[1123.] On the afternoon of Wednesday I set off for Ecklington, being due to lecture at Felton, two and a half miles from Ecklington station. I was met here and hospitably entertained by a number of the bee-keepers in the neighbourhood. Felton is par excellence the beekeeping district here. Thousands of sycamores, or, as they call them here, plane-trees, grow in and around the village. At this time the bees were 'roaring' on them. I here met the breeder of a celebrated queen that produced a colony which stored 200 pounds of surplus honey in one season in two crops, clover and heather. The bees were in fine condition; in fact, I did not see a weak stock among the large number of bar-frame hives that I examined.

Thursday I ran over to Warkworth in company with Mr. Greenwall, who lives here; had a look round its ancient eastle, and then on to Alnwick, where I lectured during the evening. Both the bees and beekeepers here were conspicuous by their absence.

The next day, Friday. I was due at Belford, where the energetic (?) organiser of this lecture was—after some trouble ou my part—discovered, but he knew, or did not want to know, much about the lecture, so that I had to set to work, and with the assistance of Mr. Colville of Chatton Heath, managed to get a few of the hee-keepers together and held our meeting.

Paxton in Berwickshire on Saturday completed the week. Here I found a gentleman greatly interested in the industry, and endeavouring to spread it abroad as much as possible. What a charming change after my my experiences at Alnwick and Belford!

After spending a rather louely Sunday at Berwick-on-Tweed—I had to wait eight and a half hours for a train -I arrived back at Morpeth at 7 p.m. I had promised Mr. Schofield to dine with him, but, alas! man proposes, but trains dispose.

On Monday I had a regular day among the bees, it

being just the right sort of weather. I was driven from Meldon station by Mr. Britain, first to his apiary, where I was most hospitably welcomed, and then on to the largest bee-keeper's apiary in the county, Mr. Codling's. I found all the bees here in grand order. In the afternoon, after another pleasant drive to Middleton station, I took train to Rothbury, where I had a most numerous and intelligent audience.

Hexham on Tuesday. Here I was nearly 'mobbed' as to who should dispose of my person while I stayed there, it falling to the lot of Mr. Bell to entertain me. A well-attended meeting in the evening, which, as we commenced and finished early, was 'wound up' by a quiet little conversazione, strictly confined to bee matters.

I had a good look round the next morning at the apiaries of most of the bee-keepers in the neighbourhood, and whilst walking to Corbridge, in company with Mr. Bell, he accosted a straw skeppist with the question, 'How is it you were not at the lecture last evening?' the said skeppist, with unblushing effrontery, answering, 'What for, mon? I ken mair aboot bees than onybody.' I did not try to make any impression here, especially as he was well aware that I was the lecturer.

Haltwhistle was my next stop. Here we had a well-organised and well-attended lecture, thanks to the energy of Mr. Maeadam. I here made the acquaintance of a blind bee-keeper, owner of three stocks. I ran over to his house the next morning and had a pleasant half-

hour's chat on bee-matters.

My last lecture was at Bellingham. Here one of the most pleasant days was spent in the company of the Rev. J. G. Flint, who piloted me about among the beekeepers of the district. All seemed pleased to get any little bit of advice or commendation. I found very little of the 'I-ken-mair-aboot-bees-than-onybody' style of bee-keeper in this neighbourhood. Indeed this was a finale that made me almost wish that I had not finished my course. But back to friend Bell's to spend the last evening in Northumberland, and then, after a long journey of considerably over 300 miles, found me safely ensooneed in my own armehair on Sunday morning. I had what is called a good forty winks that afternoon.

Unfortunately I found two districts affected with foul brood.' In one it was almost the exception to find a healthy colony. I took a gentleman round with me, and instructed him in every particular as to its detection, and also how to deal with it afterwards. He made a very apt scholar, and I trust will be of service in

eradicating the disease from the district.

I think that after this, with the assistance of such an energetic secretary as Mr. Schofield, that the North-umberland Bee-keepers' Association will be started on a good sound basis, with a local secretary to each of the districts I visited. Such were the plans I advocated, and saw well started.

Number of bar-frame hives examined, 379. Next week I will give a description of the Lancashire bee-

cellar.

IN THE HUT.

'Where golden bees by alchemical prank Make gold instead of honey.'

[1124.] I never so clearly realised the existence of 'golden bees' as I did the other day whilst watching the labours of an artificial swarm now they have fairly got to business. Bees were crowding in with their loads of nectar and pollen—the odour of the former being distinctly perceptible—

'The weary porters bearing in Their heavy burden at the narrow gate.'

About every tenth bee appeared like a yellow spectre amongst the crowd, covered as it was with glistening chrome-hued dust—head, thorax, legs, and abdomen. I can only compare the tint to that of newly electro-

deposited gold: furnace-refined gold doesn't seem to be sufficiently lit up.

The following may be new to some readers, as it was to me, copied from a friend's MS.:—

'A Yankee out a walking in Virginia (in Teeling),
While to himself a talking, experiences a feeling,
Strange, fearful, and alarming.
From his caput to his knees
(As he suddenly discovered)

He was covered o'er with bees.

They lit upon his eyelids and perched upon his nose;
They colonised his puzzled face and swarmed upon
his clothes;

Explored his swelling nostrils, dug deep into his ears; They erawled up his trowsers, and filled his eyes with tears.

Did he holler like a loon?
Or, was he sear't?
Did the crittur cut and run?
Ne'er a one.
Wasn't scar't a mite;
Never cuts nor hollers;
But hived 'em in a nail-keg tight,
And sold 'em for two dollars.'

I rejoice to see 'Amateur Expert' again amongst us. We can ill afford to do without 'Jottings.' Goodness knows, the necessary reports of Association meetings, &c., are dry enough reading at best. I know a youth who makes it a matter of almost religious duty to pore through the Journal word by word, week by week, and on winter evenings before a roaring fire it proves to him—well, an effective cure for insomnia. Therefore the columns of the B. B. J. are much more palatable when they have the peculiar twang a dose of 'Jottings Zest' gives. My poor attempts at compounding 'Yorkshire Relish' make me appreciate the light appetising sauce of 'A. E.'

How refreshing it is to stumble on something about bees in church!—I mean something in church about bees. I was caught in flagrante on the 24th morning, turning down the page whereon it says 'They came about me like bees.' I should dearly like to drop into some church and find one of our grave and reverend seigneurs preaching about bees after the manner of Canon Hole, and roses. Surely if there are 'sermous in stones,' there are 'discourses on drones;' 'words of wisdom for workers;' 'The Biblical biology of bees;' 'The quest of the queen,' &c.

If the huttites had known of the passage of Ambassador Webster through Horsforth the other day they would have tried to 'hive' him for a bit, and he might have assisted them in the fumigation of our huts 'par le fumigateur Webster,' which being translated may read 'Webster the Smoker.' By the way, the fumigator is favourably mentioned in this month's Revue Internationale.

-X-Tractor, Horsforth, near Leeds.

USE OF APIFUGE.

[1125.] In justice to your correspondents, if not to Apifuge, I should not be silent respecting the complaints of E. Musgrove in last week's issue, and confirmed in this week's, to the effect that my substance causes lumps or blotches on the hands. Such adverse comments are not in the ratio of one per thousand of the instances where the stuff is used with success, and this percentage about tallies with those idiosyncrasies of constitution which will be found occurring when any powerful drug or perfume is used—they are the exceptions which go to prove every rule. The smell and taste of honey itself—our great desideratum—produces precisely similar symtoms on certain constitutions to Apifuge (Père Langstroth and many others to wit). The seent of roses, musk, heliotrope, violets, and many flowers, the smell and taste of parsley, celery, garlic, and many culinary

herbs, are distinctly objectionable to some (pepper and other condiments as food may be also included in the list). When the use of these is persisted in we find symptoms appear such as are complained of. It will perhaps be so with Apifuge, but the instances will be so very rare and exceptional that they will be of little account, especially when I assure the subjects that the ultimate result on their skin will be beneticial, not deleterious. I did not, nor do I, desire this substance to be used as a medicine for outward application, or I might at the outset have told the public that on myself it instantly stopped the pain of stings, that it accelerated the healing of slight wounds and abrasions, that its effect in cutaneous affections is decidedly beneficial, and that, especially where there is a tendency to scrofula, it improves the skin.

In speaking of constitutional susceptibilities, the Rev. J. Lawson-Sisson (1113), to use his own witty expression about myself, has 'hit the right nail on the head' when he says 'it runs in families,' and his instance of Arnica montana is much to the point. I may, however, whilst thanking him, give him the assurance that the presence of A. montana would effectually condemn Apifuge as a bee-sting-preventer if it were used in its

composition, which it is not.

Mr. Lawson-Sisson again was right in instancing Apifuge as a pain-killer of bee-stings. He asks, 'Was it fancy?' If he will kindly try again he will find it was not.

Some people seem to think that if a little be rubbed on the hands the bees will not sting the face or neck, and that they can immediately dispense with the smoker along with the veil and gloves. This is incorrect to this extent: Apifuge certainly charms (puzzles rather) the bees, but is only a direct protective for the surface on which it is rubbed; and the smoker should only be discarded after experience. Again, it is only fair to ask people to use the same care in manipulating with, as they do without it. The application, too, of a few drops should be repeated when the odour ceases to be perceptible on smelling at the hands.

I did not say as much as I might justly have done in favour of this stuff when I first brought it out; I was afraid of the accusation of being perhaps too sanguine as to its various merits. I knew I had found a sting-preventer, and as such only I laid it before your readers.

preventer, and as such only I laid it before your readers. I need not worry you by saying anything further beside remarking that I have experimented in very many ways with Apifuge, even to the taking of it inwardly, but never with any disagreeable or painful effects.—R. A. II. GRIMSHAW, Horsforth, near Leeds.

APIFUGE.

[1126.] I have tried this soother in examining my hives at three separate times since spring. In lifting a few days since frames of a hive to one consisting of four boxes holding thirty-eight frames, every frame examined carefully on an extremely hot day, I can both testify to its great assistance and less worry and cause of gorging to the poor bees, and am thoroughly satisfied with its nse. (Page 256, Nos. III and II2.) As to the red and white eruptions, I for one have not experienced this trouble. I usually rub a few drops of glycerine on my hands and wrists first, but merely for the object of preventing the too rapid evaporation owing to the great heat of my hands, and also I find the apifuge is more easily applied to the surface and more evenly. I trust Mr. G. will be able to suggest some relief to those who suffer from the use of it from tender skins.—W. Goodall, The Knowle, Rastrick, June 18th.

STING PREVENTERS.—NEPETOS PURPUREA.

[1127.] I have tried methyl salicylate many times this year, and I have observed that it answers very well

until my hands began to get hot, and then the bees began to sting. I have only once used Grimshaw's Apifuge, but the effect of it seems to be the same, and as soon as my hands got hot, I received several stings. They both have one great advantage, namely, that they give confidence, but I am not perfectly sure that they afford any extra protection to cool hands wet with water. When the hands get warm, I have tried dipping them in water, and putting on more of the salicylate, but it was of little if any use. I think the way in which the sting-preventer operates is to prevent the bees from noticing the animal smell of the hands. On former occasions I have tried vinegar, and it had some effect. I have also used it frequently for putting on gloves after the bees have stung them, and for this last purpose it seems to me to answer admirably. When the hand is stung, a drop of honey prevents other bees following suit.

A recent correspondent speaks of the Nepeta Mussini (982). Is it the same plant as the Nepetos purpurea mentioned in Miss Cooper's letter in the Journal of the 15th April, 1885? I bought some cuttings from that lady for 1s. 6d., and I consider it was a very good investment. It is one of the few things that bees will touch in a small garden, and they are always at it—last night till about 8 p.m.—and it flowers all the summer. Patches of it look very well, and cuttings grow most easily. I have given some to a non bee-keeping friend,

as he thought it was so pretty,--L.

[We invested Is. 6d. in Miss Cooper's Nepeta purpurea, and with our correspondent have had every reason to be satisfied with it as a bee-plant. The Nepeta Mussini is very similar to it, but rather larger-leafed.—Ed.]

CHEAP PACKING-CASES FOR TRANSMISSION OF HONEY PER RAILWAY.

[II28.] Premising that 'Cottager' glazes his sections of honey before he sends them to market, I commend to his notice grocers' empties. Wrap and tie your honey in parcels of, say, a dozen in each parcel, then procure your box, say, $\frac{1}{4}$ c. starch box, cost 2d. or 3d.; then place a little meadow hay at bottom, then your parcel of honey, pack tightly round sides and overtop, cord, and label, Honey-comb, with care, this side up, and your honey will travel from Land's End in Cornwall to John o' Groats in Scotland without the least damage. I myself have sent some to India, viâ Snez Canal, packed as above described, and it has opened as clean and nice as when first packed. Then for larger quantities, say, half gross of sections, ask your grocer for a cube sugar box, cost 6d. Tie up your sections in dozens in brown paper, put a layer of hay, then a layer of two dozen sections, then another thin layer of hay, another two dozen sections, more hay, at same time well packing round each side of the parcels with hay, then your last two dozen sections, and over all pack very tightly with more hay; cord and label as above. I forgot to mention handles of cord. Make two holes large enough for cord to go through, one a little lower than the other, so that your handle crosses the grain of the wood, and about two thirds of height of case. If no handles are provided the railway porters are apt to walk cases by the corners in a zig-zag manner, thereby shaking the contents more than the journey by rail.—W. Woodley.

BALSAMS: THEIR COMPOSITION.

[1129.] 'It is asserted by a medical writer that of four celebrated quack medicines (viz., the Balm of Gilead, the Balsam of Rakasira, the Balsam of Mecca, and the Balsam of Honey), not one contains a single particle of the article of the name the proprietors have given them, the three first being composed principally

of spirits of wine, and the latter of tincture of benzoin.'

—(Herald.)'—August 1826, Galignani's Messenger.

Fancy tincture of benzoin being used to manufacture

Balsam of Honey!—J. LAWSON SISSON.

BE READY.

[1130.] Dear me, Mr. Editor, how important it is to be always ready! so much so that one can scarcely realise the same in reality unless they get into such a mess as I am in at the present time. I thought I was safe, but this beautiful weather has come and found me hehind. Plenty of honey to be got, and plenty of bees to get it, and not half enough room to store it, although my hives hold from fourteen to twenty standard frames each, and super crates on containing twenty-one and twenty-four one-pound sections, still the bees continue to cast very large swarms, in some cases from seven to eight pounds each. On the 10th inst. very little done in supers, now, the 14th inst., supers full, and nearly all the queens are crowded completely out of laying room. I had two large swarms on the 24th ult, one the 26th, one on the 28th, one on the 30th. I cannot say how they have run since, as I have been so very busy in trying to fetch up lost time that I have not had time to hook the proceedings of the bees. They keep me so very busy every evening that I scarcely know which way to turn for the best. This must teach me a good lesson, to be ready at another time, and I hope it will have some little effect upon some more of our bee-keeping friends to be ready at all times.—C. H. W., Aylesford, Maidstone, June 14.

REMOVAL OF HIVES.—FRATERNISATION OF BEES LEFT BEHIND WITH EACH OTHER AND A STOCK THAT REMAINED.

[1131.] Lately I removed seven or eight stocks in bar-frame hives, and one similarly hived stock that was in an old granary, within a hundred yards of the apiary. The hives were taken away (all except one stock) on the 25th of May last, in the early afternoon of that day when the bees were flying freely, and, of course, numbers were shut out of each hive. I had an idea that these bees might be received in the hive left behind, and so it

happened.

Within an hour after the disappearance of the last of the seven hives there was not a stray bee to be seen. I had put an open newspaper on the site of each hive, as it was removed, for the bees to collect on, and I shook off at the entrance of the hive a few score bees that were the first to gather upon it at one place; at this time the air was full of stray bees wheeling hither and thither in an evident state of excitement. Their numbers, instead of increasing, fell off as hive after hive was shut up (by perforated zinc secured over entrance), and it struck me the bees were being admitted into the hive hefore referred to. The hive in the loft was removed last, the stock was a strong one, and a large number of the bees were from home, as they kept arriving while we were securing the hive, and clustered about the entrance made for them in the weather-boarding of the old granary. Half an hour afterwards I visited the place prepared to collect the bees with the intention of carrying them to the hive in the apiary, but found they were gone; they had probably found their way themselves 'of their own sharpness.'-T. P. C.

A GOAT STUNG TO DEATH BY BEES.—About a week or ten days ago, two goats (male and female) were tethered together on a small plot of grass about fifteen yards from two hives of bees, and twenty from the cottage. The cottager, who resides in the parish of

Denham, near Uxbridge, was from home at his daily work at the time, leaving his wife in charge of hairn, goats, and bees. The wife, being very timid of the bees, and seeing a commotion near the goats, thought the former were swarming upon the latter, and at once sent for the services of the local adviser and expert, who was soon upon the scene. On his way his doubts and fears were roused as to the probability of bees choosing such a situation, knowing the peculiar odour of goats, and at the same time rejoicing to add a little more to his experience. However, on reaching the desired spot, affairs looked different from that of swarming, and certainly the bees had everything their own way, stinging the passers-by, attacking those who came near, but the poor tethered goats seemed to be the special object of their resentment, for they were most vigorously assaulted. No time was lost in releasing them from their uncomfortable position, and most speedily did they rush to their shed, still pursued and attacked by the bees, which were after a few moments 'excluded.' The piteous bleatings of the goats showed that they were suffering intense pain, and on quietness being restored more than a hundred stings were 'extracted,' chiefly from the nostrils, eyes, and ears of one of the unfortunates. The other was not quite so badly attacked. The cottager himself soon returned, and pulled out ninety-six more stings from various parts of their bodies. One goat died before morning, the other still survives, but the bees were disposed of and cleared away within a day or two after the occurrence.

Echoes from the Vives.

Chertsey Grove.—Having noticed through the valuable Bee Journal some of the 'Echoes from the Hive,' I may just echo and say that after a long winter and careful feeding I managed to bring all along eleven stocks out of twelve, the one dying from cold or short food, but the others seemed to come on very well until I found one stock was gone, and after examination it proved to be queenless, and the stronger lots had killed off the remaining bees. I removed all bars, cleansed the hive well, and having had a splendid swarm come out on June 9th, have replenished the hive, using the combs that had been deserted, but adding two bars I had saved from last year, and giving two bars fresh with foundation comb. The second swarm came out on the 13th of June, very strong, and from a hive which by weight seems full of honey. On this hive I have put on a super containing ten sections. On examination of another box I found the queen was gone, but there was live brood in the cells. In this box I put the second swarm. This led me to ask the aid and opinion of the Surrey Bee-keepers' Association's expert, who paid me a visit on the 10th, and he expelled all my fears, as I thought it must be foul brood. But there was no appearance of this. I was very glad, as I am very fond of bees, but am not an old hand at keeping them.—R. A. DRIVER.

Lowestoft, June 14th.—I have been over to my Beccles apiary to-day, and find the bees are doing well, honey coming in fast.—L. WREN.

Odcombe, Ilminster, June 18th.—We have had most glorious bee weather for the past fourteen days, and where hives are strong the bees are rendering a good account of it. I have not experienced such a 'honey flow' during the four years I have kept bees. I have given my bees plenty of room (eleven standard frames in body of hive and twelve of the same size in super); and although the thermometer in my garden has been about 86° each day for more than a week past no swarms have issued since the 5th inst.; in fact, the bees appear to forget the 'swarming fever' in their desire to fill every available space in hive and super with honey. I must be busy with the extractor next week should the weather continue fine,—J. Sarell.

World's End, Newbury, June 20th. — A fortnight of splendid bee weather. Busy with section-crates. Very

few swarms up to date from either skeps or bar-frame hives; large numbers of skeps and a good few bar-frame hives lost in this district during the winter and spring; in some cases spring dwindling has occurred notwithstanding the most vigilant care and attention. - W. Woodley.

Lismore, Ireland, June 16th.—I do not hear of much foul broad about here, and wherever it has appeared I have hitherto been successful in getting the colonies totally destroyed. When bees abound as they do here, I am sure it is better to stamp out at once any sickly stock. I never saw such work in my hives for the time of year. A hive that was working in three section-racks, and had already stored a fair share of honey, swarmed to-day. I will put the swarm on the old stand, following up directions. I have reversed two fine skeps, and will let you know the result by and by. We never had such a hot, dry spring, and the white clover is coming in now. All my eleven barhives are working in supers, most of them in two and three racks. There have not been many swarms so far, and bees have been very gentle. - F. W. C.

NOTICES TO CORRESPONDENTS & INQUIRERS.

Letters or queries asking for addresses of manufacturers or correspondents, or where appliances can be purchased, or replies giving such information, can only be inserted as advertisements. The space devoted to letters, queries, and replies, is meant for the general good of bee-keepers, and not for advertisements. We wish our Correspondents to bear in mind that, as it is necessary for us to go to press in advance of the date of issue, queries cannot always be replied to in the issue immediately following the receipt of their communication.

All queries forwarded will be attended to, and those only of personal interest will be answerd in this column.

interest will be answered in this column.

Inquirer.—Dry-sugar feeding and dead larvæ.— I only recently stated that dry sugar left in the hive during winter did more harm than good. It should be unnecessary to repeat that all stores required for winter should be given not later than the end of September. Towards spring dry feeding may be resorted to, in preference to syrup, where any colony has unexpectedly run short. It is not always a sign of starvation when bees are throwing out drone or other larvæ piecemeal. The broad along the lower edges of the combs may become chilled during cold nights, and so be thrown out. Brood may also be injured by improper ventilation and consequent overheating; or, in your correspondent's case, it is quite possible, with such an abundant flow of honey, the bees are removing the larvae to make room for storing it; the remedy in that case would be to give more sections, or combs, for extracting.

- J. B. S.—Chilled Brood.—Leave it alone; no harm will arise, and the bees will soon clear it out.
- J. S. LAWTON.—There is not the slightest cause for apprehension of foul brood being caused by the operation mentioned in your letter.
- G. G.—Transferring.—About twenty-one days after the first swarming would be a suitable time for transferring.
- A. G. R.-1. Burying Beetle.-The name of the beetle is Necrophorus respillo, one of the burying beetles. The circumstances under which you found it are common to the tribe. They burrow under dead careasses of all kinds and there deposit their eggs. It is impossible for it to have any connexion with the death of the bird under which you found it .- 2. We should be obliged by your taking the trouble to distribute spare copies of the Journal.
- F. Musgrove.—Foul Brood.—You did very wrong in placing any combs from the affected colony in the new hive. The germs of the disease can be carried on your fingers or clothes; how much more so would they be carried on a comb which had been both built and stored in the diseased hive. The germs of the disease are contained in the honey, and brood fed on such honey will assuredly become affected. We should strongly advise you, as you have only one colony, to destroy bees, combs, and frames, and start afresh, after thoroughly washing out both the hives with a strong solution of carbolic acid, then allowing them to dry, afterwards exposing to the air to get rid of the smell. This plan, without doubt, is the most satisfactory and inexpensive.

- F. W. C.—Queen.—The queen has not reached us alive she was drowned in the honey which had exuded from the piece of new comb. There was no perceptible appearance of the external feature you note. The honey from the new comb was of a delicious flavour. The old comb contained chilled brood.
- H. F.—We are pleased to hear that your erratic bees have at last settled down. Yours has been a singular experience.
- W. T. C.—Bees changing Queens.—From your description of your bees lying and clustering about the hive, halting and sluggish in their work, we should conceive that they are superseding their queen. Leave the hive and bees as they are, and wait for result.
- A LEARNER.—Returning Swarms.—Swarming cannot be absolutely prevented, but its probability may be minimised. When swarms leave supered stocks, bee-keepers desirous of honey-getting return them in the evening after having ent away the queen-cells from the stock hive. In the case of stocks supered after first swarms have issued, the returning at night of second swarms is generally sufficient, as the young princesses heading the latter will be almost sure to engage in royal combat with their sisters in the hive, and in the morning there will be only one regal snrvivor.
- Miss Daly.—Fighting.—Fighting and robbing generally accompany each other, and should be prevented by every possible means. It seldom happens between strong stocks, but is generally carried on against weak and illprovided hives, and is often induced by carelessness in feeding. Spilling syrup or leaving honey about the hives creates a spirit of cupidity amongst foragers, and the scent from the outside having attracted them, they find their way into the interior, and the destruction of the hive is imminent if the bee-master does not take means to prevent the result. Narrow the entrances, passage for the ingress and egress of two bees being for the time sufficient; or exchange the positions of the hives of the robbed and the robbers—this will nonplus the latter, and generally the fighting and the robbing will cease.
- E. Sampson.—A very full description of the Stewarton hive will be found in The Stewarton; the Hive for the Busy Man: London, 1881. By the Rev. E. Bartrum, D.D.

RECEIVED a very nice sample of this season's honey as regards colour, consistency, and aroma. This is the first we have seen this year in London, and is produced by Mr. D. A. Thomas, of Sevenoaks.

RECEIVED from Mr. H. W. West, of Stanmore, Bishops Waltham, schedule of prizes of show-honey, bees, &c., to be held in connexion with the Show of the Bishops Waltham Horticultural Society at Holm Oak, Bishops Waltham, on July 27th.

Correction.—The last paragraph but three in my letter (1009) ought to be as follows:—'It will take either two tiers of frames, twelve in each tier, or twelve frames and two tiers of sections, without any alteration to the hive.' I may further say that we give a sheet of one-ply Willesden paper all over roof and then paint .- F. F. McKenzie, The Warren, Loughton, Essex, June 16th.

Show Announcements.

Giving Name and Address of Secretary, Date and Place of Show, Date of Closing Entries. Terms: Three Insertions and under, Two Shillings and Sixpence; additional insertions, Sixpence each. No charge made to Associations whose Shows are announced in our general Advertising Columns.

June 23, 24.—Suffolk Agricultural Show at Bury St. Edmnnds, Entries close June 6. J. Huckle, Secretary.

July 11-15.—Royal Agricultural Show at Newcastle-on-Tyne. Post entries to June 1st. J. Hnckle, Kings Langley.

July 14.—Oxfordshire Association at Headington. Hon. Sec., Rev. F. C. Dillon, Enstone.

July 21.—Prescot Horticultural Show. Secretary, Station Road, Prescot, Lancashire.

July 20-22.—Lincolnshire Agricultural Society at Spalding. Entries close July 4. R. R. Godfrey, Secretary.

July 26-28. - Gloucestershire Agricultural Show at Cheltenham. Entries close July 12. W. D. Slade, Sec.

Cheltennam. Entries close July 12. W. D. Siade, Sec.
July 26, 27.— Warwick Agricultural Society at Sutton
Coldfield. J. N. Bower, Secretary.
July 27.—Bishops Waltham Show. (Hants and Isle of
Wight Association.) H. W. West, Hon. Sec., Swanmore
House, Bishops Waltham.
August 3-5.—Yorkshire Agricultural Society at York.
Scarptory H. L. Biskards, Pools, poor Loods

Secretary, H. L. Rickards, Poole, near Leeds. August 9, 10.—Irish Bee-keepers' Association at Salthill Gardens, near Dublin. Entries close August 2. Hon. Sec., Henry Chenevix, Blackrock, Dublin.

August 14.—Handbridge, Chester St. Mary's Horticultural Show. W. E. Little, Hon. Secretary, Eastgate Row, Chester.

August 24.—Lancaster Agricultural Show. W. Liddell,

Hon. Secretary, Dale Street, Lancaster. August 31-Sept. 3.—Royal Manchester and Liverpool Agricultural Show at Manchester. W. Lees McClnre,

Hon. Secretary, The Lathoms, Prescot, Lancashire. Business Birectory.

JULY 27TH AND 28TH, 1887.

(OPEN TO ALL ENGLAND.)

Judge: R. R. GODFREY, Esq., Grantham.

NINETEEN PRIZES. FEES, 1s. and 2s. 6d.

Schedules and Forms of Mr. R. Peters, 7 Downing Street, Cambridge.

YORKSHIRE AGRICULTURAL SOCIETY.

PATRON: H.R.H. THE PRINCE OF WALES, K.G.

PRESIDENT: THE RIGHT HON. LORD WENLOCK.

THE FIFTIETH GREAT ANNUAL SHOW

Will be held on THE KNAVESMIRE, YORK, 2nd, 3rd, and 4th days of August, 1887.

The Entries close on Saturday, June 25th.

Prize Lists and Forms of Entry for Stock, Bee Appliances, and Implements, will be forwarded on application to Marshall Stephenson, Secretary.

MANIPULATE WITHOUT SMOKE!

WEBSTER'S FUMIGATOR

Entirely supersedes the Smoker, both in Simplicity and Effectiveness. No 'going out.' No tainting or soiling of combs. Always ready for use without any preparation. Can be carried in pocket.

With Bellows, 4s. 6d.; postage, 41d. Without Bellows, 3s.; postage, 3d.

Can be adjusted to any ordinary smoker bellows.

6 oz. Bottles of Agent—carbolic acid, oll of tar, and water, proportionably mixed—6d. each.

NOW READY.

WEBSTER'S SWIVEL FRAME-LIFTER

With this appliance, frames can be removed from hive. Examined on both sides and replaced without inverting, and with one hand only, leaving the other free to perform any manipulation, at the same time preventing the soiling of hands with propols. 1s. 6d. each. Postage 3d.

Send for ILLUSTRATED CATALOGUE of all descriptions of Appliances. Post free on receipt of post-eard.

AWARDS LAST SEASON.

1st Prize, Silver Medal, Royal Counties' Agricultural Show. Highest Award, Bronze Medal, Colonial and Indian Exhibition, for Bec Subjugators. 2nd Prize Bronze Medal, Colonial and Indian Exhibition,

for useful Inventions introduced since 1883.

2nd Prize, Altrincham, for useful Inventions.

W. B. WEBSTER, WOKINGHAM, BERKS.

BREFFIT'S LIMITED,

THE AIRE & CALDER GLASS BOTTLE CO.

83 Upper Thames Street,

LONDON.

Crates, fitted with Holders and Dividers, on Tin Rests, for 2I Sections, 3/9; 24 Sections, 4/-.

W. H. JENKINS, Exchange Buildings, Swansea.

Finest CYPRIAN Queens.

DIRECT by MAIL from CYPRUS to any Address in EUROPE. From 1st MAY to 30th AUGUST.

For I or 2 Queens (if ordered at one time), each 14/-

,, 3 ,, 4 13/-12/-,, 5 ,, 6

For Countries out of Europe add 50 % to above prices. All Orders to be accompanied by a Remittance.

My Queens are all very prolific, long-lived, and much larger-bodied, than the majority of those supplied by others, as they are reared naturally, under the swarming impulse, in April, May, and June, from the strongest of my forty colonies of Bees kept in double-walled moveable frame-hives, and all having choice Queens, which produce workers so gentle that they can be handled without smoke, and even without a veil on the face, just as I do myself (see Mr. S. Simmins' statements on page 37 of his work entitled, A New Era in Modern Bee-keeping). This is principally owing to the fact that I have weeded out from my Apiary all such Queens which appeared to be weak or producing troublesome workers. Address-

M. G. DERVISHIAN, Larnaca, CYPRUS. A 2375 For Reference, address IMPERIAL OTTOMAN BANK, LARNACA.

SUPERIOR BEE VEILS.

IRE GAUZE FRONTS, 1s. 2d. each, 3 for 3s. Traps for Cleaning Supers, 6d. each, 3 for Is. Post free. Address, W. Crisp, Halstead, Essex.

THE only perfect pattern. The metal being flush with the inside of the Hive side, CANNOT BE FIXED TO IT BY PROPOLIS. All the so-called Improvements CAN. The Special Alloy used allows them to be LIGHT YET STRONG. One gross weighs $5\frac{1}{4}$ lbs.

Price for 1887 5/6 per gross.

DR. PINE'S VEIL

Prize Medal, 1879, for the best Bee Dress. The only Medal ever awarded to a Veil, 2/2 each, post free. Every genuine Veil bears the Registered Trade Mark.

DR. PINE'S LOTION.

The ONLY CURE for Stings, 1/8 per bottle, post free.

CURE. CHESHIRE Guaranteed, with Directions, 1 /2 per bottle, post free.

'Sting Preventer.' Salicylate, I oz. bottle, post free, 1/8.

HIVE MAKERS supplied with SPRINGS, GLASSES for Sections, PHENOL, METHYL SALICYLATE, in bulk, &c., &c., at lowest prices.

F. LYON, 94 Harleyford Rd., London, S.E.

SWARMING SEASON. TIME SAVED IS MONEY EARNED!

All Goods ready for instant Delivery.

Just to hand, a Shipment of the Finest and Whitest AMERICAN SECTIONS ever imported, 11/- per 500.

YUCCA BRUSHES, 3d. Improved BRUSH (for Extracting), 9d. each.

WIRE EMBEDDER and ROLLER, 1/6 each (Root's).

WOIBLET SPUR EMBEDDER, 1/6 each.

EDEY'S Improved SMOKER, with Moveable Shutter and Flue Cleaner, 2/9 each.

BINGHAM, Imported, 7/6. Fuel for ditto, 3d. per lb.

EDEY'S Method of Fixing Foundation in Dovetailed Standard Frames, Wired. Send for WIRING OUTFIT of 1 dozen Frames, Foundation Nails, all necessary Tools, 7/6. See List. NOTE.—Special Split Key and Woiblet Spur included in price; the Key has been used by us for FOUR YEARS. Hundreds of Frames have been extracted without a break lown. Sample Frame, 9d.

EDEY'S COTTAGER'S EXTRACTOR (52). This revolves two Combs at a time; the Honey may be emptied by the Screw-valve at foot. Not shown in engraving. Price 17/6; Crate, 2/-.

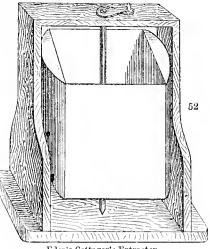

LOCK-UP TRAVELLING CAN, to hold 56 lbs. Honey. Price 5/9.

NESTED TINS for Honey, the Set of 4, holding together 35 lbs., price 1/4; postage 6d.

BEES.—English Swarms, 12/6 each; Palestine Queens, 15-; Syrian, 20/-; Home-bred ditto, half price; Black Queens, 4/-; Syrio-Carniolan Queens, the most Prolific and Best Queens in existence, price 9/- each; Imported Carniolans (BENTON'S). 8/- each.

DOUBLE your HONEY HARVEST by Using WORKED-OUT COMBS!

Clean WIRED COMBS in Frames, 10/- per doz.

CHEAP, STRONG, EASILY MANIPULATED.

EDEY'S DOUBLER (7 A). Complete for Doubling or Tiering. As shown, with 20 Frames, 2 Dummies, Waterproof Cover, Contracting Entrances, price 10/6. In flat, each, 5/-.

For Supering: Complete Hive, 6/6; Section Crate, 2/6; Additional Body-box, 2/6; Crate of 5 Hives, 23/9.

THE UNIVERSAL (No. 7). Of superior workmanship, high outer sides. A first-class Hive for general work, with Super Crate, price 12,6.

FOUNDATION.—In addition to the ordinary Brood and Super, we have a few Parcels of very Thin and Delicate SUPER FOUNDATION, for filling Sections completely. Average weight, 20 sheets to the lb. 3/6 per lb.

EDEY'S DOVETAILED FRAMES. Best and Cheapest made, No Frame-block needed. 2/- per dozen; 12/6 per 100.

For a full line of our Manufactures, see List, free.

Editorial, Notices, &c.

A NEW HONEY BEVERAGE.

It is very pleasing to note the increasing number of those who are cultivating bee-keeping as a pursuit either for pleasure or for profit. number of bee-keepers is rapidly advancing year by year. Great perfection is being arrived at in the construction of hives and in the manufacture of bee-appliances; and attention is being directed in a greater degree to the cultivation of honey-yielding flowers and plants. The result of this is that a larger amount of honey is annually produced throughout the kingdom, and the honey so produced is of superior flavour and quality. The burden that rests heavily on the mind of many bee-keepers is, In what manner can we utilise our increased yield of honey? Is the demand increasing proportionately to the enlarged supply?

These questions require a reply.

During the past few years considerable advance has been made in increasing the number of outlets for the utilisation of honey. It is but right that we as bee-keepers should acknowledge and express our indebtedness to various gentlemen connected with the Berks B. K. A. for the great interest and inventive ingenuity that they have displayed in furthering this object. In this connexion we are pleased especially to recognise the services of, and the active part taken by, the Rev. V. H. Moyle, of Ashhampstead Vicarage, looking upon him as we do as the principal agent in stimulating those in his vicinity to bestow their attention in this direction. In reply to a communication, Mr. Moyle some time ago informed us that he was engaged in compiling a pamphlet setting forth the various utilities of honey. This pamphlet has not yet reached us, and we presume that it has not been published. Some such pamphlet is a great desideratum; and we consider that no one is more competent than Mr. Moyle to produce it, he having for many years devoted much time and attention to the consideration of this subject. Messrs. Huntly and Palmer of Reading have consumed much honey in their well-known Honey Drop Biscuits. Messrs. Blatch of Theale, with their honey beverages; Mr. George, of Reading, with his confectionery; Mr. G. E. Darvil, with his

sweetmeats of all kinds, containing a large proportion of bond-fide honey; Mr. Thomas, with his honey toilet preparations; Messrs. Cross, with their various methods of applying honey in medicinal and pharmaceutical preparations, have done much towards popularising the use of honey. Besides these, Messrs. Fry and Sons, of Bristol, have produced very nice honey chocolate tablets and creams; Messrs. Fry's (of Bishop's Waltham) honey beverages, champagnes, syraps, and cordials, are well known; and our friend, Mr. W. N. Griffin, of Freshford, Bath, has invented a dubbin in which honey is an ingredient and which has been highly spoken of as a preservative of leather.

Much of the honey collected in the British Isles is especially adapted for being utilised in various articles of food, beverages, confectionery, sweets, medicines, &c., possessing as it does an exquisite flavour and aroma; and in this respect we may claim that it possesses considerable superiority over foreign honeys. It is of primary importance that bee-keepers, and all others interested in the promotion of bee-culture, should direct their attention to the increase of such manufactures, as by so doing they would create an increased demand for their own produce. The fact cannot be brought too prominently before the British public that honey is not only of good service in its old form of 'bread and honey,' but that it can be applied to manifold medicinal and sanitary purposes; that it is far superior to its younger rival, sugar; and that the more varied its applications the better for

the honey industry generally.

The British Honey Company, Limited,—who in their progress have had many difficulties to overcome and much uphill work to accomplish,—have devoted much thought and attention to this matter; and after a series of experiments have succeeded in producing from British honey and fruits a beverage, which, whilst retaining the flavour of honey in a marked degree, is quite free from the viscous properties noticeable in many of the honey beverages which have been brought before the public. The new beverage is termed 'Mella,' and, while of a highly effervescent character, is non-intoxicating. The taste of the honey is perfectly distinguishable when drinking it. It is prepared for the market with the aid of the most approved machinery; and, we are informed, it is intended to be retailed at a low price, thus bringing it within the reach of all

classes. We advise all our readers to give this beverage a fair trial.

We congratulate the British Honey Company on this success; and we trust that they will continue to be found in the forefront of those who are catering for the public in the various modes which may be adopted for the utilisation of honey.

YORK SHOW.

We beg to remind intending exhibitors that late entries will be received up to July 2nd upon payment of extra fees. See advertisement.

MANAGEMENT OF BEES FOR PROFIT.*

By L. Wren, Hon. Secretary of the Lowestoft Bee-keepers' Association.

Mr. Chairman, ladies, and gentlemen, during the short time I may occupy your attention it is my intention to speak upon the practical side of bee-keeping. My desire is to open the way for a discussion upon the subject, with a few remarks culled from experience, gained, not only in my own apiary, but also from numerous visits made to successful and non-successful bee-keepers. I have carefully watched and noted the causes which have led in the one case to success, and in the other to failure.

HOW AND WHEN TO COMMENCE.

The question is often asked, How shall I commence, and when is the best time? If a person has a knowledge of bee-keeping, and desires to spend as little money as possible, then I should say the autumn, because cottagers' bees can be had for the trouble of driving, &c., and sugar being cheap they can be fed up for the winter at a small cost. But to winter bees some experience is necessary; therefore it is not safe for a novice to begin in the autumn, except he has a practical friend to give him some assistance. The next best plan, so far as outlay is concerned, would be to procure an early swarm, not at all times an easy matter. If the season is good it will doubtless give some surplus; still I think I may safely say that not more than one swarm in twenty will give the owner any surplus the first year. If you are not limited in means, then by far the most profitable way is to commence in the spring with a good stock on seven well-built combs. I have sent out such stocks, which have given sufficient surplus the first year to pay for hive, stock, and the necessary appliances required.

CAUTION TO BEGINNERS.

Many who commence bee-keeping soon give it up. I advise starting with one stock, and not launch out further until it has paid all costs. Such advice is worth but little, for I often find the young bee-keeper with five or six hives before the end of the summer. An experienced apiarist would put two or three stocks into one hive; but that would never do for our young beginner. His stocks are often weak, and the following summer they do nothing; he is disheartened, and sells out at a considerable sacrifice, declaring bee-keeping does not pay. No, it never will in the hands of such persons. The amateur needs caution. There is a tendency to spend money upon useless articles. I am satisfied that the necessary appliances for successful bee-keeping could be printed on one or two pages of note-paper, and yet we see catalogues advertised of sixty or seventy pages with 100 illustrations. When the tyro receives such a catalogue he fancies the more he can purchase the greater will be his success, whereas a practical bee-keeper that works for profit buys but few fancy articles.

Shows.

Shows are not an unmixed benefit to the novice. True, he may learn a little, and get some useful hints in the bee-tent; but when he goes to the appliance department he is bewildered—he had no idea so many things were required. He endeavours to gain information by making inquiries for what purposes the various articles are used. Of course the vendor is there to do business, and the enterprising bee-keeper purchases a few articles such as none of his neighbours possess. By the time he leaves he has secured a drone-trap, the latest novelty in the shape of a queen-cage, transferring rack, &c., spending 20s. or 30s. over articles that are not worth a cent to him. He has bought some experience, but paid too high a price for it.

Modern Hives are Essential.

Unfortunately most of our best books upon bee-keeping are written by gentlemen who have a liberal supply of that useful commodity called money; consequently the majority of the hives illustrated are expensive, and some complicated. I would say, adopt the most simple hive that can be made—only it should be well made and painted to stand the weather and keep the bees dry; above all things it should be easy to manipulate. Don't attempt to put bees into a box which will not keep out the rain. I consider a good, sound hive a profitable investment. Always see that the floor-boards are tongued. It should also be capable of expansion for the summer to prevent swarming, and all the bars of one size. I consider reversible or invertible hives or frames require too much time for the average beekeeper. I have a hive here which I shall be pleased to explain at the close of the meeting. It may assist some of the members in making or altering their present

BEES AND QUEENS MUST NOT BE OVERLOOKED.

I do not advise the beginner to speculate in expensive bees, but to rest satisfied with the English until he has gained some experience. The native bees, well managed, will give very fair results, though I have not found them equal to the Ligurian or hybrids; neither do I advise the buying of a number of imported queens. It will pay to purchase one occasionally to improve your stock. find queens raised at home from good stock are worth double the money for work, and last longer, than any imported queen I ever bought. Whatever race of bees you keep, it is essential that stocks be strong. If you have weak stocks in April, it will pay to unite two, or even three, if very weak. It is not wise to unite too early in the year. Providing each stock has a fertile queen, some persons can hardly believe it possible to get a stock to cover twenty frames by the time honey is coming in. It can be done; and such a stock, if you prevent it swarming, will be certain to render a good account of itself when the results of the season are summed up. To bring an average stock up to that strength, get them to rear all the young bees possible before May. When the honey is coming, confine your queen to seven or eight bars, put on supers, or extra hody-boxes. To succeed you must have good queens. Last year I had one stock that made no progress. On July 26th the bees did not cover six frames, and there was scarcely any honey in the hive. I killed the queen, and two days later inserted a Ligurian queen, reared in I examined the hive on September 16th (that would be seven weeks after the young queen was introduced) when I found ten frames covered with bees, and more honey than they required for the winter; and I would also add that between August 5th and September 16th, five Ligurian and Ligurian-hybrid stocks gave me 100 lbs. of extracted honey; but the English standing in the same garden gathered no surplus during that time. I do not recommend these bees for trade purposes because I do not profess to sell queens,

^{*} A paper read at the annual meeting of the Lowestoft Beekeepers' Association, May 5th, 1887.

LOCALITY.

Much depends on locality, both for quantity and quality of honey. I would prefer a district where you are not dependent upon one kind of plant or flower, no matter how rich it may be in honey. If the weather should prove unfavourable just at the time it is in flower, the harvest is lost. To ensure success a variety is necessary, and such as will follow each other. If the season is good, bees will give a surplus in almost any locality. Still, some districts are much better than others, principally because of the greater variety of flowers, &c. I have known bees give 40 to 60 lbs. extra by moving them from one district to another in the same county.

PREPARATION FOR THE HONEY HARVEST.

In my visits to apiaries of eustomers and friends I find some rejiocing over their success, and others complaining that bee-keeping does not pay. On inquiry, I find he who succeeds gives attention, and at the proper time; sections and doubling-boxes are on ready for the harvest. The unsuccessful one leaves the bees to take care of themselves. My advice is, I lave everything ready before they are wanted, and give bees the necessary attention when required. Bees set us a good example. They do not put off until to-morrow what can be done to-day. If bee-keeping is to be profitable, it must have the same thought, care, and attention, we give to other matters of business.

PREVENTION OF SWARMING.

To secure a good harvest you must prevent swarming. Although I average from thirty to forty stocks, I have not been troubled with a swarm from a bar-framed hive for the last three years, except from a hive that was neglected. Last year I had stocks covering twenty frames and filling sections. Bee-keepers may adopt somewhat different methods for the prevention of swarming, but the principle is the same, i.e., giving plenty of room for work before the bees have a desire to swarm. I have tried different arrangements according to the hive. If the body-box holds only ten frames, just before swarming time I take out three frames with brood, moving the remaining seven bars towards the back, placing three empty frames in front with narrow guides, not more than one row of cells exposed, putting on an extra body-box, placing the three frames of brood in the centre of extra box and filling up with empty combs, adding a crate of sections on the top. If the hive will hold sixteen frames I work it rather differently. If the bees cover most, or all the bars, I take away three or four from the front, putting in empty frames as before. I leave seven or eight for the brood-nest, then a queenexcluder, and behind it five frames for extracting, and a erate of twenty-one sections on the top, leaving the three bars in front uncovered. The bees can then cluster up the front of the crate if the night is hot. The crates can be tiered if required, and the bars at the back can be extracted as filled. If the bees should fill the front bars with comb, take them away and give empty ones in their place. If the hive will hold only ten frames, and the queen is very prolific, then a shallow box filled with narrow frames containing only guides placed under the body-box is a safe preventative, adding sections on body-boxes as before. The same arrangement will prevent a skep swarming.

TAKING HONEY

Is a pleasure to the bee-keeper, and if you desire good coloured sections for sale they must be taken away about once a-week, putting those partially filled to the centre, placing the empty ones outside. If honey is coming in rapidly a strong stock will generally fill twenty-one so quickly that they can all be taken off at the same time. When one crate is partially filled place a second underneath the first. When honey is falling take away the full sections and keep the unfinished in close quarters,

otherwise many will be left only half filled. I find it does not pay so well to work for sections after the best of the season is over; they are filled too slowly to look well. If other duties demand so much of your time in summer that you cannot give attention to the bees, proceed to prevent swarming, letting them have plenty of room according to their strength. A very strong stock to be left all the season should have at least twenty frames and fifty or sixty lb. sections. The honey then could all be taken at the close of the season. There is one advantage in this plan of procedure—the honey is well ripened.

MARKETING HONEY.

Retailing, as I do, about half a ton of honey during the year, I have gained some knowledge of what best suits the retail customers. Appearance goes a long way with the general public. I often notice in offering two sections of the same weight and quality of honey, the average buyer will give twopence more for the best in general appearance. When I speak of general appearance I mean not only a white, well-filled comb, but a clean section. It is a great mistake to use old dirty sections when new ones are so cheap. The 1-lb. section is more saleable than the 2 lbs., 1 should say one hundred to one; therefore, if you desire to sell your sections do not use the ?-lb. size. The same remark applies to extracted honey. It will sell better if the colour is good, the bottle nicely tied down, and a bright label on; a tumbler to hold halfslb. sells readily at sixpence. When empty the tumbler is more useful than a bottle. The 2-lb. bottles are a slow sale. Two-lb. tins sell to those who have to carry honey a great distance. I advise all bee-keepers to retail their honey among their friends. It will bring a larger profit. Several who have tried it have been surprised by the large profits they have received by adopting this plan. You must not sell the single section or bottle at the same price you do wholesale quantities. In the one case you perhaps sell one or two ewts. at once; in the other, you call on sixty or seventy people to sell the same weight. Remember, also, the trader cannot pay rent, rates, taxes, assistants, &c., except he makes a profit. When I commenced selling honey I bought principally of my customers, but have been compelled to produce it with my own bees, for two reasons, viz., the supply was so uncertain, and some will sell their best sections at 10d. or 1s. retail, and when they had sold all they could they brought the worst to me, and expected the same price, 10s. or 12s. per dozen. They thus brought down the price and supplied me with an article of lower quality, compelling me to offer them a lower price than I had previously given. If one desires to sell their extracted honey wholesale it must not be bottled, it costs too much for carriage, and often several of the bottles come to hand broken. The wholesale buyer will generally send cans for what you have to sell. If your honey is in sections have them nicely cleaned. When sending in sections gentlemen often write stating they were too busy to clean them; therefore the buyer has to pay some one to do the work. He dared not trust any one to do it, otherwise many would be spoilt. Time is money, and to have five or six dozen of dirty sections come to hand just at the time when one is going from fourteen to seventeen hours per day to keep np with the pressing wants is no joke. At such a time, if two lots were offered, one clean and fit for sale and the other with the propolis left on, I take the clean and return the other. I do not think we shall see good English honey any lower in price than it is at present. Still I am satisfied that a person living in the country, where he has no extra rent to pay for standing his bees, can make them pay even if he sold his honey at sixpence per pound, but the bees must have attention. Persons are willing to feed their pigs two or three times a-day, but bees are expected to manage themselves, except when they swarm and the honey is ready for taking away. Do not force

your honey into the market when it is full. Extracted honey will keep for years, and sections can be kept good for two years. Honey will generally make a better price in November and December than in August.

PREPARING FOR WINTER.

I believe the success of the summer depends very much upon the attention given to the bees in the autumn. It is very essential there should be plenty of bees in each hive. By no means attempt to winter a weak stock. It is also of the utmost importance that each stock has a good supply of food. I consider nothing is equal to good honey for wintering bees, and if you do leave ten pounds or fifteen pounds more than they may require for the winter you will be compensated during the following summer. Failing natural stores then good sugar in the form of syrup is the next best. By no means give bad honey in the autumn, save that for the spring feeding. I find the loss of bees during winter and spring is greater after such summers as I885, when so much dark (almost black) honey was stored by the bees. If feeding is necessary it should if possible be completed by the end of September; still, it is possible to feed up a stock much later if necessary. On the 18th October last 1 drove two lots of cottagers' bees rather than he should burn them. As my other bees were packed for winter I had no desire to disturb them by uniting the two lots with them. I therefore put them in a hive, giving them combs from which honey had been extracted. They stored over twenty pounds of sugar made into syrup in about ten days. So far they have passed through the winter well. Not only do I advise packing early, but if you are satisfied they have plenty of food do not disturb them till February, except they have dysentery. The less bees are pulled about the better. I have briefly touched the points I think of most importance in the management of bees for profit, and I trust the bee-keepers present will supplement it by their own experience, and that such information may assist us in making this year one of the best we have known for profit. I shall be pleased to answer any questions or give any further information I can.

GREECE.

It is reported, on the authority of the *Apicoltore* of Milan, that George I., King of Greece, with a view to remind his subjects of the prosperous condition of beekeeping in former days, is writing a book on the bees of Mount Hymettus. It is added that the book is so far advanced that it will be ready for the press very shortly.

WILTS BEE-KEEPERS' ASSOCIATION.

The first show of the season was held at Swindon on June 15th and 16th, in connexion with the annual show of the Wilts Agricultural Association. The time, of course, was too early for any new honey to be exhibited, but there was a good display of hives and all necessaries

for the apiary.

Owing to the large number of entries for the Agricultural Show, the bee-tent unfortunately was hidden away behind the implements, in a field adjoining the show-yard, and so was found with difficulty even by the members of the Association, the result being a loss of nearly 8l. to Wilts B.K.A., but it is hoped that this will be paid by the Committee of the Agricultural Show. The management of the bee-show devolved entirely on the Rev. W. E. Burkitt, Hon. Secretary and expert, assisted in the tent by Mrs. Currey, of Reading, Mr. W. N. Griffin, of Freshford, Bath, and Mr. J. E. Whatley, of Blunsdon, who kindly provided bees for driving. The exhibition comprised all the necessaries for a beginner in apiculture. Some good hives were exhibited by Messrs. Abbott, of Southall, and Messrs. Neighbour and Sons, of London, exhibited their in-

genious frames and sections, which can be put together without nailing, the comb-foundation, to ensure the building of straight combs, being inserted at the time the hives are made. Mr. Griffin exhibited his now celebrated dubbin, which has been so highly spoken of, and which was recently awarded a special prize for excellence at the Devon Agricultural Show; here Mr. Griffin was awarded a first prize. Messrs. Fry and Sons, of Bishop's Waltham, sent various kinds of honey drinks; and some new section-boxes were exhibited by Mr. Woodley, of Reading; the latter receiving a first prize. Mr. Baker, of Maskham, displayed some neat section-boxes for the carriage of about one and two-lb. bottles of honey. In a small collection exhibited by Mr. Burkitt were some useful adjuncts of the apiary, as well as an observatory hive stocked with bees. During the two days of the Show manipulations with live bees were conducted at intervals, showing the various processes of bee-management, such as driving bees, and transferring combs from one hive to another, the operations demonstrating how quiet bees will remain under proper management. The quiet bees will remain under proper management. enclosure where these operations were carried on was, however, protected by a net, as a safegnard to the public. Lectures were also delivered, and various questions put by those interested in keeping bees were answered. The judges were Mrs. Currey and Mr. W. N. Griffin, and their awards were as follow:—Hives, price 15s.: 1, C. E. Payne, Yeovil. Buttermere skep crate: 1, W. E. Burkitt. Extractors, price 11. 1s.: 1, Baker, late Walton; ditto, h.c., price 15s. Collection of bee-furniture: J. Abbott; special, W. E. Burkitt. Straw skeps: 1, II. Huish, Patney. Special for travelling section-crate: Abbott. Special prize for new frames and sections filled without nails; Neighbour and Sons. Honey dubbin: I, W. N. Griffin. Special for honey drinks: Fry and Co., Bishop's Waltham. Section-boxes: 1, A. D. Woodley. Baskets for honey-bottles: h.c., Baker.

THE ROYAL COUNTIES AGRICULTURAL SHOW AT READING.

The Berks and Hants Bee-keepers' Association held their exhibition in conjunction with the Royal Counties Agricultural Show at Reading on the 20th, 21st, 22nd, and 23rd of June. The weather was particularly fine; the town was decorated with flags, banners, and illuminations, to celebrate the double event of the Queen's Jubilee and the visit of the Agricultural Society.

The Berks and Hants Bee-keepers occupied a large tent, near the entrance, in which there was a good display of hives and appliances, honey, and also of honey sweetmeats and other manufactures in which

honey was used.

The prize schedule consisted of twenty-five classes, in which there were 119 entries.

Class 1 (open to all England).—For the best 24 lbs. of super honey, 1, Hants B.K.A. silver medal, W. Woodley, World's End. Class 2.—For pure extracted honey put up in the most attractive mode for purposes of sale, 1, J. J. Candey, Landport; 2, W. Woodley; 3, H. Cobb, Dorchester. Class 3.—For the best design in honey-comb worked by the bees, 1, W. Woodley; 2, J. J. Candey; 3, A. D. Woodley. Class 4.—For the largest and best collection of appliances applicable to modern bee-keeping, 1, Abbott Bros.; 2, S. J. Baldwin. Class 5.—For the best observatory hive stocked with bees and queen, 1, W. B. Baker, Muskham. Class 6.—For the best Ligarian, Carniolan, Syrian, or Cyprian queen-bee, to be exhibited alive and visible with her workers, 1, S. J. Baldwin; 2, Abbott Bros. Class 7.—For the best bar-frame hive, price not to exceed 30s., 1, Abbott Bros.; 2, S. J. Baldwin; 3, A. D. Woodley. Class 8.—Ditto, price not to exceed 20s., 1, Abbott Bros.; 2, S. J. Baldwin; 3, A. D. Woodley. Class 9.—For the best cottager's hive, price not to exceed 10s. 6a, 1, W. B. Baker; 2, S. J. Baldwin; 3, Abbott Bros. and A. D. Woodley, equals. Class 10.—For the best honey extractor, 1, Berks B.K.A.

silver medal, Abbott Bros. Class 11.—For the best sectionrack prepared for putting on the hive, 1, Abbott Bros.; 2, A. D. Woodley. Class 13.—For any recent invention calculated to be of use to the bee-keeping industry, 1, Hants B.K.A. silver medal, A. D. Woodley. Class 14.— For the best collection of honey applied as food and confectionery. 1st prize, Hants B.K.A. silver medal, G. E. Darvil, Reading. Class 15. - For the best general collection of honey and wax in other applied forms. 1st prize, Berks B.K.A. silver medal, W. N. Griffin, Freshford. Class 16.-For the best collection of bee-flora (natural or dried). Ist prize, Hants B.K.A. silver medal, Miss H. C. Myers, Swanmore. Class 17 (open to members residing in Hants and Berks, or within three miles of the boundary lines). - For the best 12 lbs. of super honey, in sections not exceeding 2 lbs. each, 1st prize, Berks B.K.A. silver medal, H. W. West, Swanmore; 2nd prize, bronze medal, H. Cobb, Dorchester; 3rd prize, certificate, A. L. Cooper, Reading. Class 18.—For the best 12 lbs. of super honey, in sections not exceeding 2 lbs. each. Cottagers and artisans only, 1, Mrs. J. Cobb. Class 19.—For the best 12 lbs. of super honey, in sections not exceeding 1 lb. each, 1, W. Woodley; 2, H. Cobb; 3, A. D. Woodley. Class 20.—For the best 12 lbs. of super honey, in sections not exceeding 1 lb. each. Cottagers and artisans only, 1, Mrs. J. Cobb; 2, Jas. Welch, Chilton. Class 21.—For the best 12 lbs. of extracted honey, in 1 lb. or 2 lb. vessels, 1, H. Cobb, Dorchester; 2, H. Fewtrell, Reading; 3, J. J. Candey. Class 22.—For the best 12 lbs. of extracted honey, in 1 lb. or 2 lb. vessels. Cottagers and artisans only, 1, Mrs. J. Cobb; 2, Wm. Webster, Reading. Class 23.—For the best super of honey (not in sections), exceeding 10 lbs. weight, 1, W. Woodley. Class 24.—For the best sample of bees wax, weighing not less than 2 lbs., 1, W. Woodley; 2, W. Burgiss, Hinton; 3, Mrs. S. Burgiss, Hinton. Class 25 .-For the best home-made hive, the work of an amateur. 1st prize, Berks B.K.A. silver medal, A. E. Fry, Reading; 2nd prize, bronze medal, H. Fewtrell; 3rd prize, certificate, A. H. Miller, Egham.

Considering the lateness of the honey-flow the exhibition of comb-honey was very good. Mr. W. Woodley, of World's End, Newbury, had a fine lot of honey in the different classes, his large supers and his designs in honeycomb were very good, and show his skill as a beemaster. In one of the classes for extracted honey, an exhibit of fine colour and good consistency had a peculiar flavour of meal or malt, which, although not disagreeable, was so unnatural to honey that it lost the first position, which it would otherwise have obtained. Many were the suggestions as to the cause; it was thought it arose from artificial pollen having been fed the bees, some of which might not have been consumed, and that the cells containing it being only partly filled were used for honey. It transpired that the honey had been heated in a vessel.

In the hives, Class 7, that of Messrs. Abbott Bros. was a well-made hive containing twelve wide-ended frames in the body box running parallel to the entrance, with dummy and space at back for manipulating, a second hive also containing twelve frames and dummy for storifying. This top hive had moveable supports for the frames, and on their removal could be inverted to form an outside cover for the stock hive, after the method invented by Mr. James Lee, and now used in Messrs. Neighbour's Sandringham hive. In order to secure the sides and ends of hive a small angular L-shaped brass plate is nailed on the corners, and makes a neat and firm pole. The frames are made on Abbott's patented principle. A sheet of perforated zinc is provided to keep the queen in the stock hive. The floor, with legs, and the roof, are well and carefully put

together.
The second prize hive, Mr. Baldwin's, is also a double hive, each containing twelve frames, with Carr ends to keep the distance, parallel to the entrance, with dummies, zinc-excluder, floor-boards, and roof.

In Class 8, Messrs. Abbott's hive consists of three bases, each containing ten patent frames and dummy,

floor-board without legs, and roof similar to the 'Gayton'

hive—a very good model for a hive.

Mr. A. D. Woodley's hive is a shallow hive of four storeys, each containing hanging frames; in the two upper boxes the frames contain sections, but are capable of being used as ordinary frames when working for extracted honey. Some slight modifications would make this a useful hive. Many of the sections were exhibited in Mr. A. D. Woodley's enamelled glazed cases, which are a great improvement on the paper boxes, as they can be washed and used again and again for exhibition purposes. A silver medal was awarded him for his new invention.

The judges were the Revs. W. E. Burkitt, F. Selater, Dr. Andrews, Messrs. E. H. Bellairs, Evan Maberly, and J. M. Hooker.

Mr. J. M. Hooker was the examiner of experts appointed by the B.B.K.A.

Mrs. Currey, of Reading, presided at the sale counter; Mr. Fewtrell lectured and manipulated in the Bee-tent; and Mr. Darvill, of Reading, showed the different processes in the manufacture of various kinds of confectionery.

Correspondence.

The Editor does not hold himself responsible for the opinions expressed by his correspondents. No attention will be taken of anonymous communications, and correspondents are requested to write on one side of the paper only, and give their real names and addresses, not necessarily for publication, but as a guarantee of good faith. Illustrations should be drawn on separate pieces of paper.

Communications relating to the literary department, reports of Associations, Shows, Meetings, Echoes, Queries, Books for Review, &c., must be addressed only to "The Editor of the "British Bee Journal," clo Messys. Strangeways and Sons, Tower Street, Cambridge Circus, W.C.' All business communications relating to Advertisements, &c., must be addressed to Mr. J. Huckler, King's Langley, Herts (see 2nd page of Advertisements).

****In order to facilitate reference, Correspondents, when speaking of any letter or query previously inserted, will oblige by mentioning the number of the letter, as well as the page on which it appears.

A BEE TOUR IN THE NORTH OF ENGLAND BY W. B. WEBSTER.

A Lancashire Bee-cellar.

[1132.] Mr. McClure, with his usual forethought, thinking that I should like to explore all the places of note having any connexion with bee-keeping, had previously written Mr. Greenhalgh, of Hermitage Green, asking permission to look over his apiary, received a cordial reply in return, and he also kindly promised to meet us at the railway station; so that the Monday morning saw us alight from the Liverpool express, and were presently greeted by one who, at the first glance, I would 'dub' a Colonial. With a hearty shake of the hand we were quickly installed in Mr. Greenhalgh's trap and on the road to his house, which, after a pleasant two and a half miles' drive, we reached.

Having seen to the safety of the horse we walked to the apiary. Here the hives were dotted about in a young apple orchard, and quite a lively appearance they pre-All were in Langstroth hives, sloping from back to front, so that the combs were quite at an angle in the hive. Having inspected these, which I found in an exceptionally prosperous condition, our attention was next attracted by what appeared to be the roof of a house poking above the ground; this was the roof of the bee-cellar. It was formed in the sandstone. A space, after much labour, had been dug out of the solid stone, to the depth of 5 feet; this, no doubt, was a rather stupendous undertaking, and no doubt required a vast amount of perseverance, as it measured 16 feet by 7 feet. Upon the edges of this hole a double wall had been built to the height of 18 inches, and upon this was laid a double gabled roof, which was formed first by laying 1-inch spruce boards filleted and tarred; upon this 4 inches of sawdust, and over this the roof proper of 1-inch spruce filleted and tarred. Sand was piled up from the level of the ground to this roof, 18 inches. The ends were treated in the same manner. A flight of seven steps took us down to the entrance. A couple of ventilators, one at each end under the eaves, were found to be more than sufficient. A bent tube prevented any light from entering these ventilators. There was no sub-earth ventilation. What temperature, I first asked, did you register? Mr. Greenhalgh informed me that in no instance during the past winter did the thermometer fall below 40° Fahr., and never reached higher than 42° Fahr. On one day it registered 15° Fahr. below freezing outside, whilst inside it was at 42° Fahr.

The hives were piled up in tiers, each tier breaking joint with the one underneath, a space of two inches intervening between each tier. Each hive had its entrance wide open, but covered with strips of perforated zinc. A single quilt of coarse sacking (American flour-bags) covered the frames. One colony, on being placed in the cellar with roof and ordinary quilts on, showed evident signs of suffocation, which, upon removal of roof and alteration of quilts, quickly recovered. An ordinary paraffin lamp raised the temperature two degrees, but there was found no necessity for continuing it.

The nature of the ground—sandstone—being of such a dry character, dampness was no trouble; in fact, when I viewed it, everything was as 'dry as a bone.'

The bees were placed in at the commencement of November, and taken out in February. All but one were allowed to fly in January, and returned; but the necessity of this was not apparent. Their weight was scarcely diminished at all; very slight evacuations were noticed. The one hive not allowed a fly presented no difference to the others. A nucleus celony on only one frame, but having two empty ones, one on each side, was successfully wintered, and when I saw it at the end of May was in a very prosperous condition, covering, I think, five frames. Here we find a great success scored; not a single colony lost, and no traces of dysentery.

The cellar forms a capital honey house, and was used in early spring, after removal of bees, as a rhubarb forcing-house. A mushroom bed was in an evident flourishing condition when I was there.

WATER FOR BEES.

[1133.] Water being a necessity to hees, the methods adopted of furnishing an artificial supply is worthy of notice. I have just read in the *American Bee Journal* a communication from Mr. C. H. Dibbern of an excellent method of supplying this recessary, that, with your permission, I think is worth quoting.

'Set a barrel on a sack spread over a box, and put a pailful or two of water in every morning. Bore a gimlet hole in the barrel near the bottom, and allow the water to drip out on the sack, which should be kept wet all day. Occasionally throw in a handful of salt, as the bees seem to require it, and will keep the water pure and sweet'

I may be allowed to add a caution as to using salt; bees undoubtedly require it, but I should say in very limited quantities. Two barrels in use would be advisable, in one a small percentage of salt may be added to the water, and the other without the addition of salt.

While on this subject I should like to add a note of warning. Several instances having come under my notice of wooden tubs filled with water, and placed in the sun to have its temperature raised for the purpose of watering plants, &c., capillary attraction taking place at the sides of the tub is just the point our favourites delight to sip the moisture, and in taking flight from such positions they more than frequently take a gentle

swoop downwards, are caught by the treacherous water with fatal results to hundreds of bees in the course of a week.—James Lee.

BEES INJURING RIPE FRUIT.

[1134.] I trust during the ensuing fruit season further light will be thrown on this subject raised by Mr. Webster at the late Conversazione, and the discussion on the same subject in the pages of the Bee Journal. When I have been asked to express an opinion I have given a decided 'No' to the question, and I cannot but think it is only in very few and isolated cases that bees are seen attacking fruit, and then let us hope only after wasps have paved the way by piercing the skin.

The strength of the wasp's jaw is amazing, and a simple proof, after catching a specimen and applying a light pressure to its body, is to insert a human hair between its jaws; it is instantly nipped asunder with a noise plainly to be heard. They are, besides, an extremely voracious race of insects, feeding, as is well known, indiscriminately on fruit and animal matter, and the way they oftentimes treat the common house-fly, who may unluckily fall a prey is surprising; the captive's wings and legs are instantly nipped off, and the body carried in triumph to their nest.—James Lee.

