, I never saw anything equal to it before, and the only surplus honey I got this year was from my 3-banded Italians. I have 3 or 4 colonies of mongrels, one colony pretty nearly black, and they did not give me a pound of surplus honey—not a pound; while the 3-banders did; and the blacks or mongrels swarmed, and out of 30 odd colonies of 3-banded Italians I had but 2 swarms. It seems strange to me that there is such a difference in the experiences individuals have with the different kinds of bees. I do not believe I would want what they call the golden or all-yellow bee. You know the queens of the 3-banders often are absolutely, yellow, but their bees have only 3 yellow bands. I do not call such a queen as that a golden queen. I call it a 3-bander queen, although I do not see any band on the queen at all, but her bees are all 3-banders. So far as protecting their is concerned, the 3-banders beat anything I ever saw against robbers, and they will clean out the bee-moth in a very few minutes. I have put frames that were filled with the larvæ of the moth right in the center of a 3-bander colony of bees, and in a few minutes they would be all cleaned out. I like them in every respect so far as I have been able to investigate them.

Dr. Miller—I think that one way of explaining the difficulty that Mr. Whitney meets is by saying that bees vary, and that they vary very much. If you have a colony of Italian bees you are not sure, from the mere fact of their being Italians, that they will always be of exactly a certain temperament. With a hybrid bee, still less are you certain of anything of that kind. The Italian bees are more fixed in character than the hybrids. You are more sure of what you have. When you come to hybrids, you don't know, for certain where you are. Now, Mr. Taylor has very gentle hybrid bees, and I have very cross hybrid bees. I look for those colonies that will produce the most honey, without regard to their temper.

# American Bee Journal

I said, "The honey is the thing I am after; I can stand all the rest." They convinced me after a while that I couldn't stand all the rest. I had to fight with my assistant. I killed a queen and she showed some temper.

Mr. Ford—Which showed the temper, the queen or the assistant?

Dr. Miller—Both. She would insist that if they only brought the honey the queen must be allowed to live. If I had it to do over again I would not do exactly the same thing as I did, because I know that the matter of temper is a thing that must be reckoned with. They can go so far you can not stand it; at least I could not, without a veil, and I do not like to wear a veil all the time. My assistant wears a veil all the time.

Dr. Bohrer—What kind of trousers do you wear?

Dr. Miller—I don't handle them with my trousers! [Laughter.]

Dr. Bohrer—Don't the bees crawl up your trousers? They do mine.

Dr. Miller—Answering your question, I wear white trousers. It is a fact that hybrids are much more variable in character than anything like the pure blood of the Italians, and when you are working and selecting to get the best, as I suspect Mr. Taylor is—he was more fortunate in it or else more careful than I, and in his selections he has good-natured hybrids and I have them just the reverse. He shakes his head. How is that?

Mr. Taylor—I did not select. I have killed just 2 queens in my time on account of the irascibility of the bees; that is all.

Dr. Miller—Perhaps I gave a wrong impression. When I have found one especially cross lot, through the years, I have killed that queen, always; but I have not paid as much attention as I should have done to the temper of queens. There is, I think, the whole thing in a nutshell. The bees vary a great deal, and if one man says the Italians are better, and another says the hybrids are better, they may have different kinds of the same bees. I believe, as a rule, that the hybrid bees will give you more honey than the pure Italians. Now it does not follow from that that it is the best thing to breed entirely from hybrid bees, because they will split all up and you don't know where you are going, as I said before; if you keep trying to breed pretty near pure Italians, you will get enough hybrid stuff in to keep up the black. Try to keep them pretty nearly pure, and you will have more or less black blood in them.

Mr. Taylor—Some reference was made to the Doctor's trousers. I have often been amused in the remarks he has made in his writing about the bees getting up his trousers.

Dr. Miller—Please allow me to correct you. I did not say anything about their getting up my trousers.

Mr. Taylor—They don't crawl up my trousers. They fly. The trouble with your bees, Doctor, is you have too much Italian blood in them. They won't fly at all.

Mr. Kimmey—You speak of Italian and hybrid. We started out to speak

about golden. I understand there is a difference between 3-bander and golden.

Dr. Miller—Yes.

Mr. Kimmey—What is the difference, in your experience, between the 3-bander and the golden?

Dr. Miller—As I said before, the goldens vary so much it would be hard to answer that directly. Some of them are one kind and some of the goldens are another. They are a variation from the pure stock. I do not count them as pure. There may be black blood in the golden stock, in the leather-colored variety, or in the 3-banders. I would not expect to find any black blood in them, although possibly there might be some there, and the thing has got where I do not see how we are going to talk about what pure queens are. If you have golden stock with 5 bands, and then get a little black blood mixed in and cut down to 3 bands, then you can not say 3 bands is a sure sign of pure stock.

Mr. Wilcox—What is your standard of purity, then?

Dr. Miller—I haven't any.

Mr. Lyman—I don't know that I am correct in this, but it has seemed to me that there is quite a little difference in which way the cross is made, whether you start with an Italian queen or a black queen I think in my experience that the black queen cross, from an Italian drone with a black queen, produces a gentler bee than the other cross.

Mr. Sewell—I hate to hear the golden queen slandered here. I would like to speak right out in meeting and say where the golden queen comes from, and you will know what I am talking about. A golden queen from one breeder and one from another are different. If I say it comes from Doolittle, you know what it is. That queen led the yard, after coming from New York State by mail; but this year a leather-colored queen led the yard. And so it is—one year it may be one, and another year another. But those golden queens have decided advantages. One is finding the queen; another perhaps is gentleness; and those golden bees crossed with some of the other blood are very prolific. In managing and manipulating them, getting hives for them, etc., I have an idea that the 8-frame hive would be very much better for them than the 10. I have had leather-colored queens from about 5 different breeders. Some were not good for anything. Some have been very good. They are very prolific. They lay, all the year round, more than the golden, but they lay in the spring—they just fill the hive all at once, while the golden queens will lay right straight along through the year. Two years ago the flow was a gradual one all through the year, and that is the reason I think the golden produced more honey than the other bees, whose queens laid the hive full of eggs all at once, and then later on perhaps were a little scant with their brood. But I would like to hear more of an expression, or, if the thing was reliable, I would like to know just exactly which the best bees are.

Dr. Miller—That you will never learn.

Pres. York—You will have to read the advertisements, and then try yourself.

Mr. Sewell—I have read the adver-

tisements. I have had queens from at least 8 breeders; I do not know but from more. It is a very interesting study to me, the more different traits from different breeders, what I can produce and what I can get from the different kinds of queens. I can not always get the same thing even from the same man, of course. A golden queen has very decided advantages on one side, and perhaps the darker varieties have advantages on the other side, and it depends largely on the year, the honey-flow, etc., just which kind is wanted, and you can not always tell just what it is going to be beforehand.

## PLAIN SECTION OR BEE-WAY?

"Which is the better, the plain section or the bee-way section?"

Pres York—How many prefer the plain section? Raise your hands. None.

How many prefer the bee-way section? About 10, I think. Do you want to say anything about this?

Pres. York—Why do you prefer the bee-way section over the plain? I think Mr. Taylor raised his hand on that.

Mr. Taylor—Yes. One reason is that they are at least as good as a plain, and I do not have to change.

Miss Wilson—They are easier handled.

Mr. Abbott—My reason is that you have to have less traps. I do not use separators. I could not use a no-bee-way section without a separator.

Dr. Miller—Why are they easier handled? Miss Wilson has handled a good many of both kinds.

Miss Wilson—When the plain sections are filled right out plump to the wood you are apt to break the honey in scraping them and getting them ready for market; and if they fall over, as they tumble over easily, they are more apt to break.

Mr. Taylor—Let me ask Miss Wilson, if they fall over, as they evidently are bulged a little, and the comb strikes—is that what you mean?

Miss Wilson—Well, it may not be that they strike that, but there may be a little something on the board that may fall on to them, just a little tiny bit.

Mr. Taylor—In regard to cleaning and packing them, if that was the case the combs would touch.

Miss Wilson—Yes, I think they would, perhaps. You have to be very careful.

Mr. Taylor—It always seemed to me—I have never tried them, I don't want to try them—but it always seemed to me that there would be more or less difficulty in that way, that they would be slightly bulged and interfere in packing.

Miss Wilson—But in handling them and scraping them you are so apt to put your finger in them. When you handle a great many in one day it is quite a drawback.

Dr. Miller—You say when they fall over. Do either fall over?

Miss Wilson—Yes, sometimes.

Dr. Miller—Which one falls easier?

Miss Wilson—The plain section.

Pres. York—When I was in the honey business I handled a good deal of honey in plain sections, and they were put in shipping-cases just the same as the others, but I did not notice any scrap-

# American Bee Journal

ing of the combs in pulling them out. Of course, in a shipping-case they are very close together, but you can begin to take them out with a knife-blade. They are put in without separators, but I could put my knife-point in and lift them out.

Miss Wilson—I have often wondered how they got them out.

Dr. Miller—These differences refer to the separator rather than the bee-way sections. Those sections as first made, and as I used them, were the same width as those that had a bee-way or notch at the sides; but the difference was made by making the separator—a wood separator—3-16 of an inch.

Pres. York—A slotted separator.

Dr. Miller—No, a wood separator 3-16 of an inch thick, which left room for the bee in at the bottom.

Pres. York—Slatted then?

Dr. Miller—Yes. The section was a plain section, but in order for the bees to get into it they must be spaced apart, and the spacing was made in the separator. You could not use them without the separators. As you use them now, as I understand it, and I think I am right, the spacing must be in the separator.

Pres. York—They do not use the plain separator. They use the fence separator.

Dr. Miller—The question is raised as to how to get those sections out of the case when they were packed in solid. One way is to turn the case upside down carefully and dump the whole thing out. There would be no breaking in that way. That is a little awkward. Another way is, suppose your case holds 12 sections, put in 11 sections, leave one space vacant with a little bit of separator there packed in, and you can open that one. I am not insisting that you shall use the plain sections, but I am trying to tell how those things may be done. After using a number of thousands of them I prefer the old-fashioned bee-way section. But let us be fair with it. There is an advantage which the plain section has. I remember a good many years ago seeing Mr. Heddon stand up here and talk about sections with separators. At that time he had a super in which no separators were used at all, and he said, "You take the section that has been produced with the separator. It has a lean look." And that is a fact. The plain section is plumper looking than the other. I am not sure that I think of any other advantages now, but I do think we ought to be entirely fair to the plain section, and this is a one-sided business: those who prefer the plain sections ought to be allowed to tell us why they prefer them.

Mr. Taylor—Just let them tell.

Mr. Lyman—Doctor, you mean the plain section of honey looks plumper?

Dr. Miller—Yes, it looks plumper. It filled out fuller at the end.

Mr. Thompson—If paper is put around any section in a case it can be lifted readily, and that gives room for each of the rest.

Pres. York—I think we all understand that the shipping-case as made today, has a follower-board at the back and a wedge or paper is put back of it so they can be readily taken out.

Miss Wilson—In the cases that were sent to us there wasn't any space allowed. They just fitted tight.

Dr. Miller—I would like to hear the views of those who prefer the plain section.

Pres. York—Nobody voted in favor of the plain section.

Mr. Kannenburg—I do not care much for the plain section, but I like to see the looks of it, and in one way they are nicer to clean than the bee-way section. I handle both of them, and I have no trouble at all to get them out of a shipping-case or out of a super, because there is always space enough so that you can bend, turn a little on the side to take hold with the fingers. As far as the cleaning of the plain section goes, there is not so much propolis as there is with the bee-way section. You do not have to go into the corners so much with a knife to clean the corners out. The beeway sections are all filled with propolis in the corners, every time, and it takes twice as long to clean one super with the bee-way section as it does with the plain section.

Miss Wilson—I do not agree with you.

Mr. Kannenburg—Another thing I like, if you put the bee-way section and the plain section on the table before a customer, every time he will take the plain section.

Mr. Kimmey—I did not vote on this question, because I did not know anything about the bee-way section. My little experience has been with the plain section. As for taking them out of the case in packing, I have never had any trouble. Even before I produced any honey myself, or had my bees produce it, it always seemed to me that the plain sections were preferable. I drop into Siegel & Cooper's and I ask them what they are selling honey for, and I notice the looks, and it always seems to me that as far as appearance goes the plain sections are ahead. I know you come to weigh them there isn't the turn of your hand in favor of one or the other, and yet, as has been said, it always looks to me as if the plain had a better look than the bee-way. I do not feel qualified to speak for anybody else as to which is the better. I wish I had some of the bee-way myself, after hearing these gentlemen talk, and this lady. I do not want you to think because I did not vote that I did not have any opinion.

Mr. Taylor—I just want to say, with reference to bee-ways, there are a good many of these plain sections sold. I have sold some honey that way. I have one customer that I sold a ton to for 4 years, certainly each year, or perhaps 5 years, and he always says, "I can get plenty of honey, but I like your sections better." and he takes my honey on that account. That is, that decides him finally.

Dr. Miller—I would like to know whether that is anything like the general experience, whether dealers do prefer it ordinarily. Have we any testimony with regard to that, one way or another?

Mr. France—Up in our State the dealers almost invariably want bee-way sec-

tions. The large complaint is that the other one looks nice, but there is not room for handling, and they press in with the fingers, and they are hurt by handling.

Miss Wilson—The man to whom we ship our honey said he did not want any more plain sections.

Mr. Abbott—I think they have not emphasized the main trouble. It is not the section as it stands by itself that bothers me. The old bee-way section is all right. It is the traps that must go along with it in order to use it. They are frail and are easily broken up. You can't clean them, and they are a source of constant expense. I think our people probably make as good fences as anybody, but I throw away—well, I wouldn't say how many out of every lot they ship me, because they get broken, and I seldom ship out a crate of hives to anybody but what there is some complaint about the fence separators being broken. You can not handle the no-bee-way section without the slotted separator, or the old Armstrong separator which had a slot in the bottom and made the finest looking section of anything I ever saw. But there was too much lumber in that beehive—it cost five or six dollars in the flat, and you could not afford to pay that much. It is the things that are necessary in order to use them that make me object to the plain sections.

Dr. Miller—I must say that this is really a great surprise to me. I try to keep up with the procession and know what is going on, and I read and find that the plain section is away ahead, that it is the thing to use, and then I come here and find a lot of old fogies who say that the bee-way section is the thing. Their grandfathers started with the bee-way sections and they are going on with them, and it seems to me that somebody ought to do a little missionary work and wake them up and let them know they are not up to the times; that the plain section is what we ought to have.

Mr. Taylor—Why not do the work on the manufacturers of the plain sections?

Dr. Miller—Well, there is a point. Seriously, it is a surprise to me to hear the expressions here this morning, and I would like to ask this question: Suppose the plain section is very much better than the other, there are two ways for accounting for the apparent feeling with regard to it here. One way is to suppose, as I have already supposed, that there are a lot of old fogies here that don't know what they ought to do. There may be two ways still. One is that they are not old fogies, but they never had testimony enough to make them think it worth while to try the plain section.

Mr. Lyman—Some of us have been through the mill, Doctor.

Dr. Miller—I was going to say that there is still another way, that they have tried them, and, after trying them, they believe that the bee-way sections are better. I would like to ask how many have tried both kinds. If you will allow me to see the hands—just keep them up and let me count them—12. Now of those 12 I would like to ask two questions. I know that I have an answer to both of them, but I want to

# American Bee Journal

get something definite. How many of that 12 prefer the bee-way section? Let me see the hands—8. How many prefer the plain section? 3. How many do not care which? 1.

Mr. Abbott—Let me tell you another thing. Out of 10 carloads of goods sold down in Missouri, we will sell probably a wagon-load of plain sections—not more in 10 carloads.

Mr. Kannenberg—It might be that they like the bee-way section because they started in with it and hate to change to the plain. It costs money to change.

Mr. Taylor—I want to have the Doctor put another question. If a man is producing thousands of pounds of comb honey and has to handle it, that is one thing. If he is producing 200 or 300 pounds, that is quite another. I want you to ask these 3 gentlemen here who have voted in favor of plain sections, how much comb honey they handle.

Dr. Miller—Will they kindly tell us.

Mr. Thompson—A very small amount. Perhaps 2 tons would be the most in any one season.

Mr. Pease—40 tons.

Mr. Blume—The lowest I ever had was 2 tons.

Dr. Miller—Let me state that it still remains a surprise to me.

Pres. York—Maybe you are easily surprised, Doctor.

Dr. Miller—I am not easily surprised.

Mr. Arnd—My experience is the same as Mr. Abbott's, about selling sections. We sell, I think, almost 10 bee-way sections to 1 of the plain.

Dr. Miller—My reading makes me believe that the plain sections are ahead as to number, and as to quality.

The Members—No! No!

Mr. Taylor—Doctor, you have read enough and written enough to know that there is not much dependence to be put on printing! [Applause.]

Dr. Miller—There is another point. There are a good many bee-keepers who have commenced lately, and they want to take up the best thing. Here is Mr. Kimmey, he is a man who is looking out for the best—he reads, and he knows that the plain sections are away ahead, and he takes the plain sections. He is pleased with them. He doesn't know anything about any others. I don't blame a man of that kind for thinking that the plain section is the best. Now the question is whether we are doing the right thing not to try to let the whole truth be known. The whole truth is not known on that.

Mr. Lyman—I started with the plain and I shall use the bee-way hereafter.

Mr. Whitney—I do not know anything about the plain section, but Mr. Abbott says that he sells very few of the plain and a large quantity of the bee-way. We lose sight, I think, of this one fact, that the plain section has just been introduced, and it takes time, even if you introduce a good thing.

Pres. York—Especially in Missouri! Mr. Abbott lives in Missouri, you know. [Laughter.]

Mr. Whitney—I think it is hardly fair to say that the plain section is not as good as the bee-way because we do not sell quite as many of them at the pres-

ent time. It takes time to introduce a good thing—we all know that. I don't know anything about the plain section. I have not used anything but the bee-way. Some old bee-keepers up my way, who are interested a little in bee-keeping, got the plain section. They do not like them, but they are using them because they have a supply on hand. They think that the fence separator is such a frail thing and breaks up and annoys them a great deal; but I think that if the time ever comes when we get a fence separator that will be substantial—and I think that will come—they may be regarded as the best sections to use.

Dr. Miller—If you will allow another question, it will help bring out the point that Mr. Whitney makes as to the time required. That is true. It takes time to introduce a new thing, and a good thing. Now the question is, Is the number of plain sections increasing regularly through this time? Will Mr. Arnd and Mr. Abbott tell us?

Mr. Abbott—No, sir. It is the people who have tried them who object to them the most. I send them out once in a while to people as samples in the hives, and they always say, "Don't send me any more of those traps."

Mr. Arnd—I have not had real experience enough in the bee-supply business to know, because I have been in it only 2 years.

Mr. Abbott—I have been in it 20 years.

Mr. Kannenberg—The fault is this: I find with the plain section that you can not produce as much honey as with the bee-way section, because the bees have to fill out the combs on those sections, but they won't get as much honey in it, because when you weigh one super, and then the other, you will have less honey and more wax, more wax to draw out, more comb to draw out. It takes a longer time for the bees.

Dr. Miller—I don't believe it.

Mr. Kannenberg—Doctor, you take a super full of plain sections, and take a super full of honey in the bee-way section. Which will have the most honey in it?

Dr. Miller—Do you have separators in both?

Mr. Kannenberg—Yes. You will have more honey in the bee-way section than you will have in the super full of plain sections, every time; and it is because of the drawing out of the comb.

Mr. Wilcox—I have a little evidence that bears on this question, although since the fence separator came into fashion I have discontinued producing comb honey; but I have judged honey at the State Fairs in recent years, and I invariably give the premiums to the no-bee-way sections. Noticing that fact myself, I began to inquire of exhibitors as to the conditions in the market, and so far as I can learn nine-tenths of them prefer the no-bee-way sections; that is, that they sell better on the market—the plain sections; that they look better and sell better, and I am sure that, for some reason which I do not understand, they looked better to me on exhibition, and I gave them the premium. They were better filled out.

Mr. Kimmey—Will Mr. York give us

his opinion, founded on his experience?

Pres. York—I have not used very many, but I like the plain section better for cleaning. I have had the same experience as Mr. Wilcox in judging at fairs.

Mr. Kimmey—How about the sale?

Pres. York—I do not think it makes any difference in the sale, not from my experience in the groceries in Chicago, when I was in the honey-business.

Mr. Kimmey—I would like to hear from Mr. Pease, too, both as to the requirements of the trade, as to bee-ways and no-bee-ways, and as to the quantity of honey.

Mr. Pease—I find that the groceries, as a rule, make very little distinction as to a matter of preference between the bee-way or no-bee-way section. The grocer in Chicago buys his honey by weight, and sells it at so much per section. They do not want a honey full weight, but the consumer who goes to the grocery store to buy honey—you put a plain section and a bee-way section side by side, and 9 times out of 10 he will take the plain section, even if it weighs less than the bee-way.

Mr. Moore—The grocery trade wants a section weighing 12 or 13 ounces, and 12 or 13 ounces looks vastly better in a plain section than in a bee-way section.

Mr. Whitney—I have two styles of bee-way sections. I have a big super that belongs to the old Gallup hive, and it takes a section  $4\frac{3}{4} \times 5\frac{1}{2}$ , and I think if you place a section of that kind by the side of a plain section they will take mine every time. It will look larger although it is not quite as wide, but it is a little taller, I believe, judging from the appearance, of course. You take a  $4\frac{1}{4} \times 4\frac{1}{4}$  bee-way section and it looks lower, and they decide in favor of the plain section because it is tall, but you take the bee-way section that is as tall as the plain section, and I think they will take the bee-way section, every time.

(Continued next week.)

---

**Why Not Advertise?**—There are many dealers in bee-supplies, and those who have bees and queens for sale, who are not now advertising, that might increase their business by advertising in the American Bee Journal. The rates charged are very low, as will be seen by referring to the second page of this number. During the next 6 months will be done the bulk of the season's business among bee-keepers. Why not begin at once to let the readers of the American Bee Journal know that you have something to sell? Our advertising columns are open only to those who will give their patrons "a square deal." If you are in that class we will be pleased to have your advertisement in our columns.

---

**Getting New Subscribers for the Bee Journal** is something that almost any reader can do if he makes a sincere attempt. No one knows better than does he its value to every would-be successful bee-keeper. And we offer valuable premiums, to those of our present readers whose subscriptions are paid in advance, for the work of going out and getting new subscriptions. Your neighbor bee-keepers perhaps have never heard of the American Bee Journal, although it is now in its 47th year. Why not try to get them to subscribe? You may be surprised how readily they will do so upon your invitation.

# American Bee Journal

## Worcester Co. (Mass.) Bee-keepers' Convention

The second annual meeting in an Institute with the State Board of Agriculture was held most successfully in Horticultural Hall, Worcester, on Saturday, Feb. 16, 1907. At 10:30 a.m. the meeting was called to order by Pres. Burton N. Gates, who introduced Hon. J. Lewis Ellsworth, Secretary of the State Board. Upon invitation Mr. Ellsworth presided at the morning session. After a few remarks on the conditions of bee-keeping, and the progress it has made the past few years, Mr. Ellsworth presented Mr. George W. Adams, of Byfield, Mass., who gave the address for the Board of Agriculture. His subject was, "Problems in the Intelligence in Bees." This subject, while not so much before the American bee-keeping world as before the European, was most admirably presented. We are inclined to be dogmatic in things of bee-life; it does not pay to be so. We are also likely to surround the activities of the hive with mysticism and magic. But these are not the spirits of the true investigator. Mr. Adams did much to strip off the old garb of the subject, and present it in its truest light.

One fact which Mr. Adams emphasized, is that the bee has intelligence. By this he would not imply faculty of reasoning in the sense we think of the term, but rather as an intermediate between mere machine activity and reasoning as we view it. In proof Mr. Adams gave illustrations and quotations from his long experience as a bee-keeper from his reading.

Dr. James P. Porter, of Clark University, Professor of Psychology and Student of Animal Behavior, followed Mr. Adams in discussion. Dr. Porter could but commend the address of the previous speaker. He also pointed out that we are too prone to allow our own—our human—emotions to enter into the reading of animal behavior. In this state, unlike the true attitude of the scientist who looks at things in a matter-of-fact, more-or-less-cold-blooded way, we are not inclined to judge.

Investigations show that bees have memory. A bee may be intoxicated by a stimulant in the food, and made, thereby, to forget its way and bearings.

"Bees are intelligent rather than reasoning. They work in accord with their experience. The dog, trained to do tricks, will start to walk on his hind legs around a table; but when out of sight will drop to all fours, coming to his hind legs when he gets in sight on the other side. This would appear reasoning to take advantage of the master. But analyze the matter: How was the dog trained? When the truth of the matter is learned the dog received, every time that he came to all fours behind the table, a morsel of meat; whenever he failed he got no meat. In this case, superficially looking like cunning and reason on the part of the dog is really a matter of training, of experience. So it is with most animal action, though not always purposeful, or even conscious, on the part of the trainer. This does not show reasoning on the part of the dog,

but is rather the result of remembering that if he does an act in such a way he will be rewarded. Science calls this *intelligence*: it is this kind of intelligence that the bee acquires."

After the morning session there was a banquet in the dining hall. Nearly 100 sat down to the dinner, and the hall was filled with the merry din of bee-keepers, each telling the other of his fine crops, the superiority of certain honey-flows, what he will do next season, and a multitude of other bee-keeping tales.

The afternoon session, presided over by Pres. Gates, was called to order at 2 p.m. The first speaker was Dr. Fred Kuhlmann, of Clark University. Dr. Kuhlmann, like Dr. Porter, is a student of psychology, and has made some quite unique investigations of bees, the results of which we believe have never been made public before. This address, without the curves and tables which Dr. Kuhlmann used to illustrate his talk, is not satisfactory, and is best not to attempt to report.

The pith of Mr. Kuhlmann's paper was the "Rhythm of Daily Activity in Bees," and results from watching marked bees for a season, 20 minutes per hour, 24 hours per day.

It will suffice to say that work was done not only with the worker-bees, but also with the queen and the drones. The results are not in accord with the proverbial "busy bee" theory. If the Doctor is right, the bee, individually, works but a very small portion of the day. The busy appearance of the hive is due to a little work by a great number rather than from much work by a few. We hope this paper may soon be published with charts and tables.

The next speaker was Mrs. Florence Richardson, of West Medford, Mass. Mrs. Richardson is Secretary of the Massachusetts Bee-keepers' Association, and spoke on "A Woman's Experience with Bees." She is a most practical "bee-master." She says that she has tried nearly everything recommended by others, and now has the profit of much valuable experience.

Mr. Charles H. Goodell, of Worcester an old-time bee-keeper, read a paper on "The Importance of Bees to the Fruit Crop." While the writer did not pretend to be giving any startling discovery, he emphasized the importance of complete fertilization of apples and strawberries, and of the fruits. It is well known that the apple ovary is 5-parted, and in order to insure a well-filled-out apple, must receive no less than 5 fertilizations. The strawberry, too, is an aggregate of a great number of ovules, and, in order to develop well, must receive some 300 pollen-grains. This work of fertilization is largely the work of bees.

Mr. Arthur C. Miller spoke for modern investigation in bee-keeping. In part he said: "Bee-keeping is very little advanced from what it was 1500 years ago. At that time, in the Sicilian Isles, it was much developed in advance of all other parts of the world. We can not make progress if we religiously cling to the tradition of our fathers, and do not attempt to investigate doubt.

A general discussion followed the

reading of the papers. Single-walled hives, covered with tar-paper instead of air-spaced, or the miserable chaff hive, were advocated by Mr. Miller.

It was concluded that the long section-box is a more salable shape than the older square one.

The interest of the session was so great that it was 5 p.m. before we adjourned. REPORTER.

**Honey as a Health-Food.**—This is a 16-page honey-pamphlet intended to help increase the demand for honey. The first part of it contains a short article on "Honey as Food," written by Dr. C. C. Miller. It tells where to keep honey, how to liquefy it, etc. The last part is devoted to "Honey-Cooking Recipes" and "Remedies Using Honey." It should be widely circulated by those selling honey. The more the people are educated on the value and uses of honey, the more honey they will buy.

Prices, prepaid—Sample copy for a 2-cent stamp; 50 copies for 70 cents; 100 for \$1.25; 250 for \$2.25; 500 for \$4.00; or 1000 for \$7.50. Your business card printed free at the bottom of front page on all orders for 100 or more copies. Send all orders to the office of the American Bee Journal.

**"Songs of Beedom."**—This is a beautiful 16-page-and-cover pamphlet, 6x9 inches in size, containing 10 bee-songs—words and music—all the songs so far written specially for bee-keepers, we believe. It is nice, as well as convenient, to have these songs all in one binding. Every bee-keepers' organization should have copies for use at conventions. They could be sold to members after using once, or held by the secretary for use at future meetings. Of course, every bee-keeper's family will want at least one copy. It is sent, postpaid, for only 25 cents, or 3 copies for 60 cents; or, we will mail one copy with the American Bee Journal one year—both for \$1.10. Send all orders to the office of the American Bee Journal.

**The Sixth Annual Report of the Illinois State Bee-keepers' Association** has just been issued, containing 176 pages. Its contents, besides considerable miscellaneous matter, are the 1906 reports of the Illinois State Bee-keepers' Association, the National, and the Chicago-Northwestern. There are a number of very fine engravings of apiaries, the Illinois State Capitol, etc. Cloth-bound copies were issued for the members of the Association only, and will be sent out as long as they last to any who become members on the payment of \$1.00 to the Secretary, which not only secures a cloth-bound copy, but membership in the State Association one year, and the same in the National Association. A paper-covered copy of the Report will be mailed to any one who sends 15 cents to the Secretary to pay postage and wrapping. We think the Sixth Annual Report is as attractive and instructive as any we have ever issued. General Manager N. E. France says concerning this Report: "It is a credit to all concerned in getting it out."

JAS. A. STONE, Sec.  
Route 4, Springfield, Ill

**Our Wood Binder** (or Holder) is made to take all the copies of the American Bee Journal for a year. It is sent by mail for 20 cents. Full directions accompany. The Bee Journals can be inserted as soon as they are received, and thus preserved for future reference. Or we will send it with the American Bee Journal a year—both for \$1.10. Address office of the American Bee Journal.

Send Questions either to the office of the American Bee Journal, or to  
**DR. C. C. MILLER, Marengo, Ill.**  
 Dr. Miller does *not* answer Questions by mail.

#### STARTING IN BEE-KEEPING.

The Saturday Evening Post of May 25 contained an article upon "Quitting the Strenuous Life," which spoke favorably of bee-keeping as a means to that end. The author, Mr. Forrest Crissey—and I say by way of parenthesis that I am a bit proud of the fact that so excellent a writer was a pupil of mine in the days when I was "schoolmaster"—the author, made mention of my name in such a way that a small deluge of letters has come to me with inquiries upon the subject. To answer by mail is out of the question, and I am sure it will be much better for me to answer in this department, as very nearly the same answer will apply to all, and I can thus answer quite fully.

Wisely, nearly all inquire as to a book of information, and some inquire where, and at what price, the book, "Forty Years Among the Bees," can be obtained. You can get it by sending to the publishers of this paper, George W. York & Co., one dollar. That book gives in detail just how I manage my bees, as well as I know how to tell it, but I do not advise it as a sole book on bee-keeping. If you get only one book on bee-keeping, you can not go amiss to get "A B C of Bee Culture," "Langstroth on the Honey Bee," revised by Dadant, or Cook's "Manual of the Apiary." Either of these you can get from the publishers of this paper by sending \$1.20. They are written in easy, non-technical language, easily understood by one with no knowledge of the subject. Then if you want to get "Forty Years Among the Bees" as a companion book I have no objections to offer. Some make the mistake of thinking that a monthly or weekly publication upon bee-keeping is all that is needed. The periodical is all right along with the book, but if you can have only one, be sure it is a book. The book gives the foundation knowledge that you need, and the periodical keeps you up to the times.

As soon as you get your book, go to work reading. Some things, very likely, you will not understand. Don't worry; skip the hard places. Very likely they will be easier on second reading. If you are a subscriber to this paper, this department is at your disposal, allowing you to ask any questions you like. This department, however, is not intended to take the place of a text-book, but to supplement it, and when you have given your book the second faithful reading you will probably find there are still plenty of things you want to ask questions about. Indeed, one of the beauties of bee-keeping is that you never get to the end; there are always fresh questions arising to keep alive the keenest interest.

No, I don't sell bees, and if I did you shouldn't buy from any one so far away. Railroads generally will not carry bees as freight except in car lots, so you would have to pay expressage, and that's fearfully expensive. Your better way is to buy from some one close at hand, so as to save expressage. By inquiring you are likely to learn of some one within a mile or so who

will deliver them to you. If you can have delivered to you a colony of Italian bees in a movable-frame hive for \$10.00, you will do well. But you needn't be so very particular about the kind of bees or of hive. After you have studied your book you ought to know how to get into a good movable-frame hive a colony out of any kind of a hive, or even out of a cracker-box or nail-keg. You ought also to know how to change in 6 weeks' time from poor scrub stock to Italian blood by paying out only a dollar or two for an Italian queen.

Prices vary a great deal. I said you would do well to get good blood in a good hive at \$10.00 a colony, but you may happen in some neighborhoods to get the same for \$7.00 or \$8.00. For impure blood, especially in poor hives, you may pay \$5.00 or less. You'll have to pay the going rate in your neighborhood.

If you cannot buy conveniently near, and have to send to a distance, then get a 2-frame or a 3-frame nucleus and let it grow. In that case one advantage is that you can have pure Italians to start with. At any rate the expressage will be much less for nuclei than for full colonies. If you buy at a distance, you will likely find in this number of the American Bee Journal an advertisement of a good place to buy.

That leads me to speak of reliability of advertisers. One of you asks if a certain firm selling hives, etc., is reliable. Entirely so; and what's more, I don't know of any of the firms doing business in that line now that are not reliable.

"What is the best hive?" Well, a bee will gather the same amount of nectar in a day whether its home is a gilded palace or a nail-keg. The choice of hives is rather a matter of convenience for the bee-keeper than for the bees. Certainly you must have a movable frame hive, and one of the simplest as well as most popular is what is called the dovetailed hive, the same as the writer uses. If you are going to work for extracted honey, get a 10-frame dovetailed hive. If you're going to work for comb honey—it takes more skill to run for comb honey—you will still do better to have a 10-frame hive, unless you mean to give a great deal of attention to the business, in which case it may be better to have an 8-frame hive.

May or June is a good time to buy, the farther south the earlier. Still you can begin any time during warm weather.

"How many colonies shall you start with?" If you have money to burn, you can start with 100, and then the likelihood is that you will be out of business inside of a year. For most people perhaps 2 colonies is the best number to begin with. You can have a lot of fun with a single colony, but there are advantages in having 2. In any case, please don't think of starting with more than 6.

Now you will not feel hard toward me for not writing you a private letter, will you? I would hardly have got all this stuff into a private letter, and I get so many letters all the time about bees that the only way I can do is to

treat all alike and answer them in print. But don't let that deter you in the least from asking any question to be answered in this department, provided you are a subscriber. If not, better send your dollar to the publishers at once for a year's subscription and enough more to get a bee-book.

#### USING CROOKED COMBS WITH HONEY.

What few bees I had dled out last winter, and they left some combs with honey in. I intend to send for a nucleus in a few days, and I want to give the honey to the bees when they get here. The combs are in bad shape—too crooked to use. How would it do to put them into the hive with a dummy between them and the bees, or is there a better way?

MINNESOTA.

Answer.—Your plan is all right if you will look out for two things; one is, that you must not let brood be started in these crooked frames, and the other that you must not let robbers get a start. Have the entrance very small, and don't let it open into the part where these combs of honey are.

#### UPPER MICHIGAN FOR BEES.

Is the Upper Peninsula of Michigan good for bees?

Answer.—I'm not too sure about exact localities, but I know that in what is called Northern Michigan there are locations that are excellent; the pine lands being burned off and wild raspberry and fireweed coming in abundantly.

#### LATE FEEDING OF THIN SUGAR SYRUP.

The statement of F. L. Day, page 433, that he always feeds his bees all the syrup they need of half sugar and half water after Sept. 20, and that last fall he finished feeding Oct. 1, and no trace of dysentery resulted, certainly comes to me as a surprise. Of course, something depends upon how much Mr. Day means when he says his bees "are fed all the syrup they need." If each colony needs only half a pound to a pound, then there would be no harm expected. I take it, however, that Mr. Day feeds a considerable quantity. However safe it may be for Mr. Day thus to feed, in the face of reports of other cases in which results were disastrous, it would hardly be wise in general to advise such late feeding of thin syrup.

#### WEARING A BEE-VEIL.

You say in "Forty Years Among the Bees" that you wear your veil so that it can be pulled down over your face at a moment's notice. Do the bees always give you the moment's notice? Mine didn't the other day.

IOWA.

Answer.—Y-es, I think it's pretty fair to say that I never fail to have a moment's notice. Well, hardly ever. If I were to be compelled to go and open a hive at this present moment, I would have more than a moment's notice to pull down my veil. You see, I don't need to have notice from the bees always. Just now the fact that it is raw, cloudy, and cold is notice enough before I leave the house. When weather is fit to work at bees, it sometimes happens that the first notice I have that my veil ought to be down is when a bee stings me; but that doesn't often happen. Either by the way the bees appear in the hive or in the air. I generally have time to pull down my veil before I am stung. In fact, unless bees are very good-natured I generally have my veil down anyhow.

## PUTTING ON SUPERS.

1. When you commence to put on the supers for comb honey, would you examine the colony as to signs of swarming?
2. Would you leave in the hive combs containing brood, or take them out?
3. What would you do with any combs that do not contain brood, whether in the brood-chamber or below it or above it?
4. Would you take out all combs found in the brood-chamber and put frames in the place that have only starters.

INDIANA.

Answers.—1. Generally no attention is paid to the matter of swarming when supers are given.

2. In most cases no change is made in the brood-chamber at the time of putting on sections. But in the case where more than one story has been given, all but one story will be taken away at the time of giving sections.

3. I'm not sure whether I fully understand your question. At any rate, on general principles, I may answer that in some cases combs without brood are left where they are, and in some cases taken away. If taken away, they may be used where needed for other colonies, and if not needed at once elsewhere, they may be stored in some safe place away from the bees, although safer from moth if piled up over colonies where the bees can care for them.

4. If I understand this question correctly it is already partly answered in answer 2. If for any reason full combs are to be replaced with frames that do not contain comb, it is generally considered advisable to have these latter entirely filled with foundation, so that the frames may contain no drone-comb.

## MAKING THE T-SUPER.

I made a T-super on trial, but I am stuck in putting in the staples. You say, "Put the middle support exactly in the middle of the super, measuring inside." But I don't make that spacing come right. My supers are 18¼ inches long inside and sections 4¼ x 4¼ bee-way. Now suppose I put the tin exactly in the middle and a section on each side of it lengthwise, then another tin on each side, and another section on each side. This leaves a space on each end. What should be done with those spaces, and where can we nail the flat tins? It seems hard work to get us to understand all there is about the T-super.

MICHIGAN.

Answer.—Your supers are too long. Nail in one end a board ¾ thick, thus reducing to the right inside length, 17¾. Arrange to have the middle T-tin at the middle of this inside length, and the other two T-tins midway between the middle T-tin and the ends. The flat tins that support the sections at each end of the super are nailed directly on the bottom edges of the ends, the super of course being turned upside down while being nailed. In your case one of the flat tins will be nailed on the block that is nailed into the end.

If this doesn't make all clear ask all the questions you like.

## REMOVING BEES FROM A HOUSE-CORNICE.

1. I have 2 colonies in the cornice of a house. How can I get them?
2. Can I take them away several miles?
3. When, and how?

SOUTH DAKOTA.

Answers.—1. It isn't the easiest thing in the world. You must have a ladder, scaffold, or something of the kind to get where the bees are. Enough of the boards must be cut away to expose fully the combs. Cut

out the combs, put them in a basket, or other receptacle, with enough sticks between the layers of combs to prevent crushing the bees. Be sure to get all the comb cleaned out, so there will be no attraction for the bees to go back to the old place, and to make more sure daub where the combs were with carbolic acid. Let the basket hang till evening, so all the bees will be settled in it. Of course you will use smoke, and the work should be done at a season when bees are gathering or there will be a bad case of robbing.

2. Yes.

3. You can take them away the same day or evening, just as soon as all the bees are settled, and there will be a decided gain in thus taking them to a distance, for if taken only a short distance the bees would return the next day to the old place. Taken after dark, the bees will stick to the basket without fastening, or you can sew a sheet around them. When you get them to their new place (better wait, though, till next morning), you can put the bees in a hive, doing as you like about putting part or all of the old combs in frames.

## THE LYMAN METHOD OF SWARM CONTROL.

On page 411 is given the Lyman method of swarm control. I wish to ask you a few questions in relation to his manipulations with his double bottom-board.

1. Would it do not to remove the queen from the rear or old hive for a day or two, as the larger part of the bees would then be in the new hive, and thus make it easier to find her?
2. How would it do to introduce a laying queen in the new hive and let the old queen go on with business in the old hive, sending her bees forward into the new hive until her supplies were exhausted, and thus have 2 queens to supply the one hive so long as the old queen could hold out?
3. If one wanted increase, how would it do to introduce a laying queen into the new hive and remove the old hive to a new stand? How long before the old hive should be removed?
4. Suppose the honey-flow is on, and the bees are slow to enter the supers, how would it do to substitute a super or two of sections, or an extracting super, in place of the new hive, and then in a day or two place the old hive back on its stand and the supers on top, with plenty of room? Would not this manipulation prevent swarming?

5. Can not some of our most experienced bee-men see through Mr. Lyman's double bottom-board the key with which to unlock Mr. Davenport's chest of secrets of which he spoke a few years ago, but failed to reveal?

Many bee-men doubt whether Mr. Davenport made the discoveries he claimed. Let that be as it will, I believe the very things he claimed to have discovered will yet be revealed to us. We have the key already in our hands.

ILLINOIS.

Answers.—1. It probably would work, but hardly so satisfactorily. There would be no brood in the front hive, nothing to make it seem like home to the bees except what was in the super, and the bees would not be so well contented without either queen or brood. If, however, the finding of the queen in the full colony seems too serious a matter, you might compromise the matter in this way: Without paying any attention to where the queen is, put 2 frames of brood with adhering bees in the front hive. Three days later you can tell by the presence of eggs in which hive the queen is. If she is not in the front hive, find her and put her there, and put the 2 brood-frames from the front into the rear hive. If she is already in the front hive, all there is to do is to change the 2 frames of brood. I think this ought to work; but you never can be

entirely sure about a thing till you try it.

2. I don't see any reason why it might not work. No nectar coming in to the rear hive, it might be necessary to supply water in one of the combs.

3. It would be likely to work all right if the rear hive were removed in about 3 or 4 days.

4. If I understand you correctly, the bees are not yet working in supers, and an empty super is to take the place of the front hive. Certainly that would not do for sections, for pollen would be put in them, if not brood. In any case the plan you propose would not prevent swarming.

5. If I remember rightly, no queen is to be found with the Davenport plan, so the Lyman plan can not be the same. I very much doubt if many would use the Davenport plan if it were published.

## CLIPPING QUEENS—5-BAND OR GOLDEN BEES—WEIGHT OF COLONIES, ETC.

1. Are bees more likely to kill a queen after her wings have been clipped, if you have taken her in your fingers, than they are if you clip her wings without handling her?

2. Does it happen very often that the bees will kill a queen after being clipped in any way?

3. When you get a queen for the purpose of introducing, is it not a good plan to clip her wings before putting her into the hive?

4. Are 5-band or golden Italians just as likely to be good honey-gatherers as the 3-band?

5. How much should a colony of bees weigh, hive and all, at the time of packing for wintering on the summer stands, to be sure of plenty of stores for winter? Suppose the hive weighed 21 pounds without bees, honey or comb.

6. How much should the same colony weigh the next spring when pollen is first carried in, to be reasonably sure of its coming out strong?

7. Do bees get much pollen from the "sugar" or hard maple?

8. What color is it?

9. I use full sheets of foundation in my Danz. brood-frames without wiring. It gets a little wavy. Will it straighten down with the weight of the bees after it is in the hive?

10. Which, if any, of the following blossoms do bees get honey, or nectar, from: Chestnut, beech, birch, oak, sycamore, wild cherry, and strawberry?

PENNSYLVANIA.

Answers.—1. Probably they are if there is anything about the scent of the fingers disagreeable to them. But I have held hundreds of queens in my fingers when clipping them, without any bad results.

2. I think not.

3. Yes; if there is any possible danger of the bees being unkind to the queen at the time of clipping, that danger would be obviated by caging her immediately after the clipping; and of course she is generally caged for introduction. A good rule as to the time of clipping is to clip a queen the first time you can conveniently, after you know she is laying.

4. There are some very good gatherers among the goldens, but take them as a whole the 3-bauders probably excel.

5 and 6. It's a trifle dangerous to answer questions of this kind. A colony sometimes will go through the winter on a much lighter weight than others, when there's no apparent reason for the difference. If I give the lightest weight that will ever do, some one will let all his colonies go at that weight, and will lose most of them by starvation before spring. There may be a large quantity of pollen in a hive, which will be of value the following spring; but the extra weight of the pollen will not help any in wintering. Again, there is no small difference in locality and location. There is, also, a

# American Bee Journal

difference in winters. If I must give an answer to your question, I would say that to go through the winter the weight should be not less than 45 pounds on the summer stands. But it would not be at all advisable to go into winter quarters on that basis. The wise thing is to have enough to last through the spring, and 55 or 60 pounds would be a better mark. That would likely allow it to weigh about 45 pounds at the beginning of spring pollen.

7. They do in this locality.
8. It might be called light yellowish with a tinge of green in it. Possibly more green than yellow.
9. It is not likely to straighten.
10. I think they gather from chestnut, wild cherry, and strawberry; I don't know about the rest.

## Well-Bred Queens

Will greatly increase the yield of honey. Am now taking orders for **Cook's Select-Bred Queens**—to be sent as soon as weather permits mailing. Also Caucasian Queens from imported stock.

**Cook's Square Honey-Jar** is the best, cheapest, and most sanitary package for retailing honey. Send for circular and price-list of Hives, Bees, and useful Implements.

**J. H. M. COOK**

70 Cortlandt Street, NEW YORK, N. Y.

The Oldest Supply-house in the East, and only Reliable Goods sold.

10 cents brings sample jar by mail.

17A13t Mention the Bee Journal

## For Sale

50 to 75 cases of two 5 gallon second-hand Cans each. Clean and in good shape. Enquire of C. BECKER, Pleasant Plains, Ill.

22A4t Please mention the Bee Journal.

## Big Reduction in Supplies

Until May 1. Big stock of Dovetailed Hives and One-Piece Sections to draw from. **FREE**—a year's subscription with order amounting to \$15 or over. Send for 32-page Illustrated Catalog—free.

**W. D. SOPER** (Route 3) Jackson, Mich.  
28Etf Please mention the Bee Journal.

## Bee-Supplies and Berry-Boxes

Lewis B ware at Factory Prices. Bee-keepers, club together, send me list of goods wanted, and let me quote you prices, I give the regular discounts. Beeswax wanted. Send for Catalog.

6Etf **W. J. McCARTY**, Emmetsburg, Iowa.

Mention Bee Journal when writing.

## Queens of Moore's Strain of Italians

Produce workers that fill the supers, and are not inclined to swarm. They have won a world-wide reputation for honey-gathering, hardiness, gentleness, etc.

Mr. W. Z. Hutchinson, editor of the Bee-Keepers' Review, Flint, Mich., says: "As workers, I have never seen them equaled. They seem possessed of a steady, quiet determination that enables them to lay up surplus ahead of others. Easier bees to handle I have never seen."

My queens are all bred from my best long-tongued 3-banded red-clover stock (no other race bred in my apiaries), and the cells are built in strong colonies well supplied with young bees.

PRICES: Untested Queens, \$1 each; six, \$5; doz., \$9. Select, untested, \$1.25 each; six, \$6; doz., \$11.

Safe arrival and satisfaction guaranteed. Descriptive circular free. Address,

**J. P. MOORE, Queen-Breeder,**

24Etf Rt. 1. MORGAN, KY.

Mention Bee Journal when writing.

## HAND-MADE SMOKERS

Extracts from Catalogs—1907:

Chas. Dadant & Son, Hamilton, Ill.—This is the Smoker we recommend above all others.

G. B. Lewis Co., Watertown, Wis.—We have sold these Smokers for a good many years and never received a single complaint.

A. I. Root Co., Medina, Ohio.—The cone fits inside of the cup so that the liquid creosote runs down inside of the smoker.

All Bingham Smokers are stamped on the tin, "Patented 1875, 1892, and 1903," and have all the new improvements.

Smoke Engine—largest smoker made ..... \$1.50—4 Inch stove  
 Doctor—cheapest made to use ..... 1.10—3 1/4 "  
 Conqueror—right for most apiaries ..... 1.00—3 "  
 Large—lasts longer than any other ..... .90—2 1/2 "  
 Little Wonder—as its name implies ..... .65—2 "

BINGHAM  
CLEAN  
BEE SMOKER

Pat'd 1875, '92, '93 & 1903

The above prices deliver Smoker at your post-office free. We send circular if requested. Original Bingham & Hetherington Uncapping-Knife.