A SWARM ADVENTURE.

[1135.] Being a subscriber to your valuable Journal, and only an 'amateur' in the art of bee-keeping, would some of your numerous subcribers kindly state the reason of swarms taking flight after being hived in the usual way? If it is not trespassing too much on your space I should like to state the circumstances.

On the 13th inst., about 10.30 a.m., a swarm issued from one of my stocks and settled close by. I at once hived them in a straw skep, rested it on two bricks on the ground, shaded them, and they appeared to take to it wonderfully well. At about 3.30 a neighbour informed me that he had just seen a swarm pass over, and that they appeared to come from my stocks. I had a look at stocks and swarm, but did not raise the latter up as there was about the usual number flying. However, I took a stroll in the direction the bees had flown and found they had gone into a clock-tower, about a mile distant. Still believing they were not mine, and they having settled on private premises, I did not consider it was my husiness to interfere with them.

You will readily understand my surprise when in the evening lifting up skep to transfer them to bar-frame hive at finding it empty! I did not like being taken in in this way, and on the following morning I made it my business to proceed to the tower (having of course got permission to do so) to see if there was any possibility of getting them back. I soon discovered them nestled in some old combs. Bees evidently had been there before; but to cut a long story short, I drove them from their home with a smoker, and they quickly settled in an oak-tree, and after mounting a ladder of about sixty rounds I hived them once again. They also this time took to the skep well. I did not give them a chance to escape for as they had settled I packed them up with canvas and brought them home, keeping them in it until the evening, when I deposited them in a bar-frame hive with seven sheets of foundation. I am glad to say that on the following day they worked out nearly three sheets and are still going on all right.—C. E. C.

THE FIRST SECTION—HIGHER-ROOFED HIVES—APIFUGE.

[1136.] On Saturday I took off my first section for 1887. The hints for obtaining sections, as given by the two leading contributors in the *B. B. Journal*, are ex-

cellent, and beginners cannot do better than follow the advice they have given. The hive from which I have taken these sections swarmed on June 5th.

From the parent hive (which had ten frames full of brood) five frames were taken, partly for stocking an observatory hive and partly to keep in hand for strengthening swarms. Five sheets of foundation were inserted in the place of those taken, supers were put on again and the swarm returned. There are now fortynine sections on the hive, forty-two being very fully advanced, with honey of the best quality.

May I suggest that roofs should be made higher than those usually sold? Mine are specially made to take a large number of sections which it is often necessary to

have on a hive at one time.

I find 'Apifuge' a much greater success than I anticipated; no evil effects, as described in letter No. 1001, have troubled me.—Ashton G. Radcliffe, Fonthill, East Grimstead, June 20th.

HOW I LOST MY FIRST SWARM.

[1137.] On Saturday last, after a week of constant watching, a fine swarm issued from my Neighbour hive and settled close at hand on the thick bough of a mulberry-tree. I called the gardener, and we hived them in a straw skep in the most approved fashion. I propped open the front with a stone and set the hive as a table-cloth on a table just in the shade of the mulberry; this was about 2.30, and I had to leave home for four hours in the afternoon, so I left the bees as they were in the skep, meaning to transfer them to a bar-frame all ready with comb, &c., on my return. I told the gardener to keep his eye on them, and to move them into the shade as the sun got round. He neglected to do the latter part, but visited them each half-hour till 5.30, when lo, and behold! every jack-bee had left the skep and have been heard of no more, though I have searched high and low.

I have now advertised them in the local paper. I suppose it was carelessness in not keeping them shaded.—SWARMLESS.

QUEEN RAISING OR INTRODUCTION OF QUEEN-CELL.

[1138.] How long will a queen remain alive in a sealed cell after being taken from the hive? On Saturday evening, June 11th, in Kingston, while changing some bees out of a makeshift hive into a newly-painted one, I cut out a queen-cell, which not being required by the bee-keeper, I carefully wrapped in paper, enclosing it in a cardboard box, and took home with me to Richmond (nearly five miles), when I placed it in a box-cage lined with wool on the top of bars, first cutting a hole in the quilt, but divided from bees with a small piece of perforated zinc. The cell was inserted next day at 4.30 p.m. (the earliest time I could possibly spare) on a bar of comb containing worker and drone brood in hatching condition, closing all carefully up. I opened the hive one week later, when, to my agreeable surprise, there was a fine young queen walking about perfectly 'at home.' As there was not the least sign of any egg-laying, I cannot say how long 'her majesty' had been out, or whether fertilisation had taken place or not. Before closing, I wish to thank you sincerely for your last kind answer to my query; also for answers to other queries, hints, &c., which are sometimes of almost priceless worth. May an all-wise Providence richly bless and prosper our esteemed editor, committee, and other bee-keepers, this Jubilee year.—HERBERT CRAW-LEY, Richmond.

[If the queen-cells are unsealed, the larva, when deprived of the attentions of the nurse-bees, quickly dies. But if the cells are sealed when removed from

the hive, and the temperature is kept sufficiently high—as in 'queen-nursing'—the young queens will not only survive the removal, but will hatch out as well as if left in the hive. The usual plan is to remove the cells to the nursery a couple of days before hatching. We desire to thank you for your kind wishes.—Et.]

THE TRANSMISSION OF HONEY PER RAILWAY TO SHOWS.

[11:30.] I should like to endorse Mr. Woodley's statement in your last issue (I128) in regard to the packing of honey for transmission by railway. For the last nine years I have had the pleasure of unpacking Mr. Woodley's honey at shows in all parts of the kingdom, but I cannot recall one single instance in which it arrived in a damaged state. So much for the exhibitor. This method, however, requires improvement. It is perfectly impossible to repack in the same form at the close of the show, the time allowed does not permit of this being done.

I would suggest that the thin layers of hay be tacked on a piece of thin cardboard in order that the packer may get over his work quiekly. Bottles of run honey should be placed in partitions of corrugated paper or other pliable material, not wrapped up in paper or packed in chaff. Partitions made of corrugated paper sufficient for twelve hottles may now be obtained for about 1d. The sides, bottom, and top of the box should also be lined with this paper, or hay pads. In this way the work can be done quickly, efficiently, and cheaply, both by the exhibitor and the show officials.—J. HUCKLE, Secretary British Bee-keepers' Association.

[As many large shows will be held in the course of next and following months, the attention of exhibitors at their shows is directed to the above recommendation.

—Ed.]

BEES OBSTRUCTING THE QUEEN.—There are many unforeseen incidents and dangers arising in the working of our railway system, but it is doubtful whether a train was ever brought to a standstill by such a curious cause as that which stopped the Queen's progress southward on her last journey from Balmoral. Everyone knows the elaborate preparations which are made for the safety of her Majesty on her travels; therefore it was with no small degree of alarm that the down distant signal of Hincaster junction, near Kendal, was found to be out just before the approach of the Royal train. The driver very judiciously brought the train to a standstill in the darkness; and upon the signal-lamp being examined, it was found that the light had been extinguished by a large swarm of bees that prevented the signalman relighting it. The Westmoreland Gazette, which is responsible for these particulars, says that Dewhurst, the signalman, regrets he had not time to secure the unwelcome intruders in a box and send them forward with the train; but, had he been able to do so, it is doubtful whether the Queen would have been able to utilise such a novel Jubilee gift.

Making Honey Vinegar.—When making vinegar, one must know that water will turn into vinegar providing it contains the necessary quantity of sugar stuff, and is exposed to fresh air and a warm temperature. The warmer the temperature and the better the circulation of air, the sooner the vinegar forms. A barrel is laid down, and an inch hole is bored in the upper end of each head, near the upper stave. This admits of a good air-passage over the body of the honey water. Tins, with fine perforations, nailed over these holes, with the rough side outward, exclude flies and skippers. Take about one pound of honey to one gallon of water, thoroughly mix up, and nail a perforated tin on the bung-hole. We take thirty-five to forty pounds of

honey for a barrel containing forty to forty-five gallons of water. The warmest place in the yard is the best place for the barrel. If the sun shines on the barrel all day, it requires from the beginning of April to the end October to make vinegar satisfactory for all purposes. If not sour enough by fall, it will be all right by Christmas or spring if placed in the cellar or a warm room.—C. F. Muth, American Gleanings.

Bumble-bees and Clover Blossoms.—An inquiring friend would know 'Why the first crop of clover has no seed; whether it is possible to distinguish the difference, if any, between the blossoms of the plant bearing the seed and that which bears the fertilising quality; and has the bumble-bee anything to do with it? So far as examined, the blossoms of the first crop of red clover have good pistiles throughout, and good stamens, with plenty of what we should call good pollen. In other words, we cannot see why they are not just as capable of fertilisation as those which come later. Experiments, repeated on the second crop for six years, give varying results, but in all cases they show that bumble-bees in Central Michigan increase the crop from 100 to 400 per cent. Other insects may also help in this matter. In Kansas they tell me bumble-bees are scarce, but clover seeds freely. Honey bees at the Michigan Agricultural College, without any question, increase the yield of seeds of white clover enormously, in one case as 236 exceeds 5. I am satisfied that in some locations at least bumble-bees should be encouraged for the good they do to red clover. Now the problem is this: How can the entomologists rear and keep over winter large numbers of fertile queens? It seems to me not improbable that the time may come when bumble-bee queens will be reared, bought, and sold for their benefit to the crop of clover seed.—Farmer's Advocate.

THE USES OF BEESWAY. - The uses for wax are numerous and important. Its property of preserving tissues and preventing mould or mildew was well known to the ancients, who used cere-cloth for embalming, and waxed for encaustic painting, as in the wall pictures of Pompeii. Wax candles and tapers play an important part in the processions and ceremonies of the Reman Catholic Church. Wax is used by the manufacturers of glazed, ornamental, and wall papers, and on paper collars and cuffs for polishing the surfaces. It is used in varnishes and paints, and for the 'stuffing' of wood that is to be polished, as for pianos, coach work, fine furniture, and parquet floors. Electrotypers and plasterers use wax in forming their moulds. Wax is an important ingredient in preparations for covering surfaces of polished iron and steel to prevent rust. Combined with tallow, it forms the coating for canvas and cordage to prevent mildew, as in sails, awnings, &c. flowers consume much wax, and, despite the introduction of paraffin, ceresin, and mineral wax, its use appears to be extending. One of the oldest of its applications is in the laundry and in polishing woodwork.—American Bee

Sending Canadian Honey to England.—I am satisfied England is waiting to receive all the honey Canada can produce, and that the amount sent to the Exhibition was only as a drop in the bucket. I would suggest that a competent man be appointed in England, one who is thoroughly and practically acquainted with bees and honey, to take charge of our honey interests in England, and, if necessary, one in Canada to assist in grading, collecting, inspecting, and shipping the supply; and, if the supply can be depended upon, we have nothing to fear as to the final result. A bee-keeping friend in 1879 having a large quantity of honey requested me to dispose of it in England. I reluctantly consented. After six weeks corresponding with parties in England who were strangers to me, I succeeded in disposing of my trial shipment by the ton, netting 94c.

with an urgent request for a much larger shipment, requesting it to be put up in forty-pound cans, and not in casks as before, promising the sale would realise 10c. net. I also sent another shipment in casks of 300 and 500 pounds (a poor way of putting up) to a practical bee-keeper, who, being much pleased with it, immediately arranged to sell to large firms and other institutions, who agreed, in writing, provided the supply could be depended upon, to take four tons per month the year round. Of course the honey had to be unpacked in England and put up in 1, 2, 3, 4, and 5-pound cans, according to the requirements of the trade. This shipment netted 95c. per pound. I was very strongly urged to ship all honey in future in smaller packages, it being more convenient in filling orders that every man should have his own tub, &c. My limited experience is, the individual who ships honey in casks and barrels makes a costly mistake. Canadian honey at this time was comparatively unknown in England, consequently we had to start low, with the intention of gradually raising the price, and in time would make it pay well.-Lewis Marsh, Holloway, Ont. (Canadian Bee Journal.)

The venom of the wasp, bee, and hornet, is a most irritating poison, but it is quickly neutralised by the application of orret oil to the punctured part.

An intoxicating and poisonous honey is extracted from the flowers of the monkstool or aconite by the choura, or wild rock bee of Gurwhal (Apis irritabilis). These facts make it not improbable that many more persons die from eating poisonous animal food than is generally supposed, and without the cause of death ever being suspected.

Echoes from the Hives.

North Northumberland, June 23rd.—The last fortnight has been extremely good weather for bees, the 16th, 17th, 18th so warm that it was impossible to tell which hive might take it into their head to swarm. Some have swarmed that had not even queen-cells started; several have flown away. The yield of honey is very good. Clover is now just ready for work, which will be plentiful if we have a little rain. Swarming is from two to three weeks earlier than last year in this district. Many more stocks of bees than there were a few years ago.—G. A.

Brentwood, Essex, June 25 .- As I never or very seldom see an 'Echo' from this part of the world, I thought I would send a very faint one, but question very much if many of the Essex folks will see it as our County Association very unwisely took a step backward in giving up the circulation of this very valuable Journal amongst its members. On June 18th I examined a hive, and to my surprise found a large number of sections sealed, but was content to take but three for a start, as I was requested to get a crate off by Jubilee Day; on which day I took off the remainder of the twenty-one sections, every one perfectly sealed, which I have every reason to believe is the first lot taken in this neighbourhood this season, and at the time of writing this the same hive has a crate filled with fully worked out sections, and some partially sealed over. I may just add that I have had no swarms at present from any of my five hives but all are working well in the sections, and, weather permitting, shall have more off to-morrow; the strongest lot of bees are on fourteen frames and the weakest on cleven. Now one word for Apifuge, which I have tried. I find no unpleasant feeling from it in the least, and had but one sting while I have used it; so much so that I have discarded my veil while I am depriving the hives of their sections; and I think all bee-keepers owe friend Grimshaw a great debt for bringing out such a charm.—CHIPS.

North Leicestershire, June 27th.—The fourth week of uninterrupted fine weather is well on its way, and the bees are filling bars and sections quicker and earlier than usual. Many stocks have not yet attained their full strength, and drones are scarce, as are swarms also. White clover is in full bloom in the meadows, and just beginning to show a

head here and there in the pastures. One little drawback to this pleasant state of affairs is that sycamores are streaming with honey-dew.—E. B.

Kingston.—Hives appear to be doing fairly well in this district now. One lady bee-keeper had a fine swarm on May 31st. Have not heard of any others about. Most bees seemed three weeks behind as to brood.-H. C.

NOTICES TO CORRESPONDENTS & INQUIRERS.

Letters or queries asking for addresses of manufacturers or correspon Letters or queries asking for addresses of manufacturers or correspondents, or where appliances can be purchased, or replies giving such information, can only be inserted as advertisements. The space devoted to letters, queries, and replies, is meant for the gaccal good of beckeepers, and not for advertisements. We wish our Correspondents to bear in mind that, as it is necessary for us to go to press in advance of the date of issue, queries cannot always be replied to in the issue immediately following the receipt of their communication.

All queries forwarded will be attended to, and those only of personal interest will be answered in this column.

- NORTH DERBYSHIRE.—Drone Combs in lower Hive.—The absence of facilities for raising drones in the upper hive, all the combs being worker, their natural instinct prompted the bees to build drone-combs. Although the frames are set 11 inch apart you would find when the time for sealing arrived that some combs would be left thin, to allow for the caps in the opposite faces. The natural position of drone combs is in the lower part of the hive, and if you had given the frames above the stock instead of below worker combs would have been built.
- G. Anderson.—1. At this time of the season you might remove the pollen-bound combs and substitute in their place empty combs or foundation sheets, placed alternately. 2. We should prefer to retain the old queen to inserting queen-cell. Much depends on the age of the queen. If not too old, there is no advantage in risking a certainty for an uncertainty. 3. We have forwarded your letter to Mr. Webster.
- H. W. W.—Probably there may be in your neighbourhood some plant from which the bees have been gathering honey which has been the cause of their death. (See reply -to ' R.')
- Novice.—It would be desirable in building honey-comb designs to make use of excluder zinc. Mr. M'Nally, of Glenluce, or Mr. Woodley, of Newbury, Berks, would be pleased to furnish you with any further information.
- A LEARNER. -- You might improve on the piece of enamelled cloth forwarded. It has a smell which would prove offensive to the bees.
- M. AND T.—Doubling.—A reference to Mr. Cowan's pamphlet on Doubling and Storifying will show you that in his instructions he mentions that he does not use excluder zinc when doubling hives. (See p. 8.) A piece of American cloth placed over the brood-nest will generally have the effect of preventing the queen ascending to the upper hive.
- An Amatrice.—1. The bees will not ascend to the super till they find the lower hive inadequate to their requirements. When they desire more storage room they will ascend. Patience with bee-keepers is a virtue. 2. Casts should be fed. The size of the cast should determine the number of frames in the hive. We should say that six would be more than enough.
- R.—Rees dying.—From your description we should have said that the bees were suffering from Bacillus depilis, but the specimens you enclose show no loss of pubescence. It is quite possible that the colony is collecting from some poisonous plant or flower. We advise you to raise the hive slightly from the floor-board all round by small wedges, sufficiently to cause a current of air to pass beneath the combs, but not enough to admit of the entrance or exit of bees. Feed also on phenolated syrup, and do not open the live or attempt to manipulate. Under this treatment probably the colony will soon recover. We have no experience of the 'Greenock disease.'
- MATER.—1. Hybrids.—The specimens forwarded are hybrids very little removed from blacks. The three orange bands, which form the mark of a pure Italian, cover the upper half of the abdomen. 2. Drones.—There are few hives in which the bees do not succeed in raising a few drones, even when their combs are built upon full sheets of

worker foundation. But even supposing the non-existence of drones in a hive, the colony, at this season, may safely be divided, since there is no doubt that drones exist in the neighbourhood. 3. Italians, Carniolans, Blacks.— In our experience Italians are better honey-gatherers than Carniolans. The cross between Carniolans and blacks would probably be an improvement of either race pure, but the temper might be uncertain. 4. Introduction of Brood into Nuclei.—The reason for introducing brood into nuclei is that in all probability without it the becs would swarm out and desert the hive, having a virgin queen only. Besides a succession of bees is required. 5. Excluder zinc.—Foundation will be drawn out quicker when placed in the body of the hive than behind excluder We find that the zine very much impedes the work of the bees.

Walter F. Cromex.—The specimen with white flowers is Cotoneaster microphylla. The one with blue flowers is a member of the Borage family, a species of Anchusa, but from the small portion enclosed we are unable to deter-

mine which with certainty.

H. S. W.—Crooked Combs in Bar-frame Hires.—Remove the whole of the frames *cn bloc*. Separate the combs, and if possible straighten them by gentle pressure; if very crooked, cut down to the midrib on the convex side; press the comb flat, then tie on to your frames again, keeping the midrib in the centre of the top bar; never mind the outsides, if the midrib is straight you are right. The small amount of brood sacrificed will be of no moment. The assistance of an expert would be desirable.

NEW SUBSCRIBER.-Mrs. Tupper says, 'Bees do nothing invariably.' It is difficult to control the ways of bees they have a will of their own, which even old bee-keepers

cannot manage to dominate.

J. Edwards.-1. The best time for manipulating bees is the middle of the day when the larger number of them are busy foraging. 2. By laying a handkerchief moistened with carbolic acid solution on the top of the sections, the bees will be driven down, and then it will be a comparatively easy matter to remove the sections. See last week's 'Useful Hints.'

RECEIVED from Mr. W. J. Green, 36 Friars Street, Sudbury, Suffolk, the model of a hive which he purposes to style the 'Imperial' hive. This hive has various novel features and answers the double purpose of an ordinary and an observatory hive. It will be exhibited at the next conversazione, when those present will have an opportunity of passing their opinion on it.

Show Announcements.

Giving Name and Address of Secretary, Date and Place of Show, Date of Closing Entries. Terms: Three Insertions and under, Two Shillings and Sixpence; additional insertions, Sixpence each. No charge made to Associations whose Shows are announced in our general Advertising Columns.

July 11-15.—Royal Agricultural Show at Newcastle-on-

Tyne. J. Huckle, Kings Langley. July 14.—Oxfordshire Association at Headington. Hon.

Sec., Rev. F. C. Dillon, Enstone.
July 21.—Prescot Horticultural Show. Secretary, Station Road, Prescot, Lancashire.

July 20-22,—Lincolnshire Agricultural Society at Spalding.

Entries close July 4. R. R. Godfrey, Secretary.

July 26-28.—Gloucestershire Agricultural Show at Cheltenham. Entries close July 12. W. D. Slade, Sec. July 26, 27.—Warwick Agricultural Society at Sutton

Coldfield. J. N. Bower, Secretary.

July 27.—Bishops Waltham Show. (Hants and Isle of Wight Association.) H. W. West, Hon. Sec., Swanmore House, Bishops Waltham.

August 3-5.—Yorkshire Agricultural Society at York. Secretary, H. L. Rickards, Poole, near Leeds.

August 9, 10.-Irish Bee-keepers' Association at Salthill Gardens, near Dublin. Entries close August 2. Hon. Sec., Henry Chenevix, Blackrock, Dublin.

August 14.—Handbridge, Chester St. Mary's Horticultural Show. W. E. Little, Hon. Secretary, Eastgate Row, Chester.

August 24.—Lancaster Agricultural Show. W. Liddell, Hon. Secretary, Dale Street, Lancaster.

Angust 31-Sept. 3.—Royal Manchester and Liverpool Agricultural Show at Manchester. W. Lees McClure, Hon. Secretary, The Lathoms, Prescot, Lancashire.

Business Directory.

For the use of Manufacturers and Purchasers of Beekeeping Appliances.

The Name and Address and Business of any Manufacturer will be inserted in this List, under one heading, for One Pound per annum. Additional headings, Five Shillings extra. Advertisers in 'The Bee Journal,' whose orders amount to Five Pounds per annum, will be inserted Free.

MANIPULATE WITHOUT SMOKE!

WEBSTER'S FUMIGATOR

Entirely supersedes the Smoker, both in Simplicity and Effectiveness. No 'going out.' No tainting or soiling of combs. Always ready for use without any preparation. Can be carried in pocket.

With Bellows, 4s. 6d.; postage, 42d. Without Bellows, 3s.; postage, 3d.

Can be adjusted to any ordinary smoker bellows.

6 oz. Bottles of Agent—carbolic acid, oil of tar, and water proportionably mixed—6d. each.

NOW READY.

WEBSTER'S SWIVEL FRAME-LIFTER

With this appliance, frames can be removed from hive. Examined on both sides and replaced without inverting, and with one hand only, leaving the other free to perform any manipulation, at the same time preventing the soiling of hands with propolis. 1s. 6d. each. Postage 3d.

Send for ILLUSTRATED CATALOGUE of all descriptions of Appliances. Post free on receipt of post-card.

AWARDS LAST SEASON.

1st Prize, Silver Medal, Royal Counties' Agricultural Show. Highest Award, Bronze Medal, Colonial and Indian Exhibition, for Bee Subjugators.

2nd Prize Bronze Medal, Colonial and Indian Exhibition, for useful Inventions introduced since 1883.

2nd Prize, Altrincham, for useful Inventions.

W. B. WEBSTER, BINFIELD, BERKS.

Reversible Section Holders.

(PROTECTED).

Set of Six, with Dividers for 21 Sections, 1/6.

Crates, fitted with Holders and Dividers, on Tin Rests, for 21 Sections, 3/9; 24 Sectious, 4/-.

W. H. JENKINS, Exchange Buildings, Swansea.

SUPERIOR BEE VEILS.

WIRE GAUZE FRONTS, 1s. 2d. each, 3 for 3s. Post free. Address, W. Crisp, Halstead, Essex.

Finest CYPRIAN Queens.

DIRECT by MAIL from CYPRUS to any Address in EUROPE. From 1st MAY to 30th AUGUST.

For Countries out of Europe add 50 of to above prices.

All Orders to be accompanied by a Remittance.

My Queens are all very prolific, long-lived, and much larger-bodied, than the majority of those supplied by others, as they are reared naturally, under the swarming impulse, in April, May, and June, from the strongest of my forty colonies of Bees kept in double-walled moveable frame-hives, and all having choice Queens, which produce workers so gentle that they can be handled without smoke, and even without a veil on the face, just as I do myself (see Mr. S. Simmins' statements on page 37 of his work entitled, A New Era in Modern Bee-keeping). This is principally owing to the fact that I have weeded out from

M. G. DERVISHIAN, Larnaca, CYPRUS. A 2375 For Reference, address Imperial Ottoman Bank, Larnaca.

my Apiary all such Queens which appeared to be weak or

producing troublesome workers. Address-

LYON'S Patent METAL ENDS

THE only perfect pattern. The metal being flush with the inside of the Hive side, CANNOT BE FIXED TO IT BY PROPOLIS. All the so-called Improvements CAN. The Special Alloy used allows them to be LIGHT YET

STRONG. One gross weighs $5\frac{1}{4}$ lbs.

Price for 1887 5/6 per gross.

DR. PINE'S VEILS.

Prize Medal, 1879, for the best Bee Dress. The only Medal ever awarded to a Veil, **2**/**2** each, post free. Every genuine Veil bears the Registered Trade Mark.

JULY 7, 1887.

[Published Weekly.]

Editorial, Notices, &c.

BRITISH BEE-KEEPERS' ASSOCIATION.

Address of Secretary. — All communications from this day until Thursday next, the 14th inst., should be forwarded to 6 Simpson Street, Newcastle-on-Tyne.

THIRD CLASS EXAMINATIONS,—Arrangements have been made for holding a Third Class Examination of Candidates at the Royal Agricultural Show, Newcastle-on-Tyne, on Tuesday next the 12th inst.

Examiners' Report.—The following Report has been made by the Board of Examiners, in reference to the First and Second Class Examination held on April 20. 'Four Candidates submitted themselves for examination, three of whom held Second Class Certificates, one being a Candidate for Second Class only. The result of the Examination is as follows, the names of the Candidates being placed in the order of merit:-

'First Class.-1. W. M. Graham, Church Street, Lower Edmonton; 2. W. G. Campbell, Hornefield, Tottenham; 3. W. de Lacy Ahern, Sutton, Surrey. 'Second Class.—G. Munday, Aylestone Park,

Leicester.

'As on former occasions weakness was displayed in the lecturing and vivâ roce portions of the examination; and we express a hope that future Candidates will give their best attention to the subjects as set forth in the Syllabus and to lecturing in public. Clearness and simplicity with a thorough knowledge of the subjects being of the utmost importance, those who aspire to First Class Certificates will do well to bear in mind that a fair acquaintance with orthography and English composition is a sine quô non for obtaining them.

> THOS. W. COWAN. F. G. JENYNS. GEO. RAYNOR.' -

OUR HOBBY.

How often are we brought face to face with the directly beneficial effects on the mind of a healthgiving hobby!

Save us from our friends without hobbies.

The harassing cares of business, and the worrying anxiety of professional duties, bring one down to a nervous, fevered state in which some soothing influence is almost absolutely necessary, in order that the calm equilibrium of 'a healthy mind in a healthy body' may be restored. In such cases comes forth 'the hobby,' be it the art of gardening, the study of botany, or what not.

A stroll in the woods; a lounge on the waysides of the country (magnifying-glass in hand, perhaps); the vigorous handling of a spade in the trenches (the celery trenches); the calm contemplation of the beauties of nature; all these we say, tend to produce that change of labour and thought which is rest.

When the optical sense becomes saturated and charged with any certain key of colour, the eye becomes weary and inflamed; it seeks repose by resting upon the complementary colour, the absence of which prevented an harmonious combination such as would satisfy the visual nerves by its completeness. Unrest and irritation resulted, and did we not voluntarily supply the missing link, kindly Nature herself would have stepped in to fill the gap and give the eye rest. That is to say, the rest colour springs into the retina; for example, the greenery of our fields and woods turns the grey walls and rocks into soft, harmonising purples; the brighter greens appear almost yellow, whilst in the shade they deepen into blueish purple. Thus does Nature give us her own perfect harmony and

The great hero of rose-growers* was once impelled to return to his country home by the contemplation of a fresh rose in the hands of a London flower-girl—a penny rose—the unrest and agitation of a sojourn in town needed but a suggestion from his beloved hobby, to urge him into taking the next train down to his roses. A year ago we stopped to watch a honey-bee rest a while on the steps of St. Paul's Cathedral, alone as she was in the very core of civilised and unsuitable places, and where no one would expect to find such a connecting link between ourselves and home. Then arose a vision of our hives in June; filled sections; the much-dreaded natural swarms; and all the other ills that can befall a bee-keeper away from his bees. We seek in vain for consolation in the saving that 'it is the unexpected that happens,' for it is the dread expectancy itself we find, on our return, to have occurred.

A few weeks ago we noticed a queen humble-bee flying about under the railway arch on the Borough side of London Bridge. Speculation as to what brought her there only reopened the vista of longing for a return to other humble-bees.

Revenons à nos abeilles. Who but a bee-keeper can feel that delightful thrill of satisfaction which fills the breast on the return to refreshment from labour? The merry hum of workers; the lazy boom of drones; these sounds are such sweet contenting music to his ears, that if he do not give a sigh of mingled joy and thankfulness for being permitted to enjoy such a recreative hobby, well—he must have a coarse appreciation indeed of blessings bestowed, coarser than, we apprehend, is generally found amongst bee-keepers in this land.

'Man goeth forth to his work and to his labour, until the evening.' The evening meal being over, how joyfully does he hie him to the neighbourhood of his hives! Soothing influences are around him; all is quiet; calm reflection fills his mind, bringing into it that very repose which rests his world-torn spirit, and fitting him anew to recommence the harassing grind of duty in the morn, a duty he is better enabled to continue, because his mind and body obtains there rest.

His bees, however, unlike him, are working continuously on to their death, for the moon is rising and their day's work still goes on, still they set forth in their quest for nectar. Let him listen at this time near the back of a prosperous hive, and it seems as though the real labour of the day is only just begun, for all are at home, yet rest not.

In the morning he is up with the lark, for how can he, for very shame, remain at rest on such a bright morn, when he knows his little slaves were at work as soon as either lark or chanticleer heralded the day? The dew is yet on the grass ('ilka bled o' grass has its ain drap o' dew'), there has been no rain for weeks perhaps, so his bees have said they must draw water. The doorstep of the hive is cold and moist by reason of the condensed vapours of the night; two or three weary, sleepy-looking bees crawl lazily about just under the porch, tired of the night's sentry dnty; a few more, which have the air of having been up all night, venture forward, as if testing the barometrical and thermometrical conditions of the air—diagnosing the new-born day, so to speak. All at once the fit seizes one to fly round on a more extended meteorological expedition; and returning, it sallies forth on a far voyage, accompanied by a confiding sister bee. Single bees return, and pairs go forth, until soon all is activity, and the joyous bee-keeper is assured of a fine day by his own true little weather prophets. And yet, how quietly they work during the early morning! He cannot hear the usual hum of noon, and thinks, maybe, their little wings are softly damped with early morning mist, and do not buzz as they surely will when crisped and dried by the sun's allvivifying beams.

Solomon sent the sluggard to the ant; but, as bee-keepers, send us to our bees.

JUBILEE DESIGNS.

In almost every hamlet and town throughout the kingdom the spirit of loyalty has been demonstrated in the various processions of the trades, manufactures, and societies that have perambulated through the principal streets and roads. It may be possible that Bee-keepers' Associations have borne a part in these enthusiastic displays, though the record of such has not reached us. Tableaux vivants after the frontispiece of Modern Bee-keeping, or some of the plates in Mr. Jenyns' work on beekeeping, would have proved most effective, and would have given a local place to bee-keeping amongst the other industries of the respective places. When we visited the Reading Show last week we were much gratified at the Jubilee designs of Mr. W. Woodleigh, of Newbury, which we consider much in advance of those exhibited by him at South Kensington.

At Blandford, Mr. J. J. Alsford, the expert of the Dorset B.K.A., exhibited in Jubilee week in his shop-window in the Market-place a very beautiful work of his bees, which he had caused to form the letters 'F. T. T.' (the initials of a local celebrity), with comb filled with honey, flanked with the workers in a glass hive. Large crowds of spectators were continually gathered round the window. Mr. Alford had also, exquisitely worked, the word 'Jubilee' in honey in comb, about six inches deep and fifteen inches long, with this declaration in verse—

'My bees unite to swell with me The universal Jubilee.'

At Bedford Dr. Wray, the inventor of the 'Mel-pel,' displayed the following amongst the decorations of the town:

The Royal Arms, surmounted by a real straw-hive or skep, upon which was inscribed—

'THE HONEY BEES.'

'Creatures that by a rule in nature teach. The art of order to a peopled kingdom.'

Atop of the hive stood a 'smoker,' by means of which the modern bee-man keeps *peace* with his bees, and shares with them their *plenty*. The legend, therefore, on the smoker was:—

'V.R. PEACE AND PLENTY.'

Next above this came a queen-bee, much enlarged; and over her (with the following lines between) was a portrait of our Gracious Queen Victoria:—

'First in the throng, and foremost of the whole, One stands confest the sovereign and the soul.'

The background was a red curtain, and the whole surmounted by festooned flags; the Royal Flag in the centre of those of All Nations; St. George's, flanked by Union Jacks; the Royal Standard; and, above all, Medallions of the Queen in 1837 and 1887.

GLEANINGS.

In the Bee-keepers' Magazine, G. W. Demaree, describing his system of controlling increase, says that when a swarm issues it is hived on five frames of standard Langstroth size, the rest of the brood-chamber being filled with division boards cleated on the sides, so as to make them stand half-inch apart. Over all goes a metal queen excluder, and the surplus cases are tiered on

The new top, as many as needed for the surplus crop. hive occupies the old stand, and the old hive is set at its rear and disguised by spreading some cloths over it. In six or seven days after the swarm issues, he lifts out the combs in the old hive, shakes nearly all the bees off of them in front of the new hive, and moves the old hive to a new position in the apiary. If there is a case of partly filled sections on the old hive, it is transferred to the new, as the old colony will be some time getting ready to gather surplus honey. The result of this management is that the new swarm is sure for sur-plus for all it can get. The queen can occupy but a small space for brood, and the honey is forced into the surplus cases. The honey is all taken from them as fast as completed, and the colony goes down to a mere nucleus by fall, and the 'way of all the earth,' unless you choose to unite them in the fall. In this way he gets a good yield from the swarm, and the old colony rears a vigorous queen, gathers sufficient stores for winter, and so gets no increase. He says the plan, in a 'nut shell, is to use up increase in producing surplus honey.

In Gleanings, A. I. Root gives the results of his experiments on the protection of bees from heat and cold. He says that some years ago he made such full and complete experiments in trying to decide whether the chaff hive was an advantage in winter as well as in summer, and that he was not mistaken in thinking he would get more honey in a well-protected super than in one exposed directly to the weather, especially when there are cracks admitting rain and wind. He verified it again in the house apiary, by having the bees build and store comb-honey in sections protected by good warm covering, and without any protection except a piece of sacking. He repeatedly caused the bees to commence storing and stop storing in supers by putting a close, warm top over them and taking it off again. The fierce heat of the sun would stop work, and within a week or ten days cold nights would also stop work; whereas if an outer hive or top confined the air at such a time, work would go right along. Colonies of equal strength were tested side by side, and more bees went to the fields and more pounds of honey were gathered when protection was given.

In the Canadian Bee Journal, Dr. C. C. Miller says he prefers giving for brood-chamber the smallest room the queen will fill in early spring, then increasing to the largest room just before harvest, to be again contracted on putting on the supers. He prefers top storing to any other, although G. M. Doolittle recommends top and side storing combined. Of eleven bee-keepers who give their opinions, nine prefer top storing.

In the Journal of the Royal Microscopical Society, M. A. Forel gives an account of past and recent experiments on the vision of insects, and sums up the conclusions as follows:—

(1.) Insects direct themselves in flight almost wholly, and on the ground partially, by means of their facetted eyes. The antennæ and buccal sensory organs cannot serve for directing flight. Their extirpation makes no difference.

(2.) J. Müller's mosaic theory is alone true. The retinulæ of the compound eyes do not each receive an image; but each receives a simple ray more or less distinct in origin from that of its neighbours. (Müller, Grenacher, Exner.)

(3.) The greater the number of facets, the more elongated the crystalline cones, the more distinct and

the longer the vision. (Müller and Exner.)

(4.) Insects can see particularly well the movements of bodies, and better during flight than when at rest, the image being displaced in relation to the eye (Exner). This perception of the mobility of objects diminishes as the distance increases.

(5.) Contour and form are only indistinctly appreciated

and the more indistinctly the fewer facets, the shorter the crystallines, the farther and smaller the objects. Insects with big eyes with several thousand facets can see with tolerable distinctness.

(6.) In flight insects can by means of their compound eyes appreciate with accuracy the direction and distance (not too great) of objects. When at rest they can also

estimate the distance of fixed objects.

(7.) Certain insects (bees and humble-bees) can clearly distinguish colours, and that better than form. In others (wasps), the perception of colour is very rudimentary.

(8.) The ocelli seem to furnish only very incomplete vision, and to be simply accessory in the insects which

possess also compound eyes.

In The production of Comb Honey, by W. L. Hutchinson, he says that separators are needed when sections two inches wide are used, or when they are to be glassed. They are also needed with any system that does not admit of tierring-up; because when sections are removed singly, or by the wide frame full, bulged combs will be the result, unless an unprofitable amount of manipulation is performed, when the spaces are filled with new sections. With wide frames separators are certainly a convenience, that is, they furnish a 'strop' against which to push the sections, thus keeping them in line, and their edges even with the edge of the wide-frame. It is only by the adoption of 'tiering-up' method, in which a whole case of sections is removed at one time, that separators can be abandoned with any hopes of success. Black bees, he says, or those having a dash of black blood in their veins, are more inclined to build straight true combs without separators, than in any variety of bees which he has tried.

USEFUL HINTS.

Hot, scorching days, with close, stifling nights, mists in early morning betokening another sweltering day. Such has been the order of the day with us for over a month—not a drop of rain. Oh! may we shortly see—

' At last

The clouds consign their treasures to the field, And, softly shaking on the dimpled pool Prelusive drops, let all their moisture flow In large effusion o'er the freshened world.'

This dry weather suits the clover, and where the grass is not already cut, the bees are working it well. The acacias are just over; there is a large tree here which the bees have been working from morning to night. The lines are in bud and promise a plentiful supply of honey if we only get a few days' rain, already some of the earliest trees are bursting into blossom; with us there are trees in different stages which usually yield a honey-glut for a full month. Dutch clover will be reappearing in fields which have been mowed; last year the greater part of the surplus consisted of that

gathered from the aftermath of clover.

Hives should be well shaded from the scorching rays of the sun, and water provided if not obtainable, near at hand; of course not forgetting the pieces of stick or cork placed on the water to afford a foothold for our protégées. Plenty of ventilation should be given by propping up the hive from the floorboard; those whose hives possess moveable floorboards will now experience their benefit, the fanners at once relinquish their labour as soon as a free wide entrance is provided. A large board leant against each hive, if not already in the shade, gives great relief from the heat, although it may be rather unsightly. A plan which we adopt is to drive a yoke of wood in front of the hive, the cross-piece some six inches higher than the top of the hive, and stretch a piece of unbleached calico across to the back of the hive, and have always found it very useful.

A Wond of Wanning.—You who have new untried hives, look to your roofs when this dry spell of weather is over, or rather, look to them at once before the rain

comes, for the sun may have opened the joints, and the first shower will soak the quilts, and if not noticed, occasion great damage.

Sections have been deserted or not taken to in consequence of the continuous drought. Even brood placed in the supers has been abandoned. There is very little fear of the queens being crowded out by the honey-gatherers, still fresh room must be given them in the brood-nest. Doubling will give us the best returns. If we do not provide our queens room in advance of their requirements, we must expect swarms which will issue too late to give us satisfactory results. In those cases where swarms have been returned to the parent hive, they have refused to occupy the supers and have swarmed out again. Swarms of three weeks or a month old that have not yet been supered may have a case of sections placed on them if the other stocks are collecting a surplus.

Manipulations should never be undertaken in the heat of the day, the bees are very savage, and well they might be, when thus disturbed; the early morning or before sunset are the most favourable times for making

an inspection.

SENDING HIVES TO HEATHER .- Where it is intended to convey the hives to the heather preparations should be made for the bees' safety on the journey. A special single walled travelling box is best, provided with squares of wood tacked on the sides to take the ends of the frames and prevent the combs from jarring. These strips of wood should not reach to the bottom of the box, but should afford a space of half an inch or more all round below them. With such a box provided, the frames and bees can be readily lifted out from their hive, placed in the box and fastened down for the journey. This is much safer than attempting to pack them up in their permanent hive, and is very little extra work, as doubling boxes would come in very well for this purpose.

EXTRACTING.—This should be performed in the cool of the evening, after the bees have ceased flying. Great care should be taken to prevent the bees, if possible, getting a scent of the honey. In many instances, especially with Ligurians or Hybrids, even when the bees refuse the supers, honey may be extracted from the body-box, but do not extract from those frames containing brood. The best way to obtain the honey from these is to uncap it, and place the frame between two combs well filled with broad in the centre of the nest, when the bees will speedily clear it out, and store the honey in the outer frames. Do not extract the honey from unsealed combs, as it will only spoil the rest, if mixed with ripe honey.

BEES AND ROSES.—During this hot, dry weather, we have noticed several hive bees working double roses, but only those that distinctly show the stamens and pistils, such as, of course, are useless for exhibition purposes.

PACKING HONEY. - Those who have sections and bottled honey to sell cannot do better than follow the advice of friend Huckle (1139) in last week's Journal, and of Mr. Woodley (1128) of the week before; every pains certainly should be taken to relieve the show officials of unnecessary labour.

GOAT AND BEES .- The account on this subject in the issue of 23rd June should be borne in mind by every beekeeper, not only goats but horses and cattle should be rigidly excluded from proximity to bee-hives. owner evidently did the best he could under the circum-

stances; namely, got rid of the bees at once.
DISPOSING OF HONEY.—Let me remind bee-keepers now is not the time to get rid of your honey; keep it in a dry, cool place, and it will remain good till the winter, and if it is then kept in a dry, warm place it will keep till next year without any danger of spoiling. Honey will fetch a much better price in the winter than now, and last year's sections are often allowed to compete in early shows, when the present year is a bad one. We have seen and tasted honey in sections kept over some years, and should not have known it from freshly gathered, of course care was taken to keep it covered from the air.

METHYL SALICYLATE (OIL OF WINTER-GREEN).-We have tested this, and must say it affords a great protection, the bees do not seem to object to it; in fact, it rather soothes them, and though it does not attract the bees, two or three occasionally crawl on the hands and commence licking it off; we have experienced no unpleasant effects from its application.

ASSOCIATIONS.

NORFOLK AND NORWICH BEE-KEEPERS' ASSOCIATION.

This Association held their annual show in conjunction with the Rose Show on June 30th in the grounds of Carrow House (the residence of Mr. Colman) and of Carrow Abbey. It was a glorious day, and the show was well attended by the élite of the town and county. The roses were very line indeed. The Rev. F. Page-Roberts, who we believe is a bee-keeper, obtained no less than four first and one third prizes for roses in the different classes.

In the bee department the exhibition of hives and appliances was small and not up to what one usually expects to see at an important show of this kind, the large firms of manufacturers of hives and appliances being conspicuous by their absence, although the prizes offered for the collections were good. It is a great question whether the time has not come when this class should be altered, and that the largest collection, which entails a large outlay for carriage, packing, unpacking, &c., and which limits the competition to one or two firms, should give place to a specified number of hives, &c., after the collection class in the Bury St. Edmunds schedule, which should increase both the number of exhibitors and the usefulness of the exhibits. The only hive of any merit, and well made, was exhibited by Mr. Blake. It consisted of body-box, a super, with shallow frames same size as hive, and a rack of sections with deep covers, the price being only 10s. 6d. The exhibition of both comb and extracted honey was very good, and the four judges took considerable time and pains to arrive at their unanimous decisions. The following is a list of the awards:-

Class 1.—For the best stock of Ligurian or other foreign bees: 1st prize, Mr. H. Beswick; 2nd, Mr. J. J. Rice. Class 2.—For the best collection of hives and bee appliances: 2nd prize, Mr. J. J. Rice. Class 3.—For the best complete and most practical hive: 1st prize, Mr. J. Blake, 2nd, Mr. Wren. Class 5.—For the best exhibition of super honey from one apiary: 1st prize, Mr. H. Beswick; 3rd, Mr. A. G. Copeman. Class 6.—For the best super of honey not in sections: 1st prize, Mr. C. G. Cooke; 2nd, Mrs. Kendle. Class 7.—For the best twelve 2-lb. sections of honey in the comb: 1st prize, Mr. H. Beswick; 2nd, Mrs. Kendle. Class 8.—For the best twenty-four 1-lb. sections of honey in the comb: 1st prize, Mr. C. J. Cooke; 2nd, Mr. M. Mason; 3rd, Mr. H. Beswick, Class 9.—For the best 24 lbs. of extracted honey in 1-lb. or 2-lb. glass pars: 1st prize, Mr. M. Mason; 2nd, Mr. J. Lawrence; 3rd, Mr. Reeve; extra 3rd, Mr. C. J. Cooke; highly commended, Mr. H. Beswick. Class 10.—For the largest and best collection of extracted honey in glass jars, Mr. A. West. Class 12.—For the best twelve 1-lb. sections, bonafide cottagers: 1st prize, Mr. R. Howes; 2nd, Mr. J. Nichols; 3rd, Mr. J. Spanton, jun. Class 13.—For the best twelve 1-lb. hottles of honey, bona-fide cottagers: 1st prize, Mr. M. Mason; 2nd, Mr. Chaplin; 3rd, Mr. G. H. Richmond; highly commended, Mr. Goldhawke. Class 14.—For the best super of honey, open to bona-fide cottagers only: 1st prize, Mr. R. Howes; 2nd, Mr. Moore.

Mr. J. M. Hooker, who assisted in the judging, was also appointed by the B.B.K.A. to examine expert candidates. The Abbey and grounds were illuminated with much skill and taste during the evening.

BURY ST. EDMUNDS SHOW.

The following awards were made in the classes allotted to bees, hives, honey, &c., at the Suffolk Agricultural Show, held at Bury St. Edmunds on June 23 and following day, viz.:—For the best collection of hives, &c., 1st, Mr. Wright; 2nd, Edey & Sons. For the best twelve sections of comb and honey, $6\frac{1}{4} \times 5\frac{1}{4}$, Mr. II. Beswick; no second prize was awarded in this class. For the best twelve sections, $4\frac{1}{4} \times 4\frac{1}{4}$, 1st, G. E. Kemball; 2nd, H. Beswick; 3rd, G. E. Kemball. Highly commended, Miss Gayton and Dr McNab. Commended H. Beswick. This was an excellent class, consisting of thirteen entries. For the best exhibit of honey from one apiary. A third prize only was awarded in this class to Mr. H. Beswick. The Rev. George Raynor judged, and the arrangements were most efficiently made by Mr. Mr. H. C. Bunbury.

BERKSHIRE BEE-KEEPERS' ASSOCIATION.

The annual show of the above Association was fixed to take place at Windsor on July 14th. This date has been altered. It will probably take place the week after, but the day is not yet settled. The Hon. Sec. hopes this will catch the eye of those to whom he has sent schedules, and so apprise them of the change of

Correspondence.

The Editor does not hold himself responsible for the opinions expressed by his correspondents. No attention will be taken of anonymous communications, and correspondents are requested to write on one side of the paper only, and give their real names and addresses, not necessarily for publication, but as a guarantee of good faith. Illustrations should be drawn on separate pieces of paper.

Communications relating to the literary department, reports of Associations, Shows, Meetings, Echoes, Queries, Books for Review, &c., must be addressed only to 'The Editor of the "British Bee Journal," clo Messrs. Strangeways and Sms, Tower Street, Cambridge Circus, W.C.' All business communications relating to Advertisements, &c., must be addressed to Mr. J. Huckle, King's Langley, Herts (see 2nd page of Advertisements).

***In order to facilitate reference, Correspondents, when speaking of any letter or query previously inserted, will oblige by mentioning the number of the letter, as well as the page on which it appears.

HOW COUSIN JONATHAN GETS COMB HONEY.

[1140.] Most of our readers have heard of Mr. Henry Alley, of Wenham, Mass., of queen-raising fame; he is the present editor of the American Apiculturist, a monthly bee-paper that is second to none in the value of its articles on points of real practical interest to bee-keepers. The number for June has five articles on comb honey from the pens of the following well-known American bec-keepers:—G. M. Doolittle, Dr. G. L. Tinker, A. E. Manum, Dr. C. C. Miller, and G. W. Demaree. To reprint them in extense would be beyond the limits of these columns, so I will endeavour to give you a digest of them: the information is too late to be of benefit for the present honey crop, but as our minds are now occupied with honey-getting the facts will probably be more firmly fixed in our memories at the present time than they would be in the winter when bees are quiet.

Mr. Doolittle strongly emphasises the necessity of having good queens at the head of all stocks, and also the absolute necessity of having stocks full of young bees by the time the clover blooms, which with him is about June 15th. He advises spreading brood cautiously by turning sides to comb, uncapping sealed stores, removing the outside combs to the centre when bees are sufficiently strong to bear that treatment, but not till then, never letting the bees feel their larder is getting low, and by keeping the stocks warm with packing. He gives full sheets of foundation in his sections and gives the sections in rows, not a crate full at once, and does not give his sections in tiers, but spreads them out laterally even beyond the limits of the brood-chamber. Mr. Doolittle does not give full sheets of foundation to swarms in the brood-nest, and in common with most of our transatlantic cousins uses the 'honey-board,' or queen-excluder.

Dr. G. L. Tinker shows his appreciation of a strong stock of young bees by giving details as to wintering and building up in spring. He recommends sufficient stores in late autumn to last till May 1st, then give frames of sealed stores sufficient to last till the fruit-blossom crop and wraps all up warm. He winters on about 800 square inches of comb surface, and at the time of the fruit-bloom gives another case of combs of about the same capacity underneath the original one, so that the queen can extend her brood downwards and thus get from 1400 to 1800 square inches of brood ready to hatch out by about June 1st. This, the doctor contends, exhausts the queen so that she requires a rest, and will not hatch so many bees after the honey-glut is over. He uses full sheets of foundation in the sections for economy but starters for looks, and $4\frac{1}{1} \times 4\frac{1}{1} \times 1\frac{7}{9}$ sections with dividers, but seven to the foot without. Narrow sections, he says, on a contracted brood-nest leads to pollen being stored in the sections, he also recommends the open-sided sections where separators are used. Dr. Tinker always puts at least one section containing comb partly built out the previous season as an inducement to the bees to enter. He tiers his super crates as we do in England, and has a say about inverting the brood-chamber and insists that no brood frame should be less than six inches deep. The doctor is very fond of swarms, having evidently never tried the non-swarming system of Germany and England, and gives a long description of his treatment of swarms and the construction of a honey board, on which the success of his system in his opinion entirely depends.

Mr. Manum uses the $\frac{1}{4} \times 4\frac{1}{4} \times 1\frac{7}{8}$ sections filled with full sheets of foundation, and fitted with wood separators. He goes in for quality and appearance, and gets his stocks strong enough to swarm by the time the white clover and raspberry bloom. He only allows each hive to swarm once, and gives one third of the swarm back to the old stock, unites the two-thirds of the swarm to the two-thirds of the next swarm that comes from another hive, and so has large colonies without impoverishing the old stocks or increasing the number of his hives unduly. If the stocks swarm late he returns one-half and puts four half swarms together, his object being, of course, to have all sufficiently strong to work in supers. He also tiers his sections, having had, he says, as many as six sets, containing in all 192 sections on at one time. He sometimes inverts the sections to get them better finished, and places the outside ones in the middle and vice versa if necessary. He also gives a chapter on introducing queens by cages, a subject on which they can all learn from John Bull if they will.

Dr. C. C. Miller says the two first requisites of success are plenty of bees and plenty of pasturage. To get this he gives plenty of stores in antumn and little or no meddling. The doctor's crates hold each twenty-four I-lb. sections, and he points out the advantage of giving a partly-filled section as an inducement to the bees to commence. If one stock is earlier than another he goes so far as to divide the first crate of partly-filled sections amongst the others. He also gives his sections by crates, adding the empty crate underneath in the early part of the season and on the top later on. He uses the Heddon slat honey-board as a queen-excluder, and takes the middle sections away as soon as filled, putting the outside ones into the centre of the crate to be finished. Dr. Miller's honey-flow is evidently not so good as some of the other contributors.

Mr. Demaree prepares for his honey harvest late in the previous autumn, packing his hives up strong with young bees, plenty of stores, and takes care to leave them alone during winter. He deprecates 'brood-spreading' and inverting brood combs, but is not dictatorial to others who prefer that plan. He also prefers to contract deep frames to tiering shallow frames, and contracts his brood chamber by allowing the outer frames to he filled with honey instead of contracting them by dummies during the time the bees are filling supers. This gentleman uses full sheets in sections if the honey flow comes in a short 'rush,' but starters only if it is continuous and steady. He also tiers sections by crates, grouping the partly-filled sections downwards to get them finished off at the end of the season, but says nothing about the use of partly-filled sections as a start to the bees.

The number of the Apiculturist is an excellent one and can be read by all with profit. By it we can test our own methods and practice, and see how far we are behind or before our cousins over yonder.

In all probability, by the time my readers are conning over these lines Mr. Cowan will be on the deck of one of the best 'Cunard liners' on his way to see 'Cousin Jonathan' as well as our old friends in Canada. I hope he will see some of these sections taken off and the efficient bee-masters that have written the articles, and that he may have a prosperous trip and a safe return to the old country, his brother bee-keepers, and the B. B. J. —AMATEUR EXPERT.

APIFUGE: A LADY'S EXPERIENCE.

[1141.] With regard to Apifuge I should like to say that I find it most successful. Hitherto my bees have always stung my hands (I wear a veil) as I do not like working in gloves. The stings with me are most inconvenient, as they swell and stiffen, rendering me help-less for fully a day. Since using the Apifuge I can put my hands into a hive without fear; and on Saturday last I removed seventeen filled sections crowded with bees from the top of a not very good-tempered lot without receiving one sting. As for my smoker I never light it now. I do not suffer from any after effects, it is as innocuous to me as water. This from a lady bec-keeper ought to give others confidence. I hope many will try it, and find the comfort from it that I do.—Bee-Kay, Waltham Firs, Great Grimsby.

DE QUIBUSDAM.

[1142.] I am trying 'Apifuge' with success. It has no ill effect on me, and the bees seem startled at it. One suddenly alights on your hand and—'Halloo! what's this?' he seems to start in amazement and forgets to sting. That he will never do so while you use the article must not be expected. Its use increases confidence, which is a great thing. Moreover it seems to have a similar effect on the bees to smoke. They run down and bury their heads in unsealed cells. Wasps are unusually scarce this year; I don't think I have seen half-a-dozen.

At the beginning of this week bees were very busy on laurel, ilex, sycamore, and various other leaves. There had been a refreshing dew, and small dots of moisture were visible on the foliage. There the bees were at work for honey dew, 1 presume, and it seemed to me that the warm, moist drops draw forth some flavour from the foliage, and that the bees get moisture and some other article at the same time.

You have lately given some useful directions to beginners. To some of them a difficulty may arise in getting bees out of certain crates. If you have not helped them I hope I shall not be considered presumptuous if I point out how easy the work is after all.

Three days ago I took from a skep a good example of Abbott's Cottager's crate. Through the four glass sides you see four fine seams of honey. Of course there were hundreds of bees in it. I put a seacale pot just out of

the sun near the hive, month up, with two slips of wood laid parallel to one another towards one side. On these I placed the crate, covering it over with a cloth on all sides, but letting light in to the pot between one of its sides and the crate. Late in the evening I returned; all the bees except two had gone down and out. I removed the crate, laid it gently on one of its sides, still covering all, turning the opening at the bottom (a round one) to the light. In two or three minutes the captain and mate left the ship.

Why does my good friend Mr. Griffin spell his excellent article 'dubhin' after the fashion of an illiterate country saddler? We do not put 'blackin' on our boots, or clean our tinned ware with 'whitin.'—C. R. S.

HONEY ASSOCIATIONS.

[1143.] In the editorial for June 30th of British Bee Journal the important question is asked, Whether the demand for honey is increasing proportionately to the enlarged supply? I say that it is not. The supply of honey is not so great as it might be with better management, but it increases every year, and at a faster rate than the demand. The abolition of the sulphur-pit is the fundamental cause of the rapid increase in the number of stocks, and to a great extent the enlarged supply of honey. The amount of honey imported is insignificant and on the decline, and no longer any justification for the reckless policy of our Bee Associations.

Every Association has for its avowed object the benefit of bee-keepers, especially the cottager, and anyone who did not know better would imagine that all their efforts were devoted to that end, but, unfortunately, by some means or other, the hee-keeper, and especially the cottager, derives but small benefit. The motives of B. K. Associations are good, no doubt, but their policy is bad. The all-important question is obtaining new members, and if the Report shows an excess of new members over those who have left disappointed and disheartened, to say the least the Association is said to be in a prosperous condition. It matters not how many leave, so long as others are found to join. Then, as regards expenditure, how can we account for the almost invariable deficit at the end of the year? Has the cottager cost too much? Certainly not; the money has heen expended in fishing for new members so as to make the Association strong. But, alas! they vanish. An Association's strength does not lie in its numbers, but in the unity, prosperity, and satisfaction of those it does possess. One volunteer is worth two pressed members, and it is better to let them come than drag them in.

How much money has there been expended on the bee tent manipulations, and where is the single member who has derived one pennyworth of good from them? The bee tent is not for bee-keepers, and they never ought to enter after keeping bees one season. A skep of bees is taken into a netted arena, and after a good supply of smoke and honey to make the bees harmless, an expert, perhaps covered with some intimidant, bravely frightens them from one skep to another, and then the said expert, who is often a manufacturer of appliances, gives a 'lecture' on bee-keeping, which is simply an advertising medium for his goods.

What exaggerations! How the dark side is kept out! How painful to the experienced apiarist to stand and listen to such statements as the following—'Scarcely any outlay and but little risk!' 'A hundredweight of honey per hive at from a shilling per lb. upwards!' But these are mild compared with some I have heard. However, a convert is made and some appliances sold, the poor bee-keeping cottager's money having done both. Shows ought to be held when possible for the exhibition

of our produce, as they are beneficial to bee-keepers, but the bee tent and 'lectures' ought to be done away with at once.—LOOKER-ON.

MR. S. SIMMINS ON BUYING AND INTRO-DUCING QUEENS.

[1144.] In your issue of the 23rd inst. there appears a letter from Mr. Simmins offering to purchasers of young queens some excellent advice; and as the advice he gives applies so very aptly to myself, I purpose, in great measure at least, in future to follow it. 'In spring,' says your correspondent, 'how many there are who, finding a stock queenless, send off for a new queen. much better to unite at once, for what does the dealer from whom he purchases? He runs considerable risk in wintering nuclei for the sake of the young queens, as he is aware they are much sought after early in the season. As the queens are disposed of, often to be introduced to colonies (?) weaker than the nuclei they are sold from, the dealer unites, thus gaining strength while pocketing eash into the bargain, the purchaser often finding, to his regret, that his bees have not sufficient "backhone" left to do the new queen justice. If one must try a new variety, why not give her foreign majesty a fair trial, with at least an average stock in good heart, and thus be in a position to give a full and faithful report?

About the middle of April, examining my stocks, I found three whose queens were drone-breeders, two of which were young queens hatched out in the early part of the season of 1886, and exceptionally active and fertile. A mild open winter before Christmas, an inordinately severe and prolonged one afterwards, had in my opinion injured the young queens, and I determined therefore to replace them at the earliest. The stocks were crowded upon eight frames, and were, to say the least, strong. I wrote to one of our largest queen-rearers and dealers, asking when, at the earliest, he could send me queens of a certain kind. He replied that, weather permitting, he could let me have them by the middle of May. I thereupon ordered two, and of course forwarded the amount due for them. Now, sir, this is the 25th of June, and my queens have not arrived. I have waited from day to day, hoping and trusting, but up to this present in vain. In May I wrote and asked the dealer to apprise me, by letter or post-card, two days before sending on the queens, of his intention of doing so, in order that I might have the old queens removed and the hives ready for the reception of the new, and this he very kindly promised to do. On June 16th I am informed that having had no fine weather here until the 9th, we are behind with queens, but hope to attend to you very soon now.' Despairing, I wait no longer, but, taking out the drone-breeders, unite the bees to other hives; a course of action that I clearly should have two months before

I am quite aware that the spring has been exceptionally severe, and that, do what one could, hives were and are backward, and the coldness and severity of the weather here are much greater than in the south of England at any time. We seldom have less than seven months' winter, and more frequently eight, i.e., from October until May; and yet young queens, even in this cold region, have hatched out in April, and been fertilised by the end of May, nearly a month agone. Let me give a case in point. In the early part of April, one of my strongest hives—the strongest then—swarmed out (it being an unusually warm bright day) to get a cleansing flight. The bees were crowded upon ten frames, and the hive was increasing mightily. The queen was of last year's rearing. Well, as I have remarked, they swarmed out. I was from home at the time, and did not return until evening, when a friend of mine, who was working in my garden told me of the circumstance. Going to the hive, I found it still in a state of great

excitement, and I concluded, therefore, that her majesty had been lost in the flight. Some four days after this, it having become warm again, I opened the hive and found five unsealed queen-cells. This confirmed my opinion respecting the loss of the queen. I had purposed opening the hive again in due time, cutting out three queen-cells and introducing them into the two hives in which were the drone-breeding queens; but, unfortunately the weather became so prolongedly and intensely cold that I dare not. When I did open the hive, however, and which was about three weeks afterwards, all the queen-cells had been cut down, and the young, unfertilised queen was upon the combs; all others of the young queens, if any had been permitted to hatch out, having disappeared. A fortnight passed, and the hive having again become restless and excited, I again opened and examined it. No evidence of a queen, no young brood, not an egg. I thereupon introduced a frame of eggs from a Syrian stock as a test experiment, i.e., if the bees drew down queen-cells, their young, unfertilised queen must have been lost; but if no queen-cells were drawn down, she, although still unfertilised, was safe among them. Some four or more days after this, I again examined the frame I had introduced, but not one queen-cell existed, and as further proof of the young queen's presence, she was actively laying, and was therefore fertilised.

But, sir, what I would wish to be understood, as deducing from the foregoing is this: - While many beekeepers are (and truly according to Mr. Simmins) wrong in not at once uniting, and thereby, although diminishing the number of their stocks, increasing the strength of those which remain, dealers in queens may possibly err in misleading their customers as to the length of time they may have to wait before their wants are supplied. My young queens were first expected to be forwarded about the middle of May. June 16th arrives, and 'it is hoped that the queens may be sent very soon.' June 25th is here, but the queens are not. Surely if we, living in one of the coldest counties in the north of England, hundreds of feet above the sea-level, with searcely ever less than twelve feet of snow from first to last during the winter, and this of almost arctic length and severity, can have swarms (and these are neither few nor far between), and can get queens hatched out in April, and fertilised and laying in May, surely, I say, dealers and queen-rearers, domiciled in the south, and owning, perhaps, 300 or 400 stocks, should be able to despatch queen before June 25th, in this the year of Her Majesty's Jubilee! My queens are coming, and so is Christmas. They are to be beauties of their race, and this, from my knowledge of their rearer, I can very easily credit; but they must come soon to be of use, and even then I must impoverish some of my strongest stocks to 'give each her foreign majesty a fair trial.'

Mr. Simmins opportunely indicates how, by the insertion of a comb with eggs, to prove the existence or non-existence of a virgin queen in a hive. It will have been seen from the foregoing that I am enabled to verify the correctness of his statement.

In concluding this letter, I have to remark that my stocks were strong when I placed myself in communication with the queen-rearer, i.e., they were crowded each upon eight frames. Had uniting with other stocks not been had recourse to, upon how many frames would they be had they been permitted to remain to this day? How much 'backbone' left to do the new queen justice?—Edward C. Anderson, Lydgate House, Wolsingham, Darlington, June 25th.

P.S. Much has been urged against Syrians and their non-wintering characteristics, and, in addition their fierceness and vindictiveness. The Syrian stock, from which I took the frame of eggs to place in the hive as a test experiment, I have had three seasons. They are pure, or very nearly so. I have found them the hardest

workers, the most prolific, under careful, gentle management the most docile, and the best winterers of any bees of any kind in my apiary. The queen of this stock I have had three seasons. She now reigns over eighteen standard frames, twelve of which contain brood, most of them full from top to bottom. The stock is contained in a twin hive, with south and east entrances, and both are open. I shall, after the bees are thoroughly accustomed to go in and out of both the entrances, i.e., in the course of a week, place a division-board in their midst, and thus separate them into two. The one therefore queenless will, I doubt not, soon proceed to erect queencells, &c.; meanwhile, I anticipate that the becs in each hive will remain of their average strength.

AMERICAN 'ARTIFICIAL HONEY.'

[1145.] At the annual conversazione of our North-east I.B.K.A. one of the queries, which it fell to my lot to answer, was, 'What is Californian honey?' and my reply was, 'Californian honey is honey or nectar gathered by bees just as our own do, but what is sold as "Californian orange-blossom and cherry-blossom honey" is a chemical compound of syrup with a little flavouring;' and I am sure any one who knows the taste of pure honey, and has 'sampled' the 'Californian honey,' will agree with me. Of course, if persons are satisfied with the imitation article, they are welcome to the delusion; and for their benefit, that they may have a cheap and as little nasty article as possible, I send them the following receipt for the making of artificial honey from an American print :-

'Artificial Honey.—Three pounds loaf sugar, one pint water, two ounces gum arabic. Dissolve the gum in the water, add the sugar, and boil for twenty minutes taking care that it does not burn. Now flavour with five drops of a mixture made as follows:—Oil of rose, ten drops; oil of peppermint, twenty drops; oil of spearmint, ten drops; essence of jasmine, half ounce; alcohol, two ounces. When the five drops of this mixture are stirred well in, add a little tincture of saffron, and the "honey" is ready for sale when cold.'-H. W. Lett, M.A., Aghaderg Glebe, Loughbrickland, Co.

'MELLA.

[1146.] I am pleased to see you refer to this refreshing drink in last week's Journal, for I believe it only requires to be tasted to insure its being appreciated. I supplied my friends with half a gross on the day of the Queen's procession to Westminster Abbey, and they one and all spoke in high praise of it. One great charm it possesses over similar beverages is that it leaves the palate so perfeetly clean and fresh, whereas most of the sugarsweetened drinks leave the palate clogged and sticky, and this advantage that 'Mella' possesses is, I believe, solely due to its being sweetened with pure honey. Its peculiar power of assuaging thirst is due to the healthy action of the honey on the salivary glands.—II. Jonas.

Mr. Spurgeon and the Hornets' Nest, - Mr. Spurgeon, speaking at a Blue Ribbon Society meeting, related the following anecdote;-He had once had a hornets' nest in his garden. He tried to kill the hornets singly, but it took him a long time to dispose even of one. At last, on a fine night—he did not previously tell them of his intention-he heated a poker red-hot and dropped it in the hole where they were. He did not stay any longer, but at once went in for meditation. He never saw another hornet. They seemed to be so pleased with the poker that they stopped in their hole for ever afterwards. The living fire of the Gospel was wanted to burn, not one special sin only, but all sins from the human heart.

FOR BOYS AND GIRLS.

THE QUEEN AND THE BEES,

I want this morning to do three things. I want to tell you a story; to give you a text; and to ask you to learn two lessons. The story is one which I saw in the papers only last week, and it is this. A fortnight ago, the Queen, as you may remember, was travelling from Scotland to London. She was coming up from her Highland home at Balmoral to take part in those great Jubilee festivities of which, ten days ago, we all heard and talked so much. Now all of you know that when the Queen travels by rail every provision is made for her comfort, and every precaution is taken for her safety. And so, no doubt, it was then. But there are things which even kings and queens, and those who make arrangements for them, are unable to control, and thus it was in the case before us. At a certain point on the road there was a signal, and in proper course the signal should have shown a light. But when the driver of the Queen's train approached, behold all was dark! There was the post, and there was the lamp, but in it was no light. Under such circumstances the rule is to stop. Accordingly the driver stopped his engine, and with i: stopped the royal train.

What was the explanation? The explanation is said to have been this: a swarm of bees attracted by the light had crowded into the signal lamp, and by the sheer weight of numbers had extingnished its light and so made the signal void. Thus the bees put out the light by which the Queen of England had to travel, and stopped her royal progress. Now I want you to learn from this curious story these two lessons:-

I. Learn, first, what great things can be accomplished by very little things when they are united, or, as we say, banded together.

One bee could have done nothing towards extinguishing the light: it would only have been itself destroyed had it attempted to have done so; but united, banded together, these bees succeeded in accomplishing the task. So, boys and girls singly are weak, and comparatively powerless, but united, banded together, how much they are able to accomplish. This is why we ask you to join Bands of Hope, and Sunday Schools, and Christian Churches, that you may be the better able to do good work in the world, and so to serve your day and generation.

11. Learn, secondly, how much harm may be accomplished by little things, and especially by little

things combined.

The bee is a very tiny creature, but the bees combined put out the Royal light, and stopped the Royal progress. Now, God wishes you all to be His kings and queens—' He hath made us kings and priests to God.' But if you are to be kings and queens, you must have light—the light of conscience—the light of truth—and the light which comes from Jesus Christ, God's Son. You must have light by which to travel; and you must also make progress—a royal progress, though it be a pilgrim's progress-from this world to the brighter, better world which is on high.

And what you ought to remember is that it is quite possible for your light to be extinguished and your progress stopped, and that by very little things. You are not likely, while you are children, to be tempted to commit great sins—you are not likely, so long as you are boys and girls, to be guilty of murder, or of burglary, or of forgery, or even of intemperance—but you are very likely to be tempted to little sins, or sins which you regard as little, to little untruths, to little dishonesties, to little acts of disobedience, to little failures in work and duty, to little thoughts of envy or jealousy, of unkindness, or of pride; and these little sins indulged in are quite sufficient to put out your light and stop your onward progress,

As the bees made the lamp, which should have been light, all dark, so will these little sins make your souls all dark; and as the bees stopped the onward progress of the Queeu, bound though she was to all the joy and the triumph of her Jubilee, so will these little sins hinder and stop your progress to glory and eternal life.

So now I will give you my text—'They compassed me about' (says the Psalmist), 'they compassed me about like bees; but in the name of the Lord will I destroy them.' These little temptations, as you may call them, will certainly compass you about. There is not one of you whom they will not compass about. If you would retain your light-if you would continue your heavenward journey in the name of the Lord by His grace and with His strength-in the name of the Lord you must destroy them. God help you all to do so!

[The above sermonette was preached on the morning of Sunday, July 3, by the Rev. J. Byles of Ealing to the children of his flock. The circumstance on which it was founded was given by us last week. Some of our correspondents have cast some doubt on its authenticity, and have promised to endeavour to verify the story.-

Echoes from the Vives.

Odcombe, Ilminster, July 2nd.—I have been very busy for the past fortnight extracting and removing sections, but now, although the weather continues most splendid, the flow of honey is diminishing in consequence of the mowing machines having completed their work round here, but the white clover will afford supplies for some time to come, especially if we get a few showers of rain shortly. I have given a fair trial to the four bee-way sections without separators, and find they are completed more quickly and quite as evenly as the close-sided ones with separators. On the 30th ult. I removed two erates of sections of twenty-four each from one hive all perfectly sealed and even, in fact, quite interchangeable; these had the open sides and no separators, no propolis, and sections almost as clean as when put on. I have always looked on separators as a nuisance, but a necessary evil, and for the future shall work without them, hut such good results will not, according to my experience, be obtained unless open-sided sections he used, as the bee-ways appear to form the boundary between each comb. I am always careful to apply the spirit level to each hive hefore supering or putting in foundation. I have tried the plan of putting a handkerchief damped with weak carbolic solution over the sections or frames when removing them, as I have seen recommended in the Journal, and find it quite a success, as it is much more effectual in driving the bees down out of the supers than smoke and no troublesome smoker to be attended to.

South Cornwall, July 2nd. - We have certainly been having a very remarkable season. In May the orchards were ablaze with such a display of blossom as had not greeted our eyes for sixteen years. But for many days there was a great deal of fog, and the bees could not fly freely. Yet it was warm, and nectar seemed in process of being developed, so that when the sun shone out of an afternoon the bees worked with a will. Then came the great heat suddenly, and hawthorn followed apple bloom, to be succeeded by charlock, which has been more abundant than usual, to the trouble of the farmer, for 'what is one man's meat, is another man's poison.' At a far earlier date than usual, we found white clover opening, so that for six weeks there has been no cessation of work. Alas! that the heat has dried up the pasture, and clover is well-nigh at an end for the time. I say 'for the time,' for should the muchdesired rain speedily fall, I have great hopes that we may have a second crop of that on which our honey harvest chiefly depends. The first crop has been a small one, and for some days the flow of honey has not been great. Nevertheless, I can show a nice lot of well-filled sections. I should say that clover is about three weeks earlier than usual.

Glanelywedog, Llanidloes, July 4th.—I have just taken about 35 lbs. of honey from one of my hives, samples of which I send you, and I should very much like to know your opinion of it. I have been getting my bees to build out as many sections as possible, to be ready for the heath honey. The above honey is some extracted from unsealed sections. It was just twelve months to-day I commenced bee-keeping, but the first stocks I had got so much knocked about in transit that they all died in about three weeks. About last Angust I got a hive of bees on ten frames. Later on 1 got three lots of condemned bees which I successfully hived, making two lots of them. These three stocks came through the winter safely. No. 1 stock: 2 bodies with 22 standard frames, and 1 crate of 21 sections, ready for 2nd crate. No. 2: 10 frames and 108 sections, 35 lbs. of honey extracted to-day, remaining sections three parts filled. No. 3: 2 bodies (22 frames) and about 90 sectious, more than half sealed. How is this for success? I may here say that I have taken the B. B. J. and attribute most of my knowledge of bee-keeping to its pages. As one of a great many I tender you my best thanks for the very valuable information it contains week after week. Beside the 35 lbs. extracted to-day, I have taken at least 25 lbs. from the frames in the different hives this season.-W.H. H.

The darker honey is unexceptionably good, both in flavour and consistency; the lighter requires ripeuing, and though of good body, you would not find it marketable. success has been grand.—ED.]

NOTICES TO CORRESPONDENTS & INQUIRERS.

Letters or queries asking for addresses of manufacturers or correspondents, or where appliances can be purchased, or replies giving such information, can only be inserted as advertisements. The space devoted to letters, queries, and replies, is meant for the general good of bec-keepers, and not for advertisements. We wish our Correspondents to bear in mind that, as it is necessary for us to go to press in advance of the date of issue, queries cannot always be replied to in the issue immediately following the receipt of their communication.

All queries forwarded will be attended to, and those only of personal interest will be answered in this column.

LL. E.—The bees will leave the glass jar if it be taken to a darkened room where they will fly to the light; or use a box fitted with a bee-trap so that they can get out but not in. 2. Extracting and Feeding .- Extracting should be completed as soon as possible after the close of the honey harvest. If, after the honey harvest you keep the bees breeding by stimulative feeding, this should be discontinued by the middle of September, and the stocks then fed up as rapidly as possible with syrup of a thicker consistency than that used for stimulative feeding.

3. Swarms have heen known to fly long distances in search of a location. 4. Bees in a tree. - The only way of driving bees from the tree would be to inject smoke through a hole below the nest and drive them into a skep placed above. It will be necessary to secure the queen. The operation is a difficult one; and except in the hands of an expert there is much probability of its failure.

A. H.—1. Erratic Swarm.—Bees do nothing invariably: so it is with swarming. Whenever we find a swarm leave a barframe hive, after placing them in one, we provide them with a frame of uncapped brood. They, like many insects and animals have a strong attachment to their youngalthough with bees it is any other bees' young as well; and this prevents their leaving the hive. An idea prevails among several advanced bee-keepers, that when a swarm clusters they send out scouts in order to find a location, these returning lead the swarm off to the place they have chosen; if so, moving the hive some distance away from the position they clustered on before sconts returned would have the desired effect. 2. Cast on Back Frames .-Remove the front frames now they have got properly to work on back ones, and add gradually. 3. Bees tumbling out of Hive.—No doubt it was one carrying out a dead bee or a robber. The queen does not 'tumble out' in the arms of her consort in so unceremonious a manner.

Northumberla.—Mr. Webster's Tour in Northumberland.— You will see that a further account of same is published in the Bee Journal of the 23rd ult., and also another in the issue of 30th.

M. E. Kirk.-I. Injured Queen.-The queen sent was very badly injured on the third segment of her abdomen. This could be seen from the outside; any internal examination was impossible, as she was dried and decomposed beyond such. You did quite right in adding the swarm. It is sometimes eight or ten days before a queen commences to lay, and even longer. 2. Bees attacking Chickens.-Numberless cases of this description have come under our notice.

D. M.—American Cloth.—There is no objection to the use of American cloth over sections.

Exton.—Winter Stores.—Leave the capped stores in the body hive untouched, they will be of service for the

Ashleigh.—Re-queening.—When you observe symptoms of failure in your queens will be the proper time for re-

queening.

T. D. Schoffeld.—The bees are best-tempered when they are busy bringing in honey, this would be the best time for manipulating. Manipulation should only be performed when absolutely necessary. Over-manipulation will make the bees savage, and is injurious to the stock.

J. A. J.—Bees building outside Super.—As the super does not cover the frames, and the bees have made their way into the space outside the super and bar, and built comb between the inside and the outside walls, the sooner the extra comb is excised the better. Use a little smoke to remove the bees, and the comb can be easily cut away to the level of the top of the frames with a common tableknife. To prevent the repetition of such an occurrence cover the ends of the frames with a piece of flannel or wood, and so oblige the bees to store their honey in the recognised receptacle. If one super be not sufficient place a second under it.

C. D .- Transferring .- The bees are re-establishing themselves now, and transferring should be postponed to the

end of the season.

E. Sag.—1. Separators. — Have you foundation in your sections, and has it been inserted in the middle of the top-bar? If these conditions have been observed the bees would not, except in isolated cases, have built to the separators.—2. Bees Hanging Outside.—To prevent the bees hanging outside in the idle way described, we should recommend that the hive be raised, and a frame-hive or a flat-topped skep be placed on the stand under the old hive, when the bees would in all probability take possession of it; or drive them in by smoke. Most probably the skep is clogged with honey, and the bees have nowhere to store their honey.

Show Announcements.

Giving Name and Address of Secretary, Date and Place of Show, Date of Closing Entries. Terms: Three Insertions and under, Two Shillings and Sixpence; additional insertions, Sixpence each. No charge made to Associations whose Shows are announced in our general Advertising Columns.

July 11-15.-Royal Agricultural Show at Newcastle-on-Tyne. J. Huckle, Kings Langley.

July 14 .- Oxfordshire Association at Headington. Hon.

Scc., Rev. F. C. Dillon, Enstone.

July 21.—Prescot Horticultural Show. R. Rigby, Secretary, Station Road, Prescot, Lancashire.

July 20-22.—Lincolnshire Agricultural Society at Spalding. Entries close July 4. R. R. Godfrey, Secretary.

July 26-28.— Gloucestershire Agricultural Show at Cheltenham. Entries close July 12. W. D. Slade, Sec. July 26, 27.—Warwick Agricultural Society at Sutton Coldfield. J. N. Bower, Secretary.

July 27.—Bishops Waltham Show. (Hants and Isle of Wight Association.) H. W. West, Hon. Sec., Swanmore

House, Bishops Waltham.

August 3-5.—Yorkshire Agricultural Society at York. Secretary, H. L. Rickards, Poole, near Leeds.

August 9, 10.—Irish Bec-keepers, Association at Salthill Gardens, near Dublin. Entries close August 2. Hon. Sec., Henry Chenevix, Blackrock, Dublin.

August 14.—Handbridge, Chester St. Mary's Horticultural Show. W. E. Little, Hon. Secretary, Eastgate Row,

August 24.—Lancaster Agricultural Show. W. Liddell, Hon. Secretary, Dale Street, Lancaster.

August 31-Sept. 3.—Royal Manchester and Liverpool Agricultural Show at Manchester. W. Lees McClure, Hon. Secretary, The Lathoms, Prescot, Lancashire.

Business Mirectory.

For the use of Manufacturers and Purchasers of Bee-

keeping Appliances.
The Name and Address and Business of any Manufacturer will be inserted in this List, under one heading, for One Pound per annum. Additional headings, Five Shillings extra. Advertisers in 'The Bee Journal,' whose orders amount to Five Pounds per annum, will be inserted Free.

LYON'S Patent METAL

THE only perfect pattern. The metal being flush with the inside of the Hive side, CANNOT BE FIXED TO IT BY PROPOLIS. All the so-called Improvements CAN.

The Special Alloy used allows them to be LIGHT YET STRONG. One gross weighs 51 lbs.

Price for 1887 5/6 per gross.

DR. PINE'S VEILS.

Prize Medal, 1879, for the best Bee Dress. The only Medal ever awarded to a Veil, **2**/**2** each, post free. Every genuine Veil bears the Registered Trade Mark.

DR. PINE'S LOTION.

The ONLY CURE for Stings, 1/8 per bottle, post free.

CHESHIRE CURE.

Guaranteed, with Directions, 1/2 per bottle, post free.

Salicylate, or 'Sting Preventer.'

HIVE MAKERS supplied with SPRINGS, GLASSES for Sections, PHENOL, METHYL SALICYLATE, in bulk, &c., &c., at lowest prices.

F. LYON, 94 Harleyford Rd., London, S.E.

MANIPULATE WITHOUT SMOKE!

Entirely supersedes the Smoker, both in Simplicity and Effectiveness. No 'going out.' No tainting or soiling of combs. Always ready for use without any preparation. Can be carried in pocket.

With Bellows, 4s. 6d.; postage, 4 d. Without Bellows, 3s.; postage, 3d.

Can be adjusted to any ordinary smoker bellows,

6 oz. Bottles of Agent-carbolic acid, oll of tar, and water proportionably mixed-6d. each.

WEBSTER'S SWIVEL FRAME-LIFTER

With this appliance, frames can be removed from hive. Examined on both sides and replaced without inverting, and with one hand only, leaving the other free to perform any manipulation, at the same time preventing the soiling of hands with propolis. 1s. 6d, each. Postage 3d.

Send for ILLUSTRATED CATALOGUE of all descriptions of Appliances. Post free on receipt of post-card.

AWARDS LAST SEASON.

Ist Prize, Silver Medal, Royal Counties' Agricultural Show. Highest Award, Bronze Medal, Colonial and Indian Exhibition, for Bee Subjugators.

2nd Prize Bronze Medal, Colonial and Indian Exhibition,

for useful Inventions introduced since 1883. 2nd Prize, Altrincham, for useful Inventions.

Opinions by a few Bee-keepers of WEBSTER'S FUMIGATOR.

Opinions by a few Bee-keepers of WEBSTER'S FUMIGATOR.

'I am delighted with its action. In about five minutes I had all the bees out of a very large skep. It does its work much more clear than the Smoker, and your vision is not obstructed by smoke in operating.'—A. W., MONMOTHENIE.

'Was away on expert work and came across a strong cross-bred stock with a very bad character, a few days before they had completely baffled their owner. I found them with very slight unigation as quiet as sheep. I and all who have seen it used are very much pleased with it.'—W. E. B., WILTS.

'I have used your Fumigator and find it more effectual than a Smoker.'—S. L. G. H., Herts.

'Fumigator was more effective with a hive of Syrians than anything I have yet adopted.'—B. E. W.

'I have the pleasure of hearing the strengest testimony to the value of your Fumigator as a bee-quieter.'—G. A. P., IRELAND.

'I think it is a great been; myself, I shall never use a Smoker again.'—W.W. W., Yorks.

'The most vicious Eastern hees are utterly beateu.'—F. CHESHIRE, Actor.

'Heaving used your Fumigator I am so estisfied with it that I

'The most vicious easeer a nees are enterry occavea. — F. Chestiffer, Acton.

'Having used your Fumigator, I am so satisfied with it, that I shall not use a Smoker again. — A. H.

'It does its work quickly and well, and has the advantage of being ready at a moment's notice without lighting or any preparation. — W. R. F., Middlessex.

'Found it succeeded admirably. — W. F. H. M.

'I drove a skep in five minutes with your Fumigator; never could be the moder of fetaen minutes with smoke. No more smoke for me.'—

do it under afteen minutes with smoke. No more smoke for me.'-

do it under fifteen minutes with smoke. No more smoke T. E., Ireland.

'I am quite satisfied with it.'—H. B., Essex.

'I find it acts well with the bees.'—C. D. C., Surrey.

'I have much pleasure in bearing testimony to the value of your invention.'—W. V. R., Devon.

'I have used your Fumigator with great success and appreval.'—W. G. C., Experr (Ist Cluss), British B.K.A.

'I like it exceedingly.'—B. L., Sussex.

'It gives me great satisfaction.'—A. H., Berks.

'I must say that it is most efficient; I have done with smoke.'—H. W. W.

H. W. W.

'It gives me great pleasure to be able to praise your grand invention so highly.'—J. M.

SWARMING SEASON. TIME SAVED IS MONEY EARNED!

All Goods ready for instant Delivery.

Just to hand, a Shipment of the Finest and Whitest AMERICAN SECTIONS ever imported, 11/- per 500.

BEES.—ENGLISH SWARMS, 106 each. We also have on hand Benton's First Grade CARNIOLAN QUEENS, 9/- each; SYRIANS, 17/6; PALESTINE, 12.6.

NUCLEI (THREE FRAME).—CARNIOLAN, 20/-; PALESTINE, 25/-; SYRIAN, 30/-; including Combs, Brood, and Food. SWARMS at same prices; if in Hives (TEN FRAME), add 5/-.

SYRIO-CARNIOLAN Home-bred QUEENS.—These are extremely Prolific, stocks Winter well, and are good Honey gatherers. See B. B. J., p. 22. A limited number from 7/6 to 10/- for selected.

WOIBLET SPUR EMBEDDER, 1/6 each.

EDEY'S Improved SMOKER, with Moveable Shutter and Flue Cleaner, 2/9 each.

Fuel for ditto, 3d. per lb. BINGHAM, Imported, 7/6.

EDEY'S COTTAGER'S EXTRACTOR (52). This revolves two Combs at a time; the Honey may be emptied by the Screw-valve at foot. Not shown in engraving. Price 17/6; Crate, 2/-.

EDEY'S Method of Fixing FOUNDATION in Dovetailed Standard Frames, Wired. Send for WIRING OUTFIT of 1 dozen Frames, Foundation Nails, all necessary Tools, 7/6. See List.

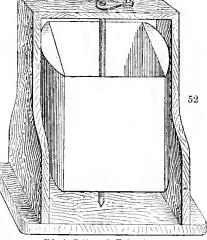

LOCK-UP TRAVELLING CAN, to hold 56 lbs. Honey. Price 5/9.

NESTED TINS for Honey, the Set of 4, holding together 35 lbs., price 1/4; postage 6d.

A Large Stock of HIVES, FRAMES, SECTIONS, and most other Goods of approved Quality are waiting Orders. Promptly, and have not received a complaint. These we can fill

DOUBLE your HONEY HARVEST by Using WORKED-OUT COMBS!

Clean WIRED COMBS in Frames, 10/- per doz.

CHEAP, STRONG, EASILY MANIPULATED.

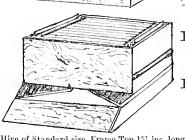

EDEY'S DOUBLER (7 A). Complete for Doubling or Tiering. As shown, with 20 Frames, 2 Dummies, Waterproof Cover, Contracting Entrances, price 10/6. In flat, each, 5/-.

For Supering: Complete Hive, 6/6; Section Crate, 2/6; Additional Body-box, 2/6; Crate of 5 Hives, 23/9.

THE UNIVERSAL (No. 7). Of superior workmanship, high outer sides. A first-class Hive for general work, with Super Crate, price 12/6.

FOUNDATION.—In addition to the ordinary Brood and Super, we have a few Parcels of very Thin and Delicate SUPER FOUNDATION, for filling Sections completely. Average weight, 20 sheets to the lb. 3/6 per lb.

EDEY'S DOVETAILED FRAMES. Cheapest made. No Frame-block needed. 2/- per dozen; 12/6 per 100.

Hive of Standard size, Frame Top 151 ins. long.

For a full line of our Manufactures, see List, free.

WASPS.

We have of late been much exercised in our minds by the reports which have reached us respecting the paucity of wasps. What has become They have not recovered from the of them? singular fatality which swept over them last year. They have 'fallen from their high estate,' and they now appear to be lying in a low and abject condition. One correspondent lately remarked that he had not seen a single wasp this year, and inquired whether they had disappeared from the face of the earth; another said in our last issue, 'Wasps are unusually scarce this year; I don't think I have seen half-a-dozen.' In the spring we heard little of the appearance of queen-wasps; and so far as reports reached us we might say that their number might be counted 'on the fingers of one hand.' And this condition draws forth no sympathy for these insects. While we hear of hobbies being made of humble bees, beetles, ants, butterflies, &c., who ever heard of wasps being so affectionately treated, or of anyone desirous of cultivating a closer acquaintance with them? Wasps are a kind of Ishmaelitish insect, 'their hand is against every man, and every man's hand is against them.

What a contrast does the report of queen-wasps this year present with the large number that were seen and captured in the spring of the preceding. Then we heard of these wasps being killed by the hundreds; and in one Devonian village above a thousand were destroyed. We fear that the 'wasping season' this year has not been a success, or very profitable to those village lads and lasses who by the capture and destruction of those insects manage to gain some little addition to their pocket money. We are inclined to think that last year the employed gained an advantage over those that employed them; for, as the result proved, not one in the hundred of those destroyed would have become, had their lives been spared, founders of colonies of wasps. It was evident, that, owing to some natural obliquity, the female wasps at the close of the autumn of the previous year when they retired to their winter's sleep had not been mated. It is a curious problem for those who take an interest in natural history to solve how it came about that the number of queen-wasps was so abnormally large in the spring of 1886. Was it that the wasps had by some mysterious intuition become aware that something had gone wrong in the 'even tenour' of their existence, and that there was some fear of their numbers being so reduced that they would not be able to perform that portion of work which by Nature's law is allotted to the species; and were they therefore prompted to raise a larger number of queens than usual, so that, haply, the mistake might be rectified, and the 'permanence of the kind' at the end of the season might not be endangered? Evidently some such apprehension must have passed through the communities of Waspdom. The attempt to ward off the impending danger was not successful, and at the end of the season throughout the United Kingdom the cry arose, Where were the wasps? We can point only to two places, Freshford near Bath, and a village in Aberdeenshire, where the wasps were as numerous and as troublesome as usual.

We do not apprehend that the usual destruction of queen-wasps in spring by bee-keepers can be considered as a very great factor in the reduction of the species in the autumn. From time immemorial a destructive warfare has been waged between beekeepers and wasps with the view of keeping down the number of the latter. One example will suffice. In an old Wiltshire paper we read: 'The Earl of Radnor has for many years paid 1s. per nest for wasps' and 2s. per nest for hornets'—the queen in each case being invariably produced with the nests. It is a kind of harvest for the men "the wasping season Upon referring to the books we find that the sum of 506l. 2s. has been paid for the destruction of wasps and hornets within the last twelve years, being on an average of 42l, 3s, 6d, per year.' But does this extermination have the effect of preserving the hives from the visits of wasps, or prevent fruit from being damaged by them? The zone thus denuded forms a hunting-ground for all the wasps in the surrounding country, and the destroyers do not fare any better or find their fruit less damaged than that of their neighbours.

There can be no doubt as to the injury inflicted on bees by wasps. The author of British Bee Farming says: 'Wasps abound in woody wild districts. I have noticed in one wild woodland in Cheshire that wasps abound in such prodigious

quantities that the peasantry state they cannot from this cause keep bees. One cottager in particular had four large colonies of bees in his garden last summer, strong enough, he thought, to resist any foe; however, every stock was destroyed in the autumn by wasps.' By reference to the past volumes of the British Bee Journal several instances will be found of the same destructive results.

The wasps, however, have their part to perform in the economy of Nature. They destroy an infinite number of aphides, flies, caterpillars, spiders, and other annoying insects. The year 1811 was very similar in respect to wasps as last year; it was remarkable for the small number in the autumn, though that of the females in the spring had been very great; and it is said in consequence of this, that flies in many places were so numerous as to be quite a nuisance. Dr. Ormerod mentions instances where the destruction of wasps has resulted in swarms of flies almost as bad as the plague in the days of Moses. And we were not much surprised to hear that the flies last year were most annoying and persistent in their attacks. One gentleman who had thus been troubled found a vent to his feelings by inditing a letter to the Times newspaper, indignantly declaring that this plague of insects was due to the selfishness of a few bee-keepers, who, for the sake of obtaining a little more honey, had destroyed all the wasps, and the consequence was that insects were everywhere in the ascendant.

Réaumur has observed that in France the butchers are very glad to have the wasps attend their stalls, for the sake of their services in driving away the flesh-fly. As wasps collect little or no honey, they are continually engaged in predatory excursions, and the number of bees, flies, spiders, &c., that they take to their young is enormous. their young increase in greater quantities towards the end of the season, the wasps are not particular whence they obtain their supplies; they then cannot resist the temptations of saccharine substances; they rob hives of their honey; they purloin the sugar from grocers' shops; they enter into the secret places where good house-wives keep their preserves, and they suck the juice from the peach, the pear, or other ripe fruit. So strong are sweets temptations for them that they, like poor peccant humanity unequal to the resistance of surrounding enticements, incontinently rush to their destruction, and easily fall victims to their predacious habits. But wasps, it becomes us to say, though given so much to pillaging, cannot be said to be selfish creatures; the Sic vos non vobis element is as strong in them as in bees, for their object is to provide food for the young brood of their colonies.

Though wasps may be so few at present, they may soon be in our midst again as numerous as ever. White of Selborne says that in 1781 there were no wasps in his neighbourhood; but in 1783 they were to be found in myriads.

There are many ways by which wasps may be trapped to destruction. Dr. Butler says, 'Set by them Sider, Verjuice, sonr drink, or grounds, in a shortnecked vial, open, or other glass, covered with a

paper that hath a hoal in the middle, and so you shall catch many.' Another preventive is, Keep colonies strong and protect the entrances.

We shall be pleased, as a phase of natural history, if bee-keepers will keep notes as to the prevalence, or otherwise, of wasps in their respective

BEESWAX AND ITS CONVERSION INTO MONEY.

By J. Dennler.

(Continued from page 147.)

By the invention of the moveable bar-frame hive and honey slinger the production of wax has sunk to the lowest minimum. The bee-keeper who uses moveable bar-frame hives only allows his bees to build as much wax as he needs comb for brood and honey. The combs designed for the latter are never worn out, and can be used not only ten, twenty, or fifty, but even fifty times fifty years and more, as the damage caused by the slinging is always repaired by the bees. Brood-comb, on the contrary, must from time to time be melted down and replaced by new.

An apiary of twenty to thirty bar-frame hives will only yield very small quantities of wax. It is therefore all the more necessary carefully to collect together all wasted wax in order to melt it down. The most suitable apparatus for this is the sun wax-melter, which consists in a little box of pine-wood with a moveable glass cover. In the middle there is an inclined plate of tin, upon

which the waste wax is laid.

If the wax-melter is placed in a very sunny place the wax melts and flows into a little tin trough, which is placed under the tin plate. The refuse is taken away when the flowing down of the wax has ceased.

Whoever through want of a wax-melter wishes to melt down small quantities of wax should put them in a loose box, place a few laths in a kettle, so that the bag shall not touch the bottom, weight it with a stone, pour water over it, and then let the mass boil. The wax melts and rises to the surface of the water, when it is

taken off after it has got cold.

In order to free the so-called raw wax, which has been obtained in this manner, from any impurities which it may still contain, it is melted once again in a kettle half-filled with water, stirred well together for a few minutes, and then left for about two hours over a moderate fire, that is to say, so that the mass never boils. When the kettle is taken off the fire, it is skimmed and left until the cake of wax has got stiff. The impurities which have attached themselves to the wax have now partly sunk to the bottom of the kettle and are partly sticking to the under side of the lump of wax, from which they are carefully separated with a knife. Many bee-keepers repeat this melting down a second time, and thus get a better, purer wax.

The Adulteration and Analysis of Wax.

It does not altogether redound to the credit of the present age that it is often called the century of adulteration, and this is not to be wondered at. The impure spirit of adulteration has crept into all branches of human work, so that now the predicate 'pure' can be ascribed to only very few articles of trade. Of late attempts have been made to dispossess the honey of our bees by any possible substitutes, and it is not a hair better with regard to our wax. Tallow, stearin, vegetable wax, earth wax (ozokerit), and other inferior kinds of wax are mixed with bees-wax, and as such are used in commerce,

The adulterations of wax, writes Dr. A. von Planta,

are so difficult to detect, that it is scarcely practicable for those who are not experts. Pure bees-wax melts at 6:3°.5°C. I have proved the melting point of twenty-five such pure specimens of bees-wax obtained from different countries, and it entirely agreed with that stated above. But since then adulteration has been attempted with earth-wax, paraffine, and animal fats, the melting point does not provide enough security. Otherwise this method will provide a good criterion for those who are not experts.

There remains, therefore, no other way but to go to the chemist with his analysis of wax, who will undertake the fixation of cerotinic acid and the non-fugitive fatty acids, and from that will provide a much safer

criterion with regard to adulteration.

The following domestic analysis has, however, often afforded good service:—(a.) When wax is chewed there should be no unpleasant taste, and it should not stick to the teeth. If wax is adulterated with other ingredients the taste can be usually recognised. It sticks fast to the teeth, so that the existence of rosin can be assumed. (b.) To separate pure beeswax from adulterated is also determined by first bumping quickly on a hot iron plate a small bit of beeswax which is known to be pure. The smell which is given off is noticed. Then a piece of wax is burnt which is to be examined. If it contains ceresine there is given off a disagreeable, fatty, white shoke, which differs the more from the smell of wax the more ceresine there is mixed with the wax. This is a simple way of proving the purity of the bought artificial combs.

(To be continued.)

HOW MAY I RE-QUEEN MY STOCKS?

This is a chapter for small bee-keepers. The above question was put to me during the past week by the owner of seven stocks. He has kept bees for three years only, and as he has managed to prevent swarming, except in one instance last year, some of his queens are old, and consequently he has three colonies not up to the level of the others, which he rightly attributes to his queens being past their prime, and hence his appeal to me for advice, which I gave him, and now repeat in these columns for the henefit of any who may be in a similar position.

I need scarcely go over the ground of showing the necessity of having vigorous queens at the heads of all colonies if we wish to make bee-keeping profitable. Some queens are vigorous even at the age of four years, but by far the larger majority are not so. Others are almost worthless at the outset, and as the only real 'proof of the pudding is in the eating,' having proved such and found them worthless, the wisest precaution is

to be careful not to breed from such.

As to superseding, the bees will do it, but they will often lose a lot of time over the operation in the very height of the homey season, whereas if we do it for them we can choose our own time and that when honey is not so plentiful. But I will assume that you take all this as granted and proceed to give you the advice I gave my

neighbour.

He wished to re-queen three colonies, so I advised him to proceed thus:—Remove one of the old queens and destroy her; now take the young queen from the stock that swarmed last year, which is his strongest and best, and introduce her to the stock from which the old queen was taken and destroyed. You have thus given one good queen in the place of a bad one, but you still require three queens. Five days after this prepare two empty hives and place them on stands somewhere apart from the rest of your stocks, open the strong stock that is queenless, and you will find several queen-cells, scattered doubtless on two or more frames. If this is so take one frame containing one or more of these queen-

cells with all its adhering bees and place it in one of the empty hives; now give two more frames, without queen-cells if possible, but with its adhering lees, and close and wrap them up snug and warm. Proceed to treat the second empty hive the same way. You will then have divided your strong stock of, say, ten frames, thus:-No. I, three frames; No. 2, three ditto; and the original hive has four left. If they should not each have an equal number of bees you may take a frame from the strongest lot and shake as many of the bees from it on to a sloping board in front of the weakest lot and allow them to run in and thus equalise them. You must be careful to give each lot one or more queencells and its fair portion of young brood. Should all the queen-cells be on one or at most two of the frames you must cut some of them out and insert them into a frame that contains none, as failure must result unless each lot has at least one queen-cell—it is so important that I repeat it to emphasise it. Care must be taken not to crush or violently jar the queen-cells during the operation. 1point out these matters that you may be guarded, but the operation is not so difficult as it reads if you will only go coolly along and neither bustle nor fume nor flurry.

Fourteen days after you may look and see if they are hatched out; let it be done in the evening, because if done at midday it is possible the young queens may be out for a fly while you are examining their home, and you may prevent their safe return. If they are hatched out and there is no young brood in any of the nuclei hives it will be advisable to give a frame from some other hive, and thus prevent all the bees from boiling out with the young queen on her wedding trip. Ten or fourteen days after you may hope to find eggs and brood, and then, of course,

you know success is assured to you.

During this time two of the old queens have been at the head of their colonies, your next operation is to remove them and introduce the young ones into their places; you can unite the bees and combs back again to their original hive or you can give some of them with the young queens when you introduce them into their new homes; for myself, I prefer to give the queens singly. If honey has been abundant the combs in the nuclei will have been filled with stores as fast as the brood has hatched out; if this is so it is advisable to extract at least the lower part of the combs, which should be the brood-nest, thus giving the young queens full room to develop their egg-laying energies.

develop their egg-laying energies.

When is the best time to commence queen-raising? Now; before the drones are killed off, and while the colonies are vigorous and have not naturally lost the swarming impulse. How would you introduce the young queens? By Mr. Simmins' method, if done singly, but by drawing the nucleus step by step alongside the colony and feeding both for one night with scented syrup, and lifting the frames, bees, and all complete, out of the nucleus and placing them alternately with the other frames in the original stocks, if I preferred uniting. I hope none will run the risk of losing next year's harvest on account of having doubtful queens at the head of colonies because of the little trouble involved.

There is still another course which is simple; it is BUY, but it must be from those that have queens to sell, not from—AMATEUR EXPERT.

FRANCE.

In commenting upon the outlook of the French wax market, the Apiculteur of Paris expressed an opinion in one of its recent numbers that the footing which France had set in Madagascar with the supposed pretext of finding new outlets for French goods, was not likely to produce the desired effect so far as the home apiculturists are concerned; for it would appear that at Marseilles, which is one of the greatest wax markets of Europe, prices have already been forced down in consequence of

supplies coming in from Madagascar, now offered at from 2.20 francs to 2.30 francs per kilo. In view, therefore, of this new intruder, the Apiculteur arges home bee-keepers to agitate for an import duty to be put upon Madagascar, as well as upon all foreign wax, except, of course, where existing treaties of commerce render such a step impossible. The *Apiculteur* promises to return to this subject in a future number. It remains, of course, to be seen whether wax-manufacturers, who are large buyers of this article, and consumers generally, will side with bee-keepers in their endeavours to raise the price of this important commodity at their expense.

IRISH BEE-KEEPERS' ASSOCIATION.

A meeting of the Committee was held on the 5th Present: Mr. Read, in the chair; Dr. O'Farrell, Dr. Traill, Dr. Knight, Dr. Allen, Messrs. Sproule, Gillies, and the Hon Secretary. A Sub-Committee had pre-yiously been appointed to draw up a specification of a hive to be recommended for general adoption by the Association with instructions that it should be capable of being made cheaply.

Mr. Gillies, on the part of the Sub-Committee, read

the following report:

Cheap Standard Hive.—Resolved, That the length of top-bar shall be 16 in., out to out, width \(\frac{7}{8}\) in., thickness $\frac{8}{5}$ in., sides $\frac{1}{1} \times \frac{7}{8}$ in., bottom $\frac{1}{8} \times \frac{7}{8}$ in., outside measurement of frame $8\frac{1}{2} \times 14$ in. The top-bar of the frame to be what is known as open-ended with screw distancekeepers I inch in length and $\frac{5}{16}$ in. across the eye outside measurements; the eye screws to be inserted immediately over side-bars. Hive to be 22 in. long, I4½ wide, and 95 deep from top of frame to floor-board inside. Walls, if single, to be of $\frac{3}{4}$ in. weod, with a strip of wood at the top to cover the ends of the frames, and 10½ in. deep; if double, these details may be varied where recessary. The floor to be of 1 in timber planed on both sides, nailed to rabbet in the sides, and, if joined, to be tengued and grooved.

A hive made by Mr. Sproule according to the above specification was exhibited. It will be observed that the dimensions given for the frame are the same as those of the British Association's frame, except as regards the length of the top-bar. Some objection was made to this alteration, but it was pointed out that a considerable saving in the expense of making the hive was

effected by it.

It was also suggested that the best method of keeping the proper distance between the frames should be left an open question; but the Committee decided in favour of the distance-keepers recommended in the report. These, which were introduced by Mr. Gillies some years ago, possess the very important advantage that, according as they are screwed a longer or shorter way into the top-bar, the distance between the frames is varied at the pleasure of the bee-keeper. In the end, after much discussion, the report was adopted without alteration.

THE USE OF HONEY IN CURING ERYSIPELAS.—A neighbour lady tells me that she completely cured a case of this disease with honey, after the doctors had given her child up and said it could not possibly get well. The way she applied the honey was by saturating a sheet with honey, and wrapping the patient in it; but it was a very bad case, and the disease had spread all over the child's body. I suppose all that would be necessary would be to cover with a cloth the part affected, saturating it with honey.—Gleanings in Bee Culture.

Mr. W. Couse, Secretary of the Ontario Bee-keepers' Association, desires us to convey his thanks to Mr. T. B. Blow, of Welwyn, for the donation to the Library of the Association, of his work Among the Queen Raisers of North Italy and Carniola, and to 'Amateur Expert' for forwarding the same.

Correspondence.

The Editor does not hold himself responsible for the opinions expressed by his correspondents. No attention will be taken of anonymous communications, and correspondents are requested to write on one side of the paper only, and give their real names and addresses, not necessarily for publication, but as a guarantee of good faith. Illustrations should be drawn on separate pieces of paper.

Communications relating to the literary department, reports of Associations, Shows, Meetings, Echoes, Queries, Books for Review, &c., must be addressed only to 'The Editors of the 'British Bee Journal,' c/o Messrs. Strangeways and Sons, Tower Street, Cambridge Circus, W.C.' All business communications relating to Advertisements, &c., must be addressed to Mr. J. Hughle, Kings Langley, Herts (see 2nd page of Advertisements).

**In order to facilitate reference, Correspondents, when speaking of any letter or query previously inserted, will oblige by mentioning the number of the letter, as well as the page on which it appears.

OUR HONEY IMPORTS.

The value of honey imported into the United Kingdom during the month of June, 1887, amounted to 17371. [From a return furnished by the Statistical Department H. M. Customs to E. H. Bellairs, Wingfield, Christchurch.

THE NEW RACES, AND THE BEST MEANS OF INTER-BREEDING AND SECURING FERTILISATION.

[1146.]We have now to consider the methods most serviceable for securing the fertilisation of our queens. We can but make every preparation, and the rest must be left at the mercy of the weather. From my own experience I know only too well how sadly disappointing it is to have dull or windy weather just when young queens might be flying. But bee-keepers are ever hopeful, and sooner or later the good time generally

A plan often recommended is that known as the 'Köhler' process. The queens are confined in nuclei placed in a dark, cool room, as also the hive containing drones. About 4 p.m. each day after the queens are five days old, these are stood out facing the afternoon sun, in positions to be numbered, or otherwise marked, to ensure that each occupies the same position daily until the queens are mated. Where a few only are raised this does very well, if the evenings happen to be fine, but when many are wanted, it is quite out of the question.

Though mating by selection can be carried out in spring occasionally, I have found autumn the most favourable time, as the weather, as a rule, is more settled. By making a colony populous with drones queenless early in August, the annual slaughter will not occur; feed heavily, see that they raise no young queen, and you are sate.

Another method that will be generally successful is as follows. Place all queen nuclei and drone hives of one kind facing the south; another variety stand with all entrances facing the west, with a shade board on the south side of each of the latter. The drones and queens of each respective position will then be more likely to fly at the same time. Those facing south at the usual hours, and the others about the time they have ceased.

It has been stated that drones take up favourable positions where they congregate in large numbers awaiting the arrival of the young queens. I have seen the same thing, and am aware of two favourite resorts near here where the roar of hundreds of drones fills the air, and many of them are to be seen sweeping by. Nevertheless, I know as a fact, that where many drones fly from near the starting-point of the queen, she is almost certain to mate with such nearer neighbours if only in sufficient numbers. It appears strange that while many queens may fail to get mated while the weather happens to be not quite favourable, some few do meet a drone, but these, upon examination, will almost always prove to be fine, extra-developed queens. The hint should

therefore be taken, and one should strive to breed only

But to return. Another plan is to restrain all undesirable drones by excluder zinc. Great care must be taken that hives containing confined drones are opened only at early morning and evening, as when once at liberty any hive will accept them during the season; in fact, a large number of those which start on flight from a certain hive, never return to the same, but make their home with any neighbouring stock, until flying again another change is made. Without due care, therefore, little good will be done by uning expludors.

little good will be done by using excluders.

Fertilisation in confinement! What a desirable accomplishment that would be if only it could be reduced to a practical certainty. For many years I have experimented in this direction, as also with artificial fertilisation, but until this season in vain; valuable points have been gained, but the end is not yet. Details of the many trials and experiments would fill a volume in themselves, but would be of little use to the reader. Should present more extensive experiments reduce the matter to practice, then the same shall be explained at some future date.—

S. Simmins.

JULY 4, 1887.

[1147.] 8 a.m.—Well, vesterday was a broiler. I wonder what to-day will be like. Glass falling the least bit. Other things just the same as yesterday. Good morning, my dear bees! Are you all happy and going to be good to-day? You know you have given me but little rest lately with your perpetual threats of swarming; but you have all got plenty of room now and plenty of work to do; so you need not go dawdling and wasting your time like young lovers. The sun is at your back till noon, and the whole dozen of you seem happy and contented. Now, please be good, and do not swarm.

12.0.—Thermometer in shade, 82°. Alighting-boards are black already instead of grey. This is getting serious, and the sun will be round in front of you in half an hour, and burn savagely till six. Can I not help you in any way? Let me see—my wife is away—why not the best pair of sheets? Come, John, and help me to arrange them. Yes, you must put on your veil, for the heat makes them very peppery, and each hive has two sentinels; one has orders to fly straight at your nose, and the other to buzz about your head, asking where you will have it, generally ending by himself selecting the nape of your neck. Now, quick is the word. I have run forward the roof of each hive about a foot. We will lay the sheets along the tops, weighting them with stones, so as to hang down in front and keep the alighting boards in shade. There, my dears, you look now like the old-fashioned bathing-machines I remember in my younger days, with big awnings in front, under which that horrid ogress used to duck me. Now do not fly about wildly as if you had lost your way; your homes are all safe there under the awning, and have all got their numbers painted very large upon them; so you cannot mistake your own rooms.

you in the evening.

3 p.m.—85°. No. 5 really means business. What is to be done? Happy thought, the hydropult! There is still some water in the pond, though the pump in the yard is dry. Now, is not that nice? Ah! I thought

ladies would not risk getting their bonnets wetted, and that you would go quietly to your rooms for a bit. But has it not cooled the air all along the line, and made you look more like bathing-machines than ever?

4.30.—No, I see your majesty of No. 5 will not be put off. I will have all my stuff ready at sunset, if you will only keep good till then. A little more hydropult? By all means. Glass fallen nearly a tenth. I think it

will rain to-night.

8.30.—Decidedly the air is cooller. Now, ladies of No. 5, excuse a little baccy smoke at the front door and on the clusters about it. My screwdriver has prised up your super-do not be alarmed, it is but half full, and you shall have it back again in a few minutes. Then this cloth, damped with nice solution of carbolic, will soothe you while my masons are at work; they have just a smack of apifuge about them. What do I see? Twelve frames all beautifully finished and two section frames nearly full in the rear, besides the super half filled—well, you do deserve praise for good use of your time since you were hived on June 10. Excuse my moving your bedrooms a little; I will do it as gently as I can, beginning from the rear. Now I have slid them all back, leaving a space between the third and fourth, which will just take these three pretty new frames, with their tempting foundation-comb. You can build some splendid nurseries for her majesty in them. I do not think you can want this beautiful sheet of honey; I will give you two more section frames instead. Now you have got your super back, and are safe in bed again, with sheet and blanket comfortably tucked in. Good night, dears; you have been very good, and when I have 'extracted' the comb I have taken, you shall have it close to your house to lick clean.

July 5, 2 a.m.—Hurrah! it is raining.—C. C. James,

Papworth, St. Agnes.

YORKSHIRE NOTES.

[1148.] Prevention of swarming being all the fashion now, and as I still work on the swarming principle, perhaps some of your correspondents will tell me if my present prospects are as good as they would have been without the swarming.

I wintered thirteen stocks—ten in frame-hives and three skeps. I have sold five swarms and have eight additional swarms. Up to this time I have taken 330 lbs. of extracted honey from nine stocks, and have the eight swarms and one stock, with about 350 lbs. of sections on them, mostly finished off. I see in the British Bee Journal of June 30 the Hon. Sec. of the Lowestoft Bee-keepers' Association says that not one swarm in twenty will give a surplus the first year. This is quite contrary to my experience. The first frame-hive I ever possessed, which is ten years ago, filled me ten frames with guides only, and gave me 32 lbs. in sections, and the swarm was only hived on the 27th June and was not taken to the moors. As I stated in a letter to the British Bee Journal this spring, on the swarming plan you always get your old queens superseded, and in doubling in the autumn you get the late brood from two hives, besides having a lot of spare combs to store away for the following year. However, if all is well next year I shall try a hive or two on the non-swarming principle. I forgot to say that, in addition to the 350 lbs. in sections on the swarms, I have taken 33 lbs. in sections.

In answer to Mr. Simmins about queen-excluder zinc, I may say that for six or seven years I have crowded my bees on seven frames (with zinc above) to get them into supers, and have never had a queen go up into the supers, although the swarms would swarm again, for want of breeding room I expect, which causes me always to add a few combs now after they are well started in the supers. I have always got the zinc from Abbotts', but expect it is the same as sold by all the trade.

In 'Useful Hints' this week I see it stated, 'Manipulations should never be undertaken in the heat of the day: the bees are very savage,' &c. &c. [This was written in one of the hottest days of the present hot season.] And in Notices to Inquirers, in the same number, you say, 'The bees are best-tempered when they are busy bringing in honey; this would be the best time for manipulation.' Is not this rather puzzling for beginners?

My bees are always savage for some reason or other, and I could not walk amongst them without a veil and gloves on. I have never bothered them with manipulations, but I fancy that by extracting every year from the same strain of bees they breed more savage every year. I always smile to myself when I see that any one has taken honey, &c., without any protection, and then writes off to the Journal congratulating themselves on their narrow escapes. I always think what a 'funk' they must have been in all the time.

I should much like to see any one come among my bees without protection: I will give them Grimshaw's Apifuge to boot if they will do it. [We recommend our correspondent himself to test its powers, and report.] It would be a deciding test as to its efficacy, but I don't think they (the bees) would ever have the chance to smell it, as they always seem to me to fly tail first.

I quite agree with 'Looker-on' as to Bee Associations, and have always held the same opinions. Unless the Associations can find you a market for your honey, what earthly good are they? They increase the demand for hives and appliances and benefit the manufacturers, but certainly not the honey producers; indeed, they do actual harm to the latter by persuading so many to keep bees that the working man is out of the race altogether from the low prices and difficulty of getting a market of any sort, and yet the Associations were started with the object of assisting the working classes. I hope I shan't bring too great a storm on my head for my heresy, but I am open to conversion.—ARTHUR J. II. Woon, Bellwood, Rapon, July 8th.

WATER FOR BEES.

[1149.] Reading the method of giving artificial supply of water to bees, in last Journal (page 280), I will, with your permission, give you a few details of how I constructed an artificial supply for my bees at the beginning of this year, and which not only gives them plenty of water, but looks ornamental into the bargain, and now, on July 2nd, at 7 p.m., is literally covered by the little water-carriers. In my garden grows a very old and large hazel bush, in middle of which I firmly fixed a barrel and which is now quite hidden from sight by the leaves. This barrel is about a yard from the ground, which here is a little higher than where I give the supply. I have the top end taken out and made into a lid to keep out dirt; the tap hole is in the bottom, and into this I secured one end of a piece of half-inch piping, which piping I run underground to the required spot, where I turn the end straight up about a yard. In this end of pipe I fastened a straight tap, the uppermost end of which I confined with a wooden plug, having a small hole through it into which I inserted a very fine metal tube, so that my stream of water should be as fine as possible.

I then got some mossy stones and made a mound of them some four feet wide at bottom, and finished it off in haycock fashion; at the top I placed a flat, mossy stone through which I drilled a hole into which the wooden plug loosely fitted. The tap is just underneath the flat stone at top, a small space being left for my hand to set on the supply or take off, a small, mossy stone covering the opening when my 'bee-fountain' is at work.

Amongst the stones I filled in soil and planted snow-drops, bluebells, small ferns, thyme, arabis, &c., which

not only look well, but afford a safe footing for the bees as they alight, for the sprays of water which fall on them from the fountain, which rises about two feet above the mound of mossy stones, and is sent hither and thither by every breath of wind.

Many who have known my small apiary for some time, and have come and seen this for the first time, ask, 'Where does the water come from?' In all honesty I am obliged to answer 'From the pump.' But this does not satisfy them, and I then explain the very simple means of conveying the supply, which altogether, giving my labour in, cost me something like five shillings.—ELIHU CLOWES, Blackbrook.

MIDDLESEX B. K. A. AND THE WOOD GREEN HORTICULTURAL SOCIETY.

[1150.] The Wood Green and District Horticultural Society held their Show yesterday and to-day in the grounds of R. D. M. Littler, Esq., Palmer's Green. The Middlesex Bee-keepers' Association were to have held an exhibit for the purpose of showing the great improvement made in the management of bees, and an expert was to attend and give short lessons, &c., in the bce-tent, as per announcement on placards and programmes. Myself and many visitors were much annoyed at their being no exhibit whatever, except a little honey shown in the flower-tent by a member of the Society.

Now, sir, I wish to enter my protest against this had behaviour, whomever it may concern. The officials on the ground were very courteous and extremely sorry—to those who made inquiries—that the expert and the beetent had not arrived, although some telegrams had been sent by them without receiving a reply. No mention of this disappointment was made at the distribution of prizes, and the show passed over as if no bee exhibit had been advertised. As a visitor who went specially to see the bee-tent, I was much annoyed. This kind of treatment will tend to do an incalculable amount of damage to the Wood Green Horticultural Society.—A VISITOR, July 9.

CAUGHT IN THE ACT.

'The sad-eyed justice with its surly hum, Delivering o'er to executors pale The lazy yawning drone.'

[1151.] These three last lines of the Home Rule practices in the commonwealth of bees always struck me as being hard upon us 'the drones,' However being educated I've learnt to deal with facts as I find them; therefore availed myself of my knowledge of hive laws and early last week took the liberty of lodging ontside our strictly governed and well-stored butt; and as through the glass I was contemplating the symmetrical cells of our well-filled and scaled 'super' was surprised to see one of them occupied by a bee, who was again occupied in filling himself with the public property. On looking closely to see where the burglar had entered I observed at the mouth of the cell four other bees just finishing the business of scaling it up—in fact, the thief caught red-handed had been pushed in and scaled up *alive*, 'like maudlin Clarence in a malmsey butt,'—a prompt, albeit severe, yet, as I think, more richly deserved reward for evil doing than the death yearly meted out to us for doing what nature framed us to do. Well, sir, I continued to watch, and in the evening the thief was dead sealed up and left on the scene of his wickedness as a warning and caution to all bees and humans who would sacrifice country to self and the commonwealth to personal aggrandisement. For three days the traitor's body was left to public gaze, then with that regard to sanitary measures in which we are so far ahead of poor humanity, it was unscaled, exhumed, and buried without the camp; and on the next day-again an example of our

unrivalled economy—the cell was refilled with the best lime honey, alas! poor simpletons, not for the workers, Sic ros non robis; but, there, they'll kill me, so I needn't cry for them: they go on as usual, only since the event I relate no more cells have been broken into and a wholesome lesson has been taught that those who are to shuffle on may well lay to heart, as coming from a doomed yet wide-awake, though maybe—A LAZY YAWNING DRONE, July Sth.

P.S.—I think I saw enough of the deceased to state that he was not a foreign invader, but a traitor in the

camp. From which are we most in danger?

EXTRACT FROM A MANUSCRIPT GAME LIST, FISH LIST, &c.

[1152.] 'Glis or Glys, Switzerland, January 28th, 1821. —On the side of a mountain, exposed to the south, many insects came forth and bees swarmed. This was bad management on the part of the farmer, who should have chosen a northern aspect for his hives. The bees, revived by the premature heat, were exposed to considerable inconvenience from the frost a night.' (No doubt.—J. L. S.)

The writer of the above was a well-known sportsman, and in his manuscript book, which I possess, he inserted feathers from various birds, those feathers are not only as fresh in colour as at first, but have printed on the opposite pages a 'photograph' (a photograph without light!) of themselves—especially teal, heron, heathcock, plover, &c., exquisitely defined in brown.—J. Lawson

Sisson.

A LOST AND FOUND QUEEN.

[1153.] I had a swarm of bees out of a bar-framed hive on the 16th June, and removed the queen-cells on the 19th, or rather, thought I did, but being only a novice, must have let an additional one escape me, as a east left the hive on the morning of the 28th, which was at once hived in a skep. About half-an-hour after hiving, it left the skep and returned to the hive. next morning the cast left the hive again, and was again hived in the skep and protected most carefully from the great heat, and in the cool of the evening I searched for the queen, but without success, so left the bees in the skep, and, having to leave home early the next morning, gave my gardener orders to watch the bees most closely and note their proceedings. Early in the day they all left the skep, and went back to the parent hive, when they clustered on the top and upper parts of sides and front. The gardener, thinking something was strange in their conduct, opened the hive and found the queen on the inside of the roof. As soon as he had secured her the bees all quietly returned to the hive, and resumed work, and have almost completed a crate of sections since. I suppose when the swarm was leaving the hive, the queen must have escaped through some opening in the bars, and did not accompany the bees. But what appears to me strange is whether she did not accompany them on the first oceasion, and did they leave the hive on the next day without having had the queen with them from the previous morning?—E. A. Gibbon, Russlare, co. Wesford, Ireland.

FLOWERS AND HONEY.

[1154.] I thought it might be interesting to some of your numerous readers to hear a word or two from me again now that I think I have discharged all my orders for cuttings of Nepeta mussini, borage, and Limnanthes seed. Still, I have got some left. I have received many acknowledgments from those who have received some of the above. Some say they arrived in good condition, while others say that they were so withered that they are afraid they will not strike. No doubt it would have

been better if all had been sent per parcels post and packed in damp moss, more particularly for long journeys. I thought such a thing might happen that I have omitted sending to some who have applied, or any other mistake which may have occurred upon my part. If so I beg them to send me a post-card and they shall be attended to immediately, or if any have failed in striking they can have a fresh supply, but I would advise them to have them sent as above. I have decided to strike a large quantity of Nepeta mussini, and will offer them to our bee-keeping friends later on. Some have inquired what distance apart the plants should be. I have advised 3 feet 6 inches apart each way, thinking that to be an average distance for all kinds of soil, but if the soil is rich and strong 4 feet apart would be better. It is a very pleasing sight to see the large masses of bloom, which look so very handsome more so when a bee-keeper approaches, and sees the multitude of bees at work upon it from early morning until late at night.

When I get away from home I sotice large numbers of bees upon blackberry bloom and other wild flowers, but it is very seldom I see any on them near my home, hence the quantity to be found on the borage and Nepeta mussini. No doubt some would like to know how I get on for honey. Well, Mr. Editor, with your permission I will tell them later on, but it must not be understood that I possess a very large number of stocks, and, again, I have lost some very valuable time this year through not being able to attend to the bees at the proper time. Still, I have no reason to complain. For example, being in want of a little comb honey on Saturday, the 9th inst., I went to one of my best stocks to see if a little could be got. There were three crates of sections upon the same, two containing twenty-four each and one twenty-one, all $4\frac{1}{4}$ by $4\frac{1}{4}$ by 2, the top one contained twenty-one beautifully filled and sealed, the second twenty-four equal to the first, and the third had about one dozen completed and the remainder in a more or less advanced stage of completion. This erate I did not disturb; but being a large hive I could examine four frames at the end of the section crate without disturbing the crate. The outside comb had nearly two inches of room; this was completely crammed with beautifully sealed honey and fastened to the hive on the outside, apparently for support. This comb weighed 7 lbs. gross weight. This I took away. The second had sealed honey about twothirds of the way down, and the third and fourth about half-way down; the remainder parts of the three combs being completely crammed with beautiful-looking and sealed brood. The hive holds fourteen frames, so there were ten which I could not examine without disturbing the last set of sections, which I did not do. I gave the bees, in exchange for the forty-five sections and the heavy frame, one frame of foundation placed between two frames containing brood. It should be distinctly understood and well borne in mind that all plants grown for the production of honey should have a good airy and sunny position, or the honey which they produce will be of an inferior quality and very much less in quantity.— C. H. W., Aylesford, Maidstone.

DIVIDING FOR INCREASE.

[1155.] To do this successfully, queens should be reared and ready to furnish each new swarm with a fertile queen at the time of forming such colonies; the time

saved in breeding is very important.

To Rear the Queens.—Form a nucleus from the strongest colonies, select a comb containing capped brood and plenty of eggs and young larvæ; look it over carefully lest the old queen is on it; cut one-third or one-half the lower part out of this comb, which gives the bees room to build cells on the lower edge—a convenient place for the operator to remove them, when forming

other nuclei. Place this, with its adhering bees, in an empty hive, and next to it another comb containing honey and bee-bread; this affords food and protection. Give the nucleus colony at least a quart of bees, and put it on a new stand, and confine the bees there until the next morning. Then contract the entrance so that but one or two bees can pass out at the same time. They will usually build six or ten or more queen-cells on the eighth or ninth day after the nucleus was formed. Then open the hive, and, with a very thin-bladed knife, cut out all the queen-cells but one, and use them immediately in forming other nuclei, by attaching each to a frame of comb and bees taken from an old colony as before described, and placed in an empty hive.

In transferring queen-cells care must be taken not to expose them to cold or heat, or to denting the cell. Leave about an inch square of comb at the base of the cell, and insert it among the young brood. Never leave a nucleus colony destitute of young brood after the young queen hatches, as the bees are very apt to abandon the hive when the young queen goes out to meet the drone. Now watch and care for the young queens until

they become fertile.

When and how to Increase.—When your colonies are strong and you are ready to form new ones, first cage the young queen, then from a number of colonies take sufficient frames and bees to form a good colony of bees; close up the hive of the new colony until the next morning, then open it, and on the second or third evening liberate the queen. Continue in this manner until you have such increase as you desire, but in all the operations use plenty of smoke.

Again the forwardness of the season must be your guide as to the time to form colonies. You can rear queens early and keep them in readiness; a colony of bees without a fertile queen build mostly drone-comb. The bee-keeper that rears queens for new colonies must have the hives for the season ready early. Success is not in the number of colonies on hand; it is not bees we want, it is honey. It is not a great number of workers in one field that will secure this, but a large force in each hive.

The apiary should have the cheerful ray of the morning sun. A very good way to check robbing is to place a bunch of grass or wet hay over the entrance to the hive. The bees will find the way to their own hives, but robbers will be caught by the sentinels while passing through the grass. The moth is a scavenger which comes to clean up the wreck of the negligent bee-keeper.—S. D.

BARBER (Semi-tropic California).

Reviews.

Praktisk lommerbog i tidsmæssig biskjötsel. By Ivar S. Young. (Christiana, 1887.)—This is a handy little volume on bee-keeping much in the style of Modern Beekeeping published by the British Bee-keepers' Association, and from which some of the illustrations are taken. The well-known frontispiece entitled 'Hiving under Difficulties' has been adapted to the super skep in use in Norway. This book is nicely compiled, the illustrations neatly executed, and it cannot fail to be useful to the Norwegian bee-keeper. Mr. Young has added at the end a list of honey-plants with their times of flowering and values. We wish this work every success, and hope it may be the means of spreading a knowledge of bee-keeping amongst the agricultural classes.

Förer i biavl efter Thos. Wm. Cowan, translated by Hans Ersler, editor Tidskrift for biavl. (Kjobenhavn, 1887.)—This is a translation of our Guide-book into the Danish language. In order to make it of additional service to the Danish bee-keeper, the descriptions of several of the best frame-hives in use in the country have been introduced, making it a complete guide-book

for the practical management of bees in moveable comb hives. The same illustrations have been used as in the last English edition, and the printing is well done.

Nouvelle flore du Nord de la France, et de la Belgique pour la determination facile des plantes sans mots technique avec 2282 figures par Gaston Bonnier et Georges de Layens. (Paris, 1887.)—This is a new work just received. It is on the same principle as the Nouvelle flore we reviewed some time ago (p. 132), and what we said then applies equally to this book. There is one advantage the English student would have in perusing the present work—namely, that it approaches more nearly to the British flora as it contains all plants found along the sea-coasts of Belgium and France, which are mostly also common to our shores. The figures are a great assistance in determining floras with the greatest ease, and we only wish it could be translated into the English language for the benefit of those who do not understand French.

The Production of Comb Honey, as practised and advised by W. F. Hutchinson. Those who want to know all about how to produce honey in sections should get this pamphlet. Mr. Hutchinson is a well-known American bee-keeper, and he writes from practical experience of the subject. The pamphlet contains chapters on supers, separators, sections, tiering up, driving swarms on empty combs, foundation, and on empty frames. Mr. Hutchinson hives his swarms upon empty frames, although the nonuse of foundation is only one part of the 'system.' The reasons are fully explained in the pamphlet, which we recommend to our readers.

FOR BOYS AND GIRLS.

BEES FOR BOYS.

The bees I like best are Humble Bees. I have kept them now for three successive years and am improving upon their habits. Last year it was Bombus lapidarius, but this year it is Bombus terrestris. You have given a sketch of my hive before in the Journal, though I have made alterations in it; for instance, I took part of a section, cut a hole in it, and made it as a porch to keep out the light. Then I put a dividing board, with a hole in it, and between that and the porch was the 'feeding-place.'

Situation of Nest.—While one of my playmates was finding the nests of birds in the woods he turned up a sod, and saw a lot of pieces of grass, hay, &c., and, being on the look-out, as I had told him, for a humble bee's nest, he gave it a few taps, to see if there were bees inside. But he heard no noise, and when I arrived I looked into it more closely and found it was really a

nest.

It was behind a holly-bush, under a sod, and it seems as though the queen built there to be out of the sun's rays, so, according to nature, I placed the hive out of the sun's rays when I got home. When I saw the nest you may be sure I was not long in leaving bird-nesting,

running off home for the 'Clock-case' hive.

Taking the Nest.—I laid the hive down near the nest, and began pulling the outside straws away and packing them in the clock-case, the bees buzzing all the while. At one time out came a very large bee, fluttered its wings as if in anger at being disturbed, and then went back, but never took to flight. I guessed this was the queen, because all the other bees were small ones, and you may judge I kept still while she was out, lest I frightened her and she flew away. When she had got nicely settled I commenced operations again, and lifted out the whole nest, wrapped round with hay and fastened together with wax, which, by the way, is not like the honey-bee's wax, it is nearly black; but, as soon as I was sure of the queen, bees, and combs, I packed it temporarily and hastened home. I will tell you more about them shortly.

I should like my young friends to note that when I mention bird-nesting, it is not to rob them.—Darcy GRIMSHAW, Horsforth, near Leeds, June 25th.

ON BEES.

[The following has been forwarded to us as a first attempt at poetry by a young beginner in bee-keeping.]

At early morn, if clear and bright, The busy bee will take her flight To gather food from fields around, Where sweetest nectar doth abound.

To clover bloom she hies in haste, Nor does she useful moments waste, But flits about from flower to flower With merry hum each golden hour.

Well laden with the treasured sweet, For occupants of hive to eat, She wings her way on homeward track, Nor thinks her fastest speed too slack.

With haste she journeys on her path, O'er tree, and hedge, and nearest rath, And flying straight for open door Arrives thereat with many more.

Discharging now her honey sack With eager haste she hurries back, Nor stops to work each sunny hour Till forced to fly from passing shower.

Her sister worker with her feet Collects the bread for brood to eat; And toiling home with laden spoil Arrives exhausted with her toil.

Within the hive is ever rifc The constant din of active life, Where none employment ever lacks From queen to bees secreting wax.

The mother-bee her calling plies To crowd the hive with busy lives; Within the cells with graceful bend She drops the tiny eggs on end.

Her subjects which remain at home Engage with will at building comb, While some, with half-digested food, Proceed forthwith to feed the brood.

Some more are using nature's glue, Collected by a merry few From poplar bads, and other such Buds from which it oozes much.

The 'lazy drones' (?)—how much they eat Of luscious honey pure and sweet-Keep up the heat, 'tis understood, Of hive, and help to hatch the brood.

But their chief good and greatest need Is surely this in very deed-To fertilise the virgin queen In aerial regions seldom seen.

At length, the hive being overstocked, And future work being well-nigh blocked, Some bees with queen proceed to roam Iu search of such another home.

J. Smyth, Drumwhan, July 5th.

Echoes trom the Yives.

'Honey Cott,' Weston, Leamington, July 4th .- Glorious time for bees and bee-keepers, both are kept well awake by plenty of hard work, the roar of the bees continually is something to make one glad. An old-fashioned bee-keeper, who has five stocks in skeps and only had one swarm and would not feed his bees because it was end of May and beginning of June, and nearly let one lot die, sees the folly of it, but I dare say he will hold to his old ways still, as he has been shown and told the right way many times before.— JOHN WALTON.

NOTICES TO CORRESPONDENTS & INQUIRERS.

Letters or queries asking for addresses of manufacturers or correspondents, or where appliances can be purchased, or replies giving such information, can only be inserted as advertisements. The space devoted to letters, queries, and replies, is meant for the general good of bee-keepers, and not for advertisements. We wish our Correspondents to bear in mind that, as it is necessary for us to go to press in advance of the date of issue, queries cannot always be replied to in the issue immediately following the receipt of their communication.

All queries forwarded will be attended to, and those only of personal interest will be answered in this column.

J. J. W. C .- The hees forwarded are but a slight remove from pure blacks.

W. H. A.—Excluder-Zinc.—Your experience in the use of excluder-zinc is similar to our own. It is, however, approved and much used in America. Much depends on the manner of application. The adapting-board should allow full three eighths of an inch as a bee-space on the under side of the zinc. When this is allowed bees will often work quite freely through the zinc into the supers above. Probably your bees would have swarmed zinc or no zinc.

LANARKSHIRE.—Hives, &c.—The least complicated hive substantially built of well-seasoned wood is the best. A plain hive, taking twelve standard frames, capable of doubling and storifying, will suit you best. For such a hive you will be charged about 15s. We cannot recommend dealers. W. B. C. are the initials of the inventor of the metal ends, which are simply distance guides for frames. Wired foundation has thin wires embedded in the wax, to strengthen the combs and prevent falling from heat, and from breaking in the extractors.