**T. F. BINGHAM, Farwell, Mich.**

Patented May 20, 1879. BEST ON EARTH.

## ITALIAN BEES FOR SALE

I have 50 colonies of all Italian J. L. Strong stock and Quirin's. All are in good condition in new Danzenbaker hives. Price \$4.50 per colony f.o.b. here. Satisfaction guaranteed.

**BERT GANDER,**

23A4t PANORA, IOWA.

## 3-Banded Italian Queens

J. P. Moore or my own strain. My apiary is stocked with thousands of choice drones that are not kin to my breeding queens.

Queens, \$1 each; dozen, \$10

I guarantee satisfaction, and superior honey-gatherers. **W. M. Parrish,**  
28A4t R. R. No. 8. LAWRENCE, KAN.

## 29 Years Means QUEEN Quality

100 pounds to the colony in a poor year, like last, and 250 to the colony the year before. My Italians are non-swarmer. Every queen purely mated or money back. Circular tells of Italian and Caucasian.

SEtf **A. D. D. WOOD, Lansing, Mich**

 Capon Book Free.

G. P. Pilling & Son Co., Arch St., Philadelphia Pa

## Ideal Hive-Tool—"Best on the Market"

Bee-keepers have long needed a special tool to aid them in properly manipulating the hive-parts during the bee-season. The one shown here does the work to perfection.

Best Hive-Tool

Only 30c, by mail

(This picture is exactly one-half the size.)

DESCRIPTION.—The Ideal Hive-Tool is made of high-grade malleable iron, much like wrought iron, 8 1/4 inches long. The middle part is 1-16 inches wide and 7-32 thick. The smaller end is 1 1/4 inches long, 1/2 inch wide, and 7-32 thick, ending like a screw-driver. The larger end is wedge-shaped, having a sharp semi-circular edge, making it almost perfect for prying up supers, as it does not mar the wood.

## What Some Bee-Experts Say of It.

Louis C. Dadant (son of C. P. Dadant) wrote us May 10, 1907: "Your Hive-Tool is certainly the best on the market, and after having used one of them no bee-keeper would do without it."

In the first edition (1903) of Dr. Miller's "Forty Years Among the Bees," page 58, he says: "Of all the hive-tools I have tried, I like best the Muench tool." On Jan. 7, 1907, he wrote us, saying he thought "just as much of the tool as ever."

Miss Wilson, Dr. Miller's assistant, says this of the Ideal Hive-Tool: "It is an ideal tool. In fact, I don't see how it could be improved upon. I am sure we would feel utterly lost in the apiary without it. . . . You will have to try one yourself if you want to know its worth."

## The "Ideal Hive-Tool" Free as a Premium.

We will mail an Ideal Hive-Tool FREE as a premium to any present paid-in-advance subscriber to the American Bee Journal, for sending us ONE NEW subscription for a year at \$1.00; or we will send the American Bee Journal one year and the Ideal Hive-Tool—both for \$1.20. Price of the Ideal Hive-Tool alone, postpaid, 30 cents.

# American Bee Journal

## A GREAT IMPROVEMENT

Will be found in

## The American Bee-Keeper for 1907

It is profusely illustrated and enlarged, and contains only articles of the most practical as well as scientific nature. A special corps of the best writers has been engaged. The editors are Harry E. Hill and Arthur C. Miller, than whom there are no more practical or experienced bee-keepers in this country. We have published the American Bee-Keeper continually and regularly since 1890.

Regular subscription price, 50 cents a year. One year to new subscribers, 35 cents; three years for \$1.00.

Send for sample copy and our new illustrated price-list of BEE-SUPPLIES OF ALL KINDS.

Guaranteed highest quality at lowest price.

**THE W. T. FALCONER MFG. CO.**  
Dept. B. JAMESTOWN, N. Y.

(Established 25 years.)

Mention Bee Journal when writing.

## Honey and Beeswax

**CHICAGO, May 9.**—Very little honey on the market of any kind. Prices are therefore nominal. A little choice white clover comb sold at 17c, and would bring that at present, but supply seems to be exhausted; even with this scarcity there is no demand for No. 2 grades. Extracted, white, 7@8c; amber, 6@7c. Beeswax in good demand at 32c. **R. A. BURNETT & Co.**

**CINCINNATI, May 23.**—There is no material change in the honey market at this writing. Extracted honey is not moving so rapidly as it could, owing to the cool weather. We quote amber in barrels at 5½@6½c; fancy table honey in crates of two 60-pound cans at 8@9c. For choice, yellow beeswax, free from dirt, we are paying 31c cash, delivered here.  
**THE FRED W. MUTH Co.**

**PHILADELPHIA, May 25.**—The honey market has been quite brisk for this time of the year. The continued cold weather has made both the comb and extracted honey sell much higher than usual. A number of odd lots have been cleaned out of the market. We quote: Fancy comb, 14@15c; No. 1, 13@14c; amber, 12@13c. Fancy white extracted, 7@8c; light amber, 6@7c. Beeswax firm at 32c.

We are producers of honey and do not handle on commission.  
**WM. A. SELSER.**

**NEW YORK, May 21.**—White comb honey is practically cleaned up, and there is very little demand at this time. There is some dark and mixed comb on the market, but no demand to speak of, and some of this will have to be carried over until next season, or sold at a sacrifice. Therefore we cannot encourage shipments of off grades or dark honey at this time. Extracted honey is in fair demand and prices are ruling firm. There is very little new crop arriving as yet from the South, and while it is rather early, we doubt whether we will have any large shipments from the Southern States this season, as we fear there will be a short crop, judging from the reports we are receiving. There is quite a good stock of last year's crop still on the market, sufficient to last until the new crop from various states arrives. There is no change in price as to extracted honey since our last. Beeswax firm and likely to remain so for the next 2 months.  
**HILDRETH & SEGELKEN.**

# C. H. W. WEBER CINCINNATI OHIO

Office and Salesrooms, 2146-48 Central Ave. Warehouses: Freeman and Central Aves.

**INDIANAPOLIS, April 12.**—comb honey is not plentiful, but demand is slack. Fancy white comb brings 16@17c; No. 1 white, 14c; amber, 12@13c. Best grades of extracted honey bring 8@9c; amber, 6@7c. Good average beeswax sells here at \$35 per 100 pounds.  
**WALTER S. POWDER.**

**TOLEDO, May 3.**—There is very little demand for comb honey as is usually the case at this season of the year. Fancy white would bring in a retail way 16@17c; No. 1, 15@16c, with no demand for dark honey. Extracted is very scarce and none being offered for sale. Beeswax is bringing 28c.  
**THE GRIGGS BROS. & NICHOLS Co.**

**KANSAS CITY, June 1.**—The honey market is almost bare of comb honey, and demand good; receipts of extracted are light, and demand light; we quote: No. 1 white comb, 24-section cases, \$3.25; No. 2, white and amber, \$2.50@3.75. Extracted, white, per pound, 8c; amber, 7½c. Beeswax, 30c.  
**C. C. CLEMONS & Co.**

**DENVER, Feb. 14.**—Producers in this State are practically closed out of both comb and extracted honey. We have not sufficient good comb honey to supply our local trade, but have a good supply of white extracted of excellent quality. We quote strictly No. 1 white comb honey, per case of 24 sections, at \$3.20; No. 1, light amber, \$3; and good No. 2, \$2.80. White extracted, 8@8½c per pound; light amber, 7½@8c. Clean, yellow beeswax, 27@28c, delivered here.  
**THE COLO. HONEY-PRODUCERS' ASSN.**

**CINCINNATI, May 21.**—The market on fancy white comb honey is entirely bare. No. 2 is selling slowly at 12c. Extracted, light amber, brings 5½@6c. Beeswax is selling here at \$35 per 100 pounds.  
**C. H. W. WEBER.**

# HOW TO PAINT

Buggies, farm wagons, farming tools, barns, outbuildings and houses often need painting. "Everybody's Paint Book," written by a thoroughly practical painter, will be found a complete guide to the art of outdoor and indoor painting. It is designed for the special use of those who wish to do their own painting. It gives practical lessons in plain painting, varnishing, polishing, staining, paper hanging, kalsomining, etc.

It also tells how to renovate furniture and gives many hints on artistic work for decorating a home. Precise directions are given for mixing paints for all purposes.

If farming tools and farm vehicles are kept painted, they will last twice as long, and anybody can do the work with the aid of this book. It is handsomely and substantially bound in cloth. A copy will be sent postage prepaid on receipt of price. **\$1.00**

## SPECIAL OFFERS

For \$1.60 we will send the above book and the Weekly American Bee Journal one year; or for \$1.40 we will send the Paint book and a Standard-Bred Untested Italian Queen. Address **GEORGE W. YORK & CO., 118 W. Jackson Blvd., Chicago, Ill.**

50 to 75 cases of two 5-gallon second-hand Cans each. Clean and in good shape. Enquire of C. BECKER, Pleasant Plains, Ill. 22A4t Please mention the Bee Journal.

## Queen-Clipping Device Free!

The MONETTE Queen-Clipping Device is a fine thing for use in catching and clipping Queens' wings. It is used by many beekeepers. Full printed directions sent with each one. We mail it for 25 cents; or will send it FREE as a premium for sending us One New subscriber to the Bee Journal for a year at \$1.00; or for \$1.10 we will mail the Bee Journal one year and the Clipping Device. Address,

GEORGE W. YORK & CO., CHICAGO, ILL.

"If goods are wanted quick, send to Pouder."

Established 1889

## Full Value, and Then Some

By the Bee-Crank

It is the easiest thing in the world to make promises in an advertisement that it is impossible to fulfill. Indeed, the temptation to do so is so strong that it requires care to avoid it. I have always tried to lean toward moderation, rather than exaggeration.

Instead of complaints of scant treatment, I have received from my customers many letters like the following:

PERU, IND.

WALTER S. POWDER, Indianapolis, Ind.

Dear Sir:—In my capacity as distributing agent for your Bee-Supplies I have been mentally scanning the past. You have sent me value received for every dollar that I have ever sent you, and with each shipment some extras thrown in, in the form of promptness, accuracy, care in packing, and so forth. I sincerely thank you for your tokens of appreciation. You will please fill the following order.

Very truly yours,

GEO. S. DEMUTH.

I would rather publish a statement of this kind from an unbiased customer, telling what treatment he had actually received than a dozen pages of promises.

Root's Goods at Root's Prices. I give you the advantage of freight-saving, prompt, careful service, and quick deliveries because of special shipping facilities that are equaled by few cities in the country outside of Indianapolis.

Send for my Catalog. It is full of illustrations and descriptions of devices that interest the bee-keeper.

Beeswax Bought. Highest market prices paid. Send by freight or express according to size of package, and attach your name.

Walter S. Pouder 513-515 Massachusetts Avenue INDIANAPOLIS, INDIANA

### ROOT OBSERVATION HIVE

In recent years there has been an ever-increasing interest in bees as a subject for nature study in the schools, and a corresponding demand for observation hives to facilitate the study of bees at work, without exposing the student directly to them, as is necessary with ordinary hives. To meet this demand we offer several styles and sizes of observation hives. These are made with skeleton frame, with glass in sides and ends of the brood-chamber, and in sides only of the super. Shutters are provided to cover the glass. These shutters have brass rings to handle them by and brass buttons to hold them in place. Brass hooks are also provided to hold the several sections of the hive together. The hives are finished in the natural wood, oiled and varnished, and altogether they are very attractive in appearance. We furnish them regularly in 8-frame, Langstroth depth. The super is fitted for the 4x5x1 $\frac{3}{8}$  plain section. Hives are usually furnished put together and finished. We can supply material in the flat, but it is work for a cabinet-maker who understands his business to put them up, and we do not care to furnish them in flat unless you order one complete as a model.

The bottom is no longer than the hive, and a covered extension is provided to lead the bees out-doors under the window-sash or other opening provided. In the full-sized hive a colony of bees can be kept by a window the year round, or for only a part of the season, as may be desired. The work of the hive, including the building of comb in the sections, can be watched at intervals without opening the hive or disturbing the bees. For work in the school-room before a class we recommend the one-frame hive. With the one-frame observation hive it is necessary to remove the frame of bees and put in a fresh one about once a week at least, for the best results. As a rule, arrangements may be made with a local bee-keeper to provide a frame of bees each Monday morning, returning at end of week.

*Observation Hive Inside a Room with Entrance under the Raised Sash.*

*Observation Hive with Panels Removed.*

We make one-frame observation hives for L. frames or for Danz. frames and a row of sections above, or the L. frame with a row of sections above. These are provided with a wood case to slip over to shut out the light when you are not watching the bees. We show this one-frame hive and the case in accompanying illustration. This consists of turned-wood corners with glass inserted in grooves in ends as well as the sides.

For work in the school-room before a class we recommend the one-frame hive. With the one-frame observation hive it is necessary to remove the frame of bees and put in a fresh one about once a week at least, for the best results. As a rule, arrangements may be made with a local bee-keeper to provide a frame of bees each Monday morning, returning at end of week.

### PRICE-LIST OF OBSERVATION HIVES

Observation Hive (8-frame), complete with super, including frames, sections, glass—and bees with queen .....	\$15.00
Observation Hive (8-frame), complete with super, including frames, sections, glass—no bees.....	7.50
Observation Hive (8-frame), without frames.....	7.00
“ Super “ complete, with sections.....	2.50
“ Hive “ without super.....	5.00
“ Brood-chamber, complete, with frames—no cover or bottom .....	3.75
Observation brood-chamber without frames.....	3.25
One-frame Observation Hive for Danz. frame, no super, with case .....	2.50
One-frame Observation Hive for Hoffman L. frames, no super, with case.....	2.50
One-frame Observation Hive for Danz. frames, with super, with case.....	3.00
One-frame Observation Hive for Hoffman L. frames, with super, with case .....	3.00

(For bees and queen in one-frame hive, add \$3.00.)

*One-frame Observation Hive with Case Removed.*

Vol. XLVII—No. 25

## Editorial Notes and Comments

### Invention of Movable Frames

The editor of the *Far-Western Bee-Keeper* wields a facile pen, his matter and manner both good, but surely he must have been napping when he wrote: "Dzierzon was the man who first made bees build combs on slats, and starters, which was the beginning of the movable frame."

If credit is to be given for what was done previous to the invention of the movable frame by Langstroth in 1851, as "the beginning of the movable frame," why not go back to the "beginning" at an earlier date of combs built on slats? In Dadant's *Langstroth*, paragraph 282, occurs the following:

"The bee-keepers of Greece and of Candia seem to have been the first to provide their hives with movable bars, under which bees suspended their combs. Della Rocca mentions these, and gives some engravings of them in his work, published in 1790. In 1838, Dzierzon revived this hive and improved it."

### Virgin Loafing on Her Wedding-Trip

The distance to which a virgin flies on her wedding-trip is a matter of practical importance, the question often being asked how far it is safe to be from other bees to make sure virgins shall not meet drones from them. It has been advanced that by noting the length of time a virgin is absent from the hive one can figure upon the distance she has flown. That this is not to be depended upon is shown by the following testimony from Thomas Johnson in the *British Bee Journal*:

In one case the queen, returning, missed the board and settled heavily on the brick wall, where she remained while I fetched a hand-magnifier from the house and examined her as she sat. Under the glass the drone-trail (a silvery-looking filament) could be plainly seen. The queen remained so long on

the wall brushing herself that I began to think she was disabled, but on touching her she took wing, and, after taking one circling flight around the yard, she entered her own hive, and is now at the head of an excellent colony from which I hope to rear more queens this season.

This experience is, I think, valuable, because it is evidence that when a queen is absent on her mating-flight, it is by no means certain that she is on the wing the whole time. While the watching bee-man imagines her flying miles from home to consort with a favored drone from a distant apiary, she may be sitting preening her ruffled "feathers" within his reach, but unnoticed.

### Bees and Colors

On another page in this number will be found an article of much interest discussing the color of flowers as related to bees, written by Prof. Gaston Bonnier. It was sent by Mr. Stadler Menhall, as a clipping from the *New Orleans Times-Democrat*, and was, no doubt, translated from the French. Prof. Bonnier stands high in the council of bee-keepers in France, and what he says is worth considering. He is not likely to antagonize the views of such an authority as Sir John Lubbock without thinking he has good ground for it.

The question whether bees go by sight or scent is an interesting one. When one observes the actions of would-be robber-bees in the apiary, they will be seen sneaking about cracks between hive and cover, where certainly they can see no honey inside, but no doubt can smell it. But watch closely at a hive where desperate attempts are being made to break through, and while most attention may be given to the cracks, one will often see a cluster of bees attacking a solid knot on the side of the hive. Sight, not scent, evidently in that case.

Look again at the bees upon the flowers.

Here is a flower that has just been rifled of its sweets, and a bee comes along, looks it over, and quickly leaves it without getting anything from it. Was not the bee, in that case, attracted by sight? Or was there just enough nectar to attract by its odor, and not enough to be worth spending time upon it?

It is quite possible, indeed probable, that both sight and scent play a part, but the careful investigations of Prof. Bonnier seem to give to scent the chief part.

### Metal Frame-Spacers

The chief objection urged against metal frame-spacers has been that they would injure the uncapping-knife. Producers of comb honey have protested that it was unfair to them, since their combs were never used for extracting, to deprive them of the advantages of metal spacers just because such spacers might be objectionable when extracting. Now comes Editor Root, who goes so far to think it possible that metal spacers may even be allowed on extracting-combs. He says (*Gleanings*, 754):

The oft-repeated objection to metal spacers, to the effect that they will interfere with the uncapping-knife, exists more in the imagination than in fact. There are not wanting extracted-honey men who use metal spacers of various sorts; and when we have talked with some of them on the question whether they dulled the uncapping-knife edge on these spacers, they ridiculed the very idea. One of them in particular made the remark that "any one who would dull his knife on a small projection at the end of the frame must be a blundering manipulator." Unless some one will actually testify that the metal spacers make uncapping difficult and annoying, let us scatter this man of straw to the four winds.

### "Bees Exterminating Bugs"

C. G. Chevalier sends the following item with the above heading, clipped from the *New York Herald*:

Professor S. J. Hunter, of the Entomological Department of the [Kansas] State University, who, for the past month, has been collecting and sending free to the farmers of the Southwest, parasite bees to kill the green bugs that have been destroying wheat, received a telegram to-day from Secretary of Agriculture Wilson at Washington, asking for full particulars of this work.

Professor Hunter replied that he had distributed 2000 boxes containing the parasites

to Kansas farmers with uniform good results, but that a larger fund was needed to make the work comprehensive and decisive. Reports from Texas and Oklahoma are that the bees have practically exterminated all the bugs in those States.

The likelihood is that the item is substantially correct, only the reporter in the case is not an entomological expert. It is not likely that any bee is a parasite, neither is there any parasite in the case. Put "lady-bug" for "parasite bee," and the story is probably all right. It is well known that the larva of the lady-bug is quite fond of green lice.

### Takling Surplus in Olden Times

Dr. Follenius says in *Prak. Wegweiser* that the introduction of movable combs was the beginning of taking surplus honey in the fall instead of in the following spring. However, that may have been in Germany, was it not the custom in this country to "take up" in the fall, before movable frames were known? The heaviest and the lightest colonies underwent the brimstone ordeal; the heaviest because they had the most honey, and the lightest because they were not likely to survive the winter.

to have 115,000 readers—which contained the following clipping, which I take the liberty to submit. I think it is stretched a little, otherwise the climate around Preston, Minn., must be more suited for bees than anywhere else that I have heard of. Here is what Mr. M. V. Facey says in *The Farmer*:

"It is not possible to estimate accurately the amount of income to be derived from the honey-resources of the farm, but it is certainly much greater than our most extravagant estimates. In proof of this I will present a few facts as they have come up in my experience.

"First example is a field of buckwheat of only 5¼ acres, to which a yard of 30 colonies of bees had access. No other buckwheat was near, and the bees most clearly devoted their whole attention to the only available field. It was very much alive each forenoon, and the bees gathered between 750 and 800 pounds per acre therefrom, or an income from honey alone of over \$40 per acre. Wild buckwheat will often do as well.

"It has been estimated that a large, thrifty, well-flowered basswood will fully supply a colony during its flow, and I do not think the estimate is out of the way. When clover is secreting nectar, a field of 15 or 20 acres of thick white or alsike clover will keep a good-sized apiary going."

I will be listening with upstretched ears to hear what our "Afterthinker" thinks about the Minnesota climate. I think even Mr. Alexander, of New York, will think, and even say, "That was a bumper report."

The weather here has changed to the better—warm, nice weather all last week. We had a warm, nice rain yesterday and to-day.

CHAS. O. BERGSTRAND.

As Mr. Facey is a reader of the *American Bee Journal*, we would be pleased to have him to tell us more about the report he sent to *The Farmer*. Just what an acre of bloom can be depended upon to yield in the shape of honey is an interesting problem. It comes up for solution quite frequently. Perhaps Mr. Facey has the right answer.

### The Song of Songs

Poets write of honeysuckles, roses red and lilies white,  
Of forget-me-nots and bluebells, and of daises fair to see;  
But of all the flowers in all the world in which men take delight,  
The basswood and white clover are the sweetest far to me.

Artists paint the towering mountains with their frozen caps of snow;  
Picture mighty icebergs floating in the heaving Arctic Sea;  
But I love the springtime picture when the earth is all aglow,  
And the air is filled with fragrance of the blooming apple-tree.

People rave of song of nightingale, of bobolink and wren,  
Of the oriole and robin nesting in the shady tree;  
But the song of songs—the melody excelling birds and men—  
Is the song of the home-coming, nectar-laden honey-bee.  
Bellevue, Mich. C. H. BENSON.

**Our Wood Binder** (or Holder) is made to take all the copies of the *American Bee Journal* for a year. It is sent by mail for 20 cents. Full directions accompany. The *Bee Journals* can be inserted as soon as they are received, and thus preserved for future reference. Or we will send it with the *American Bee Journal* a year—both for \$1.10. Address office of the *American Bee Journal*.

## Miscellaneous News - Items

**An Average Honey Crop** is now promised for the orange-growing district in Southern California. Mr. John Stewart, of San Bernardino county, sent us the following item taken from the *Los Angeles Times* of June 5:

The honey crop, which is now being gathered, is proving that this is an average season for apiarists, although many cloudy days have decreased the yield of nectar. There are a number of apiaries in the vicinity of Redlands, and these first June days are busy ones for the bee-men.

The season promises to be an average one notwithstanding the cold, wet winter. The fogs are as bad for the bees as rains, for the insects will not work in the fog except in rare cases.

The black sage of the canyons has been the source of most of the honey gathered in the past few weeks. This flower produces the clearest and most delicious honey, which brings the highest price. Next comes the white sage, which makes just as good and nutritious an article, but not quite so white.

The "Muth Ideal Bee-Veil" appears again this week on page 558. It is put out by The Fred W. Muth Co., of Cincinnati, Ohio. The illustration shows the veil so well that a description is hardly necessary. We may say, however, that the center part is made of very light wire-cloth, which is far ahead of the common limp cotton or silk netting which is so often blown against the face so that the bees can easily get at you. This Muth veil is very cool and pleasant to wear. We bespeak for it a large demand among bee-keepers.

**A "Pancake Turner" Comb Leveler.**—We have received the following:

Herewith I send a crude drawing of a little affair that I think is the best comb leveler that I know of. I have used such as have been advertised, but do not think them as good for the purpose as this. I discovered this by experimenting.

Get a common pancake-turner, cut the sides on a slant back to the handle, and round the end of the blade slightly. This can all be done with a pair of tinner's shears. Turn it upside down so as to make a smooth surface

on the underside, grind the upper edge to a bevel, and file fine, sharp teeth in it, and the thing is ready for use.

After taking the section in hand place the leveler in the bee-way space and vibrate it from side to side. It will cut as neatly as the reaper sickle does grain.

I send in a separate package some of the clippings which will give an idea of the work it does. I have used this for the last 2 years, and am well pleased with it.

Some time during last year I sent a drawing to the A. I. Root Co., and they seemed to think it very good. I shall prosecute no one for infringing upon my rights, if he should think enough of it to try it.

My bees are doing splendidly in the way of brood-rearing just now; in fact, many of them are very strong. I have sold 2 colonies for \$10 each. Wm. M. WHITNEY.  
Walworth Co., Wis., May 29.

This differs from the Taylor handy comb-leveler in that it allows one to cut down objectionable surface of the comb wherever it may be, without cutting down the whole surface to the same level. Also, the whole work is in sight, allowing one to know just how deep he is cutting.

**The Apiary of N. P. Anderson**—We have received the following from Mr. Anderson in reference to his apiary, which is shown on the first page:

The picture of my apiary was taken during the fall of 1906. It contained at that time 36 colonies, having increased from 15, spring count. A part of the colonies were worked for comb honey, some for queen-rearing, and most of them for increase.

The honey crop of 1906 was very light, and here in Minneapolis it closed with the basswood, while a few miles from here, in the country, the bees worked on white clover for 10 days after the basswood ceased; this made my honey-flow very short, and left many unfinished sections; but those will come handy as bait for this year. N. P. ANDERSON.

**Amount of Honey Per Acre.**—Charles O. Bergstrand, of Amery, Wis., wrote us as follows on June 10:

EDITOR YORK:—To-day I received a copy of *The Farmer*—a Minnesota farm paper said

Conducted by J. L. BYER, Mount Joy, Ont.

Queens in Supers

One of the things I could never understand, is *why* Mr. Dadant's queens do not go into the supers where no excluders are used. Is it locality, race of bees, or what? Certainly it is not size of hive, as the hive I use is considerably larger than that used by Mr. Dadant, yet the queens will go into the supers every time where no excluders are used. As intimated, the majority of my bees require supers at once, and on Friday, May 24, the weather having moderated a little, a super of brood-combs was put on each of 4 very strong colonies at the home yard. No excluders were put on, as I wished the queen to occupy these combs so that they could be used for nuclei later on in the season. Friday night the weather turned cold, and remained so till Wednesday evening; yet on examining these supers on Wednesday—more out of curiosity than anything else—sure enough, the queens had established a brood-nest already in the upper stories, one colony having 3 combs (Quincy dimensions) nearly full of eggs.

A Backward Season, Spring Dwindling, Etc.

FRIEND BYER:—As the season advances (backward) in this locality, prospects do not look at all promising. The bees are doing just a little better than holding their own. I am consoling myself, however, that it will not be necessary for me to buy a gasoline engine to turn my extractor this season.

FEEDING FOR SPRING DWINDLING.

I had a little experience with a case of spring dwindling a short time ago. The bees from several of my strongest colonies were crawling in great numbers through the grass. I picked up a few of them and found they were filled almost to bursting with pollen. I examined these hives and found them nearly bare of honey. When I commenced feeding, the "dwindling" disappeared. I suppose the bees were trying to eke out a living on pollen. Evidently bees "can not live by (bee)-bread alone."

BEES MOVING EGGS OR LARVÆ

I believe I had an example last season of bees moving eggs or larvæ. A colony with an extracting super over an excluder swarmed. I hived the swarm on the old stand, and during the operation I happened to lift a frame

out of the extracting super where I found 2 fine queen-cells. There was not another cell of brood in that super, nor had there been. The combs were built in the super from foundation, and were perfectly white, except for those queen-cells. Did the queen squeeze through the excluder just to lay 2 eggs, and then return to the brood-nest?

CARELESS BEE-KEEPERS.

I think fully 75 percent of the bees of this locality are dead, and the most of them went under this spring. I pity the bees, but have mighty little sympathy for the bee-keepers (?) who allow their bees to die from neglect. I tell you, Mr. Byer, we can work to get laws to suppress foul brood, but when we get laws to deal with careless, heartless bee-keepers, and weed them out of the business, foul brood inspectors will be a thing of the past. However, a poor season followed by a hard winter probably does the "weeding" far better than any law.

I hope you will have a prosperous season, and that the present prospects are not telling the truth for the bee-keepers of Ontario in general.

H. A. SMITH.

Palermo, Ont., May 27.

Yes, the season is certainly a record-breaker. As I write (June 1st), we have a fire going in the house as though it were March instead of June. Apple-blossoms are not open yet, and clover is correspondingly late. Yet, for all the bad weather, bees that wintered well have more than held their own. The majority of my colonies are as strong as usual at this time of the year. In fact, I hardly know what to do with them in order to keep back swarming.

The weather has been so steady cold that we have had only a few days fit to open hives. I hesitated to unpack the hives, and now find about one-fourth of the colonies have queen-cells started.

The case you mention would seem to prove beyond a doubt that bees do move eggs and larvæ. Personally, I have been convinced for some time that such a feat was quite possible.

As to pollen injuring the bees, after thoroughly examining the combs of honey left in hives where our bees died from dysentery last winter, I feel pretty sure that too much pollen was the cause of the loss, and that the small quantity of honey-dew present in the hives was only a minor factor in the business. All during the clover flow last season the majority of the bees coming in would have pollen, and although the most of this pollen was sealed over, yet with an exceptionally steady winter, and the absence of a suitable day for a cleansing flight, the excess of pollen brought on dysentery early in February. Most of the colonies that perished left from 20 to 30 pounds of stores in the hives, and when a portion of the comb is uncapped the majority of the cells have pollen in the bottom.

Please Mention Bee Journal when writing advertisers.

Conducted by LOUIS H. SCHOLL, New Braunsfels, Tex.

Cheap, Suitable Bee-Veils

There are many kinds of veils, and one is apt to find this out if he travels and visits among bee-keepers. But there are good veils and bad ones. A crude veil, much used, is that made of wire-screen cloth, generally fastened to the edge of the rim of an old hat. To the lower edge of the wire-cloth is sewed a width of cloth which falls over the shoulders and is fastened so the bees can not get in. For me, such a head-gear has its faults. First, it is rather bulky or heavy; it is warmer than some of the other veils, and the

screen-wire hurts the eyesight to a great extent. It is also quite cumbersome to take along from place to place.

I should prefer something that can be folded up and carried in the pocket, like the silk and cotton tulle veils generally listed in the catalogs. These I have used for years, after trying many kinds. There is an objection to the material these veils are made of, however. The all-silk veil is rather more expensive, and soon wears out. Those made of cotton tulle obstruct the vision too much on account of the heavier material. To remedy this, cotton tulle veils are made with a silk face, a

square piece of silk tulle being sewed in the veil so it will come in front of the wearer's face when worn. This is the kind I have used most, but the silk facing is not desirable enough, and soon wears out, like that of the all-silk veils.

Needing a number of new veils this season, I looked around for some material that would be better suited for the purpose than the cotton tulle especially made for bee-veils—something that would not interfere with the vision as much—and it had to be stronger than the silk veiling.

The only thing "on the market" was different grades of bobbinet, commonly used for "mosquito-bars," but this material was "all white." The prices ranged from 20 cents to 30 cents per yard, the material being over 2 yards wide. The 20 cent material gave me enough for 3 large veils for 30 cents, or 1½ yards. This made the veils long enough to come well down over the shoulders, which most of the finished veils do not do.

Five cents worth of black diamond dye made this white material as nice for bee-veils as could be desired. After coming out of the dye the piece of bobbinet, still uncut, is stretched to dry. This leaves the meshes large and open, and the threads of the material well stretched, making the finished veil much more open to the eyesight and cooler than the regular black cotton tulle, more durable, and very much less expensive than the silk veils.

A plain white cord is sewed in large stitches in the end that comes over the hat, and serves as a draw-string, tied in a bow-knot to adjust to different sizes. A rubber-cord or elastic may be used, but it wears out. Nothing is done with the lower edge, which falls over the shoulders and is pinned down to the front of the shirt with a large safety-pin. My aim is to make these veils "good enough," and as cheap as possible, and I think I have accomplished this, as 35 cents worth of material and a little sewing for 3 veils—a dozen cost just \$1.40, and a little more sewing.

## Shallow Hives

The plain, sensible way in which Mr. Scholl has recently discussed the shallow hive, its advantages, etc., makes one almost wish he had his bees *all* in shallow hives. But the very thought of having so many of these little shallow hives and frames to put up and handle for extracted honey, to be the equal of say one 3-story Langstroth hive—well, what would we have to do to rig up an apiary of say 100 hives of this class? Oh, I don't know; it fairly staggers me to think of it, Mr. Scholl.

With no desire to get up a hive discussion with any one, I would say to the average beginner to go slow on changing from the Langstroth hives to the shallow hives. They are all right perhaps for the expert bee-keeper, but for the novice I would say, try only a few, and then they will be used only as supers on the standard hives with 9 out of 10 in less than 5 years.

It has been said by some writers that they never knew any one that gave the

shallow hive a thorough trial that ever went back to the Langstroth hive. Let me say to that writer, that I do not know what *all* the bee-keepers have done, but I do know of a number that

have given up the shallow hive in disgust, and W. Z. Hutchinson is one of them. I could give the name of others if it were necessary. L. B. SMITH, Rescuer, Tex.

The "Old Reliable" as seen through New and Unreliable Glasses,  
By E. E. HASTY, Sta. B. Rural, Toledo, Ohio.

### THAT FRENCH RECORD OF SWARMS.

Like the proverbial dog barking at a squirrel-hole, I incline to return to that French record of swarms. It is of use to us to fix the degree of temperature below which we need expect only occasional swarms. They fix it at 68 degrees. Only 11 percent swarmed when it was cooler than that. Their bees are more accustomed to temperature below 68 degrees than ours are; so we are not likely to have more than 11 percent below that figure. I have no records of temperature with which to compare.

They never could catch a swarm coming out when it rained. Same here. In my total experience of some 3000 swarms, I have had just one that got on the wing *just before* a misty, fine rain began, in which water fell quite fast. It was interesting to see that they paid no attention to the rain—or next to none—took their own time to cluster.

Another thing is the same here: Wind has a very repressive influence, although not entirely prohibitory like rain and cold. Their finding is that only 18 percent swarm when it is windy. Don't believe the figure would be quite as high as 18 at my yard; but of that I'm not sure. Manifestly the figures of this point don't depend wholly upon the bees, nor yet on the continent and nation. At a yard so blest as to have no winds in swarming-time, the percentage would necessarily be 0. And the yard with stiff breezes every day would have a percentage of 100.

I do not agree with Mr. Getaz that they vitiated their barometer observations by not observing the other points of the weather in the same connection. Something still left. Useful to us to be able to say in the morning: "Barometer high; this will be a swarmy day—other things being equal; or, "Barometer low; this is likely to be a non-swarmy day, as compared with other similar days." Page 391.

### SOME THINGS THAT INFLUENCE SWARMING.

Sunshine, cloud and shade are three words to conjure with, and so they proceed to conjure with them. Just to say things off-hand without records, I

should say sunshine is decidedly promotive of swarming, and cloud somewhat repressive, *but only slightly so if the temperature is high*. As to the shade of trees, I think the total number of swarms is decreased but little by it—such shade merely making the swarms a little later in the month and a little later in the day. Still a possibility that I'm wrong in that, however.

Very likely, as Mr. Getaz suggests, young queens in France would show a less swarmy record were it not that their hives are generally very small. But still, I shouldn't wonder if our folks have been overrating quite a bit the repressive influence of a young queen. Some *almost* want to say that colonies with a young queen never swarm. Here's a good point for our boys experimentally inclined to strike in at—and find out just how it is at our house.

I should call the dictum of Mr. Thibault, that no colony swarms when there are no drones—I should call that a pretty good-sized mistake. Successfully exterminate, and keep exterminated, all the drones of a colony and it would be more likely to swarm than if left alone—if you let me judge. That the colony that doesn't try to rear drones will not swarm—I guess that's probably so. Also another thing may be so: If a colony's own drones are all exterminated, some may come in from other quarters. Of 10 such colonies suppose you find 5 with quite a sprinkle of immigrant drones and 5 with none. The 5 that immigrant drones find it pleasant to stay in are the ones that are intending to swarm, I guess. Or is this getting too far into the domains of the fanciful?

They found that 30 percent refrained from swarming from hives with about the capacity of a cubic foot, and 70 percent from hives with a capacity of 2 cubic feet. Just about what we would expect over this side—but swarmy locations worse, and some locations better. Page 391.

### BREEDING NON-SWARMING BEES.

That some colonies swarm themselves into tribes in the course of the years, and some other colonies disappear, progeny and all—that's one of the least thrashed out. Perfectly cor-

(Continued on page 553)

## Nucleus Method of Increase

BY G. M. DOOLITTLE

A correspondent wishes me to give him a plan in the American Bee Journal whereby he can increase his 4 or 5 colonies to as many as possible for wintering the coming fall. Well, here is the way I have done something of the kind in bygone years, when I was anxious to increase a few colonies to as many as could well be done:

I first get out boxes of suitable sizes, according to the size of the colonies I wish to make, holding from one pound of bees up to 6 or 8, the latter being a very large swarm. For ordinary nuclei nothing is better than a 20-section shipping-case nailed up, and leaving off the side strips that hold the glass. On one side of it, where the glass would go, I permanently nail on a piece of wire-cloth, and for the other side nail a piece of wire-cloth the same size as the first, to 4 strips of suitable length, so these strips surround the wire-cloth as a slate-frame does a slate.

Now, with 4 small wire nails (one in the middle of each strip) I tack this wire-cloth frame to the opposite side of the box, when I have what I term a "nucleus-box," one side of which can be removed at any time with the blade of my jack-knife. I next had a tinsmith make me a very large funnel, 18 inches across the top, with the usual slope of side, coming down to a 2½-inch upright, or outlet, which was about 2½ inches long. Having the funnel made I pressed the top together from opposite directions till I had it oval at the top about one foot wide and 22 inches long, in the diameter of the two ways across the top. It was fixed thus so as to collect in the bees better, when they were shaken from the frame, than would be done if left in the ordinary shape.

I then bored a hole in the top of the nucleus-box, which would just let the small or upright end of the funnel into it, and over this hole I fixed a slide to cover it when the bees were in and the funnel out. In one end of the box is fastened a section of honey, of those that were not quite salable and left over from the year before, the same being held in place by a screw going through the end of the case and screwing into the section. This is for feed for the bees should they be kept in the box longer than the honey they take with them lasts, as is quite often the case. This completes the box and funnel part.

I now boomed ahead as fast as possible the colonies I wished to increase, by using any of the plans given in the books for keeping them warm, stimu-

lating, etc., and as soon as one became strong enough I prepared it for queen-rearing, as I have given in the bee-papers and in "Scientific Queen-Rearing," continuing to rear queens from this colony as was required; for queens can be so reared and not hinder the colony from contributing its share of bees for increase as well as the others, as the queen is laying all the time in it. This gets us along much faster than where a colony is to be made queenless to provide queens, as is advised by most of the other plans of rapid increase. With this plan no colony is made queenless at all, but all queens are kept laying at their best all the time.

As soon as any of the colonies are full of bees so they can spare bees from 2 frames, or from half a pound to a pound, and there are ripe queen-cells, take the cells out and put them in the queen-nursery to hatch. As soon as the queens are one or two days old, go to the hives which can spare bees, take from each 2 frames, being sure the queen is not on either of them, and shake the bees from them down through the funnel into the box, doing this at about 10 a. m. Having the bees in the boxes, set them in the cellar or in some shady place where outside bees can not get at the bees which are confined, leaving them till about 5 p. m.

Now get a virgin queen for each box, putting each in a cage having a stopper in it filled with queen-candy, so that it will take the bees about half a day to eat out the candy and liberate her. Take these queens to the boxes of bees, picking each up in turn and suddenly setting it down, when all of the bees will fall to the bottom, when the funnel-hole is quickly opened, the caged queen put down through it, and the cage secured by means of a bent wire clamped between the slide covering the hole and the top to the box. Then close the hole, the cage hanging about one inch below the under side of the top to the box, so the bees can cluster all about it while they are hanging in a cluster, as they soon will be.

After the queens are all in the boxes in this way, they are to be set away where they can remain undisturbed till near sundown of the next day but one, or allowing the queen and bees to remain a little more than 2 days in the box, when the bees are found all contented with their new queen, and hanging to the top of the box like a swarm.

I now go to the hives that can spare it and take as many frames having a small amount of brood in them as I have boxes of bees, shaking all the bees off from each and replacing with a frame of empty comb. Put one of these frames in a hive where you wish

your new colony to stand, together with a frame of honey, or enough in it to secure the bees from starvation, and another frame of empty comb, placing the one having brood in it in the center. Having each hive thus fixed, the bees from one of the boxes are to be put in each. To do this, lower the box down into the hive near the outside comb, and with a knife pry the wire-cloth frame off enough so the bees can run out freely on the combs, when the hives are to be closed and the entrance adjusted to suit the size of the little colonies.

When the full colonies are strong enough to take more bees from them, get the boxes, now free from bees, fixing them and proceeding as before. As the season advances one little colony can be formed from each decent colony twice a week, the colony furnishing the queen-cells being equal to any of them in this regard. If you do not have the combs, frames filled with comb foundation will have to be used; but in this case your progress must necessarily be considerably slower.

When the honey harvest arrives, keep plenty of combs on the strongest colonies, so that plenty of honey can be stored in these for winter, and as the season advances use more bees each time in making the colonies; and when fall arrives, if you do not have all the colonies you desire, and you have plenty of combs of sealed honey for stores which you can use, take bees from several hives, thus forming a strong colony at once, and hive them on these frames of sealed stores. I have so formed colonies in September many times, and had them prove the best of any the next season.

With plenty of combs at one's command, 10 colonies in the spring can easily be increased to 100 in the fall by this plan without feeding, or any outlay in cash for queens or feed or anything of the kind, and if the season is really a good one some surplus can be secured besides. But the success of the plan lies very largely in not commencing operations until the colonies are strong, nearly enough so as to swarm, and then not robbing them of bees till they are too weak to work to the best advantage, using few bees for each little colony in June, and more and more as you go along, thus having all come up to full colonies in August and September.

Half a dozen nucleus-boxes and a funnel have become a part of my outfit in bee-keeping, and I use them much more often than any one would think, for with them I can handle bees almost as well as could be done with potatoes; and they will stay where put, when this plan is used, almost as well as would the potatoes. With almost all the other plans of making colonies or nuclei, the great trouble is, that so many bees return to the parent colony that the nuclei or small colonies are so weak as to be of little value, even if the return is not so great that they are absolutely worthless.

## Spring Feeding of Bees

BY EDWIN BEVINS

I have read with considerable interest the articles by Mr. Scholl and Mr. Dadant, relating to the spring feeding of bees and the best kind of feeders to use at that season of the year. Mr. Scholl's arrangement has advantages over the other feeders mentioned by him, but my objection to it is that, like the others, it takes the bees too far from the brood-nest. This may not be true to any great extent of the division-board feeder, but I object to its use for the same reasons as given by Mr. Scholl. I want a feeder which can be placed right over the cluster of bees, which, in spring, is right on the brood; I want no space but a bee-space between the tops of the frames and the bottom of the feeder; and I do not want any bees to be made to crawl up the outsides of any feeder in order to get feed from its open top.

There is no feeder so satisfactory to me as a modified Hill feeder. The make-shifts for the Hill feeder, mentioned by Mr. Dadant, will not do at all for the man who has many colonies to feed, as they take up so much time in preparation for use. The quart Hill feeder is the one I have been using, but I object to it on account of its depth, which prevents packing around and over it sufficiently close to prevent escape of heat from the brood-chamber.

A feeder, with recessed and perforated cover, half the depth and with greater diameter than the Hill feeder, is all right. Where to get the ready-made shallow atmospheric feeder does not yet appear. Not every tinner has the machinery to form the cover out of a solid piece of tin. Any tinner could cut the regular sizes of the Hill feeders down one-half too small in capacity. I want a feeder to hold not less than one quart, and incidentally I will say that I use no Hill feeder without enlarging a few of the perforations with the point of a wire-nail. This, perhaps, is not necessary where feeders are new, but with long use it will be found an advantage. Probably in order to get the required form of the Hill feeder, I shall have to get my supply dealer to order some from the factory where the Hill feeders are made.

The use of the Hill feeder in its present form has enabled me to feed 100 colonies of bees since the middle of March more satisfactorily, I believe, than I could have done it with any other feeder, but a shallower Hill feeder would have saved me some work, and, I think, have been better for the bees, because I could have made the packing a little tighter above them in many instances.

Mr. Dadant's caution about using rusty feeders may be all right for those who feed when the weather is so cold that the bees will not take down the feed without leaving them on for several days. I have fed in rusty feeders many times in the fall, and have never had a case of dysentery amongst my bees. If the feed is given warm, and the quilt and cushion are tucked down closely around and over the feeder, the feed is always taken within a few hours after giving, if the perforations

are all clear. Sometimes a large number of them get clogged, and hence the use of the hammer and wire-nail.

I will add here what may be a benefit to some. I put supers of varying depths on all of my hives in October. These supers are sometimes the ones used for 4¼ sections, sometimes half-depth extracting supers, and sometimes full-depth hive-bodies.

I will also add, though not pertinent to the subject, that I place 2 corn-cobs about an inch apart across the top-bars of every hive. Over these, and covering the whole surface of the frames inside of the super, is placed a piece of heavy burlap, and above this is placed a gunny-sack, or any sack made of cheap material, partly filled with chaff from the straw-pile after the thrashing is done.

When I wish to give feed in an atmospheric feeder, all I have to do is to raise the back end of the cushion and the piece of burlap below with one hand, and shove in the feeder with the other. It is done so quickly that the bees do not realize what is going on until all is over.

In the deep supers the feeders can be covered very well to prevent the escape of heat, but not so satisfactorily in the comb-honey supers; hence I devised a shallower feeder that can be packed around and above easily in any super, and does not call for very much movement among the bees in order to obtain the feed.

At this writing (June 6) the winter packing around my hives has not been removed, and will not be until weather conditions are less provocative of swear words. These conditions have prevailed here most of the time since April 1st. The supers with chaff cushions will be left on every hive as long as feeding is necessary. With frequent rains and warmer weather I think there will be some kind of a flow from white clover in the not distant future. In the meantime there will have to be quite a liberal "flow" of granulated sugar and water, half and half. My colonies now are not in very bad condition to take care of a honey-flow.

## The Bee's Antennæ—Pollen Color

BY PROF. A. J. COOK

Mr. B., of Delaware, Ohio, asks me to explain in the American Bee Journal how the bee finds the nectar in the flowers, or how it is guided in its search for what it desires. Of course, the bee has eyes, and very remarkable ones. All insects have the large compound eyes, which are made up of thousands of simple eyes in many cases. Each of these simple eyes is quite complex, being made up of several parts, much as we find them in our own eyes. They often have three simple eyes—or ocelli, as they are called—which are well marked in all bees. Thus we would expect that bees would see well, and would use these eyes in their quest for nectar, pollen, and whatever they seek as they leave their hives. We have reason to believe, however, that bees are not so much

guided by vision as we should expect. We know when we move the hives slightly how the bees will come down to the old place for days. They seem to be guided by sense of direction, or habit, and not by direct vision.

I have another case that seems to show that their vision, rather than sense of direction, guides in some cases, but that it is often at fault. I once lived in a house exactly like my neighbor's, though the trees surrounding each were quite different. When I would put honey on my back porch for the bees my neighbor was annoyed by swarms of bees on his similar and similarly placed back porch. The bees were obviously fooled, and returned to the wrong house. Our company, and that of our neighbor, often made the same mistake.

I have no doubt but bees see well, and use their eyes to their great advantage, yet in the hive where they do much work they can not be thus guided, as the interior of the hive is totally dark. I much doubt, however, if bees do use the sense much in the quest for nectar of flowers or other sweets.

Many insects like bees, ants, wasps, moths, etc., have very delicately sensitive organs of smell. The scent organs are the antennæ. Wherever we find the antennæ—the horn-like organs appended to the head—well developed, we may be sure that the sense of smell is pronounced. Male moths, drone and worker bees, many beetles and ants, have such antennæ. In all such cases we may be sure that the insects have need in their functional activities to detect odors, that it may be, in some cases, are entirely unperceived by us. We have one large silkworm here, that when a female comes forth from her cocoon, though the room may be closed all but a slight lift of one window, males often enter to the number of 50 or 100. I have known of just such curious entrances to rooms twice in my life. I have known of one case where a swarm of the male moths were flying outside about the closed windows of a room, when, upon examination, it was found that a female had emerged from the cocoon inside. It is authentically reported that in one case males of these moths came down a chimney through a stove, and into the room from a stove-damper, when a female had just come forth from its cocoon in the room. If we approach close to these moths we smell the peculiar odor, but we must get close. Think how wonderfully sensitive the nose (?) of the male moths must be to detect this outside the room with all the windows closed!

Here in California we often note a butterfly—*Pyrameis cardui*, or the thistle butterfly—going by countless thousands in one direction. This migration often lasts for hours, or even for days. In some cases we find that they are going against the wind. The explanation is not far to seek. There are, without doubt, a thicket of thistles, their food-plant, in some distant neighborhood. The faint odor of the plants, which we do not detect at all, is perceived by the butterflies, and they are impelled by a marvelous instinct to seek the plants on which to lay their

eggs, and so their young—the prospective caterpillars—which they will never see, may have a comfortable larder.

The queen-bee flies out to mate. It is well that she be not away long. The drones have a marvelous development of the olfactory sense, and so are able to find the queen very quickly. We all know how quickly the queen mates, and how short the time after she goes forth when she returns bearing the signs of having met the drone. In the case of bees, the drone has much the best antennal development of all the bees, though the workers are not poor in this peculiarity.