- S. M. Moving to Heather. If the weather prove five during the heather bloom it will pay well to remove your bees to the centre of their work. A friend who kept bees within two miles of heather repeatedly noticed that his bees did not visit it at all, even in fine weather; but when he moved them to the heather, they rewarded him with a plentiful harvest of the finest honey.
- J. C. I.—Honey.—We think the flavour of the honey forwarded good, and find nothing in it objectionable what-ever. We should think it probably got from sainfoin, or clover. The taste of prussic acid we are not acquainted with.
- Antrim.—1. Removing Bees from Trees.—It is always difficult to give advice as to removing truant swarms from trees and other awkward places. Probably by placing a skep over the hole 10 inches in diameter, and smoking from below, they may be induced to leave and ascend into the skep; but we rather doubt it. Failing this, can you cut out the combs they have built and brush the bees from them into a hive containing some combs and brood, andt place the latter over the top hole to induce the straggling bees to join their fellows? This will depend on whether you are able to reach them through the top hole. If not removed they will, as you say, probably die during the winter. 2. Driving. -We should drive a swarm from the straw skep now, and place them in a bar-frame hive on, say, four sheets of foundation. In twenty-one days after all the brood has hatched drive all the bees and unite them to those in the bar-frame hive, giving more foundation, then secure all the honey in the straw skep; and should the season remain favourable those in the bar-frame hive will be in good order for winter. If necessary you must feed the swarm, and if the stock has not enough about the middle of September to last them over winter, that must be fed up as well. 3. Probably No! except the season is remarkably fine in late autumu to allow comb-building and feeding.
- J. B. S.—Red Clover.—Being red clover, it is very questionable whether the returns would compensate you for the trouble; moreover, being only half a mile distant, the bees will work it if they can find nothing more profitable. Were the distance greater, and the crop white or alsike clover, or better still, sainfoin, it would probably be worth your while, but under the circumstances, you had better 'let 'em alone.'

Robert Welford.—Books on Bee-keeping.—We can confidently recommend for your use as a beginner Management of Straw Skeps (1d.); Modern Bee-keeping (6d.), Cowan's Guide-book. These will give you all the information you require, and will be sufficient till you are further advanced in bee-keeping. The above books are procurable from J. Huckle, Kings Langley, Herts.

- High Peak.—Bleaching Honey.—Exposure to the sun will cause the wax of sections to whiten. Stirring honey will, by destroying the grain, give it a whiter appearance. But we should prefer honey to remain in its natural colour.
- T. P. M.—I. Specific Gravity of Honey.—This depends on the chemical composition of honey. Sometimes honey is found as liquid as sweetened water, at other times so dense that it becomes granulated before the cells are sealed. There is consequently much difference among the authorities; but the average specific gravity of honey is 1:350. 2. Cubic Contents of one Pound of Honey.—If we take as our basis clover honey, the specific gravity of which is 1:370, it would be rather less than twentyone enbic inches to the pound.
- H. J. C.—Rotten Brood.—The five pieces of comb were forwarded to Mr. Cheshire. This is his reply:—'There seems some mistake. I have been unable to find any evidence of rotting broad, and but one cell sealed, and that contained a mature bee (dead). Bees do die in the cell from other causes than either foul brood or chill, but the question is too large to discuss in small limits .--F. C.
- IGNOBAMUS. The easiest method would be to melt the combs.
- E. C. T .- I. Carbolic Acid Solution. The carbolic acid solution consists of lour tablespoenfuls of the acid to one quart of water, and well shaken before using. A portion of the mixture is kept in a wide-mouthed bottle, and applied with a goose-quill. 2. Sections.—Sections must be carefully scraped to remove propolis.

Received from Messrs. Abbott Bros., Southall, their catalogue, containing prices for June, July, and Angust, 1887.

Show Announcements.

Giving Name and Address of Secretary, Date and Place of Show, Date of Closing Entries. Terms: Three Insertions and under, Two Shillings and Sixpence; additional insertions, Sixpence each. No charge made to Associations whose Shows are announced in our general Advertising Columns,

July 21.—Prescot Horticultural Show. R. Rigby. Secretary, Station Road, Prescot, Lancashire.

July 20-22.—Lincolnshire Agricultural Society at Spalding. Entries close July 4. R. R. Godfrey, Secretary.

July 26-28. — Gloucestershire Agricultural Show at Cheltenham. Entries close July 12. W. D. Slade, Sec.

July 26, 27.—Warwick Agricultural Society at Sutton Coldfield. J. N. Bower, Secretary.

July 27.—Bishops Waltham Show. (Hants and Isle of Wight Association.) H. W. West, Hon. Sec., Swanmore House, Bishops Waltham.

July 27 .- Kent Association, at Ashford, Kent. Hon. Sec., J. Garratt, Hockenden, St. Mary Cray, Kent.

August 3-5.—Yorkshire Agricultural Society at York, Secretary, H. L. Rickards, Poole, near Leeds.

August 9, 10.—Irish Bee-keepers' Association at Salthill Gardens, near Dublin. Entries close August 2. 1Ion. Scc., Henry Chenevix, Blackrock, Dublin.

August 14.—Handbridge, Chester St. Mary's Horticultural Show. W. E. Little, Hon. Secretary, Eastgate Row,

August 24.—Laneaster Agricultural Show. W. Liddell, Hon. Secretary, Dale Street, Lancaster.

August 31-Sept. 3.—Royal Manchester and Liverpool Agricultural Show at Manchester. W. Lees McClure, Hon. Secretary, The Lathoms, Prescot, Lancashire.

JULY 21, 1887.

[PUBLISHED WEEKLY.]

Editorial, Hotices, &c.

THE FORMATION OF AN ASSOCIATION FOR NORTHUMBERLAND.

A meeting of bee-keepers and others interesting themselves in the formation of this Association was held in the bee-tent in the Agricultural Show Ground at Newcastle on Thursday, July 14, Mr. McAdams, of Haltwhistle, in the chair. The following resolutions were passed unanimously:—

(1.) That a Bee-keepers' Association be formed for the County of Northumberland in affiliation with the British Bee-keepers' Association.

(2.) The objects of the Association shall be to teach the residents of the county the most profitable and humane system of bee-culture, and to spread a knowledge of the uses and disposal of bee-produce.

(3.) That the Duke of Northumberland be requested to act as President of the Association.

(4.) That the following do form a provisional Committee with power to add to their number, viz., Messrs. R. W. Bell and G. Charlton of Hexham, Messrs. McAdam and J. F. Graham of Haltwhistle, Messrs. Sisterson and Kyle of Bellingham, Messrs. T. W. Atkinson and W. Codling of Morpeth, Messrs. J. Luck and J. Mack of Felton, Messrs. Greenwell and Carr of Alawick, Messrs. Colville and Best of Belford, and Robson and M. J. Archer of Rothbury. The duties of the provisional Committee being to prepare rules, secure members, and make such suggestions as may seem to them advisable for the future government of the Association, and to report to a future meeting to be held not later than the third Monday in September at Newcastle.

Residents of the county being desirous of assisting in the formation of the Association are requested to communicate with the Hon. Secretary. Mr. F. E. Schofield, Newcastle Street, Morpeth.

THE STEWARTON HIVE.

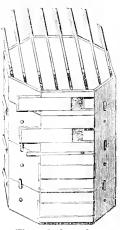

A correspondent who has purchased some Stewarton hives, requests that some instructions should be given in our columns as to their management. He reminds us that since we last described this system of bee-keeping many years have passed away, and

that many new subscribers to the Journal have not had an opportunity of gaining any knowledge of it. In the first volume of the Journal this system was well ventilated by the communications of 'A Renfrewshire Bee-keeper,' who has introduced many improvements into the Stewarton hive, and who has ever had a high opinion of its excellence. In November, 1880, the Rev. Dr. Bartrum read a very valuable and excellent paper entitled 'The Stewarton Hive, the Hive of the Busy Man,' at a conversazione of the British Bee-keepers' Association. Since that time there has been no description of it in the Journal, and, therefore, we have much pleasure in complying with the request of our correspondent.

The hive, as Dr. Bartrum informs us, derives its name from the town of Stewarton or Stuart-town, in the north of Ayrshire, on the borders of Renfrewshire. It is said to have been invented about the year 1819, by a cabinet-maker named Robert Kerr, of that place, a man as remarkable for his skill in bee-keeping, as in the secrets of his particular trade. 'Bee Robin' was the nick-name given by his neighbours to Robert Kerr, and we can well imagine that his skill as a workman assisted him in no slight degree in improving the form of the wooden boxes in which he kept his bees. The octagonal form of the Stewarton hive was without a doubt known before Kerr's time. 'The Renfrewshire Bee-keeper' informs us that its invention is generally ascribed to the Rev. William Mewe, minister of Eastlington in Gloucestershire, about the year 1652. In April, 1675, John Gedde obtained a patent from Charles II. for his octagon boxes. They appear, however, to have been used in Scotland with good success before that date. These octagons consisted simply of a series of boxes of uniform depth, with a 5-inch square central hole in each top. Robert Kerr seems to have introduced the moveable slides of wood working in grooves I_2^1 inch bars on top of what are called the body boxes. Of late years various changes have been introduced by 'The Renfrewshire Bee-keeper.'

Mr. James Allan, Stewarton, Ayrshire, who is the principal manufacturer of these hives, gives us the following information:—

The Stewarton Hive.—The non-swarming or storifying system of keeping bees in colonies has been successfully wrought in Scotland for centuries, and the principle is now being adopted by advanced bee-keepers in England and America under the name of tiering.

Three Body and one Honey Box.

This honey - yielding hive originally consisted of three octagon body or breeding boxes, 14 inches wide inside by 6 deep. These formed what was was called a set, 18 inches being usually deemed sufficient depth of breeding space for a colony; while the octagon supers or honey boxes were also 14 inches wide by 3, $3\frac{1}{2}$, and 4 inches deep, and were divided sectionally when so required. All the boxes, breeding and supers, carried alike seven immoveable bars $1\frac{1}{3}$ inches broad. The $\frac{3}{8}$ beespaces between these were filled with moveable strips of wood called slides - with shuttered windows, front and back, sliding doors (locally termed mouth - pieces), hooks

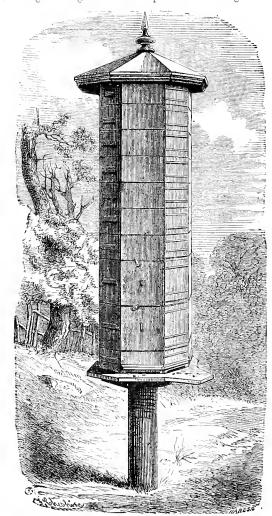

or screws for tying together or weighing, wooden buttons to prevent displacement, with pegs to take the place of slides and plug when the slides were withdrawn, complete the description. The breeding-boxes are now supplied with 9 1½ inch moveable bars.

The Renfrewshire Stewarton.—Nearly thirty years ago 'A Renfrewshire bee-keeper' met with the Stewarton hive and improved it by introducing the moveable comb system, increasing the depth of boxes to seven and nine inches respectively, so as to make them available singly for a swarm, or two 9-inch boxes forming a set for a colony, narrowing the width of bars in the breeding boxes to 1½ inches, the natural thickness of brood combs, retaining the 1½-inch width for end and super comb bars, as most suitable for honey storage. The four central complete frames, as well as the bars in all the boxes, are grooved to receive comb-foundation, and kept in position with ½-inch brass screws, having triple instead of single entrances to the breeding boxes. So changed the hive became known to the trade as 'The Renfrewshire Stewarton.'

Management.—After a breeding-box has been fitted with comb-foundation guides, and a set of slides run in, it is ready to receive a prime swarm. This hive being detachable from cover and free of legs, can be set over a swarm and bees run up, or shaken into it, with as much facility as a straw skep. So soon as a second prime swarm can be obtained—say within eight or ten days it is similarly hived in another breeding-box, and is immediately set down alongside the earlier. At dusk, same evening, the first is set on top of second hive swarm, closing sliding door of upper box at once, and the slides of the lower box withdrawn one after the other, and as quickly as possible spaces plugged with corresponding pegs to keep in the bees. It is well for expedition these be previously arranged on top of upper box ere a slide be withdrawn. Should the evening be at all chilly, a puff or two of smoke at entrance expedites the ascent and union. The object of combining two prime swarms in one colony is to ensure a harvest of finest virgin honey the same season. A single prime swarm could only at most be expected to fill the colony for the first summer without yielding any surplus.

If weather continue line and honey abounding, the conjoined colony will speedily comb their breeding-boxes, and require one or two supers for honey storage. If after sheeting with narrow strips comb-foundation, two supers be used, run a full set of slides into the upper, and a full set of pegs into the lower. Every subsequent addition to the super file must alone contain a set of slides; every super below it be pegged so as to give the

honey-gatherers unrestricted passage through all the supers. Access to the supers from the breeding-boxes is to be afforded by withdrawing the outermost slide on either side and substituting pegs therefor. Should honey flow continue with settled fine weather, the second outermost slide may be drawn, either in whole or in part, in keeping with the weather, but on no account must other slides be touched, otherwise the queen would in all probability ascend, and the beauty of the supers be destroyed. So soon as the supers are set on, they must at once be covered all round with four-ply warm woolles at ted round closely. After honey is being stored in supers, if 7-inch breeding-boxes be employed, a third pegged breeding-box is given below to prevent swarning.

The colony must be protected from wet, and shaded on sunny side by a full-sized archangel mat hung loosely, and when in full work all the three entrances in lower box fully drawn for the sake of ventilation, besides affording freest egress and ingress to the overflowing population. This hive offers facilities in skilled hands for supering and nadiring to any extent.

All fresh additions of super space must be given by placing the empty on the top of the filling ones and breeding space at bottom of the pile. In an extra good season the 'Renfrewshire Stewarton' colony required seven full-sized supers (see illustration) to keep the bees fully employed, and yielded close on 200 lbs. of honey by the end of the season. The lowest and successive supers had better be removed to preserve their purity so soon as

central comb can be seen through windows to be sealed out. This is best effected in the middle of a fine day, when a large proportion of the workers are absent in the fields, by temporarily running in the slides of upper breeding-hox, and carefully drawing a strong thread or thin brass wire below and above each completed super to sever comb attachments. The preceding illustration of a 'Renfrewshire Stewarton' in full work, from a photograph, rests on a 6-inch glazed fire-clay pipe, faucet end sunk 16 inches firmly into the ground, a long bung of wood in upper end, on which is screwed a 9-inch square of inch wood, to which the moveable floor-board is held down with 2-inch iron button.

By the kindness of Dr. Bartrum we are informed that he has received a telegram announcing the safe arrival of Mr. and Mrs. Cowan at New York on Monday, the 18th.

We note that Dr. Bartrum has been presented by the Earl of Verulam to the Rectory of Wakes Colne, Essex. The headmastership of King Edward VI.'s School, Berkhamsted, will therefore shortly be vacant.

Mr. W. G. Campbell, Hornefield, Tottenham, who, we announced in our issue of July 7, passed his examination for first-class certificate, has sailed for Australia.

USEFUL HINTS.

Weather.—In our locality the drought still continues, and the bees in consequence languish. In the shorn meadows the white clover blooms not, and from their surface all verdure has vanished. The fields will soon be whitening for the harvest, and the honey-flow in the year of grace '87 is all but over. Even the limes yield not their accustomed nectar, and no refreshing shower revives their drooping foliage. Short has been the harvest, but in many districts bountiful and the quality most excellent. The heather is yet to comeheather, true Scotch heather—the queen of honey plants, alone yielding nectar fit for the gods. We southerners must content ourselves with honey from inferior plants, as blackberry, buckwheat, ivy, &c. For ourselves we look forward with hope to an ingathering from the Statice limonium (sea lavender), from which, in the month of August last, our supers were refilled with sections of the whitest, and withal of well-flavoured, comb-honey.

Changing Queens.—From the present time to the end of next month we consider the best time for dethroning aged or unprolific queens. Remove a superior queen in her prime from a populous colony, and let her replace one of the condemned ones. In the queenless colony select a couple of brood combs and break down in each a few cells, beneath and around newly laid eggs, towards the end or the middle of the combs, thus inducing the bees to build queen-cells around these selected eggs to the number of six or eight at even distances, and close the hive. On the eleventh or twelfth day afterwards, remove the queens to be superseded, and having carefully cut out from the queenless colony as many queen-cells as required, leaving one or two only, insert them one by one near the centre of the brood-nest in each of the colonies deprived of its queen, and protect each cell by a wire-cloth cage. On the fifth or sixth day after inserting the cells, the young queens will have hatched, and may be liberated if this has not been already done by the bees, any other queen-cells which may have been formed having been previously cut out. Great care is necessary in handling the queen-cells, as the least pressure will destroy the nymph. At the base of the cell a triangular piece of comb should be cut out and inserted with the cell. In actual practice the operation is most easy, and failures rarely occur. As a rule, however, the bees, particularly Italians, will supersede their own queens when requisite, and in an apiary where natural swarming is allowed, there will be little necessity for practising any artificial method.

ITALIANS BEST.—Let us give a word of advice in fayour of the Italian bee. After an experience of some twenty summers, our good opinion of this race is not only maintained, but increased. An experienced friend who lately visited our apiary, after inspecting colony after colony of Italians busily at work in piled sections of the finest quality, exclaimed, 'Have you no blacks?' Yes, we had blacks also, but on them were no sections, and from half-a-dozen colonies only one swarm had issued, while case after case of first-class sections has been removed from the Italians. Our present strainthe best we ever possessed—are dark-coloured Italians, larger bees, better workers, and more hardy than the lighter strains, and were procured for us from Switzerland by Mr. Neighbour. As producers of comb-honey, both as regards quantity and quality, they have, in our experience, no equals. Quiet as Carniolans to handle, prolific as Cyprians, and in wintering qualities surpassed by none, the dark Italians are, par excellence, the bees for us. Even in this exhaustive drought they manage to scrape together and store a little surplus, while others remain at home idle; and where room is given, they are less inclined to swarm than any kind we have tried.

Bacillus Minor. — We notice in several American communications, also in our contemporary, the Record (current number), descriptions of diseased brood, which differs considerably in its symptoms from the ordinary foul brood (Bacillus alvei). Of this disease we have had cognisance for some years, but always felt inclined to consider it incipient foul broad, which, if allowed to remain undisturbed, would end in the malignant Bacillus alvei. The symptoms are—listlessness in the bees, while other colonies are energetically at work; death of the larvæ at all ages, but chiefly in its early stages; putridity, free from the usual offensive smell of foul brood; death of the nymphs, unable to emerge from the cells, but free from putrescence, and pierced and sunken cells: of the few young bees which emerge most are imperfectly developed, some being wingless, others having one wing only, some minus a leg, and many extremely diminutive—the prettiest little dwarfs, indeed, that can well be imagined. Gradually the colony dwindles: although, when possessing a prolific queen, the population is often maintained at par for many months—even to the end of the second year after the commencement of the attack.

On opening a diseased hive there is no offensive smell perceptible, but still there is an absence of the pure fragrance emanating from a healthy colony during the storing season,—a certain acidity which betokens fermentation. With the editor of the Record, we are inclined to the opinion that the disease is partly congenital, but not entirely so, since we have known cases in which the contagion has been conveyed from hive to hive, and in which a change of queens has resulted in the infection of the newly-introduced and healthy queen. We have been in the habit of designating this disease by the title of Bacillus minor, although its deadly effect, though slower, is equally sure with that of 'Bacillus major alvei.' That its cause is a species of Bacillus we have not the least doubt, and we hope to be able to induce Mr. Cheshire fully to experiment upon some diseased colonies, and to report the results. Some of the queens lose their pubescence, and become feeble and languid, and whenever, in such cases, an attempt has been made by the bees to supersede the queen, it has invariably failed, the embryo insect perishing either in the larval or pupa stage. Much of the dead larvæ in the early stage becomes desiccated, and is extruded by the bees, and may often be found on the alighting-board, while beneath may be seen, often in considerable number, the abortive nymphs. Our attempts at curative measures have always failed, although we have applied phenol, salicylic acid (both in syrup and as disinfectants), camphor, coffee, &c. Queens of other infected colonies have, to all appearance, continued in a perfectly normal condition, retaining their pubescence and fertility to the very last. We trust a remedy may soon be found for this insidious and most dangerous disease.

TIME OF MANIPULATION.—Mr. Wood (1148) takes exception to the advice given in the last 'Hints' (which were written for us under exceptional circumstances). Truly, we can sympathise with those who have avoided exposure to the sun's rays, during the heat of the day, while manipulating. We have always advocated the following rules:—1. During spring and autumn, when bees are inclined to robbing, manipulate in early morning or late evening, provided always that the temperature is sufficiently high to prevent chilling bees or brood.

2. During the honey-flow, let all manipulations whether for taking off or putting on sections, examining brood-nest, exchanging queens, withdrawing combs for extracting, et hoc genus omne—be performed while the bees are at work in the fields, and not when they are all at home, in the morning or evening. The difference between 'spotting' a young queen (or even an old one) will be fully realised only by those who have made trial of the above rules, as also will the ease, or difficulty, of removing sections or other supers. But there are exceptions to all rules, and even now, in the middle of July, we scarcely dare open a bive or expose a comb of honey during working hours, since, in consequence of the severe drought through which we are passing, their inclination to rob in our apiary is as keen as at any period of the year.

FECUNDATION OF QUEENS.—Examination should be made at evening to ascertain whether the young queens are in existence, and laying, which all should be during the present hot season at ten or twelve days of age, if not five or six days earlier. Our queens have all mated

successfully without an exception.

SECOND SWARMS RETURNING. — Mr. Gibbon's experience (1153) is not singular. Small second swarms will often return to the parent hive, as if aware of their inability to found a colony through paucity of numbers. His young queen failed to gain admittance to the parent hive, and sheltered beneath the roof. Had she not been secured she would have led forth the swarm again, or, the bees refusing to follow, would have perished in the

attempt. Space beneath Frames — The amount of space which should be allowed between the bottom bars of frames and the floor-board seems to be a moot point. Some recommend $\frac{1}{4}$ in., others $\frac{3}{5}$ in., which appears rarely to have been exceeded. Experimentally we have allowed to several newly hived swarms 2 inches, and have not contracted the hives. As we expected, the becs have confined themselves to the frames, building out the combs on full sheets of foundation, adding no brace combs below. The result would, in all probability, have been different had we confined the bees to the frames they were able to cover. Our object in the experiment was to provide space at the bottom of the hive, with a view to a more perfect system of wintering, having repeatedly observed that colonies wintered with an eke beneath the hive had emerged from the most severe winters in a more perfect condition than others not so treated. In case of internal winter dampness, where in space only is allowed, the lower parts alone of the combs are injured. When from two to four inches have been allowed, perfect dryness of the whole interior has been the result, and there has been no blocking of entrances (left at summer width) by dead bees and refuse.

Honey Prospects.—From most parts of the United States complaints reach us of the failure, to a great extent, of the honey crop. Such reports as—'The lightest honey crop for many years,' 'Clover dried up by drought,' 'Plenty of bees, but little honey,' 'Bees can hardly make a living,' 'Not a pound of surplus taken in this neighbourhood,' and much else to the same effect we frequently read in the American journals. Not since '68 have we in England experienced so dry a summer, and yet in our journals, so far from reading desponding reports of the honey yield, all appears to be conleur de rose. Can it be that Englishmen report their successes but not their failures? At all events we venture to forecast a better price for honey, especially of the higher grade.

REMOVING SECTIONS.—Even where unfinished we are removing section cases. Our plan of operation is as follows: On a fine day, between ten o'clock and four, while the bees are in full work, the section case is uncovered and a cloth steeped in carbolic solution and squeezed dry, is spread over it. The entire case is then slightly and gently raised by the leverage of a couple of chisels, allowed to fall back into its place, and slowly screwed round to thoroughly separate all attachments. It is then carried to the honey-room and the sections are removed one by one, the few adhering bees, being brushed off with a feather, quickly return to the hive. The finished sections are stored, and those uncapped are returned to the hive for a few days for the bees to finish. Care is taken to spread a carbolised cloth over the hive while the sections are under manipulation. A weak solution (one part of the acid to twenty parts of water) only, must be used, or all the bees will be driven out of the hive.

ITALIANISING.—The present and next month are the best time for introducing Italian, or other foreign queens. These may now be obtained at moderate prices, and we strongly advise a trial of the dark strain of Italians, being careful to obtain a guarantee of purity of race. Our supply dealers may be fully trusted to send out pure queens, and purely mated, while amateurs, unfortunately, though chiefly no doubt through ignorance, often send out impurely mated queens.

May the fertilising showers soon descend and procure for us a second harvest from revivified white, and second

crops of red, clover, ling, cole, mustard, &c.

BEESWAX AND ITS CONVERSION INTO MONEY.

By J. Dennler.

(Continued from page 297.)

THE EMPLOYMENT OF WAX FOR ECONOMICAL PURPOSES.

Beeswax, on account of its lighting powers, is used for the manufacture of candles and wax-tapers. Besides, on account of its tenacity and ductility, firmness and difficulty of melting, it is indispensable for the great industry of making wax figures and for modelling. But also in house-keeping wax renders us important services. In the following we have some of these remedies and recipes:—

(a.) Sewing Wax.

The beeswax is made into little round balls to give more stiffness and smoothness to the thread for sewing.

(b.) Wood Wax.

Mclt together one part of yellow wax, two parts of rosin, one part of turpentine, and some lard. Let it get slightly cold, and roll out the mass on a slab into sticks. This is the warm-melting wood wax. At the present time the cold-melting wood wax, recommended by Dr. Lucas, is often used, which is prepared from rosin and spirit.

(c.) Primitive Wax.

Melt two parts of wax, and stir into it, after it is taken off the fire, one part of turpentine.

(d.) Wax Polish

Mix 200 grammes of potash and 200 grammes of water, heat it to boiling point, and gradually, after repeated stirring, 400 grammes of yellow wax. After this has been boiled again, pour in 900 grammes of water, and heat it until a milky fluid results. This is useful for polishing furniture and floors. (Els. Loth. Bee-keeper.)

(e.) Waterproof Packing Paper.

Take twenty-four parts of blue soap and four parts of white soap, fifteen parts of wax, and boil it with 120 parts of water. Dip the packing paper into it and let it well soak, and hang it up on cords to dry.

(f.) Leather Greese.

For the preparation of this, mix $I_{\frac{1}{2}}$ kilogrammes of pure yellow wax in $I_{\frac{1}{2}}$ kilogrammes of turpentine oil, $I_{\frac{1}{2}}$ kilogrammes of castor oil, $I_{\frac{1}{2}}$ kilogrammes of linseed oil, and $I_{\frac{1}{2}}$ kilogrammes of tar, and let the whole be thoroughly well mixe4. The leather by repeated applications (some six months altogether) is protected by this grease against the influence of air, heat, perspiration, or other moisture.

(g.) Wax Ointment for making Boots Waterproof

(9.) What Oriente for mattery Boots When Proof 1. Sprepared by melting together $6\frac{1}{2}$ parts of yellow wax, $26\frac{1}{2}$ parts of mutton tallow, $6\frac{1}{2}$ parts of thick turpentine, $6\frac{1}{2}$ parts of olive oil, and 13 parts of lard, and stirring into this 5 parts of well-mixed lampblack, and the mass is then poured into little wooden boxes. The wax is made warm and is rubbed in with the fingers, by means of which the hard leather is softened, and becomes perfectly water-proof.

(h.) Means for Removing the Cracks in Horses' Hoofs,

Wax and honey in equal parts are well melted together over a slow fire, and thoroughly well mixed. It is used after this manner: the hoof having been thoroughly cleansed with tepid water the above mixture is well rubbed in with a brush. After several applications the fissures and cracks disappear, and the hoof gets an advantageous softness.

APPLICATION OF WAX IN MEDICINE.

(a.) Remedies for Coughs, Expectoration, Erysipelas of the head.

Breathe the vapour of wax which has been melted on a hot iron or a brazier.

(b.) Healing Salve.

Honey, oil, and wax melted together into a salve hastens the healing of old wounds and fistulas.

(c.) Marigold-flower Plasters for Wounds.

Out of marigold flowers a plaster can be made by bruising the flowers and the stalks and mixing it with as much lard as will cover them, letting it boil over a moderate fire for an hour, and it is then squeezed through a cloth. The stuff that is pressed out is put over the fire, and as much yellow wax added as will make it of the consistency of a plaster. If less wax is used, marigold flower salve is obtained. Both preparations are useful in all kinds of wounds.

(d.) Remedy for Diarrhæa.

In France the following remedy is found of frequent use: --Scoop ont the core of a quince, fill it with hot wax, let it roast for a long time by the fire, and eat it night and morning for three days consecutively.

(e.) Salve for Wounds left after Removing Warts. Prepare a salve of white wax and fresh unsalted butter equal parts, and mix a little white wine with it.

(f.) Salve for Burns.

Wax and linseed oil give an excellent plaster for burns. Stahl's burn-salve is made of equal parts of butter and yellow wax.

(g.) Corn Plaster.

For corns a good plaster is made of wax, tallow, and some verdigris.

(h.) Tooth-stopping.

The tooth-stopping is prepared by melting together 3 parts of pure white wax with $3\frac{1}{2}$ parts of mastic and a few drops of oil of peppermint, and making it into the pill on a marble slab. The hollow teeth are filled with this so that the food may not lodge in them and irritate the nerves of the teeth.

(i.) Wax Salve for Skin Diseases.

5 parts of white wax, 5 parts of spermaceti, 5 parts of sweet almond oil, are melted together in an enamelled vessel, and are poured out into little paper boxes, and when cold are cut up into little slabs.

COSMETIC SPECIALITIES.

(a.) Glycerine Wax Balsam.

2 parts of white wax, 2 parts of spermaceti, 8 parts of sweet almond oil, 4 parts of glycerine, $\frac{1}{8}$ part of attar of roses, are carefully melted together in an enamelled vessel before a slow fire, stirred till it is cold, and put into glass vessels.

(b.) Crème Céleste.

 I_2 parts of white wax, 3 parts of spermaceti, 3 parts of sweet almond oil, are melted together in a porcelain dish over a water bath, and after it is cold 2 parts of rose water are added, with continual stirring.

(c.) Cold Cream

Is used to keep the skin delicate and soft. It is prepared by rubbing together in a water bath I part of white wax, 2 parts of spermaceti, 8 parts of sweet almond oil, and 5 parts of rose water.

(d.) Cosmétique.

Melt in a porcelain dish over a water bath 500 grammes of yellow wax, with 125 grammes of white soap, take it from the fire, let it get cold, and mix in it before the mass has set 5 grammes of bergamot and 1 gramme of Peruvian balsam. It is rolled out into little sticks on a glass or marble slab, and these are covered with paper.

ASSOCIATIONS.

WORCESTERSHIRE BEE-KEEPERS' ASSOCIATION.

A meeting of the Committee was held at Worcester on the 16th inst., Mr. C. II. Haynes presiding. It was with great reluctance that the members present unanimously resolved that owing to an insufficiency of funds it was inexpedient to hold a show of honey, &c., during the present year.

ROYAL AGRICULTURAL SOCIETY'S SHOW.

The Annual Meeting of this Society was opened at Newcastle-on-Tyne on Friday, the 8th of July, when the general exhibition and trials of implements, and the trials at the working dairy commenced. The public were admitted to the whole of the show-yard, including that of the hee-keeping appliances and honey, on Monday, the 11th.

It will, I think, be interesting to give the scope of this

Show as compared with that held at Kilburn and those since held, which are as follows:—

		Stock Exhibited.	Number of Implements Exhibited.	Number of Persons Admitted.
1879	London (Kilburn)	2879	11,879	187,323
1880	Carlisle	1485	4196	92,011
1881	Derby	1229	5960	127,996
1882	Reading	1450	6102	82,943
1883	York	1653	6058	128,117
1884	Shrewsbury	1664	5241	94,126
1885	Preston	1563	5318	94,192
1886	Norwich	1823	4656	104,909
1887	Newcastle	1833	3616	126,133

Thursday was the first day of a shilling entrance, when upwards of 77,000 people paid for admission. At Norwich last year there were 42,000, and at York, in 1883, there were 63,000.

No doubt the knowledge that the Prince of Wales and his two sons would visit the Show was an additional attraction to many, and assisted in increasing the numbers to such extent as has never before been witnessed on one day at any agricultural show. Throughout the whole time of the Show we were favoured with magnificent weather.

The bee department had its full share of patronage, and, if possible, more interest was shown than at Norwich. On Thursday the tent containing the hives, &c., and honey, was erowded from end to end by people anxious to learn something of 'modern bee-keeping,' and, if we mistake not, hive-makers had a busy time of it taking orders. The bee-tent was thronged during manipulations, and many were the inquiries as to what time the 'mon was going to perform with the honey flies.' Conld 'Looker On' have seen what we saw, he would not then think that 'the bee-tent and lectures ought to be done away with at once.'

The exhibition was truly educational, and the omission of 'the largest collections' of the many obsolete and useless bee appliances which are usually sent to swell the numbers, was, we think, most beneficial. Those who wish to commence bee-keeping, and followed the awards in the various classes of appliances, would not be led into making purchases of articles unsuited to their purpose. The schedule was drawn with this idea, and we think the result most satisfactory.

There is one thing which we would like to mention, and that is, the careless way in which some of the exhibits are sent notwithstanding the trouble taken by the Committee of the B.B.K.A. in drawing up rules and instructions to which the approval of the county delegates was obtained, and which were embodied in the prize schedule. Some of our largest firms of hive-makers sent their exhibits without fixing the labels upon them, so that it was impossible for the Secretary or show manager to stage the goods. It is evident the rules on the schedule are not read, or the mistakes could not be made, and the articles disqualified in consequence.

In Class 212, for the best hive, not to exceed 15s., it says, 'The exhibit must include two similar body boxes,' &c., &c. Notwithstanding this, four out of the ten hives sent were disqualified on account of the two body boxes being quite different in size, and in no way similar except that they were made of wood. Again, in the extractors, Class 214, the schedule reads, 'With arrangements for reversing the sides of the combs either automatically or by hand, without necessitating the taking out of the frames of comb or the wire cage containing the same in order to turn the other side for extracting.' Surely this is plain enough, and yet three or four were disqualified because they did not comply, and the frames had to be

taken out of the extractor before the sides could be changed. In Class 215, Section Racks, two or three were disqualified, as they did not comply with the schedule. In hives, the first prize was awarded to Messrs. Neighbour for a well-made hive, which is a marvel of cheapness, and is certainly all that can be desired; and as they are bound to supply similar hives at the same price, 15s., for twelve months, we describe it, that those who did not see it at the Show may have an opportunity of availing themselves of procuring such a bargain. They supply floor-board and stand with two similar body boxes with Lee's patent frames, an additional body box with moveable frame supports which can be taken out when frames are not used, when it will form an outside protection for racks of sections, or can be inverted and slipped over the stock hive in winter as an additional protection, a rack of twenty-one sections and separators with suitable roof. The second prize went to Messrs. Abbott Bros. for two suitable 'Gayton' hives, both filled with their patent frames and a good rack of twenty-one sections floor and roof; the materials and workmanship are good and well worth the money, 15s. The third prize was given to Mr. S. J. Baldwin, for a well-made hive, two similar body boxes, rack of sections, floor-board, and roof. In the class for the best storifying hive for 10s. 6d., the hives were all very good and cheap for the money. It is somewhat surprising that although Newcastle is so close to Scotland, none of our Scotch friends exhibited either hives or honey. The chief prizes, both for comb and extracted honey, were awarded to bee-keepers in the Southern counties,—4 to Berks, 4 to Herts, 3 to Norfolk, and 1 to Suffolk, I Lichfield, I Nottingham, and I Yorkshire.

The sections were not so good as we have sometimes seen them, but we understand that the judges considered the extracted honey of very fine flavour and quality.

The judges were Mr. John M. Hooker, Mr. Walter Martin, and Mr. W. Raitt.

The following are the list of awards:-

Hives, Honey, &c.—For the best and most complete Frame-Hive for general use in an apiary, with arrangements for summer and winter use—I, G. Neighbour and Son, 1l.; 2, Abbott Brothers, 15s.; 3, S. J. Baldwin, 10s. For the best and most complete Storifying Frame-Hive, with arrangements for summer and winter use, price not to exceed 10s, unpainted-1, G. Neighbour & Son, 11.; 2, Dines and Son, 15s.; 3, Abbott Brothers, 10s. For the best honey extractor—I, W. P. Meadows; 2, Abbott Brothers, 10s. For the best two Section Racks, price not to exceed 3s. 6d. each—I, Abbott Brothers, 15s.; 3, W. Bellen, 15s.; 2, W. B. Baker, 10s.; 3, Turner & Son, 5s. For the best feeder for slow stimulating feeding—1, W. P. Meadows, 10s.; T. B. Blow, 5s. For the best Feeder for quick autumn feeding, capable of holding at least 5 lbs. of food Brothers, 5s. For the best large Smoker—1, T. B. Blow, 10s.; 2, W. P. Meadows, 5s. For the best ordinary sized Smoker—1, G. Neighbour & Son, 10s.; 2, W. Dixon, 5s.; 3, W. P. Meadows, highly commended. For any other appliance for quieting Bees.—W. B. Webster, 10s. For the best sample of Worker Comb Foundation in sheets for Standard frames, to consist of 2 lbs. of thin for supers and 2 lbs. of thick-Abbott Brothers, 15s. For Useful Inventions introduced since 1885. Special prizes according to merit—Silver Medals were awarded to A. D. Woodley (Tin Section Crates), W. P. Meadows (W. B. Carr's Metal Ends), A. Goodman (Comb Foundation Mill), James Lee (new Method of making frames, James Lee (Self-fastening Section), James Lee (System of Hive Construction for sending out frames in the flat, no nailing required), Abbott Brothers (Patent Frame Groove), British Honey Com-pany (Mella). Bronze Medals, W. P. Meadows (Raitt's Honey Press), A. Goodman (Metal ends). Certificates, W. P. Meadows (Howard's Section Glazing); W. P.

Meadows (Lamp and Can for Uncapping); W. P. Meadows (Stand for Uncapping); T. B. Blow (Queen-introducing stage); W. B. Webster (Swivel Frame introducing stage); W. B. Webster (Swivel Frame Lifter). For the best twelve Sections $5\frac{1}{4} \times 6\frac{1}{4}$ of Comb Honey—I, W. Woodley, Il.; 2, H. Beswick, 10s.; 3, Miss M. L. Gayton, 5s. For the best twelve Sections $4\frac{1}{4} \times 4\frac{1}{4} \times 2$ of Comb Honey—I, W. B. Baker, Il.; 2, H. Beswick, 10s.; 3, H. Wood, 5s. For the best twelve sections $4\frac{1}{4} \times 4\frac{1}{4}$ of Comb Honey—I, H. Beswick, 1l.; 2, Miss M. L. Gayton, 10s.; 3, A. D. Woodley, 5s. For the best twelve sections $4\frac{1}{4} \times 4\frac{1}{4}$ of Comb Honey—I, H. Beswick, 1l.; 2, Miss M. L. Gayton, 10s.; 3, A. D. Woodley, 5s. For the best twelve 5s.For the best twenty-four 1 lb. glass jars of Run or Extracted Honey—1, W. Woodley, 17.; 2, Miss M. L. Gayton, 10s.; 3, W. F. Askew, 5s.; W. E. L. Duffin, George Colville, and J. Lane, highly commended. For the best twelve 2 lb. glass jars of Run or Extracted Honey, I. Miss M. I. Garton, H. 1, 2, W. C. Berger, H. 1, 2, W. C. Berger, 1, 1, 2, W Honey—I, Miss M. L. Gayton, Il.; 2, W. C. Brown, 10s.; 3, J. Townsley, 5s. For the best Exhibition of Honey from one Apiary in quantity not less than I cwt. —1, W. Gulston, 30s.

We regret that the following numbers in the Catalogue were disqualified, not having complied with the conditions of entry, viz. 1, 3, 8, 11, 22, 24, 25, and 34, belonging to

—Messrs. Neighbour (1, 3, 25, 34), James Blake (8),
Dines (11), W. B. Baker (22), W. P. Meadows (24).

The Judges were Messrs. J. M. Hooker, Walter

Martin, and W. Raitt.

The Bee Department was throughd with visitors throughout the Show. Sir M. White Ridley, Bart., Lady Ridley (at whose residence H.R.H. the Prince of Wales stayed during the Show), Lord Armstrong, and other notabilities, paying the department a visit. A large number of sales was effected, a very small portion of the exhibits being returned 'unsold.'

Correspondence.

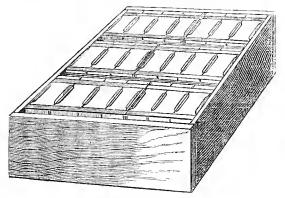

The Editor does not hold himself responsible for the opinions expressed by his correspondents. No attention will be taken of anonymous communications, and correspondents are requested to write on one side of the paper only, and give their real names and addresses, not necessarily for publication, but as a guarantee of good faith. Illustrations should be drawn on separate pieces of paper.

Communications relating to the literary department, reports of Associations, Shows, Meetings, Echoes, Queries, Books for Review, &c., must be addressed only to "The Editors of the "British Bee Journal," clo Messrs. Strangeways and Sons, Tower Street, Cambridge Circus, W.C.' All business communications, relating to Advertisements, &c., must be addressed to Mr. J. Huckler, Kings Langley, Herts (see 2nd page of Advertisements).

***In order to facilitate reference, Correspondents, when speaking of any letter or query previously inserted, will oblige by mentioning the number of the letter, as well as the page on which it appears.

REVERSIBLE SECTION-HOLDERS.

[1156.] I now send you a sketch of my reversible section-holders, they are made of stout tin to hold either

Crate of Section-holders.

three or four $4\frac{1}{4} \times 4\frac{1}{4}$ sections, the width of sections being so variable I have, after consulting the best authorities, had the holders made to suit a section $I_{\frac{15}{16}}^{\frac{15}{6}}$ in width,

the ends are connected with strip of tin flat top and bottom one side and angled on the other, to keep the sections in place. The ends are $4\frac{1}{4} \times 4\frac{3}{4}$ with slots on the four sides, allowing the bees free access to the sections all round the extra $\frac{1}{2}$ -inch in width $(4\frac{1}{1}\times4\frac{3}{2})$ projecting 1" on each side, being to keep the rows this distance apart.

The dividers have also $\frac{1}{4}$ " slot on the four sides, and are therefore most suitable for use with four bee-way sections. All are made by machinery, of stout material, with a view to their lasting, they are quickly reversed, easily removed from the section-crate, a single section can be taken out and replaced without trouble or loss of time, they also afford a safe means of packing sections for In the crates I have had made, I rest the section-holders on the edge of a strip of angled tin, thus offering the least possible surface for propolisation.—W. H. Jenkins, Swansea.

BEES WORKING IN THE SECTIONS.

[1157.] The one-pound sections for comb honey have become very popular. They are attractive in appearance, and hence sell well. They hold about the quantity an ordinary family desires for one meal. In some quarters the two-pound sections are used extensively, but the tendency is to the smaller section. In buying sections be sure that they are clean, and that they are accurately made, so as to fit together neatly and firmly. Nearly all the sections are now dovetailed. White poplar is much used in making them, because it is easily worked, and

makes a smooth, clean, sweet section.

The hives made in the last few years are mostly intended to take on a section-case for holding these sections. This case fits down close on top of the broodchamber, and then the top of the hive fits on the case and becomes its top. These cases hold the sections and bring them close down to the tops of the brood-frames, leaving a passage of about three-eighths of an inch between.

Sometimes bees are a little slow about going to work in sections. They will fill the brood-chamber with honey and then swarm, refusing to store in the sections. This can usually be overcome by having one or two of the centre sections already full or partly full of honey. If you saved carefully the partly filled sections last fall you can now use them very profitably by putting one or two of them in the centre of the sections on each hive. The bees are at once attracted into the sections, and almost always will go to storing in them immediately—provided there is any honey in the fields for them to store.

It is always best to use starters in the sections. A starter is a piece of comb, or of comb-foundation, put in the section just where you want the bees to begin work. If you have nice white comb you can cut this in small pieces and fasten a piece in the centre of the top bar of each section. To fasten these comb-starters you can use a cement made of one-fourth resin and three-fourths beeswax. Melt these together, dip the edge of the starter in the cement and set it quickly where you want it. The cement cools rapidly and holds the starter firmly.

Of later years nearly all producers of comb honey are using starters of comb foundations in the sections. For this purpose very thin foundation is used. A very small piece of the foundation will do, but if it nearly fills the section, so much the better. This foundation starter can be fastened in the centre of each section by carefully pressing the edge of it down on the centre of the top-piece with a knife. Where many bees are kept this process is rather slow, and a small foundation-fastener is used that does the work quickly and well.

As fast as sections in the centre are filled with honey and sealed it is a good plan to remove them, moving the partly filled ones to the centre, and putting empty sections with starters at the outside.—O. Clute (Philadelphia

17:ess).

BROTHER JONATHAN.

[1158.] It would seem from the Jottings of 'Amateur Expert,' culled from the American Apiculturist, that there is as much diversity of opinion amongst our American cousins as amongst ourselves regarding the royal road to success in bee-culture, and I do not think any of them can give us much start in the race for honey; indeed, were we to exchange places, i.e. take our bees to their climate and pasturage, and let them bring theirs to ours, I almost dare stake a dollar on ours.

I see one or two of them put a partly built-out section of the previous year to entice the bees into the racks of sections. This is a plan I have adopted for the last few years and find it very successful. If I have plenty I put one in each corner of the rack, and if they contain any honey I uncap it and it quickly fetches the bees up. A partly filled section of heather honey is so powerfully scented the bees cannot resist such a bait, and they rush

up at once.

I notice Mr. Manum tiers a large number of sections on a hive at one time; this is, in my opinion, a retrograde plan. I have tried it and don't think I shall soon do so again, after seeing the state of the sections. What with the heat of the hive and the constant travelling of the bees over the lower sections, to say nothing of the propolis, they are so discoloured as to be nearly unsaleable; besides, where is the advantage? Bees don't like travelling over sealed honey so much, and the lower racks being filled and sealed nothing is to be gained by leaving them on the hives, and the plan necessitates a large outlay in racks.

On the other hand, Dr. Miller removes the middle sections as soon as sealed. This is bad policy; I think it upsets the bees and the breaking up of the cluster, when comb-building is decidedly a backward movement, besides the loss of time incident to such frequent manipulation. I find nothing better than the plan advocated by the writer of 'Useful Hints' in the Journal, viz. to give a rack beneath when the first one is about half finished. I never have more than three racks on a hive at once and seldom more than two, and I may add seldom less. I see our cousins use full sheets of foundation in supers. No doubt the sections are more quickly filled by this mode, but those who adopt it in this country must remember that American super foundation is very much thinner than our English is, and the latter leaves too thick a midrib for some people when used in full sheets, and is expensive too.

So Mr. Cowan is off across the little pond! We all wish bim a pleasant trip and safe return.—F. Boyes, Beverley, July 12.

QUEENS IN SECTION CASES.

[1159.] Thrice within the last few days I have found a queen in the *upper* row of sections whilst taking honey. I carry away the section cases to a distance from the hive, and shake or brush off the bees into a straw skep; and afterwards throw the bees down in front of the hive. I did not use smoke or carbolic cloth in these cases, and never do unless the stock is very savage. I think it is advisable to warn bee-keepers of the risk they run of loss

of queen. I suppose the queen was seeking in vain for cells in which to lay eggs. I believe one of the queens was a young one running away for refuge, as after I put her back in the hive I found two dead ones in front next day just like her. Still I believe my experience proves there is some risk in the method of taking honey.— L. Williams, Wheatley, Oxon, July 13th.

[With regard to your inquiry as to the minimum wholesale price of honey, we have heard that bee-keepers have offered 1-lb. sections at 7s. per dozen.—En.]

HONEY ASSOCIATIONS.

[1160.] 'Looker-on' runs full tilt at our Bee-keepers' Associations in his letter of July 7th, and some of his points hit the mark. The manipulations in bee-tents, for instance, are now, I think, of but little value in advancing the cause, for the really practical manipulations of modern bee-keeping cannot be shown there, and the class it is most desirable to get at—old-style apiariansseldom attend. In our county we have, during the present and past seasons, done some useful work by means of private demonstrations held in the garden of some enthusiastic member. Six in the evening is the time selected, and in each case a thoroughly representative audience of working people have been drawn together. A screen is put up in the most suitable place, either round the hives or perhaps on a lawn. Anything which happens to be required to be done to the hives is taken as the basis of an informal lecture—perhaps supers want taking off and replacing; perhaps a swarm requires more room; and if a hive has recently swarmed the ripe, or newly vacated queen-cells, are always objects of interest. It is also well to extract from a few combs, and, in fact, there is far more scope for showing practical work than at a show. The most essential point is that the gathering be held during the long evenings and during the honey-flow.

Perhaps 'Looker-on' will explain how an Association

Perhaps 'Looker-on' will explain how an Association spends its money in hunting up new members; I find no funds are spent in that direction, but in organizing shows and in sending the expert round to members who apply for his services. I see, too, that whenever an Association finds that the bee-tent ceases to pay its way they gradually give up its use. The statement, also, that very little is expended on the cottager, is, in my opinion, utterly unfounded; for these members, with their visit from expert, prizes at local shows, and perhaps loan of Bee Journal, certainly cost more than the 2s. 6d. per annum which they contribute, and my experience is that as soon as the average cottager ceases to draw his full money's worth out of the Association he does not resign,

but stops paying.

I am afraid that the efforts made by some Associations to promote the sale of honey are somewhat amateur and feeble. Honey, like any other commercial product, can only be pushed on the market by some business means; and the formation of a central depôt to which each member can send his honey is quite useless, unless the manager of such a depôt has means of disposing of the honey through the ordinary retail channels—grocers and others. It is very certain that the public will not

flock to purchase at any depôt.

The other method of selling honey is through the means adopted by Lincolnshire, Herefordshire, and perhaps some other Associations, viz., an annual honey fair, held on market-day in a good business town. This means has in every case been fairly successful, and draws general attention to the important subject of 'Honey as Food;' but the advertising must be thorough and the selling arrangements business-like and complete, not the bazaar and flower-show-style of thing at all. A good proportion of the honey should be in bulk to be weighed out into purchaser's jars at moderate prices, and the public should be advised of this beforehand.—

Alfred Watkins, Hon, Sec., Herefordshire B. K. A.

QUEEN-REARING.

[1161.] I note that in two instances in the last issue (July 14th) of this Journal advice is given as to rearing queens; and in both instances-notably the American extract—it has been advised to raise the same in nuclei. This is a very grave mistake. Bear it well in mind, all who wish to raise strong, healthy, and vigorous queens, that it is absolutely imperative that the larva should be fed in full colonies, in which there are plenty of young (nurse) bees. When the cell is sealed over then they may be transferred to nuclei. It is principally in the rearing, i.e. feeding, that the vigour of the future mother is implanted. Place a queen-cell with a larva but recently hatched in a nucleus, and you obtain a second, maybe a third-rate queen; but allow this to be fully fed in a full colony and then transferred, the same egg would produce one both vigorous and healthy. Remember that in dividing a stock and putting these divisious, or nuclei, in different positions, fully one third of the bees will return to the original stock and frequently more than one half. You thus have quite a depopulated nucleus to rear that which it is our greatest desire to bring up strong and healthy. There is pleuty of time, eight days between the sealing over of the cell and emerging of the queen, to form nuclei; do not form these on any account until the cell is sealed over and turning dark in colour. This is very perceptible when the larva is getting nearly fully developed; when it is in this condition a little rough usage will not cause any damage. I have carried such cells out of the hive two or three miles without injuring them in the least. The cells are then in the same condition as if reared and matured in full colonies.

I am quite sure our old friend 'A. E.' will pardon my calling attention to this fact, of which I know he is quite cognisant. I am rather of opinion that it was a slip of the pen or memory to advise transferring the queen-cell five days after formation, as in the case of a cell being formed over an egg the larva would have but recently hatched. I will find yet another fault; do not leave it so long as fourteen days, making nineteen in all, before you look to see if the virgin queen has come forth, as perhaps she may have been reared from a two or three day-old larva. This would make its age twenty-two days, and instead of finding a virgin it would most likely be a matron, which in the event of your wishing to mate with a selected drone would be rather disappointing.

I will venture a little advice as to the manner of rearing the queens as 'A, E.' advises, where most of the queens will be of one age—and this is quite a desideratum. Place a nice new comb in the centre of the hive before removal of the queen. Look at in three days; if eggs have been deposited cut two or three oblong holes right through the comb and among the eggs, these holes to be quite an inch deep. Now take a match and with its rounded end twist this in every other cell along the row on top of the holes cut; this destroys the eggs in these cells operated upon; then so destroy every egg in the corresponding row on the opposite side of comb; then replace this comb and remove the queen. Bees always prefer to build queen-cells on new combs, they also prefer a position such as is offered them at the top of each of these holes. You will find on looking at this comb in nine days after that you have a nice row of queen-cells in just the right condition for transferring and also both easy and safe to remove to nuclei.

Do not bother about cutting your combs to insert these cells, but just shift the frames in your nuclei a little bit apart, and place the queen-cell between the top hars of the frames, securing it there by passing a narrow strip of tin flatways, right through the piece of comb attached to the queen-cell and allow this to rest on the two top bars of the frames, press the frames together just to steady the cell, but be sure and not squeeze the cell itself; in about two hours the bees will have fixed the cell quite

firmly in this position. By these means you can easily see whether it is hatched out at any moment by simply turning up the quilt,—W. B. Webster.

KILLICK'S WAX-EXTRACTOR.

[1162.] The article on 'Beeswax and its Conversion into Money' on page 296 of B.B.J. induces me to say that I have just been giving Killick's wax-extractor a thorough trial, and tind it the cleanest and simplest contrivance possible, and the wax as it runs out is fit for exhibition without any second heating or scraping. I tested it with some very old comb containing stale beebread, also with new comb. I am sure it will be a great boon to all who desire to economise time and money. I have on two or three occasions done some fair work with the sun wax melter, but you must be continually looking at it to replenish, and if a cloud comes over, work ceases.—W. E. BURKITT, Hon. Sec. and Expert Wilts B.K.A.

Echoes from the Pives.

Summerhill, Aberdeen, N.B., July 11th.—All my stocks are doing remarkably well this season. One fills four storeys of ten frames each, another nineteen frames and three crates of fourteen 2-lb. sections, while others are nearly as good. I had a swarm weighing over five lbs. on June 15 (early for this northern part), which is now crowding two crates of 1-lb. sections. I have not taken off any sections yet, but a good many are just ready.—A. CADENHEAP.

Kilmington, Axminster, July 12th.—We certainly have had a splendid honey season throughout the month of June. The bees have done splendidly. I have taken off forty-six sections from one of Neighbours' bar-frame hive, and have taken six bell-glasses from Neighbours' cottage straw-hive. I have nineteen hives of different sorts, which, I am pleased to say, are full of honey that was gathered in the month of June. All through the month of May it was very cold so as to keep the bees from gathering, so I stimulated them by feeding; consequently they were strong by the time the warm weather came. There are about 120 stocks of bees in this neighbourhood, chiefly straw skeps, which are very strong. I have just been to a person to try and get her to let me drive them for her instead of burning them; but I have not succeeded in doing so, as she seems to think burning them the best plan. I think it will be a good day when such bee-keepers have their blind eyes open; if they were to take up the Bee Journal, which I advise every one to do, they would see the advantage of modern bee-keeping over ancient, and which gives us every information needed.

—J. W. Sanders.

Chippenham, July 18th.—Not seen a wasp at present. Flies considered unusually numerous, sale of fly-papers much beyond average.—Q. E. D.

Evesham, July 18th.—Since June Ist we have had glorious weather, and bees have been hard at work. The 'Garden of England' has literally been flowing with honey, and one hears all round of supers and sections filled very rapidly and frames in the hives full from top to bottom. Swarms, as a rule, have not been very prevalent, the bees being almost completely overwhelmed by the honey-glut and able to think of nothing else. We have suffered very much the last fortnight from the heat and want of raim, and there are no flowers in bloom now, and though we have had some soft refreshing showers the last few days honey gathering is practically at an end. In this district the Jubilee year will be remembered as one of the best we have had for a long time, and if the season has been short the honey is of most excellent quality and great in quantity.— A. H. Martin.

'Excelsior Apiary,' Cheltenham, July 18th.— Doubtless, at least for this district, the 'honey-flow' of '87 is over. It has ceased equally as suddenly as it began. For five weeks the sun has shone gloriously, and for that period our little

pets have wrought nobly and well. I suppose the white clover has really been the only harvest here, and from this source some beautiful honey has been gained, but even this has been much limited by the extreme heat and extended drought. Our last hope was the 'limes,' but these, from the above cause, have been the most utter failure that I ever remember, countless numbers of the blooms having never opened, and those which did only to wither in the effort. Still, 'big stocks' have done well, and had the limes yielded would have done grandly. I have taken 2 cwt. up to the present time in sections, and have now over 300 on, nearly the whole of which, a few fine days with a flow, would complete, beyond which many frames are blocked up with honey, some of which weighing 6 lbs. The rain has come, and upon the latest rows of limes in this town, which I find are still in bloom and very near to my apiary, the bees are working with a mighty roar, and my hopes rise of yet securing, for two hives at least, the expected cwt. per hive. In regard to 'Yorkshire Notes' and the question of surplus from a swarm the first year, on June 10th, from a small skep, I hived a swarm, giving one brood-comb, three empty combs, and four with starters only, from which, on July 4th, I had taken 18 lbs. in sections, and twenty-one more are now on, most of which I trust will be completed. The parent stock I divided and are both strong. T. Fowler.

NOTICES TO CORRESPONDENTS & INQUIRERS.

Letters or queries asking for addresses of manufacturers or correspondents, or where appliances can be purchased, or replies giving such information, can only be inserted as advertisements. The space devoted to letters, queries, and replies, is meant for the general good of bec-keepers, and not for advertisements. We wish our Correspondents to bear in mind that, as it is necessary for us to go to press in advance of the date of issue, queries cannot always be replied to in the issue immediately following the receipt of their communication.

All queries forwarded will be attended to, and those only of personal interests will be answered in this column.

interest will be answered in this column.

- J. Ward.—Name of Insect.—The insect forwarded does not belong to the order Hymenoptera, which includes the Apida, or bee family; we are not much interested in the Diptera, to which your specimen belongs. We have, however, much pleasure in informing you that its specific name is Tabanus borinus (the large Gadfly); it lives by sucking the blood of horses, oxen, and other animals. It is more common on the Continent than in Britain; and rarer in Scotland than in England. For further particulars, consult Walker's British Diptera, vol. i. p. 175. An illustration of the T. hovinus and larva will be found in Chambers' Cyclopædia.
- James Ball.—Sample Foundation.—The sample sent is of very fair quality, its melting point being 144° Fahr. Pure bees-wax melts at 146° Fahr.—a variation of two degrees is of small moment with super foundation. It is made from bleached wax. This white-coloured foundation is coming much into vogue. It being white gives it a much thinner appearance than if made with unbleached wax. Although, at the same time, it may be thicker, the flatbottom also adds to its thin appearance; but, according to our experience, bees work upon a natural-shaped base a great deal better. Pure bees-wax (white) cannot be obtained without bleaching.
- J. Sanders:—1. Ripe Honey.—Honey is ripe when scaled over. Flavour is not a criterion. As to ripeness, unripe honey is thin, and will ferment very soon after removal from hive; especially in warm weather. 2. Time for Driving from Skeps .- If you mean for the purpose of removing the honey, as soon after the cessation of the honey-flow in your district as possible.
- C. A. J .- 1. Queen joining Swarm .- The queen does not lead the swarm, as supposed by many inexperienced beckeepers, but joins it when on the wing; the swarm commences to settle and then the queen settles with them. In your case she evidently was one of the last to do so. 2. Queen-cells and Droug hatching from same.—The large number of queen cells is very unusual, if your bees are English. A queen (?) cell with drone inside is always abnormally formed; not only as to its surface, but also as to its position on the comb. We have opened numberless such cells, the drone being invariably dead. How long was it from the time you cut out the cell until the

- drone hatched out? 3. Giving Bees Salt .- Salt cannot possibly make your bees savage, as if you do not give it them they will get it elsewhere. Our bees are always regaled with several saucers of salt and water. They do not chase us round the apiary. Bee-keepers who keep their bees near the sea do not, as a rule, have to scamper round their garden whenever they go into it. 4. Queen mating.-We do not consider your argument sufficiently cogent to prove the possibility of fertilisation of queens in confinement. This, which has often been attempted, has hitherto presented difficulties which appear to be insu-For many reasons, which we cannot mention in this short reply, we believe that the fertilisation in mid-air is the more satisfactory, and therefore more desirable.
- A. M.—Sections fastened to Separators.—Is your bive perfectly level? This sometimes causes it. Did you put any starters in your sections? this would be another cause, if omitted. Always have your separators perfectly clean and free from pieces of wax. If separators have any wax sticking on then the bees are very likely to fasten their combs to them. Zinc separators are the least likely to have the sections affixed to them.
- J. C. I.—Honey with Taste of Prussic Acid (see p. 303).— Diluted prussic acid has the odour and taste of peachblossom and bitter almond. At Ipswich a few years ago I was told by a clergyman (a bee-keeper who had a peachhouse), that he dared not let his children eat the early honey because it had so strong a taste of prussic acid.-J. Lawson Lisson.
- Hydro.-1. Removing Hives to Heather.-Great care should be taken in fixing the frames, otherwise there is danger in their breaking. Directions will be found in previous numbers as to the best method of fixing frames. 2. Extracting Heather.—Heather-honey may be extracted with ease when first gathered, but in a few days it settles into a solid jelly, which cannot be extracted by an ordinary The comb should be cut into cubes, placed in extractor. a conical bag, and exposed to the heat of a fire, when the honey will exude.
- T. Fisher.— Orret Oil.—We have not been able, from British sources of information, to obtain any knowledge of this oil. Probably it is a local designation. We will endeavour to ascertain particulars of it from Canada.
- A Constant Subscriber.—Fertile Worker.—The most expert bee-keeper cannot always restrain the swarming impulse in bees; and we are not surprised at your inability to effect this. We are inclined to think that the young queen has been lost in her matrimonial flight, and that, from the excessive number of drones and drone-cells, a fertile worker is at present in your hive.
- T. D. J.—1. Uniting.—There would be no danger in driving and uniting the bees at the time mentioned, taking the precaution to see at the time of the operation that both the stocks are gorged with scented syrup. 2. Close of Honey Harrest. - No general rule can be given as to the time when the honey glut will be over; but in most districts this year, where there is no heather, the harvest will be over before August. In many parts the 3. Third-class Certificate. harvest is over already. There is no difficulty in obtaining this certificate. It is necessary for the candidate to prove to the judges that he has a fair knowledge of bees and au ability to manipulate. The second and first are more difficult, and require some acquaintance with the literature of apiculture. The place and time of examination are arranged by the secretary of the county in which the candidate resides.
- S. L. B .- Wasp .- The name of the specimen forwarded is Vespa Norvegica. Our correspondent writes: 'Could you name the enclosed wasp for me?-evidently quite distinct from the common wasp. It built a paper nest in a hedge, which when I destroyed another was immediately begun and finished in a few days; but the colony was very small, I think less than twenty in all. I cannot compare the common wasp with it, for, strange to say, in this locality (Fermanagh), where usually they appear in myriads (sometimes a veritable plague), this year I have not seen one single specimen male or female!

W. F. Askew,—The name of the 'large insect resembling a wasp' is Sirex giyas, or gigantic sawfly. The Sirex is an internal borer of trees; the larvæ cause much damage to fir and other trees. It is remarked that the larvæ take a very long time before they reach maturity. It belongs to the order Hymenoptera. See Kirby's Entomology, p. 121. Being a fine specimen we presented it to the Eutomological Department, South Kensington.

G. T.—The bee forwarded is an *Apis Ligastica*, or Ligarian bee, with some slight modification of the usual bands.

J. M. P. — White-headed Drones. — The cause of this abnormal appearance is that the drones are aborted in development. Sometimes the workers, in their impatience during the glut to fill the cells with honey, will not wait for the full growth of the drones, but incontinently lug them out in all their immaturity. On p. 117 of Mr. Cheshire's work on bee-keeping will be found an account of albino drones.

Beeswing.—Queen-rearing.—Consult 'Useful Hints' on this subject in this issue.

Novice.—I. Combs fixed together.—Remove both frames at once and divide the combs with a kuife, and turn the frames round so that the same two surfaces are not opposite to each other. Any time of the day will do. 2 and 3. Transferring.—Drive the bees as you propose, cut or break out the combs from the skeps and tie each into a frame, being careful not to injure the brood. The outside combs being built of drone cells should not be transferred. Having tied the combs into the frames and placed them in the bar-frame hive, turn the bees among them, and place the quilts over them. When the time arrives for reducing for the winter, remove such frames as are not covered by the bees.

RECEIVED from Mr. John Walton, Honey Cott, Leamington, a section of honey. We found it of excellent quality and flavour and delicious in taste. Such honey ought to fetch a good price in the market.

Show Announcements.

Giving Name and Address of Secretary, Date and Place of Show, Date of Closing Entries. Terms: Three Insertions and under, Two Shillings and Sixpence; additional insertions, Sixpence each. No charge made to Associations whose Shows are announced in our general Advertising Columns.

July 26-28.—Gloucestershire Agricultural Show at Cheltenham. W. D. Slade, Sec.

July 26, 27.—Warwick Agricultural Society at Sutton Coldfield. J. N. Bower, Secretary.

July 27.—Bishops Waltham Show. (Hants and Isle of Wight Association.) H. W. West, Hon. Sec., Swanmore House, Bishops Waltham.

July 27.—Kent Association, at Ashford, Kent. Hon. Sec., J. Garratt, Hockenden, St. Mary Cray, Kent.

August 3-5.—Yorkshire Agricultural Society at York. Secretary, H. L. Rickards, Poole, near Leeds.

August 11.—Taunton Flower Show, at Vivary Park, Taunton, Somerset. Entries close August 8. Hon. Sec., W. B. Maynard, 5 Hamnet Street, Taunton.

August 12.—Maer Fète and Honey Show. Entries close August 5. John R. Critchlow, Hon. Sec., Maer Farm, Newcastle, Staffs.

August 9, 10.—Irish Bee-keepers' Association at Salthill Gardens, near Dublin. Entries close August 2. Hon. Sec., Henry Chenevix, Blackrock, Dublin.

Angust 14.—Handbridge, Chester St. Mary's Horticultural Show. W. E. Little, Hon. Secretary, Eastgate Row, Chester.

August 24.—Lancaster Agricultural Show. W. Liddell, Hon. Secretary, Dale Street, Lancaster.

August 31-Sept. 3.—Royal Munchester and Liverpool Agricultural Show at Manchester. W. Lees McClure, Hon. Secretary, The Lathoms, Prescot, Lancashire.

Business Birectory.

For the use of Manufacturers and Purchasers of Beekeeping Appliances.

The Name and Address and Business of any Manufacturer will be inserted in this List, under one heading, for One Pound per annum. Additional headings, Five Shillings extra. Advertisers in 'The Bee Journal,' whose orders amount to Five Pounds per annum, will be inserted Free.

SIMMINS' FACTORY, For HIVES and APPLIANCES.

CARNIOLAN

BEES have come to stay, and will hold their own wherever introduced. Good workers; amiable and beautiful; and for wintering are perfection. We are now booking Orders for SIX-FRAME STOCKS, in full-sized Hives, with Cover, @ 27/6, to be delivered in July and August, STANDARD FRAMES, good sound Combs, with Brood and Stores. Also THREE-FRAME NUCLEI in like condition.

SIMININS, ECTINGDEAN, BRIGHTON.
NOTE.-ALL SIMMINS' QUEENS ARE REARED FROM MOTHERS WHO HAVE NOT SWARMED.

SUPERIOR BEE VEILS.

WIRE GAUZE FRONTS, 1s. 2d. each, 3 for 3s.
Traps for Cleaning Supers, 6d. each, 3 for 1s.
Post free. Address, W. Crisp, Halstead, Essex.

HOME-RAISED Healthy CYPRIAN QUEENS, bred from BENTON'S FINEST SELECTED 1886 QUEENS, delivered safely at 8s. each. Sample Workers of each Queen if desired. Address Ennest E. Davis, Bookham Mills, Leatherhead.

POR USE WITHOUT SEPARATORS OR with the SIMMINS' SEPARATOR thickened at the Corners by a Half Bee-space.

20,000 4½×4½×1¾ V-CUT, Open or Close Sided, First-Class AMERICAN SECTIONS, now landed at Liverpool, Free on rail or steamer there, 20/- per 1000; 10/6 for 500. For smaller quantities apply to J. H. HOWARD, Holme, Peterborough; or to R. White & Co., Importers, Patrickswell, Limerick. The Trade supplied.

Self-acting Fountains & Aquariums.

Suitable for Greenhouses, the Dining-room, &c.

Send for Catalogue, Post free,

NEW PATENT HONEY SQUEEZERS.—Having made Special Terms with Manufacturers, can sell this handy utensil at 1/6, 1/9 Post free.
'LITTLE WONDER' EXTRACTORS at 7/6.

SPENCE, Manufacturer, &c., Spilsby, Lincolnshire.

HONEY TINS.

CATALOGUE

Post Free. (100 Pictures.)

G. STOTHARD, British Hive Factory, Welwyn, Herts.

WEBSTER'S FUMIGATOR

Entirely supersedes the Smoker, both in Simplicity and Effectiveness. No 'going out.' No tainting or soiling of combs. Always ready for use without any preparation. Can be carried in pocket.

With Bellows, 4s. 6d.; postage, 4½d. Without Bellows, 3s.; postage, 3d.

Can be adjusted to any ordinary smoker bellows.

6 oz. Bottles of Agent—carbolic acid, oil of tar, and water, proportionably mixed—6d. each.

WEBSTER'S SWIVEL FRAME-LIFTER

With this appliance, frames can be removed from hive. Examined on both sides and replaced without inverting, and with one hand only, leaving the other free to perform any manipulation, at the same time preventing the soiling of hands with propolis.

1s. 6d. each. Postage 3d.

Send for ILLUSTRATED CATALOGUE of all descriptions of Appliances. Post free on receipt of post-card.

AWARDS LAST SEASON.

Ist Prize, Silver Medal, Royal Counties' Agricultural Show. Highest Award, Bronze Medal, Colonial and Indian Exhibition, for Bee Subjugators.

2nd Prize Bronze Medal, Colonial and Indian Exhibition, for useful Inventions introduced since I883.

2nd Prize, Altrincham, for useful Inventions.

W. B. WEBSTER, BINFIELD, BERKS.

QUEEN VICTORIA'S TRAIN AND THE BEES.

We published in a recent number a story taken from a Westmoreland paper relating to the alleged stoppage of the Royal train on Her Majesty's last journey from Bahnoral. It was said that a swarm of bees, by getting into a signal-lamp, had extinguished the light, and had thus obliged the driver of the Queen's train to pull up to inquire the reason that no light was showing. We had our misgivings about the entire correctness of the incident, and finding that other bee-keepers were similarly exercised in their minds, we determined to get information of an unimpeachable kind with regard to the facts of the case. We, therefore, wrote to the signalman in charge of the lamp which has become so famous, and we have received from him a full reply. We are now consequently in a position to furnish our readers with a true and particular account of what did take place.

The locale of our story is Hincaster Junction, near Milnthorpe, Westmoreland. The lamp-posts on the line are fitted, it seems, with cases to receive the signal-lights. These cases have lids, in which, for letting out the heated air, are holes from half an inch to an inch in diameter. Through these holes a swarm of bees did find their way into the lamp-case at Hineaster Junction. The lamp was put into its position at 11.30 p.m. on the night of Her Majesty's last journey from Balmoral to Windsor, and with such force as to shake the bees down in sufficient numbers to close the ventilating holes and thus put out the light. The astonished signalman was unable to rekindle the lamp owing to its novel occupants, and he left the swarm until the following night, when he took an old strawhive, the inside of which had been treated with syrup or some sweet liquid, and placed it on the top of the lamp-case. The bees gladly accepted the proffered home, so much more comfortable than the strange abode they had selected. They were again left undisturbed for twenty-four hours, when the signalman carried the hive down the post, a distance of fifty feet, to the ground. Having reached terra firma he wrapped a cloth round the hive-bottom and conveyed the swarm to his garden

half-a-mile away, where, he says, 'they are doing well and appear content with their new home.'

A further point of interest, and one that clears up some difficulties which had occurred to us, is that the lamp in question is only lighted on special occasions during the period from March to August each year, as it is connected with simply a 'daysignal box.' It is not easy, therefore, to decide the exact date when the bees settled on the post; but as combs had been begun it is certain some timeprobably half-a-day—had passed before their first discovery. Any way, the story of the swarm having been attracted by the light of the lamp, and so flying at night, is effectually disposed of by the facts narrated. Moreover, Her Majesty's train was not stopped, nor her journey in any way interfered with, by the strange vagary of a scout choosing so extraordinary a place for a settlement as the lamp-case on the top of a railway signal-post. It is certain that from time to time these scouts surprise us by 'the unexpected,' and show that they will not be treated or represented as if 'unconscious automata.' Their manifestations of will and wilfulness occasionally become annoying enough to apiarians, but we are sincerely glad to find that the vagary of the Westmoreland leader or ruler of the swarm did not, as was reported, cause any discomfort, or even a momentary delay, to our gracious Sovereign Lady as she journeyed from her northern to her southern home. Had any such inconvenience occurred it would have been an unworthy requital on the part of the bees for the interest that some members of the Royal Family take in apiculture.

We wish the Hincaster Junction signalman all success with his swarm which has attained such wide-spread notoriety, but we hope he will instal the colony in a bar-frame hive, and, discarding the 'old straw hive,' will become an enthusiastic beekeeper using modern methods. We give him hearty thanks for enabling us to put the facts of this curious case distinctly and truthfully before our readers.

MANCHESTER EXHIBITION.

We beg to call the attention of exhibitors to the fact that the entries for the Manchester Exhibition close on August 1st. Liberal prizes are offered. The Bee Department is under the management of the Lancashire and Cheshire Association. We feel sure a good entry will be made.

ASSOCIATIONS.

BRITISH BEE-KEEPERS' ASSOCIATION.

Committee Meeting, held at 105 Jermyn Street, on Wednesday, July 20th. Present: the Hon. and Rev. H. Bligh in the chair, the Rev. Dr. Bartrum, Revs. F. G. Jenyns, G. Oddie, and F. S. Selater, Captain Bush. Captain Campbell, J. M. Hooker, and the Secretary. A letter was read from the Treasurer regretting his inability to be present. Correspondence was read from Mr. T. Bonner Chambers respecting the appointment of an examiner to attend the Tref Eglwys Exhibition. The Secretary was requested to inform Mr. Chambers that the application must come through the Secretary of the Montgomery Association, in accordance with the rules of alfiliation.

Judges were appointed for the following country shows, viz.: on July 26 at St. Ives (Herts), and Cheltenham (Gloucester); on July 27th, at Bishops Waltham (Hants), and Ashford (Kent); on July 28th, Ashby-de-la-Zouch (Leicester); on August 16th, Salis-

bury; August 18th, Aberdare.

A report was read from Mr. W. B. Webster respecting his course of lectures and visits to bee-keepers on behalf of the Association in the County of Northumberland. Resolved that the best thanks of the Committee be given to Mr. Webster for his report and services. The Secretary reported what steps had been taken by the residents of Northumberland to form an association for that county.

It was resolved that the prize list for the bee department of the Royal Agricultural Show of ISSS be con-

sidered at the next meeting.

Quarterly Meeting of County Representatives held at the close of the above Committee Meeting. Present: W. de Lacy Ahern (Surrey), Mrs. Curry and W. B. Webster (Berks), W. Rushton (Beds), Rev. W. E. Burkitt (Wilts), Jesse Garratt (Kent), F. H. Meggy (Essex), — King (Bucks).

The minutes of the last Quarterly Conference were read and confirmed. The Secretary reported that the rules for the management of country shows had been further considered in accordance with the resolution of the last Quarterly Conference and had since been issued

to each County Secretary.

The advisability of the British Bee-keepers' Association offering prizes for honey at county shows, open to members of the B.B.K.A. only, was fully discussed. On the motion of Mr. Webster, seconded by the Rev. W. E. Burkitt, it was unanimously resolved, 'That this meeting of County Representatives fully approves of the proposal of the B.B.K.A. to offer prizes, open to its members, at the county exhibitions.' Mr. Garratt supported the motion, as tending to identify the counties more with the central Society, and at the same time giving additional attractions to the county shows.

Mr. Rushton reported that, with the consent of II.M. Inspector of Schools, the subject of bee-keeping had been taught in their night-school during the past winter. The scheme as arranged was intended to extend over three years. The examination subsequently took place at the end of the term. A good proportion of the schools passed the examination. The grant earned amounted to nearly 2l. The Educational Department had since repudiated the arrangement and refused the amount

of grant earned.

Mr. Rushton was requested to send full particulars to the Secretary of the B.B.K.A., in order that the central Society might be enabled to take the matter up.

Mr. Meggy raised the question as to the advisability of making it compulsory for the 'queen' to be caught in 'driving competitions,' the general opinion of the meeting being that it was not advisable to alter the rule in this respect.

The Quarterly Conversazione of the Association was held at 6 p.m., when among the audience assembled were the following members and county representatives:—Mrs. Curry, Mr. Hooker, Mr. Garratt, the Rev. Mr. Burkitt, Mr. Bunbury, Captain Campbell, Mr. Lyon, Mr. Grimshaw, Mr. Heuderson, Mr. Meggy, Mr. Webster, and Mr. Daintree.

Mr. Bunbury (Suffolk) having been voted to the chair, called upon Mr. Grimshaw to read the paper he had

written on

THE VISUAL ORGANS OF BEES.

The worker-bee has about 12,000 eyes, the drone more than twice that number, and the queen only some ten thousand (quite plenty, one would think), but, as we know, all three kinds possess the three large simple eyes—stemmata or ocelli—fixed quite in the central line of the head; those of the drone being on what we may term the forehead of the bee, whilst the simple eyes of the female are on the top of the head. Observation, in addition to anatomical structure, tells us that the bee has a vast range of vision, and that this must be of a telescopic nature goes without saying when we consider that she has to discern minute specks of colour at what (remembering the small comparative size of the insect) must be called immense distances; the flower on its part making these specks easiest to be seen by using as a colour-bait the attractive and somewhat gaudy primaries -red, blue, and yellow, most frequently.

Each of these myriad eyes series as a minute long or short range telescope, according to its position on the curved eye-mass, the longer distances being taken by those nearer the centre, and the shorter by the separate eyes near the margin. The bee thus gets an accurate picture of the country extending in a semicircle before it, but in all probability appearing like a flat wall; that is, without perspective. The circle of its vision may be represented by a circumference of twelve miles, or two

miles in every direction.

At this range any bright speck of colour is a bid of wages, which, in the majority of instances will be paid for services rendered by the bee, the flower doing its utmost to attract its attention by using, as I said, most frequently, the glaring primary colours. Large flowers are single and solitary, whilst small ones are massed together by the plant into a head, a spike, or an umbel. These conglomerations of small flowers are again massed together by the hand of nature into sheets of bloom, of which mountain thyme, the sages and saxifrages of the Alps, or the purple heather of the moors, are familiar examples; and, so that there shall be little chance of the bee not seeing them, the most telling background or setting is used in nature's colour-grouping-red is set in green, blue in orange, yellow in purple, and vice versâ.

Green, orange, and purple set each other off, as do russets, grays, and browns. All for a purpose, and nothing without a purpose. Thus, so far as the bee is concerned, colour is for the eye, and the eye for colour. So, we may say the telescopic eyes of the bee are intended and used for little else than as first guides to flowers. On approaching a flower, now come into play the guides to its contents—scented nectar—these are the organs of smell, situated, as we are told, in the antennæ; and these organs discriminate which flowers ought or ought not to be visited, for many of the colour-baits prove 'a vain delusion and a snare.' These perfumeguides are an infallible means of detecting bee-food, for where there is not nectar there is pollen; besides we must not conclude when we see bees paying visits to flowers which are to us odourless that they are nectarless, and that consequently the bee's search is fruitless, for nectar and perfume exist in minute quantities far beyond our discernment. Fortunately, or unfortunately, for us our sense of smell is by comparison a very coarse and untrustworthy affair.

I think that before a bee alights on a flower its compound eyes become useless, that is, superseded, and during its search in the flower-folds they are protected from friction and stickiness by the countless hairs serving as eye-buffers, the antennæ and tongue doing all the searching and gathering. Indeed, these telescopic eyes must be useless at such very close quarters, or they would be provided with an adaptable focussing arrangement somewhat similar to our own. They are admirable for their purpose, and when that fails some other power takes up and continues the sense chain, notably, touch and smell, these being intensified at short ranges in the same measure as the vision of the compound eye falls short. What, then, is the use of the three large simple eyes, microscopic in their action? For use in the flower-depths where the hairs of the bee become bathed in sweet liquid, or in narrow flower tubes laden nolens volens with pollen granules? I think not. Other senses are of more service.

I will lay before you two hypotheses as suggestions of the true place occupied by these eyes in the economy of the bee. The first of these suggests them as homing We have dazzling tints tempting the bee guides. We have dazzling tints tempting the bee through its compound eyes (flower-guides); nectar appealing to the food-guides; and as there must be a guide somewhere to dulce domum, where shall we look for it? Let us test the return journey by the same means as the outward trip. Dazzling tints for the telescopes there are none; landmarks for the telescopes plenty; but, alas! as soon as the neighbourhood of these landmarks be reached, the next guides, the scent-discerning antennæ, totally fail, as is proved by the frequent dying of hees when with a few feet of home, the hive having been removed from its old stand. Telescopic and microscopic eyes, hearing, touch, smell, all fail the bee when its home is interfered with to the extent I name. Where is the homing power? If it be instinct, instinct fails a few feet from home. Instinct will not lead it to take advantage of hedges, houses, or drains in strong winds. If reason be its homeward guide, reason fails also a few feet from home. So also do these three eyes, as organs of visiou simply.

My first proposition is, that as the simple eyes are arranged in a triangle on the head of the bee it makes use of some superior kind of trigonometry in finding its way home, just as it uses some more intricate system of mathematics than we are acquainted with in its cell-construction. The three simple eyes are not arranged in an obtuse triangle without the angle principle being brought into play as a factor in its vision, for it is in accordance with the triangular principle that the two side eyes have an outward aspect and inclination whilst the lower and front eye looks forward.

From our limited knowledge let us reason from what we do with triangles in optics to what the bee may do. By a system of triangles, aided by telescopes (like the bee) we ascertain the distance of remote objects, the height of mountains, the distance to the earth's centre, its diameter and circumference, the form, size, and distance from us of the sun, moon, and stars. The vision through the bee's three eyes must perforce give it the bases and apex of an inverted triangle, whatever use it puts the knowledge to, thus obtained. This local triangular vision in connexion with distant telescopic vision is certainly an actual occurrence, and is in singular similitude to our own triangulations, whatever may be thought of such a coincidence. Now it is a well-known fact that upon a bee's first trip from home it circles round it a few times, then approaching and receding (without turning round) from the entrance in an almost straight line, is if taking hearings to use the stereotyped phrase. Yes, but taking bearings on what basis? mariner take bearings without his angles, and his instru-

ments as correct bases, and note the disastrons result.

On the other hand, let the bee with its telescopic range

note prominent objects in its range of vision, and at the same time note with its short focussed three simple eyes the position of near objects with regard to distant ones, and its way home is assured, so long as the distant landmarks are kept in view. It can return to its own garden and hive to a certainty. Remove the hive and all its local triangular calculations are disarranged. It is lost. The unerring aim of the insect for the old spot, whether its home he there or not, goes a long way to support the suggestion that its homing guide within well-known landmarks is by calculation almost entirely mathematical, and that without this triangular calculation all its other guides—sight, smell, hearing, and touch—fall with the

bee to the ground.

My second hypothesis as to the use of the ocelli is not quite so vague in its character as the foregoing. We find the worker-bee in the deep darkness of its cell carving out with its jaws the unshapely little heaps of wax into a series of triangles of almost mathematical exactness. Well, darkness is only a comparative term—absolute darkness we can scarcely obtain. The skull-like framework in which these eyes are set is so waved or convoluted that the two upper eyes are directed outwards and the lower one forward, this triangular outlook being further secured by an arrangement of hairs which prevent the eyes seeing in any other direction. We have next the wedge-shaped head of the bee, apex downwards, and from the centre of the cell-base we have a series of wedge-shaped results in wax, one triangle being from the middle of two walls to the centre (this gives us the cellfloor) and another from the corners of the cell-walls to the centre (thus we get the wall). As the bee works upon the plastic wax it supports itself by its six legs on six rudimentary cell-walls and gnaws away the superabundant wax from the circular to the angular form, its guide in this operation being probably, first, the immoveable staring simple eyes, fixing the triangles, next the highly sensitive tactile antenne, and, finally, for smoothing down and chiselling purposes we have the wedge-like head. As for the existence of stemmata in the queen, which does not build, a moment's reflection will show you that as the worker is but an imperfect queen, or the queen an imperfect worker (I don't care which), this point is disposed of. With regard to the drone, a little physiological reasoning will discover the necessity for their existence. I put these two theories hefore you more as suggestions for interesting speculation —at least so they have proved to me—than as distinct statements of proven fact, for such I fear they will

Mr. Garratt did not think he could add any remarks of interest to the paper which had been so ably prepared, but would like to ask one or two questions. He did not feel quite sure whether it was intended that the meeting should regard the statements Mr. Grimshaw had made as ascertained facts, or as speculations. It seemed to him that they were speculations, and he thought towards the conclusion of the paper just read Mr. Grimshaw admitted that. He was startled at the outset to hear that bees had so large a number of eyes. Many writers on bees had fixed the number of separate eyes at 800 in each compound eye, and now it was said that instead of hundreds there were many thousands. He would like further light thrown on this matter. It seemed quite reasonable that if bees had as many eyes as stated they must serve different purposes, or nature would not have been so prodigal in designing such an organ of vision. Also with regard to the organs of smell being contained in the antennæ, he thought that statement was purely speculative. Certainly more light had been thrown on the subject by Mr. Cheshire in recent times than before, but Mr. Grimshaw had gone further than Mr. Cheshire. It occurred to him that that subject, like many others of a scientific character in relation to bees, might be taken into consideration by the Association with the object of promoting further research and discovery. One of the aims of the institution should be to encourage experiment for the purpose of gaining increased scientific information. Many of the points touched on by Mr. Grimshaw were well worthy of further elucidation. The knowledge of the habits, instinct, and mode of working of bees was in its infancy, and he recommended that the Association should organize a system of close and methodical observation in the direction suggested.

Mr. Webster thought Mr. Grimshaw's figures respecting the number of facets in a bee's eye far more correct than Mr. Garratt's computation of 800. He had counted 100 facets in a bee's eye which occupied no more space than a pin's point, but he had no instrument fine enough to compute the number of facets in a single eye. With regard to bees building their cells hexagonally he thought the bees build the cells round in shape, and that by pressure they became hexagonal. He did not believe the triangular eyes had any influence on the building of hexagonal cells. As to bees taking points by triangles in the same way as mariners, he doubted the assertion, because bees frequently made mistakes by entering the wrong hives. They became mixed up to a considerable extent. Where two species of bees were kept like the black and Italian, dozens of the latter might often be found in the black bees' hives. On the other hand, Italians would not permit strangers in their hives.

The Chairman would like to know what colour bees had a preference for. In his garden there were large patches of yellow flowers, which were generally supposed to be bee flowers, but the bees did not appear to work on them in nearly such large force as on the mignonette.

Mr. Grimshaw said that in his remarks about colour he had excluded from consideration clover, heather, or any flowers which attracted bees by their odour. He thought it could not be questioned that the eye was intended to distinguish colours. Sir John Lubbock's experiments showed that they preferred flowers with a blue tint. He believed the object of bright colours was to tempt the bee to visit such plants, and when the bee arrived within a certain range it knew whether or not anything could be gained by an inspection of the flowers. Its telescopic vision enabled it to see these colours at a great distance. There was no doubt that both humble bees and honey bees visited flowers without finding nectar therein; and it must be taken for granted that colour was the attraction in the first instance. With regard to Mr. Webster's remarks about cells he thought if an examination of the outer edges of the comb were to be made it would be found in many instances that the cells were quite angular, where there could be no With regard to the hexagonal shape of the pressure. facets of the separate eyes of the compound eye-mass the outer walls were not hexagonal but circular; therefore it might be that the chitine in a soft condition was pressed into hexagonal form, but in its outer edges it was free to assume any shape. In reply to Mr. Garratt he could say that his (the speaker's) figures were quite within the mark when estimating the number of facets at 12,000 for a worker, upwards of 24,000 for a drone, and about 10,000 for a queen. The queen did not require so many eyes as a worker, and the drone, needing a very extended vision, had double the number of a worker. A drone flew only in fine weather and at a different altitude to other bees, and the object of its search was so rare that extraordinary powers of vision were necessary.

Mr. Meggy would like to know how far the statement was to be considered reliable that the bee had a sensation of feeling in its antenne; and he would also like to hear a few words from Mr. Grimshaw in reply to Mr. Webster's remarks as to the failure of bees to find their right homes, probably owing to a want of sight. Mr. Cheshire's observations tended towards the belief that

the antennæ were the seat of feeling. Mr. Grimshaw could perhaps say whether the Germans agreed with Mr. Cheshire's views. Possibly Ligurian bees went to other hives for the purpose of robbing, and not because they had lost their way, as Mr. Webster suggested. In an early volume of the first edition of the Popular Educator, published about twenty-five years ago, a statement was made on the question of Euclid as to the exactitude of the bees working in the hexagonal. The writer tried to show that the bees were not quite exact in their mathematics, but his arguments were afterwards vigorously assailed, and the bee's measurement found correct.

Mr. Grimshaw said with regard to bees not always coming back direct to their own hives, he thought one or two exceptions must not be taken as upsetting the rule. There was a saying that if a strange bee went to a hive with its honey sac full it was received with open arms. With regard to the smell organs being situated in the antennæ, experiments had been made by clipping off the antennæ of insects for the purpose of seeing whether or not the latter would find nectar. The result of such experiments was that drone, queen, worker-bee, ants, and other insects possessing antennæ, and which feed on scented substances, went wandering about in a very aimless manner after being deprived of their antennæ. In addition to that there were certain depressions on the antennæ provided with nerves, which the highest authorities argued could be put to no other purpose than that of smelling.

Mr. Webster did not know whether it was that the bees went visiting one another, or that by mistake they entered the wrong hives and were accepted for the time being because they brought supplies with them; but an examination of his stocks of black bees, night or morning, would often show more than a hundred Ligurian

intruders.

Mr. Grimshaw said Mr. Webster's remarks struck at the root of one of the bee-keeper's articles of faith. They all knew that sentries were placed at the entrance to a hive day and night, which were able to detect strangers by the smell. All bee-keepers must have witnessed the conflicts which took place from time to time on the alighting board between strange visitors and the inmates of the hive.

Mr. Daintree endorsed Mr. Grimshaw's views. He frequently searched his hives, but seldom or never found an Italian bee in the wrong hive. He thought bees had a keen sense of hearing. A party of hand-bell ringers came into his district twelve months ago, and immediately they began to ring their bells, although at a long distance off, the bees flocked out of all the hives in large numbers.

Mr. Webster was of opinion that bees going to a hive to rob were stopped by the sentries not so much by a sense of smell as by the particular action of the strangers in approaching the hive. He believed that the sentries could tell the difference between a bee which had lost its way and a bee which came for the purpose of robbing. A robber bee going to a hive made a peculiar kind of hum, which was totally distinct from a bee bringing in honey.

Mr. Grimshaw said that in cases where hives had been moved in the day time, the bees belonging thereto would fly about the old stands, and frequently die from inability to find their homes instead of entering other hives. With regard to the bees' eyes, there was no doubt they were so placed for the purpose of giving triangular vision. They represented the instruments which the civil engineer used in his measurements, and combined a triangular system of optics with telescopic arrangements.

Mr. Hooker thought Mr. Grimshaw's arguments very feasible, and suggested that Mr. Webster should propound an alternative theory if he did not believe them.

Mr. Webster believed that the two sets of eyes were for seeing far and short distances, but he did not think that the bees acted on the principles of trigonometry.

Mr. Meggy thought that the ocelli were placed so as to give the triangulation, but that the compound eyes gave the short sight for use in the flower especially. From observations made in his own apiary, he believed it was very rare for bees to make a mistake and visit the wrong hive.

Mr. Grimshaw believed the bee saw objects near to it by means of the short telescopes. The telescopes varied in length, the compound eye-mass being rounded. The facets near the centre had a longer range than those at the outer edges. He did not think the bee used the three simple eyes for ordinary vision at all, because

the other eyes answered the purpose admirably. In answer to Mr. Meggy, Mr. Grimshaw said that the eye was shaped like an orange, and that if a section were taken, it would be found that some of the eyes had short tubes and others long tubes. He believed that bees saw short distances with the short tubes, and long distances with the long tubes, in the same compound

eve-mass.

Mr. W. J. Green, 36 Friars Street, Sudbury, Suffolk, sent for exhibition a model of his new patent 'Imperial' Hive. This hive is a bar-frame hive, with the greater part of the bottom and all the four sides removeable, so that the brood-nest is practically in mid-air, thus affording access to frames at any part without the necessity of taking off the supering case or doubling body, which might prove of service for removing pieces of dropped comb or for requeening, and would enable the bec-keeper to remove extra queen-cells. A small hook goes with the hive for the purpose of pulling the queen-cells down. It has glass sides for summer use, so that the progress that the bees make from day to day may be noted. For winter use glass, being a conductor of heat, is taken out and wood panels inserted, which would make it a complete double walled hive all round. The entrance is, although very simple, different, as it enables it to be closed against robbing bees, but not to exclude the air. The top bar is formed in two distinct pieces, sufficiently for apart to allow foundation to be easily inserted. The glass being kept up to the top of frames any description of frames may be transferred into this hive by simply cutting ends short and gradually introducing its own frames. The bar sustaining frames will be of iron. A model of a doubling box for the above hive had also been forwarded.

Mr. Garratt said if the hive would be the means of producing more honey than any other hive, that would be its greatest recommendation; but on that point the

inventor was silent.

A conversation ensued on the merits of the invention,

without any unanimous opinion being expressed.

Mr. Green had also forwarded for exhibition a feeder, the idea of which occurred to him when he was transferring a lot of bees into his Imperial hive, and, desiring to feed them, he took a piece of old comb and poured some honey on it, which soon sunk into the holes; the bees went down head first into the combs. On the same principle Mr. Green had formed his feeder.

Mr. Hooker, Mr. Lyon, Mr. Webster, and Mr. Garratt commented on the contrivance, the general opinion being that the zine would be too cold for bees in winter time, and that the invention, although ingenious, offered no advantage over systems at present in vogue.

A foundation-fixer, on the principle of Parker's, was exhibited, which Mr. Hooker disapproved, because the motion thereof was not always parallel, like the Parker

foundation-fixer.

Mr. Lyon and Mr. Grimshaw used the haft of a pocket-knife, which answered the purpose, and was cheaper than any foundation-fixer.

The Rev. W. E. Burkitt exhibited a new wax-

extractor, introduced by Mr. Killick, and which he had tried. He spoke in praise of the article, saying that he had never found any way of extracting wax so successfully as by means of the invention now before them.

Mr. Garratt, Mr. Lyon, Mr. Daintree, Captain Campbell, and the Chairman discussed the matter, some of them referring to other modes of extracting wax which they considered to be considered to be equally effectual

as the method in question.

The Chairman moved, and Mr. Garratt seconded, a vote of thanks to Mr. Grimshaw for his valuable and

interesting paper.

Mr. Grimshaw briefly thanked the audience, and said he had been amply repaid for his trouble in preparing the MS. by listening to the very interesting conversation which ensued thereon. He thought the B.B.K.A. should take some formal notice of scientific research amongst its members. The Editor of the British Bee Journal was, he believed, also of the same opinion, for that gentleman had written a very interesting article on scientific subjects for conversazione. They must blend practice with theory, and he hoped other members would be induced to turn their intention in a scientific direction, and communicate their observations through the medium of the *Journal* or at the quarterly meetings of the B.B.K.A. He would be happy to assist in any way practicable.

Mr. Hooker moved, and the Rev. Mr. Burkitt seconded, a vote of thanks to the Chairman, which was suitably acknowledged, and the proceedings terminated.

LINCOLNSHIRE AGRICULTURAL SHOW.

This is one of the most popular and prosperous Associations in connexion with agriculture in all England, and is celebrated for its hospitality to the judges and for the kind consideration shown to the exhibitors and general good management. This year the annual exhibition was held at Spalding, and was opened on Wednesday, the 20th, continuing during Thursday and Friday. Spalding is a nice old agricultural town. The show ground was situated on the eastern side of the town, about a quarter of a mile from it, on the Halmer road leading to Fulney and Weston. The greater part is attached to Cley House, the residence of Mr. Clarke. Seldom have we seen grounds so eminently suited for the purpose of an exhibition of this kind held during the very hottest days of this season. The fine old trees surrounding and intersecting the grounds (about seventeen acres) seemed almost as if they had been planted for the purpose of affording shade from the scorching sun, and adding picturesqueness and beauty to the occasion. The town and the whole length of the streets and roads from the station to the show grounds gave evidence of the liberality and good taste of the people of Spalding, and their hearty desire to welcome the Lincolnshire Agricultural Society. Venetian masts were placed at short distances from each other on both sides of the roads, and a continuous line of bright and various coloured pennons stretched from pole to pole. The whole effect was very good indeed. The refreshing breeze assisted in showing the decorations off to the best advantage.

Passing through the turnstiles, by the implements in motion and under some trees into a second open space, the visitor has on his left under the trees in a prominent position the shed in which the exhibition of bee appliances, honey, &c., is placed; on one side of this is the bee tent and in a lean-to building on the other side are observatory hives with the different races of bees with their queens. In the classes for bees there were seventeen entries, in which Ligurians, Carniolans, Syrians, and blacks, were fairly represented. In honey in the various classes there were forty-two entries, the greater part being of very good quality. In Class 4, for the largest exhibi-

tion of extracted honey, Mr. J. R. Truss, of Bainton Heath, Stamford, obtained first prize with 527 lbs., and Mr. Robert Thorpe, of Swineshead, near Boston, the second prize with 395 lbs., both exhibits being of good quality. The section honey was fairly good, but not such as we sometimes see. In the class for appliances there were thirty-five entries. The hives were an average class, there being no new features that require noting. The same may be said of the supers. The Raynor Extractor exhibited by Mr. Meadows is considerably improved since it obtained the first prize last year. It was far in advance of the other exhibits and well deserved the first prize which was awarded it. The most complete collection of hives, &c., is still part of the schedule here, but we trust this may give place to more useful classes, as at Newcastle and Bury St. Edmunds.

The following is the list of awards:-

BEES .- I. For the best specimens of Ligurian honeybees, to be exhibited with the queen in an Observatory hive—1, W. B. Baker, North Muskham, Newark; 2, R. Thorpe, Swineshead, Boston; 3, C. M. Hufton, Cowbit, Spalding. II. For the best specimens of Carniolan, Cyprian, or Syrian honey-bees, to be exhibited with the queen in an Observatory hive—1, W. Edey & Son, St. Neots, Hunts; 2, S. J. Baldwin, Bromley, Kent; 3, C. M. Hufton. III. For the best specimens of Old English honey-bees, to be exhibited with the queen in an Observatory hive-1, F. W. Riggall, The Grange, Gayton-le-Wold, Louth; 2, H. O. Smith, Louth; 3, W. B. Baker.

Honey.-IV. For the largest and best exhibition of extracted or run honey in glass jars, computed to contain one or two pounds net weight of honey respectively, the produce of one apiary during the year 1887-1, J. R. Truss, Bainton Heath, Stamford (527 lbs.); 2, R. Thorpe (395 lbs.). V. For the best twenty-four 1-lb. sections of comb honey, in crate—1, F. W. Riggall; 2, W. Sells, Uffington, Stamford; 3, Lydia Brown, Whaplode, Spalding. VI. For the best twelve 1-lb. sections of comb honey, in crate—1, W. Sells; 2, H. O. Smith; 3, Amy Hanson, Whaplode, Spalding. Sells; 2, H. O. Smith; 3, Amy Hanson, wnapaoue, spanding, VII. For the best twelve 1-lb, glass jars of extracted or run honey—1, J. R. Truss; 2, F. W. Riggall; 3, W. C. Brown, Appleby, Doncaster. VIII. For the best glass super of comb honey—1, W. Sells; 2, W. Emington, Alford Street, Grantham; 3, W. Sells. IX. For the best super of any other description of comb honey—1, E. Brown, Spalding. other description of comb honey-1, E. Brown, Spalding.

HIVES, &c.-X. For the best, complete, and most practical hive on the moveable-comb principle, two of the frames to be fitted with comb foundation, with arrangements both for storing surplus honey and for wintering. Price not to exceed 11. 10s.-1, S. J. Baldwin; 2, Abbott Bros., Southall, London; 3, S. Dickens & Co., Friern Park Apiary, North Finchley, London, N. XI. For the best, complete, and most practical hive on the moveable-comb principle, two of the frames to be fitted with comb foundation, with arrangements for storing surplus honey. Price not to exceed 7s. 6d.—1, W. B. Baker; 2, W. Edey & Son; 3, Turner & Son, Radcliffe-on-Trent, Nottingham. XII. For the cheapest, neatest, and best super for harvesting honey in the comb in a saleable form—I, Turner & Son; 2, Abbott Bros.; 3, W. B. Baker. XIII. For the best honey extractor—I, W. P. Meadows, Syston, Leicester; 2, Abbott Bros.; 2, W. B. Baker. XIV. For the best and most complete collection of hives and bee-furniture most applicable to modern bee-keeping, no two articles to be alike—1, Abbett Bros.; 2, W. Edey & Son; 3, W. B. Baker. XV. For the best straw hive complete, with floor-board, cover, super, and feeder, showing the most simple and ready means of managing with a view to obtain super honey, and the best method of feeding—I, Abbott Bros.;

2, W. Edey & Sen; 3, S. J. Baldwin.

BEE DRIVING.—XVI. To the competitor who shall show the greatest skill in driving a stock of bees from a straw hive and in capturing the queen, and who shall best explain the method and objects of the operation—1, J. R. Truss.

Lincolnshire is one of the best counties in all England for the production of honey, and we are surprised to find that there is no County Association in affiliation with the British Bee-keepers' Association. There are now no less than some forty County Associations in affiliation with

the parent Association, and we hope that some of the leading bee-keepers in Lincolnshire will call a meeting and form a Committee for the purpose of establishing a Lincolnshire Bee-keepers' Association, with proper rules for the future management, the appointment of the Committee, the keeping and auditing the accounts, and publishing yearly report with balance-sheet, as is done by the other County Associations. We are confident that the B.B.K.A. will do all they can to assist a Committee in such an object. With the encouragement given to bee-culture by the Lincolnshire Agricultural Society, and the general interest now taken in the same, there ought not to be any difficulty in the matter.

The judges appointed by the Lincolnshire Agricultural Society were Mr. Frank Cheshire, Tweedy Road, Bromley, Kent, and Mr. Walter Martin, Wainfleet, Lincolnshire. The Steward was Mr. R. R. Godfrey, Grantham,

and Mr. S. J. Baldwin was expert.

PRESCOT AND DISTRICT HORTICULTURAL SOCIETY.

The third annual exhibition under the auspices of the above Society was held on Thursday, July 21st, in a field in Parkside, Prescot. A new feature in this year's show, and one that indicates the thorough activity and energy of the Committee, was an exhibition of bees, hives, and honey, from the Lancasbire and Cheshire Bee-keepers' Association, introduced for the purpose of encouraging bee-keeping, through the exertions of Mr. W. L. McClure and Mr. W. Tyrer, the secretary and treasurer of the Lancashire and Cheshire Bee-keepers' Association. Prizes were offered for the best comb honey, and for the best twelve jars of run or extracted honey.

The first three prizes were for the best comb honey in sections (from 12 lbs. to 20 lbs. in weight): I, H. T. Gibbs, Lower Bebbington, Cheshire; 2, Jas. Scotson, Holt Hall, Gateacre. The second three prizes offered in this section were for the best twelve jars of run or extracted honey: 1, H. T. Gibbs: 2, Major Dean, and for the third prize Wm. Tyrer (Prescot) and Thomas Munnerley were each entitled to the certificate of the B. B. K. A.

Correspondence.

The Editor does not hold himself responsible for the opinions expressed by his correspondents. No attention will be taken of anonymous communications, and correspondents are requested to write on one side of the paper only, and give their real names and addresses, not necessarily for publication, but as a guarantee of good faith. Illustrations should be drawn on separate pieces of paper.

Communications relating to the literary department, reports of Associations, Shows, Meetings, Echoes, Queries, Books for Review, &c., must be addressed only to 'The Editors of the 'British Bee Journal,' c/o Messrs. Strangeways and Sons, Tower Street, Cambridge Circus, W.C.' All business communications relating to Advertisements, &c., must be addressed to Mr. J. Huckler, Kings Langley, Herts (see 2nd page of Advertisements).

****In order to facilitate reference, Correspondents, when speaking of any letter or query previously inserted, will oblige by mentioning the number of the letter, as well as the page on which it appears.

A SCOTCH BEE-KEEPER.

[1163.] There is nothing gained without perseverance, and this truly may be said about the subject of our memoir, Mr. William McNally, Glenluce, better known in the bee-keeping world as the 'Wigtownshire Bee Farmer.' The name McNally is of late years well known as that of a Scottish family who have attained some degree of prominence as bee-keepers. The originator of the 'hobby' in the family is Mr. William, who is the second son of Mr. Ebenezer McNally of Glenluce. He was educated at the Glenlace Academy, and after passing all the necessary requirements was apprenticed to the joiner trade. Having served a period of four years he went to push his way in the world in Glasgow; but after a few

years of city life he returned to his native home and started business on his own account about the year 1876; and since then he has made a very remunerative trade, his obliging manners and strict attention to business winning him a well-deserved name among the farmers and others in his locality. In the year 1877 he began bee-keeping with one single hive, or rather a skep, for up till that period nothing else was used in the south of Scotland. The following year Mr. McNally paid a visit to some friends near Manchester, where he was introduced to the late Mr. Pettigrew, whose kindly advice was appreciated by Mr. McNally, and with the impressions left on his mind by Mr. Pettigrew he commenced bee-keeping in earnest, and in the following years he gradually increased his stocks until now he has about 140 hives, the majority on the bar-frame system, though he does not entirely discard the straw skep. Any amateur starting for the first time he invariably advises to adopt the frame system. In Wigtownshire, which has seventeen parishes, Mr. McNally has induced hundreds to take up the hobby, and is always ready to give any advice required by beginners. It was not until the year 1884 that he began to step out from home and meet his brother bee-keepers. In that year he and his brother Richard, who also owns a large apiary, exhibited at Edinburgh, and carried off the lion's share of prizes in connexion with the Caledonian Apiarian Society and the Highland Society's Silver Medal for the best display of honey-comb. The following year, at Aberdeen, the same victory was won by the brothers, and the medal was secured for a second time for the best display of honey. The following year, however, Mr. William preferred exhibiting alone, with the result that singly be won the medal for a third time for the best display of honey; his brother Richard on this occasion securing the second place. A visit to his apiaries, which are all located within easy reach of each other, will at once show the visitor that Mr. McNally possesses a great knowledge of bee matters. His neat and well-arranged hives, all painted white, have a very striking appearance: these are seen to great advantage when passing by rail, which is close by his largest apiary. There is abundance of bee plants, specially planted for the bees in the vicinity; and this with the great supply that the district produces places Glenluce as second to none in the kingdom for producing large quantities of honey in a good season. There are miles of clover and heather hills which produce the far-famed Scotch heather honey.

Leaving the apiary we come to the 'honey warehouse,' where an endless variety of all kinds of bee-keeping appliances is to be seen, as well as hundreds of wellfilled sections, supers, and extracted honey just from the hives. Here it is made up into marketable form and sent by rail to Edinburgh, London, and Glasgow; and the very attractive way it is put up secures the highest price. A look round the 'honey house' shows the walls literally covered with prize cards won at the various competitions, not only in Scotland but England as well. This with the large variety of silver and bronze medals goes to prove that Mr. McNally must be a hard opponent to beat in competition. Within the last three years he has had to devote his whole time and attention to beekeeping and to keep a steady output in season of from five to six hives per day, which, he informs us, is a regular thing.

We can think and judge that bee-keeping will not at least decrease in Scotland. Mr. McNally has many new ideas and novelties in the way of bee furniture that we have never had the privilege of seeing previously till now. The honeycomb letter building is a novel thing, Mr. McNally being the originator and inventor, and makes this class of work a special feature. His premises and workshops are commodious and well adapted for doing a large business, and being so near to railway there is no difficulty in despatching orders. The extreme kindness

of Mr. and Mrs. McNally is beyond all praise, and our first visit to this apiary will not soon be forgotten. As it is our intention to return again to this veteran and give some of his sayings on bee topics, for the present we wish him continued success and a large honey harvest during the present season 1887.—'Au Revoir.'

HYBRIDS.

[1164.] No more Ligurians for me; when they have become crossed they are something too awfully fierce. As long as they remain pure, well and good, but when black blood comes in, then look out! However, I have managed fairly well with cross-breds for three years past, but this year I have had two hives which it is impossible to do anything with; smoke or carbolic is of no use whatever. I have been obliged to wear double cotton gloves, but they have stung me through them, and even through my clothes; the cause of their ire being raised was that I was examining one of the hives, being tiered, to see to what extent the grubs in the upper division had hatched out. I found that some of the grubs were those of drones in worker-cells; this I considered to be a sign that something was wrong with the queen, therefore as I knew them to be fierce I decided to replace her. Accordingly I set to work to do so, but their ferocity was so great that I further decided to put them all down, and this I have done, and am glad of it too, for they stung servants about the house, people in the road, men on the haystack, even hens and chickens.

Can you give me any reason for queen laying drone and worker eggs at same time? I mean why had one worker cell a worker grub, whilst the next door cell contained a drone? Do you think Apifuge would have quieted the brutes?—E. W. P.

[The cause of the queen laying worker and drone eggs thus promiscuously may be caused either by accident or old age. Mr. Cheshire says that old queens have been forwarded to him for dissection, and he 'invariably found the spermatheca either quite denuded of its spermatozoa, or only containing such a miserable residue as to clearly show that the eggs could, at the best, be but occasionally fertilised.' We believe that the Apifuge would have been found effective.—Ed.]

CAUGHT IN THE ACT.

[I165.] I have been hoping that some one more able than myself would ere now have issued a protest against that which appeared in July 14th, from the pen of 'A Lazy Yawning Drone' [1151]. He begins with, 'those last lines, i.e., the last—the last before the last—and the last before it—those last lines, indeed! Will the writer tell us how he was able to contemplate the symmetry of the cells of a well-filled and sealed super? Being educated perhaps he will also tell us how in such well-filled and sealed super there could be a bee in one of the cells helping himself to honey? 'Himself,' indicating that the said bee was one of those whom Shakespeare is said to have been so 'hard' upon in the 'three last lines' quoted by 'A Yawning Drone.' Perhaps, also, we may be told how this drone, forced into a cell and sealed up alive, was 'left on the scene of his wickedness as a warning and caution, &c. For three days the dead body of the bee, sealed in the cell, was left to public gaze? How's that, umpire? The said body was then exhumed, for sanitary reasons, and buried (?) 'without the camp,' and the next day the cell from which the corpse had been removed was re-filled with the best lime honey. The 'Yawner' is particular as to its being 'lime,' probably because lime is disinfecting, and the proper sort of thing to put into a newly emptied corpseholder. If this be not so, I fail to see how bees show

'that regard to sanitary measures' which puts them so far ahead of 'poor humanity.' Please remember, Mr. Editor, that your readers are of the 'humanity' order, poor and suffering, and that they will ever be grateful to you if you will, at least during the hot weather, kindly protect them against 'A Lazy Yawning One's' effusions, lazy and yawning not being the only adjectives applicable.—C. N. Abbott, Fairlawn, Southall, July 23rd.

P.S.—I think it a good thing that July the 4th [1147] passed off so well, and trust bee-keepers will not be afflicted with such another 'hot'un.' Fancy, a swarm twenty-four days old 'meaning business' at 3 p.m., and will not be put off at 4.30, notwithstanding the best pair of sheets and the hydropult! 'Bees be werry warious.'—C. N. A.

FOUL BROOD.

[1166.] I am sorry to have to raise this cry when all around seems so fair and promising, but my feelings have received lately such a 'damper,' that out of regard to others I would earnestly warn 'new hands,' like myself, of the prevalence of this pest. Strong hives, cleanly surroundings, are of no avail. To recite my case: everything seemed flourishing, when, in looking for queencells after a very strong swarm had issued, I noticed a peculiar-looking worker-cell. The cap was barely raised above the walls; it looked darker, and I fancied a little crack was at one part, so I opened it, and there was the fatal brown matter instead of a perfect bee! Then a few similar cells could be seen, and some on another frame.

True mine is but a slight attack and of recent origin,—only one hive affected—but there it is; and I am convinced that the disease is much more common than is admitted. It was not in my case easy to detect, many would have passed it over, and yet I had never seen foul brood before. What then of those frame-hives rarely examined, and of skeps which are a closed book to their owners!

I at once placed the case in the 'doctor's' hands, and he bids me take heart, although I am so disgusted I would fain consign all to the old brimstone pit! Perhaps such experience, however, may stand me in good stead, if I persevere: at any rate, I will no longer pity those who find it of long standing in their apiaries, as I now know how easy it is to detect. Is there no physician to aid us and our bees? Can it not be prevented by 'stamping out' and the aid of an insurance society?

That it was introduced into this hive by robbing I have no doubt, as the hive is so strong, and the infected cells few and scattered. I have always put salicylic acid in the bees' drinking water, a precaution taken by few, by none that I know of. My bees drink it readily, and I hope stranger bees frequent the same vessel, as the locality is thereby benefited. I intended giving my address, in order to warn the neighbourhood, but this is styled 'Quixotic,' so I will merely sign myself, with your permission,—West Kent, July 12th.

HIVING BEES.

[1167.] There was a lively bee-hiving out at Judge Odom's 'oakey wood' place the other day—the whole affair being fully up to reputation as regards the tragic and ludicrous. Judge Odom had charged Mr. Roberts, the overseer, to watch the bees, and let no swarms get away. Swarming season approached, and Roberts made ready for his apiarian harvest by preparing hives, and conveniently placing tin pans, bells, horse-shoes, and other instruments of music likely to compose and detain a swarm of bees on taking French leave.

He did not have long to wait. The other morning

He did not have long to wait. The other morning the hottest kind of a swarm darkened the air, and Roberts put his orchestra in motion with a vigour that

would cause any musically educated bee to pause, reflect, and turn back. They did pause, and with one accord pitched upon a tree in the yard, where they formed themselves into a funnel-shaped mass.

Roberts then played upon them with a huge syringe from a bucket of water, and having effectually, as he supposed, put out the incipient flame that lurks in their tails, prepared to gather them into his garner. The bunch of bees were some ten or twelve feet from the ground, and the object was to land them safely within the bee-hive. A serious difficulty here met Mr. Roberts, to wit, how to bring the hive in proximity with the bees, and retain it there. The gods of genius were propitious; necessity, prolific old mother of invention, brought forth a son in the person of 'Blind Phil,' a coloured man on the place, who is nearly or quite blind.

coloured man on the place, who is nearly or quite blind. 'Phil, come here,' said Mr. Roberts, 'I want you to hold this bee-hive under that bunch of bees, while I climb the tree and sweep them in.' And without ceremony or unnecessary delay, he seized Phil, and placed him directly under the bees, put the bee-hive on top of his head and directed him to stand fast.

Broom in hand, Mr. Roberts then ran up the tree with the nimbleness of a cat or squirrel, and, crawling out, hung himself on a limb, and cautiously began to sweep them off, letting them fall in lumps into the open box on the negro's head below. Mr. Roberts congratulated himself on the success of his scheme. Sometimes a wad of bees would miss the hole and strike Phil on the shoulder, which made him restless.

'Stand firm, Phil,' said a voice from above, 'and they will not sting you. If a bee finds out that you are afraid of him, he will sting you certain. Just let him know that you are not afraid, and there is no danger,' remarked Mr. Roberts by way of encouragement.

remarked Mr. Roberts by way of encouragement.
'Ouch! golly! I'm stung for shuah! Whew! Mars Roberts, I'm got to drap dis box!'

'Stand still, you chicken fool you! I'll soon have them all in. Who cares for a bee?'

Just then an old-liner marched down Phil's back, under his shirt, and Phil became still more uneasy, but Mr. Roberts spoke soothing words from above. Suddenly, however, the bees seemed to realise who was disturbing them, and about forty 'business fellows' popped Mr. Roberts simultaneously, and he dropped his broom, lost his hold, and came down with a crash upon the negro and box.

With a whoop and a wild screech, Phil got upon his feet and lit out, followed by a crowd of bees. He forgot his blindness and went he knew not whither, striking the garden palings broadside, and levelling three panels with the ground. He never stopped, but continued to charge around the inclosure until the vegetables were all destroyed.

In the meantime Mr. Roberts was fully employed; in fact, he was 'very busy.' Around the house and through it, then under it, out to the gate, through the house-lot, and 'over the hills and far away.'

Neither were the bees idle, but diligently 'improved each shining hour,' flitting from flower to flower (Roberts and Phil were the blossoms), culling all the sweets and raising merry 'Hail Columbia.'

The swelling has all gone down now, and if any one sees a stray swarm of bees in the neighbourhood they need not hesitate to hive them, as Mr. Roberts and Phil will lay no claim on them.—Albany, Ga., News.

FERTILISATION OF QUEENS.

[1168.] Mr. Henry Alley, in his very valuable *Handy-Book of the Apiary*, expresses the opinion that if one has a considerable number of colonies of Italian or Syrian bees, and half a mile away there are numerous colonies of black bees, not one queen in twenty-five will be mismated. From this opinion I must respectfully dissent.

If one has a small number of one race of bees, and from one to two miles away there are a considerable number of another race, it is not uncommon, as I know by observation, for one-half the young queens to mate with drones of the other race. When I had the only Italian bees in this vicinity, a black queen five miles away produced banded bees; and it is almost an absolute certainty that she had mated with one of my drones.

It is impossible to tell with any certainty how far drones and queens will fly. It is probable that the former fly several miles, and queens may fly further than is generally supposed. It is my opinion that a young queen is never fertilised on her first flight, no matter how many drones there may be in the air in the vicinity of her hive. I have watched a great many for the purpose of finding out all that may be known concerning their habits, and

my observations are to the following effect:

A young queen, before she comes out in earnest, familiarises herself with the locality of her hive. She comes out and this around in the vicinity of the hive for not more than five minutes at a time, and then enters the hive and remains for about five minutes. During the time she is on the wing, she may be observed to approach her hive, in some cases several times, without entering, and she is probably not out of sight of it at any time. 1 have observed five of these five-minute excursions in less than an hour; but I have never known a queen to return, having mated with a drone in less than seventeen minutes from the time she left the hive. I do not say that they never do mate and return in less time than that, but none that I have observed have done so. This gives a queen time to travel several miles, if need be, and her frequent short flights seem designed to enable her to take a longer flight, if necessary, without getting lost.

Now I venture the opinion that, other things being

Now I venture the opinion that, other things being equal, a queen is quite as likely to mate with a drone belonging to a colony half a mile or more away as with one from a colony in the same apiary. The instinct that prompts the queen and drone to fly abroad, prompts them to leave the vicinity of their homes, and thus prevents

in-and-in breeding.

I think it beyond dispute that drones have places of rendezvous, where, from I know not how far, they congregate. In my early bee-keeping days, from twelve to fifteen years ago, the place of meeting was in the edge of a wood a quarter of a mile east of my house. In 1883 and 1884 the playground seemed to be partly over my own premises, and this year over a woods pasture just south of my place. Now, it is a question of some importance whether in a given locality there may not be more than one place of congregating, and also whether the resort of my drones may not be farther away than that of some other drones. In that case my queens would be more likely to meet drones from a neighbour's apiary than from my own.

The above facts and surmises have a bearing upon what I am about to relate. I had in the spring thirty colonies of bees, all except a very few were Syrians, the rest being Italians. There were but two colonies showing any black blood, and I presume that in an area of two miles in diameter there are not as many colonies of bees belonging to other persons as I have, and I am confident that there is not a colony of blacks within half a mile. I have purposely allowed my bees to have a liberal supply of drone-comb, and the number of drones has been large; and yet, out of thirty-one queens reared, twenty-three have mated with black drones, and of the eight remain-

ing two or three are doubtful.

I have never before had such an experience, and I am at a loss to account for it. Have black drones come from a mile or so away and established a resort into which my queens have gone? Or have my queens passed by the resort of their male neighbours, and gone to that of the drones of some other locality? Or is there somewhere in this vicinity a colony of blacks having drones that are

more amorous and enterprising than my Italians and Syrians? One of these hypotheses must be true, but which one I have vainly tried to ascertain. There is no doubt at all that these queens mated with black drones, and not with mixed ones, because they produce many bees that are entirely black; and the queens themselves are pure Syrians and Italians.

It is commonly recommended to rear queens early in order to have them purely mated. In this I have generally failed. My early queens would not mate with my early drones until the weather became warm—almost hot—and by that time black drones were plentiful. More of my queens are purely mated in the late summer and early autumn than in the earlier months. The reason may be that at that time drones and queens do not venture so far from home.—M. MAHIN, D.D., New Castle, Ind. (American Bee Journal.)

MY PET BEES.

[1169.] I said in my last letter I would tell you more about my humble-bees. During the winter I made spare hives, one out of a small yeast-box. It resembles a Cowan hive. Most of your readers will laugh when they hear of me taking an artificial swarm off humblebees, but I did so; and this is the way I proceeded I have helped my father to take artificial swarms, so 1 knew how to manage. The stock was in the 'Clock-case' hive, so I took the 'Cowan' hive and placed it near. Then I took out some of the brood and cells containing honey, which I placed in the 'Cowan' hive, and put it in place of the old stock. The latter I removed to another part of the garden. But I forgot to tell you that I had a lot of queens in the hive (here is a difference between humble and honey-bees), so I took one or two of the newly-hatched ones for the artificial swarm. But all the bees, with the exception of a queen, one or two workers, and a few drones (which the boys about here call 'double-steng'd 'uns,' because they cannot sting', have gone to the place of the old stock.

At the interval of rest while writing this letter, I go to see a new lot of humble-bees, and find one tugging at a piece of straw to take into the nest. You will hear undoubtedly about the new lot, which is very prosperous, soon.—Darcy Grimshaw, Horsforth, near Leeds.

PROFESSOR VON SIEBOLD.

Karl Theodor Ernst von Siebold was born at Würzburg, in Bavaria, on February 16, 1804. His brother was the well-known traveller and philologist. Karl was brought up chiefly, under the superintendence of his father, for the medical profession, and he carried on a practice for a few years as a physician at Heilsberg and Königsberg. In 1835 he received the appointment of Master of the Lying-in Hospital at Dantzic. Early in his life he showed an interest in zoology, and in 1840 he removed from Dantzic to Erlangen, where he taught comparative anatomy, zoology, and veterinary medicine. In I845 he was appointed Professor of Zoology at Friburg, and shortly afterwards he made a prolonged sojourn on the Adriatic. At this time he worked with immense zeal and ardour at the anatomy of the marine invertebrates; and as the result of this work and his lectures combined he commenced the elaboration of his well-known Lehrbuch der vergleichenden Anatomie der Wirbellosen Thiere. In his preface to this work, which has been translated into English and French, he insisted on the importance of a knowledge not only of the minute anatomy but also of the developmental stages of the forms described. Generous aid in the completion of this at the time most excellent treatise was given to him by C. Vogt, H. Stannius, A. Krohn, H. Koch, and A. Kölliker; and in 1849 he founded, in connexion with the

last-named of these eminent biologists, the Zeitschrift für wissenschaftliche Zoologie, a journal which has ever held a leading position among the scientific publications of our day, and one which is still known and esteemed wherever zoology is studied.

In 1850 Von Siebold was appointed to the Professor-ship of Physiology in the University of Breslau, and also received the charge of the Physiological Institute of that

In 1853 he was appointed Professor of Zoology and Comparative Anatomy in the University of Munich, and Director of the Zoological and Zootomical Cabinet in that city. These positions he filled during the remainder of his life.

Shortly after his appointment to the Munich Professorship he commenced an elaborate series of investigations into the vexed question of 'Parthenogenesis,' entering on the subject with a belief that facts had been misunderstood; and his treatise on this phenomenon, as found by him to actually exist in bees and moths, was a genuine contribution to science. This work was published at Leipzig early in 1856, and was translated by Mr. Dallas the following year into English.

Somewhat earlier in date he published a memoir on 'Tape and Cystic Worms, with an introduction on the Origin of Intestinal Worms,' which was deemed worthy of being translated into English, by Professor Huxley, for the New Sydenham Society. The good that this translation effected by introducing some scientific facts to the notice of our medical men it is not easy to

calculate.

In 1858 the Royal Society elected him as one of their honorary members. In 1867 he was made a correspond-ing member of the Institute of France. There seems little need to enumerate all the honours that were conferred on him during the half century that he was known as one of the distinguished zoologists of Europe.

In the important and indispensable catalogue of Scientific Papers published by the Royal Society, we find a list of over 130 memoirs ascribed to Professor von Siebold.

Failing health during the last few years interrupted this, up to 1874, steady flow, and Dr. Ehlers undertook much of the labour of editing the Zeitschrift. Those who had a personal knowledge of Von Siebold will remember his pleasant and friendly manners, the readiness with which he placed at the students' disposal all the information in his power, and the visitor to the Zoological Museum at Munich will not soon forget the vast stores, not only collected, but scientifically arranged, under the superintendence of Von Siebold.

Professor Von Siebold died at Munich on Tuesday, April 7, 1885. He favoured the moveable frame inven-

tion, and was a progressive apiarian.

Echoes from the Pives.

Bournemouth, July 19th.—My bees, twelve stocks, have done fairly well through this dry season, with the help of a little feeding with syrup, and now that is not wanted, as we have plenty of heather in blossom on the surrounding moorlands and among our pine-trees, but the absence of rain since the early part of last month or the end of May has seriously decreased supplies from other bee flowers. I notice in this land of rhododendrons (Bournemouth) the honey bee seldom visits its flowers, and they were all 'ablaze' with blossom this season,—at a time when other flowers were scarce here; but the 'humble bee' seems to glory in it, and loves the rhododendron blossom, 'tumbling over and over in it' for its pollen .- Thomas W. Blake.

Chertsey Grove, July 20.—Some three weeks ago I made an 'Echo' in your valuable Journal, when my fears were that I had foul brood, but only turned out to be queenless. Well, I may just say that I had then put on a crate of sections to two of my boxes, and on July 12th 1 looked at one of them and was able to take off seventeen well-filled sections, leaving the rest partly capped and replacing others in place of those I took off. On July 14th I looked at the other box, and was able to take off eighteen well-filled sections first, and the rest were nearly all filled and partly capped over, and of course I replaced the ones by wellcombed sections and cach of these boxes had twelve wellfilled bars of brood and honey. I also saw in your last issue something said about wasps. Since then I have taken close notice of them, and last night I saw five flying about my hives and to-day about the same number. I only hope they will not increase; I kill all I can to lessen them. I hope all your readers have done better than I have, although I do not complain.—Robert Driver.

Caerleon, South Monmouthshire, July 25.—Bees doing nothing in the way of storing since July 5th. The effect of the long-continued drought will be a serious loss to bee-keepers down here. The aftermath clover and limes, from which we get our surplus, failed entirely this year through want of moisure. All the sections I have taken were finished before July 1st; nothing since. I fancy that many when they remove their sections will find they have more unfinished than finished ones.—SILURIAN.

East Malling, Maidstone, July 25 .- My experience in this neighbourhood is very like many others this year. May nearly a failnre from bad weather, but June a success, the bees taking full advantage of the white clover; but I was surprised, considering the sunny weather, at the small quantity they were bringing in from the limes until I saw your remarks last week about the effects of the long drought even on the limes. Some of my early honey had rather a milky appearance, but if allowed to stand was beautifully clear. I think this was from the white clover. I never saw fewer queen-wasps than I have this year.-E. P.

Kingsbridge, South Devon.-Wasps are plentiful in this district. I have two nests within ten feet of each other in my garden. Bees have ceased gathering unusually early this year; I suppose owing to the long absence of rain. Average time for the last fifty years of ceasing to gather has been about 20th July. By what I can ascertain it has been a bad breeding season, as I believe showery weather is more favourable. - Jonn E. Adams.

NOTICES TO CORRESPONDENTS & INQUIRERS.

Letters or queries asking for addresses of manufacturers or correspondents, or where appliances can be purchased, or replies giving such information, can only be inserted as advertisements. The space devoted to letters, queries, and replies, is meant for the general good of bee-keepers, and not for advertisements. We wish our Correspondents to bear in mind that, as it is necessary for us to go to press in advance of the date of issue, queries caunot always be replied to in the issue immediately following the receipt of their communication.

All queries forwarded will be attended to, and those only of personal interest will be answered in this column.

Rees Evans.—Foul Brood.—Yours is a case of foul brood, with pierced and sunken cells, rotten larvæ, and the peculiar scent attaching thereto. Place a lump of camphor, the size of a walnut, enclosed in a bag, inside the hive to which you have joined the diseased bees, and feed on phenolised syrup according to Mr. Cheshire's recipe.

East Dulwich.—Cause of Dead Queen.—In all probability, your bees were superseding their queen for some reason best known to themselves, and the dead queen you found was either the old one or a supernumerary. Do not interfere with them. It is as well, however, to lower the hive sufficiently to prevent the entering of bees, in cases of robbing, but allowing a current of air to pass beneath the combs.

R. E.—Drones.—On the approach of the swarming season, drones are brought into existence; their purpose in life is to fertilise the young queens. At the close of the season, when their services are no longer required, and when their presence is a burden, the drones are mercilessly driven out of the hives and allowed to perish.

Robert Driver,—1. Drones,—Your difficulty with regard to your drones has been settled by the bees themselves by this time. 2. Driving and Uniting.—Your proposed plan will act very well, and should produce a large colony for wintering. The other portions of your letter we have transferred to our 'Echo' column.

East Kent.-It very much depends on the state of the comb whether they are worth keeping after three or four years old. Foundation is now so cheap that it is a very easy matter to renew comb. If combs at that age are tough, clean, and free from moth, they can be used for colonies which are being worked for extracted honey, or for the bees to winter on. Bees winter on old, tough combs better than new. 2. The honey-harvest has now in most districts been gathered in, and the thought of the bees is now devoted to the destruction of the drones.

Ekaon.—1. Keepin; Honey.—Not lower than 45° F., and in a perfectly dry place. 2. The above applies to this query. 3. Extracting Honey from Brood Combs.-It is preferable not to extract honey from combs containing brood. 4. The honey surrounding the brood-nest will be best left for the bees' consumption. 5. Driven Bees.— Unite the driven bees to the stock in bad condition. If healthy, first remove the queen from the hive, then feed up fast. Why not get the driven bees from a greater distance? You will lose a great number by their returning to the original stand. 6. Re-queening Stock.—This cannot be done without loss of breeding time, unless you purchase or raise the queens in nuclei. 7. Inverting .-Let it alone.

Jas. Merson.—1. Driving Becs.—You can drive the bees as soon as possible after the honey flow ceases. If you do so now, no doubt much of the brood would be destroyed. It is very bad policy to place driven bees in an empty skep for them to build combs; they must be placed in a frame-hive on combs or combs and foundation, pre-ferably the former. You must feed up as fast as possible, and finish doing so before the commencement of October. 2. Address of Hon. Sec. Devon and Exeter Bee-keepers' Association.—Mr. Jas. Dallas, Albert Memorial Museum, Exeter. 3. British Bee Journal.—You will find that with its aid every information on modern bee-culture can be obtained.

E. SPILLER.—Sending Bees to Heather.—Ready built combs are much better than foundation for such purpose.

Novice.—Cowan Hive.—1. There are several successful beekeepers living in the neighbourhood of Highgate and Finchley with no greater facilities than yours; consequently we see no reason why you should not attain to the same measure of success. 2. None of Mr. Cowan's inventions are patented or registered, consequently all hee-keepers are quite at liberty to copy any or all of them, 3, 4, 5, and 6. Your better plan will be to purchase one 'Cowan' hive from one of the respectable dealers, and copy that in every detail. When ordering, say you want it fitted with 17 in. top bar, standard size frames; ten frames will be large enough for your district. Each frame takes $\mathbf{1}_{20}^{90}$ or $\mathbf{1}_{2}^{10}$ bare. 7. Pine is the most suitable wood for hive-making, get it free from shakes and knots and well seasoned. Your sketch is very neatly done.

Show Announcements.

August 3-5.—Yorkshire Agricultural Society at York. Secretary, H. L. Rickards, Poole, near Leeds.

August 11.—Taunton Flower Show, at Vivary Park, Taunton, Somerset. Entries close August 8. Hon. Sec., W. B. Maynard, 5 Hamnet Street, Taunton.

August 12.—Maer Fête and Honey Show. Entries close August 5. John R. Critchlow, Hon. Sec., Maer Farm, Newcastle, Staffs.

August 9, 10.—Irish Bee-keepers' Association at Salthill Gardens, near Dublin. Entries close August 2. Hon. Sec., Henry Chenevix, Blackrock, Dublin.

August 14.—Handbridge, Chester St. Mary's Horticultural Show. W. E. Little, Hon. Secretary, Eastgate Row,

August 16-17.—Wilts County Show at Salisbury. Hon. Sec., Rev. W. E. Burkitt, Buttermere Rectory, Hungerford. August 24.—Lancaster Agricultural Show. W. Liddell, Hon. Secretary, Dale Street, Lancaster.

August 31-Sept. 3.—Royal Manchester and Liverpool Agricultural Show at Manchester. W. Lees McClure, Hon. Secretary, The Lathoms, Prescot, Lancashire.

NORTH-EAST OF IRELAND BEE-KEEPERS' ASSOCIATION.

THE FOURTH ANNUAL SHOW of HONEY, BEES, HIVES, & BEE-KEEPERS' APPLIANCES will be held in the Y.M.C.A. Hall, WELLINGTON PLACE, BELFAST, on Friday, 19th August.

Entries close 12th August.

Schedules and Entry Forms can be had on application to PAUL M'HENRY, Linen Hall, Belfast; or SAMUEL CUNNINGHAM, Glencairn, Belfast. NOTICE - (F If you would Sell your Honey, place it before the Public in an attractive form, for which purpose use only

For the SALE and EXHIBITION of SECTION HONEY, coloured by Patent Process in four different tints, with Glass both sides. Price 22/- per gross; 2/- per dozen. Sample post free for 6 stamps.

A. D. WOODLEY, Manufacturer of every Description of Bee-keeping Appliances, Donnington Rd., Reading. GREAT REDUCTIONS IN PRICE.

Stock Foundation, 2/- per lb.; 5-lb. Parcels, 9/3; 10-lb. Parcels, 18/-. Super Foundation, 2/9 per lb. 5-lb. Parcels, 13 6. Guaranteed purity.

On each occasion these Cases have been Exhibited they have been awarded FIRST PRIZE, as follows:—

Newcastle Royal Agricultural Show — Silver Medal. Reading Royal Counties Agricultural Show — Silver Medal. Windsor: Berks Bee-keepers' Association — Bronze Medal. Swindon: Wilts Agricultural Show - First Prize.

Straw Skeps, thoroughly well made, with wood tops and large Supering Hole, 18/- per dozen, 1/8 each.

SEND FOR PRICE LIST, FREE ON RECEIPT OF POST CARD.

Send for Illustrated, Descriptive, and Instructive Circular.

For HIVES and APPLIANCES.

CARNIOLAN BEES have come to stay, and will hold their own wherever introduced. Good workers; amiable and beautiful; and for wintering are perfection. We are now booking Orders for SIX-FRAME STOCKS, in full-sized Hives, with Cover, © 27/6, to be delivered in July and August. STANDARD FRAMES, good sound Combs, with Brood and Stores. Also THREE-FRAME NUCLEI in like condition.

SHMININS, ECTTINGDEAN, ERIGHYON. NOTE.—ALL SIMMINS' QUEENS ARE REARED FROM MOTHERS WHO HAVE NOT SWARMED.

SUPERIOR BEE VEILS.

WIRE GAUZE FRONTS, 1s. 2d. each, 3 for 3s. Traps for Cleaning Supers, 6d. each, 3 for 1s. Post free. Address, W. Crisp, Halstead, Essex.