Now I think we know how the bees find the nectar. The nectar has a very attractive perfume. We have smelt it here about the splendid orange orchards which have made all outdoors deliciously fragrant the past few weeks. The worker-bees perceive this odor, and so hie themselves to the fields that they may gather the tiny nectar-drop which they transform to honey.

Our answer then to B. is, that bees are guided to the harvest by odor mainly, and find some aid doubtless by sight. It is probable that sense of direction is no small aid to them in returning to their homes after procuring their load of nectar.

A word as to the structure of this smelling apparatus! It consists of very numerous microscopic pits, each with a peg at its bottom. Both pit and peg are surfaced with a delicate membrane. The more sensitive the sense of smell the more of these pits and pegs. Of course, it is necessary that the antennæ should be kept clean. Bees will, of necessity, get the antennæ dusted with pollen. Ants and wasps will get the dust of the earth on their organs of smell. The antennæ-cleaners on the front legs of all hymenopterous insects are admirably adapted for this purpose. I know of nothing neater or more admirable in the whole round of animal anatomy than these antennæ-cleaners. At some future time I will explain how they work.

#### COLOR OF POLLEN.

While most pollen is yellow, yet it is interesting to note the variety of colors that we see by watching the bees. We see yellow, orange, brown, black, white, red, green, and even blue.

Claremont, Calif., May 10.

## The Pearl Agnes Bee-Hive

BY PROF. EDWARD F. BIGELOW.

The Pearl Agnes hive was designed by me in 1905 and placed on the market.

The body of the hive has five frames with a total comb capacity of five-sixths of two full-sized Hoffman frames—that is, each is exactly one-third that of a full frame (16 $\frac{7}{8}$  × 8 inches interior). The frame itself has somewhat the appearance of a large section 5 $\frac{1}{2}$  × 8 inches. It is supplied with full comb foundation, or with a starter across the end as may be desired. The length (8 inches) of these small sections is the same as the depth of the interior of a Hoffman frame, and the depth (5 $\frac{1}{2}$  inches) is one-third the

length of the Hoffman, so that three may be fitted into the length of a Hoffman, if placed side by side and on end.

The super is fitted with sections 2 $\frac{1}{2}$  inches deep by 2 inches wide—that is, one-fourth the size of the Danzenbaker 4 × 5 section, and hence it may be used, if desired, in the regular Danzenbaker super as “toy” or “sample” sections (Fig. 2). These little sections, when filled either in the Pearl Agnes hive or the regular full-sized super, are convenient, dainty, attractive, and, to the young folks, “just too cunning for anything.” They may be used as sale samples, or novelties for the table, or as gifts to friends and to visitors at the apiary. The fences of the super are in the same form, but of smaller size than the regular fences. The cover is shaped like a gable and roof, so that, together with the fanciful painting of the three parts in three different colors, the whole has the appearance of a doll’s play-house (Fig. 1). This effect is further enhanced by the feeding-bottle (with perforated cap) which extends down through the roof, and is of the proper

length to project far enough to have aspect of a chimney (Fig. 1). The inventor is in such hearty sympathy with Old Saint Nicholas, and a magazine of that name so full of good things for the young folks, that it seems eminently fitting that the honey-bees should get their presents of sweetness—a la Saint Nick—down the chimney!

The house-like appearance is further increased by a neat label on the gable end, in the place usually occupied by the attic window.

The door is a swinging wire screen, so that the entrance may be easily closed when the hive is to be carried from place to place for observation or experiment, and when the professional bee-keeper desires to take it to an outdoor apiary as an enlarged nucleus for breeding purposes.

In the invention of this hive I have had in mind several purposes.

1. To supply the educator with an inexpensive, attractive miniature hive, all complete with comb and colony by the manufacturers or by a large apiary. For demonstration in the yard it prevents the disturbance of a full-sized working colony. For the schoolroom it can be

easily carried, taken apart, and put together, and yet it shows in miniature everything that could be shown by a large hive, which it would be difficult or impossible to take into the school-room.

2. For the young folks a hive that will give them a start in the fascinating work of bee-keeping and observation, at a minimum of cost. To the large apiarist it is what the flower-bed or school garden is to general horticulture or to agriculture. It is a sample. It shows the thing and gives the simple scale. In floriculture or in vegetable gardening the child enjoys the small bed more than he would do if obliged to cultivate an acre, or even a market wagon full of lettuce or radishes or popcorn. But before the coming of the Pearl Agnes hive there was nothing for the interested boy in which to keep a colony, except the regular hive used by the large apiary, which often contains a thousand colonies. This hive is, then, for the young folks a play apiary, as well as a means of nature study.

3. For the commercial apiarist this Pearl Agnes hive is better in some respects than the usual “baby nucleus” for mating, because “the nucleus” is too small for that purpose, except with close and continued attention. It is a hive to be kept especially for exhibition to visiting friends. This is better and easier than to disturb one of the regular colonies by taking it out. It may also become a source of income if it be purchased empty from the manufacturers, and filled with a complete colony and supplied to nearby teachers. As previously explained, the supplying of the hive thus filled would be equivalent, in number of bees and quantity of comb, to five-sixths of a two-frame nucleus. Simply put six of these section frames into two full frames, and fill the Pearl Agnes hive with five of these frames. But, better than all this, perhaps, to the professional apiarist, it solves the problem of plenty of queens in early spring, when queens are not only the most valuable but the rarest. Queens are most easily obtained in the latter part of summer or in early autumn. They are most needed in the spring. A ten-frame hive fitted with thirty of these large sections may be divided into six Pearl Agnes hives, and thus five extra queens for that one hive carried through the winter. In early spring all the thirty frames may be put back into the ten-frame hive, and there will then be five extra queens to be used when queens are queens.

The first Pearl Agnes hive was roughly made up in 1905 from my drawings and specifications, and was placed in the hands of my esteemed friend and honored fellow-townsmen Mr. L. C. Root, who is well known as the author of “Practical Bee-Keeping,” and an apiarist with an experience of almost half a century conducting apiaries of the largest size, and he is still an enthusiast with many colonies. He reports at the present writing (last week in March 1906) the bees have wintered astonishingly well (indoors) in this Pearl Agnes hive. I am indebted to him for the suggestion in regard to the pos-

session of plenty of queens in early spring.

4. To the experimental apiarist, the advantages of the hive are so many and so important that I prefer to defer even suggestion in reference to them till later, when I may be able to announce and to illustrate some of the things that have been done, rather than predict what possibly may be accomplished. I will merely advise the reader to procure one or more of these hives; and my assurance is that, if he will handle them, study them, and dream about them as much as has the inventor, some of the suggestions will come to him spontaneously, and thus give him all the charm and pleasure of original discovery. The results of such discoveries may add much of value to the apiarist as well as to the scientist. It would be, you know, difficult to play a game of chess through all its entrancing situations if the men were of full size. One can often imagine and theorize better in miniature, better with a plan than with the completed house, better with a map than with the country itself. Perhaps these advantages

will be yours if you become an experimental apiarist with the Pearl Agnes hive.

It is not for me within the province of this article to tell you what I think the manufacturers intend to do with this hive. But I will give you a small hint as to what I suspected was in the mind of one of the managers when he said a certain thing. From this I infer (and I "guess" that the inference is well founded) that they no more expect to make a profit directly from this hive than the fisherman expects to eat the chubby little "shiner" that he puts on his hook when he goes angling for pickerel. These shrewd manufacturers know that bee-keeping is fascinating, and that all they have to do is to get you started. Everything else follows easily. So this hive will be put on the market at less than net cost, and in this laudable action the manufacturers will not be hampered by any patent to be taken out by the inventor. He has too strongly at heart the interests of apiculture as an educational factor.

But, to revert to the figure of the fisherman and his bait. The parallel is not quite true, and so far as it is inaccurate it is to your advantage. This "bait" (the Pearl Agnes hive) in itself is good, and the more freely it is offered (by the manufacturers) the more reason for your pulling it off the "hook" and taking it home with you—in fact, get several of the "baits."

The name "Pearl Agnes" is in honor of the 10-year-old sweetness-maker of the "B(igelow)-hive" in which I am writing.

## Where Do the Flowers Get Their Color?

BY GASTON BONNIER.

Why are the flowers adorned with rich colors? The poets have found many answers to this query, which today is raised anew with violent controversies among the learned. There is a theory, first expounded by a bizarre personage under the name of Christian Conrad Sprengel in 1793, which has been everywhere believed. This theory postulates a perpetual strife on the part of the flowers for brilliance in order to win recognition at a distance from the honeyed insects. It is to attract these that the corolla is decorated with bright hues.

I occupied myself with this question for a long time when I was doing some work for my thesis for the doctorate of sciences. I was taught the absolute reciprocal relations between the insects and the flowers, the attraction of the bees by the colors. I was convinced in advance, with the enthusiasm of youth, that my observations and experiments served to confirm all the points of these propositions in bringing fresh proofs to bear upon them. The excellent Decaisne, a little skeptical on this point, encouraged me to go on in my work. At the end of some months I was desolate. All my observations and all my experiments contradicted the theory of reciprocal adaptation, and in particular the role attributed to the color of the flowers in the attraction of the bees.

After a continuation of my observations I prepared a list of plants whose flowers are scarcely visible, obscure, uncolored, or green like the leaves of the plant itself, but which all are most nectariferous and abundantly visited by bees and other insects. To this list I added that of all the trees on whose leaves the bees sought their honey stuff—leaves not colored otherwise than neighboring leaves without the honey—and all the plants where insects come for nectar, besides flowers, the various parts of a vegetable, not colored, not visible, and wherein are situated the nectars termed extra-floral.

I prepared another long list, including the names of plants with highly colored flowers, but wherein there was no secretion of sugared liquid, where, in consequence, the insects did not come.

As for experiments, I made many and varied, all of which bespoke the same truth, that there exists no correlation between the presence of a lively color and the quest of a sugary liquid by the bees. I will cite but one. I disposed squares of many colors on a uniform green foundation of grass. The same quantity of syrup or honey was placed in the middle of each square. The bees discovered these various depots of sweet liquid in the same time without the color influencing their search. The red

square on a green foundation attracted them no more than the plain green square where the same amount of syrup was to be had.

The result of all my experiments was the following:

The development of colors in floral organs and that of nectar are not concordant.

Under the same conditions the most highly colored flowers are not the most visited by insects.

The visibility of flowers is not proportioned to their adaptation to cross pollination.

The insects go in the largest numbers where the nectar is the most abundant, the richest in sugars, and the easiest to take.

The researches made by M. Felix Plateau, professor of the University of Gand, are important, his observations most numerous, his experiments varied.

First he verified with many details one of the points which I proved, that bees show no preference or antipathy for the diverse colors, which the flowers of the different varieties of the same species can present.

But this Belgian scientist did not content himself with verifications. He made artificial flowers, excellent imitations, of paper or cloth, and the bees did not visit them. He constructed others of living leaves with the natural vegetable odor. If he put honey in them the bees visited these false green flowers; if the honey was withdrawn they ceased their visits.

When the nectariferous part of the natural flowers was removed, leaving the brightly hued corolla, the insects came no more on their quests. If, on the contrary, the nectariferous flowers were hidden beneath green foliage the insects knew how to trace their invisible prize.

Finally, M. Plateau placed a glass in front of a nectariferous flower. If it were the sight alone which guided the insects they would go as soon to the perfect image of the blossoms reflected in the mirror as to the blossoms themselves. But the insects were undecieved. Instead of striking against the glass as they entered the room they turned directly to the flowers as if the mirror did not exist.

The general conclusion of M. Plateau's researches is identical with that which I formulated twenty-five years ago; the insects are guided to the flowers by another sense than vision and which only can be smell.

This does not say that it is the perfumes of the flowers which attract the bees, because perfumed and nectariferous flowers seem in general to be without sensible result.

It is not the fragrance such as we conceive subjectively, it is a special, subtle odor which permits the sugared matter to be recognized.

Indeed, substances which we cannot recognize by their odor are found by the bees. I have often made the following experiment—for example: Bits of ordinary sugar, which have no appreciable odor at a distance, are placed in a dark pavilion, closed, where there is no honey or objects having a special

fragrance, and where the bees do not come. On the morrow, sometimes the day after, the bees have discovered the sugar and have recognized it as a useful material. Nibbling at the morsels with their feeble little mandibles, they realize that this process is not practical for gathering the sugar. They go for water to dissolve the sugar and then pump out the sugared water.

The preceding suffices, I think, to raise doubts as to whether we owe the colors of flowers to the bees, as Sir John Lubbock said.

Then why are flowers colored? Why

not inquire to what mysterious adaptation we owe the color of the rocks, of precious stones, or of sunbeams? This, evidently, is neither a reply nor an objection. But the partisans of the Sprengel theory have this to answer: Why are mushrooms rich of hue? Many who are convinced of the floral adaptation to insects say that the edible mushrooms are colored like the poisonous varieties so as to prevent being gathered. As well might we say that the poisonous varieties assume the colors of the edible kinds so that they may be sought!—Times-Democrat.

Mr. Abbott—I have said it in the American Bee Journal several times, commenced about 25 years ago, and I have been saying it ever since. I want to say again, for the benefit of those who have not heard me say the same thing, that I never make a colony queenless. I do not rear queens any more, but on every cage I find directions, and those directions I invariably tear off because they say to make the colony queenless 48 hours, and then introduce the queen.

Dr. Bohrer—Do you simply remove the queen, destroy her, and turn the other one loose?

Mr. Abbott—No, sir. When I have a queen or a half a dozen queens that I want to keep, I put them on top of the frames of a colony and leave them there 2 or 3 days. If I want to introduce one of those queens I hunt out the old queen, pinch her head off and turn one of the others free. If I wanted the old queen free in the hive day after to-morrow, having introduced one today, I would take that old queen out, put her into a cage and turn another one free, and in a very little while the queen in the cage is out on the combs laying, and the bees never know they have been queenless. They have no feeling of resentment towards those queens in the cage any more than they have to the one free on the combs. They are just as friendly with any one of the 5 queens on top of the frames as the one in the hive laying eggs, and they take one just as well as another. What is the use of killing the queen and having them start queen-cells, which they will in 48 hours, and take the chances of their killing the queens? When they start cells they are antagonistic to any queen, even their own queen.

Dr. Miller—How long after you put that queen in before the bees liberate her?

Mr. Abbott—I fix it so that she will be out in an hour—not to exceed an hour.

Mr. Whitney—I purchase a considerable number of queens usually, and I have been anxious to find the best way of introducing queens, having tried various methods. I heard Mr. Abbott give his method of introducing queens here, a couple of years ago, I think, and thought I would try it. I sometimes get a half-dozen queens in rainy weather. Perhaps there will be 2 or 3 days of bad weather; I can't introduce them. I know what colonies I wish to introduce those queens to, and I distribute them around over the frames and leave them there till the weather clears up so that I can introduce them, and then I remove the old queens and let young queens free immediately. I have never lost a queen, when introducing them in that way. Of course, I would do the same thing if the weather were not bad, but it is a convenience if the weather is bad, to take this plan of doing it, and it never fails under any circumstances with me. Always place the queens over the frames of the colony in which you wish to introduce them, without removing the little paste-board or cork, and when you get ready

**Report of the Chicago-Northwestern  
Bee-Keepers' Association, held in  
Chicago, Wednesday and  
Thursday, Dec. 5  
and 6, 1906**

(Continued from page 521)

**INTRODUCING QUEENS.**

"How do you introduce queens?"

Mr. Taylor—I seldom introduce a queen except in the spring. If I want to change a queen, or the colony is queenless, I open the hive and observe the conduct of the bees, and you can tell, if they have a peculiar way of acting, running together, perhaps running towards your hand a little, with their wings lifted and a slight shaking motion, you can turn your queen right in. They are all right. Sometimes, if I am in doubt, I will put a queen-excluder on the top, let a few bees come up, let the queen loose and decide then. I hardly ever cage a queen in the spring, because the bees are so anxious to get to work that they will almost invariably accept the queen; in fact, I do not know that I remember when a colony that was queenless refused to take a queen early in the spring.

Mr. Abbott—Suppose you had a black queen and you wanted to give them an Italian.

Mr. Taylor—Take her out and wait a day or two to let them find out they had lost a queen. They are terribly anxious to get a queen in the spring, and that running together a little and a slight shaking of the wings shows that they are looking for one.

Mr. Abbott—I supposed that among all the progressive bee-keepers the one most in advance and at the forefront was R. L. Taylor, of Michigan.

Mr. Taylor—No; I am a fogy, sir.

Mr. Abbott—But I see he says that the hive should be left for a day or two for the bees to find out that they are queenless. Now in the name of common-sense, I want to ask *why*? I asked that question, and I asked it that I

might bring out just that one idea. *Why* make a colony know it is queenless? There is something to this. You are wasting a great deal of time when you wait 2 days for the colony to find out that they are queenless. Now if Mr. Taylor will tell *why*, perhaps I will say something more.

Mr. Taylor—Two days early in the spring do not count very much, and you do not have to wait to see whether they are ready to receive her or not. It is the easiest way. Of course, I remember at one time that I was handling some bees, when I used to fool with them, and had a lot of them shaken on the ground, and in stumbling around with my big feet I must have hurt the queen. I noticed before I got through the colony that the bees were in a turmoil. They were running up on the front of the hive, and on the side, and looking around as lively as possible. I concluded something had happened to the queen. I looked on the ground and found I had stepped on her. I got another queen and they were perfectly satisfied with the other queen.

Mr. Abbott—I have been trying for 20 years to get into current bee-literature and bee-books this one statement, that it is not necessary for any colony to be made queenless in order to introduce a queen safely a day, or an hour, or a minute, except what time is necessary between pinching the queen's head off and turning the other queen out, or putting her in a condition to get out. After 20 years' trial I do not think that that statement is in a bee-book, or in any bee-literature that has not come directly from my mouth in reporting something that I have said in a convention about it.

Dr. Miller—Allow me to speak and say right here that Mr. Abbott perhaps never reads anything I write, or he would not say that sort of thing.

Mr. Abbott—I beg your pardon, then. It is not in any book.

Dr. Miller—It is in the American Bee Journal.

# American Bee Journal

to introduce them, remove the old queen from the hive and let the queen free immediately; and, as Mr. Abbott has said, you do not then stop the production of bees in the hive. The old queen goes on laying all the time up to the very moment of her exclusion from the hive, and the new queen takes her place. I think it is the best method I have ever known.

Mr. Wilcox—If you could not place her over the colony, would you place her between the combs?

Mr. Whitney—Yes, you might do that; but I have placed the cage at the entrance of the hive. My hive-entrances are wide, but just about high enough.

Dr. Miller—You could not do that in cool weather.

Mr. Whitney—Not very cool weather, no. I would not do it in cool weather. But I merely mention that I have done it in warm weather, but with my kind of hives there is scarcely any necessity for it.

Mr. Wheeler—What do you do with the attendant bees—bees that are with the queen? Do you kill them?

Mr. Whitney—O, they take care of themselves, or the other bees will take care of them. I don't pay any attention to them at all.

Mr. Abbott—Let them alone. They will do no harm.

Mr. Kimmey—You say turn the queen loose immediately; make the opening so that she can walk right out?

Mr. Whitney—Yes; run a pencil through and puncture the queen-candy and let the queen out. She will usually remain in the cage for several hours, and the bees will go in. They do not often run out immediately, but I will let them free and turn them right out. Ordinarily they remain in the cage for several minutes, or hours, possibly.

Mr. Hutchinson—I think that the idea of letting the queen free at once without leaving the colony queenless until they find out they are queenless is probably all right. The only reason that I could see in keeping a queen caged 2 days or more before letting her out is that sometimes it seems as though the mood of bees changes. You will come to a hive sometimes with a queen-cage in it, and you will find bees sticking right over the cage like so many burdocks, and perhaps the next day they have changed their mood and are walking peacefully over the cage. If you release the queen when they are inclined to bother her, they might kill her. I think it is much better never to let a colony know they are queenless. Don't leave them queenless long enough so that they find it out. I introduced a queen last fall after the honey-flow had ceased, when it is somewhat different. I went over the hives and found the queen. As soon as I would find the queen I would kill her and open that cage at one end and fill it perhaps an inch or an inch and half with sugar candy, and put it back in. I do not suppose those bees knew they had a new queen, and out of the 40 I lost 2 queens. Those were strong hybrid colonies.

Mr. Moore—Mr. Hutchinson, what would you do now to save the queens

to those 2 strong hybrid colonies, in addition to what you did before?

Mr. Hutchinson—I don't know that I could do anything.

Mr. Whitney—I have introduced a strange queen to a queenless colony and she was accepted immediately. There would be a buzz of bees all over the frames and down through the hive the moment she struck the top. An exception, of course; that would seem to be a sort of freak of the bees. I don't know why they accepted her so suddenly or willingly, but they did.

Mr. Taylor—They will almost invariably do that in the spring.

Mr. Abbott—Never turn a queen free if you have one or more cages, if the bees are not walking around naturally, no difference whether they have been on there 1 day or 3. Never turn a queen free under those circumstances. Simply close up the hive. You have the old queen laying. That is the advantage of having a queen on top. Tomorrow, if all is quiet, and they are walking around naturally, hunt out the old queen. If they have had 48 hours and have started queen-cells, then if you can't put her in, it leaves another day to work on the cells.

Dr. Miller—I want to say just a word on introducing as Mr. Abbott advises. I think I objected at one meeting here that there was some delay in doing that way, but a good deal of experience since has made me appreciate very much the advantage of having a queen in the hive some time—that is, the new queen in the hive—some time before the old one is removed. As probably all here know, it is not an easy thing to introduce a virgin queen, and since that time I have introduced a good many virgin queens, using simply the advantage that Mr. Abbott speaks of, of allowing that there is just a little advantage in having the new queen get acquainted while the old queen is in the hive. When you take away the old queen you are throwing them into an abnormal condition and they are likely to show fight. When she is put in the hive beforehand, they are indifferent to the new queen. I don't know if it is because she gets the scent of the hive, or for any other reason, but I do know that a virgin queen, or any other queen that has been imprisoned in the hive for some time while the old queen is present, will be accepted kindly if freed by the bees a short time after the old queen is removed.

## REQUEENING OR SUPERSADING QUEENS.

“Shall we requeen colonies having old queens, or let the bees do the work of supersading?”

Dr. Bohrer—It is questionable when a queen may be considered old. I have had queens 4 years old that were very prolific and laid as many eggs as any queen I have, and I think it would be policy for a bee-keeper to watch his queens and see what they are doing. If, for any cause they do not seem to lay the requisite amount of eggs at any age, I would supersade them; but as long as the queen is fertile and in good condition, keeping the colony up, I would not molest her, even to 3 or 4

years old, because from my observation they will lay eggs until they are that old; so that there is no fixed rule about that, perhaps.

Mr. Whitney—I suppose that when one discovers drone-larvæ in worker-cells it is a pretty good indication that the queen ought to be supersaded, whether she is old or young. Usually you may find those in a colony where there are old queens, but I have a case which I have written up twice, and some people questioned my accuracy. I had a queen that I found in the spring laying drone-eggs in worker-cells. She was only a year old. I thought very much of her. She was the daughter of the old queen that so much has been said about, and she looked very poor. She came out poor in the spring. I commenced feeding her bees with good, rich honey, a little at a time, each night, and within 2 weeks she was laying worker-eggs in worker-cells, and during that summer I made 4 colonies of bees from that queen.

Dr. Miller—Does Mr. Whitney think that an exceptional or a usual case?

Mr. Whitney—It was the first I ever knew, or ever heard of.

Dr. Miller—It is the last you will ever know of.

Mr. Whitney—Some say, “You must have been mistaken; it must have been a young queen that supersaded the old one, and you thought it was the same old queen.” The fact is that queen was clipped soon after she commenced laying, and I watched her from that time until she died, and it was the same old clipped queen. A doctor in Switzerland has taken the question up and asked me whether I was certain it was that queen. He said it was a very unusual thing, and something he never heard of. But 2 of my old bee-keeper friends were there when I took the frames out of that hive, and showed the worker-comb full, or two-thirds full, of drones, and they said, “Isn't that too bad?” Well, I thought so. I expected to have to supersade the queen, but I did not. I kept her that summer and made 4 good colonies of bees from that queen by feeding. She was a young queen, though. I would say that an old queen should be supersaded, but the question is, What is an old queen? Some queens are old at a month, and others not old at 2½ years. It depends upon how hard the queen has been worked. A good queen you might keep 2 or 3 years, and with a poor honey-flow she would not exhaust herself for 3 or 4 years.

Mr. Hutchinson—What I want to know is, shall we do this work, or shall we leave it to the bees to do it? Who has been at work supersading the queens themselves? Mr. France, do you supersade the queens or let the bees do it?

Mr. France—As a rule, I supersade them.

Dr. Miller—Does a queen do better work, as a rule, in her first or her second year? That will help us a little in deciding, if we can get some testimony about that.

A Member—The best queen I had last year was 3 years old. She made the record of the yard.

# American Bee Journal

Mr. Taylor—My object in keeping bees is to make something out of them. I want to make the largest percent on my labor, efforts, and expense, that I can, and I think I can make more by letting the bees do the work; and nowadays I do not practice meddling with the queens except in an occasional—very exceptional case. Of course, once in a while, when I see that there is any need of a new queen, and that the bees are not likely to supersede the queen themselves immediately, I may interfere! but I let the bees do that work, and I do not believe that I could improve much on it any way.

Mr. Whitney—If you find you have an old queen, and she is liable to be superseded, perhaps in the fall, it seems to me it would be a good deal better to supersede her in August than to let the bees supersede her in October when there are no drones flying, when you are liable to have a virgin queen there, to be a drone-layer in the spring.

Mr. Taylor—That is not likely to be the case. Bees supersede their queens in the summer-time. Of course, that is the time to do it, and they seem to know that that is the time to do it. Of course, there may be exceptional cases, but I should very much dislike to overhaul 50 colonies of bees to find out whether there was one queen that needed superseding, because the bees were going to supersede her in the fall. It doesn't pay.

Mr. Whitney—Keep a record of the age of the queens.

Mr. Taylor—That makes lots of work.

Mr. Wilcox—I am astonished, and I want to know if anybody else has ever thought of such a thing as queens being superseded in October, a month or two after the season's harvest was over. I did not know that such a thing ever happened except by accident.

Mr. Abbott—I confess I am astonished. I am like Dr. Miller now. I am more astonished than he was, to think that any one would advocate at this time that we should let nature alone. Let me give you an illustration from the dairy business: The Babcock test has eliminated from the dairies of this country about half the cows that were in the hands of intelligent dairymen, because they were eating more than they produced. It is not necessary to overhaul a colony to see how old the queen is. It is unnecessary to "count the rings on her horns" as you do on a cow to see how old she is. It is only necessary for the intelligent manipulator to know that there is a colony, No. 22, that is not paying its way. If 22 is not paying its way, 9 chances out of 10 the queen is responsible for the non-payment. An intelligent answer, it seems to me, would be to take off the head of No. 22's queen and put one in there that you thought was better. That would be improving on what we call the "natural method," just as the dairy people by selection have improved the Jersey cows and the Holstein cows until they have nearly doubled the butter-production of the Holstein herds. If they can double the butter-production of the Holsteins by careful selection, can not the bee-keepers and queen-

breeders eliminate the poor queens and double the production of the colonies of bees in the country in the same way? It seems to me we can. This is an age of progress and scientific investigation, and we ought to take advantage of it, it seems to me. Take the heads off the queens whose colonies are not paying their way.

Mr. Taylor—I do not like to take up the time of this Association in talking. I like to say a word once in a while, but I do not like to talk so much. If you are willing to bear with me a few minutes, I will try to explain this thing that Mr. Abbott seems to be entirely astray on. Now the two cases are not parallel at all.

Dr. Miller—Correct.

Mr. Taylor—I am glad you are with me, Doctor. They are not parallel at all. It will take me 2 or 3 minutes to explain why they are not parallel. Take cattle. I suppose originally they were in a wild state, and they had long horns and they were fleet of foot, and they had great courage, and they were rustlers. That is, they were fitted to their environment. They were so "bred and so developed that they were able to survive under the hard circumstances in which they were placed. They were able to fight. They were able to escape their enemies by flight, when it was really necessary. They were able to hunt their food in difficult places. Now, then, suppose Mr. Abbott had some of those cattle and he wanted to develop them in the line of fighting and rustling for their food and fleeing from enemies, and this sort of thing. Would he be so particular about picking out animals that were not fleet and not fighters? Why, no. He would not expect to develop them very much. They have been developing for ages and ages. The weak ones have gone down always. They could not get food. They could not escape their enemies. They could not repel their enemies, and they have developed, I may say, to the highest possible stage of that sort of existence. Now take bees. The bees have not been developed as fighters particularly, except what was necessary to keep out certain enemies, but they have been developed from the very first for the production of honey, because upon that alone has the existence and continuance of the race depended. Now I know it is against the generally received opinion among bee-keepers, but bee-keepers are all astray in this everlasting talk about improving the honey-gathering qualities of bees. Why, we can do a deal better than that. They are developed. Of course, we may do a little something in the way of increasing that, but we perhaps better do it negatively. We ought to let those that are not doing well perish of themselves, as they will. We make a mistake in nursing up those that are not able to survive of their own efforts, and feeding them and trying to get them through the winter, and all this sort of thing; but if we turn our attention to developing bees in the way of right capping of honey, in the way of making white comb honey, in the way of properly filling their sections, making straight

combs—for there is quite a difference in that—and in some other points that I might mention if I could take the time to do it, I tell you we would make a big improvement in bees, for the reason that the bees have not found it necessary to develop in these lines. It didn't make any difference to them whether the comb was white or dark, or what was the matter with it, only that they had honey where they could get it. Now I say, if I had any influence among bee-keepers I would have them turn their attention to doing something that there was some prospect of their being able to accomplish.

Dr. Miller—I want to apologize to Mr. Taylor for agreeing with him. [Laughter.] I am very sorry I said a friendly word toward him. Mr. Abbott, I think, switched off entirely from the question, and when Mr. Taylor followed and drove the wild cattle, he went still farther. The question was raised whether it is better to allow the bees to supersede, or for the bee-keeper to take the matter in his own hands. Then Mr. Abbott raises a very important question and he did not say too much about that, and I am with Mr. Abbott and dead set against Mr. Taylor, that he can not improve the bees. But they are both away from the question. The question is not whether we are going to improve our bees, but whether, with the bees we have, it is better for us to take the matter of superseding into our hands or leave it in the hands of the bees. I regret to say I am with Mr. Taylor in thinking it is best to leave it to the bees! [Laughter.]

Mr. Wheeler—I stand for Mr. Taylor.

Dr. Miller—Keep to the question now.

Mr. Wheeler—No, I think for the benefit of the convention, if you will allow us a word about this very important question—

Dr. Miller—Yes; but let us finish this other question first, and then go to that.

Mr. Wheeler—Mr. Taylor and Mr. Abbott have been talking on a question that I think is very vital to bee-keepers.

Mr. Todd—Take it up after lunch. It is a big question they are discussing.

Mr. Wheeler—Just as you people say. I would like to say a word about the requeening of bees.

Mr. Taylor—I would suggest to wait until it comes up. We will have it up after this, I presume.

Mr. Whitney—I simply wish to reply to Mr. Wilcox in regard to superseding. Perhaps I made a little strong statement, but when I close up my hives with a clipped queen and in the spring I find a young queen with two good wings, I conclude that the queen has superseded.

Mr. Wilcox—I asked that question for the interest of the published report, not particularly for the bee-keepers present, but it will be read by the people all over the world, and I did not want it to appear, unless it was true, that the queen was superseded in October. I did not know it was.

The report of the Committee on Resolutions was read by Mr. Hutchinson, which, on motion, was adopted.

A photograph was taken of those

# American Bee Journal

present, and then an adjournment until 1:30 p. m.

## SECOND DAY—AFTERNOON SESSION.

After calling to order, Mr. Lyman described his management of the hive during the swarming and honey season.

Dr. Bohrer—What is the principal advantage you claim for that arrangement?

Mr. Lyman—It keeps the bees all at work in the front brood-chamber undisturbed, and at the same time prevents swarming. In my experience, after you make this change, there is no danger whatever of the bees swarming for at least 21 days.

## QUEEN FERTILIZATION AFFECTING DRONE-PROGENY.

“Does the fertilization of the queen affect her drone-progeny?”

Dr. Bohrer—I wrote that question, and the reason I did so was not to make an attack upon any queen-breeder at all, nor upon any author, but to call attention to what I regard as an error. I will name the gentleman, and I regard him as a high-toned gentleman, and a very honorable man—stands so, I think, before the bee-keeping fraternity throughout the United States and everywhere he is known. I have reference to Mr. Doolittle. When I first commenced to read bee-keeping and study it carefully, I was attacked through the press several times. I went all the way through the State of Michigan and discussed it before the Michigan Bee-Keepers' Association, at the request of Prof. Cook. Two or 3 years ago I wrote him asking whether he had experimented any concerning that matter, that is, the effect the fertilization had upon the queen's drone-progeny. He said he had not only experimented, but he had proved my theory to be correct. Mr. Doolittle takes the position that it does affect the progeny of the queen, and I believe he says the fourth generation has produced a queen no one could tell from a hybrid. While I believe he is candid and sincere in his conclusions, the manner in which his experiments were conducted I am satisfied was erroneous. I doubt very much whether Mr. Doolittle is so situated that he can have four generations of bees and the fourth queen successfully fertilized where he is situated, on account of the fact that there are hybrid bees all around him, and on that account I think it is true that the drone-progeny is affected by her fertilization. The spermatozoa are lodged there—never escape at the will of the queen. When depositing a worker-egg she fertilizes that at will as it passes the mouth of the spermatheca. To suppose that affects the drone-progeny is to suppose it becomes a part of her system, that the spermatozoa become food and consequently part of the system of the queen. That is an utter impossibility. The revelations of the microscope prove the contrary, and I am satisfied that Mr. Doolittle, although honest and sincere in what he teaches, is mistaken, and I would not like at this time to have the idea go out that such a thing is possible, because it is not.

## REQUEENING OR SUPERSEDING QUEENS.

Mr. Wheeler—Before dinner I was going to speak of the value of changing queens. We read a great deal, and it was the talk of some of the gentlemen before dinner, about when a colony showed weakness or anything the matter with it, to change queens, and by selecting the right queen you improve your stock of bees. That is right to a certain extent, but I think it is carried too far. In the spring, quite often when the bees come out of the cellar, they will fly together and are quite apt to kill off the queen. There will be a very strong colony of bees, and when I look a little later they will have their queen killed, and there is a great lot of bees, and what am I to do with those bees? They are losing their time. I will look around and find a colony withered away—a few bees with a queen. I put that queen in the colony with the colony of bees and that queen will lay eggs, when she gets started, for all the bees that are there—fill 2 or 3 hives. If she had been left with that little colony, her stock was bad and not worth saving. I think that the bees have a great influence over the queen. The care they give a queen determines how many eggs she will lay, and determines her life as long as she has her youth and strength, and I think there is a great deal too much stress laid on the point of the queen being to blame for a colony being weak and dwindling.

## PROGRESS OF BEE-KEEPING.

“Have we made any progress in our industry in the last twenty-five years? If so, what is it?”

Dr. Miller—I think we have made some progress right in that very way, if Mr. Wheeler will pardon me, in trying to do something toward getting better stock. It is all very true that it makes a big difference. You put a queen into a little handful of bees or with a strong colony—she is a different queen altogether. But, after all, there is a material difference in the queens themselves, and I would deprecate the idea of trying to discourage any one from doing all he can to improve his bees by getting better stock. As far as improvement is concerned, I think we have made some changes within the last 24 hours, in our views—some of us. There is a change going on. I am very sure that I know some things I did not know 25 years ago, and I am very sure that there are some things I do not know now that I thought I knew 25 years ago. Whether it is an improvement or not I am not so certain, but there are changes going on, and when we are not standing dead still there is a possibility of our improving, so that I think the thing is hopeful that we are going on a little.

Mr. Wilcox—It is 25 years or more since I commenced attending the “Northwestern” convention and other conventions in this city, and as I compare what I have heard today and yesterday, with what I heard then, I am very emphatically of the opinion that the great mass of bee-keepers who attend conventions have made improvements, have improved themselves in

knowledge. At that time half a dozen men would run a large convention. The rest knew nothing, or said nothing, anyway, and did not seem to understand fully what they heard. I am sure that bee-keepers as a whole are advancing. They are better advanced, on an average, better educated in the science and art of bee-keeping; and when he says “we” I suppose he does not mean, has there been something new learned that was never known before? but have we, the bee-keeping industry, learned anything in the last 25 years? The most of us have.

Dr. Bohrer—I was, I believe, in the first bee-keepers' convention in the United States, and I do not know but one other man now living that was in that convention. That was Mr. M. M. Baldrige. I am satisfied there is great progress in one particular. Then it was almost impossible for a bee-paper to live. Now there are 5 or 6. I hope the subscription list of the American Bee Journal is much greater than it was then. I was one of its first readers. There are other bee-papers. Gleanings has a good circulation. Mr. Hutchinson's paper has a good circulation. There are thousands of people reading bee-literature now. Now we do not call a man insane for paying \$10 for a queen in order to Italianize a colony of bees. So there is progress shown in that respect.

Pres. York—I think Mr. Taylor can remember 25 years. Does he think there has been any progress made?

Mr. Taylor—Why, yes. You can't stir around 25 years without knowing something more than you did before.

Pres. York—If so, what is it? is the question.

Mr. Taylor—That would be a pretty long story if I told it. We have made a great improvement in hive-fixtures, for one thing. We get our honey in a great deal better shape than we used to. When I commenced keeping bees we would have a box made of half-inch stuff to reach across the hive.

Dr. Miller—You are going back more than 25 years, now.

Mr. Taylor—Not much more. Have a hole in one side and two pieces of glass on the end and a board laid over the hive, with a couple of holes in it; set two boxes in it under the cap on top of that board. There is quite a difference between that and the comb honey that we produce now. I might go on and tell you about 20 things of that kind.

Mr. Todd—How have the average tons of honey increased in 25 years?

Mr. Taylor—Well, they used to tell some big stories 25 years ago. One thing we have lost in—we do not get so much per pound. I have paid 20 cents per pound for honey in those old boxes, and some of it was not very good at that. A good many of us have learned a good many things, and some of us have learned a good many things that are not so, I think. But, on the whole, of course, we have made a wonderful improvement.

Mr. Abbott—I asked that question to bring out a point. It has not come out yet, so I will see if I can not get it out. I was just thinking over what

growth and progress had been made in 25 years. It is 23 since I came from the East into the West. The growth of the industry as a whole is simply remarkable, when you think of it, the way it has spread and the way it has been reaching out, the growth of a factory here, a factory there, and factories do not grow for the production of anything unless there is a demand. The factories sometimes push ahead and introduce new things, and I think that the manufacturers of bee-supplies have done more for the country than any other class of individuals, or more for the bee-keepers of the country than any other class of individuals, owing to the fact that they have pushed to the front. They have pushed to the front some things that are worthless from my standpoint, but they are not worthless from the standpoint of other people, and therefore they are good. If a man puts to the front anything people want, he is a benefactor. When we think about the things that were not in existence, that were not obtainable 25 years ago, that are a help to the bee-keepers today, it would take the whole afternoon to tell about them, and these things have come to us on account of the push and energy of a half a dozen men in the United States. Some of our people say they have gotten rich, and are bloated bondholders, and have got more factories and great institutions, and they have done great things, and they ought not to be permitted to speak. They have gotten rich, they have made a few dollars, but the bee-keepers of the United States are millions of dollars better off than they would have been had these people not existed.

#### AGE WHEN QUEEN DOES BEST WORK.

"How many think a queen does her best work in the first year?"

Pres. York—All who think so, raise your hands. 3. How many think a queen does her best work in her 2d year? 9.

Dr. Bohrer—I do not raise my hand in either case, because I do not know. My observation has taught me not to be positive about that.

Dr. Miller—Maybe somebody thinks the 3d year.

Pres. York—All who think the 3d year raise your hands. I do not see any one on that.

Dr. Miller—With that in view you may add one more to the 2d year. I did not vote. I know now!

Pres. York—You wanted to see which way it was going?

#### INTRODUCING A QUEEN TO A LAYING-WORKER COLONY

"How shall we successfully introduce a queen to a colony with laying workers?"

Mr. Wilcox—We don't want to.

Dr. Miller—One way is to introduce a virgin queen just out of the cell. Almost invariably, if not invariably, she will be accepted.

Mr. Whitney—I asked that question, because last season I had a little experience with a laying-worker colony, and I had a great deal of trouble. I was removing some queens from other colonies for requeening, and I thought I would use those to test that laying-

worker colony, and I introduced one in the usual way, kept her until I thought she had been recognized by the bees, and then I let her free. They killed her in a few minutes. Then I tried another plan. I took the bees all out and shook them on the ground at a distance, carried the combs back and introduced another of the same kind of queens, and the bees came back and killed her. I took the frames out of the hive-body and put them into supers. I filled up the lower story with frames of empty comb and put the queen in, put a queen-excluder over her and set the super of laying workers right on top, and they accepted the queen. But I guess it would have been better if I had broken up the whole business. I think that is the better way.

Mr. Wilcox—I said I did not wish to, and I do not; but I have done it a great many times by introducing a comb of hatching brood and about 48 hours after introduce another comb of hatching brood, and those hatching bees usually destroy the laying workers, or they cease to be laying workers, and will accept a queen or queen-cell. It will not work every time, but it does in a majority of cases. Sometimes I try the third or fourth time. Meanwhile they are hatching their bees.

Mr. Whitney—I had forgotten that. I tried that very thing. I put in one frame and then another, but they did not produce any queen-cells at all, and I just adopted the other plan.

"What percent more honey can be secured with the Danzenbaker than with other hives?"

A Member—Not any more.

"Which is best, to increase by natural swarming or artificial?"

Dr. Miller—It depends altogether upon circumstances, the man and his desires.

Mr. Abbott—Locality?

Dr. Miller—Yes; a great many things come in.

#### HIVES IN CELLAR—PUTTING OUT BEES.

"Should hives be set on an incline forward in the cellar? What are the conditions indicating the proper time to set them out in the spring?"

Dr. Bohrer—Yes, I would say to the first; and second, any day in March that is warm enough for the bees to fly out. That is in central Kansas. Farther north it would perhaps be too soon.

Mr. Taylor—As I set them I would not incline them. I set them directly up one on another. As to taking them out, Mr. Wheeler speaks of when he sets them out, they gather into the hives that are not their own. I can tell him how to prevent that. Do not take them out when it is warm enough for the bees to fly. Take them out rather early in the season, and taken out when it is too cold for them to go out of their hives. I generally take them out about the last of March and they are quiet, just as quiet out there on their stands as they would be if they had been there all winter; and when it becomes warm enough for them to fly they begin to fly just as they would in the spring if they had been out there in the winter, and we have no difficulty with their

"drifting," as it is called, or swarming out, or anything of that kind.

Mr. Thompson—I would like to ask, in the case of drifting in the spring, is there danger of carrying foul brood at that time if there is any foul brood in the yard?

Mr. Taylor—I don't know, but I should think very likely there would be.

Mr. Kimmey—Two years ago I took my bees from the cellar, carried them out and put them on the stands on a bright, warm, sunny day. Immediately upon my moving them out, I narrowed the hive-entrances so I thought I would prevent any robbing, and they flew out and went back of their own accord, seemingly every bee in its proper hive. Last spring I took them out on a cool day and they staid out 2 days. I took them out Friday, and on Sunday morning the air was full of bees, and they "drifted" right into that corner of the yard, and this corner had scarcely any. That is an actual experience.

Mr. Taylor—Locations must differ.

Mr. Wilcox—I will say, in answer to that question, I agree with Mr. Taylor emphatically. I put my bees into the cellar without bottom-boards, and consequently they stand level. If the bottom-boards were on I would prefer they should be slanting, so that the bees in a warm spell might clean out the dead ones more easily. But in carrying them out in the spring I find it more convenient to move them while the temperature is going down. For that reason I carry them out between 4 o'clock and bedtime, and if they fly a little before dark all the better, but if they do not, they take their chances in the morning. It may be a foggy, wet day, in which case it would be bad for them, but otherwise it is all right.

Miss Wilson—We commence carrying out ours in the morning and carry them out as fast as we can. When we close the entrance down to a small entrance we have had no trouble with their mixing.

Mr. Kimmey—Perhaps I would better say I did not close the entrances, and perhaps that is the secret. The year before I was careful to close them, but having carried them out and leaving them from Friday to Sunday, left them open. I have the bottom-boards off all winter.

Mr. Taylor—In regard to closing the entrance, I think it is of prime importance that the entrance be closed up to say an inch just as soon as they are set out. As surely as you leave the entrances wide open, when a warm day comes robbing will be begun; but if you close them up to about an inch, you will never hear anything about robbing.

Mr. Pease—On that same theory, setting bees out in the spring and closing the entrances to prevent their robbing or drifting, as I understand the question, if bees are wintered outdoors, with what we call a small opening, in the spring when our bees come out, does the same theory apply to close the entrance to prevent bees from drifting or mixing when they take their flight in the spring?

Mr. Taylor—They are not apt to drift if they are out all winter.

# American Bee Journal

Mr. Whitney—With me, I never close the entrance, but mine is a double-wall hive, has a subway, and I do not have to close it in the spring or any time in the winter. It stands out all winter and I do not have any trouble with their drifting or going to other hives when they come out in the spring, because they come out always when it is warm enough during the winter any time.

## THE BEST SUPER.

"What is the best super for comb honey?"

Dr. Miller—T-super.

Mr. Taylor—I would not have one on my place.

Pres. York—What does Mr. Taylor prefer then, a section-holder super?

Mr. Taylor—No, not exactly; I want a wide-frame, single tier.

Mr. Wilcox—That is mine exactly, for my locality. I think if I lived where Dr. Miller does I would not care so much for it. The reason I prefer the wide frame is because the top of the section is covered, and the bees can not fill it with propolis. They surely would in my country and they surely would not do it with white clover.

Pres. York—How many prefer the T-super? 4. How many prefer the ordinary section-holder super without a top-bar, like the wide frame, the ordinary section-holder super? 4. How many prefer the wide-frame super that Mr. Taylor speaks of? 5. Any other kind of a comb honey super?

Mr. Abbott—What does Mr. Taylor mean by wide frame—with slats in the bottom or what?

Pres. York—As I understand, it is enclosed all around, single-tier instead of double-tier.

Mr. Taylor—Top and bottom reversing, enclose the thing. If made right they are the best thing you can get, not excepting the T-super.

Mr. Abbott—I wouldn't have them.

Mr. Arnd—How do you get the sections out of such a frame as that?

Mr. Taylor—The great thing is to get them in. There is no trouble getting them out. I can show you. What do you mean, get the frames out of the hive?

Pres. York—How do you get the sections out of a wide frame?

Mr. Taylor—Supposing this is a wide frame (indicating). Of course the wide frame is made to clasp the section so that the bees can not get much propolis in between the top-bar and the section. Ordinarily, unless it is cold weather, they will come right out, unless there is considerable propolis there. In that case the top-bar may stick to the sections a little. In that case you want to just run a knife a little between the top-bar and the sections, then take your thumb-nail and press on the section at this end and just start it a little, and take that end the same, and they drop right out.

Mr. Abbott—You will wear your thumb-nails off.

Mr. Taylor—It won't wear mine off. Everybody that works with bees ought to have thumb-nails and finger-nails. It is just as necessary as to be ingenious. You can't get supers made right in the

shop. I will tell you why. The manufacturers are careful to save every sliver of their lumber, and they cut the bottom and top-bar straight across. You want to cut them the right length and then let the saw run over the bar so it is not straight. It is a little bending. Then in nailing them together you put those bends in so they will hold on to the section, and they keep the propolis out.

Mr. Wilcox—I think there is a better way to get them out than that. I would not use the wide frames if there was not. I would adopt the T-super. I have used for many years a "back," or you might call it a "push-board." I wish I could illustrate it and possibly I can.

Mr. Taylor—To get them out of the wide frames?

Mr. Wilcox—Yes, sir.

Mr. Taylor—Where is your separator?

Mr. Wilcox—My separator is nailed right on to the side of the wide frames. It is a 4 1/4 section and a 3-inch separator, and there is a little space both above and below the separator. It doesn't extend clear to the top nor clear to the bottom. There is space enough so that a thin board, it may be wood or metal, is fastened on to the edge and sticking up an inch on each side, and then you take the wide frame with the tin separator side down, and lay it on that block so that the edge of the sections both top and bottom comes right along the edge of this strip nailed on to a little block here, or, if it is metal, screwed on. Then you push a little down on it and all your sections are pushed right up and out as far as you wish them.

"Is the T-super suitable for a beginner?"

Mr. Taylor—No.

Pres. York—It is all right for a man who has had bees for 40 years, and has written a book on them, I suppose!

Dr. Miller—I would advise a beginner, if he wants to begin with the best, to begin with a T-super.

"If the T-super is the great comb-honey super, how is it that it is not listed by manufacturers?"

Mr. Taylor—They know better.