MPROVED British Bee-keepers' BAR-FRAME HIVE, made of One-inch Well-seasoned Wood, Eight Frames, Waxed, Quilt, Walker's Feeder, Excluder Zinc, Floor-board, Waterproof, and Cover. Hive complete, 5s. each. Directions for Management, 1d. Address Isaac Hale, Maker, Horncastle.

OR USE WITHOUT SEPARATORS OR with the SIMMINS' SEPARATOR thickened at the Corners by a Half Bee-space.

20,000 4½ × 4¼ × 1¾ V-CUT, Open or Close Sided, First-Class AMERICAN SECTIONS, now landed at Liverpool. Free on rail or steamer there, 20/- per 1000; 10/6 for 500. For smaller quantities apply to J. H. Howard, Holme, Peterborough; or to R. White & Co., Importers, Patrickswell, Limerick. The Trade supplied.

Self-acting Fountains & Aquariums.

Suitable for Greenhouses, the Dining-room, &c.

MANIPULATE WITHOUT SMOKE!

Entirely supersedes the Smoker, both in Simplicity and Effectiveness. No 'going out.' No tainting or soiling of combs. Always ready for use without any preparation. Can be carried in pocket.

> With Bellows, 4s. 6d.; postage, 41d. Without Bellows, 3s.; postage, 3d.

Can be adjusted to any ordinary smoker bellows,

6 oz. Bottles of Agent-earbolic acid, oil of tar, and water, proportionably mixed-6d. each.

WEBSTER'S SWIVEL FRAME-LIFTER

With this appliance, frames can be removed from hive. Examined on both sides and replaced without inverting, and with one hand only, leaving the other free to perform any manipulation, at the same time preventing the soiling of hands with propolis. 1s. 6d. each. Postage 3d.

Send for ILLUSTRATED CATALOGUE of all descriptions of Appliances. Post free on receipt of post-card.

AWARDS LAST SEASON.

1st Prize, Silver Medal, Royal Counties' Agricultural Show. Highest Award, Bronze Medal, Colonial and Indian Exhibition, for Bee Subjugators.

2nd Prize Bronze Medal, Colonial and Indian Exhibition, for useful Inventions introduced since 1883.

2nd Prize; Altrineham, for useful Inventions.

CONDEMNED BEES.

The approach of the time when cottagers are wont to consign their bees to the brimstone pit causes numerous inquiries to be made as to the best means of rescuing them, and, at the same time, making the best use of them. Where condemned bees can be obtained they offer a convenient and inexpensive method of increasing stocks, and are often most useful in strengthening stocks which otherwise might not survive the winter.

When stocks are made up entirely of condemned bees, some disappointment is sometimes experienced in spring from dwindling. When this takes place it is owing to faulty management in autumn. It should be borne in mind that the bees when taken have done their work for the year and are preparing for a season of rest. It is quite contrary to nature to take them, put them into empty hives, and call upon them to undergo the exhausting labour of comb-building, at a season too in which naturally combs are not built. Every one knows, or should know, that the life of a bee is measured by the labour performed by it, and thus the condemned bees, if exhausted by combbuilding in autumn, succumb to the trying work in spring; they have not strength and vitality left to resist the fatal influence of cold winds, and so they die, and the stock dwindles away before sufficient young bees are produced to keep up its strength.

All this teaches us that we must give these bees as little work to do in autumn as possible by giving them ready-stored combs, and placing them, as far as possible, in the same position as they would have been had they been left undisturbed, and thus the process of making up stocks from condemned bees should commence now. As in most districts the honey harvest is practically over by the end of July, a few strong stocks may be set to work to provide combs for the bees which will be taken, as a rule, towards the end of August. By feeding rapidly, removing outside combs as soon as sealed, and giving sheets of foundation in the middle of the hive, a few stocks may provide sufficient combs, with the addition of those which may be removed from other stocks for the winter, to furnish several lots of condemned bees.

guide to the number to be provided, we may reckon that six combs will be required for every two skeps taken. Of course, it depends upon the size of the skeps in use. In most places from two to three pounds of bees will be as much as we may expect to get from each skep. Five pounds will about cover six combs, standard frames.

Providing Combs.—Combs are so valuable for this purpose that even unsightly ones are better than none; and it may not generally be thought of that even small pieces, such as are trimmed off in transferring, may be utilised. Crowd them into a frame, place a piece of wire netting on each side, place the frame in the middle of a strong stock, and in forty-eight hours a very fair comb will be produced. Old black combs in frames need never be cut out and destroyed; if they are roughly scraped down to near the mid-rib and given to bees they will be speedily rebuilt, and such rebuilt combs are tough and excellent for extracting purposes.

When some fifty stocks or more can be obtained, the providing combs for them, and more especially making syrup for the stores, is rather a heavy job, and by the usual plan of boiling a very messy one. Some feeders are sold in which sugar is placed in a perforated zine basket and water added to dissolve it. This plan saves the boiling, but as the bees can only feed from the top of the solution, which is thin, while the dense is at the bottom, they have more labour to evaporate the food down than if very thick syrup is given them. Good thick syrup may be made in large quantities by

the following plan:-

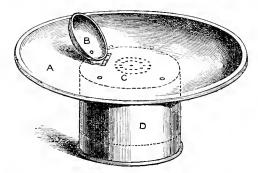

Take a cask, stand it on end, and take out the other head. Make a strong canvas bag, long enough to hang within six inches of the bottom of the cask, and fix it in by means of a hoop resting on the top edge. Put a tap, or, better still, a treacle-valve, near the bottom, and the apparatus is ready. Fill the bag with sugar, which should be 'preserving lump' or crystal, not raw, and fill up the cask with cold water. As the sugar dissolves the dense solution sinks to the bottom and can be drawn off. More sugar and water being added, a nine-gallon cask will provide a hundredweight of syrup a day if required. Having suggested plenty of work for the present preparation for the expected condemned bees, we will touch upon the methods of taking them in a future issue.

MIDDLESEX BEE-KEEPERS' ASSOCIATION.

A third-class examination will be held at Southgate on Saturday, August 20th, in connexion with the Middlesex Bee-keepers' Association's North-east Provincial Show of Honey, Hives, and Bee-furniture on that day. Candidates should at once send their names, with 2s. 6d. entrance-fee, to the Secretary, the Hon, and Rev. H. Bligh, The Vicarage, Hampton Hill.

KILLICK'S WAX-EXTRACTOR.

This extractor was exhibited at the late Conversazione by the Rev. W. E. Burkitt, Hon. Secretary to the Wilts B.K.A. The mode of using it is very simple, and from the samples we have seen of the work it has done we should say it is most effective.

The pieces of comb are placed on the round dish, a, with lid, B, closed. The wax as it melts runs under lid through strainer, c, into pan, D, in which a little water is placed. The whole is put in a slow oven. If the oven is hot the wax will not get burnt or discoloured, because as soon as it melts it runs under the lid through the strainer into the water in pan. If placed in the oven about an hour, more or less according to heat, this would prove sufficient. It then should be taken from the oven, and when cold the wax will turn out in a cake.

USEFUL HINTS.

Weather.—Although showers have fallen in many districts they have avoided our locality, and our fields are still parched, affording no forage for the thirsting bees. Honey storage has long since ceased, and colonies, though not drawing upon collected stores, are living from hand to mouth.

Robbing.—The greatest care must now be used in manipulating hives. During the dearth of honey, in this bright hot weather, the temptation to robbing is so strong that it is unsafe to open a hive during working hours. We have witnessed the destruction of a colony in the short space of five minutes under similar circumstances to those which now prevail. When, therefore, manipulation is necessary let it be done in early morning or late evening, before or after the hours of flight.

EXTRACTING.—Where colonies have been working in sections, or other supers, the brood-nest will often be found blocked with honey, no available space for brood-rearing being left in the hive. In such cases it is of the utmost importance that breeding space be provided at once, since on the September hatched bees successful wintering chiefly depends. About half the combs in each hive should be thoroughly extracted, those being

chosen which contain the greatest amount of pollen, and the remaining combs of sealed honey reserved for winter store for the bees. The extracted combs should be returned to the centre of the hive to form the future brood-nest. The queen is thus stimulated to laying, and the batching out of a good batch of September brood is secured. This, like many other operations in apiculture, admits of delay only at the serious loss of the apiarist.

When taking cottagers' bees at the end of September we have often found a whole hive an entire mass of sealed honey, with a young and evidently prolific queen followed by a handful of old bees. We need hardly say that such a colony is doomed to perish before the spring,

if not before the winter arrives.

AFTER SWARMS headed by young queens, and not over-burdened with stores, may be fed up to strong colonies, or spare combs of sealed honey may be given on either side of the brood-nest. Such colonies generally winter well, and are often found amongst the best at spring.

RE-QUEENING, and the introduction of imported queens, may now be successfully carried on, and by such means the working power of the apiary another season may be largely increased, but the introduction must be

made at night for the reasons stated above.

FEEDING.—The sooner colonies in want of winter stores are fed the more opportunity will be afforded them of getting all food sealed, and of setting their house in order for winter, and, in view of the prevalence of foul brood, we strongly advise that phenolised syrup be used. If Mr. Cheshire's recipe is adhered to bees will never refuse the syrup. At least this is our experience.

WATER should be supplied to every apiary where a natural supply in the immediate neighbourhood does not exist. During the present drought our bees consume a large quantity, the troughs being covered with thirsting bees from morning till night. These troughs should stand clear of shade, with the sun's rays full upon them,

as the bees prefer tepid water to cold.

Condemned Bres will now be eagerly sought, but we advise caution in this matter while foul-brood exists to a large extent in too many localities. Bees taken from an infected hive will convey the seeds of the disease on their antenne, legs, and indeed on almost every part of their bodies, and we have little doubt that the disease has often been introduced into apiaries by condemned bees. Skeps should be thoroughly examined before driving, and if the slightest suspicion exists of the presence of the disease, we advise the entire apiary being left, if not to the sulphur pit, to the devices of the owner, aided by the county expert, to endeavour to work a cure. These condemned bees are very useful as an autumnal addition to small or queenless colonies, and many a strong colony, headed by Italian and Cyprian queens, have we huilt up of such material. For doing this we prefer August to September, as the bees have more time for breeding and making preparation for winter before the cold is upon them.

Cottagers and others, who work on the skep system, will be willing to part with their bees earlier than usual owing to the present dry season, as they are well aware that their bees are wasting rather than gathering. Driving or 'bumping' should be neatly and quickly done without any mess, and the emptied skeps given back to the bees to clean before being stowed away

for use another year.

Unfinished Sections are best extracted, and, when thoroughly cleaned by the bees, should be stored in a dry place for use next season. Funigation with sulphur will keep them free from moths, and racks filled with these should be tied up as parcels in paper to keep them free from dust. A little attention bestowed now will be amply rewarded on the approach of another season. If the honey-flow has ceased, all supers should be removed

from the hives; and where the latter are crammed with honey, extracting, as advised above, should be practised, but if, owing to the removal of large quantities of super honey, a sufficient quantity has not been left for wintering, a supply of sealed combs must be given, or otherwise the colony must be fed up to sufficient weight on

phenolised syrup of a thick consistency.

Heather should be in full bloom by this time; and if the fine weather continues, we may hope for an ample yield of the delicious nectar afforded by this plant. We are often asked by those who reside within a couple of miles of the heather, whether a larger quantity of honey would be gathered by the bees, if they were moved over the intervening space, and placed in the midst of their labour. To such we reply undonbtedly, Yes. Those only who have tried both plans can realise the advantage of the bees being close to their work, especially during the latter part of the season. We have known colonies located two miles distant from the heather, never to visit it at all during even the finest weather; while those set down in its midst have filled hives and supers, yielding an ample return.

Delicious Honey!—From a paper contributed by Miss Gordon Cumming to the Nineteenth Century of June last on 'Strange Medicines,' we cull the following:—'Abdallatif, a traveller of the twelfth century, relates that one of his friends found in the tombs at Ghizeh a jar carefully sealed, which he opened and found to contain such excellent honey that he could not resist eating a good deal of it, and was only checked in his feast by drawing out a hair; whereupon he investigated further, and found the body of an ancient Egyptian baby in good condition, and adorned with jewels. He does not record how he enjoyed that meal in retrospect. Imagine dining off the honeyed essence of

a haby of Pharaoh."

ASSOCIATIONS.

BERKSHIRE BEE-KEEPERS' ASSOCIATION.

The seventh Annual County Show of the Berkshire Bee-keepers' Association was held in the Home Park, Windsor, on Tuesday the 19th, in conjunction with the Prince Consort's Association. There are branches of this Association at Ahingdon, Bradfield, Farringdon, Maidenhead, Newbury, Twyford, Wallingford, Wantage, Windsor, Wokingham, most of which were present in the competition for the prizes.

The day was all that could be desired. The situation of the tents among the magnificent trees of the Home Park, with a grand view of Windsor Castle standing above the green trees and shrubs, was truly beautiful, and

more than words can describe.

At an appointed time, her Royal Highness the Princess Christian drove on to the ground, went through the tents, and afterwards gave the prizes away to a very large number of persons from both the Associations, and

then left for London.

The exhibition of hives and appliances was small, and it was evident that the show could not have been so well advertised as it ought to have been. In the best collection of hives and appliances there were only two entries, which the Judges considered about equal, the first and second prizes being added together and equally divided between Messrs. Abbott Bros., Southall, and Mr. A. F. Hutchings, of St. Mary Cray, Kent. Mr. Hutchings also took the first prizes in both classes for hives.

In the honey classes there were a fair number of entries, the extracted honey was very good, but the sections were not so good as this county usually produces. Mr. William Woodley exhibited a design in honeycomb. It had a crown above the letters 'V. R.,' and the words 'Jubilee, 1887,' below. There was a stall supplied with various articles of food and beverages, of which honey was a principal ingredient.

The Judges were Mr. Otto Hehner, of Billiter Square, London, and Mr. John M. Hooker, of 76 Tyrwhitt Road, St. John's, S.E. The Hon. Secretary is the Rev. R. Errington, Clewer Rectory, Windsor, and Mr. A. D. Woodley, of Reading, is Assistant Secretary and Expert. The following is a list of the prizes awarded:

Open Classes .- For the best Observatory Hive, stocked with bees and their queen-1, A. F. Hutchings, of St. Mary's Cray, Kent, 20s. For the best collection of Hives and Bee Appliances, no two articles to be alike—A. F. Hutchings, and Abbott Brothers, of Southall (bracketed equal). For the best Hive complete, with facilities for harvesting honey, with arrangements for wintering; price to be a consideration—1, A. F. Hutchings; 2, Λ . D. Woodley, Reading. For the best and cheapest Frame Hive, price not to exceed 10s. to be purchased by the Committee—1, A. F. Hutchings; 2, C. Redshaw, Wigstone, near Leicester. For the Straw Hive best adapted to modern bee-keeping, price not to exceed 5s.—1, W. B. Webster, Wokingham. For the neatest and best Rack containing I lb. sections, prepared for placing on the Hive—1, C. Redshaw; 2, A. D. Woodley. For the best Crate for the safe conveyance of honey, by rail or otherwise—1, A, D. Woodley. For the best Honey Extractor, price to be considered—1, A. F. Hntchings, 10s. For the best sample of Thick Comb Foundation manufactured in the United Kingdom from pure bees' wax, not less than 2½ lbs., with price per lb. attached—1, T. B. Blow, Welwyn, Herts. For the best sample of Thin Comb Foundation manufactured in the United Kingdom from pure bees' wax, not less than $2\frac{1}{2}$ lbs, with price attached—1, A. F. Hutchings. For the best Feeder—1, W. B. Webster, Wokingham. For the best exhibition of Honey from one Apiary, the prizes presented by Mr. Richardson-Gardner, M.P.—1, W.Woodley; 2, Woodley, Bros. For the best Super of Honey (not sectional)—1, J. Rayer, Jun., of Stanmore; 2, W. Woodley. For the best 21 1-lb. Section of Honey—1, J. Rayer, Jun.; 2, W. Woodley; R. W. Bunce, Theale, highly commended; and Champion, of Reading, commended.

Special Class (open to Members of the Berks Bee-keepers' Association).—For the best 21 1-lb. Sections of Honey, the prizes given by the British Bee-keepers' Assaciation—1, J. Rayer, Jun., silver medal; 2, W. Woodley, bronze medal; 3, Woodley Bros., certificate. For the best 12 1-lb. Section of Honey—1, W. Woodley; 2, J. Rayer, Jun.; Woodley Bros., highly commended. For the best exhibition of Run or Extracted Honey in glass vessels—1, W. Woodley; 2, H. Fewtrell, Reading. For the best 12 lbs. of Run or Extracted Honey, in 1-lb or 2-lb. glass vessels—1, W. Woodley; 2, H. Fewtrell; J. Rayer, Jun., a special prize; and Woodley Bros., highly commended. For the best collection of Pure Beeswax—1, W. Woodley; no second prize awarded.

Special Prizes.—For Recent Inventions (open to all)—
1, A. D. Woodley, for Section Cases, bronze medal; 2, H. Augur, Windsor, for 'Winter Passages,' certificate. For the best collection of Honey applied as food; 1, Darvill, Reading, silver medal. For the best collection of Honey applied as beverages—1, S. Fry, Waltham, for 2d. honey beverages, silver medal.

The humane system of procuring honey is generally adopted by cottagers who keep hees, and the Association are able to trace satisfactory results of their efforts in this respect.

THE GLOUCESTERSIHRE AGRICULTURAL SOCIETY.

This Society held its annual show on July 26th and two following days at Cheltenham in the Pittville Grounds. The Gloucestershire Bee-keepers' Association held their annual show in conjunction with the above Society, and we understand that it was the largest exhibition of honey ever held in the county. The amount entered for competition was about three quarters of a ton. The honey in the comb was of good colour, but the sections were not so well filled as they ought to be, having lots of 'pop-holes' at the corners, which in some cases were partly covered by the lace on the glass boxes and by the wide coloured paper used to fix the glass at

the sides of the sections. This paper covering over edge of section and on glass should never be more than three

eighths of an inch.

The extracted honey was very good indeed, some of the exhibits being remarkable for colour, consistency, and delicate flavour. Lord Sudeley was an exhibitor in most of the honey classes, one being for a design in honeycomb—his Lordship's crest with 1887. We understand that Lord Sudeley has planted some two or three hundred acres of fruit-trees of all kinds, and has established an apiary of over two hundred hives of bees in the centre of it, so as to ensure the proper fertilisation of the fruit blossoms. He will no doubt be amply repaid in both fruit and honey for his forethought in the matter.

In hives and appliances there were very few entries, and the question was naturally asked, Where are our leading hive-makers? Are they willing to let smaller men come to the front, having themselves already more orders than they can execute? Mr. A. F. Hutchings, of St. Mary Cray, Kent, obtained first prizes in both the hive classes. In the collection of hives, &c., there was only one entry, that of Mr. E. J. Burtt, the expert of the Association; there were no other exhibits requiring special mention. Mr. W. D. Slade, of Cheltenham, is the hon. secretary, and took the management of the show. Mr. John M. Hooker, one of the Committee of the British Bee-keepers' Association, acted as judge. Mr. flooker also examined and passed Mr. R. Woodward, of Charton Kings, Cheltenham; Mr. Geo. Newman, of Sutton House, Gloucester; and Mr. Arthur James Brown, of Bradley, Wootton-under-Edge, as third-class experts. The awards were as follows:—

HIVES.—Best moveable frame hive for doubling—1, Mr. A. F. Hutchings, Kent; 2, Mr. A. J. Burtt, Gloucester. Best moveable frame hive—1, Mr. A. F. Hutchings; 2, Mr. A. J. Burtt. Best flat-topped straw hive, with roof—Mr. A. J. Burtt. Largest and best collection of hives and beefurniture—Mr. A. J. Burtt. Best cylinder extractor—1, Mr. W. P. Meadows, Syston, Leicester; 2, Mr. A. F. Hutchings. Best stock of bees in observatory hive—Mr. H. A. Purnell, Cheltenham. Best 24 1-lb. sections of comb honey—1, Mr. A. A. Cole, Cirencester; 2, Lord Sudeley, Toddington; 3, Mr. F. Butler, Cothham, Bristol; H. C., Mr. R. W. Lloyd, Chippenham, and Mr. C. Marshall, jun., Cheltenham. Best 12 1-lb. sections of comb honey—1, Mr. W. Woodley, near Newbury; 2, Mr. A. A. Cole; Mr. R. W. Lloyd, Badminton; H. C., Mr. F. Butler; C., Lord Sudeley. Best exhibit of 24 1-lb. glass jars of run or extracted honey—1, Mr. A. A. Cole; 2, Mr. R. W. Lloyd; 3, Mr. C. Marshall. Best exhibit of 12 1-lb. glass jars of ditto—1, Mr. W. Woodley; 2, Mr. R. W. Lloyd; 3, Mr. A. A. Cole, Best super of honey in the comb, not sectional—1, Mr. E. A. Brown, Gloucester; 2, Mr. T. W. Swinbourne, Winchcombe. Designs in honeycomb—1, Lord Sudeley (his Lordship's crest was worked in honey and comb weighing about 25 lbs.); 2, Mr. F. J. Chinnick, Cheltenham ('1886,' worked in about 15 lbs. of honey and comb).

Special District Prizes.—Largest, best, and most attractive display of honey in any form, from any one of the districts in the county of Gloucestershire—1, Cheltenham district, 455 lbs.; 2, Gloucester, 301 lbs.; 3, Winchcombe, 184 lbs.

Cottager, a member of the Gloucesterehire Bee-keepers' Association, who is not a joiner or carpenter by trade—Mr. F. W. Shearman, Dursley. Largest, best, and most attractive display of honey, in any form or forms.—Mr. J. J. Smith, Beckford. (This competitor showed 85 lbs. of honey, and also a wasps' nest, perfect, under a case.) Best 61-lb. sections of comb honey—1, Mr. D. Sheppard, Winchcombe; 2, Mr. J. Smith; 3, Mr. A. Jones, Gloucester Exhibit of run honey in glass jars, not less than 6 lbs.—1, Mr. Samuel Martin, Great Winchcombe; 2, Mr. D. Sheppard; 3, Mr. Wm. Harris, Winchcombe.

In a smaller tent, adjoining the one devoted to exhibits, Mr. E. J. Burtt gave illustrations of manipulating with live bees.

HANTS AND ISLE OF WIGHT BEE-KEEPERS' ASSOCIATION.—SOUTHAMPTON SHOW.

This Association held its chief Annual Honey Show upon Saturday and Monday last at Southampton as usual in connexion with the Royal Horticultural Society of Southampton. In consequence of the heavy outlay incurred last year at the several shows held within the county the executive of this Association had wisely decided upon a policy of retrenchment, and the schedule only extended to one third of the prizes offered last year when H.R.H. the Princess Beatrice attended to distribute the prizes.

As a consequence this show was in some respects very much smaller—a much smaller marquee being employed, and the exhibits in the hives and appliances classes being, in fact, conspicuous by their absence. There were no entries at all in Class IV. for general collections, and it seems likely the offer of prizes will not be repeated in this class, as it was generally felt the show, as a whole, did not suffer in consequence. But in the hive classes it is not a little remarkable there were only two entries for cottagers' hives, and even one of these was not forthcoming, so that prizes went literally a-begging.

But if the hive-manufacturers were not forthcoming the bee-keepers themselves mustered in a manner hitherto unknown in even so well worked a county as Hants; and although upon the occasion of the royal visit last year a truly magnificent exhibition of honey, &c., was staged, a belief was generally expressed that the show this year, as regards honey, was even finer. There were only five classes proper to honey, and the entries for these numbered no less than ninety-one, Class XI. (for one pound sections) staging as many as twenty-seven exhibits. The task of the judges was, in fact, herculean, for with hardly an exception every section and bottle was of first-rate quality, and we fear many exhibitors who came with a conviction that they could not be beaten went home disappointed.

Although the judging of honey is amongst the most difficult of tasks, and there exists so great a diversity of opinion on the subject, it must have been some consolation to disappointed exhibitors to find the Hants B. K. A. had secured the services of Mr. W. N. Griflin, than whom it would be difficult to find one more learned in the subtle variations of different honey samples. Of course there was some heart-burning, in one or two instances audibly expressed; and as the judges had to do their work whilst exhibitors were still staging their goods in other classes it was unfortunate that these did not always understand that judges' comments should not be overheard or listened for

It is worthy of note that the Hants B.K.A. has for some time instituted a regular class for honey-comb designs, following the example of the Scottish beekeepers, and we think the system might well be followed by other county associations. Now that it is known that Hants will regularly give premiums for such, bee-keepers have an opportunity of exercising their ingenuity in this direction, with a prospect of recognition; and there can be no doubt that these designs attract more attention from the general public and are more generally admired than anything in the Shows. It may be that a 20-lb. super worked in the letters spelling Jubilee is not so remarkable as a 1-lb. section, but on the other hand it draws attention to the really wonderful control we now have over our bees, and often secures a wealthy purchaser for the whole, who otherwise would have been content with the humble section.

In the 'Inventions' class Mr. Woodley's tin sectioncases were properly awarded the highest honour the Hants Association gives, viz., the Special Diploma, as marking the most valuable invention of the year; and Mr. Fry of Bishop's Waltham, for his acrated honey drinks, and Mr. Darvill of Reading for his honey sweetmeats, were also specially honoured. Mr. Griffin displayed his 'Honey dubbing,' but as extended trial of this is necessary to prove its usefulness, it was felt a medal could not now be awarded. We understand, however, that it is to be well tested in the Highlands this autumn, so that Mr. Griffin may hope for the honour upon a future occasion.

As usual the exhibits of Hampshire bees-wax were of exceptional merit, and Mr. Allen Broom is to be congratulated upon his method of making it more generally marketable. He displayed a number of small cakes moulded from egg cnps which were retailed at 2d. each, and we understand he was successful in clearing a good profit upon the number he sold. The silver medal for the best home-made hive was carried off by Mr. Arthur Stephens, gardener to E. H. Beilairs, Esq., for a thoroughly well-made serviceable hive, Mr. J. J. Candey of Landport being awarded the bronze medal.

Annexed we give the list of awards:-

Open to All England.

Class I. For the best 24 lbs. of super honey, in sections not exceeding 2 lbs. each.—Ist, silver medal, W. Hunt; 2nd, bronze medal, W. Woodley; 3rd, certificate, H. W. West. II. For pure extracted honey put up in the most attractive mode for purposes of sale. The exhibits to consist of 12 lbs., in vessels not exceeding 2 lbs. net.—1st, 10s., W. Woodley; 2nd, 5s., J. J. Candey; 3rd, 2s. 6d., W. Hunt. III. For the best design in honey-comb, worked by the bees.—1st, 10s., W. Woodley; 2nd, 5s., A. Privett; 3rd, 2s. 6d., J. J. Candey; 1V. For the largest and best collection of hives and appliances applicable to modern bee-keeping (no two articles alike, and honey excluded from the exhibit. No entries. V. For the best Observatory Hive, to be exhibited stocked with bees and queen. No entries. VI. For the best and most complete Bar-frame Hive, price not to exceed 20s.—1st, 10s., T. Tanner. No other awards. VII. For the best Cottager's Hive, price not to exceed 10s. 6d.—2nd, 5s., T. Tanner. No other awards. VIII. For the best section rack prepared for putting on the hive,—1st, 10s., T. B. Blow; 2nd, 5s., T. B. Blow. IX. For any recent invention or inventions calculated to be of use to the beekeeping industry.—1st, Special Diploma, A. D. Woodley; 2nd, S. Fry; 3rd, G. Darvill; highly commended, W. N. Griffin.

Open to Members residing in Hants, or within three miles of the boundary lines.

X. For the best 12 lbs. of super honey, in sections not exceeding 2 lbs. each.—Ist, silver medal, E. J. Ainsley; 2nd, bronze medal, Rev. P. P. Izard; 3rd, certificate, W. Hunt and C. Richmond; highly commended, Rev. W. E. Medlicott. XI. For the best 12 lbs. of super honey, in sections not exceeding 1 lb. each.—Ist, 1l., T. Giles; 2nd, 10s., W. Hnnt; 3rd, 5s., Rev. W. E. Medlicott; highly commended, E. Ainsley; commended, G. Horner. XII. For the best 12 lbs. of extracted honey, in 1 lb. or 2 lb. vessels.—Ist, 10s., J. Dauncey; 2nd, 5s., J. Candey; 3rd, 2s. 6d., E. Russ; highly commended, Rev. P. P. Izard. XIII. For the best 12 lbs. of extracted honey, in 1 lb. or 2 lb. vessels, for cottagers and artisans only.—Ist, 10s., A. Stephens; 2nd, 5s., G. Holley; 3rd, 2s. 6d., A. Broom; highly commended, G. Horner. XIV. For the best sample of bees' wax, weight not less than 2 lbs.—Ist, 10s., W. Burgess; 2nd, 5s., Mrs. Burgess; 3rd, 2s. 6d., A. Broom. XV. For the best homemade hive, the work of an amateur (not being a carpenter and joiner), cost of material to be stated.—1st, silver medal, A. Stephens; 2nd, bronze medal, J. J. Candey; 3rd, certificate, G. Isaae.

HANTS AND ISLE OF WIGHT BEE-KEEPERS' ASSOCIATION.

SWANMORE BRANCH.

The second annual exhibition of honey, bees, &c., took place on Wednesday, July 27th, at Holm Oak, Bishop's Waltham, in connexion with the Bishop's Waltham Horticultural Society's Annual

Show. There was a capital display of honey and bee appliances in the tents set apart for the purpose. The exhibition, consisting as it did of one of the very best displays of honey we have ever seen, amounting to nearly 9 cwt., shows that the branch is doing an immense amount of good in inducing the cottagers to take an interest in the rearing and proper treatment of bees.

Mr. A. Privett had a capital show of bee appliances and honey in his tent, and Mr. S. Fry staged a good display of his celebrated honey drinks and syrups; Miss Myers, of Swanmore House, exhibited a large and varied collection of bee flora—the sources from which bees derive their sustenance and procure honey —and for this she was deservedly awarded a special first prize. The other prizes were given by the judge as follows, the judge being the Rev. F. S. Sclater:—

Class I. For the best 12 lbs. of super honey, in sections of 1 lb. and not exceeding 2 lbs. each, presented by Mrs. Myers -I, C. Richmond, Swanmore; 2, Rev. W. E. Medlicott, Swanmore; 3, Edward Ainsley, Swanmore. II. For the best 12 lbs. of extracted honey in bottles of 1 lb. or 2 lb. each, presented by W. H. Myers, Esq., J.P. (President of the Branch)—1, Mr. H. W. West, Swammore Park; 2, Miss Myers, Swammore House; 3, Mr. A. Privett, Bishop's Waltham. III. For the largest and best display from one apiary, comb and extracted -1, Mr. H. W. West, a bronze medal and 10s.; 2, Mr. W. Candey, Botley, certificate and 5s. IV. For the best super worked on the top of a straw skep (cottagers and artisans only), given by the Misses Goodlad — I, F. Sparksman, Bishop's Waltham; 2, F. Quintin, Corhampton. V. For the best single comb taken from a straw skep (cottagers only), presented by the Rev. W. E. Medlicott, hon. treasurer—3, J. Scorey, Corhampton. VI. For the best 12 lbs. of super honey in sections of 1 lb., not exceeding 2 lbs. each (cottagers only)—1, J. Griffin, Bishop's Waltham; 2, C. Nicholson, Preshaw. VII. No entry. VIII. For the best and strongest skep of bees not being a swarm of this year—1 and 2, J. Scorey; 3, E. Singleton, Swanmore. IX. For the best 6 lbs. of super honey (cottagers only)—1, C. Nicholson; 2, J. Griffin. X. For the best 6 lbs. of super honey (confined to members who only possess one hive)—1, E. J. Ainsley, Swanmore; 2, Miss Bessie Martin, Swanmore; 3, W. G. E. West, Swanmore Park. XI. For the best piece of pure bees' wax not less than 2 lbs. in weight—1, Mr. H. W. West; 2, Mr. G. Homer, Swanmore. XII. For the best piece of pure bees' wax, weight not less than 2 lbs. (cottagers only)—1, F. Sparksman; 2, T. Quintin.

The best thanks of all were heartily conveyed to the judge for the very satisfactory and painstaking way in which he got through an arduous task, and to the B. B. K. A. for its kind assistance in sending down a judge free of charge.

MONMOUTHSHIRE BEE-KEEPERS' ASSOCIATION.

The Caerleon Horticultural Society held their annual exhibition on July 21st. One of the novelties of the show was the bee exhibition of Mr. W. Williams, Round Table Apiary, to whom was also awarded an extra prize and a very highly eommended eard. A pretty honeyeomb had been worked out by the bees, the design being the figures 1887, and the various combs displayed the processes by which the honey is worked. At his apiary Mr. Williams has twenty-one stocks, twenty of which are on the new principle, whilst one is kept on the old to show the marked difference between the two. These stocks are capable of producing with careful and proper management no less than 1000 lbs. of honey during the season. At the flower show the proprietor had a swarm of bees together with the queen and all her attendants, the sight of which proved exceedingly interesting.

EAST LOTHIAN BEE-KEEPERS' ASSOCIATION.

This Association held their bee and honey show on the 9th of July in Aimesfield Park, Haddington, in connexion with the County Agricultural Show. This being the first bee-show held in the county, and too early in the year for this district, there was not a very large display. The attendance during the day was large, admittance being free. Messrs. Pringle, Copath, and

admittance being free. Messrs. Fringle, Copain, and Mason, Dalkeith, officiated as judges. List of awards:—Class 1.—For the best twenty-one 1-lb. sections: 1, Mr. Wood, Whitekirk; 2, Rev. Mr. Kerr, Dirleton. Class 2.—For the best super of comb honey: I, Mr. Wood, Whitekirk; 2, G. D. Clark, Kirklandhill; 3, Mr. Taylor, Haddington. Class 3.—For the best collection of appliances: 1, Rev. Mr. Kerr; 2, Mr. T. Robertson, Wastbarns. Class 4.—For the best observatory live Class 4.—For the best observatory hive Westbarns. stocked with bees: 1, Rev. Mr. Kerr; 2, Mr. G. D. Clark. Class 5.—For the best frame-hive for cottagers: I, Rev. Mr. Kerr; 2, Mr. G. D. Clark; 3, Mr. T. Robertson.

There were also some designs and letters wrought in comb-honey, shown by Mr. G. D. Clark, and some specimens of honey-producing flowers by Rev. Mr. Kerr.

CALEDONIAN APIARIAN SOCIETY.

The fourteenth show of this Society was held at Perth on the 26th July, and the three following days in connexion with that of the Highland and Agricultural

There was a very marked improvement in every department. The exhibits were numerous, and the arrangements of the different articles, as well as their general appearance, were such as to produce a favourable impression on all the visitors. An immense quantity of honey, in sections, boxes, &c., and of very superior quality, was submitted to the Jndges, who must have had very considerable difficulty in making the several

The variety of implements and appliances was large, and some of the more recent were regarded with interest, notably a new patent mould for securing wax foundation in frames and sections, exhibited by Mr. Neighbour of London, but not for competition. Designs illustrative of the anatomy of the bee, and dried specimens of the flowers which it frequents, adorned the sides of the tent. Liquors, confections, and sweet eakes, in which honey is the leading ingredient, occupied a prominent place in the collection. Altogether the show was one of the best, if not the best, of the series of exhibitions for which this Society has maintained an honourable place. Much of this may be traced to, and connected with, the indefatigable zeal and industry of Mr. Bennett, the Hon. See. and Treasurer.

The Judges were the Rev. J. Balfour Robertson of Leswalt, Rev. A. R. Findlay, Birnam; Alfred Neighbour, Esq., London; Messrs. McNally, Glenluce, Wood, Kilmun, and Bailie Lauehland, Kilmarnock.

STRABANE (IRELAND) HONEY SHOW.

The thriving little town of Strabane, in Co. Tyrone, had its annual festival of combined Shows on the 27th and 28th of July, at which honey, hives, and bees were well to the front. Ever since modern bee-keeping was introduced into Ireland, these items have always formed part of the yearly programme at this place, but the display on Wednesday and Thursday last was superior to that of any former occasion. In honey alone there were forty-three entries, the quality and appearance of which was excellent, all produced in bar-frame hives in the immediate neighbourhood, where the old straw skep is fast passing out of use. It is in great measure owing to the encouragement afforded by this local Show that the better way of bee-keeping has taken such a firm root in the counties of Tyrone, Donegal, and Derry.

This has been a prosperous year with bees in the northwest of Ireland, one gentleman near Strabane, having but two stocks, has harvested 140 lbs., another with twenty has taken 600 lbs., while a third, at St. Johnston, has got 2000 lbs. off his forty colonies, and within a mile of the latter place there are seven bar-framists. The following is the prize-list:

Bees.—For the best hive for observation purposes, ex-Bees.—For the best hive for observation purposes, exhibited with the queen and bees.—I, W. R. Orr; 2, George Turner. Honey.—One super of honey, under 25 lbs., and over 10 lbs.—I, W. J. Smith; 2, J. C. Boyd; V.H.C., Thomas M'Gonagle; V.H.C., William M'Ghee; V.H.C., Lady Alexander Hamilton. Twelve sections of honey, 1 lb. size.—I, James Elliott; 2, James Clarke; V.H.C., Miss Jane Clarke; V.H.C., W. J. Fnlton; V.H.C., G. W. Hatchell, M.D.; V.H.C., Dr. Britton. Six sections of honey, 1 lb. size.—I, James Elliott: 2. Miss Jane Clarke and H. W. chell, M.D.; V.H.C., Dr. Britton. Six sections of honey, 1 lb. size—1, James Elliott; 2, Miss Jane Clarke and H. W. Lett (equal); V.H.C., S. H. Orr; V.H.C., Dr. Britton. Twelve sections of honey, less than 1 lb. size—1, William M'Ghee; 2, S. H. Orr; H.C., George Turner. Six sections of honey, less than 1 lb. size—1, S. H. Orr; 2, George Turner. Six jars of honey, 2 lb. size—1, George Turner; 2, S. H. Orr. Six jars of honey, 1 lb. size—1, George Turner; 2, W. J. Fulton. Best hive for general use in an apiary—1, W. J. Fulton; 2, W. R. Orr. Best hive for obtaining honey in sections—1, W. R. Orr; 2, W. J. Fulton. Special Prize.—For the best exhibit of super honey, sectional or otherwise, produced in a bar-frame hive purchased tional or otherwise, produced in a bar-frame hive purchased from W. R. Orr-I, Dr. Britton.

As regards the judging it was evident that perfectly white sealing was the only point attended to; full sections, perfectly filled, and free of popholes, were nowhere, and neither consistency, flavour, nor colour of the honey was tried, as in no instance did the judges take a section out of its ease, or taste it.

A peculiar feature among the exhibits was a large elass of non-sectional supers, measuring $14 \times 14 \times 3$, some of which looked particularly good. The narrow 11 inch sections were present in another class, but the general opinion is not in their favour.

The Hon. Secretary of the Shows, Mr. W. R. Orr, de-

serves eredit for his arrangements.

He is also a very successful bee-keeper, well deserved the first prize, won by his Jubilee hive, which is of small size, which he considers suitable for his district of country, the feature of the hive being that the super-cover also constitutes the section crate, thus simplifying the operation of tiering up storeys of section-holders.

The Show was erowded on both days, and useful lectures on bee-keeping and hive-management were given by the Rev. H. W. Lett to many inquirers and intending

bee-keepers in a plain and coneise manner.

Correspondence.

The Editor does not hold himself responsible for the opinions expressed by his correspondents. No attention will be taken of anonymous communications, and correspondents are requested to write on one side of the paper only, and give their real names and addresses, not necessarily for publication, but as a guarantee of good faith. Illustrations should be drawn on separate pieces of paper.

Communications relating to the literary department, reports of Associations, Shows, Meetings, Echoes, Queries, Books for Review, &c., must be addressed only to 'The Entron of the 'British Bee Journal,' olo Messys. Strangeways and Sons, Tower Street, Cambridge Circus, W.C.' All business communications relating to Advertisements, &c., must be addressed to Mr. J. Huckler, Kings Langley, Herts (see 2nd page of Advertisements).

**In order to facilitate reference, Correspondents, when speaking of any letter or query previously inserted, will oblige by mentioning the number of the letter, as well as the page on which it appears.

MR. SIMMINS'S APIARY.

[1170.] If I wanted to describe in two words the contrast between the localities of Mr. Blow's bee-garden, which I visited ten months ago, and Mr. Simmins's apiary which I saw yesterday, I should call the former a paradise and the latter a rolling prairie. I well remember my feelings when about five years ago I made my first excursion to Rottingdean, how, between surprise and disgust, and

more and more surprise, I had a good time of it. As I rode the four miles a-top of the bus which, to begin with, starts from Brighton within an hour of noon (!) my mixed feelings shaped themselves into one question many times repeated, 'Whatever could Mr. Simmins have been thinking about?' meaningless enough to the reader till I explain that I had known Mr. Simmins when he lived in a paradise (I still speak comparatively) and had taken his bees regularly every autumn to the skirts of a real forest where the beather spread away as far as the bees could reach. But here was a long dusty road all ups and downs, the sea on the one sidebeautiful! ah, yes, but the bees couldn't forage there,and on the other side never a tree. Positively not a tree can be seen all the way, excepting only at Ovingdean, a little place which lies half a mile off the road to the left, in a hollow in the downs, there a group of trees can be distinguished by the careful observer, but it seems to have leen doing its best the last fifty years or so to hide itself, and has succeeded pretty well, for I don't suppose one out of fifty passers-by has ever seen it. Near the road there were fields of waving wheat and oats and barley, as yesterday, but beyond only the bare downs, not even sheep-dotted. However, by-and-by I came to fields of sainfoin, then sighted Rottingdean down in a valley at right angles with the sea, and beyond, more sheep-forage, and sheep too, of course. Then it began to dawn on me that perhaps (!) Mr. Simmins did know what he was about after all, and readers of the Bee Journal will, doubtless, confirm the correctness of my changing impressions as to that conclusion. Twice have I been to see Mr. Simmins since; which brings me down to my visit of vesterday.

Rottingdean, spite of its name, has not decayed yet. It has two laggard busses now, and boasts, perhaps, a hundred trees, mostly grouped at the upper end of the one street, as if for company, and mostly sycamore. There is a ruined cottage, a large horse-pond, and an oldfashioned little church with nothing particular about it, except that it has a pent-house roof over the clock, which, perhaps, objects to have its face washed! The village consists of about sixty houses, all told.

Mr. Simmins is a genial man, of few words and weighty; age about thirty, tall and well built, brown hair, eyes, and beard, which he keeps well trimmed as most bee-men do. I have not heard him laugh (he seems too busy), but I saw him smile a good deal at the baby, and that is something when there are four more—children I mean, not babies. The three eldest were away, and Mrs. Simmins told me during dinner she longed to have them home again. I saw their pictures, and quite believe Mrs.

Simmins.

Now I feel sure the readers of the Bee Journal will forgive all this personal talk, for everybody knows that Mr. Simmins never appears at the 'shows,' so I have just been showing him up a little—at home. apiary is away from the bouse, and covers an extensive area, a parallelogram surrounded by a substantial seven-feet high stone wall and subdivided within by two other walls, that is to say, there are three square enclosures communicating each with each. No. I contains an apiary and manipulating buildings; No. 2, the factory and a waving field of melilot clover just blooming and yielding a scent which was quite new to me and very pleasant. My! how much pleasanter to the bees, they were thick upon it! No. 3, another apiary, and in it some semi-wild rabbits burrow at will.

Of the factory I shall say nothing, except that Mr. Simmins intends springing therefrom one or two real surprises in the matter of extractor, uncapper, &c., but alas! they will not be ready for this season's harvest. A new book is also on the tapis, at a popular price too. My business with Mr. Simmins was to buy a couple of queens. I paid 7s. 6d. a-piece for them—a Carniolan

and Ligurian, the latter imported. Cyps. Mr. Simmins had sold out of. I can testify to the careful selection of my home-bred Carniolan, as also to the fertility and youth of two or three others selected from stocks while I was present for customers. The hives are seattered about in diagonal lines, though at first sight appearing to be in picturesque confusion, but nevertheless it was perfectly evident that Mr. Simmins knew each one, somewhat after the manner of a shepherd with his sheep I suppose. To me they seemed all alike. There were Cyprians crossed with Carniolans,—and Carniolans pure, —Ligurians pure and crossed with Carniolans.—an Albino (a strain of bees selected from Italians by American breeders), and several hives of Syrians, one of them just then in an awfully bad humour. The Cyprians, however, were as gentle as could be desired; we looked at several; no smoke, yet beautifully quiet; all of which had had their queens taken from them for sale and were supplied with home-raised queens on point of mating. I saw Mr. Simmins pack a six-frame stock and a three-frame nucleus for a customer. I plied Mr. Simmins with a few questions, but what with other callers and general busy-ness my information came rather disconnectedly. I really intended to 'interview' him, you know. How long have you been in the bee way, Mr. Simmins? About twenty years. Have you had any experience of foul brood? In the past I have, before I came here. How did you get rid of it? I starved it out. What do you think of Mr. Cheshire's Cure? I think it will prove effectual if you re-queen as well. Do you use apifuge? I use smoke of rotten wood. What sort of a honey season have you had? Bad, for combespecially. We have had no rain for seven weeks, but have been sadly troubled with sea-fogs; and these thistles, you see, (we were walking up the downs) will come to nothing, whereas they generally yield much honey. The wild thyme, too, has been a failure. But I depend more upon my bees at Balsdean for honey, that is a very fertile valley two miles further on. This is my breeding place, being isolated, nobody has any bees within mating distance, so I nave it all my own way and can ensure purity. Here I told Mr. Simmins my impressions about the surrounding country, and he smiled; but then had I not just come through the delighful scenery which lies between Dorking and Brighton, viá Horsham, across the Weald of Sussex, and was I not fresh from the glories of 'my own, my native land,'-mine to look at and to hoast about, -Boxhill and Norbury, Leith Hill and Holmbury?

Good-bye, Mr. Simmins, I shall (all well) come and see you again and walk over to your honey factory at Balsdean.—W. Hollier, Dorking.

THE STEWARTON HIVE.

[1171.] In your article on the Stewarton hive you refer to the fact that in 1880 I read a paper before the B. B. K. A. on this hive and you proceed to give numerous details respecting it. Allow me to express a hope that none of your readers will be thereby beguiled -especially when they gaze on the wondrous representation of body boxes piled on each other which adorns your columns-into the purchase of a Stewarton. There is a vast difference between I880 and 1887. Bee science has advanced by leaps and bounds in the interval. What I could conscientiously recommend in 1880, I should hesitate even to approve in 1887. The Stewarton has had its day and has done excellent work. It has taught bee-keepers the importance of storifying, of enlargement of the hive above and below with the increase of population. But of late years the same principle has been applied to the bar-framed hive and with even more satisfactory results. The enormous harvests sometimes secured in the Stewartons have been surpassed when three or four bar-framed hives have been piled one upon

another. The slides of the Stewarton cannot be compared in point of convenience to the frames of the modern hive. In dry weather they shrink and perhaps fall into the hive when you endeavour to draw them out or to put them in their place; in wet weather they swell to such a degree that it is often almost impossible either to draw them out, or to return them if you have succeeded in extracting them. The manipulation of bees, moreover, in the bar-framed hive is infinitely more easy than in the Stewarton. In point of expense the bar-framed hive of 1887 will bear comparison with the Stewarton.—E. Bartrum, Berkhamsted, Herts.

RE FOUL BROOD.—SPACE BENEATH FRAMES.

[1172.] I would advise 'West Kent' to remove the queen on suspicion, for we know that sometimes the disease takes possession of her and every egg she lays has the gems of disease in it. This advice I gave last year to the 'Man of Kent,' and it would be interesting to hear from him how he has fared this year after the robbing of a diseased stock by all his other stocks. I hope he will favour us with another letter on this subject. I know from experience how difficult it is for a novice to get rid of the disease, while at the same time he is using phenol the queen is producing it in every cell. Take her away, and for three weeks the disease may be stamped out by the Cheshire cure; if, however, it should appear again when the young queen begins to lay a little patience and repeated application of the medicated syrup with Mr. Cheshire's directions will effectually cure any attack.

I am very glad to see that you, Mr. Editor, are giving attention to 'space beneath frames,' for I am convinced that it is a very important subject since the adoption of a system of frames running parallel with the entrance, and many good stocks have come to grief in winter through the want of more space below the frames. It is quite a mistake to suppose that a few inches of vacant space below means draught, and many years ago when I used the old straw skep I frequently observed how much healthier and stronger these stocks were which had not time to complete comb-building in the autumn; and even in the good old time of the Woodbury hive I seldom lost a strong stock in winter, but since adopting the parallel system I regret to say the winter destruction has been great with me, and I have seen some painful sights in other apiaries; I trust, therefore, that we shall soon have a hive combining with other advantages a clear twoinch space below the frames for winter use only; and if proper attention is given to top packing we need have no fear for the safety of our bees even in such a winter as the last.—Thomas F. Ward, Highgate.

NOTES ON CURRENT TOPICS.

[1173.] Four Bee-way Sections.—As I anticipated in the Journal, these are a failure with me when used without separators. To be sure they are filled and sealed, and, I think, rather more quickly than when separators are used, but they cannot be glazed, nor can they be packed without bruising one another unless kept in the same order they occupied in the rack; besides, the propolis has to be scraped off four sides instead of two, and they are also much more difficult to handle without breakage.

Taking off Sections.—I take off the rack complete, place it at the back of the hive, then take out the sections one by one, and shake out the bees in front of the hive, having first placed a sloping board from the entrance to the ground. Five minutes suffice to clear a rack of twenty-one sections of every bee, and as each one is cleared it is placed in a Coleman's starch box. Scarcely any smoke is necessary, just a few puffs to send the bees down from the rack before lifting off.

Bees and Roses.—As a rosegrower on rather a large scale, and an exhibitor occasionally, having for years had some thousands of rose-trees constantly under observation, I wish to state my opinion that there is not a shadow of anything to support the supposition that bees do injury to rose blooms, that is, spoil any that would be otherwise fit for exhibition. Bees frequent roses for two purposes, i.e. for pollen when the honey season is about over, and when flowers are scarce, and for water which has been held by the cup-shaped flower after a shower, or has been condensed on the petals during the night. I quite agree with the opinion expressed by the writer of 'Useful Hints' that if a bee can reach the stamens of a rose bloom that flower would never stand the exhibition table.

Re-queening Stocks.—I seldom raise queens, and Mr. Webster's letter is a well-timed caution against raising them in nuclei, as at this time of the year I can get more than I want for the asking, i.e. condemned bees, and by keeping separate those from hives which have swarmed and casts, you can either unite the bees and queen or queen alone after having taken away the old one by any of the methods so frequently mentioned in the Journal. Be careful in uniting bees, it is easier said than done. They should be put together on the evening of the day they are driven, as they are then gorged, and will be accepted. If delayed until the next day, it is more difficult.

Excluder zinc.—When Mr. Simmins asks where excluder zinc can be procured, he means, no doubt, the correct size, and yet he knows better than I do that queens vary much in size, therefore to get 'the correct size' we must first measure our queen. The best excluder zinc that can be used in a hive is plenty of room below for the queen with a reasonable quantity of drone comb. Are we not ourselves to blame a good deal by trying to work against nature by filling our hives with all worker comb, the result being that in accordance with the natural instincts of the bees to rear drones, they fill the supers with drone-comb? Mr. Simmins tells us, if I remember rightly, that he supers on nine combs. No doubt there is a difficulty in keeping down a vigorous laying queen on nine bars. I cannot do it with our native bees. I like supering on from eleven to fifteen bars, then there is little fear of the queen ascending the supers if only some drone-comb exists in the hive. And why should we exclude drones? where is the hive that has any prosperity about it without them?

Wasps.—Are you not a little premature in proclaiming a scarcity of wasps? After long observation I have come to the conclusion that the number of queen-wasps seen in any spring is no criterion as to the abundance or otherwise of wasps in the autumn, and no reliable conclusions can be drawn therefrom. My own opinion is that, like bees, they have good and bad years, and that their abundance or scarcity depends very much on the season—a dry summer being favourable to their increase and a wet one the reverse, hence I shall not be surprised to hear they are more plentiful than agreeable in some parts of the country this autumn, notwithstanding the scarcity of queens in the spring; besides August is the month when they become so intrusive, and with they ware the propriet them.

until then very few people notice them.

I was glad you mentioned some of this beautiful, active, intelligent, and useful creature's good qualities; it is without doubt one of the most harmless creatures in existence, seldom or never taking the offensive, indeed, unless you interfere with its home, scarcely any amount of ill usage will make it attack you. This is contrary I know to public opinion, but I don't care a rap for public opinion on natural-history matters; it is generally made up of old exploded notions, popular prejudices, and superstitions, having their origin in inaccurate observation, therefore in nine cases out of ten it is erroneous.

Wasps, like humble bees, fly at a lower temperature than hive bees, which they excel in beauty, intelligence, and courage; bees being their equals in one point, viz., untiring industry. No doubt they do much injury to ripe fruit, but then they do an incalculable amount of good to the trees by ridding them of aphis, &c. I think the injury they do to bee-keepers has been much overestimated. I cannot recall to mind a season when they have done me sixpenny-worth of injury, and this is a great district for wasps.—F. Boyes.

CARNIOLAN BEES,

[1174.] As Carniolans are to a certain extent still on their trial against other foreign races, I would like, with the Editor's permission, to give my experiences with them, although I am only a bee-keeper of twelve months standing. Last year I commenced bee-keeping by getting two rather late swarms, and with the help of a friend I put them safely into bar-frame hives. However, I was very unlucky with them, as the queen of one swarm died suddenly soon after all drones had been killed; and the other swarm proved to be a cast, the queen of which failed to get fertilised with me. Under these eircumstances I had either to let them die out or send for queens to a dealer. Well, after a great deal of debating as to what race I would go in for, I decided to go in for Carniolans, and I sent to Mr. Simmins for two of his homeraised Carniolan queens, which, with much fear and trembling, I introduced according to the Simmins fasting method, and to my great delight I found both queens laying when I examined at the end of sixty hours. Well, both hives wintered well, and I devoted one of them to increase, and I have made six good stocks out of it besides having extracted nearly 40 lbs. and taken 15 lbs. in sections. The other hive I prevented from swarming, and up to to-day, July 25th, although this is not a very good district and the limes have been an utter failure, I have taken 90 lbs. in sections, 12 lbs. extracted from brood-combs, and there are still 21 lbs. in sections on the hive which are nearly finished. I think this is not a bad score for any race of bees, and I daresay it would have been better if the hive had been in the hands of an expert.-W. B. M., Donnybrook, Dublin.

CAMOMILE WEED, &c.

[1175.] I should be much obliged if you would answer me the following questions in next number of B. B. Journal. Two or three large fields near my apiary have not been cultivated this year, but the camomile weed has seeded itself all over them, and now the fields are one mass of the white flowers, and on het days it is very unpleasant walking near them, as they give off an offensive smell; they also give off a very loud hum of bees. What is camomile honey like? Is it poisonous or unpleasant in any way? I have heard of camomile pills for indigestion; if I find my honey very objectionable I think I had better put it in small bottles and sell it as a crack cure for indigestion (camomile honey 2s. 6d. a bottle).

Is there any way of making honey bright? The first lot I took this year is very good flavour, very light in colour, thick, but not bright, which, of course, makes it impossible for me to show it. What makes it dull?

I wish you would use your influence against a practice which is becoming very common, viz., putting extracted honey into bottles which only hold 12 or 13 onnees and then selling them as 1 lb. bottles. I find that a Bottle Company (who seem to do a large honey bottle trade) are offenders; their (reputed) 2 lb. screw cap bottles hardly hold $1\frac{1}{2}$ lbs. Why shouldn't prizes be offered for honey bottles at bee shows? Of course only those holding exactly the right amount would have a chance of getting a

prize, and bee-keepers would know where to get the best bottles without writing to different firms for samples. The prize winners would do the best trade, and therefore the trade would be obliged to make their bottles the right size.

My bees have done fairly well. The clover has failed owing to want of rain. The limes are just coming out, but unless we have rain very soon, the bees will leave everything for the honey dew, which is very abundant.—E. B. Downer, Surrey, July 4th.

[We have had no experience with camomile honey, we presume it would partake of the qualities of the flowers, which have a strong though not ungrateful smell, and which possess tonic and stomachic virtues. Honey may be made brighter by continuous straining—Ep.]

BACILLUS MINOR.

[1176.] I am much obliged to the writer of 'Useful Hints' for his description of *Bacillus minor* in a recent issue.

By it I have been able to identify the state of one of my hives as being affected by Bacillus minor during the last three weeks. I knew it was not true foul brood as described in British Bee-keeper's Guide, and could not make out what it was. As you say there is no cure for it yet discovered, on Saturday I took out all the frames containing any brood—there were seven—and inserted in their places six other frames of healthy brood and a partially finished queen-cell, as there seemed a desire on the part of the affected bees to rear another queen.

The frames of brood, &c., I am going to hoil down for the wax. I believe the disease to have been imported about a month ago, when I added a 'colt' to this hive to strengthen it—said colt was a stray one, from a straw skep, I suppose.

Our honey crop has been quite up to the average; no rain for forty days, which shortened the clover crop considerably.—W. H. PANTON, Glensford, July 23rd.

[If you are right as to the nature of the disease you have taken very effectual measures for curing it.—ED.]

TWO QUEENS IN ONE HIVE.

[1177.] From one of my hives a swarm issued about six weeks ago unknown to me, but I thought they appeared in greatly reduced numbers round the entrance, and I therefore took off the sections and went over the frames, when I was fully satisfied that my conjectures were right. There were two empty queen-cells and also two young queens, so I closed up again, and left them, as I thought, to the enjoyment of a battle royal. To-day I went over them thoroughly again, and took away sections. On looking at each frame separately, lo! I discovered the two queens still in existence, and all the nine frames completely covered with brood and eggs. Now my object in giving these particulars is that you may be able, if you will be good enough, to advise me whether I ought to destroy one of these, or leave them both in their glory.—S. Pratt, Fakenham, Norfolk, July 30.

[The bees will in due time record their preference. Wait and watch.—Ed.]

LIGURIANS.

[1178.] A great deal having been said lately in your columns in praise of Ligurian bees, I trust you will allow me to relate my first experience with them. On examining my stocks (blacks) in April last I found one queenless, and seeing an advertisement in the B. B. J. by Mr. Simmius of Ligurian queens, I ordered one, and success-

fully introduced her by his simple and excellent method-The hive was getting very weak, and I gave it two frames of brood from another lot. Towards the end of June the bees appeared much stronger than I had anti-cipated, and gave signs of swarming. The hive was a small one—ten frames. I had added a rack of sixteen sections, and they had been taken to rather reluctantly. In the second week in July I gave them a body-box, and they appeared very busy, but on the 25th instant they swarmed, not having drawn out any combs in the body-box. The brood-chamber is full of brood, but there is practically no honey; they have not even filled the small section-crate. They have worked all along, early and late, and yet seem to have but little to show for it.—HERBERT H. PRATT, Stokeville, Stoke-on-Trent, July 27.

[The bee enclosed in your letter was so utterly smashed that it was beyond all recognition as to race.—ED.]

Echoes from the Yives.

Beverley, July 25th.—This grand season—the Jubilee year for bee-keepers-is at last over. Bees have ceased work and killed off the drones. No rain, all parched up.— F. Boyes.

North Leicestershire, August 1st.—The honey-flow terminated rather suddenly on Sunday, July 17th, but not till the bees had secured large quantities of first-rate honey in both bars and supers. Here and there a stock is still adding a little to its stores, but, as a rule, unfinished sections are being cleared out, and their contents carried below. On the whole it has been a very remarkable season, bees starving until June 4th, and then enjoying an uninterrupted revel in plenty for a period of six or seveu weeks' duration.—E. B.

Lismore, Ireland, July 28.—Such a honey season as it has been here! It has been nothing but extracting, and supering, and taking off sections, so that for the most part I have just had to lump my record. But one hive was noted, and worth noting, for it gave 110 lbs. of sections of really first-rate appearance, of which I removed sixty-three the day before yesterday. I have had four skeps inverted which have yielded me excellent returns. I put boxes over them, holding eight or nine bar-frames each, with wide flat wooden covers made weather-tight with tarred felt or calico. I was under the disadvantage of having only a very limited number of old combs, so many of the bars had to be drawn out, as I only use guide combs. Still I was able to extract from the combs three times, getting a fine lot of honey each time. One of the skeps I supered, but did not get more than eighteen perfect sections and about eight pounds extracted. I am sure for skeps there is nothing like inverting. I let them get a good lot of honey sealed before I inverted, and am going to put them back again into the old position now. If I find they are not heavy enough to go through the winter well, I will feed; but we get so much heather and ivy honey here I do not think it will be necessary. From one of my skeps I got as much honey for extracting as from a bar-frame hive of three storeys, because in the latter I was so hampered by the queen laying in each storey. Next season I shall try excluder with my doubled hive, at any rate between the second and third storeys. I found the skeps so convenient with the excluder zinc over the hole in the bar-frame super boxes; the queens never once got up, and I extracted away in peace and security. I have had great ease and comfort in the removal of my sections. I follow the plan which I observe some of your correspondents advise for glass supers. I take off the whole crate or crates in the morning with a little smoke to quiet the flying bees, and then remove each crate and place it on top of an empty hive, narrowing the door to one or two beespaces. Then I put on the cover of the hive, having previously stuffed the ventilating holes with paper. I also put a cloth sprayed liberally with carbolic solution over the sections. The empty hive, or hives rather (for I generally take four or five racks at a time), I place in a shady spot

among goeseberry-trees, or under a tree some little distance from the hives. In three or four honrs I return and find the sections empty, except half-a-dozen bees who are only too glad to be sent off homewards. All the others have made their way out through the deor and go home. As I have to send off almost all my sections by rail it is very important for me to get them off quite undamaged, which is not easy to do at the hives; the bees here propolise so much. Mereover the plan is so stingless and quee.—FANNY W. CUBREY. [The grub enclosed in the queen-cell therefore interesting. forwarded was that of a drone, and therefore interesting. Of course it would not have come to maturity.—Ed.]

Dublin, July 30th.—It is a long time since you have had an echo from my hives. I had not time to look after many stocks, as my profession would not admit of it, but I again started with two hives in May last. No. I on five frames, the brood of which I spread to seven, and in a day or two added two frames more, making eleven frames by the end of May. By June honey was coming in rapidly, and I placed them in one of Abbott's doubling hives (10s. 6d. one), which, I consider, the cheapest and most serviceable in the market, as will be seen by results. I got seventy-eight 1-lb. sections off this hive by the end of June, and one frame of honey weighing 63 lbs. (which was next to impossible to extract it was so thick). Very little honey coming in since (though they have still a crate of sections, twenty-one, which are nearly complete from mignonette and other flowers). I keep my bees in a suburb of this city, Dublin. We are greatly burnt up, no grass, and no flowers on the limetrees, all dropped off from the great drought. I sold all my sections at 9d. and $9\frac{1}{2}d$. to grocers, but sections (1-lb.) are now retailing as low as 7d. per section in the grocers' shops here. Many grocers have offered as low as 4d. per section to country customers of theirs, so I have heard from a country friend of mine. It is thus destroying our honey market, where as high as 1s. per section was paid in the early season. Hive No. 2 yielded only 30 lbs. of extracted honey in frames. It was a transferred stock in May. So you see the great difference in bees (both blacks) under similar circumstances in the same locality. What do you think of stock No. 1-nearly one hundred 1-lb. sections ?-JNO. PURSER ALLEN. [A very satisfactory report, indeed.— ED.]

NOTICES TO CORRESPONDENTS & INQUIRERS.

Letters or queries asking for addresses of manufacturers or correspondents, or where appliances can be purchased, or replies giving such information, can only be inserted as advertisements. The space devoted to letters, queries, and replies, is meant for the general good of bee-keepers, and not for advertisements. We wish our Correspondents to bear in mind that, as it is necessary for us to go to press in advance of the date of issue, queries cannot always be replied to in the issue immediately following the receipt of their communication.

All queries forwarded will be attended to, and those only of personal interest will be answered in this column.

R. Auld.—I. Suspected Foul Brood. — We are of opinion, from the condition of the piece of comb forwarded, that your suspicions of foul brood have not been borne out. From several cells healthy bees were being hatched out, and the usual indications of diseased brood were not Some of the brood were, however, dead, and it visible. would be desirable to make a thorough examination. 2. Removing Supers. — About midday, when bees are at work in the fields, apply a carbolised clothe to the upper box, after removing the covering, or smoke, if you prefer it, to drive the few bees at home downwards, and then remove it to a room or outhouse, and, taking out each comb, brush off the bees, allowing them to fly home. Proceed similarly with the lower box. When extracted give back the combs for the bees to clean.

A Welsh Bee-keeper.—1. Sugar.—The samples of lump sugar forwarded would answer your purpose for making syrup for winter feeding. We have a preference for pearl crystallised sngar. 2. Size of Hives.—Consult on this point Modern Bee-keeping or Cowan's Guide-book. The size of the one mentioned has not met with approval from experienced bee-keepers. A review of British Bee-farming will be found in Vol. VIII., p. 181. We shall be pleased to have, at your convenience, your remarks on the 'size of hives.'

- R. C. H.—Casting out Immature Drones.—When immature drones are east out early in the season it is an indication that the bees require feeding; when cast out after the cessation of the honey-flow, it proves that they desire no useless mouths to feed.
- K. D.—1. Feeding Swarm. Your action in feeding the swarm was in accordance with the usual practice. 2. Earwigs.—If your stock is strong the bees will give a good account of the earwigs. These insects are very much sirable companions of bees. They do not, however, much harm to the bees; their principal object in resorting to hives is warmth. We should not recommend you to use Keating's powder.
- Benton Shipping Case.—An illustration of this was given on p. 345 of Vol. XI. Modifications of it may be procured from most hive-makers.
- East Kent.—1. Drone Comb.—We think it a great mistake to put starters only in frames at the commencement of the season; there is a desire then to raise drones; consequently, the comb built from the foundation to bottom is invariably drone. 2. Stock Dwindling.—Your stock has not recovered from the swarming. It will get stronger directly, as evinced by its having a large quantity of sealed brood. This applies to it if it is perfectly healthy, of which condition you say nothing.
- R. MIDDLEBROOK.—Breaking up Sections.—Cut out of section-frame; then slice the comb across the cells close to the midrib, and drain through a piece of strainer cloth. If you have an extractor, you can pile up—after uncapping—a lot in each cage and extract.
- R. S.—Using Fermented Honey.—Boil it, and add to every 10 lbs. a tablespoonful of solution of salicylic acid. Skim it thoroughly. Do not boil honey in the day-time when bees are flying, unless you want the house full of them.
- John Haigh.—1. Honey Wine.—In order to ascertain the necessary gravity for this, dissolve your honey in warm water until the liquor will support an egg, the surface of which above water should equal the size of a two-shilling piece. Your wine will be very intoxicating if made with honey. 2. Relative Sweetness of Honey and Sugar.—Sugar itself varies so greatly in sweetness that it is difficult to make a comparison.
- J. H. D.—Condemned Rees.—It would be very bad policy to purchase them from any one so close. The greater portion would fly back, even if you gave them brood comb. Do not try it.
- Rosbergon.—1. Uniting.—The advice given in the book should be followed if either of the queens is known to be inferior; but if you have no choice between them you may leave them to fight it out. 2. Your swarms which have filled only three and a half frames since the end of June must have been very small or the weather very unpropitious. Unless they increase so as to cover at least five frames when crowded for the winter they are likely to die out.
- E. P.—Condemned Bees.—You had better unite on the spot. Take one lot in the skep into which it was driven and place it, mouth up, on the ground, place another on it mouth to mouth. Lift both together and give a violent hump on the ground. Have ready your canvas and string, throw away the upper skep (now empty) and tie the bees in as quickly as possible before they have time to recover from the bump. They will require no scent or any other preventive to fighting; being without combs they will have nothing to fight for, and therefore will peaceably unite. One of the queens will be killed unless you pick one out before uniting.
- Lascelles Carr.—1. Crowding.—When the time arrives for this operation all the brood will have hatched out, except perhaps in one or two of the centre frames. As to the outside frame containing honey, you may extract it and put the combs behind the divider for the bees to lick out, or you may preserve them in a dry, warm place to give to the bees in spring. You may with care extract honey from combs also containing brood, but it is not advisable for fear of injuring the brood. 2. Sections not completed.