Dr. Miller—Another question might come up on that: How is it that manufacturers list T-tins and do not list T-supers?

Pres. York—Because they want to sell them, I suppose. What do you know about that, Mr. Abbott?

Mr. Abbott—I know we have some we would like to get rid of. If the Doctor wants to make any T-supers we can furnish the tins. We have had them a long time.

Dr. Miller—I have some wide-frames I might trade for them. [Laughter.]

## ADVERTISING HONEY.

"What can bee-keepers do to advertise honey?"

Pres. York—Mr. Burdette is here, who has had considerable experience in helping other organizations advertise.

Mr. Burdette—I was in charge of a press bureau that has been tried by the National Council of Horticulture, which is an organization to which applications have been sent by all of the trade associations of the seedsmen, florists and

nursery men. The President of it is Mr. J. C. Vaughan. Horticulture has been taking quite a spurt in public interest in the last 2 or 3 years, and Mr. Vaughan conceived the idea of trying to give it a little impetus by teaching the public the value of shrubs and flowers, and the National Council of Horticulture has undertaken to supply the newspapers throughout the country with articles on horticulture—articles that would deal with the subject in a purely elementary way, and intended for amateurs. They are trying to get people to grow flowers and to plant shrubs in their yards. We conducted an experimental service a year ago for 10 weeks, sent articles to 2500 newspapers all over the country, and in most of those papers the articles were printed. Mr. York thought it would be possible to apply the same system to arousing public interest in honey. I do not see why it would not be possible. Horticulture, of course, appeals to more people perhaps than honey would, as horticulture appeals to more people than bee-keeping, but still everybody can be induced to eat honey, and if you put the advantages of honey before them in the newspapers, I should think it would help broaden the market. I have outlined in a letter to Mr. York a plan based on the experimental service that we conducted for the National Council of Horticulture, to send out to the newspapers about 4 articles every 2 weeks for a period of 20 weeks. That would be practically the same amount that we distributed along horticultural lines, except that it would extend over a longer period, not to give them so much matter at a time, and by keeping a check on that, a check of results, it would be very easy to determine what its value would be to the bee-keeper. We can find out just how many newspapers use that matter, and then the bee-keepers themselves could tell what effect it had upon the public, and it would be a very simple matter to determine just how far that method of publicity could be used to benefit the bee-keepers. Mr. York asked me to come here and explain this to you; it is pretty hard to explain in detail, and I am sorry I did not bring some of the clippings. We had great success with the horticultural matter. The Chicago Tribune published all we sent. The Daily News did also, and practically all the large newspapers all over the country we sent it to were glad to get it, and it seems to me similar matter might be gotten up about honey which could be used with equal success.

Mr. Taylor—I would like to ask a question. You say you are highly successful in this advertising. In what did your success consist?

Mr. Burdette—We succeeded in getting the matter in the newspapers all over the country. The seedsmen seem to be of the opinion that it helped them decidedly.

Mr. Taylor—In what way did it help them?

Mr. Burdette—It helped them by increasing the public demand for seeds and shrubs.

Mr. Taylor—Was it advertising seeds or novelties?

# American Bee Journal

Mr. Burdette—Practically old stocks. Mr. Taylor—Weren't people pretty well advised as to old stocks?

Mr. Burnette—They certainly were not. The newspapers seem to believe what the people want is elementary instruction in horticulture. The fact is, most people don't know much about it.

Mr. Taylor—Did the instruction consist in directing as to gardening, as to plan?

Mr. Burdette—Simply general instructions.

Mr. Taylor—Not particularly as to purchase of seeds, simply how to take care of the plants?

Mr. Burdette—What plants are suitable for certain places. One article might be how to make a backyard garden, what kind of shrubs or perennials to plant, and how to take care of them. So about the color of the blossom, the kind of soil, whether to plant in a shady or sunny place.

Mr. Taylor—And what parallel is there between advertising in that way in regard to horticulture and in regard to honey?

Mr. Burdette—Of course, we would have to advertise in a different way in regard to honey. The only parallel is generally that all advertising, if good for one thing, is good for another.

Mr. Taylor—What instruction could you give in an advertisement in regard to honey that would be of benefit?

Mr. Burdette—Of course, it is not an advertisement. It is simply a little article.

Mr. Taylor—The effect is the same. That is, you look for an effect from the advertising, though you manage to get your advertising done without paying. Still, that is all the good effect you get, because your things are advertised.

Mr. Burdette—I should say that you could publish interesting facts about honey. Tell the people some things about honey, and they would begin to think about honey. If you told them the value of honey from the food standpoint, perhaps they would buy some.

Mr. Todd—There are two kinds of advertising. There is the plain, straightforward kind of advertising and the insidious. Mr. Burdette has been directing the insidious campaign in favor of the seed-business.

Mr. Burdette—It is more in the nature of general publicity than advertising.

Dr. Miller—If Mr. Burdette knows how to put the things before the public that we would like to get before them, we can get them to want honey a little more than they do now. Do you believe you could do anything of that kind?

Mr. Burdette—Well, I do believe that I could get interesting facts about honey published in the newspapers. I suppose unquestionably that would increase the sale of honey. I do not see why it should do otherwise.

Dr. Miller—Then I would say if you could increase the demand in that way we could sell it for a higher price. Do you believe, sir, that you can get the papers to put in some suggestion that honey is a good thing, that it is more wholesome to have honey than candy

for children, and that they would live longer if they had honey?

Mr. Burdette—Of course not in those words.

Dr. Miller—I am not asking that.

Mr. Burdette—Of course, I have never tried to get anything about honey in the newspapers, but we have got stuff in about flowers and plants.

Mr. Todd—Entirely different; very different.

Dr. Miller—I don't know, sir, that it is entirely different. I think he could do it.

Mr. Burdette—My personal opinion would be that I can.

Mr. Chapman—I would like to state that Mr. Hutchinson had an article in the *Cosmopolitan* a few years ago that was interesting enough for the magazine to publish it, and was widely read over the United States. I had friends tell me that the best they ever read about bee-keeping was that article, and such articles could be put in the daily newspapers, not as extensive as his, and they would awaken an interest in honey.

Mr. Thompson—When it comes to newspapers printing anything that is given to them on the subject of bees, I think they will print anything—some newspapers will. Perhaps there are some here that will remember two or three months ago the *Chicago Record-Herald* had an article stating that a bee-keeper in Iowa who had kept bees for a number of years died, and his bees commenced to sulk, they would work no longer, and they had trouble keeping them away from his remains—they followed him to the grave, they had such an attachment for him. So if a newspaper will print anything like that, you can get them to print anything, can't you?

Mr. Abbott—It seems to me very clear that here is a plan of advertising that is almost unlimited. I have had a good deal of experience. I am a newspaper man myself, and I haven't an ax to grind and I am not scared at advertising. But let me tell you about a class of advertising that is done all over this country that you have read and did not know it. There is a woman who writes from some place in Kentucky, that signs her name "Kentuckian" mostly. She is employed by the Sapolio people, and the Pearline people, and the borax people, and several other people, and she writes home articles for papers. Her articles appear all over the United States in agricultural papers in the home department, and the only thing that is in them—for instance, she will tell how to clean carpets, and the only thing that smacks of an advertisement is that she gets in the name Sapolio once in a while. The borax trust have women employed in the same way. One writes from Emporia, Kans., to the home department of agricultural papers. She recommends borax for sore eyes, and boric acid for all sorts of things. They try hard to "work" us. They "worked" my wife for a little while. She is better natured than I am. I eliminated the borax. I said, "some good disinfectant." I eliminated Pearline and said, "some good washing powder," and of course the articles stopped when I edited them, which was a good thing. It could just as well

be honey as borax, and if General Manager France would arrange with a half dozen men like Dr. Miller and Mr. York and others that I can mention, to write the articles, they can be put into 99 out of 100 of the newspapers of the United States tomorrow, without any trouble at all. That will boost honey just as high as you want it before the public, and it will double the demand for honey all over this country in a little while. I wish the National Association would just take up that kind of thing and spend two or three thousand dollars lying in the treasury doing nothing in advertising honey all over the United States.

Dr. Miller—I want to endorse what Mr. Abbott has said, and then add this: The material that we would want to go before the public, there would be in it no trick. This is no "Sapolio" business. It is all square, honest work. Here is information that the public needs, it is for their benefit. We can get it in. I believe, further, that instead of having me do a part of it and Mr. France, and so on in that way, if this work has been done for the horticulturists, the experience that has been gained in doing that work will be of immense advantage in our work. But, as I said before, I have not examined carefully the material of which this man is made. If he is put together so that he can get things into papers, I would rather a good deal get some man who is expert at it to do it than to have us bunglers go at it. It would be worth a great deal more. I don't know him at all, and I don't know what commission he may get on what he can do, but if he or his concern to which he is attached can do the work, I believe it would do us a lot of good to pay something for it.

Pres. York—I know Mr. Burdette a little bit, and anything he would prepare would be submitted to Mr. France or a committee designated to revise anything he might write. But I am satisfied that he can get things into papers that we could not at all, because he has been doing it.

Mr. Kimmey—I was surprised when Mr. Burdette came in today. I have known Mr. Burdette for a long time, but I did not know he had been engaged in the horticultural business. I did not know he knew Mr. York, nor that he was coming here. I also know something about the seed trade. Mr. York has told you that I am Secretary of the National Poultry Association, whose business it is to give a poultry show in Chicago. For every meeting I have been in the habit of employing some press agent. Last year I employed Mr. Burdette, and he is head and shoulders above any other men and women I have employed. I have a new contract, signed a few days ago, agreeing to pay him two or three hundred dollars for three weeks' work. You have all got articles in your papers. We worked it up. We have them in nearly all the papers. It is an educational business. You don't need to hide a single thing when we talk about honey. We don't have to misrepresent a single thing. Without knowing that Mr. Burdette was at all to blame for it, or had anything

# American Bee Journal

to do with it, I know that the demand for seeds, bulbs and such as he mentioned last season was phenomenally large in Chicago. Every seed-house was burdened with work, and they did not have to burn a single pound of their seed nor to throw away a single one of their shrubs. It is a matter of notoriety, known throughout Chicago. I am glad it happened so that I could give this testimony in favor of Mr. York's project, and of Mr. Burdette's idea. As to just what persons shall do this work, I have no doubt—pardon me for saying it—that I could write an article just as well as Mr. Burdette can, but I have other things to attend to. I think Dr. Miller could write better about honey than Mr. Burdette. But I think to entrust the matter to a man like Mr. Burdette, who will bore Dr. Miller for facts, and go to Mr. Hutchinson and Mr. York, and then sit down and trim it all over, will do more effectual work than you can if you scatter your energies.

Mr. Whitney—I feel great interest in this matter of the education of the public with regard to the value of honey, and it is my opinion that there is nothing that we can say in a public way as to the use of honey that will not do the bee-keeper good. I have had a little experience up at our place. Our local editor there wanted to know if I would not write something for the local paper, and I wrote a few articles, and they appeared every week for 5 or 6 weeks, and people became very much interested in bees and honey, and since then I have not asked a single person to buy any honey; I could sell more of it than I can possibly produce or get. I know that publicity is a good thing for honey, if you talk right, and tell the truth.

Mr. Burdette—Some misapprehension seems to exist as to the nature of the articles that we sent out. It was not our purpose in doing this horticultural work to trick anybody. We simply filled a legitimate demand for horticultural information.

Mr. Todd—How to do.

Mr. Burdette—Yes, exactly. For one thing, we had the experience of Mr. Keeley, Managing Editor of the Chicago Tribune, who once conducted a department of gardening on that paper, and he told us it was astonishing the number of people who were absolutely ignorant of the first principles of gardening—people who would buy bulbs and plant them upside down; didn't know how to plant seed or anything of that sort. The papers all seemed to know that there is a great deal of interest in that sort of thing, and were glad to get the information that we furnished, and they understood thoroughly that we furnished it, and why we furnished it. We had a large number of scientists on the National Council—Professor Tracy, of the Department in Washington; Professor Taft, of the Michigan Agricultural Experiment Station, and Professor Irish, of Shaw's Gardens, in St. Louis. I believe there is also a great deal of interest in bees all over the country, and in honey, and that the papers would be willing to print whatever we might send out about bees and honey, provided

it was written in the right way. Of course we could not send out what was purely advertising, saying people ought to buy honey. Papers could not print that unless we paid them for it; but I have gone on the assumption that there is a great deal of information about the use of honey, and facts about bees, that the public would be glad to know, and the papers would be glad to print, and the effect of those articles would be to interest the public in bees and in honey, and the indirect effect would be to increase the sale of honey. Of course, the only thing projected here is an experimental series to see just exactly what kind of articles can be prepared along that line, and what effect those articles will have. I think it is worth trying. Don't you think that there is material for articles on the use of honey and facts about bees?

Mr. Todd—Most people use honey simply raw. You might have one article acceptable about honey, but you would not have a series which would give it the force of cumulative advertising.

Dr. Bohrer—what was Mr. Burdette's question?

Mr. Burdette—I was asking if there was not material for articles of that sort. I am not very well acquainted with bee-keeping or with honey. I don't know what material there may be.

Mr. Todd—How many different ways could honey be served up?

Mr. Abbott—I want to say, without any egotism, that I can sit down here in an hour's time and write an article on honey that will go into any paper in the United States. There isn't a paper in the United States that would not publish it.

Mr. Todd—And a second one?

Mr. Abbott—Yes, sir, and a third one, and I can write a fourth one that any paper in the United States will print, and pay me money for doing it, and I can write a fifth one that the papers will take and pay me for it, and there won't be any nonsense in it. There won't be any bees following their master to the grave or anything of that kind. But you need not talk about anybody that does not know the honey-business from A to Z and has not been in it 25 years, as I have, because they can't do it. You don't have to tell people to buy honey. You have to tell people to eat honey, and then if they haven't got the honey they will come to you and buy it.

Dr. Bohrer—Isn't it also important, and of greater importance at this time than anything else, to satisfy the people that what they are getting is absolutely pure?

Mr. Abbott—Yes, sir. I could write on the purity and the probability of being adulterated. There is no doubt about the facts. The papers will publish that.

Pres. York—I do not think I could write many articles on photography, as Mr. Todd could do, but I think I could write a few articles on honey.

Mr. Clarke—Probably I might give an illustration in a small way of what people want to know about honey. I have conducted a bee-department in an agricultural paper for 7 years in Iowa.

I have undertaken to answer any question anybody asks me pertaining to bees or honey, and I do not know exactly the number of inquiries that I have had in 7 years, but I think it is over 7000 in regard to bees and honey.

Mr. France—I would like to get the expression of the honey-producers on this subject. They are interested in the disposition of their product. Various ways have been suggested, and this means of advertising is a good one. There was a fund transferred over to the National Association, and it has been waiting for effective work until we could get a system and something that would give satisfaction. To get a committee that would be satisfactory to the producers and to those who had transferred this fund to the National has been a difficult matter. That, I think, is about through with, and the next question came up wherein or how we shall begin the use of that fund to advertise and create a demand for more honey. This proposition that has just now been discussed will be one of the first that that committee will consider. Two at least of the three I know are favorable to starting such a move in the near future. Other ways have been suggested, and the more that you can suggest to this committee the better, and save your time for the convention. I believe one of the things we have got to employ, as has been done in other lines, is telling the usefulness of honey to the public. When they realize the value of it as a food, then enlighten, in some way, the public, that when they are buying honey they are getting Nature's purest wholesome sweet for their stomachs, and you have established a demand for honey.

Dr. Bohrer—And that what they will buy will be honey.

Mr. France—Yes, sir.

Mr. Burdette—I want to say I do not know anything about honey. I would not attempt to write these articles myself. The horticultural articles were all of them prepared under the direction of experts. Most of them were prepared by Professor Irish, who is in charge of Shaw's Gardens at St. Louis, one of the largest botanical gardens in the country, and they were sent to me. I simply took them—most of them were too long—I made it a rule not to send out any article of over 300 words—divided them into appropriate lengths, and re-wrote them so as to get the "feature," as we call it in the newspaper business, at the top; simply put them into shape so that the newspaper editors would not have to revise them; and that is all I did, simply to distribute these things to the newspapers in the proper form. As has been stated here, they should be written first by men who know honey; that is, the material should be supplied by those men, and all I could attempt to do would be to put that material into the form for the newspapers. There are a good many things to consider when you do that. I am a newspaper man. I think I know the way to do that, although I don't know anything about honey. That is all that I would do, and the estimate I made for this experimental work was simply putting it into shape and send-

# American Bee Journal

ing to the newspapers. For preparing material it would be different.

Mr. Hutchinson—Speaking of writing some articles to do some good to sell honey, I have some honey of my own this year and I wrote an advertisement advertising that honey. I tried to write it in such a way that a man reading that advertisement would want some of that honey. A man wrote me, "I have been tasting that honey ever since I read that advertisement." That is the kind of an article we want to write for the papers; when a man reads the article he wants to go right out and get some honey and try it.

Mr. Taylor—There is a distinction I think we ought to make in this matter of advertising. That is, the difference between advertising a person and advertising a product. Now Mr. Hutchinson sold his honey because he advertised himself; he advertised the fact that he had honey to sell. It was not because he gave any new information about honey that enabled him to sell. It was because he advertised himself.

Pres. York—Mr. Hutchinson said the man was tasting the honey all the time, and not tasting Mr. Hutchinson!

Mr. Taylor—Because he had a good deal of faith in Mr. Hutchinson, and knew any honey he extracted of course would be extra-good.

Mr. Chapman—I would like to call attention to a fact that is really before the meeting here. I see by the newspapers that one of the women's clubs here is discussing the reading of Dickens' works because he always refers to eating and drinking, claiming that the references to eating and drinking cause a great many people to go out and overeat and drink. It is along this line that our friends refer to—discussing honey, referring to the fact that it is one of the oldest foods known in the world, that it has come down through the ages to be a blessing to the people, that people with delicate stomachs who can not eat sugar or syrup can still eat honey; such statements will set a person thinking that he hasn't had any honey for a good while, that he would like some now, and he goes out and buys it.

Mr. Arnd—I was a contributor originally to the fund for advertising. I move that the Chicago Northwestern Bee-Keepers' Association recommend to the National that they use the fund mentioned by Mr. France, in just such advertising as we have spoken of today.

The motion was seconded.

Pres. York—I ought to say, perhaps, before we take a vote on this, that the experiment will not cost over about \$300 to make the first engagement. It is moved and seconded that we recommend to the National, or to the Directors, that the money in their hands from the Honey-Producers' League be used in such work as has been outlined here. Of course there may be other methods, used also.

The motion was put and carried.

**FOUL-BROODY COLONY DEFENDING ITSELF.**

"Is it a fact that a foul-broody colony defends itself against robbers with less

vigor that a healthy one of corresponding strength."

Mr. Taylor—Yes, I think so. It makes them have less heart, don't care whether school keeps or not; and, more than that, there is a scent about the hive that I think attracts robber-bees. Don't you think so, Mr. France?

Mr. France—Yes, sir.

Mr. Taylor—If there is a colony that has any foul brood about it, you will notice the robber-bees are prowling around there. I don't know whether it is the scent, or whether they appreciate that the defenders are not very anxious to defend their hives. Any way, you have got to look out if you have a colony of foul brood.

Mr. France—I think Mr. Taylor has pretty nearly covered the ground. The bees seem to lack the defensive, and the odor also seems to have a tendency to warn the outside bees that there is something wrong.

## BROOD-CHAMBER IN WINTER.

"For wintering on the summer stands in 10-frame Langstroth hives, is it advisable to contract the brood-chamber with tight-fitting division-boards?"

Members—No.

Mr. France—That depends upon your location. The farther north you are the more you need to contract them. You do not need any of that if you are down in Missouri; and if you go into the extreme northern part of Wisconsin where the thermometer goes to 40 below, you have other conditions. There are other conditions for an outdoor winter. I want a good, vigorous queen in the fall, and more than honey enough.

Mr. Wilcox—I would say from what experience I have had in outdoor wintering that I would contract a little, but more especially put on another story, use the second story for outdoor wintering, always with 4 or 5 combs in, and of course a division-board at each side and packing behind. I think the second story is the most important part of outdoor wintering.

Mr. Jones—I would say it depends not alone upon the locality but upon the strength of the colony. With a really good young colony with plenty of bees in there, there would perhaps be no necessity of it, and perhaps no advantage; but a small colony, I say by all means to contract. I have wintered bees in Wisconsin outdoors. Up there I do not think there would be any show of their wintering if they had not been contracted.

Mr. Chapman—I believe 2-frame division-boards, in our locality of Chicago, are of great benefit to the bees. Mr. Wright, at one time attending our convention, said if you would take a super of dry extracting combs and place it underneath the hive-body where you wished to winter them, it would be far better for the bees. I have practiced that now for 6 years; placed it underneath, put a super the section-size on top of either excelsior or ground cork, and I have never lost a colony of bees. I did not lose them 3 years ago when so many were lost here, and I have my bees right on the roof of the house, where they are exposed to all the winds

and weather that can be, and I think I have struck an excellent plan.

## POINTS IN JUDGING BEES.

"In judging Italian bees at fairs, what points should be taken into consideration?"

Mr. Wilcox—I did not ask that question, but that is just the information I want. I may say what I have done, but I don't know what I ought to do. I have considered as of first importance uniformity of markings. This, of course, speaks of Italian bees. Uniformity of markings of the worker-bees is my standard for purity. If all the bees are alike—size, color and shape—I consider it proof positive that they are pure-bred. It is the only standard I have, absolutely, in judging bees. If I had them in my apiary where I could observe their actions, then I would have additional standards, but we can not have that at the shows, consequently we must judge from the looks only. Size and uniformity of markings are the principal things. Size, however, is an uncertain standard, because the more agitation, excitement and jarring you give them the larger they will be. You go in the morning and look at the bees on exhibition and they are small, and in the afternoon they are much larger. The fact is, they have gorged themselves with honey. So you can not depend very much upon the size, but you can upon the markings.

Mr. Jones—Wouldn't it be a little advantage for a person to get them in show condition, if he knew when the judge was coming around?

Mr. Wilcox—If size were important he could, but size is not a very important point.

Mr. Hutchinson—Uniformity is all you can go by. You can't tell by the size. If they are uniform in marking that is the best we can do.

## FOUL BROOD LEGISLATION.

Dr. Bohrer—It may be a mere matter of criticism upon my part to call the attention of this Association to the matter of foul-brood legislation. I understand that here in Illinois you have a law for the use of the bee-keepers of the State, but that does not clothe a bee-inspector with authority to go upon the premises of a man who may have foul brood, except at his will and pleasure. I don't know if you want to get the legislation to take cognizance of a matter of that kind. Find out and make a report of such persons as refuse flatly and absolutely to allow a bee-inspector to cure the disease or stamp it out, destroy his bees or make an effort to get them cured. If you can gather sufficient evidence, even perhaps one or two cases of that kind, where men have refused, then go to some influential member of the legislature, and some man who knows something about the business, if you can find one. We succeeded in our State in finding a man who knew something about bees and the wants of the bee-keepers. He laid it before the legislature. They were ready to hear it, when they found it was about to destroy an industry—an infant industry but growing rapidly—and we

# American Bee Journal

got a law. I believe if you can go before your legislatures with something of that kind and send men who understand what foul brood means, the destruction that it will bring to the industry in the State if not stamped out—and there is no question about that, it is unquestionably spreading, and where there is any carelessness tolerated it will continue to spread—if you will lay the matter before the legislature in that shape, get an influential member that will work, you may get a foul-brood law through that will clothe you with authority to stamp out the disease. I have been twice to our State legislature and have learned something about the way these things are managed, and it depends

largely upon whose hands you get it into.

## GETTING BETTER CONVENTIONS AND ATTENDANCE.

"How shall we have a big attendance and a good meeting next year?"

Mr. Taylor—Advertise.

Mr. Jones—Everybody come again and bring one with them.

Pres. York—I think that is a pretty good idea, and perhaps it could be pushed a little more in the various newspapers. Is there anything further? If not, we will stand adjourned until the call of the Executive Committee next year.

to be sealed as worker-brood you needn't worry. If brood in worker-cells is sealed so it looks like little marbles instead of having a flat surface, then you must kill the queen and treat the colony as a queenless one.

I wish you'd tell us how it comes out.

## Managing Nuclei, Etc.

1. I have ordered some nuclei which will be here about June 1. How shall I manage them for the best result? I never did any work of that kind.

2. Early in the spring of 1906 I had a nice, large swarm come out, and I hived them in a good hive. They worked well, and in about 4 or 5 weeks they sent out a swarm. On examining them, after a few days, I saw no bees in my first hive. The comb was nice and white and the hive was full of it, but the bees were gone. They had been carrying in pollen far ahead of any other bees I had. What was the matter?  
KENTUCKY.

Answers.—I. Put the frames of the nucleus in a full-sized hive in the middle of the hive, in the same relative order in which they were in the nucleus. Then fill out the hive at each side with frames that are entirely filled with foundation. Look out sharply for the matter of stores. The probability is that there was not a very big lot of honey in the frames of the nucleus, for it is not best to ship too heavy combs. If you have combs of honey, it will probably be a good thing to give 2 of them to the nucleus, one on each side pretty close to the brood.

2. Hard to say. The young queen may have been lost on her wedding flight, but there probably was some other trouble besides that, and I don't know what it was.

Send Questions either to the office of the American Bee Journal, or to  
DR. C. C. MILLER, Marengo, Ill.

Dr. Miller does not answer Questions by mail.

## Changing from Closed-End to Hoffman or Miller Style of Frame

We became interested in bees about three years ago, and now have twenty colonies in Danzenbaker hives. We want to increase to fifty or more colonies. So far we have no reason to regret our selection of the Danzenbaker hive, but we sometimes think there are other brood-frames that would suit us better. Having always to cut or break the frames apart is considered a drawback, and it occurred to us that we would fit up our next hives with Hoffman metal-spaced frames, or Miller frames, of the same depth as the Danzenbaker frames. In this way we would be able to judge which is preferable, as we have had no experience with any but the Danzenbaker frames.

The only change in the Danzenbaker body would be the cutting of the rabbet to receive the end of the Hoffman or Miller frame.

After our trial of the other frames, the hives we now have could be easily changed to suit the Hoffman or Miller frames, or should we decide to continue with the Danzenbaker frames it would only be necessary to fill out the rabbet cut to receive the hanging frames.

Our preference is to run for comb honey, and so far we consider the Danzenbaker super equal to any in use, but we are unable to decide as to the brood-frames.  
MISSOURI.

Answer.—Your scheme is feasible, but it still leaves undecided the question as to the difference between the two depths of frames. Perhaps, however, you do not care for this.

## Management of Swarms

On May 17, hive No. 5 cast a very heavy swarm. It was hived on foundation starters and set in place of hive No. 5 on the old stand, No. 5 being removed to a stand several feet away. Today (May 28) hive No. 5 cast another swarm. I caught the queen, clipped her wings, and put her and the swarm back into hive No. 5, from whence they came. Then I went through hive No. 5 and cut out four or five queen-cells, or what I thought were queen-cells. Now I am told by a bee-keeper that I

should not have clipped the queen's wings. He says that in all probability the queen was not mated. Did I do right? If the queen is not mated, what shall I do? There is a great deal of unsealed brood in the hive from which the bees could rear a queen, but would they do so with the clipped queen in the hive? It does not seem reasonable to me that this young queen did not mate before the swarm settled. Please put me straight.  
WESTERN IOWA.

Answer.—When No. 5 first swarmed, you set the swarm on the old stand. Orthodox, so far. Then, at about the same time, you set the old hive on a new stand some feet away. Heterodox. Please never do that again—well, don't do it again unless you want the bees to swarm again. Set the old hive close beside the new one, and a week later move the old one some feet away. That will throw all the flying force of the old colony into the swarm, weakening the old colony so much at the right time that it will give up all thought of swarming. But you moved the old colony to a new stand at once, and eleven days later they had gained so much in strength that they felt competent to swarm, and it was the orthodox thing for them to swarm with the first virgin that emerged. Then you clipped the queen that came out with the afterswarm. Heterodox. She may have been fertilized, and she may not; but in any case you were running a big risk in clipping her. You returned swarm and destroyed all queen-cells. Orthodox. Then you found unsealed brood, lots of it, in the hive.

Now, look here, I'm willing to try to help you out in any of your misdeeds, but when you get the bees to doing unorthodox things, that puts me out. After the old queen had left the hive eleven days, those bees had no business to have a single cell of unsealed brood, to say nothing of lots of it. The whole thing looks abnormal—heterodox. Where did that brood come from? Did a laying queen from some other colony get into the hive by some freakish performance after the hive was moved to its new stand? At any rate, there must have been a laying queen in the hive after the swarm issued, and if that's the queen you clipped, then all right—unless the bees swarm again. At any rate, with plenty of unsealed brood in the hive there is no immediate danger.

I don't know enough to tell you just how things are, but so long as brood continues

## Rearing Queens for an Amateur

1. Not long ago I wrote you asking if good queens could be reared in a queenless colony, and you said, "Yes, if rightly managed;" but you did not say how, and how to do it was what interested me. Again, I asked if another plan would work. You said probably, but would advise me to take a little more trouble and have the best queens obtainable. This is what I would do if I knew how, but here again I was left in the dark. It was not curiosity that caused me to ask the questions; but because I did not know better. Perhaps I did not make my meaning plain.

2. Can good queens be reared in a queenless colony?

3. If so, how?

4. Is there a better way of rearing queens for an amateur without queen-rearing tools, when queens are wanted before the swarming season? If so, please explain.

5. Would you advise getting a queen-rearing outfit for one who would need 10 or 15 queens a year?  
IOWA.

Answers.—1. One of the unfortunate things in attempting to answer questions in this department is that it is not easy sometimes to know by the question what is in the mind of the questioner. Don't you think it's all that ought to be required of me if I answer the questions that are asked?

2. Yes.

3. Remove a queen from a colony of best stock in the height of the season, and the bees will of themselves rear one or more good queens.

4. If you mean a better way than starting cells in a queenless colony, I think not.

5. No.

There, I've answered your questions, haven't I? But I may as well own up that I've purposely answered the mere letter of your questions, without paying much attention to the spirit. I always do better than that, and answer the spirit of the questions, as nearly as I can guess what the spirit is, and so

I'll do as well by you now if you forgive the answers I have made.

You don't need any special queen-rearing outfit for 10 queens a year, nor for 100. I'll tell you how you can rear just as good queens as can be reared from your stock, with no other outfit than what every bee-keeper is supposed to have on hand:

Take a frame out of the hive containing your best queen, and put in its place a frame with a starter an inch or so deep. A week or so later you will find the bees have filled the frame  $\frac{3}{4}$  full, more or less, with new comb, with larvae well advanced down to eggs around the outside edge. Trim off that outer edge that contains only eggs, leaving the larvae. It isn't easy to be exact about this, and it isn't very particular, only don't cut away any of the larvae; no harm if you leave some of the eggs. Indeed it is not absolutely necessary to cut off any of the comb; only that outer margin is in the bees' way. Now put your prepared comb in the middle of a strong colony from which you have removed the queen, and in 9 or 10 days cut out the cells and give them to nuclei. In about 2 weeks later you ought to find most of them changed into laying queens. You see, it isn't a very complicated matter, and needs no special outfit.

You note that I give no date as to when you are to do these things. I can't, because it may be 3 weeks later one year than another. But be sure not to begin too early. In your locality, if you were to begin in March you wouldn't get one good queen out of 20. Figure so as to give the brood to the queenless colony when bees are working prosperously in the fields. In your locality that probably means that the bees should not start to build queen-cells until white clover begins to yield, or any time later; and of course the empty frame must be given to your best colony a week or so earlier.

Now if I've failed to answer just what you want to know, don't hesitate to ask again.

## Methods of Filling T-Supers

On page 995 (1906) is a discussion of the T-super by you and Frank H. Drexel, both favoring that kind of super. Like Mr. Drexel, I have blamed the manufacturers for forcing and keeping them out of the market, which I believe to be that the section-holder can be got up a little cheaper, yet when I send them a sample of mine, they get them up for the same price. The kind I use were gotten up by Elvin Armstrong over 25 years ago. He got up a hive and T-super which was spoken well of at that time by the American Bee Journal. Soon after that I learned that he had gone out of the business. About 10 years ago, I wanted to get some more of those supers, and sent to a firm for some T-supers, and after an aggravating length of time they sent me the section-holder, and I have not forgiven them for it to this day. I never put them on hives the second time.

I then sent a sample of the Armstrong to a firm in Minneapolis. That firm changed hands before I wanted more, but the pattern with the change was lost, so next I sent to another firm, and I suppose they have the pattern yet. In all the catalogs I have received for years I looked for the Armstrong T-super, but in all I found the immutable section-holder, with ever and anon words of some one that they don't like the T-super for some reasons which I think do not exist in the Armstrong super. And I know some of the objections which you urge in yours do not exist in mine. One of these is that they are liable to fall to pieces if you are not careful. Now, I don't care who doesn't use them, or who dislikes them, but I have paid out \$1.00 in expressage besides losing 2 supers to get what I wanted. I suppose you and Mr. Drexel use the same kind of supers and both bank on the short time it takes you to fill them, but time has cut no figure

with me, as I have but few bees and plenty of time on my hands, but, all things considered, I don't think you can distance me much.

1. I was amused by your direction how to make a super-filler, page 140, of "Forty Years Among the Bees." A queer super-filler, thought I. Miss Wilson page 247, is the super-filler, and your super-filler is the super. It seemed to me as I read it, your super-filler was filled, and its contents to be dumped into the super.

2. It seems from you and Mr. Drexel you fill the super crosswise, while I fill the other way, and I think in the long run I can do the work about as quickly as you. You fold the sections and stack them on a board. You must take some extra time to do that or you will have a scatterment of them, and may have occasionally anyway. I fold by a section-press different from yours, but perhaps no better, and I may pitch them into a bushel basket and save time over you. Sitting as Miss Wilson does, having the starter put in, I can put it into the super quicker than she can stack the empty supers on a board. Putting the far left-hand corner section in and adjusting the tin to it, I take the next, and so on until I have the far side filled. Putting the separator in, I can put the next row in nearly as fast as I can pick them up and lay them down. It appears that you put the separators in after you have all the sections in. How you get them in except one at a time, I don't know, but perhaps you do.

3. You claim that you have seen every kind of a T-super but I feel satisfied that you have never seen my kind or you would never object to some things, such as its falling to pieces. The only way of getting it to pieces is to tear it to pieces. I could turn it either side up as I use starters only in sections.

As to section-holders, the only fault I ever raised against them was that the bees would glue them fast so that I had to tear them to pieces to get them out. I did not have them long enough to warp. How those who used them kept the bees from sticking them fast, I don't know, and I don't care to know, for I don't want them.

I had a letter from Elvin Armstrong last fall from Colorado, saying he had improved his super and was going to get several thousand of them cut out by some factory and would come in when he had sold his honey. He had several thousand pounds. He said he would bring you and me a super, and if you did not say it was the best, he would be surprised. Iowa.

Answers.—1. You are quite right when you say "Miss Wilson is the super-filler," and quite wrong when you say, "your super-filler is the super." The same word, as you well know, may mean two different things. Looking in the dictionary, I find the definition of the word "filler" in part as follows: "One who or that which fills or is used for filling. Specifically: (1) A funnel." If a boy were filling a barrel with water, using a funnel for the purpose, you would say the boy is the filler, and at the same time you would hardly dispute the dictionary that the funnel is also a filler. So while Miss Wilson was the filler, was not the implement "used for filling" also a filler? When you say that my super-filler is a super, you evidently misunderstand the whole affair. Please turn to page 148 of the book, and you will see that the super-filler is not a super at all—doesn't in the least look like a super, as you will see by the picture of a super-filler on page 139.

2. It takes less time to pitch sections in a basket than to put them in a straight pile. You are quite right in that. But please note that it takes less time to pick them off the pile when putting in foundation than it does to pick them out of the basket, because when they are piled they are always standing the same side up, always in the right position to go to the foundation-fastener, but in the basket they are all sides up, and you must take

time to put them in the right position. Occasionally we may use the basket method, but we think the other way better in the long run. We've tried both ways; I wonder if you have. We've also tried putting the sections into the super your way, which, if I understand correctly, is to put the T-tins in place before all the sections are in, so that most of the sections must be put in between the tins, and that takes ever so much more time than to slip each tin under the sections after the sections are in. But to do this easily the super-filler is essential.

3. If I ever claimed that I had seen every kind of T-super it was a wild claim, certainly. There may be a dozen kinds that I have never heard of. Still, I've seen quite a few different supers.

## More About Texas Sumac.

Referring again to the kind of sumac spoken of in my article on page 279, I will say that I do not know enough of botany to enable me to give a correct description of this shrub; but it is a large, rather bushy kind, seldom having many branches low down on the main body. The leaves are oblong, pointed, smooth, dark green, branching out from a common stem. The berries, when ripe, are a bright scarlet color, and hang, or rather stand, on a short, stiff bunch of stems. It begins to open its bloom about July 25, seldom varying more than a few days. The period of bloom extends, as a rule, to the middle of August. The flower buds form at the extremities of the season's growth of new wood, and are often as large as a teacup. They seem to be altogether composed of a series of small petals, each containing a nectar cup or gland. Bees alight on the bunch and work over the entire flower. It is a composite plant, yielding both pollen and honey in great plenty. The pollen is a fine creamy-yellow color, and during the first few days of its blooming season the bees seem to gather an immense quantity of it, but later they gather only honey.

I am sending some of the leaves and berries. They taste very acid, but that is not strange, for, as you know, all of this species are tannic-acid plants.

This is about all that I am able to tell about it. The natural habitat of this shrub is West Texas, though it extends to a part of the Central Texas counties. I have never met with it in Southwest Texas, though a few of this kind grew near my old home in Bee county.

The honey from it is a very light yellow or pale straw color, very thick and heavy, and fine flavored. I had a sample at San Antonio. It is, according to my experience, a most certain yielder, and if we had even one more plant its equal bee-keeping would be a very profitable business here. As it is, we get an average of 50 pounds to the strong colony, though I have managed to get 210 pounds from a few choice colonies, and I feel sure that I will be able to get a heavy yield the coming season.

I have a new system by which I am able to get the most powerful and efficient working force. This contemplates the use of two queens in each hive, though not used in the manner lately described by some writers. My non-swarming board is used for the purpose. As I stated, by its use last year I was enabled to get 210 pounds from some few colonies. I think its possibilities are very great along that line, but I am not trying to urge its use; I know that I have a good thing for my own use, at least.

Concho Co., Tex.

[The leaves sent differ greatly from those of the sumac common in the North, being only  $1\frac{1}{4}$  inches in length and scarcely  $\frac{3}{8}$  in width.

By all means tell us about your plan of working two queens in the same colony.—EDITOR.]

J. E. CHAMBERS.

### The Caucasian Bees

I was so interested in E. A. Morgan's experience, on page 483, that I wish to say a word too.

I have been loth to say anything in praise of Caucasian bees, for so many have condemned them who have had no experience with the true Caucasian that I thought it would be powder burned to no effect. I am convinced that when the Caucasian bees have been with us long enough to know them, there will be a large number, who, at this time condemn them, will be converted to our side.

I got my first queens from the Government, and soon after I began to import direct from the Caucasus, and now have as fine a lot of Caucasian breeders as there are in this country. I have always prided my yard as being the most gentle bees to be found. But when I handle the Caucasian then I know they are the gentlest bees to be found on this continent. Instead of picking up the smoker to drive them back I simply blow on them and they leave as if smoke were used. If I wish to show them at any time of night they act just the same as in the daytime. The light doesn't seem to affect them in the least; no crawling on the hands as with almost any other race. I find them to be the best of honey-gatherers, cap their comb snowy white, and their sections are as clear of propolis as the old blacks. They enter the sections readily, and I have less burr-combs than with any other kind of bees.

I am trying a cross between the Italian and Caucasian, using the latter as the mother, and I have the gentlest and the finest yellow bees that can be found. If they gather honey as fast as they breed they will be all I ask. They cannot help but winter, for I find that the more quiet bees are the better they will winter. I wintered 2-frame nuclei in the cellar, and they came out without a spot in the hive. I am sure that all who will try the gray Caucasians will find them just as has been stated by those who know, and not as by those who "don't know."

A. D. D. WOOD.

Ingham Co., Mich., June 8.

### Discouraging Outlook

Bees are in as poor a condition just now as I have ever known them to be at this time of the year in this locality. Last fall the honey-flow was almost entirely limited to the juices of fruit and grapes, so that the winter stores were of the poorest kind. But on account of the mildness of the winter the bees got through fairly well; and in the fine, mild weather during the whole month of March, they built up well, and gave promise of fine results this summer. But, alas! the cold, blustery weather during all of April and half of May played havoc with many of the most promising colonies. Much of the brood chilled and starved. Bloom containing nectar is now plentiful, but the field-laborers are too few to collect much surplus. On the whole, the outlook for bee-men is not very bright in this locality.

H. A. SCHOPPENHORST.

Marthasville, Mo., May 24.

### Successful Wintering of Bees

In reading the American Bee Journal this week it seems that we Eastern bee-keepers are in the "cold swim" with our Central and Western brothers. This is the coldest April and May that I remember, but, with it all, my bees that wintered well are in fine condition. On May 15 I had one of the largest swarms I ever hived; it filled a 10-frame hive practically full. Now I think the secret of my bees being in the condition they are, is not from feeding in the spring and fall, but because each was a strong, heavy colony in the fall, and wintered on 50 pounds of thoroughly ripened honey.

I put into winter quarters last fall 25 colonies, but during the long, cold winter they were taken with dysentery and I lost 6 colonies through that cause. Now I think I have

found two reasons for the same trouble in this location—one is from honey that was gathered late in the fall (and our fall crop is very heavy here about every 3 years in 5); and also from some of the hives becoming damp, as that was part of the time that they were under snow. I notice in the early spring, in going over my bees, that the hives were pretty damp. The dampness was not due to sweat inside.

My way of wintering is this: I am a great believer in newspaper for warmth, which I used as packing for supers over the comb honey over the Hill's device, and after putting the lid on I laid quite a number of newspapers over the top of hives; and hive-covers made of heavy duck canvas thoroughly dipped in pure boiled linseed oil thoroughly tied down over the whole hive, and then a sheet-tin frame laid on top of the cover with a weight on to keep the water from the top of the hive.

I can box, on a short October day, thoroughly, 25 hives for winter, and barring dysentery, which they had this year, I find that 99 percent with heavy stores will go through in any winter, which can't be worse than the past one. In all of the colonies I lost there was at least from 15 to 35 pounds of stores left. I have 16 boxes now with 2 and 3 supers for comb honey, filling fast. The rest are for extracted. I have at least 35 pounds of apple-blossom honey in one hive—the first that I ever have succeeded in getting, and I tell you it is fine. When I take it off I may forward a box to the editor.

My apiary is located in one of the largest white clover belts in Chester Co., Pa. Last year I had one colony that I run only for honey in sections, and it carried in 176 pounds of strictly white clover; all the others I run for increase, and reached to the above number of colonies from 8 stored as described for wintering.

GEO. M. STEELE.

Philadelphia, Pa., May 25.

### Cold and Backward Season

It is very cold and backward here. I have been feeding my bees for some time, which makes them very strong and active in spite of the cold weather. I have had 8 swarms. I put them on full empty combs and feed them every day. Alfalfa will be out in bloom in about 2 weeks, and then I look for a good honey-flow. The sweet clover is looking fine, and I am preparing for a good crop unless it stays cold all summer.

E. S. ARMSTRONG.

Olathe, Colo., May 30.

### Very Backward Season

The season has been very backward here. White clover is as yet not more than  $\frac{1}{4}$  of a crop. Raspberry and blackberry are in bloom, the former being nearly over.

Centralia, Mo., June 4. J. K. BORD, SR.

### Feeding to Keep from Starving

I am feeding my bees to keep them from starving, although the orchard has been white with bloom. The weather is too wet and cold.

Peotone, Ill., June 1. C. SCHRIER.

## Agricultural Exhibit in Chicago

Here is something different, yet practical—a permanent exhibition of things agricultural. The idea is to have on daily free exhibition almost anything from husking mitts to manure spreaders. This practical idea has been worked out and is now an assured fact.

The exhibition will be held in the commodious new quarters recently acquired by White's Class Advertising Co., 118 W. Jackson Boulevard, Chicago. This company, of which Mr. Frank B. White is President, occupies the entire top floor of the "Electrical Building," corner Jackson Boulevard and Desplaines Street.

The exhibition hall is 88 feet by 50 feet, in the eastern half of the floor. It is light, airy, and very pleasant. Each exhibit will be enclosed by a neat metal railing, and be kept in show condition for daily inspection. A special attendant will have oversight of the articles, and will devote his entire attention to explaining their merits and uses, to visitors and purchasers.

This is an excellent opportunity for manufacturers who advertise direct to consumers, yet sell through dealers throughout the West. Chicago is a great trading center, and many

excursions daily bring great crowds of pleasure-seekers, dealers and business-men from all parts of the Ohio, Missouri and Mississippi Valleys. If they know of this exhibition many will visit it, learn the good points of the articles they are interested in, and make arrangements for purchase.

Being thus represented also saves manufacturers the expenses of a Chicago office and a special salaried representative.

The sizes of spaces run in multiples of 5 square feet, from 5x5 up to 10x20 or more, as desired.

An attractive folder entitled, "WOULD YOU LIKE TO HAVE YOUR GOODS ON DISPLAY IN CHICAGO AT A VERY LOW COST?" will be mailed free by White's Class Advertising Co., to any one. It has a map of Chicago's business section, with railroad depots, hotels, prominent clubs, elevated railroads, etc. It also shows a large ground-plan to scale of the Exhibition Hall, with full, detailed explanations.

Our readers, when in Chicago, are urged to visit this novel exhibition. They will be courteously received, and all questions answered by the gentleman in charge. Much that is profitable can be learned from the exhibits of new, novel, and practical articles that relate to agriculture.

Mr. Hasty's Afterthought

(Continued from page 536)

rect, no doubt. Why? On the whole it is a little surprising that as high as 42 percent should so disappear in 20 years. That's a bad, big rock on which efforts to breed the non-swarming bee are going to go to wreck. All the same, boys, breed that non-swarming bee. In choosing your "timber" to start with, choose some totally disinclined to swarm, if you can find such, and some not totally, but only somewhat disinclined. And with both sorts great care about vigor should be exercised all along—everything inclining to peter out like the above, to be thrown overboard at once.

The puzzle why colonies with 40 pounds of honey don't swarm seems to me to be an easy one. Abnormal. Normal colony uses up the honey rearing young bees, and don't have 40 pounds in swarming-time. Such bees dreadfully lethargic in disposition—else queen a poor one, I ween. Page 392.

Back Numbers One Cent a Copy.—

We have quite a stock of numbers of the American Bee Journal running back for several years, which we will mail at one cent per copy so long as they last. Send as many cents as you wish copies. We have them complete since Jan. 1st of this year. If desired we will send all the back numbers of 1907 and to the end of the year for only 50 cents. First come first served.

Amerikanische Bienenzucht.

by Hans Buschbauer, is a bee-keeper's handbook of 138 pages, which is just what our German friends will want. It is fully illustrated, and neatly bound in cloth. Price, postpaid, \$1.00; or with the American Bee Journal one year—both for \$1.75. Address all orders to this office.

ITALIAN BEES FOR SALE

I have 50 colonies of all Italian J. L. Strong stock and Quirin's. All are in good condition in new Danzenbaker hives. Price \$4.50 per colony f.o.b. here. Satisfaction guaranteed.

BERT GANDER,  
PANORA, IOWA.

PRACTICAL POULTRY BOOKS

For Sale or Free as Premiums

(postpaid) for sending New Subscribers to the Weekly American Bee Journal; or we will club them with the Bee Journal, as follows:

For each NEW yearly subscriber to the American Bee Journal (at \$1.00) that is send us by an already paid-in-advance subscriber, we will allow 25c to apply on any poultry book in the list; or, for \$1.10, we will mail to any one the Bee Journal a year and the last book mentioned in the list; for \$1.35 the Bee Journal and any one of the 50c books; or, for \$1.80 we will send the first book and the Bee Journal a year. Send all orders to the address as given below,

**SUCCESSFUL POULTRY KEEPING** Contains, we believe, more and better practical, reliable information on the subject of "Poultry for Profit" than any other book published. Gives the cream of established facts. Compiled by the editor of the RELIABLE POULTRY JOURNAL, who has given many years of careful study to the poultry business. 160 pages, nine by twelve inches, illustrated. Price \$1.00

**POULTRY HOUSES AND FIXTURES** Shows plans of all styles of low-cost, practical and labor-saving houses, designs for inside fixtures, such as nest boxes, drop boards, etc., also roosting coops and coops for young chicks, and all necessary appliances for the poultry yard. It is the most valuable and up-to-date book of the kind that has been placed before the poultry public. Used as a text book at Cornell University. 96 pages, nine by twelve, ill. Price 50c.

**ARTIFICIAL INCUBATING AND BROODING** Solves all problems of artificial incubating and brooding. Tells how to obtain strong-germed, fertile eggs, how to operate incubators and brooders, grow the greatest percentage of chickens, etc. Results gained from practical experience. 96 pages, nine by twelve inches, illustrated. Price 50c.

**THE CHICK BOOK** Tells how to obtain good hatches under different conditions, with hens and with incubators; how to feed and care for chicks of all ages, with hens and in brooders; how to feed for breeders and for broilers and roasters; how to build coops; gives complete instruction in all work connected with successful chicken growing. 80 pages, nine by twelve inches, illustrated. Price 50c.

**THE PLYMOUTH ROCKS** Barred, Buff and White. Make money and save years of useless breeding by adopting the rules of mating followed by the most successful Plymouth Rock Breeders, with a chapter and chart on line breeding. Specialists describe clearly and concisely their methods of mating and breeding. Contains color plate of each variety. 110 pages, nine by twelve inches, illustrated. Price 50c.

**EGGS AND EGG FARMS** Is made up of articles from experienced and successful breeders, giving methods of housing, breeding, rearing and feeding to increase egg production. The lengthy chapters on pedigree breeding will be found invaluable to breeders of exhibition or utility fowls. 96 pages, nine by twelve inches, illustrated. Price 50c.

**THE LEGHORNS** The best illustrated standard of all varieties of the popular Leghorns. Mating schemes clearly described. You cannot afford to be without this valuable information. Color plate of S. C. White Leghorns. 78 pages, nine by twelve inches, illustrated. Price 50c.

**ASIATICS** A work on Brahmans, Cochins and Langshans. Contains "inside" information necessary to success, and impossible to secure elsewhere. Contains standard and ideal charts for all varieties. Color plates of Buff and Partridge Cochins. 100 pages, nine by twelve, ill. Price 50c.

**DUCKS AND GEESE** Gives all details of hatching, rearing, fattening and marketing. Contains the actual labor-saving methods followed on the great duck ranges, and by farmers who make duck and geese growing profitable branches. 68 pages, nine by twelve, ill. Price 50c.

**TURKEYS** Every detail of the turkey business explained fully and clearly. It solves comprehensively the different branches of the market and standard-bred turkey industries. Written by the world's foremost turkey growers. Contains color plate of ideal Bronze turkeys. 84 pages, nine by twelve inches, illustrated. Price 50c.

**THE BANTAM FOWL** Mr. T. F. McGrew, judge and breeder, tells how to house, feed and grow Bantams, how to treat their diseases, how to select and fit the best for the shows. The most complete illustrated Bantam book published, 72 pages, nine by twelve inches. Price 50c.

**RELIABLE POULTRY REMEDIES** Points out the causes, describes symptoms and gives simple and tested remedies for all diseases. 84 pages, six by nine inches. Price 25c

## Langstroth on the Honey-Bee

Revised by Dadant—Latest Edition.

### Standard-Bred Italian FREE PREMIUM QUEENS

We are booking orders now for those Fine Untested Italian Queens that we offer every year FREE to paid-in-advance subscribers as premiums for getting NEW subscribers for the Weekly American Bee Journal. These orders are taken for May or June delivery.

#### What Some Say of our Standard-Bred Italian Queens:

*George W. York & Co.*—The two queens received of you some time ago are fine. They are good breeders, and the workers are showing up fine. I introduced them among black bees, and the bees are nearly yellow now, and are doing good work. A. W. SWAN.  
Nemaha Co., Kan., July 15.

*George W. York & Co.*—After importing queens for 15 years you have sent me the best. She keeps 9½ Langstroth frames fully occupied to date, and, although I kept the hive well contracted to force them to swarm, they have never built a queen-cell, and will put up 100 pounds of honey if the flow lasts this week. CHAS. MITCHELL.  
Ontario, Canada, July 22.

*George W. York & Co.*—The queen I bought of you has proven a good one, and has given me some of my best colonies. N. P. OGLESBY.  
Washington Co., Va., July 22

*George W. York & Co.*—The queen I received of you a few days ago came through O.K., and I want to say that she is a beauty. I immediately introduced her into a colony which had been queenless for 20 days. She was accepted by them, and has gone to work nicely. I am highly pleased with her and your promptness in filling my order. My father, who is an old bee-keeper, pronounced her very fine. You will hear from me again when I am in need of something in the bee-line. E. E. MCCOLM.  
Marion Co., Ill., July 13.

#### How to Get these Queens Free

To any one whose own subscription to the Weekly American Bee Journal is paid in advance, we will mail a Fine Standard-Bred Untested Italian Queen next May or June, for each new name and address sent to us with \$1.00 for the Bee Journal a year. No one can get for himself the Bee Journal a year and the Queen for \$1.00. The Queen is offered as a premium for the work of getting some one else to take the Bee Journal a year. If you, yourself, want the Bee Journal a year and the Queen, send \$1.50 for the two, and we will book your order for a Queen. Queen orders will be filled in rotation—"first come, first served." Address,

**GEORGE W. YORK & CO.**  
118 W. Jackson Blvd., CHICAGO, ILL.

This is one of the standard books on bee-culture, and ought to be in the library of every bee-keeper. It is bound substantially in cloth, and contains nearly 600 pages, being revised by that large, practical bee-keeper, so well-known to all the readers of the American Bee Journal—Mr. C. P. Dadant.

Each subject is clearly and thoroughly explained, so that by following the instructions of this book one cannot fail to be wonderfully helped on the way to success with bees.

The book we mail for \$1.20, or club it with the American Bee Journal for one year—both for \$2.00; or, we will mail it as a premium for sending us THREE NEW subscribers to the Bee Journal for one year, with \$3.00.

This is a splendid chance to get a grand bee-book for a very little money or work.

**GEORGE W. YORK & CO.**  
118 W. Jackson Blvd., CHICAGO, ILL.

## Well-Bred Queens

Will greatly increase the yield of honey. Am now taking orders for **Cook's Select-Bred Queens**—to be sent as soon as weather permits mailing. Also Caucasian Queens from imported stock.

**Cook's Square Honey-Jar** is the best, cheapest, and most sanitary package for retailing honey. Send for circular and price-list of Hives, Bees, and useful implements.

**J. H. M. COOK**  
70 Cortlandt Street, NEW YORK, N. Y.  
The Oldest Supply-house in the East, and only Reliable Goods sold.  
10 cents brings sample jar by mail.  
17A13t Mention the Bee Journal

## Something for Our Bee-Keeping Sisters

We think all ladies will agree with us in saying that every man should at least understand some business with which, in case of necessity, he could support himself and family. The wealthiest people frequently come to want, and wretched, indeed, is the man who can not earn a living after his wealth is gone. He sometimes fills the grave of a suicide. And why, in this enlightened age of progression, should not woman, as well as man, be able to depend upon her own resources? In case her husband dies in poverty, must she starve or depend upon charity? In case her husband fails to provide and grossly mistreats the woman he has sworn to cherish, must she humbly submit? **A THOUSAND TIMES, NO!** Let every woman, before she marries, have some knowledge that can be used to make her a living. Every mother, rich or poor, should make her daughters, in a certain degree, independent, by giving them some kind of a trade, and teaching them to be self-reliant. Mothers should have their daughters learn to sew, and not neglect this important part of their domestic education. The daughter so taught will not only make a better wife and mother, but will also be more likely to secure a better husband, and will always command his respect. He will not look upon her

as a helpless "know-nothing," but will know that if he fails in his duties, she can live without him, and this can only strengthen the bond between them. A thorough knowledge of dress-making can always be turned into gold, and become the means of support for the mother and her little ones. She may never have to use this knowledge in this way, but she has a trade and can use it if necessary.

The outline cut shown herewith is a condensed copy of **THE NEW LONDON LADIES' TAILOR SYSTEM** for drafting and cutting ladies' and children's garments. For simplicity and accuracy it has no superior among the more expensive systems. Thousands of girls have learned more about drafting and cutting with this system than they knew about it after serving their apprenticeship in some of the dressmaking shops of the United States and Canada. Thousands of the best garment cutters have laid their complicated and expensive system aside, and are now using **THE NEW LONDON TAILOR SYSTEM**. Thousands have been sold at \$5.00 each, but we will mail it **Free** to a paid-in-advance subscriber to the American Bee Journal for sending us two new subscribers at \$1.00 each; or we will send it to any one with a year's subscription to the American Bee Journal, both for \$1.75; or, we will mail the Tailor System alone for \$1.00. Address all orders to

**GEORGE W. YORK & CO.,**  
118 W. Jackson Blvd., CHICAGO, ILL.

### Moore's Long-Tongue and Golden QUEENS

Fine Select Untested Queens, \$1; 6, \$5; 12, \$9. Tested, \$1.50; 6, \$8. Best Breeders, \$1.50. Safe arrival guaranteed. W. H. RAILS, Orange, Cal. 9D18t Please mention the Bee Journal.

## DOOLITTLE & CLARK

Have some fine Italian Queens of last fall's rearing that are ready to be sent out, by return mail, at \$2.50 and \$5.00 each.

Borodino, Onondaga Co., N. Y.  
21Dtf Please mention the Bee Journal.

## Engravings For Sale

We are accumulating quite a stock of engravings that have been used in the American Bee Journal. No doubt many of them could be used again by bee-keepers in their local newspapers, on their stationery, or in other ways. Also, if we can sell some of them it would help us to pay for others that we are constantly having made and using in our columns. If there is any of our engravings that any one would like to have, just let us know and we will quote a very low price, postpaid. Address,

**GEORGE W. YORK & CO.**  
CHICAGO, ILL.

### Standard-Bred Queens

Rared from Imported and Home-Bred Caucasian, Carniolan, Hall's Superior Goldens, and Leather-Colored Italian Breeders. Their bees are honey-getters. Untested Queens, \$1; 6, \$5; 12, \$9. Select untested, \$1.25; 6, \$6; 12, \$10. Tested, \$1.50; select, \$2.50; best, \$5. List free.

T. S. HALL,  
11DSt JASPER, Pickens Co., GA.  
Mention Bee Journal when writing.

## The Emerson Binder

This Emerson stiff-board Binder with cloth back for the American Bee Journal we mail for but 75 cents; or we will send it with the

Bee Journal for one year—both for only \$1.50. It is a fine thing to preserve the copies of the Journal as fast as they are received. If you have this "Emerson" no further binding is necessary.

## HAND-MADE SMOKERS

Extracts from Catalogs—1907:

Chas. Dadant & Son, Hamilton, Ill.—This is the Smoker we recommend above all others.

W. B. Lewis Co., Watertown, Wis.—We have sold these Smokers for a good many years and never received a single complaint.

A. I. Root Co., Medina, Ohio.—The cone fits inside of the cup so that the liquid creosote runs down inside of the smoker.

All Bingham Smokers are stamped on the tin, "Patented 1878, 1892, and 1903," and have all the new improvements.

Smoker Engine—largest smoker made.....	\$1.50—4	inch stove
Doctor—cheapest made to use .....	1.10—3½	"
Conqueror—right for most apiaries .....	1.00—3	"
Large—lasts longer than any other.....	.90—2½	"
Little Wonder—as its name implies .....	.65—2	"

The above prices deliver Smoker at your post-office free. We send circular if requested.

Original Bingham & Hetherington Uncapping-Knife.

BINGHAM  
CLEAN  
BEE SMOKER

Pat'd 1878, '92, '02 & 1903

T. F. BINGHAM, Farwell, Mich.

Patented May 20, 1879. BEST ON EARTH.

## Dittmer's Gomb Foundation

Why do thousands of bee-keepers prefer it to other makes?  
Because the bees like it best and accept it more readily.

### Dittmer's Process is Dittmer's

It stands on its OWN NAME and its OWN FOUNDATION, to which alone it owes its reputation and merits.

We are now ready to make prices for next season for WORKING WAX for CASH and for full line of Supplies. Wholesale and Retail. Free Catalog and Samples.

GUS DITTMER, Augusta, Wis.

Mention Bee Journal when writing.

## Ideal Hive-Tool—"Best on the Market"

Bee-keepers have long needed a special tool to aid them in properly manipulating the hive-parts during the bee-season. The one shown here does the work to perfection.

Best Hive-Tool

Only 30c, by mail

(This picture is exactly one-half the size.)

DESCRIPTION.—The Ideal Hive-Tool is made of high-grade malleable iron, much like wrought iron, 8½ inches long. The middle part is 1 1-16 inches wide and 7-32 thick. The smaller end is 1½ inches long, ½ inch wide, and 7-32 thick, ending like a screw-driver. The larger end is wedge-shaped, having a sharp semi-circular edge, making it almost perfect for prying up supers, as it does not mar the wood.

### What Some Bee-Experts Say of It.

Louis C. Dadant (son of C. P. Dadant) wrote us May 10, 1907: "Your Hive-Tool is certainly the best on the market, and after having used one of them no bee-keeper would do without it."

In the first edition (1903) of Dr. Miller's "Forty Years Among the Bees," page 58, he says: "Of all the hive-tools I have tried, I like best, the Muench tool." On Jan. 7, 1907, he wrote us, saying he thought "just as much of the tool as ever."

Miss Wilson, Dr. Miller's assistant, says this of the Ideal Hive-Tool: "It is an ideal tool. In fact, I don't see how it could be improved upon. I am sure we would feel utterly lost in the apiary without it. . . . You will have to try one yourself if you want to know its worth."

### The "Ideal Hive-Tool" Free as a Premium.

We will mail an Ideal Hive-Tool FREE as a premium to any present paid-in-advance subscriber to the American Bee Journal, for sending us ONE NEW subscription for a year at \$1.00; or we will send the American Bee Journal one year and the Ideal Hive-Tool—both for \$1.20. Price of the Ideal Hive-Tool alone, postpaid, 30 cents.

GEORGE W. YORK & CO., 118 W. Jackson Blvd., CHICAGO, ILL.

## BEE BOOKS Sent postpaid by GEORGE W. YORK & Co., 118 W. Jackson Blvd., Chicago, Ill.

**Advanced Bee-Culture.** Its Methods and Management, by W. Z. Hutchinson.—The author of this work is a practical and helpful writer. You should read his book; 330 pages; bound in cloth, and beautifully illustrated. Price, \$1.20.

**A B C of Bee-Culture,** by A. I. & E. R. Root.—A cyclopedia of over 500 pages, describing everything pertaining to the care of the honey-bees. Contains about 400 engravings. It was written especially for beginners. Bound in cloth. Price, \$1.20.

**Scientific Queen-Bearing,** as Practically Applied, by G. M. Doolittle.—A method by which the very best of queen-bees are reared in perfect accord with Nature's way. Bound in cloth and illustrated. Price, \$1.00; in leatherette binding, 75 cents.

**Bee-Keeper's Guide,** or Manual of the Apiary, by Prof. A. J. Cook, of Pomona College, California. This book is not only instructive and helpful as a guide in bee-keeping, but is interesting and thoroughly practical and scientific. It contains a full delineation of the anatomy and physiology of bees. 544 pages. 295 illustrations. Bound in cloth. 19th thousand. Price, \$1.20.

**Langstroth on the Honey-Bee,** revised by Dadant.—This classic in bee-culture has been entirely re-written, and is fully illustrated. It treats of everything relating to bees and bee-keeping. No apian library is complete without this standard work by Rev. L. L. Langstroth—the Father of American Bee-Culture. It has 520 pages, bound in cloth. Price, \$1.20.

**Honey as a Health Food.**—This is a 16-page honey-pamphlet intended to help increase the demand for honey. The first part of it contains a short article on "Honey as Food," written by Dr. C. C. Miller. It tells where to keep honey, how to liquefy it, etc. The last part is devoted to "Honey-Cooking Recipes" and "Remedies Using Honey." It should be widely circulated by those selling honey. The more the people are educated on the value and uses of honey the more honey they will buy. Prices: Sample copy for 2-cent stamp; 50 copies for 70 cents; 100 for \$1.25; 250 for \$2.25; 500 for \$4.00; or 1000 for \$7.50. Your business card printed free at the bottom of the front page on all orders for 100 or more copies.

**Forty Years Among the Bees,** by Dr. C. C. Miller.—This book contains 328 pages, is bound in handsome cloth, with gold letters and design; it is printed on best book-paper, and illustrated with 112 beautiful original half-tone pictures, taken by Dr. Miller himself. It is unique in this regard. The first few pages are devoted to an interesting biographical sketch of Dr. Miller, telling how he happened to get into bee-keeping. About 20 years ago he wrote a small book, called "A Year Among the Bees," but that little work has been out of print for a number of years. While some of the matter used in the former book is found in the new one, it all reads like a good new story of successful bee-keeping by one of the masters, and shows in minutest detail just how Dr. Miller does things with bees. Price, \$1.00.

**"The Honey-Money Stories."**—A 64-page-and-cover booklet, 5¼x8½ inches in size, printed on best quality paper. Many short, bright stories interspersed with facts and interesting items about honey and its use. The manufactured comb honey misrepresentation is contradicted in two items, each occupying a full page, but in different parts of the booklet. It has in all 33 fine illustrations, nearly all of them being of apiaries or apian scenes. It also contains 3 bee-songs, namely, "The Hum of the Bees in the Apple-Tree Bloom," "Buckwheat Cakes and Honey," and "The Bee-Keeper's Lullaby." This booklet should be placed in the hands of everybody not familiar with the food-value of honey, for its main object is to interest people in honey as a daily table article. Price, 25 cents, or 3 copies for 50 cents.

"In every country the successful advertiser is the continuous advertiser"

# American Bee Journal

While the Present Stock of these BEE-HIVE CLOCKS lasts, we will sell them at only **\$1.50 each**, by express; or \$2.00 for the Clock and the Weekly American Bee Journal one year. **Better order at once**, before all are gone.

## The Bee-Hive Clock A \$4.00 CLOCK FOR \$2.50 ... With the American Bee Journal <sup>1 Year—</sup>Both for **Only \$3.00**

We have originated and had made specially for our readers, a bronzed-metal Clock, called "The Bee-Hive Clock." It is 10 1/4 inches wide at the base, 9 3/4 inches high, and deep enough at the base to stand firmly on a mantel or elsewhere. It is a beautiful piece of work, and would be both ornamental and very useful in any house, and particularly in a bee-keeper's home.

The Clock part itself is warranted for 3 years to keep good time. So it is no plaything, but a beautiful and needful article for everyday use.

Clocks like "The Bee-Hive Clock" usually sell in the stores at from \$4.00 to \$5.00 each, but having them made for us in quantities enables us to offer them at \$2.50 each by express, or with the American Bee Journal a year—both for only \$3.00. Either Clock or Journal would make an ideal gift.

### How to get "The Bee-Hive Clock" FREE

Send us 5 New Subscribers to the Weekly American Bee Journal for one year, at \$1.00 each, and we will send you this beautiful "Bee-Hive Clock" FREE (excepting express charges). Or, send us 4 New Subscribers (at \$1.00 each) and 50 cents—\$4.50 in all. Or, 3 New Subscribers (at \$1.00 each) and \$1.00—\$4.00 in all. Or, 2 New Subscribers (at \$1.00 each) and \$1.50—\$3.50 in all.

Only \$2.50, f.o.b. Chicago, by Express. Weight, with packing, about 4 pounds.

### What Dr. Miller Thinks of the Bee-Hive Clock

Busily ticking away, in the room where I am sitting, stands a genuine bee-keeper's clock (please understand that the word "genuine" belongs to the clock and not to the bee-keeper) or, as the legend upon the clock has it, "The Bee-Hive Clock." I don't know

whether the idea of getting up such a clock was conceived in the brain of the Editor of the American Bee Journal, or whether he got it elsewhere, but the wonder is that such a thing was not thought of long before.

Setting aside all idea of its association with the business of a bee-keeper, there is a peculiar appropriateness in having the minutes and the hours "told off" in a case representing the home of the busy little workers. The glance at the clock, with its ceaseless tick, tick, tick, can not fail to remind one that the flying moments must be improved now or be forever lost, and that suggestion is reinforced by the thought of the never ceasing activity of the little denizens of the hive, always busy, busy, working from morn till night and from night till morn, working unselfishly for the generations to come, and literally dying in the harness.

Let us be thankful that the form of the old-fashioned straw hive or skep was adopted, and not that of any modern affair, patented or unpatented. The latter smacks of commercialism, but the former of solid comfort, for no other form of hive has ever been devised that contributes so fully to the comfort and welfare of a colony of bees as does the old-fashioned straw-hive. It appeals, too, to one's artistic sense as can no angular affair of more modern times. As an emblem of industry, artists have always used—probably always will use—the old straw skep.

Thanks, Mr. Editor, for furnishing us a time-keeper so appropriate for all, and especially for bee-keepers. C. C. MILLER.

## American Bee Journal Novelty Pocket-Knife Gold Fountain Pen

All for **\$3.00**

(This cut is the full size of the Knife.)

### NOVELTY POCKET-KNIFE

(Name and Address on one side—Three Bees on the other side.)

Your Name on the Knife.—When ordering, be sure to say just what name and address you wish put on the Knife.

The Novelty Knife is indeed a novelty. The novelty lies in the handle. It is made beautifully of indestructible celluloid, which is as transparent as glass. Underneath the celluloid, on one side of the handle is placed the name and residence of the owner, and on the other side pictures of a Queen, Drone, and Worker, as shown here.

The Material entering into this celebrated knife is of the very best quality; the blades are hand-forged out of the very finest English razor-steel, and we warrant every blade. It will last a life-time, with proper usage.

Why Own the Novelty Knife?—In case a good knife is lost, the chances are the owner will never recover it; but if the "Novelty" is lost, having name and address of owner, the finder will return it. If traveling, and you meet with a serious accident, and are so fortunate as to have one of the "Novelties," your Pocket-Knife will serve as an identifier; and, in case of death, your relatives will at once be notified of the accident.

How to Get this Valuable Knife.—We send it postpaid for \$1.25, or club the Novelty Knife and the American Bee Journal for one year—both for \$2.00. (Allow two weeks for Knife order to be filled.)

### SOLID GOLD FOUNTAIN PEN

Finally we have found a good Fountain Pen that is reasonable in price. The manufacturers of this pen say that if you pay more than \$1.25 for other fountain pens, it's for the name.

This pen is absolutely guaranteed to work perfectly, and give satisfaction. The Gold Nibs are 14 K., pointed with selected Iridium. The Holders are Para Rubber, handsomely finished. The simple feeder gives a uniform flow of ink. Each pen is packed in a neat box, with directions and Filler.

We mail this Gold Fountain Pen for only \$1.25, or for \$2.00 we will mail it and the weekly American Bee Journal for a whole year.

Sample copy of the American Bee Journal free; trial trip of three months (13 copies) for 20c; regular yearly price, \$1.00.

## A GREAT IMPROVEMENT

Will be found in

## The American Bee-Keeper for 1907

It is profusely illustrated and enlarged, and contains only articles of the most practical as well as scientific nature. A special corps of the best writers has been engaged. The editors are Harry E. Hill and Arthur C. Miller, than whom there are no more practical or experienced bee-keepers in this country. We have published the American Bee-Keeper continually and regularly since 1890.

Regular subscription price, 50 cents a year. One year to new subscribers, 35 cents; three years for \$1.00.

Send for sample copy and our new illustrated price-list of BEE-SUPPLIES OF ALL KINDS.

Guaranteed highest quality at lowest price.

## Honey and Beeswax

CHICAGO, June 8.—Not any of the honey yield of 1907 has appeared on this market, and with the choice white grades of last year's comb being exhausted there is practically nothing to base values on other than that of history, for there is always a limited demand for honey. New white comb of good flavor would sell at 16c; no demand for other grades. Extracted is very scarce and none being offered for sale. Beeswax is selling on arrival at 32c. R. A. BURNETT & Co.

CINCINNATI, May 23.—There is no material change in the honey market at this writing. Extracted honey is not moving so rapidly as it could, owing to the cool weather. We quote amber in barrels at 5½@6¼c; fancy table honey in crates of two 60-pound cans at 8@9c. For choice, yellow beeswax, free from dirt, we are paying 31c cash, delivered here.

THE FRED W. MUTH CO.

PHILADELPHIA, June 10.—The honey market has been quite brisk for this time of the year. A number of odd lots have been cleaned out of the market. We quote: Fancy comb, 14@15c; No. 1, 13@14c; amber, 12@13c. Fancy white extracted, 7@8c; light amber, 6@7c. Beeswax firm, 32c.

We are producers of honey and do not handle on commission. WM. A. SELSER.

NEW YORK, May 21.—White comb honey is practically cleaned up, and there is very little demand at this time. There is some dark and mixed comb on the market, but no demand to speak of, and some of this will have to be carried over until next season, or sold at a sacrifice. Therefore we cannot encourage shipments of off grades or dark honey at this time. Extracted honey is in fair demand and prices are ruling firm. There is very little new crop arriving as yet from the South, and while it is rather early, we doubt whether we will have any large shipments from the Southern States this season, as we fear there will be a short crop, judging from the reports we are receiving. There is quite a good stock of last year's crop still on the market, sufficient to last until the new crop from various states arrives. There is no change in price as to extracted honey since our last. Beeswax firm and likely to remain so for the next 2 months.

HILDRETH & SEGELKEN.

## C. H. W. WEBER CINCINNATI OHIO

Office and Salesrooms, 2146-48 Central Ave. Warehouses, Freeman and Central Aves.

INDIANAPOLIS, April 12.—comb honey is not plentiful, but demand is slack. Fancy white comb brings 16@17c; No. 1 white, 14c; amber, 12@13c. Best grades of extracted honey bring 8@9c; amber, 6@7c. Good average beeswax sells here at \$35 per 100 pounds.  
WALTER S. POWDER.

TOLEDO, May 3.—There is very little demand for comb honey as is usually the case at this season of the year. Fancy white would bring in a retail way 16@17c; No. 1, 15@16c, with no demand for dark honey. Extracted is very scarce and none being offered for sale. Beeswax is bringing 28c.  
THE GRIGGS BROS. & NICHOLS CO.

KANSAS CITY, June 1.—The honey market is almost bare of comb honey, and demand good; receipts of extracted are light, and demand light; we quote: No. 1 white comb, 24-section cases, \$3.25; No. 2, white and amber, \$2.50@2.75. Extracted, white, per pound, 8c; amber, 7½@7c. Beeswax, 30c.  
C. C. CLEMONS & CO.

DENVER, Feb. 14.—Producers in this State are practically closed out of both comb and extracted honey. We have not sufficient good comb honey to supply our local trade, but have a good supply of white extracted of excellent quality. We quote strictly No. 1 white comb honey, per case of 24 sections, at \$3.20; No. 1, light amber, \$3; and good No. 2, \$2.80. White extracted, 8@8½c per pound; light amber, 7½@8c. Clean, yellow beeswax, 27@28c, delivered here.  
THE COLO. HONEY-PRODUCERS' ASSN.

CINCINNATI, May 21.—The market on fancy white comb honey is entirely bare. No. 2 is selling slowly at 12c. Extracted, light amber, brings 5½@6c. Beeswax is selling here at \$35 per 100 pounds.  
C. H. W. WEBER.

# AMERICAN BEE JOURNAL

## An Important Announcement

*To the subscribers of the American Bee Journal:—*

Believing that the old American Bee Journal should occupy a wider field, and thus be a help to a larger number of readers, we have decided to issue it *monthly*, beginning with July (next month), instead of weekly, and at 25 cents a year. This very low price will permit every bee-keeper everywhere to subscribe for it, even if he or she has only one colony of bees. Yes, and any one who is at all interested in bees as a Nature study will, no doubt, be glad to read it regularly.

For 26½ years the American Bee Journal has been issued every week, but it has been found that there are only about so many bee-keepers who are sufficiently interested in bees to think that they need a *weekly* bee-paper. What we want is a larger constituency, hence we believe that by publishing the American Bee Journal once a month, and making the subscription price 25 cents a year, we will be able to reach the goal of our ambition sooner, and at the same time do a better service to all. (The yearly price to Canada will be 35 cents; to England and other foreign countries in the Postal Union, 50 cents a year.)

We believe that after a few months at least 99 percent of our present list of readers will see that we have done wisely in making the change mentioned.

We are not quite ready to announce more of our plans just now, but will do so in the July number and in those immediately following it. We trust we may have the continued co-operation of all our old friends, and, of course, we expect very soon to enlist that of many thousands of new ones all over the world.

We may say that the monthly American Bee Journal will contain at least 32 pages each issue. The weekly number was supposed to contain 16 pages, so that under the new plan there will be half the quantity of reading matter at only one-fourth the former cost.

The July number will be issued about the 15th of the month; then thereafter we expect to mail it on the 10th of each month. The advertising forms will close on the 5th.

Of course, all who have paid their subscriptions in advance at the regular \$1.00 rate (or the extra foreign rate) will be credited just four times as far ahead as their present address-label indicates. Those who are in arrears will pay at the rate of \$1.00 a year up to the end of this month.

In the next issue we will be able to make further announcement. In the meantime let us all hope that bee-keepers may harvest a good crop of honey, and that although the prospects may have been discouraging, the silver lining of the clouds may be revealed and all be prosperous and happy.

# Where the Little Things Count

By the Bee-Crank

THE BEE-MAN has before him a constant reminder of the importance of little things. If the bee ignored the tiny drops of honey in the blossoms, and collected it only when it came in chunks, there would be no honey in the combs. If I gave preference to the large orders and neglected the small, I

should soon find a falling off on my hands, that, in the aggregate, would mean a big loss.

It is because I realize this and take the same pains to please the small customer that I do with the large, that my business keeps growing.

I want your small orders. I will take good care of them. You will get as good service from me on small as on large orders, but I promise you good, prompt delivery on either.

I sell Root's goods at Root's prices, and save you time and money on shipments.

Beeswax bought, and the highest market price paid. Send large shipments by freight, and small by express, and put your name on package.

Have you seen my new catalog? It's yours for a postal card request.

A Select Untested Hoosier-Italian Queen—the gentle strair—in return mail for one dollar.

Freeport, Ill., June 11, 1907.

The A. I. Root Co.,  
 Medina, O.

Gentlemen:

I received five of your AE52S-10 hives yesterday and find that I cannot make my own hives and supplies as cheap as yours and use the same quality of lumber. You can see by the head of this letter that if anyone can make hives cheaper than your prices or any of the so-called "trust hive" manufacturers, I ought to be able to do it, but using the same quality of lumber I cannot.

Yours very truly,  
 (Signed) John H. Bamberger.

The above is a representative letter from the many we have to the effect that our hives and other supplies can be purchased cheaper than a local mill can possibly make them. Our enormous output enables us to reduce the cost to the minimum without sacrificing quality.

## Editorial Notes and Comments

### Bees Building Up in Spite of Weather

The following was written June 11, at Marengo, Ill.:

MR. EDITOR:—On page 430 is a note from me, written May 16, in which I mentioned the deplorable weather, and said, "No matter how good the season, it will hardly be possible for colonies to build up in time to do good work on clover." Well, I didn't know as much as I thought I did. At that date I had not opened a hive for a number of days, but I thought I knew enough about bees on general principles to know that when the weather was so cold right along that seldom a bee could leave the hive, increase would be very slow if it did not cease altogether. But when I opened the hives a few days later I was agreeably surprised to find that to all appearance matters had been progressing just as if the bees had been hard at work on the flowers every day. So my humble apologies are hereby tendered the bees for underestimating their ability to withstand adversity.

Surprise No. 2 came when I found at this later opening that some colonies were about destitute of honey, although they had gone into winter quarters heavy—very heavy—and I had counted them safe till clover. Assuredly they would have starved before that time if I had not come to their assistance with solid combs of honey, of which I had a good store.

C. C. MILLER.

The moral of all this is that bees will build up under quite adverse conditions, if they have an abundant amount of stores in sight. Something like this seems to be the case: Take 2 colonies of equal strength in early spring, the first with enough stores to last, if economically used, till clover bloom, and the second with 10 pounds more honey than the first. At the opening of the clover harvest, the one may be found just as much reduced in stores as the other. But while alike in the amount of stores, they are greatly different in strength. The one has turned its extra 10 pounds of honey into bees, while the other has seemed to feel it could not indulge in

such expansion. Of course, the figures in this supposed case may never occur in actual practise, but the principle illustrated is not easy to dispute.

### The Isle of Wight Bee-Disease

The following note has been received at this office, dated at Chicago, on June 10:

EDITOR AMERICAN BEE JOURNAL:—I enclose a cutting from a recent issue of the London Daily Mail, describing a peculiar disease which has attacked bees in Great Britain, as perhaps you may not have seen it; and I should be glad to know if you have had any experience with any such disease and can account for it.

THOMAS ERKINE,  
British Vice-Consul.

The clipping is in part as follows:

The ravages of the bee-disease in the Isle of Wight are much worse than at first reported, for among over 30 bee-keepers in different parts of the island, which a special correspondent of the Daily Mail has interviewed, he finds that 3 years ago they had an average aggregate of 326 colonies, which are now reduced to 29, while 14 of these are more or less affected and are not expected to survive many weeks. In 15 cases the bee-keepers have lost all their bees, and the array of empty hives tells its own melancholy tale.

The symptoms are that the bees in hundreds—and where several colonies are kept in thousands—are found on a warm summer day crawling upon the ground unable to fly. When examined and dissected the intestine is full of a bright yellow pollen, moist and sticky. When the diseased bees sting, some of this yellow matter is deposited with the sting, and after the swelling has subsided the flesh is stained yellow, as in yellow jaundice; but in the case of a healthy bee the sting is white, and the effect on the flesh is red.

The article goes on to say that the suggestions of the Board of Agriculture, "such as requeening, disinfecting, spraying and feeding, have already been tried without any

beneficial effect," and then gives, as the best treatment, the treatment for foul brood with the addition of feeding salicylic acid and boric acid for two weeks.

Considerable has been said in the British bee-papers about the matter, and at least one continental bee-paper has called the disease bee-paralysis.

The case is no doubt bad enough, although the newspaper account, as in most newspaper accounts when bees are under discussion, may not be entirely reliable. It is hard to believe that a bee with life enough to sting would deposit "yellow matter" with the sting, and a bee-keeper is somewhat puzzled to be told that "in the case of a healthy bee the sting is white." After reading that, he is likely to have some question as to the rest that may be said.

However serious the case may have been, no further loss can occur, since only 29 colonies are left on the island, and one would think that the surest way out would be to destroy the 29 and begin again with a clean bill of health. Little interest has been manifested in the matter on this side, partly because so far away, and partly because of the limited extent of the disease, the Isle of Wight being less than a third as large as an average county in Illinois. Yet if it should turn out to be a new disease, more terrible than any other yet known, it is well that we should be informed about it in advance, for bee-diseases have an insidious way of invading quite distant territory, no matter how small the area originally affected.

### Does the Queen Consciously Fertilize Eggs?

As a contribution to this unsettled problem the following Stray Straw is given in Gleanings in Bee-Culture, page 754:

I don't know whether worker-eggs are fertilized by the will of the queen or automatically. But I want to enter a protest against what is generally considered as a knock-down argument against the automatic theory. It's given something like this:

"The claim that the smaller size of the worker-cell compresses the abdomen of the queen, automatically fertilizing the eggs, is shown to be groundless by the fact that, when a queen lays eggs in worker-cells not more than  $\frac{1}{2}$ -inch deep, there can be no com-

# American Bee Journal

pression, and yet the eggs are fertilized."

Good friend, you must know that there is no real squeezing of the abdomen, either in a worker-cell or a drone-cell. The worker-cell is a trifle shallower than the drone-cell. May not that difference in depth cause such a difference in the position of the queen as to produce fertilization in the shallower cells? And would not fertilization be expected in a still shallower cell? Did you ever know drone-eggs to be laid in drone-cells only  $\frac{1}{2}$ -inch deep? I don't think I ever saw such a case; but I may not have observed closely enough.

One who has watched the queen at work laying eggs can not fail to have noticed that while the egg is being deposited the abdomen is curved to no small degree, and it is easy to believe that this curving is greater in a worker than in a drone-cell, and still greater in a cell only partially built out. It certainly looks like scoring one for the compression theory.

Botanists classify plants in their relation to fertilization into two classes, viz.: Those fertilized by the wind and those fertilized by insects.

In many varieties of plants and trees the stamens that bear the pollen, or male element, are on one plant or flower, and the pistils that grow the ovules—the female element—on another. If it were not for the fact that insects—chiefly bees—carried the pollen from one flower to the stigma of another, there would be no seeds or fruit grown. The pollen-grains are so constructed as to adhere to the insect that visits them, and then be carried from flower to flower.

In the large green-houses near our large cities where early cucumbers, etc., are grown for the market, it is always necessary to have one or two colonies of bees inside to fertilize the blossoms. No bees, no cucumbers, unless men go around with a brush and dust the pollen from one flower to another, which is very laborious and expensive work.

Those who grow flowers doubtless have observed that the fuchsia and begonia never produce seed in a closed room; yet when set out-of-doors where bees can get at them they seed abundantly.

All kinds of fruit are greatly benefitted by bees, and a large proportion of our fruit, such as apple, pear, and particularly the plum, would be barren were it not for the honey-bee; therefore, the intelligent fruit-grower, farmer or gardener, is always glad to have a bee-keeper locate in his immediate vicinity, for he always derives very much more benefit from the bees than the bee-keeper himself. In fact, profits from keeping bees are so uncertain that it is very rare indeed that a bee-keeper tries to make a living from it.

Lastly, I will inform Messrs. Lasher and Petsil, as well as all others interested, that the National Bee-Keepers' Association will back all of its members. Any number of legal decisions have been handed down to prove that bees are not a nuisance *per se*; that when they are properly kept, and due precautions used, as on my isolated place, that they can not be driven out of the town. There are several precedents from various courts, even from a State Supreme Court, to show that bees have a right to be kept, even within a corporation like any other stock, and any village ordinance not in conformity with these decisions is unconstitutional; and that several ordinances declaring bees to be a nuisance have been repealed. This, probably, is the reason why Amasa P. Lasher could not get the State Board of Health to take action in the matter, and explains why his paper of complaint was returned to the Germantown officials; but as the matter is to come up at the next meeting of the Germantown Board of Health, it remains to be seen what they will do.

F. D. CLUM, M. D.

The six paragraphs following the heading, "Value of Bees to Horticulture," contain just the kind of information that should be republished far and wide in local newspapers. No doubt almost any of our readers could have his local editor use it if he requested him to do so, and if, at the same time, he were given a copy of it.

It is just as Dr. Clum says, ignorance is at the bottom—and also at the top—of nearly every complaint against bees. Most people do not know the value of bees to fruit-growing else they surely would not oppose the presence of bees.

It will take quite a long time to inform all the people who need to be taught concerning bees and their great importance, but bee-keepers should do all in their power to see to it that, so far as possible, apicultural knowledge shall "cover the earth as the waters cover the sea." Let us all do what we can to hasten the coming of the brighter bee-

**Claim Bees are a Nuisance.**—F. D. Clum, of Cheviot, N. Y., is one of the many "M. D.'s" that are interested in bee-keeping. Recently he wrote us as follows:

EDITOR AMERICAN BEE JOURNAL:—I notice in the American Bee Journal of May 23d, that a subscriber living in a small town in Wisconsin complains about a troublesome neighbor who claims that honey-bees are a nuisance. The subscriber wants to know "What to do with such a man?" The great remedy is education. You notice by the enclosed that we also have troublesome neighbors in New York State, and my reply to their complaint. After the complainants became convinced of the value and the importance of bees, and that they are just as necessary to the farmer, the gardener and the fruit-grower as to the bee-keeper himself, the opposition promptly ceased, and the complainants felt heartily ashamed of their previous ignorance. If other bee-keepers would publish similar communications in their local newspapers, I think it would greatly benefit all parties concerned. F. D. CLUM, M. D.

The newspaper article referred to reads as follows:

## COMPLAINT AGAINST A BEE-KEEPER.

A complaint composed and written by Amasa P. Lasher, and signed by John Petsil, was recently presented to the Germantown health officer, "protesting against the continuance of a colony of bees located on the premises of Dr. F. D. Clum, in Cheviot."

Why should the gentle Italian bees, which every one knows never sting unless molested, be complained of when the 10 to 20 colonies of the stinging black bees owned for the last 20 years by Charles Rockefeller (who is just as near a neighbor to Messrs. Lasher and Petsil as is Dr. Clum) have not caused a single complaint in times past? Moreover, there are, all told, about 100 bee keepers in the town of Germantown who own colonies of bees, varying in number from 1 to 135. Why have none of these been complained of?

Taking these facts into consideration, it looks as if the complaint were made for the purpose of making trouble for Dr. Clum, or as a matter of revenge or spite.

Any fruit-grower who will, year after year, kill and eat robins and other birds in violation of the law because they destroy a few cherries, is probably so ignorant that he does not know or appreciate their value on his fruit-farm as destroyers of various injurious insects and worms. It is not expected that such a person has sufficient intelligence to know the value and necessity of bees on his fruit-farm; but Amasa P. Lasher has spent the greater part of his life teaching school,

and for that reason is supposed to have a least average intelligence. Now can it be possible that he does not know that bees are a necessary insect for the fruit-grower? That as they live over winter, in the early spring they fertilize the fruit-blossoms when there is no other insect to do the work? He, as an instructor of the young, should know that bees are as necessary to plants as plants are to bees.

In the complaint, composed and written by Amasa P. Lasher against the bees on Dr. Clum's place, appears the following statement:

"Complainant further alleges and believes that the bees have a destructive power that robs the fruit-grower of the legitimate profits that should accrue from his exhaustive labors by destroying a large percentage of the small fruit."

The above statement is so directly antagonistic to the true facts that I would not believe that Amasa P. Lasher had written it until I saw it in his own handwriting. Can it be possible that a man who has taught the Cheviot school the greater part of his life does not know better? If he does not, it is my opinion that the school needs a more enlightened teacher.

It is like thrashing old straw to state that bees never touch perfectly sound fruit. Their physical make-up renders it impossible for them to do so; but if fruit is crushed or injured and the juice exudes, the bees gather to collect what could otherwise go to waste.

Messrs. Lasher and Petsil own vineyards, and for their information I will state that if they care to investigate the matter they will find that the English sparrow is most destructive of grapes, and in the city of New York have been seen to tear open packages to eat the grapes within. There is also a small, swift-flying, shy bird, called the Cape May warbler, which appears about every vineyard. It comes early in the morning, just at the break of day, and for that reason is seldom caught in the act. It has a long, sharp, needle-like beak, and after alighting on a bunch of grapes it will puncture grape after grape as fast as one can count. The bee that follows later to collect the sweet juice that exudes and goes to waste gets the blame for puncturing the grape.

Perhaps it is well to republish the following extracts from one of my communications to the Register of May 1, as follows:

## VALUE OF BEES TO HORTICULTURE.

The fruit-grower, gardener or farmer who does not realize and appreciate the great benefit he derives from honey-bees in the great work of cross-pollination, which is imperatively necessary to his success, does not fully understand his business.

keeping day when all the world shall know the truth about bees and honey, which truth shall make them free—from ignorance, and prejudice, as well.

**A Section-Size Correction.**—We have received the following from Mr. Wm. M. Whitney, of Lake Geneva, Wis., under date of June 17:

MR. EDITOR:—In the report of the Chicago-Northwestern Bee-Keepers' convention, on page 521, I am made to say that I have sections  $4\frac{3}{4} \times 5\frac{3}{4}$ , which is far from correct. Such a section as that, if properly completed, would weigh at least  $1\frac{1}{2}$  pounds. It so blunts the point intended to be made as to make a bad blotch. The section is  $3\frac{3}{4} \times 5\frac{3}{4}$ —7 to the foot—a little narrower than the  $4 \times 5$  plain, but taller and thicker, weighing, when nicely capped, just 16 ounces—have weighed dozens of them. The double supers, as I call them, with section-holders and fence, hold 48 sections each, which is put on a strong colony in time of good honey-flow, and often duplicated. Bees work in them better than in the  $4\frac{1}{4}$  section. I don't know why.

My hives are overflowing with bees, but I'm feeding, anxiously looking for white clover.  
WM. M. WHITNEY.

**Analysis of Pollen.**—Having on page 429 reported an unsuccessful search for an analysis of pollen, Mr. W. K. Morrison kindly comes to our aid with the following:

- |                       |              |
|-----------------------|--------------|
| 1. Albumen—7 percent. |              |
| 2. Peptic acid        | } 5 percent. |
| 3. Grape sugar        |              |
| 4. Butyric acid       | } 5 percent. |
| 5. Myricene           |              |
| 6. Palmatin acid      |              |
| 7. Stearine acid      |              |

| 11. Hyppuric acid.    |              |
| 12. Cerinthin.        |              |
| 13. Pollenin.         |              |
| 14. Cellulose.        |              |
| 15. Eritholin.        |              |

**Honey as a Health-Food.**—This is a 16-page honey-pamphlet intended to help increase the demand for honey. The first part of it contains a short article on "Honey as Food," written by Dr. C. C. Miller. It tells where to keep honey, how to liquefy it, etc. The last part is devoted to "Honey-Cooking Recipes" and "Remedies Using Honey." It should be widely circulated by those selling honey. The more the people are educated on the value and uses of honey, the more honey they will buy.

Prices, prepaid—Sample copy for a 2-cent stamp; 50 copies for 70 cents; 100 for \$1.25; 250 for \$2.25; 500 for \$4.00; or 1000 for \$7.50. Your business card printed free at the bottom of front page on all orders for 100 or more copies. Send all orders to the office of the American Bee Journal.

**"Songs of Beedom."**—This is a beautiful 16-page-and-cover pamphlet, 6x9 inches in size, containing 10 bee-songs—words and music—all the songs so far written specially for bee-keepers, we believe. It is nice, as well as convenient, to have these songs all in one binding. Every bee-keepers' organization should have copies for use at conventions. They could be sold to members after using once, or held by the secretary for use at future meetings. Of course, every bee-keeper's family will want at least one copy. It is sent, postpaid, for only 25 cents, or 3 copies for 60 cents; or, we will mail one copy with the American Bee Journal one year—both for \$1.10. Send all orders to the office of the American Bee Journal.

## No. 5.—Comb-Building and Obtaining Surplus Honey Cheaply

BY R. C. AIKIN

In the previous article I discussed nuclei and how to make them. Still further back in these articles—in Nos. 2 and 3—I mentioned the making and use of nuclei. I also have made reference to speciality in the use of bees; that is, running part for honey and now I want to speak of another special use of certain kinds of colonies, and that is—

### BUILDING OF BROOD-COMBS.

Every practical bee-keeper knows that under certain conditions much drone-comb will be built, while under certain other conditions only worker will be built. Years ago Mr. Doolittle told us how to utilize weak colonies, and specially weak ones with young queens in getting straight all worker-comb. It is a fact that a weak colony with a young queen will build almost exclusively worker-comb, and under certain conditions they will build just as pretty, straight ones as can be had from comb foundation, and do it more cheaply than by the use of it.

Here is another fact—I previously mentioned this point—a small colony just getting started with bees to cover well one to 3 combs and brood in proportion, will put up more honey (that is, gather, store and consume) than a like number of bees under other conditions. When the young are hatching fast, and there is a good proportion of nurses and comb-builders, it is astonishing how much they will build, and how well they will do it.

Suppose you have started with a 1-frame nucleus. First, put the one frame at the side of the hive, and next to this put a drone-comb, or one mostly drone. Such a colony will not use the drone-comb for anything but honey-storage, and if they begin to get crowded they will put almost every bit of the honey in the drone-cells and fill the worker-comb with brood from end to end. When the colony can use more space, move the brood from the hive side and put in a frame with a starter; this gives the hive side, which is straight, for one guide, and the face of the comb next to it, having been next to the hive side, will be as straight as a board, for it was lined by a board; there they will build as good a comb as if foundation were used.

But you may object to having them build next to the outer wall, as being too cold; in a few cases that may be a

valid objection, but you can get exactly the same results by using a dummy or follower board, putting the drone next to the hive side, and the brood-comb between it and the dummy.

As fast as the comb is built in the first frame given, it will be used by the queen, and it won't be many days until it is full, when it should be moved from the old one and a starter put between it and the old one, and also at the same time one put between the new one and the dummy; these two will be built about as quickly as the first one. And right here is the time that another drone-comb may be put on the inside next to the dummy, the presence of drone-comb will encourage the building of worker-comb. If you do not have dummies to use just let a drone-comb serve in its place; I often use a comb instead of a dummy.

We have now given the colony 3 starters, and with a young, vigorous queen you can depend upon 99/100 of the comb in them being worker, if you have followed the plan outlined. At this time, if there has been free gathering of nectar, the drone-combs should be full of honey, and now 2 more frames may be given, this time putting them as near the center as may be, and they may be put both together and between the 2 nicest, straightest sheets of brood. Note this fact: A sheet of brood to build comb next to is better than a board, every time; it is a warm place, and where the nurses are doing much business; there the fewest bees necessary to the work can build.

Note also that a sheet of brood will remain just as straight as when you find it until the brood hatches from it, or until they cease to breed in it and put honey therein. Always, in any colony, when you want to have a comb built, put the starter next to or between sheets of brood; if between store-combs, and nectar is coming freely enough to cause the combs to be promptly filled, there is always a tendency to lengthen the cells out into the space in which the new comb is to be built, until it is too narrow to build even deep enough cells to rear brood in. I have often seen full sheets of foundation made into very thin combs with a very thick one on either side, and have seen even the two adjoining combs with cells so lengthened that they cut out entirely the new comb at places. Yes, the best possible place to build new combs is between sheets of brood.