 —You did right in removing the crate, which was very incomplete, but very wrong in exposing it out-of-doors, as

- yon have probably found ont by now; if you have not started robbing yon are fortunate. Take it in and give the sections behind the divider in the hive, having the crate of incompleted ones on it. The emptied sections will do for next year if preserved from damp and mice. You need not fear swarming now. 3. Manipulation in a high Wind.—The free circulation of air no doubt prevented the bees feeling the effect of the carbolic acid cloth. A good smoker vigorously used would have been more effective and saved you some pain and the hees some lives.
- T. C.—Number of Frames to Winter on.—This will depend on the strength of your stock when you prepare it for winter. The frames of autumn should be reduced until those left are crowded with bees. If you can have seven frames full of bees, they should have about 20 lbs. of honey to subsist upon. It is advisable to cut winter passages in the comb about three inches from the top of the frame, for the bees to pass through.
- T. D. S.—1. Drove Eygs.—We never knew a case of a queen being reared from an egg laid in a drone-cell, but have witnessed repeated attempts of bees when in despair to raise queens from drove eggs. 2. Clearing a Bell Glass.—The best way to clear a bell glass of bees is to remove it from the hive on a fine day when the bees are at full work and to place it in a dark room, leaving the door slightly apar so that the bees may fly to the light and escape. 3. Carbolic Solution.—Probably you did not saturate the cloth sufficiently with carbolic solution. The cloth should be kept on the hive while manipulating and merely turned aside while raising a frame. By this means we find that the bees are far more easily manipulated than by means of smoke and are much quieter during manipulation.
- J. W. J.—Taking Boxes to Heather.—Slightly raise the upper box from the lower by wedges, gently inserted, and pass between the two boxes a feather moistened with carbolic solution. Then lift off the upper box and place it on a piece of canvas, which must be tied or tacked to the hive to afford ventilation and prevent the escape of bees. Place another piece over the lower box and place them in a spring van and travel slowly by night.
- AMATEUR.— Taking Bees to Heather.— Please refer to reply given to 'J. W. J.' Your proposed plan of fixing your frames will work well. Your frames being three years old, are sufficiently tough for transit. The honey should be extracted before removal.
- J.—The comb forwarded is not affected with foul brood. The cause of the bees dwindling cannot be laid to the account of the comb.
- E. Tulley.—Old Queen.—The cause of the gradual dwindling of your stock was that your queen was aged. There was no symptom of foul brood in the piece of comb forwarded.

Received from a correspondent a section of honey, which, having broken away from its attachments during transit, must have been a sad trouble to the Post-office authorities. The flavour of the honey is the reverse of agreeable. It has been contaminated by being mixed with honey-dew. Though not fit for humans, it will not affect injuriously bees.

Received from Mr. J. Walton a bottle of extracted honey. We found this, for consistency and flavour, a specimen of what good honey ought to be.

Show Announcements.

Giving Name and Address of Secretary, Date and Place of Show, Date of Closing Entries. Terms: Three Insertions and under, Two Shillings and Sixpence; additional insertions, Sixpence each. No charge made to Associations whose Shows are announced in our general Advertising Columns.

August 11.—Taunton Flower Show, at Vivary Park, Tannton, Somerset. Entries close August 8. Hon. Sec., W. B. Maynard, 5 Hamnet Street, Tauuton.

August 12.—Maer Fète and Honey Show. Entries close August 5. John R. Critchlow, Hon. Sec., Maer Farm Newcastle, Staffs. August 9, 10.—Irish Bee-keepers' Association at Sonthill Gardens, near Dublin. Entries close August 2. Hon. Sec., Henry Chenevix, Blackrock, Dublin.

August 14.—Handbridge, Chester St. Mary's Ho ticultural Show. W. E. Little, Hon. Secretary, Eastgate Row Chester.

August 16-17.—Wilts County Show at Salisbury. Hon. Sec., Rev. W. E. Burkitt, Buttermere Rectory, Hungerford.

August 24.—Laneaster Agricultural Show. W. Liddell, Hon. Secretary, Dale Street, Laneaster.

August 31-Sept. 3.—Royal Manchester and Liverpoo Agricultural Show at Manchester. W. Lees McChure, Hon. Secretary, The Lathoms, Prescot, Lancashire.

TO CO-OPERATIVE SOCIETIES.

A National Co-operative Flower Show will be held at South Kensington on August 23rd, two prizes are offered for honey, which are open to members of co-operative societies only. Space free of charge will be granted for the exhibition of appliances relating to bee-keeping; intending exhibitors should write to Mr. W. Broomhall, Secretary, 1 Norfolk Street, Strand, W.C.

CONDEMNED BEES.

(Continued from p. 332.)

While the number of advanced bee-keepers who seek to rescue condemned bees from their fate increases, the number of bee-keepers of the old smotheration school, thanks to the good work done by the various Associations, steadily decreases, and thus as the demand increases the supply is reduced. Nevertheless, there still remain numerous beekeepers, especially in remote country places, who have either not heard of the way to take their bees without killing them, or from ignorance of the best way to make use of them, or from prejudice or want of time, still continue to 'put them down,' and these should be carefully sought out, both for the sake of obtaining the bees and to teach them how to avoid their errors in the future. It is next to useless to try to find condemned bees in the immediate neighbourhood of large towns, in the suburbs of which some one most likely resides who makes a practice each year of seeking out and taking the bees. Lengthy excursions should be taken and inquiries made as soon as possible, or it may be too late for this season; and to avoid carrying the necessary implements about, perhaps fruitlessly, it is better to seek the bees one day, and, having found them, make an appointment to come at some future time to take them. It often happens that the existence of a few skeps may be found by watching for bees on the wing and noticing their flight. If brisk and rapid they are going from home; but if laden and homeward-bound the flight will be heavier and nearer the ground. Notice the direction of homeward-flying bees, and if a cottage is seen in the line of flight inquire at it.

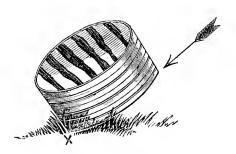

Some difficulty is occasionally experienced in obtaining permission to take the bees. There may be some prejudice existing, such as that 'bad luck' would follow. Cottagers cannot at first understand what use the bees can be to any one; they often say it is better to kill them right out than to let them starve—which opens the way for a short lecture. Then, again, they think some advantage is about to be taken of them, and that they will not get so much honey as if they put them down. In some cases, unfortunately, it happens that some one having in a previous year undertaken the task without adequate experience has made a mess of it, and perhaps set the bees all round robbing and fighting. No one should rashly undertake to teach others until he has had fair experience. Failure on the part of one who is presumably an expert discredits future visitors on the same errand. A good deal of tact is required in dealing with these objections. The best means is generally to offer sixpence or a shilling for the bees, which would be useless dead.

Having found the bees and arranged to come again and take them, the question arises how to do so. Every bee-keeper who feels himself competent to take condemned bees is necessarily conversant with the method of driving, either open or close, as explained in books and exhibited at shows.

When this method is practised, however, great danger of robbing being set up is incurred. When several lots are taken at one place, towards the end the robbers become so troublesome that it is impossible to get all the bees out. As fast as the original occupants run up robbers run down to the deserted combs, and so it happens that when the skeps of comb are delivered to the owner and placed in the house, the bees among them fly about and cause great annoyance, this being a serious reason against the bees being driven as compared with being smothered, when no bees are left among the combs to cause trouble. Moreover, robbing, when once established, leads often to all-round fighting and destruction of stocks. Robbing may be prevented by closing all the stocks in the garden by pushing a wisp of grass into the cutrances lengthways, so as to confine the bees but not to exclude air. In hot weather great caution is necessary not to leave the hives closed too long for fear of over-heating. If eight or ten lots have to be taken, which will occupy in driving at least

twenty minutes a lot, and in some cases longer, by the time all were done damage would most likely occur to the confined stocks, and therefore the process called 'bumping' is to be generally preferred. This differs from driving in that in driving the bees are taken from the combs, which are left in the skep, while in bumping the combs are taken from the bees and put into pans to be carried indoors, while the bees remain in the skep. Instead of occupying twenty minutes or longer, four or five minutes suffice to clear the combs of every bee, and no bees—or at any rate only a very few stray robbers—are taken indoors. This process has been several times alluded to in our columns, but as it may not be familiar to all our readers we reproduce the details with a few additional hints.

On arriving at the garden, get the owner to give you a history of the bees-as to which are stocks and which swarms—and proceed to mark them. A ready way of doing this is by stones placed upon the alighting-boards—one for a stock, two for a swarm, three for a cast, four for a virgin swarm. You will then know which queens to preserve when uniting. Now close all the entrances as described above, giving just a puff of smoke to prevent the sentinel attacking. Ask the owner for some large pans and some sacks to cover them; put a pan covered with a sack on the ground near the first stock to be taken, give a good puff of smoke, and at once lift the skep, turn it up, and give it a good bump on the ground in the direction shown by the arrow in the illustration, the × shows the point at which the skep should strike the ground.

It is important to note the direction of the blow, if correctly given the weight of the combs carries them forward and they break off close to the crown. If, however, the blow is delivered vertically on to the point marked with a \times , the combs will probably be broken up. If there are sticks through the combs. they must before bumping be either divided between the combs with a keyhole saw or a pair of strong shears, or they may be withdrawn by a pair of pincers, giving a screwing metion. Having broken the combs out, replace the skep on its stand, upside down of course, lift the combs out one by one, and having a stick laid across the skep, rest the comb on it, and with a goose-wing brush off the bees into the skep as each comb is cleared, put it into the pan and cover with the sack. When all the combs are out replace the skep right side upwards for the bees to cluster in; to hasten them, take a wing (not the same as you use for brushing | off the bees), dipped in a dilute carbolic acid, and brush the whole of the floorboard with it and prop up the skep at an angle of 45° with a stick in front; the floorboard being so distasteful the bees will not loiter upon it, but join the cluster at once. The old queens may be picked out from swarms at once and the bees united to another lot, but don't leave a lot of bees without a queen or they may unite to some lot which you do not wish them to. Do not forget to remove the grass from the entrances of the stocks left before going away. When several lots have to be taken in one day it is necessary to work all day, and it is best to take those nearest home first, leave them to cluster and return over the same ground to take them away. If from only one place, the evening is the best time, as little time is

lost waiting for the returning foragers.

For carrying the bees home, skeps are about the most inconvenient receptacles possible. The best way is to have some boxes made, $14\frac{1}{2} \times 9 \times 8\frac{1}{3}$ in. deep, which will just take six frames, make an entrance along the bottom of each, which close with perforated zinc. Along one edge of the top tack a piece of paperhangers' canvas, or cheese-cloth, and take with you laths cut to the right lengths for sides and ends of the boxes, and some french nails. When the bees are clustered take one lot, place the skep gently on the ground mouth up, place another lot on it mouth to mouth, lift both together, bump the lower one on the ground to shake all the bees out of the upper one into it. Have your box ready with the canvas turned back and your laths, hammer, and nails, all ready; throw away the empty skep, pour the bees out of the other into the box, turn the canvas over and nail on the laths. Carry the boxes with the canvas sides vertical and don't pack them together close, but allow plenty of air to enter. When you get home, all that is necessary is to supply alighting-boards, remove the canvas, and give six combs, which you have had already stored, as described in our last. Just put the combs in on the bees, as they feel the weight they will run up between them; put the fullest combs outside, and those not so full in the middle, open the entrance, and cover with a quilt and roof. The bees may be wintered in these boxes by placing them in larger ones with entrances and packing all round with chaff, cork-dust, or any similar warm The boxes must be placed upon the material. stands which they are to occupy before releasing the bees. This must be done in the evening, never release condemned bees in the morning. If you drive the bees, you must have as many skeps as you have stocks to take, as each lot must be left on its stand to receive the foragers. They can be brought home separately or united in twos as above.

Arrange the hives with the combs and the quilts on, place a large board sloping up to the entrance, and throw the bees on it. If the combs should not be fully stored, feed rapidly with thick syrup. All food should be sealed by the end of September. There is an additional advantage in the bumping process, viz., that as you take out the combs you can see at once if foul brood exists. Even if you should find it, it does not follow that you need

abandon the bees, but on bringing them home instead of giving the combs to them keep them confined for at least forty-eight hours, hive them by throwing them on a board, feed with fool medicated with Cheshire cure, burn the canvas which covered the boxes, and either burn the boxes—which need only cost 4d. or 6d. each—or boil them in a copper of water containing carbolic acid. A very useful hint was contained in our last to get the combs stored with medicated food. It will do no harm even if no disease exists in any of the stocks you take. Do not omit to point out the disease to the cottager, and caution him as to not allowing other stocks to rob the honey from an infected stock, and instruct him how best to cure it. As a rule foul brood is more likely to be found in low-lying localities than on high lands.

THE BRITISH HONEY COMPANY.

The second Annual Meeting of the Shareholders of the above Company was held in Jermyn Street, on Thursday, Angust 4. A full report of the meeting will be found in our columns. The Balance-sheet, which had been forwarded to the Shareholders prior to the meeting, represents the liabilities and assets, with the profit and loss accounts of the year 1886. From the balance-sheet it would appear that 6119 shares have been taken up by the public, and 16227, has been received on calls made thereon. The net sales of the Company for the year have amounted to 12261, 11s. 9d., on which after adding stock in hand there was a gross profit of 521l. 19s. 4d. The expenses of the Company show a marked diminution. In the first balance-sheet there was a debit balance of 508l. 6s. 4d., this year only 134l. 4s. 2d. The Directors are very sanguine as to the future success of the Company, and that the object of its establishment, viz. to promote beekeeping by the ready sale of British honey and to assist small bee-keepers to dispose of their stock, will be attained. The Directors have had numerous difficulties to contend against since the establishment of the Company, chiefly through the misapprehensions of bec-keepers as to its objects and intentions. These difficulties are gradually being overcome, and the public generally have confidence in the Company and the articles it produces. The experience of the past indicates that the Company must not look for success from the sale of honey alone, but that they must enlarge the basis of their operations by taking advantage of the powers couferred on them at the establishment of the Company. For this purpose they have during the past year been selling fancy boxes and bottles for the sale and exhibition of honey, and they have brought out a new non-intoxicating drink, to which they have given the name of 'Mella'; and as time advances and opportunities present themselves there is no doubt that there will be further developments by the Company. In the meantime we feel assured that the scope and position of the Company are getting more recognised, the desire for pure British honey is increasing, and the virtues of honey as food and medicine are more fully known.

THE BRITISH HONEY COMPANY.

The Annual General Meeting of the shareholders of the above Company was held at 105 Jermyn Street, St. James's, on Thursday, August 4th, at 4 p.m., in order to transact ordinary business, to elect two directors, and to appoint the auditor for the ensuing year. Among the audience were present the following directors and shareholders: Mr. D. Stewart (Chairman), the Hon. and Rev. H. Bligh, Dr. Walker, Mr. Zehetmayr, Mr. Otto Hehner,

Mr. Henderson, and Mr. Timberlake. Mr. Stewart, after being appointed Chairman, read the notice sent to every shareholder convening the meeting. He said they had all seen the balance-sheet, which he considered on the whole to be satisfactory, and although at present they were not doing a very extensive business, the Company was making decided progress, and there was a prospect of better times in store. The figures still showed a loss, but the loss was a very different one from that which they were obliged to record after the first year's trading. present loss inspired them with fresh hopes and conrage, and showed a continued confidence in the stability and success of the Company. They would remember that the Company was not started with the expectation that it would turn out a money-making enterprise, but more for the purpose of developing a trade for the benefit of the British honey-producer, and thus promote bee-keeping. They had comparatively small funds at command to carry out this object, and therefore it was necessary to act with great caution. They must always have a reasonably large amount in hand, so as to make advantageous purchases. As a trading community they sold to dealers, who looked for the usual trade profits, and the Company was, therefore, obliged to sell at such a price as would enable the dealers to attract customers. He thought they were gradually attaining one of the original objects of the founders of the Company, which was to develop a taste for and knowledge of British honey in competition against the foreign article, which had fallen into disfavour, partly owing to the adulteration of it, and generally because of its inferiority even when not spurious. He was glad to say that they were obtaining by degrees an extensive elientele. They did not depend on chance customers, their trade being done principally with buyers who came again and again, which showed that the produce supplied by the Company was trusted and approved of. That fact encouraged them to look forward to a time when their affairs would be in a satisfactory condition. They were enabled to turn over their capital again and again during the course of a year by means of sales and judicious purchases, and were thus working on sound commercial principles. The proportion between the income and annual expenses was not what it would be if they were dealing with a large business. The expenses need not grow pro rata as the business grew, which important consideration they had found out in the second year of trading. As he had already announced, two of the directors (himself and Dr. Walker) would retire from office that day, and it would by the duty of the meeting to elect two gentlemen to fill their places. The shareholders had hitherto shown confidence in the management by re-electing the retiring directors, and by allowing the Board to earry on the work of the Company in its own way without inter-ference. The shareholders kuew in many ways, from the columns of the Bee Journal, and from friends probably, how the work of the Company was being carried on, and he was happy to say that the directors had had no inquiries of a kind which betrayed any want of eonfidence in the management. It was for the share-holders to determine whether the retiring directors should be re-elected, or other gentlemen be appointed to take their place. Any shareholder could propose any one he chose for election. With regard to the auditor, it would be necessary to elect a gentleman for that

position, owing to an unfortunate death which had occurred since the last meeting. They had had the benefit of the services of the auditor of the present balance-sheet, who had done his work very well indeed; and it would be proposed to appoint him to the post. In the temporary absence of the Secretary (Mr. Huckle), he wished to say how well satisfied they were with the way in which he had fulfilled his duties. He was always at his post, and always industrious in the performance of his duties. He begged to move, 'That the balance-sheet as issued to the shareholders be accepted.'

The Hon, and Rev. Henry Bligh seconded the resolution with great pleasure, and regretted that he had not been able to devote as much time to the Company during the past year as he could have wished, owing to the many engagements which demanded his attention.

Mr. Otto Hehner congratulated the directors on the highly satisfactory balance-sheet they had presented when compared with that of the previous year. The first year's financial statement showed (he was speaking from memory) sales to the amount of 800%, on which a profit of 90% was made, which represented about ten or eleven per cent; while in the balance-sheet before them the total sales amounted to 1226%, with a gross profit of 521%, which meant upwards of forty per cent. He could not understand how it was possible there could be so much variation in the rate of percentage on two different year's profits.

The Chairman said there were several minor matters which affected the gross profits of the past year. The principal cause, however, of the increased rate of profits was that towards the end of the previous year's accounts the Company made a large purchase of honey at an exceptionally low rate. That purchase came into stock. The prices during the past twelve months had kept up to a good average, and thus a very large profit was realised on that one consignment, which was an excellent quality of honey.

Mr. Timberlake explained as an additional cause for the increased rate of profits that during the first year they had used nothing but bottles, whereas now they used stone packages. The former cost 18s. per gross, while the latter could be obtained at half that amount.

Mr. Hehner asked question in reference to the item of petty cash, which was satisfactorily explained; and Mr. Henderson suggested that the Annual Meetings of the Company should be held earlier in the year.

The Chairman assented to the proposition, and mentioned March or April as a suitable time for bee-keepers. He explained that the delay on the present occasion had arisen partly in consequence of the death of their late auditor early in the year.

The resolution was carried unanimously.

Mr. Henderson moved, 'That Mr. Stewart and Dr. Walker be re-elected on the Board of Directors.'

Mr. Hehner seconded the motion, which was carried em. con.

The Chairman moved, 'That Mr. Arthur Kenworthy be appointed auditor to the Company for the ensuing year.' That gentleman had given great satisfaction to the Board, and he thought had also acted in the interests of the shareholders, whose servant he was.

Mr. Henderson seconded the resolution, which was

passed without opposition.

The Chairman thanked the meeting for his re-election, and assured the shareholders that his best energies would be devoted to the prosperity of the Company. The position was by no means a smecure, but entailed a considerable amount of anxiety and loss of time. Nevertheless, whilst he saw a prospect of success he was glad to continue the work, and he thought the shareholders might rely on the directors faithfully discharging their duties. He was grateful to bee-keepers generally for the way in which they had supported the Company from its commencement, which had gone far towards

promoting bee-keeping and developing the honey industry.

Dr. Walker also expressed thanks for his re-appointment on the Board, and quite agreed in the Chairman's remarks concerning the arduous nature of the duties entrusted to the directors. He said there were several definitions of the word 'sinecure,' two of which were, ' plenty to receive and nothing to do,' and 'plenty to do and nothing to receive. He thought the office of director must be elassed in the latter category. (Laughter.) The work was of an anxious and responsible character, but he was pleased to place his services at the disposal of the Company. It must be borne in mind when considering the financial position of the Company that at present their task was an uphill one, for they had to contend against the large amount of pure foreign honey imported, and also against the large quantity of honey in the market which was perfectly innocent of bees. The public did not know much about honey, and it was wonderful how they could be imposed upon with glucose, which was often nothing but starch made out of old pawn-tickets and sulphuric acid. (Laughter.) Last year the Company had carried out some experiments, and produced a new honey drink, for which they had been awarded a silver medal at the Newcastle Show. He hoped the new venture would be a success. The drink was a pleasant one, and not too sweet.

Mr. Hehner proposed a cordial vote of thanks to the directors of the Honey Company, which he considered they richly deserved, because their work was of a very onerous character, for which they received no remuneration. They were trying to benefit the whole bee-keeping community of the country, and in the carrying out of such object were necessarily doing their best for the shareholders.

Mr. Henderson seconded the motion, which was

unanimously earried.

The Chairman gracefully acknowledged the compliment on behalf of himself and his co-directors. They were quite content to do the work so long as they received the confidence and support of the shareholders. He lived in London, and consequently his expenses in relation to the Company were trilling compared to those of the other directors, who often had to come to town specially in regard to the Company's affairs.

The minutes of the meeting were then read by the Secretary, and signed by the Chairman, after which the

proceedings closed.

ASSOCIATIONS.

THE LEICESTERSHIRE AGRICULTURAL SOCIETY.

The annual show of this Society was held at Ashby-de-la-Zouch on July 28th and 29th in grounds belonging to the eelebrated Ivanhoe Baths, in close proximity to the town and the railway station. The saline baths are said to be most beneficial in eases of chronic rheumatism. Ashby is purely an agricultural town of between seven and eight thousand inhabitants. There is a fine old castle standing in a commanding position, which has the reputation of never having been taken, of which there are fine views from the high ground on the opposite side of and looking over the town.

The Leicestershire Bee-keepers' Association, which is in addition with the British B. K. A., held its annual show in conjunction with the Agricultural Society, whose catalogue contains the schedule of prizes offered

for bees, honey, hives, &c.

The show of honey at Ashby was of a very superior quality with but few exceptions, particularly the honey in bottles and jars. The comb honey in sections was good for the season, but here, as at most of the shows

this year, the sections are not so well filled as usual, there being popholes in nearly all the corners.

The exhibition of hives and appliances was good, although not a large one. In the best collection Mr. Meadows, of Syston, near Leicester, obtained first prize. In addition to the hives he had several extractors, wax extractors, syrup cans, honey ripeners, feeders and smokers. The tin ware was all well made, good, and useful. His patent Raynor extractor, as now shown, is unquestionably the best and cheapest in the market: it is simple and free from the fixed cages that were once thought necessary, giving plenty of room, so that frames can be turned in the extractor without taking them out as was the case with the older patterns. He also exhibited some of Mr. James Lee's patent frames and sections, which excited a good deal of attention, which, from their strength, the ease with which they are put together and the foundation is fixed, in addition to other good points, must come into general use, and if produced at the same cost, will, we think, in time supersede all others. Mr. C. Redshaw, of Sonth Wigston, Leicester, was awarded second prize for a very good exhibit of hives, extractors, &c -- a very useful assortment of appliances generally. In the class for best hive complete for 10s. 6d., Mr. Meadows took first with a good and cheap hive. Mr. C. Redshaw took second; the third prize was withheld, the judge pointing out that the frames in the other hives were loose and would be liable to crush the bees, and generally were not up to the mark.

The following is the list of awards:-

For the best stock of bees of any race exhibited living with queen in an observatory hive—1, Mr. W. P. Meadows, Syston, 20s.; 2, A. Cooper, Ashby, 15s. For the best exhibit of super honey in 1-lb. or 2-lb. sections—1, C. Foxon, Croft, 20s.; 2, F. Berry, 12s. 6d.; 3, Rev. N. Gresley, Netherseale, 7s. 6d. For the best extracted or run honey in glass jars—1, Mrs. Rippin, Waltham, 20s.; 2, Miss Chester, Waltham, 10s.; 3, Rev. M. A. Thompson, Thistleton, 5s.; highly commended, Mr. Ball, Waltham. For the best twenty-four 1-lb. sections of comb honey—1, W.P. Meadows, Syston, silver medal; 2, Mr. Ball, Waltham, 10s. For the best run or extracted honey in twelve 1-lb. jars—1, Mrs. Rippin, Waltham, bronze medal; 2, Miss Chester, Waltham, certificate and 5s. For the best frame-hive with arrangement for summer and winter. Price not to exceed 10s. 6d.—1, W. P. Meadows, Syston, 15s.; 2, C. Redshaw, South Wigston, 10s. For the cheapest, neatest, and best super for harvesting honey in the comb—1, C. Redshaw, South Wigston, 5s.; 2, Turner & Son, Radcliffe, 2s. 6d. For the cheapest, neatest, and best show-case for sections—1, C. Redshaw, South Wigston, 5s. For the best collection of bee appliances—1, W. P. Meadows, Syston; 2, C. Redshaw, South Wigston, 5s. C. Redshaw, South Wigston.

Great credit is due to the Secretary, Mr. Ball, of Waltham, for the general management of the show and the manner in which the exhibits were staged, when we consider that he was unable to unpack anything over night, the carpenters not having fixed the tables when he left the ground at eleven o'clock, and had to be put up during the night. Everything was properly staged and all ready, so that the judging was finished and the awards fixed to the exhibits in good time.

Mr. John M. Hooker acted as judge, and examined and passed as a third-class expert Albert Henry Windsor, of Netherseale, near Ashby, who is a pupil teacher of eighteen years of age, and we understand he is a gentle

and good manipulator and promises well.

WARWICKSHIRE BEE-KEEPERS' ASSOCIATION.

The eighth exhibition of bees, honey, bee-furniture, and practical apiarian manipulations, promoted by the Warwickshire Bee-keepers' Association, was held on Tuesday and Wednesday, August 2nd and 3rd, in conjunction with the Warwickshire Agricultural Society's

Show at Sutton Coldfield. The exhibition was a very good one, notwithstanding the non-delivery of many exhibits. The prizes were distributed by the Mayoress (Mrs. Stone), assisted by Lord Leigh (President of the Association), the Mayor (Alderman J. B. Stone), and others. The following was the prize-list:—

Bees: (1) Ligurians or other foreign: 1, Brothers, Southall. (2) English bees: No award. Hives: (1) For the best and most complete hive on the moveable comb principle: 1, Abbott Brothers. Southall; 2, C. Redshaw, S. Wigston; 3, S. J. Baldwin, Bromley. (2) For the best and most complete hive on the moveable comb principle for cottagers' use: 1, Abbott Brothers; 2, A. T. Adams, Crick; 3, Abbott Brothers; C. Redshaw was commended. (3) For the best frame-hive for general use, the work of an amateur or cottager being a member of the Association: I. C. E. Harvey, Yardley; 2, W. Alliband, Claverdon; 3, T. Grosvenor. Supers:
(1) Rack containing 1 or 2-lb. sections prepared for placing: 1 and 2. Abbott Brothers. (2) Ditto, suitable for cottagers: 1, Abbott Brothers; 2, C. Redshaw. Honey: (1) Super honey from one apiary: 1, 11. Wood, Liehfield; 2, W. L. Pridmore, Hinckley. (2) Twenty-four 2-lb. sections of comb honey: No award. (3) Twenty-four 1-lb. sections: No award. (4) Twelve 2-lb. sections: 1, 11. Wood, Lichfield. (5) Twelve 1-lb. sections: 1, 11. Wood, Lichfield; 2, Baldwin, Bromley; 3, W. S. Pridmore, llinckley. (6) Super honey: No award. (7) Run or extracted honey: 1, Mrs. Heath, Knowle; 2, H. Wood, Lichfield; 3, W. S. Pridmore, Hinckley. Cottagers' class. For members of the Association residing in the county not having competed in the previous classes: (1) Honey in comb, taken from one hive, without destroying bees: 1, T. Grosvenor, Knowle: 2, W. Woolward, Brinklow. (2) Twelve 2-lb. sections of comb honey: 1, T. Grosvenor, Knowle. (3) Twelve 1-lh. sections of comb honey: 1, T. Grosvenor, Knowle; 2, S. Upton, Perry Barr; 3, W. Alliband, Claverdon. Two extra prizes, open to cottagers not having taken prizes in previous years, for the best exhibition of run honey and for the best and largest collection of honey, were not awarded. Miscellaneous prizes: (1) Collection of hives and bee-furniture most applicable to present system: 1, Abbott Brothers; 2, Baldwin, Bromley. (2) Finest samples of beeswax: 1, Abbott Brothers: 2, Adams, Crick. There were no awards in the driving competition, there not being enough competitors.

HUNTS AGRICULTURAL SOCIETY.

This Society held its annual exhibition at St. Ives, Hunts, on July 26th. The old town was gaily decorated on the occasion. Flags were suspended in every street, and most of the business establishments were closed at an early hour, so that both proprietors and assistants might have an opportunity of visiting the exhibition. There were two tents on the ground set aside for the purpose of an exhibition of bees, hives, honey, &c., in connexion with the Hunts Bee-keepers' Association. A number of experiments were conducted by Mr. C. N. White, the Secretary to the Association, who has taken a great interest in its welfare. The show was a small, but, at the same time, successful one; and has rarely, if ever, been surpassed in the history of the Society. The prizes were awarded by the Rev. F. G. Jenyns of Knebworth Rectory, who remarked that the cottagers' exhibits were most creditable. The prize list was as follows:—

BEES.—I. Best specimen of English bees exhibited with their queen, in a unicomb observatory hive: C. N. White.

HIVES.—II. The cheapest and most serviceable hive on the moveable comb principle, for general use, with arrangements for taking surplus honey: 1, J. H. Howard. III. The best straw skep with floor-board and arrangements for the storing of surplus honey: 1, J. H. Howard.

HONEY AND WAX.—IV. Best twelve 1-lb, sections of comb

heney: 1, J. H. Howard, jun.; 2, A. Sharp; 3, J. Linton. V. Best six 2-lb. sections of comb honey: 1, F. Allen; 2, Rev. J. F. Trumper. VI. Best exhibit of comb honey (not sectional): 1, J. Linton; 2, E. Allen; 3, Mrs. Allpress. VII. Best twelve 1-lb. bottle of run honey: 1, Rev. C. C. James; 2, E. Allen; 3, J. Linton. VIII. Best sample of

James; 2, E. Allen; 3, J. Linton. VIII. Best sample of beeswax (in one cake, weighing not less than three pounds): 1, Rev. C. C. James; 2, Rev. H. Gee; 3, E. Allen.

COTTAGERS ONLY.—IX. Best twelve 1-lb. sections of comb honey: 1, B. Bull; 2, F. Whybrow; 3, R. W. Allpress.

X. Best exhibit of comb honey (not sectional): 1, Z. Hobbs; 2, B. Bull. XI. Best twelve 1-lb. bottles of run honey: 1, R. W. Allpress; 2, B. Bull; 3, C. Colbert.

XII. Best sample of beeswax (in one cake, weighing not less than three pounds): 1, C. Colbert: 2, Z. Hobbs: 3, B. than three pounds): 1, C. Colbert; 2, Z. Hobbs; 3, B.

In addition to the above prizes the following from the British Bee-keepers' Association were awarded:medal for the best exhibit of twelve 1-lb. sections in the show: J. H. Howard, jun. Bronze medal for the best exhibit of twelve 1-lb, bottles of run honey in the cottager elass: R. W. Allpress. Certificate for the best exhibit of comb honey (not sectional) in the cottager class: Z. Hobbs.

GLAMORGANSHIRE AGRICULTURAL SOCIETY'S SHOW.

The above show was held at Aberdare on the 3rd and 4th inst. The following are the awards in the honey classes :- For the largest and best exhibit of super honey-1, Mr. James Lewis, Plasdraw, Aberdare; 2, Mr. D. Daniel, Llwydcoed, Aberdare. For the best twelve 1-lb. sections of comb honey—I and silver medal of the B.B.K.A., Mr. W. Williams, Blackweir, Cardiff; 2 and certificate, Mrs. Ingledew, Cardiff; 3, Mr. D. P. Davies, Aberdare. For the best twelve 1-lb bottles of extracted or run honey—I and bronze medal, Mr. W. H. Jenkins, Exchange Euildings, Swansea; 2, Mr. E. J. Gibbins, Neath; 3, Mr. G. H. Rake, Aberdare. Mr. W. Gay, Cardiff, acted as judge and manipulator at the show. The quantity of honey staged (taking into consideration the excellent prizes—11., 15s., and 10s. offered for each class) was small, there being only two exhibits, about 100 and 60 lbs. for the bulk, seven exhibits for twelve sections, and four for extracted; the quality being fairly up to this year's average.

The judging, we regret, did not give general satisfaction, the prize and brenze medal being awarded for an exhibit containing at least two different kinds of honey, both in colour and flavour. It is full time that the Council of the B.B.K.A. should take up the question of judging, especially where the Association medals and certificates are to be awarded. Six of the bottles awarded the first prize at the above show were light in colour and bad slightly granulated; one of the remaining six contained true coloured honey, a light and darker shade, the remaining five were good samples so far as taste and colour were concerned. The judge may be right in his award, but we should have preferred the prize being given to an uniform sample as far as colour went, although the flavour may not be as good as the one containing several different kinds of honey. Perhaps Dr. Walker, Messrs. Baldwin, Hooker, Blow, or any of the other gentlemen that visit shows for the purpose of judging, may be induced to form themselves into a committee, discuss this matter, and establish a judging standard.

THE FARINGDON BEE-KEEPERS' ASSOCIATION.

In Faringdon and the neighbourhood there is a branch of the Berkshire Bee-keepers' Association, of which Mr. F. Burrell is hon, sec. The annual show was held on Bank Heliday, August 1st, in the Corn Exchange. There was a very choice display of honey. The greater portion was in 1-lb. sections, or 1-lb. glass bottles, the

former looking remarkably clean and the latter very tempting. The judging of the exhibits was carried out by Mr. Woodley and Mrs. Currey of Reading, with the following results:

I .- For the best six sections (not over one pound in weight): 1, 10s., Mr. Levi Inwood, Uffington; 2, 5s., Mr. M. Whittle, Lockinge; 3, 2s. 6d., Hon. O. W. Craven, Ashdown. II.—For the best six pounds of extracted honey in 1-lb. glass bottles: 1, 10s., Mr. L. Inwood; 2, 5s., Mr. For the best and largest exhibit of honey from one apiary, gathered during 1887: 1, 10s., Mr. B. Burrell, Faringdon; gamered during 1507. 1, 1505., Mr. L. Barrell, Faringdon; 3, 2s. 6d., Mr. F. Liddiard, Faringdon. 1, 292 lbs.; 2, 246 lbs.; 3, 238 lbs. IV.—For the best super of any description, not sections: 1, 10s., Mr. L. Inwood; 2, 5s., Mr. M. Whittle; 3, 2s. 6d., Mr. R. S. Edmonds, Faringdon. V.—For the best exhibit Mr. W. Honey, not over three pounds in weight: 1, 10s., Mr. W. Hott, Woolstone; 2, 5s., Mr. W. Morris, Eaton Hastings; 3, 2s. 6d., Mr. H. Pike, Faringdon. VI.—For the best four pounds of run honey in bottles: 1, 10s., Mr. H. Pike; 2, 5s., Mr. E. Newman, Faringdon; 3, 2s. 6d., Mr. W. T. Jordan, Eaton Hastings.

Mr. F. Burrell, the indefatigable hon. sec. of the Association, deserves a word of praise for the manner in which he worked to make the show instructive and amusing.

CAMBRIDGESHIRE AND ISLE OF ELY AGRICULTURAL SOCIETY.

This Society held its twenty-fourth annual show in the grounds of Jas. Crossley, Esq., Egrement House, in the city of Ely, on Wednesday and Thursday, July 27th and 28th. As of late years in addition to the numerous other departments, the Society centinues that of bees, hives, and honey, and this year they have cause for satisfaction at the success attending it. The exhibits were arranged in a long shed with staging similar to that of the Lincolnshire, with the manipulating tent in close proximity, which attracted large numbers of visitors to see Mr. Baldwin's skilful operations, and hear his able and instructive lectures.

This is the Society's first visit to Ely since their introducing a bee department to their annual programme, and, as might be expected, drew a large number of bee-keepers of the surrounding neighbourhood to witness it, who no deubt would take home with them many useful hints, Mr. Peters, the Secretary, who is most anxious to see success in bee-keeping, and spares neither time nor trouble in keeping it to the fore, deserves the hearty thanks of all engaged in the work, and of the Cam-

bridgeshire Bee-keepers' Association especially.

The various classes, ten in number, were not on the whole so well filled as might have been expected, considering the very liberal prize schedule, and competition was small, the principal prizes going to a few. In the honey classes, with one or two exceptions, the quality was very inferior. Some sections staged by Mr. M. Mason, of Gressingham, as also the whole of his extracted honey, were as fine in quality as could be desired. Some beautifully finished sections were staged by Mr. Howard, of Holme, and Mr. Drake, of Sutton, also a nice bell-glass by Mr. Geldard, of Cambridge, which secured second honours in the class for cottagers. Mr. F. Whybray, of Peterborough, obtained first prize, 20s., with great credit to him.

In the hive classes Mr. Howard, of Holme, had it all his own way. His collection of hives and appliances was very good, and contributed largely to the effect of The judging was entrusted to Mr. R. R. the show. Godfrey, and who, by desire, also superintended the arrangements of the bee department.

Mr. R. A. Grimshaw, of apifuge notoriety, honoured the show with his presence, and kindly volunteered his

able assistance.

THE CALEDONIAN APIARIAN SOCIETY.

We inserted in our last number a report of the Show held by the above Society at Perth, the following is the prize list:—

Bees.—Best specimen of British bees—1, W. Munn, Ardenadam; 2, W. W. Young, Perth. Best specimen of Cyprian, Ligurian, or any other foreign bees—1, William Wilson, Falkirk; 2, William Sword, do.

HIVES.—Best hive for observation purposes—1, W. Munn; 2, W. W. Young; 3, W. M'Nally, Glenluce. Best frame hive—I and 2, W. M'Nally; 3, W. W. Young. Most serviceable hive for transmission to heather—I, W. M'Nally. Best straw hives and supers—1, W. M'Nally; 2, J. D. M'Nally, Springburn, Glasgow.

Comb Foundation.—Best ten sheets made of pure bees' wax—I, W. W. Young; 2, W. M'Nally; 3, J. D. M'Nally. Best two cakes of wax—1, W. W. Young; 2, W. Sword.

Honey.—Best display of honey and honeycomb—1, W. M'Nally; 2, W. Birrell, Pcrth; 3, J. Edward, Fowlis, Dundee. Best two supers above 20 lbs. each—1, Sidney Roebuck, Dumfries; 2, W. Sword; 3, W. Wilson, Falkirk. Best super above 12 and under 20 lbs.—1, W. Sword; 2, Sidney Roebuck; 3, W. Wilson. Best super of honey not under 10 lbs.—1, W. Sword; 2, Sidney Roebuck; 3, W. Wilson. Best display of honey and honeycomb under 100 lbs.—1, J. D. M'Nally; 2, W. Wilson; 3, Sidney Roebuck; 3, W. Birrell, 3, W. M'Nally; 2, Sidney Roebuck; 3, W. Birrell. Best twelve 2-lb. sections do.—1, Sidney Roebuck; 2, W. Birrell; 3, W. Wilson. Best twelve 1-lb. sections do.—1, W. M'Nally; 2, Sidney Roebuck; 3, P. M'Whannell, Perth. Best twelve 1-lb. glass jars of rnn or extracted honey—1, W. Birrell; 2, W. Low, Stanley; 3, Sidney Roebuck. Heather honey, not less than 10 lbs.—2, J. D. M'Nally; 3, W. M'Nally. Best design in pure honeycomb worked by bees—1, Sidney Roebuck; 2, Harry Wood, Lichfield, Staffordshire.

Special Prizes for Ladies.—Best super above 10 and under 20 lbs.—1, Mrs. Roebuck, Dumfries; 2, Mrs. Young, Perth; 3, Mrs. Agnew, Stranraer. Best glass super of honeycomb—1 and 2, Mrs. Low, Stanley; 3, Mrs. Agnew. Best twelve 2-lb. sections of honeycomb—1, Mrs. Young; 2, Mrs. Roebuck. Best display of run or extracted honey in glass jars—1, Mrs. Low; 2, Mrs. Young; 3, Mrs. Agnew.

Comestibles.—Best liqueur or wine made from honey— J. D. M'Nally. Best cake made with honey—I, J. D. M'Nally; 2, William Sword; 3, W. M'Nally. Best collection of articles made from honey as food and liqueur— J. D. M'Nally.

MISCELLANEOUS.—Best collection of bee furniture—1, W. M'Nally; 2, George Brown, New Pitsligo; W. W. Young. Best honey extractor—1 and 2, W. M'Nally. Best extractor or press for heather honey—I, W. M'Nally; 2, W. W. Young. Best collection of objects illustrating the economy of the bee—J. D. M'Nally. Best display of honey-producing plants—1, J. D. M'Nally; 2 and 3, W. M'Nally. Best straw hive stocked with bees—I, W. W. Young; 2, James Johnstone.

BANBRIDGE (CO. DOWN) BEE AND HONEY SHOW.

For some years the Banbridge Farming Society has devoted a special section to bees and honey, with the object of encouraging the modern improved system of bee-keeping. The Bee-tent of the North-east of Ireland Bee-keepers' Association, with lectures, and manipulation of bees in bar-frame hives and skeps, has year after year been a feature of this show. These efforts of the Committee have not been in vain, the modern hives are scattered about the district, one man in the town devotes himself to manufacturing wooden hives of the most approved kind, and at the exhibition on the 2nd inst. there was a larger number of entries of honey than on any former occasion, and all of excellent quality. The judges were Messrs. P. M'Henry and S. Cunningham,

who did their work carefully and with that thorough painstaking scrutiny which evidenced them to be practical bec-keepers, who can discern a good section as well as the best on the stalls from one imperfectly filled.

The following is the prize list:—

For best stock of specimen of Ligurian or black bees, to be exhibited with their queen, in an observatory hive—
1, William Morrow, Banbridge; 2, William A. Potts, Cappy, Banbridge.

For best section of honey in either wood, glass, or straw, and not less than 5 lbs. weight—I, Isaiah J. M'Cabe, Kilkinamurry, Kateshridge: 2. Thomas Gillespie, Banbridge.

kinamurry, Katesbridge; 2, Thomas Gillespie, Banbridge.
For best six 1-lb sections—1, Rev. H. W. Lett, Loughbrickland; 2, Thomas Gillespie; 3, Samuel Hill, Solitude House, Banbridge.

Best six glass jars of extracted honey, not less than 1 lb. each—I, Thomas Gillespie; 2, Isaiah J. M'Cabe; 3, W. A. Potts.

There was a keen competition for the different prizes, especially in the two latter classes. Here, as elsewhere in Ulster, the old straw skep, though still to be found in remote cottage gardens, is not recognised in the show yard.

In Ireland we still support big non-sectional supers, and it was a pity to see some splendid cases of pure and luscious honey, so soon (as the owners declared) to be washed and strained, and then sold for not half of what the same in 1-lb. sections would have brought. The time has surely come for those who draw up the schedules to abolish such supers, and give more encouragement to 1-lb. sections.

About Banbridge the honey yield has this year been very good, one farmer has taken as much as 120 lbs. in sections from one stock, and another bee-keeper, with seven, has averaged 50 lbs. from each live.

ATTACKED BY A SWARM OF BEES,-On Saturday afternoon, July 30th, an accident of a peculiar and serious nature occurred at Sidmouth. It seems that Miss Skinner, of Sid Abbey, Sidmouth, was accompanying her sister, Mrs. Groves, in a donkey-chaise for a drive, and on proceeding down All Saints' Road a swarm of bees, which came over an adjoining hedge, suddenly pitched upon the donkey's head, stinging the poor animal very badly. Miss Skinner, who was walking by the side, attempted to release the donkey from the chaise, but failed to do so, and the result was that the torture under which the animal was suffering caused it to kick violently, capsizing the carriage, Mrs. Groves being kicked by the donkey and dragged a considerable distance. Both Mrs. Groves and Miss Skinner were also severely stung, and the latter in her continued endeavours to release the animal was knocked down, the chaise passing over her. Mr. and Mrs. Reed, of Khandwa Villa, who witnessed the accident, immediately ran to the assistance of the unfortunate ladies and had them removed to their house not ten yards off. Dr. Pullin was quickly summoned, and after a short time the sufferers were removed to Sid Abbey, where the medical attendant discovered that Mrs. Groves had sustained very serious injuries, both her thighs, a rib, her collarbone and right shoulder being fractured. Miss Skinner, although more fortunate, was very much cut and bruised about the face and head. Mrs. Groves towards evening recovered slightly from the shock to the system, and at midnight Dr. Pullin by the aid of chloroform succeeded in setting the fractures. Last evening Mrs. Groves still remained in a critical condition.—Devon and Exeter Daily Gazette, August 1st. [We regret to hear that the lady most severely injured has since died. An inquest has been held, and a verdict of 'Accidental death' returned. A juror thought it inadvisable to hive bees so near the highway, which opinion was conveyed to the owner of the bees through the foreman.]

Correspondence.

The Editor does not hold himself responsible for the opinions expressed by his correspondents. No attention will be taken of anonymous com-munications, and correspondents are requested to write on one side of the paper only, and give their real names and addresses, not necessarily for publication, but as a guarantee of good faith. Illustrations should

for publication, but as a guarantee of good faith. Illustrations should be drawn on separate pieces of paper.

All business communications relating to Advertisements, &c., must be addressed to Mr. J. Huckle, Kings Langley, Herts (see 2nd page of Advertisements)

**In order to facilitate reference, Correspondents, when speaking of any letter or query previously inserted, will oblige by mentioning the number of the letter, as well as the page on which it appears.

OUR HONEY IMPORTS.

The value of honey imported into the United Kingdom during the month of July amounted to 1687l. [From a return furnished by the Statistical Office to E. II. Bellairs, Wingfield House, near Christchurch.]

EXPERT EXAMINATIONS.

[1179.]During the present season I have had quite a number of candidates to examine for experts' certifi-I have passed several and rejected others. Some of the latter ought not to have been sent up by the Secretaries of Associations, not being the sort of men calculated to be useful in the instructing others, in addition to want of experience and knowledge. In my opinion a man should be quick, intelligent, and fairly well educated before he is sent up for examination, even for (what the B.B.K.A. calls) a third-class, or, as I should prefer to call him, a practical expert. The time is usually very short, the examiner, frequently after a long journey by train, having actel as judge at an important county or other show, is asked, single-handed, to examine, as was my case, six candidates in the day, or rather, what remained of it.

The first difficulty that arises is that there is only one skep for all to drive, and that a swarm of the present season with tender combs and full of honey. Then the bar-frame hive is half a mile off, and several journeys have to be made this distance, as it is only fair that the candidates should not be asked to manipulate a hive that has just been gone over, and perhaps roughly handled by the last man. All this takes time, and the poor examiner must himself occupy a little in discussing the luncheon usually provided for him on such occasions.

Having pointed out some of the difficulties one has to contend with, I think it would not be too much to ask secretaries, who, I admit, at this time have much to do. that they should, in some way previously ascertain, if not from personal knowledge, from the clergyman of the parish, or from some well-known bee-keeper, or other person in the neighbourhood, if the candidate is the right sort of person to assist in instructing others, and if he would be likely from his disposition to do so, and if from his knowledge of him and his success as a bec-keeper he would be likely to pass, so that the little time at the disposal of the examiner should not be wasted when there is so much to do, and that he should be spared the unpleasant task of rejecting the candidate for his general unsuitableness and want of knowledge. Then, again, the secretaries should see that the candidates arrange, either themselves or some one for them, that skeps and bar-frame hives are provided at no great distance that their knowledge may fairly and properly be tested. In my opinion it is not advisable or fair to the candidate that the manipulations should take place in the public bee tent for more reasons than one. Remarks are frequently made by lookers-on which are not calculated to advance the object in view. Then, again, where many hives are driven, robbing is sure to commence, the bees become furious, fighting becomes general, and possibly the queen is 'balled,' and the candidate gets stung unnecessarily, and does little that he is expected to do, which, had the conditions been normal, he would probably have obtained the required number of marks in his practical work.

I am induced to make these remarks from past experience. I may also mention that on two occasions no examination took place, no bees having been provided .-

JOHN M. HOOKER.

SMOKE-CARBOLIC ACID-APIFUGE-SIM-MINS'S NON-SWARMING SYSTEM.

[1180.] In answer to 'E. W. P.' (1164), you think that apifuge would have more effect than smoke or eurbolic fumes. Well, I for one should be inclined to doubt it. Two years ago I got some bees from a neighhour, who said they were so wicked he could not manage them. I found smoke of little use; they retreated before volumes of it, but always returned to the charge whenever the smoker was laid down. Then carbolicacid fumes were tried, and had some effect, but were not quite satisfactory, because these bees would, under the influence of the fumes, allow the hive to be opened and some of the frames to be lifted quietly, then all of a sudden they would attack in a cloud. I still kept this breed of brees, because they were such good workers, though almost unmanageable, and dangerous to passersby on the road near.

When apifuge came before the public, I hastened to get a bottle, and, after donning a veil, rubbed my hands and wrists with this invisible soap, and proceeded boldly to the 'wicked' hive. Gently I turned back the quilt, spread out my hands to bless them into peace and quietness, but I think there was some mistake among it those bees, because they never stayed to feel the *pleasant* scent of apifuge. Straight they shot at face, hands, and body; and sting! did they not? My hands were about covered with their lanees, and then they went at my clothes in perfect madness. I didn't run, I am too well hardened for that, but wince I did, till I got a knife and cleared the back of my hands from poison-bags. Not to be beaten. I again put some apifuge on my hands, and with no better results, so closed that hive as soon as possible. That apifuge is useful in some cases I know, but, after repeated trials, I think that it is utterly useless with these particular bees. I disturb these bees as little as possible now, and when I do always using a cloth saturated with carbolic acid. I may say that these bees are crossbreds, black with just a touch of Ligurian, the queen being very black.

And now a word on Simmins's non-swarming system. I have tried it on three hives and utterly failed. No. 1 on June 1st was covering eleven frames, so I took away two full ones and put three empties in their place, and put on 21-lb, super with built-out combs. Bees commenced filling super and building in frame nearest the nest. Three weeks after I took out the combs in front and looked at them. The one next the nest was almost built and filled with sealed larve, second built out a little, the other untouched. I call that failure first. Right through the season the front combs as soon as built the least bit were thus filled. No. 2 did the same. No. 3 did what is rather uncommon, with three 21-lb. racks of sections on, and four empty frames in front, which the bees had never touched from the beginning of June; they swarmed on July 3rd or 4th. A friend has had a Stewarton swarm which had an empty body-box beneath it from the beginning of the I rather think the exceptionally hot weather ereated these two cases.—George D. Clark, Kirkland-

hill, Dunbar, August 1st.

WORKING FOR EXTRACTED HONEY.

[1181.] Just at the present time there seems to be a 'craze' among bee-keepers on the subject of comh honey production, many who have heretofore worked almost exclusively for extracted honey changing their tactics and are now advocating and talking comb honey to the exclusion of that which they formerly endorsed. I fear this is not a wise policy, for it can only result in soon lowering the price of comb honey and advancing the price of extracted, this eausing an expensive changing of fixtures the second time. It seems to me that the well-balanced apiarist should produce both comb and extracted honey; and as he sees the tide swaying toward the side of the one he should go a little heavier in the opposite direction, but not enough as to throw aside all his fixtures along the line the tide is moving. We have many farmers in this locality who, when mutton and wool are low, sell out their sheep for a mere song, and go into the so-seeming more profitable business of beef and butter, paying a high price for cows in high tide, for everything in the cattle line. In a few years times change, and eattle are at low tide; beef and butter are sold for a song, while mutton and wool are now bringing a good price again. These farmers now for a second time become discontented, and change their cows for sheep, only at a great loss again. So they keep on doing in a sort of will-o-the-wisp chase, losing money at every change. Others keep both sheep and eows, never running out of either, but in time of good prices with the flock, raise a little more from the sheep, and these again increase that herd when high prices are paid for the production along that line. In this way a steady growth is maintained, while by the other plan a downward tendency is a sure result.

As I have worked for years for both comb and extracted honey, and believing that the present time is favourable to the production of more extracted honey and less comb, perhaps I cannot do better than to tell the readers of the American Apiculturist how I proceed to accomplish what seems to me to be the best results. The first thing necessary in the successful production of extracted honey is a good queen to produce hosts of workers to gather the harvest. In fact, whether all realise it or not, the whole of bee-keeping centres in the queen. Without the queen it would be impossible to produce a pound of extracted honey, hence it becomes apparent that the better the queen is, the more honey we obtain. When all come to realise the great value of really good queens, we shall have taken a long stride toward successful honey production. But good queens are only of value when we surround them with favourable circumstances, thus getting large numbers of eggs laid at the right time, and causing each egg to be nourished to a perfect bee, so that we can have the bees in our colonies by the tens of thousands at the right time. Failing in this, the flowers will bloom in vain as far as filling our surplus combs with honey ready for the

extractor is concerned.

But 'what are favourable circumstances?' is asked, to which I reply, an abundance of food and warmth. The abundance of food is quite easily secured in this day of bee feeders, and especially so if the apiarist has set aside the previous season, as he should, combs solid with honey which are ready to set in the hive at any time. But the warmth is not so easily secured, especially when our honey harvest comes early from white clover, which requires the getting of a large quantity of eggs laid early in the season in order to have the bees in time. Several years ago I tried artificial heat to help forward things, but after numerous experiments which resulted only in harm, I gave it up.

As soon as all the combs are filled with brood which were first given them, more are added till the hive is full of comb and brood. In adding these combs, I prefer

to add two at a time, using one which is empty and one filled with honey such as spoken of above. The empty one is placed at the outside, and the full one in the centre. Before putting in the full one I break the cappings of the eells by passing a knife over it flatwise, for by this means the bees are obliged to remove the honey, and in doing so are stimulated to apparently greater activity than by any plan of feeding with which I am acquainted. As the honey is removed over to the outside empty comb, the queen fills the emptied comb with eggs, which, when hatched into larvæ, require the honey brought back by the nurse bees to feed said larvæ; and as the honey is now being carried again, activity is still kept up, and the queen now goes over and fills the comb with eggs also. In this way one hive is soon filled with eggs, brood, and bees just in time for the harvest.

Having the hive filled as spoken of, and the honey harvest at hand, or just commenced, if we wish no increase from our bees, no time is to be lost in putting on the surplus arrangement, otherwise the bees becoming crowded, may get the swarming fever. For extracting, I prefer another hive of the size of the first, but some prefer one of only one-half the depth. As to results, there is probably no great difference, but I consider it quite an object to have all hives and frames alike in the apiary. In putting on this surplus arrangement, I prefer to use empty combs if possible instead of comb foundation. I also prefer to use two large or wide dummies, one at each side, for a few days, so that onehalf of the room is taken up, which leads the bees along gradually instead of thrusting a large amount of surplus room upon them at once. From experience I believe them less liable to swarm where this course is taken, for they seem to bend every energy to fill this small additional room, while, where a large amount is given at once, they are injured should it become cool; or, if warm, they swarm from being loath to enter it. soon as the half of the hive given them is partly filled with honey, the dummies are taken out, the combs spread apart, and frames filled with foundation put between them. At this stage I would just as soon have foundation as empty combs, for the bees are now ready to work upon it, while before they were not. The time for taking out the dummies is when you see the cells being lengthened out with new comb along the tops of the combs.

How you will proceed in the future depends upon whether you wish your honey all ripened in the hive till the harvest is over, or ripened in a warm room by evaporation. Sometimes I think that honey left on the hive through the season is of a better quality than that extracted every week or so: then, again, I am not so sure about it. Of one thing I am certain, more honey can be secured with less hives and fixtures where it is extracted when the bees first begin to seal it than can be gotten by the other method.

As to the labour, there is little difference, except that when we extract often the labour comes at a time of year when we are the most crowded. To be sure the operation is gone through with oftener, but to offset this there is little or no uncapping to be done, while the honey leaves the comb more clean with less than onehalf the labour in turning the extractor. If the season is warm and dry, I would just as soon have honey extracted as above as that left on the hive the season through, but if cool and damp I prefer it ripened all that is possible by the bees, and even then it is not as good as the other. In my opinion the season has more to do with the quality of the honey than the process of ripening. If we desire to extract oftener, the hive we have already added (if both contain two thousand or more cubic inches) is probably all the room the bees will need, but if left on during the season, one more and probably two will be needed. In putting on the third story, I do not use the dummies, for by this time the

weather has got so warm and the bees so numerous that they will spread out so as to occupy the whole of the extra hive. This hive should be put on when the bees have the combs in the second storey sealed along the tops of the frames, or soon after you would commence extracting if working the other way. Many say, Raise up the second storey and place this third hive between the two; but after repeated trials of both, I prefer placing it on top, for I think the bees will occupy it just as quickly if the honey flow continues, while if it from any cause should be cut off at this time or soon after, we are in much better shape in not having the honey scattered through three hives with few, if any, combs full. If a fourth storey is needed, put on the same as the third, when, after the season is over, you will begin to carry the honey to the honey-house and extract.

To get the honey off, I find it is the best way to go to a hive and blow a perfect deluge of smoke down on the bees from the tops of the combs, and as soon as the bees have run below, take off that storey, and set it on your wheel-barrow or honey cart, not attempting to get more than one storey from one hive at the same time; for, if we do, the bees will return to the next storey before you can get it off, when smoke is of little use to drive them. Before extracting, save plenty of good, full combs for wintering and spring feeding. If the weather is cool when you wish to extract, place the combs of honey in a small room for three or four hours previous in which the temperature is kept as warm as 100°, when you can take them as you wish to uncap and extract them, doing this work as easily as on a hot day in July or August.

In the above I have given a brief outline of how I work for extracted honey, and as a proof that it is an average plan at least, will say that I have taken as high as 566 pounds of honey from a single colony in one

season.

In conclusion, I will say that the getting of multitudes of bees just at the right time has more to do with the successful working for honey than anything else, and when all realise this, and work for the same to the fullest extent, one-half of the colonies will gather as much surplus as the whole do under one present management.—G. M. Doolittle (American Apiculturist), Borodino, N. Y.

AN ESCAPADE WITH BEES.—GETTING THEM DOWN IN A SKEP FROM THE GABLE END OF A HOUSE.

[1182.] About the year I879 I supplied a swarm of Ligurian bees with an English-bred queen, in a large Pettigrew skep, to a friend of mine, who built a recess for them to stand in in the gable end of his house. I put them up, and they did very well there, and established themselves without feeding. As the next year was very indifferent, they did not swarm, and he did not get anything from them, but he let them stay. I believe he never fed them at all, or very little, in the spring. When summer came he supered them, and took off a straw cap between twenty and thirty lbs., and put another on, and they nearly filled that. He was at work at our place (being a master bricklayer), and used to be always asking me to drive his bees, so that he might have all their honey, &c. He promised to send a trap over for me. I told him, as it was an awkward place to get a heavy stock down from, he had better put up a scaffold to place them on, which he said he would, but he did not. He sent the trap for me, and I went over and took all things requisite for driving the bees, but when I got there I found all he had got was a single ladder raised up against the wall, and I told him that would not do. I went up and brought down the super, which was nearly full again. I went up again, and blew in a little smoke at top of the hive, also at entrance, and lifted the hive up,

board and altogether. I said to him it was too heavy for me to bring down; but he was very anxious to fetch them down, and called out to me, 'Come down, and let me bring them down;' which I accordingly did. He had his veil on, and went up and lifted off the hive at the back of the ladder and stepped down one or two steps. but then he could not get down any lower nor yet np higher to put it back again; and as the holes at top and entrance were not stopped up, the bees were recovering from the effects of the smoke. His head was just opposite the front of the hive, so that his breathing over the top set the bees on, and they came out very angry and excited. His veil had got drawn up from protecting his throat, and the bees did sting him furiously, but he stuck to the hive well; and there he had to stay till his man came back with another ladder. He kept saying he should drop the bees, but I begged him to stick to them. I went up the other ladder and helped him carry the hive down and set it on the wall, and the bees were at him awfully, but they took no notice of me. I told him to run under the shade of some kidney beans, where I heard him howling out, 'They're a-killing me! they're a-killing me!' I went to him with smoker, and at last succeeded in driving them off, when, to speak within the mark, I might say there were scores of stings in his throat; I shall never forget the job of pulling them out, they were nearly as thick set as his beard. I got him to rub some soda on it, and went to drive the bees, which I did without any further mishap. After I had done I went into his house, and had a little refreshment with him; he also had some, and after that he was very bad. He thought he was going to die. I stayed with him till ten o'clock when he had some oatmeal gruel and went to bed.

I went over the next morning, expecting to see him still very bad, but, to my surprise and joy, he said he had had a good night's rest and was quite well. He is a very hardy man, and was in good health, or I think it would have caused his death. He weighed the hive after the bees were out, and it was 72 lbs. (the thick board 6 lbs. more), which, with the supers that were taken off, made a total of about 120 lbs., which fact he very much wished me to publish, as he said it was such a good yield. He did sing the praises of the Ligurians, even though they had served him so. Of course, we ought to have stopped up the entrance and the holes at top, and then they could not have got at him, but he did not anticipate such a job—78 lbs. was no trifle to hold, and the ladder between himself and the hive. Seeing him again last week, and singing out to him, 'They're a-ailling me,' made me think, as bee-drivings were at hand, I would send the account to the Journal.—John Walton, Honey Cott, Weston.

PREPARING BEES FOR WINTER.

[1183.] Bees instinctively begin to make preparations for winter somewhat earlier in the season than is commonly supposed. In preparing for winter, as in all other matters relating to bee-keeping, the apiarist should see to it that the method of management is as nearly as possible in agreement with the instinct and habits of the bee. When bees build their combs after their own design, as in box-hives, spaces are left between wide enough to admit of elongating the cells in order that a large share of the winter stores may be placed in the top of the hive, easily accessible in the severest weather. I find it a good practice to widen the spaces between the comb-frames near the close of the honey-gathering season, in order that the bees may by elongating the cells place a large share of the winter stores above the cluster.

As soon as the storing of surplus honey is done the condition of every colony should be examined, the amount and character of the winter food ascertained, the number of comb-frames and the size of the apartment should be determined by and adapted to the wants of

each colony. After the supply of winter stores had been equalised among all the colonies, if the supply is insufficient, feeding should be done before the advent of cold nights.

Bees expected to perform the function of hibernation should not be too old nor yet too young. Both queen and worker bees should be in full physical vigour. The bees constituting the colony, when placed in winter quarters, should be such as are hatched after the midsummer working season is past and before the bees cease

flying freely in the fall.

Towards the close of the working season the workers instinctively cease stimulating the queen for oviproduction; gradually the bees cease flying, and the cluster is formed for winter. After the cluster is formed the colony should remain undisturbed. If the bees are to be packed on the summer stand the work should be done with care and without disturbing the bees, and before the temperature at night reaches the freezing point. If the bees are to be placed in a clamp, or in a cellar, or winter repository, great care should be taken not to disturb the cluster when the hives are removed from the summer stand. I have found woollen quilts or woollen blankets the best covering for winter. Wool, better than any other material which I have tried, prevents the radiation of heat and permits the escape of moisture, thus securing warmth and dryness. Hives should be placed eighteen inches above the bottom of the cellar or winter repository, and in tiering them up one above another it is better that they rest on a rack prepared for the hive rather than one upon another.—From the Official Report of Mr. McLain to the 'United States Entomologist' for the year 1886, issued by the Department of Agriculture at Washington.

VAGARIES OF BEES IN SWARMING.

[1184.] On a Wednesday, about the middle of June, I had a swarm come out about eleven in the morning. As my workshop is at a little distance from my house, there is a white cloth hoisted up to let me know when bees are swarming. I saw it up, and on reaching home I noted that the bees were going back, so I looked about on the ground in front of the old stock and there found the queen surrounded by a few bees; so, as I did not want her back in the hive till I had cut out the queencells, I got a skep and put in two or three handfuls of bees, and then put the queen to them, and set them on a board, and removed the old stock, and set the skep in the place, so that in an hour or so when I looked at them there was a good swarm. I shaded them pretty well too, and they seemed all right; but about 3 p.m. I saw the signal up again, and I went down and found the swarm had come out, but the queen could not fly with them, and had crawled up to the entrance of another stock, where I discovered her balled, and when I got her away she was dead. I cut the queen-cells out of the old stock, and set it in its place again, and of course the bees had nothing else to do but go back. On Saturday night I did not want them to raise queen-cells, so I took a queen from another hive, and introduced her to them by direct introduction. The next day, being Sunday, about 12.30 noon, they had evidently accepted the queen, as they were swarming again. I hived them all right, and, as I usually do, set them where they were to stand, or as near as I possibly could. I was very particular about shading them, more than usually so, as I thought the sun had driven them out before, but about four o'clock judge my surprise when I saw the bees swarming! I went up to see where they came from, and naturally looked at the hive where I had put the swarm, when, lo and behold, it was empty! I just looked, and thought they were going to settle in the plum-tree again, but directly afterwards they appeared to be going further, and I soon saw it was a planned job of absconding.

I went out iuto the road, and saw a young woman who told me the way they had gone. I followed, and found them going into a hole in an elm-tree not more than two hundred yards away. Fortunately it was not very high up, so that I was able to get up and put some grass in the hole, and returned home for a skep, ladder, smoker, and some carbolic acid mixture. When I got back, the bees were clustering all over a thick branch. I took my Clark smoker—'Jumbo,' as I call it—and standing on the ladder, was able to get both hands to the smoker, and pulling out the grass, sent volumes of smoke into the hole, which made the bees come out a great deal faster than they went in. I placed the skep on the branches, and by the aid of a rag tied on a stick steeped in carbolic I managed to reach them and make them run up into the I then went and got my tea, and on return found them all nicely up in the skep. I carefully carried it down, tied it up, and took it back to my apiary, when I returned them to their original hive. They settled themselves down, and went to work with a will, and filled about sixty 1-lb. sections besides cramming the outside combs with honey .- John Walton, Honey Cott, Weston, Learnington.

Echoes from the Hives.

Honey Cott, Weston, Leamington, August 3rd. - The season, which has been short and sharp, is quite over, and although stocks are heavy, there is a strong inclination on the part of the bees to try and rob a little more from their neighbours if there is a possible chance. It shows the necessity for contracting the entrances to the smallest possible limit to prevent it, also to keep out wasps, which are getting rather numerous, and to all appearance by the end of the month will be a great nuisance. Have finished taking off all sections and racks. The unfinished ones I intend to place over the tops of hives to be cleaned out by driven bees. Also have nearly taken off all top storeys that were for extracting. These hives have yielded well. I have worked several with shallow frames, same as advocated by Mr. W. B. Carr, and liked them very much. The Carniolans (with me) have shown their superior honeygathering powers again this season, both as regards quantity and quality. Queens mated with Euglish drones and bees bred from them beat English and Ligurian bees out and out. I cannot get Ligurians to equal them. — John Walton.