By the things pointed out in the last paragraph, you will see that conditions may make very different results; where you can get a good comb built one time you may not the next. I have indicated the plan that will meet nearly

# American Bee Journal

every possible condition, so that even the man of very limited experience may succeed, and such work is the finest kind of education for the beginner—it is a whole lot better than paying out money for foundation. As one gains experience, and his judgment is sharpened, he can vary from the rule because he will know when to do, or not to do, this or that. It would make this description very long and tedious to go into all the details to explain minutely the effect of variations in temperature, honey-flow, changing proportion of fielders to nurses, etc.

Now when the colony has built 4 or 5 new combs, you have just about reached the limit; after that the queen will begin to want drone-comb to lay in. Whenever a colony has reached the time they are about to occupy the entire 7 to 10 combs, they instinctively prepare for increase by the rearing of drones, but up to the time they have occupied about 6 combs it is worker-comb they want and will build. With old queens they will build less, and other conditions affect results, too.

## GETTING SURPLUS HONEY FROM WEAK COLONIES.

These comb-building colonies—whether from weak colonies that were late in getting started in the spring (for such can be made use of in getting comb built) or from nuclei—will sometimes store quite a little surplus, particularly if extracted honey be produced. The drone-combs used can be removed and their places filled with ready-made worker-combs. These removed drone-combs may be extracted at the time of removal, or an excluder may be put over the brood-chamber and an extra body put above, and these combs put into it and the rest of the space filled with either starters or other comb, or parts of comb of either drone or worker. The best way is to put these removed drone-combs in the center and fill out the sides. If starters be used there will of course be lots of drone-comb built, but the excluder keeps the queen from them, and nothing is lost. A lot of new drone or worker comb can be sold as chunk honey, or it may be extracted to be used over again, or may be broken fine and strained; or, what is the better way, is to melt it, and so separate the wax from the honey. Each 100 pounds of new combs melted when full of honey, will yield about \$1 worth of wax. It pays to do it.

There is no cheaper or easier way to produce extracted honey on a small scale than the above, or some modification or variation of the plan. Honey strained or melted out from these new combs is every whit the equal of that extracted by the centrifugal extractor; and if well done, that melted out is the finer product of the three methods. Honey separated from the comb by heat, when well done, can not be equaled for body and fine flavor; it is simple XXX.

The honey-producer who is getting up No. 1 and fancy comb honey for the general trade these days must be an expert, and as I have previously indicated in former articles of this series, the conditions that are required for ob-

taining the desired result, to a more or less extent, damage the future prosperity of the colony, especially for withstanding the following winter. It is better to specialize; but with some such method as indicated above one may produce extracted, and that with no particular skill as an apiarist, and get as good returns from the bees and leave them in better condition. Would-be apiarists with modern hives trying to run a machine and system they do not understand, nor have yet become even half-way bee-masters, usually soon "blow up the boiler," and thousands of us, with years of practise, do likewise.

The divisible hive—that is, what is known as the divisible shallow-frame brood-chamber hive, as the Heddon idea—is not understood by one in a thousand of our best apiarists, and has met with failure in the hands of many who have tried them. The hive is different from what we have been accustomed to, and must have its own methods to succeed. Lack of understanding and proper method has caused the failure, and not because of shallow frame and divisible brood-chamber. This reference to that hive and system here is merely to point out a fact, and not to discuss the merits of the hive

and its system. If one is beginning anew, such a hive and its system might well be adopted, but I am here trying to teach the simplest and best methods with the hive in common use.

No, no, we can not become experts from the start; it is well for us to learn some of the details of the whys for many things, as I have here indicated. When we know from both theory and practise what bees will do, and the why of it, then it is time to undertake the business as a business for profit, and in a general commercial way. I believe the man who allows his bees to swarm as they will, following their own instincts; the man who believes and advocates the let-alone plan, and hives swarms, and puts on supers, and shifts hives around a few times, as the sum of his management, is by no means an expert nor a master. Get to the internal workings, and know why this and that is done by the bees, and do not trust to their wisdom; learn that the bee is not half as wise as she gets credit for being. There is reason for the things she does; but her doing is not prompted by any process of reasoning, taking into consideration cause and effect. That is the master's part.

Loveland, Colo.

## Making Increase from One Colony

DEAR MISS WILSON:—I have a colony of Italian bees having a queen with clipped wings. What can I do to make increase possible from the colony? I have read a good deal about "shake swarming," taking out brood-combs, etc., but all of these methods seem to lack details in the telling that makes the operation doubtful of success for the novice.

In transferring brood-comb to another hive, what of the queen—where does the queen come in?

Would buying a queen, and introducing her to a nucleus of 2 or 3 frames of brood-comb with adhering bees, be the right way to do? or would it be better to move brood-combs with bees and queen, and allow the remaining bees to build queen-cells and hatch a new queen? MRS. J. D. BLACK.

Albion, Ind., June 5.

You can increase with a clipped queen in any way you could if the queen were not clipped. In fact, it is easier when the queen is clipped, if you increase by natural swarming. When the colony swarms, instead of bothering to hive the swarm, perhaps climbing a tree to get it down, you pay no attention to the swarm. Just watch for the queen, and if you don't see her as she comes out of the hive you'll be likely to see her on the ground after the swarm is up in the air. Pick her up and put her in a cage. If you have

no cage you can put a tumbler over her on a plate, but be sure not to set the plate in the sun unless you want to kill the queen. Set the old hive a yard or more away, put the new hive in its place, and then sit down comfortably and congratulate yourself that you don't have to climb for that swarm, which may be clustered away up high. Don't worry if it doesn't come back for 10 or 15 minutes; it will not fail to come back. Generally, however, it will not settle at all, but sail around in the air for a little while and then come straight to the new hive you have set on the old stand. When the bees have started into the hive, let out the queen to travel in with them—and there you are. About the easiest way to increase, if you have no objection to natural swarming. After the swarm has gone into the hive, set the old hive close beside it, and a week later move the old hive to a new place 2 yards or more away.

In transferring brood-combs to another hive, if you mean transferring from a box-hive to a movable-frame hive, you merely get all the bees from the box-hive into the new hive, and the queen will be among them, although you are not likely to see her.

You will get along faster if you buy the queen. In that case, it will be well

# American Bee Journal

to fasten the nucleus in its hive 2 or 3 days, otherwise too many bees will go back to their old home.

If, however, you prefer to let the bees rear their own queen, here's a good way to proceed: Take 2 or 3 frames of brood with adhering bees and the queen and put them into a hive on a new stand. Most of the force being left on the old stand, the strong force will produce good cells, ever so much better than a mere nucleus would. In 8 or 10 days you will let the hives swap places, taking all but 2 or 3 frames with adhering bees from the queenless hive and giving them to the queen. See that the frames left in the nucleus have one or several queen-cells, and destroy all queen-cells on the combs you give the queen.

If you have further questions, don't hesitate to call again.

## Another Fairy Bee-Story

When the manufacturer of news wants something better than common upon which to build, he can hardly do better than to tell what some man can do with bees. Upon the smallest foundation of truth he can build and build until his superstructure is 'way out of sight in the clouds. But if you want to see the veracious reporter at his best, just let him get an inkling of what some woman has done, or is going to do, with bees; as witness the following from the Chicago Daily News:

### QUEEN-BEES AT \$200 EACH.

Two score Italian queen-bees, valued at from \$50 to \$200 each, arrived on Saturday on the steamship St. Paul. They are the property of Mrs. R. C. Riggs, of Kansas, who accompanied them.

Salerno, Italy, it seems, is headquarters for the finest variety of Italian queens, and thither Mrs. Riggs went for the express purpose of buying a number of these valuable little insects.

"The Italian queen," said Mrs. Riggs, in speaking of her purchase, "is much larger than the ordinary bee, and is of a beautiful light gold color. It is worth literally dozens of times its own weight in gold, because of its marvelous productivity. No other bee can compare with it in this respect."

Of course, having a valuable lot of merchandise in her possession—her new bees are valued at \$1800—Mrs. Riggs wanted to have them insured. The average person wouldn't know where to go or what to do to get a swarm of bees insured, but Mrs. Riggs did. An Italian company assumed the risk for the tiny creatures on their voyage to America, so that her only danger lay in the journey between New York and Kansas.

"Of the tens of thousands of people who eat honey, or see bees flitting about among the clover blooms in summer," said Mrs. Riggs, "very few know anything of the trouble entailed in rearing bees, or realize the immense capital that is invested in apiculture. During the 16 years that I have been in the business, I have expended something like \$125,000 on my apiaries. The returns, however, have been fairly large, as I market my honey in many cities.

"Bee-farming is not a business out of which the novice can expect to reap much of a harvest. People seem to think any fool can make money at bees. It isn't so. The theoretical and practical sides of apiculture must be thoroughly mastered if one is to succeed in it, and that takes many years.

"Incidentally, the bee-farmer must not be susceptible to the virus of the sting. Every one who handles bees, or is with them much,

must expect necessarily to take a certain amount of stinging, and those who are constitutionally not fitted to stand it are seriously handicapped in the business.

Mrs. Riggs declares that she is absolutely immune. "And yet I have been stung hundreds of times at once," she says. "All my assistants are equally immune—in fact, I won't engage an employe permanently who is not."

One of the funny things about this whole business is that getting "stung" is supposed to be good for the "rheumatiz." Mrs. Riggs says she actually has people come to her—people who are tortured by rheumatism—who ask the privilege of placing themselves in the way of being badly stung. Of course, she is always willing to accommodate them.

"And, oddly enough," she laughed, in telling about the queer request, "I have known cases where getting stung really did relieve terrible attacks of the disease—at least, the sufferers declared it did, and they ought to know."

It would be interesting to know just how much basis there is for this remarkable story. Possibly there were 2 or 3 queens with a value of \$2 to \$5 each, and no one is likely to be more surprised than Mrs. Riggs to learn what large proportions her operations have assumed. Think of paying an average price of \$90 each for 20 Italian queens! But that is only in keeping with the general outlay during 16 years—"something like \$125,000." That averages annually \$7,812.50, and to recoup herself for such an outlay, even if she made a profit of 7 cents on each pound of honey, she would have to produce each year a little more than 100,000 pounds. Strange that we should never have heard of these large crops before. And very likely the lady will herself echo, "Strange that I should never have heard of it before!"

BY W. A. PRYAL, Alden Station, Oakland, Calif.

## Lungs—But Not of the Bee

Prof. Cook dilates upon lungs, in Gleanings of April 1st. Yes, California is a great State for lungs. But few who have real lung-trouble can expect to be cured by coming to the most favored portion of the State. Some may get relief for a time; better stay near home and get the treatment afforded by kind friends and dear relatives. Doctors tell us that any change is good for those thus afflicted for a time, but after a time when the patient becomes accustomed to the new climate, the system goes back, as it were, to where it was at the beginning of the "cure." I think the day will come when a remedy will be found to banish the lung-bacteria. And it will be one of the greatest boons given to man. And—but pardon me, I am getting away from bees, even if this subject may be excused as a reflection—not on the Professor nor on our climate—but as an observation on our breathing mechanism.

## Church Candles of Beeswax, Etc.

How oft we go wrong when we try to write about the other fellow's religion. And it is hard to be helped, inasmuch as there are so many of 'em—both the fellows and the religions. But let us try to be careful—have due regard for our neighbor's creed, race and politics.

Once upon a time I had a newspaper detail that took me to the places of worship of Jew, gentile and heathen; priest, rabbi and minister, I had to interview. But this is neither here nor there. Of course, I had to "post up"

in matters about the creeds and so forth. It has stood me in pretty good stead since. This is why I am making this reflection.

The other night in reading up on beeswax in one of the standard bee-books, I noticed a cut of a big candle under which was the title, "A Mammoth Candle for Sacramental Purposes"—a statement which is as incorrect as it is misleading. Candles may be used or lit during the administration of some of the sacraments in several of the churches, but they form no part of the service, that I am aware of. A lighted candle is used as a symbol; that and nothing more, so far as I know. Every Roman Catholic church uses one of these mammoth candles during a certain season of the year, commencing at the close of Lent. This reminds me that in a late number of Gleanings, the editor, in mentioning some of the uses to which beeswax is put, mentions that the Catholic and Greek churches use large numbers of them on the altars. This would lead the uninformed to believe that all the candles used in such churches were none other than beeswax. The law of the church calls for at least *two pure beeswax* candles to be lit on the altar during the offering of the mass. From this it may be seen that all others may be of any other material—sperm, tallow, etc. And the same writer further stated that wax-candles were used for the reason that they did not produce a smoke that was injurious to the ornamentation of the interior of the edifice. I do not know where the editor received his information; I know as a fact oil-lamps are used in country churches; in the city gas is the usual illuminant along with electricity

where the latter is procurable. Gas, in time, smokes up a church badly; still, it is used universally, showing that candles are not demanded.

If one is of an investigating mind, he will find that in some churches, what appear to be candles are nothing more than porcelain made in imitation of a candle. A small gas-tip or burner is set where the wick should be. If all the Roman Catholic, Greek and some forms of the Episcopal church were to use beeswax-candles exclusively during their services, there would not be sufficient wax produced to supply the demand. And, perhaps, it is well they don't, for it would, to my mind, be a useless waste of good material—a product demanded for use in the arts and sciences. The church seemed to recognize this fact, hence the minimum limit of two candles at the sacred service.

### Durable Top-Bar Ends

In examining a lot of colonies this spring, I found that a lot of the end-bars had decayed. This made it awkward to handle frames so injured. It was almost as bad as lifting a large basket full of eggs and the basket handleless. You have a dread all the time that something is going to fall. I find that Eastern (white) pine and a Western spruce were the woods most susceptible to rot. Oregon pine stood the moisture better than I supposed. I believe redwood will not rot, but it is too brittle, though. Patrick Keating uses it. Give me Oregon pine, for it is almost as hard and durable as oak.

in sections, and I never knew of brood being injured by it.

4. With a virgin in its cell the bees seem to know that drones are of the utmost importance, and so they are anxious for drone-comb.

5. When I have put the back of my hand near the entrance it has always felt as if the current were toward my hand, and so drawn out of the hive.

### Vicious Bees—Perhaps Absconding

1. On May 20, W. R. Burden and I cut down a bee-tree and found the queen and placed her in a hive and brought them home, and on the next day the bees all came out and began stinging everything within 200 yards of the hive. They killed 2 hens in a coop 30 yards from the hive, stung people 200 or 300 yards away, and were trying to settle all the time, but did not. They settled down or went back in 3 or 4 hours and have been working some, and now have 3 pieces of comb about 6x8 inches. What was the matter with them?

2. In the spring of 1906 I had a nice swarm of bees come out. I hived them in a new hive and they worked fine. They carried in a great deal of pollen. In 7 weeks they sent out a swarm, and in 10 days, on examining I did not find a bee in that hive that sent out the last swarm. The first swarm I hived lay out around the entrance and the hive was full of nice comb. No moth-worms when I noticed it, and no bees in it. Did the bees all come out, or did they die, or what was the matter?

3. What is meant by "W. K. M." in "Stray Straws" in Gleanings?

KENTUCKY.

ANSWERS.—Evidently those bees were of a very vicious disposition, and beyond that it is hard to say why they were on such a special rampage. It is barely possible that there was some robbing going on, making them worse, but one can only guess why they should swarm out.

2. Again you've given me a nut harder than I can crack. It seems to be a case of absconding rather than swarming. As I understand it, the bees left the hive, bag and baggage, 7 weeks after they had been hived as a swarm. It is very unusual for bees to desert a hive after fairly getting to work in it, but sometimes they do. Whether too hot, or lacking in food, or what may have been the cause in this particular case, is more than I can guess.

3. "W. K. M." are the initials of W. K. Morrison, one of the assistant editors of Gleanings.

### When Bees are Gathering—Best Race of Bees—Bees Starving, Etc.

1. Is there any way one can tell when bees are gathering by the appearance when they come in from the field? My bees seem to come in heavily loaded, but there is nothing in bloom except dandelion and strawberries.

2. Do they gather much from other plants?

3. What race of bees do you think is best for the production of comb honey?

4. One of my neighbors says his bees are bringing out lots of young larvae on the alighting board. Why? Some say it is chilled brood. We have had it fearfully cold here this month.

5. Do bees that gather pollen gather honey also, or are there two classes?

6. Since writing the above today (June 2) I notice the bees are coming in so heavily loaded that they drop before they reach the alighting board. They do not seem to be on dandelion. What can it be? Is it a sign that they are gathering?

MAINE.

ANSWERS.—1. If they are seen carrying in pollen, they are generally carrying in nectar also. When the harvest is plentiful some of the bees are likely to drop down in front of the hive, apparently resting a while before starting up again. You can catch a bee returning to the hive and find whether it is carrying in nectar or only water.

2. In some places dandelions are so scarce as to be of no great importance. In others they are plenty and of great value.

Send Questions either to the office of the American Bee Journal, or to  
DR. C. C. MILLER, Marengo, Ill.

Dr. Miller does not answer Questions by mail.

### Something Historical About Bees

1. Mr. Leonard Chester and Rev. Henry Smith died in 1648. In the inventory of their estates bees were valued at £8 in each case. James Boosey died in 1650. In the inventory of his estate 11 "skippis" of bees were valued at £9. Comparative: Horses £12 each, and cows £5 each.

2. Were bees always here, or were they imported? If so, when? CONNECTICUT.

ANSWERS.—1. Just as you state it, one cannot tell for certain whether it took 11 "skippis" to be worth  $\frac{3}{4}$  as much as a horse, or only 1 "skipp." If the former, bees were not rated very differently from today; if the latter, bees were away up.

2. In the latest edition of Dadant's Langstroth, page 289, is the following:

"Thomas Jefferson, in his 'Notes on Virginia,' says: 'The honey-bee is not a native of our country. The Indians concur with us in the tradition that it was brought from Europe; but when, and by whom, we know not. The bees have generally extended themselves into the country, a little in advance of the white settlers. The Indians, therefore, call them the white man's fly.'

"According to the quotations of the American Bee Journal common bees were imported into Florida by the Spaniards previous to 1763, for they were first noticed in west Florida in that year. They appeared in Kentucky in 1780, in New York in 1793, and west of the Mississippi in 1797." In 1857 they were taken to California.

So you see that the account you give antedates anything given in the book quoted by more than a century, making it a very interesting item.

### Driving Out Drones — Preventing Swarming—Hive-Ventilation, Etc.

1. I want to ask a few simple questions and give a few points for beginners to observe. First, when the drones are being run out and killed off in early spring, it is conclusive evidence of a honey-dearth, or

continued bad weather, and it is well to begin feeding at once.

2. I think there are only 2 points to be observed to prevent swarming, viz., plenty of laying space for the queen by giving empty combs when needed, and super-room for the bees to prevent crowding.

3. As we are not prohibited from reading the "Sisters' Department," I am inclined to disagree with Miss Wilson in regard to ventilation by opening the back door at the top of the brood-nest (pages 451-2), for in a climate of hot days and cool nights the brood is liable to take a bad cold with the back door left open over night.

4. Why will a densely populated colony with a young queen in the cell, on being given 2 frames, with  $\frac{1}{4}$ -inch starter, refuse to draw out the foundation, but proceed to build drone-comb in a frame with a starter?

5. When the bees are vigorously fanning with their heads to the entrance, which is accomplished, cool air driven in or hot air being drawn out?

I will offer a possible solution to "Iowa," page 469. Perhaps something in the wood the shingles are composed of attractive to the bees causes them to work through the cracks made by shrinkage. We will not credit the idea of their going down the chimney to get into the house unless some old comb should have been thrown into the fireplace with little fire. ARKANSAS.

ANSWERS.—1. Yes, if drones are driven out any time before the close of the season it is well to inquire whether stores are short. Sometimes, however, drones are driven out when plenty of honey is in the hive and the season is not yet far advanced, especially if the bees have reared a new queen.

4. Yes, crowding either the brood or the surplus apartment is generally agreed to favor swarming, but most bee-keepers would at least add to this the matter of heat and lack of ventilation.

5. If you know of any case where harm was done by doing as directed, I wish you would give particulars. The instructions were given for extracted honey, and we don't run for extracted honey here, but in hundreds and hundreds of cases we have given such ventilation to colonies working

# American Bee Journal

I understand they were introduced into this locality about 60 years ago, none having been here before that time. When I first came here they were hardly worth considering; now I prize them highly. True, I have never obtained surplus from them, but they are of the greatest value in being turned into brood, and they come just at the right time for that. If I could have in July or August the 2 weeks or more of dandelion bloom I had this year in its usual time, I think I could have a lot of surplus from it. But at the time dandelion blooms there are not enough field-bees to do more than supply the enormous amount used in brood-rearing.

It may be that in some places strawberries yield well, but they are very plentiful here and I have seldom seen bees on them.

P. S.—My brother-in-law says that on this very day bees are as thick on them as he ever saw them on buckwheat.)

3. So far as yet known, Italians probably have the general preference.

4. I am afraid it may be because they are short of stores. Possibly, however, it's only drone-brood, which they sometimes carry out when a spell of unfavorable weather comes, even when there is plenty of honey in the hive.

5. I don't think there are two separate classes. A fielder may gather nectar and no pollen; she may gather both; perhaps only pollen; yet the same bee never gathers both on the same trip. A bee may change its work on the same day, for sometimes you will see a large proportion of the bees carrying pollen in the morning and very few carrying pollen in the afternoon.

6. Looks pretty sure they're gathering, but I couldn't guess from what.

have been a boon. But I didn't have the yellow sweet clover.

You ask why I don't use dummies when the honey-flow opens. For more than one reason, but one will be enough. I suspect that you imagine that at the beginning of the honey-flow one or more empty frames are in the hive and that if I take out those empty frames and put dummies in place the honey that would go into the empty frames will be forced into the sections. That is an erroneous supposition. If I took out frames to replace with dummies I would have to take out frames of brood, or else take out the outside frame largely filled with pollen. Each frame, however, has more or less empty cells around the border, generally, when the flow begins, and if, a little before this time, I put in the center of the hive a solid frame of honey, the bees will empty this honey to replace it with brood, and this honey will be used to fill any vacant cells around the borders.

I don't quite understand your remark about using the Danzenbaker hive to get all frames full of brood. No hive fills frames with brood, and in this respect the Danzenbaker has no advantage over the dovetailed.

3. I don't know; but then you remember I had no sweet-clover honey, unless it was mixed with other honey. If I had extracted those combs I'm sure the honey would not have sold for as much as white-clover extracted, much less for as much as the white-clover sections that it may afford.

4. Either in spring or fall. Early spring is preferable.

5. Probably there isn't much difference. The Carniolans have the reputation of being the best swarmers.

6. They are probably much alike.

## Bees in Fine Shape.

I placed 131 colonies in the cellar last fall, and set out 131 this spring, all in fine shape as far as I could see, but since then I have found 3 without queens. I united them with the poorest colonies I could find in the yard. The best I ever did find was to winter 50 per cent. I have made no changes from former winters, and at this writing my bees are very strong, but it has been one of the worst springs I ever knew. Only about 1 day in 5 could bees fly since April came in, and I have made up my mind it is better, as they do not get lost if they cannot leave the hive. I never had them build up so fast. I have had several swarms and I have to give each one frame of honey or they must die, as I have had them lived 10 days and they have not been out of the hive except a part of 3 days.

I see they are killing off the drones—not a good sign, but I have seen it before and it turned out to be a good season. I always have a few swarms issue before I put on the supers, but few after, until late in the season; about the time the honey-flow stops. Then sometimes a few will swarm. I must stop now and go out into the yard for the sun begins to put forth his rays, and I want to look at it once more.

C. M. LINCOLN.

West Rupert, Vt., June 10.

## Bees in Fine Shape.

My bees are in fine shape in spite of the cold, backward spring. My first swarm issued yesterday; a rousing one, too. I have 34 colonies—did not lose one in wintering.

The American Bee Journal is one of the things I don't feel able to do without.

S. E. SCORFIELD

Enosburg Falls, Vt., June 12.

## Short Honey Crop Expected.

Our bees have had a hard struggle to get up to the month of June, but are doing fairly well now. Most of the bee-keepers in this part of the country have lost a great many bees on account of the late, cool spring. There seemed to be nothing for them. I have had 18 swarms; they build my apiary up to 60 colonies. I think the prospect bids fair for a short honey crop.

J. D. PASLAY.

Groesbeck, Tex., June 2.

## Backward Spring.

My bees came out of winter quarters without the loss of any. The spring has been backward. I hear my neighbors say that they have spring dwindling. I saved my bees by feeding and exchanging combs to equalize them. I think we have a good show for clover honey if the weather is favorable.

Success to the "Old Reliable."

JOHN CLINE.

Darlington, Wis., June 6.

## Black vs. Yellow Queens.

It seems that the black or hybrid queens have more instinct for self-preservation than the yellow races of bees. The little black queens are up to all sorts of dodges to keep out of sight. One is, to fly as soon as the comb is lifted out and be gone several minutes. I have had 2 such queens. To catch such, move her home, and put another colony where her home was; on her return she is balled and killed. Or you can hunt her out by the ducking process.

ALVAH REYNOLDS.

Altona, Ill., June 6.

## Plain vs. Self-Spacing Frames.

In reply to the editorial of June 6, and in behalf of Mr. Hutchinson, I will give the bee-men a "piece of my mind." For rapid handling and extracting, a self-spacing frame is not "in it" with the plain allwood frame, or one made on that pattern. I have run 4 apiaries with a total of 500 colonies, almost entirely for extracted honey, and my points are as follows:

1. I want a frame that is light, and not to exceed 7/8 inches in thickness, so that when uncapping the comb can be trimmed to a level with the frame, thus permitting

## Numbering Colonies—Sweet Clover Honey—Sowing Sweet Clover—Carniolans or Italians?

What is your system of hive numbering and queen record? Today No. 5 swarmed (golden Italian queen), was hived on the old stand; now, should the old hive's number be taken off and placed on the new swarm and a new number given the old colony?

2. In Gleanings you spoke of your full combs of sweet clover honey and said you counted it as just so many pounds of white clover honey this season. Why not use dummies when the honey-flow opens, or better still, why not use the Danzenbaker hive and have all frames full of brood at the beginning of the honey-flow?

3. Would not that sweet clover honey have sold for as much money as white clover honey had they been extracted?

4. When is the best time to sow sweet clover seed to get a stand?

5. Which are the best workers, Carniolans or Italians?

6. Which are best for extracted honey?

MISSOURI.

ANSWERS.—1. A small square of tin is painted white, and on this is painted in black the number. This tag is fastened on the hive by a small wire nail. The numbers run in numerical order in the rows, the same number always being on the same stand; so if No. 5 is moved to a new stand its number is changed, and any hive put in place of No. 5 will receive the tag taken from No. 5. Each year a new record book is used, the same being about 12 by 5 or 6 inches, 3 colonies to the page.

2. You must have misunderstood what I said, for I do not think I ever had a comb filled with sweet-clover honey. I have had honey that I thought was flavored with sweet clover, giving to white clover something of a vanilla flavor, which I think an improvement. I had a goodly number of frames filled with fall honey last fall, which I have been giving to the bees this year. I mentioned those combs, but I didn't say they were of sweet clover; but I said something about yellow sweet clover in another place that perhaps you have mixed up with these combs of fall honey. I said I had never valued specially the fact that yellow sweet clover was 2 to 4 weeks earlier than white sweet clover, because that made it come right in the time of white clover; but I had changed my mind about it, for last year white clover didn't yield any honey, and if I had had a lot of yellow sweet clover yielding early it would

## First White Clover Bloom.

Bees are swarming in this locality and new swarms starting. I saw white clover in bloom today for the first time this season.

P. F. CONKLIN.

Elmira, N. Y., June 14.

## Heavy Loss of Bees.

There is a very heavy loss of bees in this county this year, some losing 75 per cent. I have lost fifty colonies, and what are left are very weak and will need most of the season to build up.

Edw. McCox.

Lima, N. Y., June 10.

## Vine-Maple Honey.

I extracted 4 1/2 gallons of honey last week from one colony. It was all maple, or, I should have said, vine-maple, of a light amber color. Its flavor is excellent. I had 50 colonies spring out.

CHAS. W. HOPSEGER.

Clear Lake, Wash., June 4.

## Hope for Honey Yet.

On account of an accident to my left foot I lost half of my bees this spring. Then, the spring was very late and cold, so that the bees could not fly; still I have twelve colonies left, and yesterday I had the first swarm. If the weather now stays warm there is hope for some honey yet.

PETER WEHMEYER.

Roschud, Mo., June 14.

## Unusual Weather.

We are having very unusual weather here that takes all the enthusiasm out of one. I never have seen a season like it in my 30 years' experience. I will have some honey, but the weather conditions keep one in doubt. I am thinking of tiering up a few colonies today, but to what purpose I can't tell.

A. H. NOBLE, SR.

Nashville, Tenn., June 7.

# American Bee Journal

faster work, increasing the wax-production, making a comb that the honey can be extracted from more readily, and causing the bees to build out a cell of new wax, and thus somewhat improving the quality of the honey.

The dark combs do not impair the grade of honey very much, and, when used this way, very nearly equal new-drawn combs. If one expects to uncap 250 to 350 gallons of good, ripe honey in a day's time, he will have no time to waste in looking out for spacing devices of any kind, or sharpening uncapping knives. That is the quantity I generally figure for a day's run with a man and boy in the yard to do the "robbing," a man to run a 4-frame extractor, and a man to uncap and look after the combs in the house.

2. I want all the frames in the hive alike, so that I can change them to any part and use them for any purpose, and I have never had a man in the yard for any length of time that favored a spacing device of any kind.

As for their advantage, a beginner or a man working for comb honey might like the self-spacing frame, but I use the plain for both comb and extracted honey, and have never suffered any loss from moving. I have hauled bees around considerably, and do not fasten the frames, as the bees will cluster tight enough to hold them as soon as the jar of the wagon commences.

Of course this is a matter of "every man to his liking," but a good way to get at the practicability of the two kinds of frames would be to get the statements of about 100 bee-keepers who handle 300 or more colonies of bees, and see if the most use plain or self-spacing frames.

EDWARD G. BROWN.

Sergeant Bluff, Iowa, June 10.

### Favorable Conditions for Bees.

Conditions are favorable here for a great honey-flow if it ever stops raining, as caltapa is just beginning to bloom and persimmon will soon come along. Besides, there is clover in bloom everywhere and it is yielding very well this year. There are also great patches of yellow sweet clover scattered here and there that are blooming, and the white sweet clover is showing in considerable quantities, which promises to furnish enough to keep up brood-rearing after the early flow is gone, so that our bees can take full advantage of our fall flow, which is the greatest of our flows here. But with the bees it has been different, no hundreds of colonies have been lost, especially among the farmers, many of whom lost every colony they had. But with the professional bee-keeper it is also different. They lost few by starvation this winter, as they had hives that they could get among the bees to see the exact condition and to feed if necessary.

Such, in brief, is the condition here—plenty of flowers and yielding well, but bees scarce through the ravages of the terrible winter and spring. I lost 6 colonies by thieves that got into my out-yard, and 1 by starvation. Three were queenless and I united them with weak colonies to help them along.

JULIUS HAPPEL.

Evansville, Ind., June 5.

## ITALIAN QUEENS

Fine young prolific 3 and 5 banded Italian Queens, by return mail. Untested only 60c, or \$6.50 a dozen. Tested, 75c or \$8 a dozen. Extra fine queen, \$1.

26—28

## Langstroth on the \*\*\* Honey-Bee

Revised by Dadant—Latest Edition.

This is one of the standard books on bee-culture, and ought to be in the library of every bee-keeper. It is bound substantially in cloth, and contains nearly 600 pages, being revised by that large, practical bee-keeper, so well-known to all the readers of the American Bee Journal—Mr. C. P. Dadant. Each subject is clearly and thoroughly explained, so that by following the instructions of this book one cannot fail to be wonderfully helped on the way to success with bees.

The book we mail for \$1.20, or club it with the American Bee Journal for one year—both for \$2.00; or, we will mail it as a premium for sending us **THREE NEW** subscribers to the Bee Journal for one year, with \$3.00.

This is a splendid chance to get a grand bee-book for a very little money or work.

**GEORGE W. YORK & CO.**

118 W. Jackson Blvd., CHICAGO, ILL.

### 3-Banded Italian Queens

J. P. Moore or my own strain. My apiary is stocked with thousands of choice drones that are not kin to my breeding queens.

Queens, \$1 each; dozen, \$10

I guarantee satisfaction, and superior honey-gatherers. W. M. Parrish,  
23A1f R. R. No. 5. LAWRENCE, KAN.

### ITALIAN QUEENS

That are bred from the best stock this country can produce Bright Golden and 3-banded Queens ready to ship May 20. I am now booking orders which will be filed and filled in rotation. After May 20 all orders will receive prompt attention. Untested Queens 60 cents each; 6 for \$3.35, or 12 for \$6.50. Tested, \$1.00, or 6 for \$5.50. 2 frame nuclei with Young Queen after June 1, \$2.00. GEO. W. BARNES,  
15A26t Box 340. Norwalk, Ohio.

### Bee-Supplies and Berry-Boxes

Lewis B ware at Factory Prices. Bee-keepers, club together, send me list of goods wanted, and let me quote you prices, I give the regular discounts. Beeswax wanted. Send for Catalog.

### New Steamer Cayuga

Makes More Popular the Lake Trip  
from Lewiston, N. Y., to Toronto

The Fleet of the Niagara Navigation Company has, this season, been increased by a new steel twin screw ship, which, in speed, comfort and beauty is unsurpassed upon the great lakes. Her name, "Cayuga," has been selected to harmonize with her sisterships, the "Chippewa," "Corona" and "Chicora." The full service of this line consists of six trips daily except Sunday.

The steamers are essentially observation day boats, and have the reputation of being most admirably adapted for the service.

Excellent Table d'Hote meals are served, and each steamer is also equipped with lunch counters, where sandwiches, pastry, tea, coffee, etc., may be obtained. It is the endeavor of the Company to make the dining-room department first-class in every respect.

Coupon ticket agents of all railroads in the United States and Canada sell tickets via the Niagara Navigation Company.

### The Niagara-Toronto Route

The Niagara Navigation Company, Limited, popularly known as the Niagara River Line, consists of four fine, fast, steel steamers, making, at the height of the season, six round trips daily (Sunday excepted) between Toronto, Ont., and Lewiston, N. Y., via Lake Ontario and the Niagara River, calling at Niagara-on-the-Lake, Ont., and Queensdown, Ont. The trip occupies about two hours and a half.

## Queens of Moore's Strain of Italians

Produce workers that fill the supers, and are not inclined to swarm. They have won a world-wide reputation for honey-gathering, hardiness, gentleness, etc.

Mr. W. Z. Hutchinson, editor of the Bee-Keepers' Review, Flint, Mich., says: "As workers, I have never seen them equaled. They seem possessed of a steady, quiet determination that enables them to lay up surplus ahead of others. Easier bees to handle I have never seen."

My queens are all bred from my best long-tongued 3-banded red-clover stock (no other race bred in my apiaries), and the cells are built in strong colonies well supplied with young bees.

PRICES: Untested Queens, \$1 each; six, 5; doz., \$9. Selected, untested, \$1.25 each; six, \$6; doz., \$11.

Safe arrival and satisfaction guaranteed.

## HAND-MADE SMOKERS

Extracts from Catalogs—1907:

BINGHAM  
CLEAN  
BEE SMOKER

Pat'd 1878, '82, '92 & 1903

Chas. Dadant & Son, Hamilton, Ill.—This is the Smoker we recommend above all others.

W. B. Lewis Co., Watertown, Wis.—We have sold these Smokers for a good many years and never received a single complaint.

A. I. Root Co., Medina, Ohio.—The cone fits inside of the cup so that the liquid creosote runs down inside of the smoker.

All Bingham Smokers are stamped on the tin, "Patented 1878, 1892, and 1903," and have all the new improvements.

- Smoke Engine—largest smoker made.....\$1.50—4 inch stove
- Doctor—cheapest made to use.....1.10—3½ "
- Conqueror—right for most apiaries.....1.00—3 "
- Large—lasts longer than any other......90—2½ "
- Little Wonder—as its name implies......65—2 "

The above prices deliver Smoker at your post-office free. We send circular if requested.

Original Bingham & Hetherington Uncapping-Knife.

T. F. BINGHAM, Farwell, Mich.

Patented May 20, 1870. BEST ON EARTH.

## Dittmer's Comb Foundation

Why do thousands of bee-keepers prefer it to other makes?  
Because the bees like it best and accept it more readily.

### Dittmer's Process is Dittmer's

It stands on its OWN NAME and its OWN FOUNDATION, to which alone it owes its reputation and merits.

We are now ready to make prices for next season for WORKING WAX for CASH and for full line of Supplies. Wholesale and Retail. Free Catalog and Samples.

GUS DITTMER, Augusta, Wis.

Mention Bee Journal when writing.

## Ideal Hive-Tool—"Best on the Market"

Bee-keepers have long needed a special tool to aid them in properly manipulating the hive-parts during the bee-season. The one shown here does the work to perfection.

Best Hive-Tool

Only 30c, by mail

(This picture is exactly one-half the size.)

DESCRIPTION.—The Ideal Hive-Tool is made of high-grade malleable iron, much like wrought iron, 8½ inches long. The middle part is 1-16 inches wide and 7-32 thick. The smaller end is 1¼ inches long, ½ inch wide, and 7-32 thick, ending like a screw-driver. The larger end is wedge-shaped, having a sharp semi-circular edge, making it almost perfect for prying up supers, as it does not mar the wood.

### What Some Bee-Experts Say of It.

Louis C. Dadant (son of C. P. Dadant) wrote us May 10, 1907: "Your Hive-Tool is certainly the best on the market, and after having used one of them no bee-keeper would do without it."

In the first edition (1903) of Dr. Miller's "Forty Years Among the Bees," page 58, he says: "Of all the hive-tools I have tried, I like best the Muench tool." On Jan. 7, 1907, he wrote us, saying he thought "just as much of the tool as ever."

Miss Wilson, Dr. Miller's assistant, says this of the Ideal Hive-Tool: "It is an ideal tool. In fact, I don't see how it could be improved upon. I am sure we would feel utterly lost in the apiary without it.....You will have to try one yourself if you want to know its worth."

### The "Ideal Hive-Tool" Free as a Premium.

We will mail an Ideal Hive-Tool FREE as a premium to any present paid-in-advance subscriber to the American Bee Journal, for sending us ONE NEW subscription for a year at \$1.00; or we will send the American Bee Journal one year and the Ideal Hive-Tool—both for \$1.20. Price of the Ideal Hive-Tool alone, postpaid, 30 cents.

GEORGE W. YORK & CO., 118 W. Jackson Blvd., CHICAGO, ILL.

## BEE BOOKS

Sent postpaid by  
GEORGE W. YORK & CO.,  
118 W. Jackson Blvd., Chicago, Ill.

**Advanced Bee-Culture.** Its Methods and Management, by W. Z. Hutchinson.—The author of this work is a practical and helpful writer. You should read his book; 320 pages; bound in cloth, and beautifully illustrated. Price, \$1.20.

**A B C of Bee-Culture,** by A. I. & E. R. Root.—A cyclopedia of over 500 pages, describing everything pertaining to the care of the honey-bees. Contains about 400 engravings. It was written especially for beginners. Bound in cloth. Price, \$1.20.

**Scientific Queen-Rearing,** as Practically Applied, by G. M. Doolittle.—A method by which the very best of queen-bees are reared in perfect accord with Nature's way. Bound in cloth and illustrated. Price, \$1.00; in leatherette binding, 75 cents.

**Bee-Keeper's Guide,** or Manual of the Apiary, by Prof. A. J. Cook, of Pomona College, California. This book is not only instructive and helpful as a guide in bee-keeping, but is interesting and thoroughly practical and scientific. It contains a full delineation of the anatomy and physiology of bees. 544 pages. 295 illustrations. Bound in cloth. 19th thousand. Price, \$1.20.

**Langstroth on the Honey-Bee,** revised by Dadant.—This classic in bee-culture has been entirely re-written, and is fully illustrated. It treats of everything relating to bees and bee-keeping. No apiarian library is complete without this standard work by Rev. L. L. Langstroth—the Father of American Bee-Culture. It has 520 pages, bound in cloth. Price, \$1.20.

**Honey as a Health Food.**—This is a 16-page honey-pamphlet intended to help increase the demand for honey. The first part of it contains a short article on "Honey as Food," written by Dr. C. C. Miller. It tells where to keep honey, how to liquefy it, etc. The last part is devoted to "Honey-Cooking Recipes" and "Remedies Using Honey." It should be widely circulated by those selling honey. The more the people are educated on the value and uses of honey the more honey they will buy. Prices: Sample copy for 2-cent stamp; 50 copies for 70 cents; 100 for \$1.25; 250 for \$2.25; 500 for \$4.00; or 1000 for \$7.50. Your business card printed free at the bottom of the front page on all orders for 100 or more copies.

**Forty Years Among the Bees,** by Dr. C. C. Miller.—This book contains 328 pages, is bound in handsome cloth, with gold letters and design; it is printed on best book-paper, and illustrated with 112 beautiful original half-tone pictures, taken by Dr. Miller himself. It is unique in this regard. The first few pages are devoted to an interesting biographical sketch of Dr. Miller, telling how he happened to get into bee-keeping. About 20 years ago he wrote a small book, called "A Year Among the Bees," but that little work has been out of print for a number of years. While some of the matter used in the former book is found in the new one, it all reads like a good new story of successful bee-keeping by one of the masters, and shows in minutest detail just how Dr. Miller does things with bees. Price, \$1.00.

**"The Honey-Money Stories."**—A 64-page-and-cover booklet, 5¼x8¼ inches in size, printed on best quality paper. Many short, bright stories interspersed with facts and interesting items about honey and its use. The manufactured comb honey misrepresentation is contradicted in two items, each occupying a full page, but in different parts of the booklet. It has in all 33 fine illustrations, nearly all of them being of apiaries or apiarian scenes. It also contains 3 bee-songs, namely, "The Hum of the Bees in the Apple-Tree Bloom," "Buckwheat Cakes and Honey," and "The Bee-Keepers' Lullaby." This booklet should be placed in the hands of everybody not familiar with the food-value of honey, for its main object is to interest people in honey as a daily table article. Price, 25 cents, or 3 copies for 50 cents.

**HOW TO PAINT**

Buggies, farm wagons, farming tools, barns, outbuildings and houses often need painting. "Everybody's Paint Book," written by a thoroughly practical painter, will be found a complete guide to the art of outdoor and indoor painting. It is designed for the special use of those who wish to do their own painting. It gives practical lessons in plain painting, varnishing, polishing, staining, paper hanging, kalsomining, etc.

It also tells how to renovate furniture and gives many hints on artistic work for decorating a home. Precise directions are given for mixing paints for all purposes. If farming tools and farm vehicles are kept painted, they will last twice as long, and anybody can do the work with the aid of this book. It is handsomely and substantially bound in cloth. A copy will be sent postage prepaid on receipt of price, \$1.00

**SPECIAL OFFERS**

**Honey and  
Beeswax**

CHICAGO, June 8.—Not any of the honey yield of 1907 has appeared on this market, and with the choice white grades of last year's comb being exhausted there is practically nothing to base values on other than that of history, for there is always a limited demand for honey. New white comb of good flavor would sell at 16c; no demand for other grades. Extracted is also exhausted of best grade. Beeswax is selling on arrival at 32c. R. A. BURNETT & CO.

CINCINNATI, May 23.—There is no material change in the honey market at this writing. Extracted honey is not moving so rapidly as it could, owing to the cool weather. We quote amber in barrels at 5½@6¼c; fancy table honey in crates of two 60-pound cans at 8@9c. For choice, yellow beeswax, free from dirt, we are paying 31c cash, delivered here. THE FRED W. MUTH CO.

PHILADELPHIA, June 10.—The honey market has been quite brisk for this time of the year. A number of odd lots have been cleaned out of the market. We quote: Fancy comb, 14@15c; No. 1, 13@14c; amber, 12@13c. Fancy white extracted, 7@8c; light amber, 6@7c. Beeswax firm, 32c.

We are producers of honey and do not handle on commission. WM. A. SELSER.

NEW YORK, May 21.—White comb honey is practically cleaned up, and there is very little demand at this time. There is some dark and mixed comb on the market, but no demand to speak of, and some of this will have to be carried over until next season, or sold at a sacrifice. Therefore we cannot encourage shipments of off-grades or dark honey at this time. Extracted honey is in fair demand and prices are ruling firm. There is very little new crop arriving as yet from the South, and while it is rather early, we doubt whether we will have any large shipments from the Southern States this season, as we fear there will be a short crop, judging from the reports we are receiving. There is quite a good stock of last year's crop still on the market, sufficient to last until the new crop from various states arrives. There is no change in price as to extracted honey since our last. Beeswax firm and likely to remain so for the next 2 months. HILDRETH & SEGELKEN.

**C. H. W. WEBER** CINCINNATI OHIO

Office and Salesrooms, 2146-48 Central Ave. Warehouses: Freeman and Central Aves.

INDIANAPOLIS, June 19.—There is a strong demand for fancy white comb and best grades of extracted honey, but the market is practically bare at this writing. Evidently a new scale of prices will be established on arrival of new crop. Beeswax is plentiful and in fair demand, selling here at \$35 per 100 pounds. WALTER S. POWDER.

TOLEDO, May 3.—There is very little demand for comb honey as is usually the case at this season of the year. Fancy white would bring in a retail way 16@17c; No. 1, 15@16c, with no demand for dark honey. Extracted is very scarce and none being offered for sale. Beeswax is bringing 28c. THE GRIGGS BROS. & NICHOLS CO.

KANSAS CITY, June 1.—The honey market is almost bare of comb honey, and demand good; receipts of extracted are light, and demand light; we quote: No. 1 white comb, 24-section cases, \$3.25; No. 2, white and amber, \$2.50@2.75. Extracted, white, per pound, 8c; amber, 7½@7¾c. Beeswax, 30c. C. C. CLEMONS & CO.

DENVER, Feb. 14.—Producers in this State are practically closed out of both comb and extracted honey. We have not sufficient good comb honey to supply our local trade, but have a good supply of white extracted of excellent quality. We quote strictly No. 1 white comb honey, per case of 24 sections, at \$3.20; No. 1, light amber, \$3; and good No. 2, \$2.80. White extracted, 8@8½c per pound; light amber, 7½@8c. Clean, yellow beeswax, 27@28c, delivered here. THE COLO. HONEY-PRODUCERS' ASSN.

CINCINNATI, June 18.—The market on fancy white comb is entirely bare. No. 2 is selling slowly at 12c. Extracted, light amber, brings 5½@6c. Beeswax is selling here at \$32 per 100 pounds. C. H. W. WEBER.

**FOR SALE**

1000 sixty-pound CANS. A No. 1 condition, packed two in a case. Cases also first-class. Will sell them cheap.

## Marshfield Bee-Goods

talk for themselves; having bought once, you will buy again. Our orders show that. The reason for this is that nothing is used in the making of our BEE-GOODS that we know is not fit to go in. Why should we when we have plenty of the best as it comes direct from the forest to our mill and factory.

SECTIONS are made of the basswood timber, grown here in the basswood belt of Wisconsin.

DOVETAILED HIVES, of lumber almost clear, made accurate and smooth.

SHIPPING-CASES, strong and neat—nothing flimsy about them.

### SHIPPING FACILITIES THE BEST

You will get your orders sent on very short time, as we are located on three direct railroads to Chicago there connecting with the trunk lines for the East, South, and Southwest, and some parts of the West. The West by way of St. Paul and Minneapolis.

If you have not yet received our Catalog of BEE-SUPPLIES for 1907, just write for it.

# AMERICAN BEE JOURNAL

JULY — 1907

# American Bee Journal

PUBLISHED MONTHLY BY  
**GEORGE W. YORK & COMPANY**  
 118 W. Jackson Blvd., Chicago, Ill.

**IMPORTANT NOTICE.**

THE SUBSCRIPTION PRICE of this Journal is 25 cents a year, in the United States of America, except Chicago, where it is 50 cents, and Mexico; in Canada 35 cents; and in all other countries in the Postal Union, 25 cents a year extra for postage. Sample copy free.

**Advertising Rate, per Agate Line, 10c.**

14 lines make one inch.  
 Nothing less than 1/2 inch accepted.  
 Reading Notices, 25 cents, count line.  
 Goes to press the 6th of each month.

**National Bee-Keepers' Association**

**Objects of the Association.**

1st.—To promote the interests of its members.  
 2d.—To protect and defend its members in their lawful rights.  
 3d.—To enforce laws against the adulteration of honey.

**Annual Membership Dues, \$1.00.**

General Manager and Treasurer—  
 N. E. FRANCE, Platteville, Wis.

If more convenient, Dues may be sent to the publishers of the American Bee Journal.

**Honey as a Health-Food.**—This is a 16-page honey-pamphlet intended to help increase the demand for honey. The first part of it contains a short article on "Honey as Food," written by Dr. C. C. Miller. It tells where to keep honey, how to liquefy it, etc. The last part is devoted to "Honey-Cooking Recipes" and "Remedies Using Honey." It should be widely circulated by those selling honey. The more the people are educated on the value and uses of honey, the more honey they will buy.

Prices, prepaid—Sample copy for a 2-cent stamp; 50 copies for 70 cents; 100 for \$1.25; 250 for \$2.25; 500 for \$4.00; or 1000 for \$7.50. Your business card printed free at the bottom of front page on all orders for 100 or more copies. Send all orders to the office of the American Bee Journal.

## 3-Banded Italian Bees

The best all-around bees on earth. My stock is composed of selections from my own strain of 3-banded Italians that were awarded diploma at the Pan-American Exposition, and The A. I. Root Co. clover stock.

Tested queens, \$1.00; select tested queens, \$1.50; fair breeding queens, \$3.00; extra-select breeders, \$5.00—ready to go promptly. Untested queens, 75c; select untested queens, \$1.00—ready early in March. Yours for a prosperous 1907.

**W. O. VICTOR,**

Queen Specialist, **HONDO, TEXAS**

## ITALIAN QUEENS

Fine young prolific 3 and 5 banded Italian Queens, by return mail. Untested only 60c, or \$6.50 a dozer. Tested, 75c or \$8 a dozen. Extra fine queen, \$1.  
 J. L. Fajen, ALMA, Mo.

"If goods are wanted quick, send to Pouders."

Established 1889

**In the Bull's-Eye.**

By the Bee-Crank

**E**VER SHOOT at a target? You know when you have missed it because you don't hear anything, although you pause to make sure the ball hasn't been delayed in transit. When you hit the bull's-eye the bell rings and it rings mighty quick.

Now Indianapolis is right at the bull's-eye of this great country. The center of population as determined by the United States census is within walking distance of my warerooms. It is a direct line from you to me, and from me back to you again. When you send an order for supplies and do not hear something quick,

it's a sign you've missed the bull's-eye. Send it to me and before you know it you will realize that you've made a good shot.

I don't know much about red-tape. I just keep a lot of things on hand that I know you want, and when your order comes I pack 'em up and hustle 'em off to you—same day. The railroads are a great help to me, because they radiate in every direction from Indianapolis, and transfers and side-tracks do not have to be considered.

I carry a full line of Root's goods at Root prices, and buy your Beeswax at highest market prices, returning goods you want in exchange for it before you have time to say "scat!"

**A select Hoosier-Italian untested Queen—on return train for a dollar; six for five.**

## Trade Notes The A. I. Root Company, Medina, Ohio

Does It Pay a Planing Mill Man to Make His Own Hives?  
An unsolicited statement of the matter from an Illinois bee-keeper:

### ELIAS BAMBERGER

Manufacturer of

### SASH, DOORS, BLINDS

Contractors' and Builders' Supplies  
Including All Kinds of Window Glass

Cor. Exchange and Adams Sts.

ESTIMATES FURNISHED ON APPLICATION

Freeport, Ill., June 11, 1907.

The A. I. Root Co.,  
Medina, O.

Gentlemen:

I received five of your AE52S-10 hives yesterday and find that I cannot make my own hives and supplies as cheap as yours and use the same quality of lumber. You can see by the head of this letter that if anyone can make hives cheaper than your prices or any of the so-called "trust hive" manufacturers, I ought to be able to do it, but using the same quality of lumber I cannot.

Yours very truly,

(Signed) John H. Bamberger.

The above is a representative letter from the many we have to the effect that our hives and other supplies can be purchased cheaper than a local mill can possibly make them. Our enormous output enables us to reduce the cost to the minimum without sacrificing quality.

## Editorial Notes and Comments

### Get a Text-Book on Bees

No better advice can be given to a beginner in bee-keeping, or to one who contemplates beginning, than to tell him to get a text-book on bee-keeping, a book of instruction about bees and their management. The study of such a book will give him more knowledge than he would gain in years of actual practice without any such help. The one who gets a bee-paper, thinking to depend alone upon that, is making a great mistake. Much of what is contained in the periodical will be blind to him, as the readers of bee-periodicals are supposed to know what is contained in the text-books, and a constant repetition of fundamental principles would not be relished by them. It is to the interest of the American Bee Journal to have as many subscribers as possible, but if you can not have both the book and the paper, be sure to get the book first.

### Plan Now For Surplus Honey

Not surplus honey to use on the table or to sell; but sealed combs of honey to give to the bees next spring. It is not likely they will be needed as much next year as they were this, but there's no knowing; and the old saying is a good one, "Better be ready and not go, than to go and not be ready." In any case you may be pretty certain that whatever the season next year, you can dispose of a number of such combs to good advantage. Enormous quantities of honey are used up in rearing brood. Nothing strange about that, either. It is not merely the material used to fill the brood-cells; we are told that the nurse-bees use more for their own support than they feed to the brood. If honey

is not present in abundance, the bees seem to know enough to limit the amount of brood started, and so do not enter the period of harvest in full strength. Hence, the importance of extra combs in the early season, especially with small hives.

One way to provide such combs of honey is to have a part of all of the fall honey thus stored. Localities differ greatly in this respect; in some the fall flow being the chief harvest, in some there being no fall flow to speak of. Where one can not rely quite confidently on this fall flow, either part of the honey stored by each colony should be in these sealed combs, or else part of the colonies should be devoted entirely to such purpose. The best time to decide in what way provision shall be made to meet the case next spring is now, if the decision has not already been made.

### When to Give a Super to a Swarm

If the surplus apartment or super is removed from the old hive and given to the swarm immediately upon the hiving of the latter, the queen is likely to begin laying in the super if no queen-excluder prevents. Either use an excluder, or wait till the queen gets to work in the brood-chamber (perhaps 2 or 3 days) before changing the super from the old hive to the swarm.

### Keeping the Queen Out of Sections

Some find it necessary to have queen-excluders under section-supers to avoid the disagreeable occurrence of brood in sections. Others say it is so rare a thing to find the queen straying into the surplus apartment that it is not worth while

to have the trouble of excluders, to say nothing of the expense. The secret of the difference probably lies in the fact that one uses small starters in the sections and the other fills the sections with foundation. When small starters are used, and little drone-comb in the brood-chamber, the desire for drone-brood causes the bees to build drone-comb in the sections, and the queen to go up and lay there. If the sections are filled with worker-foundation, no drone-comb can be built there, hence no enticing of the queen out of the brood-chamber.

### Prevention of Second Swarms

Usually it is not best to have any more than one swarm from each colony. Also, if honey be the object, it is better to make the swarm as strong as possible, depending upon the swarm for surplus. When the swarm is hived, if it be set on the old stand and the old hive be put on a new stand 10 feet or so distant, that will give the swarm all the field-force, and will often prevent further swarming. A still better plan, although a little more trouble, is the following:

Set the swarm on the old stand, and set the old hive close beside it, both hives facing in the same direction as the old hive faced. In 7 days, move the old hive to a new place some 10 feet away. The field-bees that leave the old hive will, on their return, go straight to the old stand, and not finding their own hive there will join the swarm. That will so weaken the mother colony that all thought of further swarming will be given up. Not only does the weakening tend in this direction, but also the fact that no honey is being brought in, and the provident creatures do not think it wise to swarm with starvation staring them in the face.

### "We Be (e) Brethren."

It speaks well for bee-keepers in general that a more brotherly feeling among them is growing all over the world. American bee-keepers owe much to the patient researches of their eminent brethren in Europe. On the other hand, European bee-keepers are increasingly alert to pick up any good thing that

may be found on this side the water, and they are frank to give, generally, proper credit. Dr. Bruennich, a very prominent Swiss authority, is quoted by F. Greiner as scoring American bee-keepers for their kindergarten position in the matter of queen-rearing, page 455. Whether such criticism is properly deserved or not, it is quoted to mention the fact that a man who could be thus severe where he supposed it deserved, is also large-hearted enough to offer commendation when he thought it deserved, as he did when he mentioned our G. M. Doolittle as a man whom he held in highest esteem as one of the foremost leaders in the world apicultural.

It may not be amiss to say to Dr. Bruennich that conditions are not precisely the same here as in Switzerland. So far as they have been tried, it seems that the general consensus of opinion is that in that country no foreign bees can compare with the natives. That being the case it is the part of wisdom to exclude the foreigners and bend all energies to bring the natives to the highest state of perfection. But in this country there is a greater unanimity of opinion than in Switzerland, even, that opinion being that black bees are *not* the best for us; and so long as it is settled that the favorite must be a foreigner, and so long as there are foreigners yet untried, why not try them?

#### Scissors for Queen-Clipping

For this purpose a pair of small embroidery scissors has been the favorite, but of late a pair of ordinary pocket scissors has been commended. These may be carried in the pocket safely the year 'round, their blunt points allowing them to be carried in trousers' pockets when the heat forbids the wearing of coat or vest. Some who have tried them claim that they are even superior to embroidery scissors.

#### Signs of Swarming

Entire dependence can not be placed upon any outside signs. Look inside; if no queen-cells are started, the bees have not yet taken under advisement the matter of swarming. If cells are started, you may expect the bees to swarm with the old queen about the time the first queen-cell is sealed. If a second swarm issues, you may expect it in the neighborhood of 8 days after the first swarm. If a second swarm does not issue within 15 days after the first, you need not watch any longer for it.

#### Dandelion as a Honey-Plant

Gleanings for June 15 occupies no small space in singing the praises of the dandelion as a honey-plant, a valuable spring greens, its root-yielding the valuable medicine taraxacum, as valuable cow-pasture, and as a plant with a flower of rare beauty, although unappreciated because so common.

Regarding the same plant the following note has been sent to this office by Dr. Miller:

"In this region the dandelion is a

honey plant of increasing importance. I am told that the plant was unknown here 60 years ago. I know that it was scarce when I came here in 1856, but it has been gradually increasing each year, much to the distress of lawn-owners, and this year it is plentier than ever before. It first began blooming April 23, and 2 months later the bees are still working on it to a small extent. If colonies had been in full strength when dandelion was at its best, there is little doubt that surplus would have been stored from it. Only one more week left of June, and bees seem mostly occupied trying to rob, so the present outlook is for another season of failure."

#### The Mohr Extractor — A Swiss Invention

All the honey-extractors known up to the present time are inconvenient, owing to the disposition of the comb-baskets, which are placed at the lower part of the rotating cylinder. It is thus

difficult to reach the combs with the hand. It is always unpleasant to place them in and to turn them over. The work is disagreeable, for it is almost impossible to do it without soiling yourself. This extractor claims to do away with this inconvenience. The comb-baskets are placed in an open frame which can be laid back. The gearing is placed at the bottom. The bottom of the extractor is conical, which permits the honey to run out rapidly.

#### Two Queens in a Hive

Seed Time and Harvest quotes approvingly from Gleanings the plan of having 2 or more laying queens in a hive, given by E. W. Alexander, and then says:

"The worst feature to overcome in giving our colonies 2 or more laying queens is in knowing how to introduce them safely.

"Mr. A. does not give his method of introducing queens, but we will give ours. Our theory is that the antagonism shown by bees to a newly introduced queen is mainly on account of her scent, and for years the writer has successfully introduced queens, without caging, at the same time the old one was removed, by dropping the stranger in a tea-cup partly filled with honey, taken from that hive, and completely submerging her in it, after thinning with warm water if necessary, then pouring the whole into the center of the top of the hive. The bees will almost invariably proceed to lick her off and accept her without question; and according to Mr. A. it might not be necessary to remove the old queen in order to succeed."

It is no wonder that bee-keepers are set guessing as to how much a hitherto unbelievable thing can be done; but the guess of the Seed Time and Harvest does not seem the most plausible. Generally speaking, a new queen is better received when the colony is conscious of queenlessness. In the present case a queen is to be introduced where there is no thought of queenlessness, and so an unusually reliable method of introduction is needed. The method suggested is very old, and in many cases is successful, as indeed almost any plan is successful under favorable circumstances, but it has generally been abandoned as less reliable than the caging method. The guess will hardly pass muster. Next!

#### Better Top-Protection

Editor Root is enthusiastic over the advantage of having something more than a single thickness of board over a hive or a super. Some 20 years ago D. A. Jones called his attention to a row of hives the covers of which were covered with white frost except oval spots over the centers of the clusters, the stronger the colony the larger the melted spot. That set Mr. Root to thinking that the heat wasted in melting these spots might be saved if the covers were non-conductors of heat. He says:

"Quite a number of the bee-keepers of the country are beginning to use double covers.

"R. F. Holtermann and Dr. C. C. Miller are both strong advocates of such covers. The former uses an extra piece of paper felting between the two covers. Dr. Miller uses only two thicknesses of  $\frac{3}{8}$  boards with a dead-air space between. While this is good, it does not go quite far enough. Should we have a cool summer, and especially if we should have cool nights, there will be a lot of backward work in the supers unless the bees are provided with a good thick cover.

"Those bee-keepers who are fortunate enough to own a double cover, one telescoping over the other, should place between the two covers several folds of newspaper. Those who are still more fortunate in having a deep telescope cover would do well to interpose be-

tween the two some newspapers with the ends falling over the sides and ends; then shove a telescope cover snugly over the whole.

"But there will be some who will find themselves without these telescope covers. All such we would advise securing some large squares of heavy manilla

paper. Fold the old newspapers over the top of the regular hive-cover; then, with the help of any attendant, fold one of the squares of manilla papers centrally over the top. Tuck the edges neatly down over the super as you would a package of soap, and then tie a string around it, looping it into a bow-knot."

county associations. This is a wise move. It not only saves 50 cents to each member thus coming, but helps to increase the total membership so much more rapidly. Let the good work go on.

WORCESTER CO., (MASS.) FIELD-MEETING.—A. H. Estabrook, Secretary of the Worcester Co., (Mass.) Bee-Keepers' Association sent us the following on July 2:

The Worcester Co. (Mass.) Bee-Keepers' Association held a field-meeting at the apiary of Mr. J. S. Whittemore, on Pleasant St., in Leicester, on Saturday, June 29, 1907. The resignation of Pres. Burton N. Gates, of Worcester, was read to the Association and accepted. Pres. Gates leaves the society to take a position as bee-expert in the Department of Agriculture at Washington. It was then voted to leave the matter of electing a new President until the annual meeting next January. It was voted to hold a Fair in September in Horticultural Hall, the same as last year. On September 24, 25, and 26, 1906, the Association held an exhibition of bees, hives, honey, and implements used in bee-keeping; and the Fair was a decided success, so much so that we have decided to hold another one the coming September.

The same plan of popular lectures will be carried on, and every effort will be made to secure the most prominent lecturers on bee-matters in the country. The exhibitions will be, as before, for the amateur as well as the dealer in supplies. Further notice of this Fair and exact date will be published as soon as possible.

A. H. ESTABROOK, Sec.  
Clark University, Worcester, Mass.

MISSOURI'S STATE INSPECTOR OF APIARIES is Mr. M. E. Darby, of Springfield, Mo., as announced in the following from Mr. R. A. Holekamp, Secretary of the State Bee-Keepers' Association:

EDITOR YORK:—Our State Board of Agriculture met at Kansas City, Mo., on June 5, and appointed Mr. M. E. Darby, of 400 East Commercial Street, Springfield, Mo., as State Inspector of Apiaries.

Mr. Darby is the candidate supported by the Missouri State Bee-Keepers' Association, and by making this appointment the State Board of Agriculture showed the bee-keepers did right in giving the Board the appointive power when asking our Legislature to pass our Bill.

If the bee-keepers of our State will now give their inspector all the assistance they can, by reporting to him localities where foul brood exists, and following his instructions in curing diseased apiaries, we have good reason to hope that our State may become, to a certain extent, free from foul brood.

Mr. Darby is well fitted for the work, and will make a good inspector.

ROBT. A. HOLEKAMP,  
Secretary Mo. State B.-K. Association.

Missouri, like Illinois, has now an appropriation of \$1,000 a year to be used in the interest of bee-keeping. We are sure that Mr. Darby's appointment is a

## Miscellaneous News - Items

FROM A WEEKLY TO A MONTHLY.—In the American Bee Journal for June 27, we published the following:

### AN IMPORTANT ANNOUNCEMENT.

To the subscribers of the American Bee Journal:—

Believing that the old American Bee Journal should occupy a wider field, and thus be a help to a larger number of readers, we have decided to issue it *monthly*, beginning with July (next month), instead of weekly, and at 25 cents a year. This very low price will permit every bee-keeper everywhere to subscribe for it, even if he or she has only one colony of bees. Yes, and any one who is at all interested in bees as a Nature study will, no doubt, be glad to read it regularly.

For 26½ years the American Bee Journal has been issued every week, but it has been found that there are only about so many bee-keepers who are sufficiently interested in bees to think that they need a *weekly* bee-paper. What we want is a larger constituency, hence we believe that by publishing the American Bee Journal once a month, and making the subscription price 25 cents a year, we will be able to reach the goal of our ambition sooner, and at the same time do a better service to all. The yearly price to Canada will be 35 cents; to England and other foreign countries in the Postal Union, 50 cents a year.)

We believe that after a few months at least 99 percent of our present list of readers will see that we have done wisely in making the change mentioned.

We are not quite ready to announce more of our plans just now, but will do so in the July number and in those immediately following it. We trust we may have the continued coöperation of all our old friends, and, of course, we expect very soon to enlist that of many thousands of new ones all over the world.

We may say that the monthly American Bee Journal will contain at least 32 pages each issue. The weekly number was supposed to contain 16 pages, so that under the new plan there will be half the quantity of reading matter at only one-fourth the former cost.

The July number will be issued about

the 15th of the month; then thereafter we expect to mail it on the 10th of each month. The advertising forms will close on the 5th.

Of course, all who have paid their subscriptions in advance at the regular \$1.00 rate (or the extra foreign rate) will be credited just four times as far ahead as their present address-label indicates. Those who are in arrears will pay at the rate of \$1.00 a year up to the end of this month.

In the next issue we will be able to make further announcement. In the meantime let us all hope that bee-keepers may harvest a good crop of honey, and that although the prospects may have been discouraging, the silver lining of the clouds may be revealed and all be prosperous and happy.

GEORGE W. YORK & Co.,  
Chicago, Ill., 118 W. Jackson Blvd.

We wish to add a little to the foregoing. We should have said that all subscribers to the monthly American Bee Journal in Chicago will pay 50 cents a year, as the postoffice requires a 2-cent stamp on each copy of a monthly paper mailed in the city where published.

"APICULTURAL INVESTIGATIONS" is a division in the Bureau of Entomology, Department of Agriculture, Washington, D. C., entirely devoted to the interests of bee-culture. Just now there are 6 persons connected with the work, as follows:

E. F. Phillips, in charge.  
G. F. White, Expert in Bacteriology.  
J. M. Rankin, in charge of Apicultural Station, Chico, Calif.  
B. N. Gates, Collaborator, Worcester, Mass.  
Jessie E. Marks, Apicultural Clerk.

THE NATIONAL MEMBERSHIP was 2390 on July 1. So it lacks only 110 of being a round 2500. This number should easily be reached by the time of the Harrisburg meeting, exact date of which we hope to be able to announce next month.

We understand that New York State members are coming back into the National Association "in a body," even by

# American Bee Journal

wise one. If the bee-keepers of Missouri will now give him their hearty co-operation, he will doubtless be able to rid the State of foul brood in due time.

We congratulate the bee-keepers of Missouri upon the success in securing their new law, and also upon the appointment of Mr. Darby as inspector.

## MR. BENTON'S SEARCH FOR NEW BEE-RACES.

The following letter has been received by the editor of Gleanings:

UNITED STATES DEPARTMENT OF AGRICULTURE,  
BUREAU OF ENTOMOLOGY.

WASHINGTON, D. C., May 29, 1907.

MY DEAR SIR:—I am in receipt of your letter of May 16th, asking for information concerning the results of the trip by Mr. Frank Benton, in search of new races of bees.

I regret that I am unable to give you a report of this trip, since the Bureau of Entomology has received no such report from Mr. Benton, and he is no longer connected with the Bureau of Entomology. The information which we have on the subject is a verbal statement from Mr. Benton to the effect that he found very few bees, and was unable to ship any of them to this country. The tone of his statement concerning them would indicate that they are not desirable. Respectfully yours,

G. L. MARLATT,  
Acting Chief of Bureau.

THE ADDRESS OF A. J. KING, formerly editor of the Bee-Keepers' Magazine, (long since extinct), is asked for by one of our readers. Who can tell us?

INSPECTORS OF APIARIES' REPORT.—Under date of July 1, 1907, Dr. E. F. Phillips, who now has charge of the bee-keeping interests of our Government at Washington, D. C., wrote as follows:

DEAR MR. YORK:—Under separate cover, I am mailing you a copy of Bulletin No. 70, "Report of the Meeting of Inspectors of Apiaries, San Antonio, Tex., November 12, 1906." This bulletin is for sale by the Superintendent of Documents, Government Printing Office, Washington, D. C., for 15 cents. Stamps are not accepted in payment.

Yours very truly,

E. F. PHILLIPS,  
In Charge of Apiculture.

The Report referred to contains 80 pages and cover. It is a most interesting pamphlet, and should be in the hands of every bee-keeper who wishes to have the latest word concerning diseases of bees. Send a 15-cent money order or coins for a copy as directed by Dr. Phillips.

depends upon the wings, and the large leather-colored Italians that we prefer are as strong of wing as the best.

At the North of the map the reader will see an apiary marked "Champeau." We harvested our best crops at that place, owing to the moist lowlands east of it. The "Lieberot" apiary, a little over 2 miles west of it, and located on the shore of the river, never gave more than half as much honey, under a management in every way identical. The river cut half of its pasture away. We have no bees there at present.

The "Milliken" apiary is now our best apiary for yield, excepting the apiaries at the south end, which are on the edge of the low, swampy lands of the river. The reader will notice that our home apiary is just about 3½ miles west of it, and, although our bees fly mainly in that direction, they have never been able to harvest as good crops as at this apiary.

Notice a dot southwest from our home apiary. There was a small apiary there a few years ago, and when the Spanish-needles on the low islands below Hamilton were in bloom, the bees of that apiary invariably made progress on the Spanish-needle honey when our home bees did nothing. That honey was only a little over 2 miles away, but it was across hills and hollows, and timber-land, and the bees evidently did not go that far.

The "Byers" apiary is on high land, some distance from any damp waste lands, and has yielded nothing worth mentioning, except from the white clover pastures around it. It has been first-class for the white clover crop, for most of its surroundings are pastures.

The "Villemain" apiary is now in the hands of a man who formerly worked for us. It is adjacent to about 500 acres of islands, and gets quite a crop from that every year. But during one summer when those islands were pastured to excess after a heavy flood of the Mississippi, the bees in that apiary literally starved, while those of the "Lamet" apiary, and of the "Sack" apiary, which are next to the immense swamps of the river, were yielding abundantly. The "Villemain" apiary is only 4 miles from the nearest of those, and only 3½ from the edge of the swamps; but as Mr. Byer puts it, "it might as well have been 20 miles away, as far as practical results were concerned." But if instead of hills and hollows between the two there had been an uninterrupted valley, with fields of flowers attracting them, it is possible that the bees would have gone the 4 miles and into the swamp-land. I have no doubt that the bees at the "Lamet" apiary go 2 or 3 miles in a southwest direction for honey, since their pasturage is wedge-shaped.

Another apiary within a half mile gives about the same results. But the "sack" apiary, on the edge of the widest bottom-land, gives most positive results every season. In 30 odd years we have had but two failures of the fall crop there. At that place we get only about a half crop of clover honey, for their pasture is half bottom-land that grows no clover at all. Another apiary about a mile south yields similar returns.

## How Far Do Bees Go For Nectar?

BY C. P. DADANT.

I have noticed both Mr. Chambers' and Mr. Byer's articles on the above subject (pages 279 and 393) and I desire to add my experience. When any one of us thinks he knows, he should hesitate about telling others that they are wrong, for different conditions produce different results, and what proves correct in one spot is incorrect in another. Mr. Chambers himself, who says it is "all bosh" about bees going such short distances for honey, shows us that circumstances alter conditions, and that in some cases bees may not go much over a mile, for he says: "During all these years the closest watch has failed to show any great flight of bees towards the sumacs on the east, only a mile and over."

I believe the man who claims the longest distances of travel for his bees is Mr. Doolittle. If I am not mistaken, he says they will go as far as 8 miles. I do not feel like calling Mr. Doolittle's or Mr. Chambers' ideas "all bosh," for I believe that they speak the truth, but I think the distances traveled by bees depend entirely upon location.

that bees will travel farther in one direction than in another. This is caused by several things, in my opinion: The direction of the wind, its velocity, the shape of the ground (whether plains or hills), the amount of obstacles, timber, streams, houses, etc.; and, lastly, the number of honey-plants along the way to the distant pasture.

Some 20 years ago, Mr. Root requested several bee-keepers who had for a long time kept out-apiaries, to write statements of their experiences with bees located at different spots under the same management. The replies of France, Manum and myself, with diagrams, were published in Gleanings at that time, and have been since partly reproduced in the "A B C of Bee-Culture." I am sending a new diagram which will show my reasons for believing that bees do not usually travel over 2 miles in search of honey.

Perhaps it is as well for me to say at once, that there is nothing in the statement that we must despise a race of bees that are not good for a crop of honey 3 miles or more from them. We have imported fully one-half of the Italian bees that have produced the present American stock. We have tried Carniolans, Cyprians, etc., and we have found no difference in their ability to travel. In fact, the ability to travel

# American Bee Journal

The reader will see by this how dissimilar the crops may be when the conditions of the country are as dissimilar as they are in our vicinity. I have no doubt, however, that in the large plains of Texas, or of Colorado, apiaries will show more uniform results; but no one should lay down a rule, thinking that it will apply to every field.

If we look at still more irregular spots, we will find still more irregular results. In Switzerland, where the country is cut up by steep hills and snow-capped mountains, there are localities where they find differences in results within a mile or two. They are so accustomed to these differences in small areas that they have come to the conclusion, in some parts of Switzerland, that they can isolate queens and drones,

woods are probably as much a hindrance to the flight of bees as anything else.

If the pasturage is uniform all around an apiary, without any special attractions in one direction, I firmly believe that a circle with a diameter of 4 miles will about cover the pasturage used by the bees. This represents an area of over 7,000 acres, and if there is any honey at all in such an area the bees would be very foolish to go farther.

Perhaps some one will ask me: How do you know whether your bees go, or do not go, to such or such fields? By the results. This is certainly the best test. If apiaries 4 miles apart have crops differing entirely in quantity or quality, under the same management, with the same breed, and using the same kind of hives, there is nothing to make

back many years. Our out-apiary was established in 1872. In 1877 we had 6 apiaries, and have had from 4 to 6 ever since that time.

Hamilton, Ill.

## Some Queen Questions Answered.

BY G. M. DOOLITTLE.

**QUESTION.**—A while ago I had a swarm issue which was hived in the usual way. After hiving the swarm I cut out all of the queen-cells from the parent colony but 3, and there were no more such cells started. About 15 days later another swarm issued from the parent hive. On examining the hive I found that the bees had actually kept 2 of the queens confined in their cells 6 or 7 days after they should have gnawed out. One queen had been allowed to emerge from one of the 3 cells, she leading out the second swarm, while the other 2 queens were in the cells. I cut open the cells, and, when liberated, strange to say, these 2 queens could fly as well as queens which have been out of their cells several days. How would you account for this? And what kept these queens from starving?

**ANS.**—Bees do what seem to the novice as very strange things quite often, and even the veteran is sometimes puzzled over some of the things they do. The 2 queens which our questioner found in their cells were kept there by the bees so that they might have the material to preserve the existence of the colony after a second swarm had issued. In fact, it is a very rare thing for an after-swarm to issue unless one or more virgin queens are held in their cells in just this way. Had those two queens been allowed to emerge from their cells, a fight would have ensued till all but one queen would have been killed, and the killing of all but one of the queens would have prevented all after-swarming, and such preventing was just why the bees kept the 2 queens in their cells so as to preserve them till after the queen which the bees allowed to emerge from her cell first had left with the afterswarm, after which it was safe for another of the 2 queens to leave her cell, as only one queen is allowed to roam the hive at one time, for any length of time, except in case of supercedure of queens, when, in exceptional cases, the mother and daughter will dwell together for days, weeks, and sometimes months, until the old queen dies of her infirmities.

Had the questioner waited an hour or so after the second swarm issued before he had opened the hive he would have found one of the 2 queens at liberty, and the other kept in her cell by a knot of bees clustering over it, or both out and one of them killed, just according to whether the colony intended to send out the third swarm or not.

When all idea of swarming is given up then all queens old enough to do so are allowed to leave their cells, a fight ensuing, till all but one are killed, when the bees and queen turn in and gnaw into all the remaining queen-cells, when

by placing the mating apiaries at a distance of only two kilometers (1¼ miles) from the other bees. This, to my mind, is a mistake, for the drones are the strongest, on the wing, of the race. Nature has provided this so that they may more readily find the young queens. I therefore believe that drones will go further even than the worker-bees.

The Mississippi River has proven a barrier to our bees, and yet it is only a mile wide. We found but one exception to this rule. It was with a small apiary on the edge of the Keokuk bluff. The bees, penned in by the city, and finding no fall blossoms anywhere near there, cross the river every fall to harvest honey from the blossoms on the opposite bank—the islands shown in the accompanying diagram. The width of the river is about a mile, and ought not to be a complete hindrance. Hills and

the difference in results but the difference in pastures. If the bees at the "Milliken" apiary harvest Spanish-needle honey in large quantities from a pasture just east of them, and those at the home apiary get honey of a different color, and less in quantity, we will surely conclude that they do not work in the same area, even though they all appear to go in the same direction. If an apiary near the swamps produces half as much clover honey as the home apiary, and twice as much fall honey, it is evident that that apiary is in a different field as to blossoms. If our bees went 6 miles readily, in any direction, they would have something like 100 square miles to harvest from, or over 60,000 acres. There would be no limit to the crop, no possibility of overstocking.

The experience I mention here dates

the victorious young queen stings all of her embryo rivals through the holes made in the sides of the cells. But until the idea of swarming is given up, all occupied queen-cells are protected from the queen having her liberty by little knots of bees clustering about them.

And in the above we have the accounting for what our questioner thought a strange proceeding. But before leaving this part of the matter I wish to say that a circumstance similar to the one given by the questioner is somewhat rare, in that the queens were kept so long in their cells. This can be accounted for by believing that bad weather for swarming occurred at about the time the first queen emerged from her cell, and continued for a week or so, or during the time the bees held these queens in their cells. Otherwise, as is usually the case, this second swarming would have occurred in two or three days after the emerging of the first young queen from her cell.

And now as to the matter of what kept the two queens from starving. The bees fed them, of course; and had our questioner looked closely he would have found a little hole near the end of the cell through which the queen put out her tongue to be fed, as I have seen them do scores and hundreds of times.

Some seem to think that bees never feed a queen or another bee unless they are in a measure forced to do so; but this is a mistake. I have seen bees feeding these inmates of queen-cells at many times during the past 35 years. I first saw it being done in 1871, and saw the same thing during the summer of 1906, and during many of the summers intervening.

In 1871 I was immensely interested, as this was my first experience, in the matter. In 1906, I observed more closely than ever before, for the reason that a prominent bee-keeper said that the queen almost laid hold of a worker-bee in order that she might be fed, and that all of the present notions regarding the bees feeding one another, and especially the queen, were only fossil ideas drifting down through the centuries. I found, as my memory served me of other observations, that all the queen had to do while in her cell was just to push out her tongue through this slit or hole in the same, when there were bees ready to feed her. Yea, they seemed anxious to do this, for no sooner would the tongue protrude than one, 2, and often 3 bees would be there to caress it and offer food. And these young queens when thus cared for, are growing strong almost, if not quite, as rapidly as is the one having her liberty, so that it is nothing strange that our questioner's queens which were kept in their cells 5 or 6 days after they should have emerged, were so they could fly as soon as he cut the cells open.

Some years ago, I had a queen laying in 3 days from the time she emerged from her cell. It happened in this way: A colony lost its queen, casting a swarm with a virgin queen, and while they were hanging on the limb I opened the hive to cut the queen-cells preparatory to returning them. Upon looking the hive over I found only one cell besides the

one the queen emerged from, and as I had the frame having it on in my hands, a beautiful young queen came forth from this cell. I at once took the frame, bees and all, together with 2 more, and formed a nucleus with them, and in just 3 days I found the queen laying. At that time I thought I had found something extra along the line of smart queens, but a few years afterward I had nearly the same thing again with a queen which I knew had been held in the cell for at least 5 days. A queen that is thus held in her cell grows old as fast as do those which queen-breeders keep in nursery cages, and it is nothing worthy of comment for introduced nursery-caged queens 5 or 6 days old to be laying 3 or 4 days later. A queen emerging from her cell at maturity is a weak, white, downy thing, very much different from the strong, ready-to-fly queens we always have with queens held in their cells till they have been quahking for 2 or 3 days.

Borodino, N. Y.

## Rearing Pure Queens---Hive-Bottoms.

BY DR. G. BOHRER.

Please permit me, Mr. Editor, to endorse what is said on page 481, and also much that is quoted from others concerning the matter of improving bees. I find no improvement in the Italian bee, except it be the goldens where not crossed with Cyprians, which may prove to be something of an improvement upon the 3-banded bees of 40 years ago, in beauty at least. I have one of these queens whose worker progeny is as large as any I ever saw. And her queen offspring, so far, are fine in color, of good size, and quite prolific. But their workers in turn show the 4th, and some of them the 5th, yellow or golden band. This has led me to conclude that this queen has been fertilized by a drone from 3-banded Italian stock, and that her queen offspring has been mated to golden drones, as the number of yellow bands points in that direction. But while the mother-queen in question is very prolific, her workers are good-dispositioned, and as great honey-gatherers as I have ever had any experience with.

The question comes up as to what a golden Italian bee is, anyway. Is it an original and distinct race, or is it the result of selecting the brightest colored queens and drones to breed from through several successive generations? If so, then we are surely getting back towards what an original and distinct race of bees was. For it seems to be absolutely certain that if we use the darkest colored queens and drones to breed from they run back rapidly to the black races of bees. I have found it no small task to keep the 3-banded Italians up to the well-marked 3-banded standard. The tendency is to show a yellow waist and one distinct yellow band, with a very indistinct third yellow band. And to breed queens from a mother whose workers are thus marked is certain to show still more prominently black blood.

With the facts before us, of careful selections resulting in brighter yellow bees, and indifference as to selection in breeding resulting in darker and widely different colored bees, the question again comes up as to "where we are at." One will reply that we are surrounded by black and mongrel bees, and that the disappearance of the yellow bands is due to this fact only. That such a state of affairs will keep up amalgamation and retard improvement in any desirable direction, is without doubt true; but if a 3-banded queen-breeding apiary be located 10 to 15 miles from all other races of bees, is this strain of bees ever found to be distinct, that none but 3-banded bees will be produced? If so, and these bees are, as some claim, larger and harder than the goldens, and better honey-gatherers, then it is the duty of all bee-keepers to join in securing such legislative enactment as will secure protection by isolation from all other races of bees. Ten to 15 miles it would seem would be ample distance. Some think a much shorter distance would answer, but as it is known that queens are often out of the hive more than 30 minutes when on their bridal trip, no one seems able to state definitely the distance they go from the hive when out so long. But it being highly probable that in level or undulating regions they go several miles from the hive, and it being also quite likely that drones likewise go a long distance from the apiary in which they are reared, any person who breeds queens for the market should be required to get control of all the bees within a radius of 15 to 20 miles, and take out a license to breed queens near the center of his territory. And the law should prohibit any one else from keeping bees within his territory. This rule should apply to any one who breeds any other strain of bees, whether goldens, 3-banded, Carniolan, Cyprian, or any other race of honey-bees.

Any one who can answer the questions as to whether the goldens are a distinct race of bees, and whether the 3-banded bees are a distinct race, and what isolation and careful selection of breeding stock has done in producing and maintaining either or both intact, will, no doubt, confer a favor upon many bee-keepers.

### HIVE BOTTOM-BOARDS.

But permit me to join Mr. Scholl, on page 692 of *Gleanings*, in what he says concerning the flimsy and worthless bottom-boards that many factories are sending all over the country. Some of them say that they do not recommend them, but supply them when ordered. I never knew any one to order lives with these trashy bottom-boards. But they get them just the same. I will say that if it is really a fact that supply-factories do not recommend these traps, they most certainly do know that they are a pest, and not what the practical bee-keepers want, and they should so inform their patrons, if they really wish them to have actual value for their money. These traps cost quite as much as  $\frac{7}{8}$ -inch boards. The latter will last many years with proper care, while the

# American Bee Journal

thin bottoms go to pieces in a short time. Worst of all, the joints in them shrink here in Central Kansas until robber-bees find it an easy task to enter them and destroy a good colony in a short time. I have, after 3 years' use, thrown them away.

Please, gentlemen, let us have no more 5-16 bottom-boards. Many beginners have been cheated by having these trashy bottoms put off on them, not knowing how little they are worth. And some experienced bee-keepers ordered hives with 7½ bottom-boards and had the

thin bottoms sent them. I was caught in just this trap once, and was "up against" the proposition of accepting them or doing without hives, as it was too late to get others, the swarming season being upon me.

Such bad supplies with advancing, increasing prices, are causing many persons to try to make their hives themselves, which, as a rule, does not secure a hive made of good material, properly cut and put together. Let us have hives made of good material.

Lyons, Kans. (Continued on p. 601.)

time they came to prefer the middle of the day. It is not so much the middle of the day, either. Sometimes bees will be good natured in the forenoon and cross at noon. Sometimes good natured in the afternoon. It depends upon the pasturage. That's good sometimes in one part of the day, sometimes another; and when bees are busy gathering they are on their best behavior. So long, however, as your bees sting less in the morning, there is no reason why you should not take that time of day to handle them. When you have bees enough you have to work at all times of day.

Bees are not to be blamed if they don't want to go into a hot hive in the middle of the day. You wouldn't, either. You may find that it will make a great difference if you have the hive shaded, or sprinkled with water, and especially if you have the cover partly off so that the bees find it cooler in the hive than out.

If a virgin is clipped she will not mate. If you have clipped a virgin, the best thing is to clip off her head, also.

Conducted by EMMA M. WILSON, Marengo, Ill.

## "Emma" Means "Honey-Bees"

In olden times any change in the family, as the death of their keeper, was told to the bees, says Praktischer Wegweiser, and when a man entered matrimony he must introduce his young wife to the bees, and hence probably arose the maiden name "Emma," for the old German name Emma is the high German of "Imme," as the bees were called at that time. Many girls of the present time named Emma may not know they actually bear the name of our busy little honey-gatherers.

## Retarding Swarming—Bee-Sting Cure

This promises to be a good year with me. The bees are not swarming so much as at other times, yet they are storing honey in better quantities than usual. So I had made up my mind that anxiety to swarm is not an indication that they are short of room. It is with bees as with people, I guess. They must do something, and if there is nothing to gather for honey, they swarm. I have been wondering if feeding the bees during short honey-flow would retard swarming.

I wish I had a sure and prompt cure for stings. I do not get stung often, but especially if stung on the face or neck, I am badly poisoned thereby, and am sick for days. All the books, etc., I have read on the subject say to handle the bees during the middle of the day when they are flying freely, yet that is the time of all others that I avoid them, as then they are decidedly warlike with me. Early in the morning, while it is yet cool, is the time I work with them, and often I take off a super or put one on, and not a bee comes out of the hive. Often, too, a swarm that issues in the heat of the day will not enter a hive, yet will do so late in the evening, and sometimes in the morning.

If a virgin queen is clipped, how will she mate, as that takes place during flight? MRS. GERTRUDE L. GOODWIN, Roy, Wash., June 6.

It is hard to understand very much about what favors or retards swarming. It is not likely that you could retard swarming by feeding, yet bees are more likely to swarm with a very moderate yield than with nectar coming in a flood.

A thousand and one cures for stings have been given, yet it is not certain that one of them can be depended upon when it comes to the pinch. Perhaps mud is as good as anything else. Your course probably is to do one of two things. You may try the plan of taking the stings until you become immune. In your case it is just possible that it would

## T-Super Dimensions, Springs, Etc.

DEAR MISS WILSON:—Please give the inside length of Dr. Miller's T-super, that he uses on the 8-frame Langstroth hive. Also the thickness of the "follower" that he uses. (I suppose the supers are 12½ inches wide.)

Can the springs that he says are better than wedges be bought of dealers? Are they to be used loose, or are they to be attached to the super?

As I am going to make a few of those supers, I desire to have them made right. I take it for granted that the length of the T-tins are 12 inches.

I would very much like to see a description of his "super-filler." I believe he has promised to describe it some time.

MARY M. SMITH.

Caldwell, Ida., May 27.

A T-super measures, inside, when first

FIG. 1.—SUPER-FILLER.

take so long and entail so much suffering that it would not be worth while. The other course is to wear gloves, and dress so as to be proof against stings.

Your feeling about the time of day has been the same with others, but in

made, 17¾x12½x4½ inches. Ours have been in use for years, and now measure 4½ in depth, which is a better depth. But even well-seasoned lumber seems to shrink with age, so it is better to make them 4½. If they were made 4½ at

# American Bee Journal

first, and then should shrink to 43%, there would be trouble.

The follower is 17 1/4 x 4 1/4 x 5-16, of course with places cut for the T-tins.

The super springs can be bought of any dealer in bee-supplies, costing a cent apiece, or about 75 cents a hundred. At first we used 2 to each super; but now use only one, and it works all right. The spring is used loose, thrust down somewhat diagonally, between the side of the super and the follower, at the middle.

Yes, the T-tins are 12 inches long.

The following description of the super-filler is taken from Dr. Miller's "Forty Years among the Bees," page 148:

### SUPER-FILLER.

I'll tell you how to make a super-filler. Take a board as large as the outside dimensions of your super or larger. (The one in Fig. 1 is a board hive-cover.) Nail a cleat on one end of the board, and another cleat on one side, as in the picture. These cleats may be 1/2 by 1/4 inch, but the dimensions are not important. Now put a super on the board, shoving one corner snug up in the corner made by the cleats. With a lead-pencil, mark on the board, on the inside of the super, where the sides of the super come. Put eight sections in the super, four on each side, with the three T-tins in their proper places. With a pencil rule across the board each side of each T-tin, so as to show where the T-tins come. Now take off the super and its contents, and get six strips, each 11 1/2 inches long and 1/4 inch square. Nail these on as shown in the picture, so as to keep at equal distances from the pencil-mark of the super at each side, and about a fourth of an inch

It stands at a convenient height at the right-hand side of the one who operates the Darsy fastener, with the side-cleat at the farther side (See Fig. 2). A super is placed on it with one corner of the super tight against the angle made by the cleats; but no T-tin is yet put in the super. As the sections come from the fastener they are placed in the super at the end toward the back of the operator. When the first row of six is completed, the T-tin is slipped under these sections into its proper place. In like manner a second row of sections and a T-tin; then a third row and a T-tin, and lastly the fourth row. Then without rising, the operator lifts this filled super to one side and gets an empty one.

### Bees Capture a New Home

"LONG BEACH, CALIF., April 25.—Several weeks ago Mr. and Mrs. Clarence Carney furnished a new home they had built in Belmont Heights, but, having paid the rent on another house, remained in the latter until today, when they delivered up the keys and started

off with visions of a happy time in their own home.

"When they unlocked the front door they were startled by thousands of busy honey-bees, swarming in every nook and corner of the house, which were so angry at the intrusion that they literally drove Mr. and Mrs. Carney from the house by a combined assault.

"Mrs. Carney sat on the doorstep and laughed, while her husband made a trip to town for brimstone, which he threw, burning, into the house, but with little effect, and Mr. and Mrs. Carney will sleep downtown tonight and seek to allay numerous severe stings received in the day's encounter."

Isn't it a pity that all reporters are not obliged to take a preparatory course in bee-keeping to fit them to give correct reports in regard to bee-items? The above item may have occurred exactly as reported, and it may not. In any case, it shows the superiority of the feminine mind, as Mrs. Carney was able to sit on the step and laugh, while her liege lord threw burning brimstone into the house. We are not told how long it took the house to burn down, nor the amount of insurance.

The "Old Reliable" as seen through New and Unreliable Glasses.  
By E. E. HASTY, Sta. B. Rural, Toledo, Ohio.

### LYMAN METHOD OF SWARM CONTROL.

We should await with interest the reports on the Lyman method of swarm control. It may be characterized as a self-acting artificial swarmer which operates gradually instead of suddenly. My impression is that the out-and-out shaken swarm (in some of its forms) will eventually give more general satisfaction. Placing a great lot of young brood where many bees go out and few or none come in doesn't look to be the proper thing. The method evidently has this in its favor, however, that it obviates the desertions which some "shook" swarms have run against so badly. If we try to save time to the utmost, and judge from outside appearances, we may shake a swarm which had no intention of swarming at all—and so do lots of needless mischief. Same of the Lyman method. In both there would be a queen to be reared from the start under improper and bad conditions. Which would be the worse I hardly know. On the whole, I think I'd sooner trust the queen from a hive with a natural entrance, even if the bees were too few and nearly all young. Page 411.

### DETECTING A HONEY-FLOW—PUTTING ON EXTRA SUPERS.

Doolittle's way of seeing if a honey-flow is on is fresh enough to speak

about. With the sun low, as it is at 4 o'clock, get your head near the ground and protected from direct rays, view the incoming bees thus, looking nearly toward the sun, but not quite, and those carrying loads of honey will have a translucent look, while the others look opaque. I'll own up that I never tried this, but I have no doubt that it would work. Very skittish new beginners might dislike to expose unprotected heads so near to a stream of bees.

That's an honest confession Mr. D. makes also. While he practiced the orthodox way of lifting a super to put an empty super under he regularly had from one-third to one-half of his sections unfinished. The unfinished ones are from 4 to 8 out of 100 now that he always puts the empty super above. This list is not far from my own results, using the double-deck wide-frame and no tiering up at all. Page 431.

### "WHEELBARROWING" COLONIES

Nothing succeeds like success. F. L. Day succeeds at trotting his hives 25 rods on a common wheelbarrow, and gets them on the summer stands all right, and before they wake up. 'Spects if they were roaring and already waked up, and more than waked up, when he started with them the outcome might be different. Page 432.

FIG. 2.—PUTTING FOUNDATION IN SECTIONS.

distant from the marks made for the T-tins. The super-filler is now complete.

### THREE YELLOW SWEET CLOVERS.

So the annual *Melilotus* of Texas is yellow. I think the one I read of years ago was blue. Doubtless this yellow annual is responsible for some of the mix-up that prevails in the minds of the brethren about yellow *Melilotus*. If I'm right we have at least 3 yellows. One is purely and simply a yellow variation of the white, nearly identical otherwise, and therefore of no use to us except as a curiosity. One is a smaller and earlier biennial with many points of difference, among them a liking for wet ground, and different species botanically. Third comes this yellow annual which is still more a thing in itself. Page 433.

### VARIOUS KINDS OF FOOL SWARMS.

We are liable any day to have some one deny that there is such a thing as a "fool swarm;" and therefore let us fool with it a little. The fool swarm is one of the subdivisions of one of the divisions. Primes, afterswarms and deserters constitute the first divide. Proceeding to subdivide the deserters we have about 4 kinds. The first, and by far the most common kind, occur in regular swarming time, and among recently-hived swarms. They think they can do better, else haven't had frolic enough, and out they come. Some years seem to be more promotive of this contrariness than others. Next we have a

miscellaneous lot of untimely swarms that consider themselves driven out by unendurable conditions — unendurable heat, unendurable cold, draughtiness, leakage of water, inroads of insects, etc. Third comes the "hunger swarm," pure and simple. We can certainly respect their disposition not to "die and make no sign" when starving. As a last resort they start out and try to better their condition. Naturally hunger swarms are mostly in the early spring, but not all then, I believe. Fourth and last is the fool swarm. Comfortable and sweet-smelling hive, fair supply of both honey and pollen, absolutely nothing to cause them to go *except the discontent and weariness which has grown up in their minds*. We can hardly admire their wisdom, but we can admire the high-strung mental character, without which such a result would never come about. Not very different from the case of the well-situated family that migrates to a life of struggle and suffering in a new country. "Our graves were out here, and we had to come to 'em," said a lady of such a family, 20 miles from where I write, in the Black Swamp of Wood County. Human fool swarm much more common than the fool swarm of bees. Well, the case which Mr. Byer gives on page 434 is excellent to mark, and keep in reserve, in case some "Thomas" should get up and deny the whole thing.

ago. I found 2 young Italian queens that I bought last fall, with only about a handful of bees with each. Having found the queens in 2 extra-strong colonies, the combs they were on were set aside and then the bees of a couple of combs were shaken in front of these very weak colonies. The old bees return to their old location, and the young bees crawl up into the hives they are in front of. These *young bees* are indeed "friends in need," and just the right kind of strength required. Instead of having brood to get chilled, the colony has more bees to care for and rear brood, and on examining those 2 colonies to-day, after 2 weeks' time, I could hardly think it possible that so much change could have taken place in so short a time.

### Dark Bees the Hardest

Just lately I was speaking with a bee-keeper who has been in a large number of apiaries in Ontario, during the past 2 months, and he remarked that in every case the dark bees—Carniolans and natives—had stood the adverse conditions much better than the Italians. My own personal experience is exactly in accord with this view, and the very few weak colonies I have are nearly all headed by Italian queens. The very yellow, or 5-banders, have suffered the worst; in fact, through these parts they have been cleaned out entirely. It seems to be quite the general opinion that these very yellow bees are not so hardy as the leather-colored Italians, yet I have never seen a good explanation as to *why* this is the case.

### "A Cold and Backward Season"

The above phrase has become a by-word during the year of 1907, so far. However, since June 16, in our locality at least, the first-named qualifying adjective can be eliminated when speaking of weather condition. On that date a warm wave accompanied by nice showers came in, and the growth in vegetation has been phenomenal. It seems as if Nature were putting forth every effort to make up for lost time, and instead of looking forward to crop failure, the farmers are now confident of at least an average harvest. Prospects for the bee-keeper are also much brighter, and although the clover is about 2 weeks later than usual, yet it is now looking good, and with favorable weather there is no reason why a crop of honey should not be secured. Basswoods are very full of buds, and while this source of nectar is always very uncertain, yet we *never* get basswood honey when we have no basswood bloom. The acreage of buckwheat will be larger than usual, so from one source or another the bee-keeper should be able to get some honey. Clover started to yield yesterday (June 24), and now we have just had a soaking rain which should put it in good condition for yielding nectar when the weather clears again.

Speaking of bee-forage, I often won-

Conducted by J. L. BYER, Mount Joy, Ont.

### Busy With the Bees

I am very busy (June 15). Colonies got ahead of me, owing to bad weather, and it was quite a job to break up swarming after the fever was contracted. I will have quite a blank during fruit-bloom and clover, and it will pay to feed, as I will have to be away for about 2 weeks steady, so the best I can do is to leave the colonies heavy with honey and let them take chances. As the majority of them have lots of unsealed honey from fruit, in the supers, they will not suffer for a week or two.

J. L. BYER.

### Bees Starved in the Cellar

Editor Hutchinson tells, in the Review, of losing a large number of colonies in the cellar through starvation. The cold weather prevented taking the bees from the cellar until nearly the first of May, and, as a result, as has been mentioned, a lot of them starved.

While in all my bee-keeping experi-

ence I have not lost a dozen colonies by starvation, yet I am still learning the necessity of abundance of good stores in the fall.

Mr. Storer, of Lindsay, winters his bees in a perfect cellar, and yet every colony *must* have 40 pounds of stores. I am thoroughly convinced that he is on the safe side, and if necessary some years, it is no great trouble to relieve the brood-nest. This year our large, heavy brood-nests needed *no relief*.

### Alexander Plan of Building Up Weak Colonies

While the Alexander plan for building up weak colonies is good when single-walled hives are used, yet it is almost of no value to those bee-keepers who winter their bees on the summer-stands, as such hives can not be tiered up. This spring I blundered on to a plan that is simply "immense" when you want to have a good queen that has only a few bees with her.

When clipping at one yard 2 weeks

der if the bee-keepers of the northern part of the continent fully appreciate the value of alsike clover. In a recent issue of *Gleanings*, Editor Root says that those bee-keepers will be fortunate who have had lots of alsike clover scattered around their apiaries. He advises bee-keepers to buy the seed for the farmers free, believing that in the end the investment would be a paying one. Be that as it may, I am thankful that we live in a locality where alsike is grown for seed, as I know if it were not for alsike we might as well pull up stakes at once.

As to white clover, we have a little in old pasture-fields and on the roadsides, but in dry seasons it is cropped so closely by sheep that it hardly gets a chance to bloom. Occasionally a field is grown for seed, and from observation I am quite sure that it is not at all equal to alsike as a honey-yielder. I wonder if about  $\frac{3}{4}$  of the white clover honey produced throughout the country is not gathered from the alsike!

### A Swarming Surprise

Bee-keepers in this locality were caught napping this spring. With steady cold weather prevailing right through April, May, and the first week of June, with scarcely a day fit to open hives, swarming was hardly thought of. Imagine our surprise when on starting queen-clipping during the early part of fruit-bloom, we found about 1-3 of the colonies starting queen-cells. One colony had swarmed about the middle of May when pussy-willows were yet in bloom. The queen being clipped, the bees returned, and when the young queens emerged, away went the whole force of bees. This happened at an out-yard, and the loss was not discovered until a couple of days after the bees had left. This is the first time I have ever lost a swarm in the spring, and what makes the matter particularly aggravating is the fact that the queen was an extra-good one, and I was contemplating rearing a number of young queens from her.

Having said so much, I may as well tell the whole joke. The day I discovered the loss I had made a trip to the out-apiary for the express purpose of bringing that colony to the home-yard so as to give it closer attention when rearing those young queens. It has been rather a boast of mine that I have not in 5 years allowed a colony to swarm in fruit-bloom, but after this spring, I guess I would better keep "mum" when the subject is mentioned. All colonies found with queen-cells were treated to a thorough over-hauling, cells cut out, supers put on, and although the weather was cool, brood was put in the supers over the strongest colonies. Returning 10 days later 6 colonies were found to have swarmed, and 3 more were again starting cells. As fruit-bloom was just over, after cutting out cells again the 3 were considered safe, but with those that had swarmed and lost the old queens, nothing short of breaking up the colonies into strong nuclei would answer the purpose—queen-cells nearly all sealed, and also most of the brood; and the bees in that noticeable broody condition.

If thought advisable later on, these nuclei can be united and good results obtained during the flow, or, as I contemplate doing, the nuclei can be made strong in double-quick time by the giving

of brood from extra-strong colonies. Colonies made up like this, headed by a young queen, are in an ideal condition to take advantage of any flow that may happen to come.

Conducted by LOUIS H. SCHOLL, New Braunfels, Tex.

### "Snowy White" Drones

Some 5 or 6 years ago I had a large, prolific queen that would produce a drone every now and then almost pure white. These were not the so-called "Albino" strain, but were dark hybrids, and these sports were not of the white, ashy color usually found in the so-called "Albinos," but were almost of a "snowy" whiteness; even their wings having a milky cast. The few that I saw of these strange freaks of nature were never able to fly, and were soon dragged or driven from the hives by the bees.

### Distance Bees Forage Profitably

How far will bees fly for honey? This is a question often asked, and, strangely enough, you will hardly find two apiarists who will give the same answer. I think it should not be so much a question of how far bees will fly for honey, but rather a question as to how far will bees fly and gather honey at a profit.

I know that bees will fly from 5 to 7 miles for honey, and G. M. Doolittle once said they would fly from 3 to 5 miles from choice, when plenty of bloom was to be found near by. Let that be as it may, I will tell how I know they fly from 5 to 7 miles for honey.

Away back in the '80's I lived in Johnson Co., Texas, and was the first one to get the yellow-banded bees in that locality. The following spring a neighbor that lived at least 5 miles distant from my apiary told me those yellow bees worked freely on the fruit-bloom on his place, and that he lined them within less than 2 miles of my apiary with the hope of finding some of the improved bees wild in the woods.

The same year I was six or seven miles from my apiary and saw those same yellow-banded Cyprians at work on horsemint. This was on the high prairie, and only a skirt of timber between those bees at work on the mint and my apiary. They would rise high in the air and make a direct line for my apiary. I searched the woods thoroughly with the hope of finding wild bees of the improved kind, but became fully

convinced that they were bees from my own apiary. I do not mean to say that bees will always fly that distance. I am sure that the locality and season have much to do with it, and, I might add, the "lay" of the country also.

At another time (and a very dry year—the rain that we did have was just local showers), I had my colonies gather about 30 lbs. of comb honey each from wild marigold,  $\frac{3}{2}$  to 4 miles away. How do I know this? I'll tell you. As stated, it was a dry year, and everything was dry and parched in my locality. But 4 or 5 miles away there had been plenty of showers to make the wild marigold do its best, and there was nothing for bees to work on in my locality at the time. Besides, it is easy to tell when bees are at work on the marigold, by their bodies becoming dusted over with a deep yellow pollen.

Rescue, Tex.

L. B. SMITH.

Yes, it is easy to tell when bees are at work on the flowers of what is commonly called "wild marigold"—*Gaillardia pulchella* Fong. Besides the golden-yellow pollen-dust on the bees, the honey has a characteristic flavor, very sweet, and of a heavy body, dark amber or golden in color. These plants extending from the plains of Arkansas and Louisiana through Texas and to Arizona and Mexico, are often much influenced by local rains; that is, where rains do not come at the right time there will be no "marigold," while several miles away a fine crop of bloom may be open where rains prevailed. In such instances it is well that our bees should go several miles from home. But will they always do so? I remember an instance where 2 apiaries were located only  $\frac{1}{2}$  miles apart. Near one of them located on low land, a composite came into bloom in abundance during July when there was no other bloom anywhere. The bees of this yard stored the combs heavily with honey, there being the roar of a big honey-flow on in the apiary during the time of the yield. The bees at the other yard did nothing all the summer; they knew absolutely nothing of "the good time their neighbors were having," and that only  $\frac{1}{2}$  miles away. Now why didn't they find those flowers? There was a "whole valley full of them."

# American Bee Journal

## Pure Food Laws

Texas is not far behind on having a pure food law conforming with the National law. From a list of abstracts of the provision of acts of the Thirtieth Legislature of this State, which met recently, is taken the following:

"PURE FOOD LAW.—House Bill 5, is the pure food bill creating a Pure Food Commission with an appropriation of \$5,000 a year, the Commission to be located at the College of Industrial Arts at Denton, (Texas). The Commission is to be appointed by the Governor. The Bill provides for the appointment of a Pure Food Commissioner, to receive a salary of \$2000 a year, and a Deputy Commissioner, at \$1200 a year. The office is to have a stenographer at \$600 a year. The Act is to prevent adulteration, fraud, and deception in the manufacture and sale of articles of food, drink, paints, and drugs. The standard set for purity in drugs is the test laid down in the United States Pharmacopœa. By adulteration is defined the mixing with any substance anything which depreciates its strength and purity; the addition of a cheaper substance; the abstraction of a constituent or ingredient; selling an imitation for another article; if any is diseased, decomposed, putrid, infected, tainted, or rotten. This applies to milk or animal or vegetable substances."

The bee-keepers of Texas have long wished for a law of this kind, and it will help the bee-keeping industry much toward helping to maintain better prices for honey; especially for honey of good quality.

There are, however, many persons who can not see the good that the pure food law will do for them. This was a surprise to me. They complain that "it will cause all products to go up in price to such an extent that it will be impossible to buy them." But we should consider that we are getting better pay for what we sell, and that we get better food-stuff for what we buy. Yes, it is a just measure all around, and for all of us, although the adulterators may not think so.

## Organized Effort Among Bee-Keepers

In unity there is strength! This holds with bee-keepers as well as with any other class of people. The only trouble has been that their efforts to organize themselves—to get together and strive together—have been entirely too much neglected. Too little attention has been paid to this matter, although much progress was made along other lines of work. This subject was one under discussion at the last year's meeting of the Texas Bee-Keepers' Association, at College Station, and an effort will be made to make this year's convention a better one, also increasing the interest among bee-keepers and increasing the membership of the Association.

As one means of creating an interest, not only among bee-keepers but among visitors attending the conventions during the meeting of the Texas Farmers'

Congress, it was decided to have an exhibit of bee-keepers' products and supplies in connection with the convention. A premium list was provided for which is given in this department. The premiums are well worth trying for. It should also be borne in mind that these premiums, besides the blue and red ribbons that will be awarded for first and second premiums, should not be the only consideration. It will be a great advertisement for the goods of the exhibitor as well. Hence we are desirous of having as many exhibit as possible.

The visitors to the Farmers' Congress, comprising 16 State associations, besides other smaller societies, number several thousand. Therefore, a bee-keepers' exhibit would be a good advertisement.

The Committee on Exhibits would be glad to hear from any intending exhibitor at an early date, so that arrangements can be made in due time. The meeting takes place July 23, 24, and 25. During the convention there will be an interesting program of subjects this year, and a good attendance is hoped for.

In most sections of the State the honey season so far has been a favorable one, and bee-keepers are rejoicing more than they have for several years. If you have not already made up your mind to come to the meeting, and you can, do so now.

### Program of the Eighth Annual Meeting of the Texas Bee-Keepers' Association, to be Held at College Station, Tex., July 23, 24 and 25, 1907.

The Annual Address by the President.  
Reading of the Minutes of the last Meeting.  
Report of Secretary-Treasurer.  
Business of the Association.

#### Discussions:

1. "Making hives at home; some facts and figures," by O. P. Hyde, of Floresville.
2. "Why I prefer the shallow divisible hives and supers throughout over deeper ones," by Louis H. Scholl, of New Braunfels.
3. "Some short cuts in running a large number of out bee-yards," by W. O. Victor, of Hondo.
4. Are the Holyland and Cyprian bees an all-purpose bee for the average bee-keeper?" by W. H. Laws, of Beeville.
5. "Baby or larger nuclei—which are in most extensive use, and why?" by Willie Atchley, of Beeville.
6. "Bee-keepers' exhibits at fairs; and as an advertising medium," by C. S. Phillips, of Waco.
7. "The pure food laws and honey-prices for Texas Bee-keepers," by Udo Toepperwein, of San Antonio.
8. "How are the funds appropriated for foul brood inspection used?" by A. F. Conradi, of College Station.

The Question-Box is again to be one of the main features of the program, in which all bee-keepers present may take part, and ask such questions as are of interest to them.

LOUIS H. SCHOLL, Secretary-Treasurer. W. O. VICTOR, Committee on Program.

#### LIST OF PREMIUMS DONATED FOR THE BEE-KEEPERS' EXHIBIT AT COLLEGE STATION, AT THE JULY MEETING.

##### BEEES—All in one-comb observatory hives:

1. GOLDEN ITALIANS—bees and queen:
  - a. One year's subscription to Gleanings, by Louis H. Scholl. . . . . \$1 00
  - b. One Root smoker, by Texas Seed and Floral Co. . . . . 85
2. THREE-BANDED ITALIANS—bees and queen:
  - a. One year's subscription to Gleanings, by Louis H. Scholl. . . . . 1 00

3. One Bingham honey knife, by Texas Seed and Floral Co. . . . . 85
4. CAUCASIANS—bees and queen:
  - a. One year's subscription to Gleanings, by Louis H. Scholl. . . . . 1 00
  - b. Hive tool, brush, umbrella, and wax-tube, by Texas Seed and Floral Co. . . . . 80
5. CYPRIANS—bees and queen:
  - a. Subscription to American Bee Journal, by Louis H. Scholl. . . . . 1 00
  - b. Hive-tool, brush, and gloves, by Texas Seed and Floral Co. . . . . 80
6. HOLY LANDS—bees and queen:
  - a. Subscription to American Bee Journal, by Louis H. Scholl. . . . . 1 00
  - b. A novice honey-knife, by Texas Seed and Floral Co. . . . . 80
7. BLACKS—bees and queen:
  - a. Bee-veil and gloves, by Texas Seed and Floral Co. . . . . 1 00
  - b. Manum's swarm-catcher, by Texas Seed and Floral Co. . . . . 85
8. BUMBLE-BEES—bees and queen:
  - a. Bee-veil and gloves, by Texas Seed and Floral Co. . . . . 1 00
  - b. Four Porter house-escapes, by Texas Seed and Floral Co. . . . . 80
9. Best and largest display of bees of various races in observatory hives:
  - a. One complete 10-frame comb-honey hive, by W. H. White. . . . . 2 50
  - b. One complete 8-frame comb-honey hive, by Willie Atchley. . . . . 2 00
10. Best and largest display of queens of various races in mailing cages:
  - a. One Jumbo smoker, by Texas Seed and Floral Co. . . . . 1 50
  - b. One "A B C of Bee-Culture," by Texas Seed and Floral Co. . . . . 1 25
11. Best case of white section honey—12 pounds or more:
  - a. One tested golden queen, by Willie Atchley. . . . . 1 50
  - b. One untested Carniolan queen, by J. W. Pharr. . . . . 1 00
12. Best case of amber section-honey—12 pounds or more:
  - a. One tested Holy-Land queen, by Willie Atchley. . . . . 1 50
  - b. One untested Carniolan queen, by J. W. Pharr. . . . . 1 00
13. Best and largest display of section comb-honey:
  - a. Two 2-frame nuclei, by J. W. Pharr. . . . . 4 00
  - b. One breeding queen, by A. Grant Anderson. . . . . 3 00
14. Best display of special design in comb-honey:
  - a. One tested Albino queen, by Willie Atchley. . . . . 1 50
  - b. One untested Carniolan queen, by J. W. Pharr. . . . . 1 00
15. Best 12-lb. friction-top pails of white bulk-comb honey:
  - a. One select golden queen, by J. W. Taylor. . . . . 1 25
  - b. One untested Caucasian queen, by J. W. Taylor. . . . . 1 00
16. Best 6-lb. friction-top pails of white bulk-comb honey:
  - a. One select golden queen, by J. W. Taylor. . . . . 1 25
  - b. One untested Caucasian queen, by J. W. Taylor. . . . . 1 00
17. Best 3-lb. friction-top pails white bulk-comb honey:
  - a. Select golden queen, by J. W. Taylor. . . . . 1 25
  - b. One untested Caucasian queen, by J. W. Taylor. . . . . 1 00
18. Best Display of bulk-comb honey:
  - a. One Italian breeding queen, by W. H. Laws. . . . . 5 00
  - b. One Italian breeding queen, by W. H. Laws. . . . . 3 00
19. Best dozen jars of white extracted honey:
  - a. Mushroom spawn grown by Udo Toepperwein. . . . . 1 50
  - b. One untested queen (Carniolan) by J. W. Pharr. . . . . 1 00
20. Best dozen jars light-amber extracted honey:
  - a. Comb-foundation, by Udo Toepperwein. . . . . 1 50
  - b. Mushroom spawn grown by Udo Toepperwein. . . . . 1 00
21. Best display of extracted honey:
  - a. Five Italian queens, by F. L. Aten. . . . . 5 00

- b. One select tested Italian queen, by W. H. Laws ..... 2 50
22. Best display of extracted honey in granulated form:
- a. One breeding queen, by Udo Toepferwein ..... 3 00
- b. Comb foundation, by Udo Toepferwein ..... 2 00
23. Best sample cake bright yellow beeswax, not less than 2 pounds:
- a. Two Italian queens, by Grant Anderson ..... 2 00
- b. One select Italian queen, by Grant Anderson ..... 1 50
24. Best and largest display of beeswax:
- a. Comb foundation, by Udo Toepferwein ..... 5 00
- b. One select tested Italian queen, by Victor-Knolle Apiary Co ..... 2 50
25. Best display in special designs in beeswax:
- a. Select Italian queen, by Udo Toepferwein ..... 2 00
- b. Mushroom spawn, by Udo Toepferwein ..... 1 50
26. Best display of fruit preserved in honey:
- a. One Italian queen, by Udo Toepferwein ..... 1 50
- b. Mushroom spawn, by Udo Toepferwein ..... 1 00
27. Best collection of honey-plants, pressed and mounted:
- a. Comb foundation, by Udo Toepferwein ..... 3 00
- b. One Jumbo smoker, hive-tool, brush, and gloves, by Texas Seed and Floral Co ..... 2 50
28. Best Honey-Vinegar:
- a. One tested Cyprian queen, by Willie Atchley ..... 1 50
- b. One "Atchley Improved" queen, by Willie Atchley ..... 1 50
29. Best instructive display in apiarian products and of various uses made of honey and beeswax:
- a. One 8-frame colony of Caucasian bees, by Willie Atchley ..... 5 00
- b. Three untested queens, by Victor-Knolle Apiary Co ..... 3 00
30. Best and largest display of bee-keepers' supplies:
- a. One Italian breeding queen, by Victor-Knolle Apiary Co ..... 5 00
- b. One Italian breeding queen, by Victor-Knolle Apiary Co ..... 3 00

LOUIS H. SCHOLL,  
Chairman Committee on Exhibits.  
New Braunfels, Texas.

and the advertiser had queens for sale at this and that price. I sent him my order, and when I received her she was almost dead, and only two of the attendants were alive. The queen died an hour after I received her, and I did not get time to introduce her. I wrote about it, also stating that it looked as if they had been on the road a very long time, and it was only about 400 or 500 miles. The queen was very dark. He wrote me if I would return to him the dead queen he would replace her. I did not think to take care of the dead queen, but threw her away. He said it looked to him as if some one must have exchanged queen on the road, as the queen he sent me was yellow. I sent him my money, but have no queen for it. Do all queen-breeders require the return of queens that happen to die? NEBRASKA.

ANSWERS.—1. The usual way is to winter them in weak colonies or nuclei in the cellar. Some have tried wintering in cages, but not generally with success.

2. Doolittle's "Scientific Queen-Rearing" is a book entirely devoted to that subject, and Alley's "New Method of Queen-Rearing" mostly so.

3. You can probably do no better than you are doing, unless it be to keep them in nuclei. You can economize in the number of bees in each nucleus by having several compartments in the same hive separated by bee-tight partitions, having a nucleus in each compartment.

4. I think it is common to ask the return of the dead queen.

Send Questions either to the office of the American Bee Journal, or to  
DR. C. C. MILLER, Marengo, Ill.  
Dr. Miller does not answer Questions by mail.

### Bees Deserting a Nucleus Hive

As I am a young bee-keeper and have run "up against it," I'll come to you for help. I have the Italians and the "blacks," as I call them. I bought an observation hive for one frame and I took out one frame of comb with brood and enough bees to cover the brood well, but the next day the bees came out of the observation hive and into the old hive, and there was not a single bee left. What was the trouble?

MINNESOTA.

ANSWER.—There is nothing unusual in the case. Take a frame of brood with plenty of bees to cover it, and without any precautions put it in a new hive, and the proper thing on the part of the bees is to go back to their old home. If you had fastened the bees in for about three days they would have staid. If you had taken bees that had been queenless for three days or more, you would have had less trouble. If you had taken the queen with them, returning her after 2 or 3 days, more of the bees would have staid. But you probably took them from a hive with a good queen, and they very properly resented such treatment. Please read "How to Start a Nucleus," page 409.

### Do Bees Carry Eggs or Larvæ?

Two partly-filled queen-cells were found on combs (that had neither eggs nor larvæ) placed above a queen-ex-

cluder, on a strong colony of Italian bees, which had also a dozen or more queen-cells below the excluder.

OHIO.

ANSWER.—Cases have been reported in which such carrying has occurred, although many are skeptical. Lately a case was reported in a foreign bee-paper by one of the prominent bee-keepers in which it seemed hardly possible that there could be any mistake. To a colony that had been queenless for more than a week, larvæ were given in Doolittle cell-cups. These cups were emptied out and 2 cells on the edge of the comb had larvæ in them.

### Keeping Queens Over Winter—Replacing Queens that Die in the Mails

1. How can I winter queens reared this summer?

2. What is the most complete book on queen-rearing? Is the "A B C of Bee Culture" a complete book on rearing? I have read it, but I think it does not give me the information I want.

3. I have a number of queens that I reared, and will have no use for all of them for some time. In what way can they be kept alive until I should want them. I keep them now in small cages in a colony of bees, but this colony has a queen, and once in a while I find dead one of these queens that are in the cages.

4. I ordered a queen some time ago,

### Rearing Queens and Superseding

I have been trying your method of rearing queens by putting a frame with small starters in my best colony. Nine days later, on taking it out, I find the bees have filled the frame with all drone-comb. I have tried this a number of times. It is always the same—drone-comb full of honey.

Seeing so much about letting bees do their own superseding, I will tell you my experience of last fall. Fifteen colonies out of 75 had queens in their third year. I knew they ought to be replaced, but on looking them over in August I found the hives full of brood, the queens doing good work, so I let them alone. The result was that 7 died during the winter, and 6 superseded during April. The colonies are now worthless, so far as storing honey from clover. I find this so every year. Queens die during the winter or in early spring. I keep all queens clipped, so I can tell their age. After a good flow from clover a great many colonies will supersede the queens themselves, but there are too many that do not. It pays to look after the queens.

This has been the worst spring on bees ever known. The blacks are all starved out. The weather the past ten days has been fine and the bees are rolling in honey (June 24) where strong enough. The Italians are in good condition. NEW JERSEY.

ANSWER.—When bees are "rolling in honey," as you say yours have been, especially if they have little or no drone-

comb in the brood-chamber, a strong colony will often fill with honey empty combs put in the center of the brood-chamber, and fill with drone-comb an empty frame given them. If you will take from the hive 2 or 3 frames of brood with queen and adhering bees, and put the same in a hive on a new stand as a nucleus, and then give the empty frame next to the brood-nest, you will probably not have a cell of drone-comb built.

Under your conditions it would seem a good thing for you to take a hand in the superseding. I'd give something to know why your bees act differently from mine.

### Wash-Boardy Honey—Shipping-Crates

1. Does wash-boardy honey cut down the grade any, or, in other words, would honey that would otherwise grade fancy, grade any lower on account of being wash-boardy?

2. What material or size of lumber does it take to make the shipping-crate shown in the enclosed cut?

3. Does there want to be any end play around cases?

4. If this is not the best crate, give size of material of the one you use.

MISSOURI.

ANSWERS.—1. I'm not sure that a wash-boardy appearance, unless very pronounced, would throw honey into a lower grade, but it would have some tendency in that direction.

2. A shipping-crate in which a number of cases are packed for shipment is generally made of rather tough material, which is only about  $\frac{1}{2}$  inch or so thick.

3. There should be no play in the crate whatever. Any vacancy must be filled with some packing material.

4. A good size for a crate is one that will hold 6 or 8 24-pound cases, or twice as many 12-pound cases.

### Splints in Foundation—Bad Weather Conditions

1. How shall I use splints in foundation? I believe I have read your description, but forget. Wiring frames is slow.

2. I had bad luck the past winter. I lost nearly half of my bees, and with weather conditions as they are, the outlook is not very encouraging. Water froze here last night (June 8). There used to be some good crops of honey gathered in this region, but not so good of late years. The basswood is nearly gone.

WISCONSIN.

ANSWERS.—1. In the book "Forty Years Among the Bees," page 88, you will find the following:

"Little sticks or splints about 1-16 of an inch square, and about  $\frac{1}{4}$  inch shorter than the inside depth of the frame, are thrown into a square, shallow tin pan that contains hot beeswax. They will froth up because of the moisture frying out of them. When the frothing ceases, and the splints are saturated with wax, then they are ready for use. The frame of foundation is laid on the

board as before; with a pair of plyers a splint is lifted out of the wax (kept just hot enough over a gasoline stove), and placed upon the foundation so that the splint shall be perpendicular when the frame is hung in the hive. As fast as a splint is laid in place, an assistant immediately presses it down into the foundation with the wetted edge of a small board. About  $1\frac{1}{2}$  inches from each end-bar is placed a splint, and between these two splints three others at equal distances. \* \* \* A little experience will enable one to judge, when putting in the splints, how hot to keep the wax. If too hot there will be too light a coating of wax. \* \* \* If a frame be given at a time when little storing is going on, the bees will deliberately dig away the foundation at the bottom; and even if it has been built down but the cells not very fully drawn out, they will do more or less at gnawing a passage. To make a success, the frames should be given at a time when work shall go on uninterruptedly until full-depth cells reach the bottom-bar."

2. Don't be in too much of a hurry about deciding that the year will be poor. Of course I don't know what the season will be; but I have known bees to be starving in June, followed by a good crop. Then again I've known a number of years in succession with poor crops or none, and it looked as if the days of good crops were over, and then came better crops than ever. Of course, the basswoods that have been felled are probably gone forever, but other pasturage may improve.

### Brushing Bees at Night

Can bees be brushed successfully from one hive to another in the night?

CONNECTICUT.

ANSWER.—Yes, only it's likely to be unpleasant, because at night bees do more crawling than flying, and in crawling over one's person they are likely to do some stinging.

### Three Swarms in Two Weeks

Will bees swarm 3 times in 2 weeks? First swarm came out May 25; 9 days later the second; the third 4 days later.

ILLINOIS.

ANSWER.—Yes, they may swarm more than 3 times in 2 weeks. The case you mention is rather slower than the average, which is about 8 days after the prime swarm for the first afterswarm, and 3 days later for the next.

### Bee-Keeping—Average Yield Per Colony—Stingless Bees

1. Having just read an article on getting away from the strenuous life, in the Saturday Evening Post, in which some of your experience is given, I take liberty to ask: Is the article reliable, not overdrawn?

2. Is 100 pounds per colony an average or toward the maximum yearly yield?

3. Is it reasonable to suppose that a capable man can make a living of say \$1,200 per year at bee-culture?

4. What of the newly-written-of stingless bees?

MICHIGAN.

ANSWERS.—1. It is a temporarily written article.

2. Hardly one or the other. One-third of that amount is nearer the average yield of comb honey, and half of it for extracted, while a maximum annual average might go to 150 or more. It must not be forgotten that the yield sometimes is less than nothing; that is, no surplus is taken and the bees have to be fed to keep them alive.

3. Not many make so much. Some make more. The way to find out what you can do is to feel your way, beginning with from 2 to 6 colonies. It would be folly to enter bee-keeping on a large scale without first finding out what you can do on a small scale.

4. They are valuable as a curiosity. I don't believe any stingless bees will be found of any practical value as honey-gatherers.

### Black Bees from an "Italian" Queen

1. We purchased an Italian queen from a breeder in Pennsylvania, and she was a fine, large queen, yellow almost from tip to tip. She was introduced to a black colony, and when her brood appeared it was as black as "coly." I have been in the bee-business for almost 25 years, and never witnessed this before. Have you a ghost of an idea as to the cause?

2. Give me your best idea on blacks rearing Italian queens.

3. I have "A B C of Bee-Culture," "How to Keep Bees," "Langstroth," and "Forty Years Among the Bees," and I thought that my 25 years' experience was something, but I am attending some black bees that are queenless. They will "feed" black eggs, but will not "feed" Italian eggs. You see I have just wakened up.

ANSWERS.—1. If there is no mistake about pure black bees being the progeny of a very yellow queen, then I give it up; never heard of such a thing before.

2. It is generally considered that the kind of nurse-bees has no bearing on the purity of the queen. I don't know enough to know whether that's entirely reliable or not.

3. Hard to believe that bees will discriminate against any egg on account of race, color, or previous condition of servitude. If you can get them to accept eggs or young larvae of any kind, you ought to be able to fool them by throwing a young larva out of a queen-cell and transplanting in its place a young larva of the desired kind.

### What Ails the Bees?

1. I don't know what to do with my bees, or whether to do anything with them. There is something the matter with them. The brood either chills, starves, or else there is some brood-disease among them. I can't tell which. Last summer there was a great deal of

# American Bee Journal

brood died. The larvæ when about large enough to seal over would die and settle down in the cells in a white, watery mass. Later on they would turn to a dark-brown color and dry in a scale over the lower sides of the cells. There is a slight odor of decayed matter, but the dead larvæ do not rope when you stick a toothpick into it. This spring, about the last of April, I examined my bees and found them in bad shape, they having the same trouble they had last summer, only a great deal worse. So in fruit-bloom I transferred them into clean new hives on starters, melted down the combs and put the hives where the bees could not get into them. Then I commenced to feed the bees. They built up slowly, but seemed to be healthy. As soon as blackberries and raspberries were in bloom I thought the bees would take care of themselves, and took away the feed. To-day, when I examined them, I was surprised to find them destitute of honey, and the brood dying as of old, so now I don't know what to do. All I did was to put back the feed. I have sent two samples to Mr. France and he does not call it foul brood, although he said it resembled European foul brood, but did not think it was. He advised me to feed and keep the bees warm. I have only three colonies left. What would you advise me to do? As all three of them are affected alike, every brood-frame is alike, or nearly so.

2. Would not bees in cool weather protect some of their brood so that one or two frames would hatch all right, or would they try to protect it all and make it scattered; that is, the bees that hatch, the rest dying?

3. What would be the express on a 2-frame nuclei shipped a distance of about 150 miles over two railroads?

ILLINOIS.

ANSWERS.—1. I am not an expert in bee-diseases, and Mr. France knows ever so much more about such things than I. You were very wise to apply to him. It is just possible that things would have been different if you had kept on feeding. It may be that when berries came in bloom the bees did not get enough, especially as the weather was unfavorable. You can do no better than to follow the advice of Mr. France.

2. When bees in a healthy condition are hard pinched with the cold, only the outer part of the brood-nest is likely to suffer; but in a diseased condition the cold may so devitalize them the effect may be seen through the entire brood-nest.

3. I don't think there is a uniform rate. Your station or express agent can tell you what it is on your line.

## Bees' Use of Water—Swarming

This has been a pretty hard spring on the bees, and also on the beginner, as about 99 percent of the fruit has been killed, with the exception of some small fruit.

1. What do the bees do with the water they get in mud-holes?

2. Can you tell 2 or 3 days before a colony will swarm? If so, how?

3. What is the best way to get a swarm into a hive?

4. How far would a swarm go from the hive where there are plenty of trees and bushes around the hive?

KANSAS.

ANSWERS.—1. The same as they do with water from any other source; they use it for drink and to thin their honey.

2. If a colony has been working all right and then seems to stop work suddenly and hang out idly, while other colonies are busy, you may make a pretty good guess that it will swarm within a day or so. If you find queen-cells in the hive, some of them built out nearly full length, you may expect a swarm within 2 or 3 days. After a prime or first swarm has issued, you may expect a second swarm in something like 8 days, provided a second swarm issues at all.

3. That depends upon where the swarm is. If it's on a small limb of a tree, a very nice way is to cut off the limb, carry it quietly to the hive, and lay it at the entrance of the hive, allowing the bees to crawl in. Often it will be more convenient to set the hive on the ground, where the bees will fall at the entrance when shaken off the tree.

4. It may settle directly over the hive from which it issued, or on a tree close by, but sometimes on a tree or bush 10 rods away.

## No Quilt Over Bees

If you don't use a quilt won't the bees go up and build comb against the roof of the hive?

WEST VIRGINIA.

ANSWER.—Yes, if there were room enough, but when neither enameled cloth nor quilt is used over the frames or sections—just a flat cover—there is only  $\frac{1}{4}$  inch of space between the frames or sections and the hive-cover, and bees are not likely to build in so small a space.

## Settling Swarms—Cow-Peas—Difference in Bee Eggs

1. When bees swarm, is it necessary, or does it do any good, to rattle bells, pans, or the like, to get them to settle? And when settled, about how long will they stay there when not hived? Do bee-men use the above method to settle bees?

2. Do bees gather honey from cow-peas? We had about 3 acres of cow-peas here last year, and it appeared that all our bees worked on them for 3 or 4 weeks, as it seemed that there were thousands and thousands, and the queer thing to me was that they did not work on the bloom, but on the joint just below the bloom or young pea. Was it wax or honey?

3. In regard to bee-eggs, is there any difference or distinction between the eggs from which a queen and worker are hatched or reared? If I am correct, bee-men use any egg they may come to when transferring eggs to queen-cells, and the difference results from the size of cell and the material on which the young bees are fed.

ANSWERS.—1. It would be hard to find any bee-keeper nowadays who believes it does any good to make any kind of noise with the view of getting a swarm to settle. Part of the performance is to settle anyhow, noise or no noise. The length of time bees hang after clustering before going off varies greatly. It may be more than a day, and it may be less than an hour. The best thing is to get them into a hive as soon as possible.

2. Cow-peas are counted honey-plants. There are different plants which, at least at times, secrete nectar elsewhere than in the blossoms. When you see bees working as busily as you say they were on your cow-peas, you may be sure they are getting either nectar or pollen. If you see no pollen on their legs you may be sure they are getting nectar. They don't gather wax, they secrete it; but they gather bee-glue.

3. An egg laid by a good queen in a queen-cell is precisely the same as one she lays in a worker-cell. A drone-egg is a different thing. A drone-egg is unfertilized and can produce nothing but a drone, even if fed in a queen-cell; other eggs are fertilized.

## Nearness of Apiary to Highway—Bee-Houses or Hive-Covers

1. How close does the law allow an apiary to stand to the public highway? Mine are (the front row) 50 feet from the road, and a man having a horse stung says it will cost me something if I don't move them.

2. Can he make me move them? I can find no article concerning it in Cook's "Manual."

3. Which is the cheaper, to build bee-houses or hive-covers? NEW YORK.

ANSWERS.—1. I doubt there being any law on the subject in your State. If they sting people going along the road, you will do well either to move them farther away or to have a fence high enough so the bees will fly over the heads of passers-by.

2. There is probably no law by which he can compel you to move them, but you might be obliged to pay for any damage resulting from their stinging.

3. That depends upon the kind of houses and of covers. In general it will probably cost less for covers. Even if the covers cost more, probably most bee-keepers in this country would prefer them.

## Observation Hives—Size of Cells

1. I am thinking of making an observation hive. Will the bees cover the inside of the glass with propolis so that I can't see through?

2. When kept in the house do they have wood casing over them?

3. How about that statement on page 449, of bees drawing out cells as the bottoms are filled with cocoons? It looks as if they would have to be spaced farther apart. Of course, you didn't make the statement yourself. TEXAS.

ANSWERS.—1. Not to a very great extent.

2. They might be kept with nothing

# American Bee Journal

over the glass, so as to be exposed to the light at all times, but generally they are kept covered except when actually under observation. They are not so contented under full light, and much more likely to cover propolis on the glass.

3. I heartily endorse every word that is said in the paragraph to which you refer. I have plenty of combs so old that the septum has been gradually increased in thickness until the septum in some cases is  $\frac{1}{8}$  thick. Of course you know that new worker-comb is  $\frac{7}{8}$ -inch thick, and when you find a septum  $\frac{1}{8}$ -inch thick you will find the comb  $\frac{1}{8}$ -inch thick. That makes the cells exactly the same depth in the old as in the new, doesn't it? You are quite right that there is a practical difference in the spacing. When new combs are spaced  $1\frac{3}{8}$  from center to center, the alley-way between 2 combs is  $\frac{1}{2}$ -inch. When the septum increases so the comb is 1 inch thick, that leaves the alley-way only  $\frac{3}{8}$ . Whether it would not be better to increase the spacing when the combs become so increased in thickness is a pertinent question.

## Straight Wired Combs from Starters—Queen Questions

1. Will bees build straight combs in wired frames with starters only on top-bars and end-bars?

2. Does the young queen destroy the surplus queen-cells, or do the bees do it?

3. I found a queen too feeble to crawl out after the cap of the cell was off. I split the side of the cell, lifted her out, and placed her on a comb. A week later she was missing. What caused her weakness? TEXAS.

ANSWERS.—1. Not as straight as when full sheets of foundation are used. Left to their own devices bees in a state of nature generally build their combs somewhat corrugated. This for greater strength. With only starters and wiring they will, of course, start straight, but as they proceed downward the corrugations will appear. If the hive is plumb to follow the wire, but if the wire is not just where the bees want the septum and the wires straight, the comb is likely to follow the wire, but if the wire can go its own way for all they care, and they'll put the septum where they want it. The greatest objection, however, to using only starters is the amount of drone-comb that will be built.

2. If the young queens in the cells are well advanced, the young queen begins the work and the workers finish it. If the cells are not much advanced, the workers attend to them.

3. I don't know. Perhaps some constitutional weakness.

## Shiny Bees—Clipping Queens, Etc.

1. Why are there bees among the Italians that are very dark, almost glossy black sometimes, with no yellow bands and seemingly small, but smart and active at the same time? They are hunted up and driven out by the regular workers. Is it a disease or only a freak of nature?

2. Why do the bees of a nucleus, when first started by themselves, take spells of running on the outside of the hive and fussing at the cracks at the top of the hive, trying to get in, piling up in bunches and acting like crazy?

3. Is a queen reared from worker-brood in the comb by the workers that are queenless, as good and fertile as a queen reared in the regular way?

4. Can a queen-cell by careful handling, be cut from a comb and put into another comb for a colony, to any certainty, without injuring it in any way by pressure or exposure, or should it always be introduced on the comb on which it is built?

5. In addition to the foregoing questions, I would like to express myself as to the clipping of queens' wings, which in my estimation is one of the most foolish and most uncalled-for things that a bee-keeper can do. I received 2 queens last season which were clipped. The one came off with a swarm May 29, last, and fell some 10 feet from the hive, and I had quite a hunt to find her. She was put into a hive with the new swarm. The swarm came out the next day, and she was lost. They returned to the old hive and came out again on the 4th day, and went back, coming out again on the 9th day. If the queen had not been clipped, the first swarm would have been all right, as well as a second one. I can't see the advantage of having to look after the queen every time she comes off with a swarm. It is certainly a trouble and inconvenience, as well as inhuman and unnatural. PENNSYLVANIA.

ANSWERS.—1. They look black and shining because they have lost their plumage, and are probably worried by the other bees because diseased. A few such bees in a colony need cause no alarm; when there are many of them it may be a case of paralysis.

2. When bees are queenless it is a common thing for them to run about over the hive as if looking for their queen. I never saw bees of a nucleus fussing at the top of the hive trying to get in cracks, piling in bunches and acting like crazy, but I have seen robber-bees acting exactly that way. The likelihood is that the bees you saw did not belong to the nucleus but were robbers.

3. Not always; depends upon circumstances. If at a time when honey is yielding well, the colony strong, and the bees have their choice of eggs and very young brood, you can get as good queens as any. If the queen is reared when honey is not yielding, when no very young brood is present, or in a weak colony, you may count her of little value.

4. Thousands of queen-cells have been cut from the comb and fastened in or on another comb with just as good results as if left on their own comb. Indeed, in many cases, even when the cell is taken on its own comb, it is better to cut the cell and fasten it on the comb, for a large portion of cells are on the edges of combs where there is danger of their being chilled, and they should be centrally located where sure to keep warm.

5. A very large number of our most

experienced bee-keepers prefer to have queens clipped. If a queen is clipped, there is some danger she may be lost when issuing with a swarm, but that is better than to lose both queens and swarm.

## Wintering in Danzenbaker Hives—Bees Superior to Blacks

1. How do Grant Stanley and Vernon Burt winter bees in Danzenbaker hives? Do they double up, or winter in single brood-bodies?

2. Can I get a strain of golden or 5-banded Italians that will be superior to the blacks for honey-gathering? Also gentler?

I am a beginner and have 8 colonies in Danzenbaker hives. IOWA.

ANSWERS.—1. I don't know. Like enough in 2 bodies when a colony is strong enough.

2. The best of the goldens are better and gentler than the average blacks, for this country.

## Transferred Bees—Ripening Honey—Plan of Wintering Bees

1. The past spring I transferred 2 colonies of bees. After the 21 days were up I united the young bees in the old hives, putting them on full sheets of foundation. I put in a frame of brood. I did not know whether there was a queen or not. In 2 or 3 days I looked into the hive and they had started 2 queen-cells on the sheet of foundation. In a couple of weeks I looked through the colony and found a queen. The 2 queen-cells were the same, just started. What is the meaning of that?

2. One person advises ripening honey artificially; another says, let the bees ripen it, for if you do the latter it will be travel-stained. After the cells are all filled with honey and capped, why not put the super on top of the others with a wire-screen between it and the other super and the hive? The bees can not then get on the honey, and the heat will be there just the same.

3. I am planning on wintering my bees outdoors. My stands are like that picture in the "A B C of Bee-Culture," on page 26, with 2 hives on a stand. I shall move both hives together, then I will make a box some 5 or 6 inches larger on all sides than the hive. This space will be for the chaff. The box will have a movable bottom and top. I will have a hole at the bottom so that the bees will fly out of the hive. I shall put on a honey-board for a cover to the hive, then put on an empty super, filling this with straw, then put on the outer case, filling the space with straw and then putting the cover on. Do you know of any better way, or improvement on this way? The reason I will use the honey-board is because I can feed the bees in the spring without opening the hive. I will use the pepper-box feeder. I use the Danzenbaker hive. IOWA.

ANSWER.—1. If I understand correctly, there were only cups started, no eggs nor larvae in them. I don't know what

that means, but it is the common thing to find in colonies such beginnings of cells, and so long as they remain empty no significance is attached to them.

2. You do not say whether you refer to comb or extracted honey. When there is any discussion about having ripened in or out of the hive, extracted honey is the kind that is meant, and there is no harm in having extracting-combs darkened by the bees. As to comb honey, it is not desirable to remove it from the hive until it is sealed, and when it is sealed it is counted ripe. Yet there are cases in which it might be better to leave sections on the hive at least a while after they are sealed. I never tried ripening honey over a wire-screen, but I should not expect it to work the same as having it in the direct charge of the bees. To be sure, the heat would go up, and so would the moisture, and the bees would have no chance to ventilate to drive out the moisture. Besides, you would be likely to find such honey troubled with wax-worms. Very likely you will want to know how the moth's eggs can get there if all is so close that no moth can get in from the outside. I don't know how they do it, but I know they get there.

3. Your plan ought to work all right.

### The Armstrong T-Super

DR. MILLER.—I express you today one of Elvin Armstrong's improved T-supers. He sent me 2 with a request that I send you one of them. He claims it is a great improvement over his original one. You know I liked that, and I hardly know whether the improvement is very great or not. All the difference is in the side-tins and the springs in one end. In the original the side-pieces furnished the supports for the tins. In place of the springs a board was permanent like the other end. In the original there was half a bee-space above and below, making a whole bee-space when tiered. Then, he has a machine to cut out tin the size of the section to put on each one. I hardly know whether I would care to bother with them or not. You see there is no chance for their tumbling to pieces as is claimed of yours. I think either kind is away ahead of the section-holders. I should like your opinion of them.

J. C. ARMSTRONG.

Marshall Co., Iowa.

Dr. Miller.—I send by express today to J. C. Armstrong two of my late improved T-supers, and I told him when they arrived to express one of them to you for your inspection. I want you to tell me just what you think of it, through the columns of the American Bee Journal. I believe I have something that can not be beat by any one. I think that man from Indiana who found so much fault with the T-super's allowing the sections to drop out so easily, if he could see one of these would change his tune, for you can just throw my super any old way, or even jump on it with your feet, and it is still there just the same. You will find 2 super-springs on the inside at one end. I think 2 or 3 pieces of section, or a

piece of wood, will answer just as well to keep the sections up square and in place, and will be easier removed, and answer just as well. In my super you can remove any section, one at a time, or you can remove the whole 28 at once, and that with ease.

You will find a metal cap on one of the sections to keep the tops clean. I am getting a machine made to cut out the bee-ways to match the sections. I expect to use caps on all my sections. I believe they will pay for themselves in one year in keeping the tops of the sections white and clean, and then they will last a lifetime. Let me know what you think of the project.

We have had a very backward and cold spring. Bees did not get any good out of the fruit-bloom as it froze every night while in bloom. I have been feeding for some time, and will have to about 2 week longer, until the alfalfa gets in bloom. I have had 8 swarms. I put them in hives with full empty combs and am feeding them every day. Feeding my bees makes them strong and active in spite of the cold weather.

E. S. ARMSTRONG.

Colorado, May 30.

An objection to the T-super is that care must be taken in handling, so that

the super be kept right side up, for if it be turned upside down, or if placed on an uneven surface so that some object may push up against the sections, they may be displaced. To be sure, there is no necessity for such wrong handling, but accidents may occur. Mr. Armstrong has gotten up a T-super in which the sections are securely fastened, so that they can not fall out when the super is upside down any more than they can when it is right side up. Of course, it is more complicated than the regular T-super. Instead of 3 T-tins it has 10—5 above and 5 below; and instead of the single follower on one side there are 4, one on each side and one on each end, although on one of the sides it can hardly be called a follower, as it is nailed on. To allow the upper T-tins to be fastened in place, one of the sides of the super is in 2 parts, the upper part being removable. Besides the usual wedges or springs crowding up the follower at the side, one of the end followers is crowded up in like manner.

While some may not think it worth while to be at the extra time and expense for so slight an advantage, others may think differently. C. C. MILLER.

[We would suggest to Mr. Armstrong that he advertise his T-super.—EDITOR.]

By W. A. PRYAL, Aiden Station, Oakland, Calif.

### Painting Hives

Some bee-keepers, I find, claim that it does not pay to paint a bee-hive. Paint is cheap, and it does not cost anything to put it on, as one can do it when he has nothing else to claim his attention. For this climate, I find lead and ochre, and lead and any of the metallic paints, the most durable. Two coats applied when the hive is new will easily last 15 years, but it is well to repaint them in 5 or 8 years. Where an apiary is near the ocean so that it receives the sea-breezes, the paint will be destroyed sooner than if it were inland. This is said to be due to the air being charged with salt.

### Late Rains

After two months of the dryest kind of weather, we are having a spell of wet weather—a weather in which the rain falls in the night or in the early forenoon. The showers for the past 3 days—they began June 11th—have been sufficient to wet the earth down as far as where the moisture still remained. This will be a great blessing to truck-growers and those having small fruits, and all plants and fruits whose

roots are near the surface. Honey-secreting plants will be benefited.

Then, it is pretty sure that the weather will not be so cool in the nights and mornings after these rains have cleared the atmosphere of the rain-making moisture. This will be of untold benefit. While the apiarist will be benefited, the farmer who has his hay cut, and, perhaps, his grain in the shock or stack, will have much of it ruined. Then, the cherry crop on the trees will be badly damaged. At our place the last load of cherries were sent to the cannery a couple of days before the down-pour came. (You see we had a message from the clerk of the weather that rain might be expected within a few days!)

### The Weather in California

Owing to the bigness of California, the State has a variety of climates. Seven hundred miles and more of coastline, with a reach inland of 200 miles, which cuts through snow-capped mountains in places and deserts in others, can not help but be responsible for varying climatic conditions. No matter how bad a drouth may be in a large portion of the State, there will be sec-