Malvern Link, August 8th.—In reading your Bee Journal about the Lincolnshire bee-keepers, where they take honey by cwts., I think they ought in fairness to give us the number of hives, or it will act as a damper to the spirits of young bee-keepers. I have had three years, and have now six stocks. First and second years no luck; this year, 155 lbs, in sections and extracted (all from the old English black bees). I think of trying the dark strain of Italians. -A MEMBER OF WORCESTERSHIRE B. K.A.

NOTICES TO CORRESPONDENTS & INQUIRERS.

Letters or queries asking for addresses of manufacturers or correspondents, or where appliances can be purchased, or replies giving such information, can only be inserted as advertisements. The space devoted to letters, queries, and replies, is meant for the general good of bec-keepers, and not for advertisements. We wish our Correspondents to bear in mind that, as it is necessary for us to go to press in advance of the date of issue, queries cannot always be replied to in the issue immediately following the receipt of their communication.

All queries forwarded will be attended to, and those only of personal interest will be answered in this column.

interest will be answered in this column.

H. C.—Amount of Food for Wintering.—The amount of food for winter depends on the strength of the stock. Four pounds of bees may be crowded upon seven or eight standard frames. These frames should contain about twenty pounds of sealed food, be it honey or syrup, the former to be preferred. We have sought for, but have failed to alight upon, the words quoted from Modern Beekeeping; but the above information may snffice.

A Member of the Worcestershire B. K.A. - Ripening Honey.—Your best plan is not to extract the honey till it has been sealed over by the bees. Unripened honey is best put into some deep tank or vessel and allowed to remain for a week. The thin honey rises to the top, while the ripe honey descends to the bottom. Then the honey can be thickened by evaporation, but it loses the special taste and flavour of honey, and is then more like sugar-syrup.

W. B.—Removing Bees to Heather. — There is a great probability that your bees, taken the short distance named, would return to their old homes and so be lost; but is it not possible for you to convey them a little further into the midst of the heather and so safely reap the advantage which appears to be so nearly within your

E. E. H.—Loss of Queen and Uniting.—In transferring the bees from the skep to the frame-hive we fear the queen has been lost. Having a small swarm in a frame-hive it would be desirable to unite the two. In uniting, bring the hives closer to each other, about a yard a-day, reckoning only those days on which the bees are flying freely. When the weather is suitable unite the two lots by opening out the frames of the receiving stock as gently as possible, and place those of the other between them alternately. See reply to 'Subscriber.'

J. R.—Extracting.—Extracting should be done indoors. The hives you extract from should be securely covered down before leaving, or it will cause much robbing and fighting. Wired frames are preferable for extracting, but tough combs will bear the process with little fear of breaking from the frames. It is desirable to extract as soon after the honey yield is over as convenient, but September will not be found too late for the operation. We prefer the evening for taking away the frames from which you purpose to extract, as affording less inducement for robbing and an opportunity of extracting by daylight and returning the frames in the evening.

Subscriber.—Uniting.—Open the hive to receive both and separate the frames wide enough to admit the others between them. At night, lift out the frames from the other hive, place them gently between the others and close all up. No smoke or disturbance is needed. If you fancy one queen more than another the worst should be removed at the time of preparing the hives for uniting.

Watson. - I. Taking Sections. - You might have brushed the hees off with a wing, or driven them off by smoke. Never leave honey out in the open or you will 2. Refusing Sections behind Hive. surely lose it. Examine the excluder and be sure to put the side which is burred in stamping the holes away from the hive. If it was put the other way it might account for the refusal.

A. Shaw.—Honey-dew. — Although hees gather this and store it, it is not by any means desirable and spoils good honey with which it is mixed. As you have only had 12 lbs. from the lime-blossoms as yet, you must wait until next year for more from that source.

Leicestershire Amateur. — 1. Moth in Spare Combs. — Furnigating with sulphur will destroy them. 2. Cleaning out Combs.-If you put them behind the dividers and more honey was put into them, it showed that the honey harvest was not over and that you could still obtain a surplus by extracting. Do not put them out of doors, you will set up robbing. 3. Working out Combs.—Put the foundation in the middle of the hive. 4. Bees attacking Fruit.—Possibly this dry season they are in want of moisture and supply themselves in the readiest way. Try giving water.

 ${f Model.-Dead}$ Queen.—The queen externally was free from blemish; but too long an interval had elapsed since her death to make any satisfactory investigation as to the state of her productive organs.

C. W. Winton.—Artificial Swarm.—When you made the artificial swarm, the old queen was taken to the new The remaining bees, under the circumstances, would raise another queen in about twelve days, who being fertilised without delay, the original stock would soon re-establish itself. Though not consciously following the prescribed method adopted by bee-keepers, the result has been better than might have been anticipated. Your

bees have done well, and you have entered into their labours.

A. E. A. Edwards, -1. Exhibited Honey. -Honey is better exhibited in a liquid state, as it enables the judge to note its colour and consistency better. 2. 'Honey in any Form.'—Sections shown under this head should be exhibited in glass boxes; extracted in bottles; supers under glass. The more attractive the whole of the exhibit is the better. 3. Third Class Certificates. - Yes; a good practical knowledge of bee-management is the chief point. Third-class examinations are generally arranged by the Secretaries of County Associations. 4. Non-members of Associations.—Yes; but a non-member would, of course, be charged a higher fee. The terms would rest with the County Association in which he resides.

[PUBLISHED WEEKLY.]

Editorial, Hotices, &c.

AVOIDING EXTREMES.

The old copybook heading that 'Practice is more to be trusted than theory,' certainly holds good with regard to bee-keeping, yet many 'old school' men are much too apt to take the former as their sole guide in matters apicultural, and look down with pitying contempt on the teachings of modern science, greeting what they term 'new-fangled notions' with a sort of supercilious sneer.

When we speak of bee-keepers of the 'old school' we mean skeppists, whose reiterated boast it is that they kept bees when their hearers were boys, and that they 'ken mair aboot bees than onnybody,' as one of our contributors recently put it—which expression, by the

way, will live.

We often meet these ancient worthies, and find great delight in hearing of the wondrous things bees did in their day, and in the old time before them. There used to be skeps which harboured two distinct kinds of queens, the one for laying young bees, and the other for some unknown purpose. Useless is it attempting to gainsay such assertions, for such queens had been positively heard to bark at each other before the issue of a swarm. Bees, in these (shall we say middle or dark?) ages, used to know their masters. A painter's apprentice might paint a hive-stand at noon, in midsummer, without fear of getting stung so long as the bees' master stood near. And when the great Reaper gathered the old man into his garner, when the grim Forester who levels all brought the old oak down, his beloved bees were duly whispered to at night, a bit of crêpe was tied to the skep, and some, perhaps, of his favourites accompanied his remains down the pathway to the hearse. Alas that the romance has fled! During the busy circling and whizzing of a swarm, ran tan went pot and pan, for this was the master's mysterious settling charm. The swarm, too, in these times, was always headed by a young queen which lived just a year, as did the bees. Indeed, certain of the old skeppists were so superstitious and ignorant as to the living contents of their hives that they doubted the existence of the queen, for the precise reason that they had never seen one, and did not believe any one else had. Then came the horrors of the sulphur-pit, and the disgusting messes which were hawked about and called honey. True they got some fairish honey at

times from such new combs as had not been spoiled by brood and pollen, and from which the honey was drained. Of course, too, they had their mead made from the stuffed old combs, together with the sticky residue after honey had been squeezed out. It was well the ancients did not know (nor, perhaps, care much) what they really did drink as 'nectar fit for the gods.'

When we reflect that a century ago Huber was experimenting with observatory hives, citing the scientific fact of Debraw (an Englishman) having seen the queen lay eggs, and quoting Schirach's experiment on the conversion of a common grub into a queen, it really seems absolutely incredible that at this very day the most absurd ignorance still exists, and old prejudices still obtain,—aye, and to an extent little dreamt of by those who do not come in contact with the keepers of straw hives.

In medias res. We are not sure whether we ought not to recommend the Committee of the B.B.K.A. to firmly set their faces against the use of the skep in any way by discontinuing to teach ekeing, bumping, supering, or driving. Ought we not rather to seriously consider whether or not we are merely temporising with an admitted evil when we teach the cottager to manage (or rather, further mismanage) skeps?

Let us now look at the reverse of the medal. Let us regard him who has a spasm of bee-colic. He hears in the lecture-room how profitable bee-keeping is; he sees in the bee-tent 'how easily it is done,' and forthwith orders a stocked hive, probably at the fall of the year. He reads the current literature, and spies the existence of tame or harmless bees from Carniola, hard workers from Cyprus and Syria, and quiet Ligurians. These must be invested in at so much per head. Pity it is, however, he has not hives numerous enough for all the varieties he feels he must have. Veil, excluder-zinc, drone-trap, gloves, extractor, smoker, uncapping knife, foundation-fixer, wax-smelter, spray-diffuser, et hoc genus omne, these become at once absolutely necessary to him. A debtor-and-creditor account of expenditure and receipts is faithfully kept, and when a balance is struck at the end of the second season, there is a decided loss. One bee-keeper gives it up in disgust as one who has tried it, and he is thus enabled to speak with some authority when he says that bee-keeping does not pay. Modern or scientific bee-keeping gains nothing by having in her ranks such fickle sanguine subjects. Because at their Midas touch their honey was not turned into veritable gouttes d'or, they plunge to the other extreme and turn

goll into drops of honey. The mischief caused by the unfavourable reports spread by one of these disheartened 'Excelsiors' is probably greater than the good produced

by any single lecture.

Far be it for us to throw cold water on healthy enthusiasm. That is the great mainspring which keeps the mechanism of our existence as a brotherhood of beckeepers pulsating with that healthy regularity which betokens real advancement. Far be it from us also to deprecate the use of scientific appliances. They are the cog-wheels which enable the machine to record the progress made. It is only the blind, crass ignorance of the past which is so puffed out with pharisaical conceit that it will not, if it could, learn from anything of today, and the hot-headed impetuosity which looks not before it leaps (the vaulting ambition), we desire to condemn without mincing words or clipping phrases.

Rather let us turn our gaze to those forcible examples of our national and characteristic temperament—men with us at the present day—bee-masters in very sooth, with whom the new rung out the old, from whom the old traditions passed away before the march of that science yielded by their own close observation and careful study;—men who still keep an odd skep 'for auld lang syne,' yet who themselves have hidden the merely picturesque and sentimental by the glorious building to whose erection they have contributed so much, be the same a hive, a frame, an extractor, or a smoker. Pillars these of steady perseverance lasting through long years, round which we may gather and take lessons against haste in anything, bee-keeping in particular.

USEFUL HINTS.

Weather and Prospects.—Still the drought continues, and the whole country, as far as the eye can reach in every direction, has the appearance of parched stubble-fields from which the corn has been already garnered. Our meteorologists tell us that up to the present time the rainfall of the year has been two inches; the average fall should have been twenty inches at least. Want of water is causing great distress in many districts, and the springs are so low that heavy rainfalls will be required to replenish them. Fruit, still unripe, is falling from the trees, which, on heavy soils, are thenselves dying, owing to the cracked surface ad-

mitting to the roots the atmospheric air.

The Hessian fly is devastating the crops of our overburdened, ruined farmers, and the scourge of Bucillus alvei-major and minor-is decimating the apiaries of our largest and foremost bee-keepers, while corn and honey are quoted at prices lower than they have ever reached before. Call is pessimist, if you will, but there is no exaggeration here, and the season of 1887 assuredly ruin its thousands. In the midst of all our troubles we have, however, cause for thankfulness. Our honey crop is good-a full average one, we should sayand of good quality, although the continued heat and drought are, we hear, fostering the supply of that abomination which we call aphidean honey, and which the black bees delight to gather, while in many hundreds of sections, collected by the Eastern races of bees, we have not a single ounce of the black compound—honey we refuse to call it.

Sections, Extracting, and Manipulating.—Removing sections and extracting, where not already accomplished, should be completed without delay. It is impossible to lay down a hard-and-fast law to suit all

cases and circumstances.

If bees are still gathering, although but little, remove sections and other supers in fine bright weather, during midday hours, whereby much time and trouble will be saved. The same remark applies to the withdrawal of outside frames for extracting, which should be returned at night only. If the bees are bent on robbing, let all

operations be performed in the evening, and, under no circumstances, expose or manipulate the brood-nest during the daytime. The carbolised sheet is far more deterrent of robbing than the bellows-smoker. Indeed, we look upon the latter as a thing of the past, never more to be tolerated in our apiaries. Those who have tried the former will never return to the latter.

Introducing Queens may be carried on to the end of next month, but it is better to get them in as soon as possible, since the excitement of introduction generally causes ovipositing, which is undesirable after the middle of September. Some American apiarists of note cage the new queen in the hive before removing the reigning queen, keeping the former under confinement two days, at the expiration of which, if the bees appear well disposed towards her, the old one is removed and her successor released. The presence of the reigning queen is said to exert no influence over the reception of the queen designate, and the plan causes no cessation of egg-laying. Have any of our readers tried the plan?

LEE'S FRAMES AND SECTIONS.—We have a good word to say for both of these. In the body-frames, as a rule, the combs are built straight, and attached to the bottom bar. We believe this would be invariably the case if more room—say from one to two inches—were

allowed between frames and floor-board.

The sections are the most perfect we have yet seen—perfectly even, marble-like slabs, free from passage-ways at the corners, or any other irregularities. We hope the inventor will be able by next season early to put them into the market in quantity, and at a reasonable price, when we shall certainly use no other section, so far as we ourselves are concerned. His method of placing the sections on the hive is admirable, and when taken off they come out as clean and as free from propolis as the day they were put on.

Some of these sections, worked in our apiary, will shortly be exhibited in the shop of a leading London supply dealer, and, we hope also, at a future conversazione of the B.B.K.A., when all may see them and

form their own judgment thereon.

BACILLI.-We continue to receive sad reports of the destruction worked by these pests. Mr. Cheshire has kindly paid a visit to our apiary, and taken a specimen nucleus of four frames affected with the Bacillus minor upon which to experiment, and we shall hope to submit his report to our readers in due course. We have inserted in all our hives, near the entrance, a small muslin bag containing a lump of camphor the size of a walnut, so that the scent may permeate the whole interior of the hive. This, we think, will act as a prophylactic at all events, and, in the case of affected hives, will prevent the spread of disease by robber bees, if it does not effect a cure. Again we most earnestly urge the greatest caution on all apiarists, both as regards the contraction and conveyance to others of the disease in neighbourhoods where it is known to exist. We are happy to report that Mr. Cheshire believes the Bacillus minor to be quite distinct from foul brood, or Bacillus alvei.

Stories.—A correspondent, 'II. C.,' referring to the statement in Modern Bec-keeping that 'two square superficial feet of honey are sufficient for bees to winter upon,' asks—'Does this mean that two frames (which present more than two feet of surface) entirely filled with honey would be sufficient? If not, how many frames would be?' The statement, which is of importance to all bee-keepers, will be found on page 68 of Modern Bee-keeping, last edition, is as follows:—'With frame-hives, each stock, if carefully wintered, according to directions given further on, will be amply provided if it have about two square superficial feet of sealed honey,' and is, to say the least, somewhat indefinite. In the same sentence, however, we are told that, 'In the middle of September, if skeps weigh 20 lbs,'—allowance being made for old and heavy combs, when the weight

ought to be more—'they may be considered heavy enough to stand the winter.' This evidently supposes that nearly 20 lbs, of sealed honey is the required storage for an average sized colony to winter upon.

Again, if we refer to page 83, of the same edition, we find the statement, 'Six standard frames are sufficient for a strong colony —i.e., to winter upon.

Now, the inside dimensions of the standard frame are 131 × 8 inches—equal to 108 square inches as the surface of one side of a comb. But if the expression 'two superficial square feet of sealed honey' means that both surfaces or sides of the comb are to be taken in the computation, then for each standard comb we get 216 sq. in., and two standard frames will contain 432 sq. in., or exactly three square feet, of sealed honey. We have, therefore, in two standard frames one square foot of surface more than required for the winter sustenance of a strong colony,—which we all know to be absurd. Hence it is evident that the expression, 'superficial square feet of sealed honey,' refers to one side of the comb only, when it will be found in entire agreement with the recommendation 'to winter a colony on six standard frames;' since a standard frame when well filled will contain 5 lbs. of sealed comb honey, four of these will supply the required quantity of 20 lbs., and leave two frames of empty combs for the brood-nest in

But in reality the scaled honey should be-and will generally be found-stored in the upper and back parts of all the six combs, while the brood-nest also extends over the lower and front portions of every comb when

the aspect given is south of S.E. or S.W.

In our experience, however, a strong colony, when placed in winter quarters, should cover well ten standard frames, and we do not care to winter any that require less than eight. We find, also, that 25 lbs. of sealed food is not too much for a strong colony during

the six months from September to March.

FEEDING AND ROBBING.—Colonies whose stores have been closely extracted should be fed, without delay, up to the required weight for wintering, but in rapid feeding care must be taken lest the brood-nest become clogged with the food. This may be prevented by an occasional examination and re-arrangement of the combs. The strictest precautions are necessary also to prevent the 'setting up' of robbing. Not a drop of honey or syrup must be exposed in the open apiary. Once set upon raiding, bees become so thoroughly demoralised that the destruction of large apiaries has frequently been the result. The other day only we saw the drawing-room of a friend literally filled with bees. The carpet and furniture were covered with crawling bees, unable to fly because gorged with honey. And all this was caused by incantiously placing upon the table temporarily a few sections of honey recently removed from the hive, and leaving the window open. What more likely to create an inclination to rob throughout the whole apiary?

ASSOCIATIONS.

NORTHAMPTONSHIRE BEE-KEEPERS' ASSOCIATION.

The above Association held their annual show on Bank Holiday, August 1st, in connexion with the Northamptonshire Horticultural Society. About 700 lbs. of honey were staged, most of it being of excellent flavour and appearance. There were in all twenty-five entries. Mr. J. R. Truss of Ufford Heath, Stamford, carried off the silver medal with twelve 1-lb. sections which would have been hard to beat anywhere; while the first prize for extracted honey—a Cowan hive, given by Mr. Lamport Gilbert, the Hon. Sec.—went to Mr. A. Hollis of Boughton for a dark honey of excellent flavour and consistency. The bee tent having been lent to the

Cambridgeshire Agricultural Society, and having been detained by the Railway Company, did not appear, much to the annoyance of all concerned, and to the disappointment of the many visitors. Mr. J. Shaw of Moulton Park and Mr. Lamport Gilbert acted as judges.

IRISH BEE-KEEPERS' ASSOCIATION SHOW AT SALTIHLL GARDENS.

This show, which was held on the 9th and 10th of August, was remarkable from its being unconnected with that of any other society. Additional attractiveness was, however, sought to be given to it by military music and the choice of a particularly pretty and agreeable situation on the seaside. It was hoped that by these means a large number of the general public might be induced to attend, besides those specially interested in bee-keeping. In this respect the result did not equal the expectations formed, but of bee-keepers, and those wishing to become such, probably few who were able to come omitted to do so.

The Dublin press gave long reports of the proceedings, and on the whole it is believed that, in spite of the limited character of the attendance, the show will be found to have given a great stimulus to bee-keeping, and to have drawn a large amount of public attention to the

work of the Association.

A special feature in this show was that in the honey department, besides the classes open to general competition, there were also classes open, without entrance-fee, to members only. In the department for hives and appliances the exhibits were twenty-eight in number, mainly from Messrs. Abbott Brothers and Messrs. Edmondson Brothers. No exhibits were sent from England, except an interesting one from Mr. James Lee, consisting of a pair of supers, with his new sections in frames, put together by means of continuous dovetail grooves and tongues. In the honey department there were thirty-seven entries, only one of these being in the class for 2-lb. sections. In addition, Mr. Stanford had a fine exhibit of honey, but this was precluded from competition by the rule forbidding judges to compete in any class. This rule, besides diminishing the competition in honey, had a most injurious effect on the class for amateur hives, two of the best amateur hive-makers being unable to compete, since their services as judges were urgently required. The sections, except when sent in show-cases, were piled on the tables in pyramids, which had a pretty effect. Some, which had not been glazed, were covered with thin white tarlatan, to protect them from bees. This, however, but imperfectly effected its object, for on the second day much uneasiness was caused to the Committee by finding, before the slow opened, that large numbers of bees had made their way in under the coverings, while, of course, many more were buzzing about the tent. No serious consequences, however, ensued. The bees, after penetrating beneath the gauze failed to find their way out again, and were thus prevented from returning to their hives and bringing fresh marauders back with them, while the public were not frightened from the tent, but allowed the bees to buzz about their heads with the most admirable coolness.

In the bee-tent the attendance was highly satisfactory, and the greatest interest was shown in the lectures, which were given in the most able and interesting manner, accompanied with extremely skilful manipula-tions, by Mr. Roland Green, the well-known expert of

the British Association.

The weather was favourable, and the show, on the whole, passed off most satisfactorily. The Hon. Secretary, H. Chenevix, Esq., was ably assisted by several members of the Committee, especial acknowledgment being due to the indefatigable ardour and unremitting exertions of the late Hon. Sec., Mr. Stanford. Mr. T. Elderkin, one of the exhibitors, also rendered most valuable

assistance, and the warmest thanks of the Committee are due to Mr. Kelly, the stationmaster of Salthill Statiou, immediately adjoining the gardens, who, with the kind permission of the Traffic Manager, issued tickets for the show, placed porters at the gate, and gave important aid in other ways.

In the judging department the Committee were fortunate in securing the services of a well-known and very experienced bee-keeper, the Rev. II. W. Lett, who travelled a long distance to be present at the show. The

following is the prize-list:—

For the most economical (best and cheapest) hive, on the moveable-comb principle, with crate of sections, price not to exceed 15s.: 1, Edmondson Brothers, 10 Dame Street, Dublin; 2, Same; 3, Abbott Brothers, Southall, London, and Merchants' Quay, Dublin. For the same as preceding, price not to exceed 10s. 6d.: 1, Edmondson Brothers; 2, Abbott Brothers; 3, Same. For the best straw hive with super (cost to be taken into consideration), complete, with floorboard, price not to exceed 10s.: prizes equal, Abbott Brothers and Edmondson Brothers. For the frame-hive best adapted in all respects, price included, to be employed profitably for general purposes: 1, Edmondson Brothers; 2, Abbott Brothers; 3, not awarded. For the hive best adapted in all respects, price included, to be employed profitably for extracting purposes: 1, Abbott Brothers; 2, not awarded; 3, Abbott Brothers. For the best hive for general purposes, made by an amateur: 1, not awarded; 2, J. G. Barlow, Stream Vale, Clonmel; 3, not awarded. For the cheapest and best super for 1-lb, sections, adapted for frame-hives: 1, Edmondson Brothers; 2, Abbott Brothers. For the cheapest and best super for 1-lb. sections, adapted for straw hives: 1, Edmondson Brothers; 2, not awarded. For the best and cheapest collection of articles required in modern bee-keeping, other than hives and supers: 1, Abbott Brothers; 2, Edmondson Brothers. For the best twenty-four 1-lb. sections of comb honey: 1, Miss Mary Daly, Brownstown, Navan; 2, G. W. Hargraft, Woodbrook, Shinrone; 3, F. H. Jones, Mullinabro', Co. Waterlord; 4, Thos. Elderkin, Kilcarberry, Enniscorthy. For the best twelve 2-lb. sections of comb honey: Prize not awarded, but special prize given to the Rev. Robert Seymonr, Aghar Rectory, Enfield. For the best twelve 1-lb. bottles of extracted honey: 1, Miss Mary Daly; 2, J. G. Barlow; 3, Miss F. W. Currey, The Mall House, Lismore.

For Members of the Association only.

For the best twenty-four I-lb. sections of comb honey: 1, Miss Mary Daly; 2, T. Elderkin; extra prize, Miss F. W. Currey; very highly commended, T. Elderkin; highly commended, Miss E. E. Rutherfoord, The Ghan House, Carlingford. For the best twelve I-lb. bottles of extracted honey; 1, J. G. Barlow; 2, Miss Mary Daly; extra prizes, Miss Bertha Doyne, Seafield House, Goroy, and Miss F. W. Currey.

The following is the report of the judges on the hives and appliances:—

'In presenting their report, the judges regret to be obliged to state that, on the whole, the hives exhibited were not up to standard, either as regards workmanship or material used. There was a marked absence of variety of design for the different classes, the same hives, adapted to suit the specifications of the class, appearing again and again. The judges were very much struck by the great cheapness of various exhibits, as compared with former prices; but they hope efficiency will not be sacrificed for cheapness, and that the uncertain climate will induce manufacturers to build strong, weather-proof hives. The exhibits, however, showed that a spirit of enterprise was being largely diffused among manufacturers.

'Class I calls for no special remarks.

'In Class 2, second and third prizes were awarded to hives without either doors or porches, which the judges consider very essential points, but in other respects the hives were satisfactory.

'There were only two exhibits in Class 3. The judges considered neither of the hives shown to be thoroughly satisfactory, both having equal merits and faults, and,

consequently, equal prizes were awarded to each of them.

'In Class 4 the judges reductantly awarded first prize to a hive, price 2l., being the only hive exhibited deserving of a first prize.

'In Class 5, sufficient attention had not been given to weather-proofedness, and, consequently, no second prize

was awarded.

'Class 6, the amateurs' class, was disappointing, neither exhibit being worthy of commendation. The judges hope amateurs will give more attention to workmanship in future.

'Classes 7 and 8 call for no special remarks.

'The collection of appliances in Class 9 was specially good, the articles in both exhibits being very carefully selected.

'The first prize exhibit included comb Ioundation samples offDublin manufacture. This being the first venture in this direction, is deserving of great praise. The feeders were also exceptionally good, both in design and make, as were also a collection of bottles and a Raynor extractor. An observatory unicomb hive, stocked with bees, was much admired. The second prize exhibit included a collection of bee-literature and honey-tins, with patent air-tight lids and fitted with treacle-taps, being a new departure in appliances. The Rev. T. Lett, E. D'Olter, W. J. Stanford, Judges.'

The judges' report on the honey classes is as follows:— 'The display of honey was rather good, especially in the classes confined to members of the I. B. K. A., but with few exceptions the exhibits of sections were not first-class, which the large harvest of honey gathered this year made somewhat inexcusable. Very good run honey was shown, but sufficient care was not taken in some instances with the straining, and some of it was thinner than consistent with ripeness. The judges were very well pleased with the get-up of both sections and run honey; though some of the exhibitors neglected glazing their sections, which were in consequence a great attraction to the bees. They Iound the Woodley tin cases with glass sides very convenient Ior examining the sections, they were so easy to replace, also the cardboard boxes, but those glazed with paper and paste when opened had to remain so. Tom Sell's labels looked very pretty on many of the bottles. None of the bottles were fastened with sealing-wax, as had occurred in previous shows, and necessitated breaking some of the bottles to judge of their contents. Screw caps were much used, and are the best to be used in exhibits.

In Class 9 (for exhibits of twenty-four I-lb. sections), the judges had no difficulty in awarding first prize, the exhibit to which it was given being first class, and uniform throughout, which is more than could be said for the rest. Indeed the judges were very much inclined to withhold some of the prizes on account of insufficient merit. There was one exhibit of 134 sections in this class, but apparently worked with dividers, and judged too light for 1-lb., otherwise it would probably have taken second instead of third prize.

Class 10 (for exhibits of twelve 2-lb. sections.)—In this class there was but one exhibit, which the judges consider of insufficient merit for the prize of 15s. in the catalogue,

but awarded it a special second prize.

Class 12 (for exhibits of twelve 1-lb. bottles of run honey.)—This class was but little contested, and the judges had little difficulty in settling the order of merit. An exhibitor of white clover honey, which carried off first prize, was the only really bright looking one in this class.

prize, was the only really bright looking one in this class. Class 13 (for exhibits of twenty-four 1-lb. sections, confined to members of the I. B. K. A.) had a full number of exhibits, but, as in the ease of Class 10, none of them but that which was awarded first prize were first-rate, the popholes being too large, and in some cases combs not built

down to the bettom.

Class 14 (for exhibits of twelve I-lb bottles, confined to members of the I. B. K. A.)—In this the entries were full, and, in general, of good flavour, fair consistency, and bright in appearance. Some of them were not carefully strained, and some not hundled cleanly; but the remainder taxed the judges' powers of discrimination. Finally, a specimen of dark honey was awarded first prize, the second being taken by a beautiful set of hawthorn honey, which, however, was scarcely of the proper consistency. Special

third prizes were awarded to two exhibits, one of fine dark honey, and the other slightly crystallised.

Judges-Robert Sproule, J. M. Gillies, M. H. Read.

On the evening of the first day of the show a conversazione was held, by kind permission of Dr. Traill, in his rooms at Trinity College. A very interesting paper was read by Mr. 11. Read, 'On obtaining Comb-honey combined with Extracted,' and thoroughly discussed. There was a good attendance of members, and Mr. Roland Green, the lecturer at the show, was also present.

[It has given us much pleasure to receive such excellent reports of this and the other Irish shows which have been

held this year.—Ed.]

ARMAGII (IRELAND) HONEY AND BEE SHOW.

For the first time a Honey and Bee Show has actually been held in the city of Armagh, and the event took place on the 10th inst. The record deserves to be made, as, before the development of the County Armagh Beekeepers' Association into the North-East of Ireland Beekeepers' Association, the beekeepers of the ancient city never could be induced to get up a bee and honey show. However, they have got aroused at last, and had a large exhibition of bees, houey, and appliances, for which they offered sixteen prizes, and for which they had thirty-one entries on Wednesday. The judges were the Rev. 11. W. Lett, Loughbrickland, and Mr. John Burnett, Manchester, and the following are the awards:—

Stock of bees to be exhibited in an observatory hive, credit to be given for both bees and hive—I, W. R. Orr, Strabane; 2, William Lonsdale, Lurgan. Twelve sections of honey—I, Samuel H. Orr, Loughgall; 2, Wm. Lonsdale; 3, David W. Shaw, Anahilt, Hillsborough. Six sections of honey: I, Mrs. Grifiths, Killynure; 2, David W. Shaw and Samuel H. Orr—equal. Twelve jars of extracted honey: I, Robert Brown, Donaghmore; 2, David W. Shaw; 3, Rev. Robert W. Knox, Saintfield. Six jars of extracted honey: I, Robert Brown; 2, John Tufft, Moy. Collection of bee appliances, hives, and utensils for use in an apiary: 1, W. R. Orr; 2, William Porter, Jerretspass, Newry. Bee-driving competition: I, Rev. Robert W. Knox, Hillsborough; 2, Wm. Lonsdale.

The sections of honey were not as well filled as some that have been shown at other places in Ulster this season; and while the judges were unanimous in picking out the heaviest and most complete sections for first prizes, they had some difficulty in deciding between those coming second and third. In the extracted honey classes, Mr. Brown's exhibit deserves special mention as being as near a model sample as well could be, pleasant flavour, pale light amber colour, quite clear, very dense and consistent, and with a delightful aroma. There were two specimens in this division of dark honey, which one or two of the visitors called 'heather honey,' but which, on honey-dew.

The collections of bee appliances and utensils for use in bee gardens were as complete in first-class hives, extractors, feeders, foundation, veils, gloves, smokers, knives, sections, &c., as need be, and great interest was taken in them by the crowds who visited the show yard during the day. In the bee tent there was a most successful bee-driving contest between two competitors, the Rev. R. Knox catching the queen and clearing out his bees in seven minutes, and W. Lonsdale doing the same in ten minutes. A short lecture was then given, and numerous questions on modern bee-keeping answered by

the Rev. II. W. Lett and others.

DUNGANNON BEE AND HONEY SHOW.

At the Horticultural Show held in Dungannon, Co. Tyrone, on the 3rd inst., there was a large class devoted to bees and honey, of which the following is the prize-list:—1. Stock of bees to be exhibited in an observatory hives, eredit to be given for both bees and hive: W. Lonsdale, Bee Garden, Lurgan. II. Twelve sections of honey: 1, S. Orr, Loughgall; 2. W. Lonsdale; 3, J. Tufft, Drumgold House, Moy. III. Six sections of honey: 1, S. Orr; 2, W. Lonsdale; 3, J. Tufft. IV. Twelve jars of extracted honey: 1, R. Brown, Donaghmore; 2, J. Tufft and James Moore, Mullaghfurtherland (equal). V. Six jars of extracted honey: 1, J. Moore; 2, R. Brown; 3, J. Tufft. VI. Collection of bee appliances, hives, and utensils for use. in an apiary: 1, Wm. Lonsdale; 2, S. J. Baldwin, Apiary, Bromley, Kent. VII. Bee-driving competition: W. Lonsdale.

The Rev. II. W. Lett, Loughbrickland, was to have been judge, but was prevented from attending; his place, however, was well supplied by Mr. W. R. Orr, Strabane, another member of the North East of Ireland Bee-keepers' Association. Indeed, the show at Dungannon may be regarded as a braneh of the North East of Ireland B.K.A., most of the exhibitors and prize-winners also belonging to it, so that these provincial exhibitions are portions of the work that the Association, whose head-quarters are now in Belfast, has helped

in great measure to inaugurate.

Mr. Lonsdale's observatory hive was a large one, containing six standard frames, well covered with black bees. Apropos of this prize, it might be asked why at other shows have judges so often given the preference to foreign insects when all other points were equal? To say the least, it is not patriotic to do so. Again, how are exhibitors to know what is meant by 'best specimen' or 'best stock' of bees? There ought to be more definition for the assistance of all parties. The writer has seen a single frame in an 'observatory' beating one with half a dozen equally good combs, a thing which nobody could understand. There was a close competition in the honey, both sections and bottles, for which there were many entries, all of a very good quality.

many entries, all of a very good quality.

It was pleasant to see Mr. Baldwin, Bromley, Kent, showing his collection of bee-appliances, though he was not as successful as the local man. For the bee-driving competitions there were three entries, Mr. Lonsdale winning by clearing out most of his bees and capturing their queen in three and a half minutes. The Committee required each intending bee-driver to provide a skep of bees, which were then drawn for the subsequent process, an arrangement which prevents the possibility of any

unfairness.

Honey as an Article of Food.—'Whilst I was listening to these details, we discovered a number of peasants running on the hill, striking on brazen vessels to attract a swarm of bees which had just left the hive. These insects are extremely partial to Mount Hymettus, as it is covered everywhere with wild thyme and other odoriferons plants. The honey extracted is of a white colour, verging towards yellow, grows black when long kept, and always retains its fluidity. The Athenians gather vast quantities of it every year; and we may judge of the value set upon it by the use made of it; they employ honey in their pastry, as well as their ragouts, and the eating of it, it is said, will prolong life, and to be particularly salutary for aged persons. I have seen some disciples of Pythagoras take no other nourishment than honey, and yet preserve their health and strength.'—Barthelemy. Travels of Anacharsis the Younger in Greece. (London, 1798.)

[The above forwarded to us as genuine history must not be considered so. The Abbé Barthelemy was a learned archaeologist; and though his work, the *Travels of Anacharsis the Younger in Greece*, is a pure fiction, it is considered to be a faithful portraiture of the manners and customs of the country in the age of Pericles, more than four hundred years before the Christian era,—Ep.]

Correspondence.

The Editor does not hold himself responsible for the opinions expressed by his correspondents. No attention will be taken of anonymous communications, and correspondents are requested to write on one side of the paper only, and give their real names and addresses, not necessarily for publication, but as a guarantee of good faith. Illustrations should be drawn on separate pieces of paper.

Communications relating to the literary department, reports of Associations, Shores, Meetings, Echoes, Queries, Books for Review, &c., must be addressed only to 'The Editors of the 'British Bed Journal,' of Messrs, Strangeways and Sons, Tower Street, Cambridge Circus, W.C.' All lusiness communications relating to Advertisements, &c., must be addressed to Mr. J. Huckle, Kings Langloy, Herts (see 2nd page of Advertisements).

IN THE HUT.

'Oh, for lodgings in some vast wilderness—of heather.'

[II85.] On July 28th I happened to pass through Ely at the time of the Cambridgeshire and Isle of Ely Agricultural Show, and thought I would see for myself 'how they do it' in this land of keps, for a land of skeps it is par excellence (?) judging as one may from the railway carriage window. My incognito was not Iong preserved, however, for on approaching the beetent, Baldwin, S. J. (not special jurist), E.l.C. (not East India Company, but Expert-in-Chief), was just getting ready for an attack on the bucolics, and used me as X-tractor during his manipulations. Mr. Editor, there were four of us, on a fine day, and-we enjoyed onrselves. I assisted by sitting on a wooden trestle (or tressel, I don't know which) in the tent, whilst Mr. Baldwin performed on the bees, and gave them an opportunity of performing on me. Then I had her majesty to show round in a bottle. The expert had his smoker, and I had mine. He used old carpet, and I 'bacey.' Mr. Godfrey and Mr. Howard made us very welcome; but oh, for a fine extempore discourse! would that I had the flow of language of our E.I.C.; I think I would take to the Church. Well might the bees be subdued. The network of the tent was surrounded by eager faces mostly, but in truth there were a few skeptics, one of whom told the audience that 'he'd heeved more swarms then him, ay, an before breakfast, Thus did he stand condemned out of his own mouth of being either a base perverter or a beery chawbacon—or both.

A huttite asks a puzzling question. One of his hives at heather is a doubled one well filled with bees, and the owner of an adjoining skep of recently driven bees says they have left the skep and joined the hive. He claims 10s. for 5 lbs. bees. Huttite refuses to pay, for he would rather do without 'em; besides, the next morning a large cluster were on the hive roof, having been perhaps turned out. The owner of the skep was another member of the race discovered by Mr. Webster in borderland, nobody knew more about bees 'nor him, so he said. He hadn't tried frame-hives, for he didn't like 'em.

A north-of-England bee-keeper told me the other day that he overcomes the difficulty about extracting heather honey by using behind and above queen-excluder-super foundation in the ordinary frames. He had never had any mishap. We won't try it, however. Our plan this year has been to do little extracting between clover and heather seasons, because of the many cells filled with honey dew; to take the hives to the heather heavy instead of light, thus forcing the bees to store in supers. -X-Tractor, Horsforth, near Leeds.

'BY PERSEVERING,'

[1186.]—You kindly inserted two letters of mine in your valuable *Journal*, Nos. 623 and 657, last year, detailing my adventures and misadventures in trying to

become an apiarist. With your permission I should like to relate my further experiences, which, though probably not instructive, may prove interesting to some of your

You may remember that according to 657 I closed my first half-year bee practice with five stocks and eightysix stings. Having read your Journal weekly with much interest, and having noticed how often the question was asked, 'What number of stings must I receive before becoming inoculated?' I determined to pay particular attention to the number of stings I received, and to the effect they had upon me; and, knowing I was right as to the actual number (eighty-six) received last year, paid particular attention to those received this. Well, the painful score ran up by twos and threes, with an oceasional dozen to relieve the monotony, if monotony there be in such things, until 130 were scored, then the swelling in a great measure ceased, and all after ill effects disappeared; in short, I was inoculated. 'Tis true the pain at the time of being stung is excessive for a few seconds, but what of that? even that is decreasing gradually, and though a slight swelling sometimes occurs, it is of no consequence even if discernible by the public. Therefore to my fellow-novices I would say—Persevere; some may take more, some require fewer stings, but by perseverance all will in time become, as I believe I now am, inoculated.

But to return to my bees. Two of my five stocks appeared so weakly I determined to unite them, and after some trouble did so; they having since done fairly, and with the other three wintered well. In the early spring I purchased two stocks in skeps, and having transported them to my apiary, transferred them successfully to bar-frame hives. 'All these I began to stimulate in the early part of April, mostly on dry sugar; but being obliged to leave home for a month in May I filled all dummy feeders with dry white sugar, added to each a few more bars of foundation, and left hoping for the best.

Unfortunately I was detained away longer than I had expected, and just as by my previous arrangement I ought to have returned, six of my stocks swarmed, but, thanks to the watchfulness and skill of my assistant, all were secured in skeps.

On the day of my return my seventh stock showed signs of swarming, but by the addition of foundation bars I turned their purpose, and have since kept them drawing out combs for their weaker brethren. With the five swarms in skeps I had great trouble in inducing them to inhabit bar-frame hives (possibly because of the heat of the weather and that the said hives had only recently been painted), but after giving me an infinite amount of work they settled it thus amongst themselves -two should unite, one should decamp, and the remaining three settle respectably. Since then all have done well, and though I cannot lay claim to the large honey receipts described by some of your correspondents, yet, for a beginner, I do not think I have done badly, and am told the honey I have got is of good quality.

With regard to the dry dummy feeders which I on leaving home filled with sugar, I found them on my return filled with comb containing brood and honey. These proved an awful nuisance to me, for I could not drive the bees from the rear of the combs, and the latter were too weak to stand the jar consequent upon breaking off the fronts and backs of the dummies, consequently many bees paid the penalty for playing with their dinner things with their lives. My love of bees having increased with my knowledge of and power over them, and disliking to cause needless pain, I bought a Webster's fumigator, a bottle of liquid, barrel, and bellows, and having charged it strictly according to instructions on the bottle, proceeded to manipulate No. I. Was not I pleased? The bees were so quiet I could do as I liked. No fear of the fumer going out, no choky smoke to

contend with, but all serene; the pleasant hum of bees beneath me and the bright blue sky overhead. Ah, I exclaimed, this is the implement for me; henceforth this is the only subjugator I will use. Closing No. 1, I opened No. 2 (my object in both being to extract two bars of sealed stores). What a change! Before, all was peace and goodwill, but here just the reverse. Out they came boiling over the bars on to my hands, and, as if to show their scorn of the fumigator, actually running hissing up the barrel. Indeed, had it not been for the poor despised smoker, which meanwhile had been quietly smoking itself away, No. 2 would have come off victorious, whereas by its aid they, like No. I, had to yield up their stores. Since then I have tried the fumigator more heavily charged with liquid, but have decided that on the whole I prefer the smoker. I now own twelve strong stocks, and so end my further experiences as a novice, as I, having successfully managed so far, will, with your leave, discard my previous nom de plume, and, adopting my family motto, sign myself-Perseverando.

VICIOUS BEES.

[1187.] What am I to do with my vicious bees? When I read in the Journal of the extracting system I often think with a smile, I should like to see the man who would do it with my demons. On June 11th I put a large swarm in a ten-frame Woodbury, filled with foundation. The next morning they boiled out at the entrance in such an extraordinary way that, after deluging with water, shading, and trying everything, I at last raised the hive half an inch from the floorboard all round, by means of wooden blocks at each corner, and also put on two supers each holding six 2-lb. sections. I ought to have mentioned the hive had an outer case of 3-inch pine with a 2-inch space all round between it and the hive; this I now put on, and the 2-inch space was full of lees as also the supers, but they seemed more settled, so I put on the roof to cases and left them. Ten days after I went to see if they were working in sections, and to my surprise found both full of comb, and (what I had never seen before) the 2-inch space all round also full of comb, and all in ten days. I now replaced the full section with empty ones, but the 2-inch spaces being crowded with bees, thought I would leave the comb there till cooler weather compelled them to draw inside the hive. That cooler weather hasn't come, and as I thought the large entrance to outer case, and the 1/2-inch space all round bottom of hive, gave great facilities for robbing bees and wasps, I set to work yesterday at 7 p.m. to remove the outer comb, and drop the hive down on to floorboard. Veil and double cotton gloves were put on, and carefully taking off roof I laid carbolised calico (according to your directions) all round on the top of the comb to be removed, trusting this would drive the bees down into hive. After waiting five minutes, without removing the calico, I then severed the comb from the outer cases by passing a thin knife all round, and lifted it carefully off. I immediately realised I was to have a rough time of it, being at once surrounded by a crowd of angry bees, and my gloves especially covered with them. Fetching smoker, and dipping my gloves in water, used the former freely, and then with knife and dish went for the hive with the view of getting the bits of comb off the back. I got the comb it is true, and also something besides, as certain sharp twinges in my ankles and legs informed me. I now tried for the combs on sides of hive, but was met by such a volley of angry bees from beneath, back, and sides, like sparks from a blacksmith's anvil, that I determined to drop the hive on to floorboard first. All this time I had a perfect swarm of angry bees around me, and the moment my hand approached the first block it was black with stinging bees, and in the end I was obliged to lever the hive up with one long stick while I knocked the blocks away with another; smoke being utterly useless.

Now, sir, I shall be obliged if you, or some kind reader of the B. B. J. with experience, will kindly tell me where I erred in my proceedings, and how I ought to have managed the matter so as not to have so fearfully excited the stock, for now, twenty-four hours after, no one can go into the garden without being stung and driven into the house.

And what is my reward, fearfully swelled ankles and two dishes of nice-looking comb, but tasting fearfully smoky? Fancy oneself extracting with such demons; why the garden would be unapproachable all the summer.

—J. Robinson, Beyton, Bury St. Edmunds, August 11th.

[You ask 'wherein have I erred?' To be candid. then, we reply:—(1) In placing so large a swarm in a small ten-frame Woodbury hive. Such a swarm would have quickly filled two such hives. But why use an old-fashioned 'Woodbury'—the hive of thirty years ago? Why ignore all the modern expansible framehives, which possess every possible scientific improvement, and are easily adapted to small or large swarms. (2) In giving too little super space; 24 lbs. in sections are a mere trifle for a large swarm. We should have placed such a swarm upon fourteen standard frames, and upon these a 28-lb. crate of I-lb. sections, to be tiered up, after three or four days, by placing a similar one beneath it, in the midst of a copious honey-flow like yours. We only wish we had such a honey-producing country as we know yours to be! (3) In raising the hive $\frac{1}{2}$ -in. A $\frac{1}{4}$ -in. is sufficient for ventilation and for the passage of bees. Probably comb was built in the inch space you gave, between frames and floorboard, and when removing the wedges you crushed bees and combs, hence the anger of the poor bees. You need not have feared the robbing of a colony like yours. Crushing of bees, and the consequent strong smell of formic acid (sting-poison), so enraged the bees that we congratulate you on escaping with so little damage. (4) The worst error of all, if worst can be, was to attempt the manipulation of so large a colony at 7 p.m., when every bee was at home! Have we not recommended in the columns of the Journal, ad nauseam, to manipulate during the honey season only on line days and between the hours of 10 and 3? Had you followed this advice, and manipulated slowly and quietly, notwithstanding former mistakes, you would have succeeded with bare hands and escaped punishment. Our advice, under 'Useful Hints,' to manipulate in 'early morning or late evening,' only applies during a honey dearth, or when robbing is rife; and yours was not a case of opening the hive at all, from whence the great danger arises. Whenever, in future, you thoroughly irritate the bees (which never should be done) throw over the hive a small sheet steeped in carbolic solution, and leave them for an hour, when they will have become quiet, and you may then proceed and complete the operation. In such cases smoke is worse than useless. Your hive, without doubt, is clogged with honey, and about half the comb must be extracted, or you will lose your bees from want of breeding-space. Can you not obtain the help of a qualified expert?—ED.]

MY EXPERIENCE WITH FOUL BROOD.

[I188.] I know the opinions of the different authorities on the subject of foul brood, and I know what arguments can be and are going to be brought against my theory of the disease. I have a firm belief in all the experiments on the disease that have been reported to the bee papers, but I am careful not to get a party's opinion so mixed with his experiments hut that I can consider each separately. It is my intention after I state my experiments to base my arguments solely on

the evidence to be found in the American Bee Journal, Gleanings, and other bee-literature.

I am going to offer no plan of cure adapted to all circumstances, for I do not believe that a treatment is yet found, or ever will be invented, that will suit every case. Therefore every bee-keeper should learn all he can about the disease, and when it is among his bees he will know better what to do than anybody can tell him. I am determined to argue the question honestly and fairly; and if any one sees where he thinks I am wrong I would be pleased to hear of his experience, and I will not con-

tradict his experiments.

On June 16, 1885, I discovered foul brood in one of my hives in the shape of discoloured larvæ, but I do not think that it was foul brood though, because the disease always appeared in my mind as associated with 'sunken caps with pin-holes in the tops.' I was uneasy, though, about it. The honey-flow from flowers ceased that year about May 25, and as I had finished extracting I was doing very little to the bees except watching that discoloured larvæ which I could not understand. On June 2I I opened a hive that had it so badly that about twenty per cent of the brood was dead with the disease, as near as I should guess. I then began to examine other colonies. I found none free from it, though some cases were not bad. I saw that there was only one thing that could cause this state of affairs, and that was foul brood, and that I must get

I had read Mr. Cheshire's experiments and views on the subject the year before, and I was so favourably impressed with them that I took my *Bee Journal* for 1884 and re-read the articles on pages 644 and 740, and, as you may suppose, with no little interest. When I was through studying the articles I was just as sure that I could cure the complaint with his remedy as is Mr. Cheshire himself. The medicine I got was called 'chemically pure carbolic acid.' I had then sixty-five

some remedy and go to work to cure it.

colonies of bees, and as I wanted to cure them all at once I fed each colony every day. Every evening, as soon as there was no danger of robbing, I would commence to feed, raising the cover of each hive and pouring about four ounces of food down between the frames. I kept this up for eight days, and as I could see no improvement I decided on a more thorough treatment, which was this. I would extract the honey from the frames and cut out the combs all but about two inches at the top, which had never had any brood in it; I filled these strips of comb with this phenolated syrup, put them in a hive washed with carbolic soap; then I would take the brood from a colony of bees and put the bees in the hive thus prepared. I also had a lot of this phenolated foodlin a barrel, arranged so that all the bees could help themselves to it, which they did. I had prepared twenty-six colonies in the manner above mentioned before I could see whether I was curing them or not. But as soon as they had larvæ three or four days old 1 could see that I had not cured them. I stopped work to watch the result of what I had done: I soon became

Now do not put me down as saying that Mr. Cheshire did not cure this disease, for I know he did cure it; and I will explain why he could cure it, and I could not, after

I get through telling my experience.

satisfied that phenol would not cure it.

I gave up the phenol cure on July 15, and I was just as confident on that day that I could cure my bees as I was the day I commenced it. I had a boiler made large enough to boil my hives in. I sent for Mr. D. A. Jones' book on the subject, put some colonies in starvation quarters and went to work cutting out combs and boiling frames and hives. About this time the hives emitted a strong stench that surpassed anything I eversaw reported. About this time, too, I was taken with a peculiar complaint of the throat, which I attributed at the time to the disease, but since then I thought it might have been

produced by the mental anxiety I was in. I boiled everything, and when I starved a colony I put them in a clean hive with clean frames with foundation and fed them with boiled honey. I worked thirty in this way. I did not wait until time for sunken caps to appear, for I was a firm believer in the 'germ theory,' and the least indication of disease in the larvæ satisfied me that I did not cure it. I did not cure one; but I am ashamed to say two colonies were starved to death and two very strong colonies smothered. Please do not understand me to say that Mr. Jones never cured this disease; I know he has cured it. And I will explain why he could cure it, and I could not, after I get through with my own experience.

I began to wonder why the disease did not get any worse in some colonies that I had not worked on. I doctored the worst ones it is true, but they had it as long as the others, and I could not see why it did not get worse. (I will in the future give my opinion, which is founded on observation, why some colonies have the disease worse than others.) Just about this time I saw the following in Gleanings from Dr. O. M. Blanton, of

Greenville, Miss.:

'Last year, about June 1, one of my neighbours, Mr. S. C. Vaught, discovered dead brood in his apiary, It first commenced with the capped brood, but soon extended to the larvæ, which in some instances in both soon became decomposed. On examination I found some of the capped brood with minute holes in the cappings and the decomposition complete. Some of the pupe just dead I found reversed within their cells. There was a very disagreeable odour from the decayed brood, but not such as described in articles on foul brood. Upon inquiry I found ten apiaries within a radius of fifteen miles of me affected by it; some to the extent of fifteen per cent, and most of it confined to the capped brood. Two colonies in my home aniary were affected slightly. The colonies in my home apiary were affected slightly. "Refuge Apiary," with its bright new combs, had it in every colony, but it did not reach putrefaction before the bees removed the dead and filled the cells with honey, and the queen commenced laying as vigorously as ever. Mr. Vaught's apiary of about 250 colonies was so diseased that he determined to let them work out their own salvation, which they did. I uncapped the dead pupæ of some colonies and the bees soon cleaned the cells. Just before the discovery of this condition of things the bees gathered a great deal of dark, sour honey-dew (aphides), and I attributed the disease to that cause. This year, as far as I can learn, there is no evidence of the disease. It certainly cannot be the forerunner of foul brood, or we should have it this year.'

Nearly sick with worry, and almost despairing of ever curing my bees, I need not say that I gladly welcomed the small ray of hope that my bees possibly had the same disease as Dr. Blanton's. Still I could not help feeling pretty much like a broken merchant as I left my bees and went out into the country to get a rest, which I badly needed, having worked very hard for over two

months of the warmest weather we have.

When I came back to Mobile about September 25 my bees were gathering fall honey, the disease had almost entirely disappeared, and even the three and four storey hives (six in number), in which I left a lot of diseased brood from other hives, had developed into populous colonies and had queens of their own rearing, some of which colonies did as well last year as any I had, but some never did amount to anything until I gave them another queen.

Feeling satisfied that my bees never had foul brood I went to work putting them in the best condition to winter, almost all of them being reduced to nuclei from my attempts to cure them. When I had finished that job I thought I would find the difference between the disease that my bees had and genuine foul brood. I have looked through my bound Bee Journals, Gleanings, and other bee-papers; I have read Dzierzon's experiments

and also Mr. Cheshire's: I have read Jones, Muth, and Kolmke, on the subject, and I have yet to see a symptom laid down for the detection of the disease that I have not witnessed among my bees. Hence the origin of my theory: and though if proven it will show our best authorities to have made a mistake, it will also show that the mistake in each case is pardonable though a very serious one.—G. H. Hoyle (Amer. Bee Journal.)

'CAUGHT IN THE ACT.'

[1189.] Putting aside, for a minute or two, the tone and temper of 'C. N. A.,' I will answer the questions he asks me, and also put in quite plain shape a small piece of what was intended to be information to people interested in bees and their wonderful habits and instincts. I. 'How was I able to contemplate the symmetry of the cells of a well-filled and sealed super?' I answer, Through the glass. 2. 'How in such well-filled and sealed super there could be a bee in one of the cells helping himself to honey?' I answer, The bee was there, and, as I said, impaired the symmetry, &e., and so attracted my attention. But, perhaps, the relation of the story as plainly as I can put it will be best.

The super in question is a square box, wooden on three sides and on top, a glass plate forming the fourth side. Against this glass, when the super is full, six pieces of comb are fixed, leaving open to inspection a considerable number of cells, the glass itself forming one side of each cell. Being about to deprive the stock of this super, I noticed on looking in a bee alive in one of the cells that on the previous evening had been sealed up full. I called my gardener's attention to it, and on looking more closely we observed that the cell was then just finished sealing up, three or four bees round it at work. Later in the day I showed the bee dead, sealed up, to my wife, children, and several friends who happened to be at tennis. (I called the bee *himself*, perhaps leading 'C. N. A.' to conclude that I meant a drone. It was a bee himself, herself, or itself—not much matter.) For three or four days that bee remained in the cell, plain, against the glass. Then, as I said, the cell was opened, the dead bee removed, honey put in, and the cell resealed. I said that 'lime-honey' was put in, simply because our lime-trees were then in full bloom, and the bees in full work.

There, sir, is a plain statement of facts. I can produce twenty vitnesses to the various facts that I relate. I can show the super and point out the cell, even supposing that my own evidence be put aside as unworthy of belief, and only worthy of other adjectives suggested as applicable to me besides 'lazy and yawning' by the kindly and courteous 'C. N. A.' Surely that gentleman -unless he he one of those who will believe nothing but what he himself knows-must see that my story may have a little interest for some perhaps not so learned as he may be, and that his appeal to you, sir, to protect the public from such 'effusions' may not be quite reasonable. I am not aware that my tale was told in a manner to be offensive to any one; it certainly was not intended to be. Let any lady or gentleman read the article from Fairlawn, and decide whether or not such a tone as pervades it is calculated to promote friendly intercourse and exchange of ideas between people who have a common object—truth,—be it about bees or those who labour with them.—LAZY YAWNING DRONE.

[At our correspondent's suggestion, we have communicated his name and address to 'C. N. A,' so that the latter gentleman, if so disposed, may have the opportunity of verifying the above statement.—Ep.]

FIXING COMB FOUNDATION IN SKEPS FOR CONDEMNED BEES.

[1190.] I quite agree with your remarks upon putting driven bees into empty skeps. Having tried two lots

last August (6th and 9th), fed regularly, they did live, but both were very weak. In May you advised me to unite, but as they were thirty yards apart I let them alone; they have now filled their hives with comb and have a little honey. I trust they will gather enough stores from the heather to carry them through winter.

I succeeded in fastening with wire four half sheets comb-foundation in a straw hive and put two stocks condenined bees (weighing together five lbs.) on them about nine days ago; they very soon worked them out. I never heard of this being tried before, so I thought I might do some good by giving your readers a hint, for many like myself cannot afford the time to work and study the bar-frame system to any great extent. I shall (D.V.) take some eight or ten stocks next week again and intend giving them the same fair play. I will describe the way I fasten comb-foundation if desired. I have taken forty sections and thirty lbs. run honey from one box and about fifty sections and five lbs. run honey from the other box; I have only two boxes. I owe my success principally to reading the British Bee Journal, which I have received weekly since April. I enclose two samples of heather and ask your opinion on the same, and also on another shrub which my bees are very fond of visiting.—Cymro Bach.

[No. I is the common ling (Calluna vulgaris); No. 2, the cross-leaved heath (Erica tetralix); No. 3, Snowberry (Symphorocarpus racemosus), all noted for their honey-yielding qualities. If convenient, we shall be pleased to receive an account of your method of wiring foundation in skeps.—Ed.]

ONE-POUND BOTTLES.

[1191.]—Your correspondent Mr. E. B. Downes, who writes in the Bee Journal of August 4 (1175), is quite right with regard to I lb. bottles in many cases not holding I lb. I have some bottles from a firm who advertises in your columns, and to my extreme annoyance and aggravation they will only hold 14 ozs., and that in many hardly comfortably. They are decagon-shaped, and advertised in the very Journal Mr. Downes letter appears in, and I consider this note of warning should be allowed to appear in the Journal.

I consider it a very reprehensible practice to make a bottle and call it a 1 lb. bottle when it really holds less. Of course I can only sell them for I4 ozs., but consider the trouble in doing so, the exact price has to be calculated, viz., $\frac{1}{16}$ or $\frac{7}{8}$ of the price of 1 lb., and on any increase or reduction there's another arithmetical calculation; but the worst of the matter is that customers are dissatisfied.—S. J. B.

[Manufacturers of bottles, as a rule, do not understand the nature of honey, and nearly always make the bottles either under or over weight unless they are instructed in the matter.—ED.]

LIGURIAN BEES.

[1192.] I this day (10th August) divided a stock of bees in order to get some queen-cells made. Is it too late? Is there any chance of the queen being fertilised? I have raised seven young queens successfully from this stock this year, which are now all laying, and the carliest batch of three are now at the head of colonies on seven and eight frames full of bees and sealed brood, and I gave them each an additional frame of foundation to-day. The second batch of three are on five frames, each with a good lot of bees and brood, and I gave two a frame of foundation. The other did not want it, as one frame was only just worked out, and have only a little sealed honey at the top at one side. All those were from the one stock. I dare not give a single frame of brood to any of them, but I took a frame of brood and eggs from the parent hive to requeen another hive, and when I divided it to-day it had eleven frames full of

bees and brood. The queen was hatched in '85 from an imported Ligarian. She is fertilised by a black drone, and I raised five stocks from her last year, which are by far the best I have this year. The worst is better than the best of six blacks. None of them ever got any feeding. I did not look at them till the beginning of April, and they were all full of bees and brood, and enough stores. The parent stock wintered on fifteen frames, and they all had the floor-board down half an inch in front, and no doors all the winter. I have raised eleven stocks and requeened another from this queen in two years.—G. J. II.

[The fertilisation of the queen will depend on the presence of drones in your apiary or neighbourhood. In some parts they are still to be seen.—Ed.]

RAISING QUEENS.

[1193.] I should be glad if you would publish the following in your next issue if possible. In your issue of July 14th, page 297, 'Amateur Expert' gives instructions for raising young queens to replace old worn-out ones; and strange to say,—it seemed almost as though I had been communicating with him on the subject,—as at the time I received the Journal containing his instructions I was considering which would be the best way to obtain three young queens, as I was of opinion that my present queens were not so prolific as they might be. I read the instructions very carefully and determined to at once adopt his plan. I went straight to my apiary and selected my best queen, and placed her, under Simmins's direct introduction, in a hive that had an old queenwhich I destroyed—and she was at once accepted. I then followed the advice given, with this exception, that instead of placing the hives apart from the rest I placed them between my other stocks; they were, therefore, only two feet apart, as I was pushed for room: the results further on will show that amateurs with small gardens need not despair.

On looking into the hive, which I had deprived of its queen, I found that I had twenty-two royal cells formed, distributed on four frames, and thirteen of them had occupants; so I decided to raise four queens, and divided the frames accordingly, adding one or two frames of hatching brood from other hives; I then covered up the hives and left them. But now comes a blow to my adventure. In your issue of July 21st, is a letter from 'W. B. Webster,' where, according to his account, I had done wrong; however, it was too late to alter, and I must rest and wait for the result. I may here add that I took good care to well supply the nuclei with plenty of young bees, for I brushed them off the combs in front of the hives, and so I am in hopes that with such care and the hot weather we had that my queens will be

strong, healthy, and vigorous.

The following is the result of my nuclei:—A queen hatched in each; saw two leave their respective hives and returned fertilised, but I did not see the others; however, they are all laying, the last commenced August 11th.

I have taken away my other two queens now and introduced my new queens, and with the fourth I have made a new stock. All the queens have been introduced on Simmins's system, and the bees have been completely mixed up, and they have all made a jubilee meeting of it.—E. Woon, 49 Temperley Road, Balham, S.W.

SLINGING SECTIONS.

[1194.] I offer the following plan for your acceptance, in the hope it may be of use to your readers. Having several partly filled sections to extract from, I have found the arrangement I am going to describe answer well. I put the section into a tin box half an

inch each way larger than the section. The lid fits on one end. I then sling the box in a piece of strong cord and whirl the box round my head, having left twenty inches or so of string to hold it by. Turn the string to the other side and whirl it again.

When both sides have been thus emptied, turn out the section and the honey, leave the section to drain on a dish, and proceed with the next. The tin box I use was one that contained, I think, mustard. It was too long, but right in section, so I cut off the extra length.—B.,

Bideford, August 13th.

GLAMORGANSHIRE AGRICULTURAL SHOW.

[1195.] In your report of the above show I see that dissatisfaction was expressed in regard to the award for extracted honey. I cannot claim to be a judge in honey, but I should certainly have thought that the presence of two or more kinds of honey in an exhibit would be sufficient, in a close competition, to disqualify it for first

place.

I have, however, another complaint to make-namely, in regard to the driving in the bee tent. The lecturer first brought in a skep which it was discovered had one or more combs broken. He did not care for tackling this, so it was returned to its stand and another brought in. A few preliminaries, and the skep was upturned, revealing the presence of a very few bees. Driving commenced, and continued for about ten minutes, with the result that not half-a-dozen bees had gone up. The lecturer gave up the job, explaining his non-success by the fact of there being so few bees. Not to disappoint the onlookers, he again brought in the skep with broken comb. He turned this up, and managed to get about half the bees to crawl up in a very leisurely fashion. The broken comb, the expert now explained, obstructed the upward passage of the bees, so he turned the skep half way round in order to give the bees free egress.

Alas! the bees would not budge. The audience—not a large one at any time-had dwindled to less than a score, and I, after witnessing the expert's exploits for about thirty-five minutes, left before seeing that stock of bees driven. I am curious to know whether the feat was accomplished in the end. I imagine that those who witnessed the operations in the tent were not very favourably impressed by this exhibition of one of the incidents of modern bee-keeping.

It is as well, perhaps, that I (though only a novice) should endeavour to show the lecturer (though an expert) wherein he erred. The weak lot he should not have attempted to drive, for if he had succeeded it would have made but a poor show. Nor should he have placed the inverted skep in a cheese-box, the edge of which came within four inches of the edge of the skep. Nor, again, should his tupping have been so spasmodic. In future let him have his hive so placed that the front may be struck anywhere from top to bottom, and let him strike regularly and without intermission (save when giving a necessary puff of smoke) until all the

bees are driven out. - Welsh Novice.

GLAMORGANSHIRE SHOW.

[1196.] I think it is a pity that your correspondent, in his report of the Glamorganshire Agricultural Society's meeting at Aberdare, had not sent you a correct statement of facts. The honey with which I won the first prize was, as he states, of two different kinds, in colour and flavour, but there was no single bottle different from either of the two samples; each of the six bottles was filled at the same time, respectively from the same extracting, the same straining, and the same jar, so there could not possibly be any difference. I expect your correspondent has either seen or heard of a bottle which I had filled with the two kinds of honey for the pur-

pose of ascertaining their respective specific gravity, and which I brought with others on the afternoon of the second day of the show and sold, but which formed no

part of my exhibit.

A little discussion took place at the time as to whether an exhibit should be uniform, from which I entirely dissented, and promised to endeavour to raise the question in your *Journal*, and shall be glad if readers will state their views. I intentionally exhibited two distinct samples. I could have shown twelve or more pounds of either, but it did seem to me better to show two good samples than one, for it is in nearly all cases as easy to stage twelve pounds of any particular kind of honey as one, and therefore one pound would answer the purpose as well as twelve. If quantity is to be the gauge, then the British Bee-keepers' Association are going away from their true function, and encouraging the larger beekeeper as against the smaller.

I read that the prize to be given for the best twelve pounds of honey is to be taken literally, not for the twelve most expensive bottles, or the prettiest coloured honey, but for the best honey in density, flavour, and colour; of course, giving due regard to the staging; but if an exhibit is to be judged from a purely artistic point of view alone, the sooner we leave the judging in the hands of the Society of Artists the better. My idea is that a proper specimen of what one can produce would be samples of different kinds-twelve if you likeranging over the whole season, commencing with the

fruit and ending with limes and blackberries.

Mention is made of one of the samples in my exhibit being slightly granulated, which is true, and as far as my experience goes, I should say that any properly-ripened honey will granulate this season in a very short time. This particular sample had only been in the bottles about a week, was quite clear when put in, and had only been taken from the cembs a short time before. I certainly think it would be wrong to pass by an exhibit because it was granulating.

As this is the first time I have exhibited honey, I am ignorant of the points to be made, and from what I read in the Journal no rules have yet been laid down for judging; but it does appear to me that this is a point that can be settled, whether an exhibit should be uniform or not.-W. II. Jenkins, Exchange Buildings, Swansea.

QUERIES:—PARALLEL v. RIGHT-ANGLED FRAMES, OR THE 'HOT v. COLD' SYSTEMS.

[1197.] Will any of my fellow bee-keepers kindly give me their experience as to the most judicious placement of combs in hives? Which plan is the more conducive to the health and prosperity of a colony, placing the frames parallel with or at right angles to the entrance? I have raised the question because I was struck a short time since when reading in the British Bee Journal (Vol. for I886) an article by a contributor on foul brood that he had some hives with frames parallel and others with frames at right angles to the entrance. In the former he was troubled with foul brood, while in the latter he was exempt from it. Should this have been more than a simple coincidence, the freedom from disease in the latter case must, I judge, be attributable to the more perfect ventilation. I think, if my memory serves me, it was also stated in the same article that bees, following their own instincts, almost invariably build their combs at right angles with the entrance, ninety per cent of them at least, yet most manufacturers of hives place them parallel with the entrance. This subject appears to me to be one of some importance in this day of wide-spread foul brood.—E. Musgrove, Sidcup, Kent.

[We are fully in accord with your views on this

subject, viz., that the plan of placing frames parallel to the entrance of the hive impedes ventilation and cleanliness, and encourages the propagation of foul brood. Long ago we discarded the system from our apiary. It is always with regret that we see prizes awarded to hives built on this plan. In a natural state nine colonies out of ten will build at right angles to the entrance side. See answer to 'Ligusticus,' Vol. XIV., p. 416 of B.B.J. –E₽.]

THE BEES.

When breaks at morn the beaming light From out the dark and clouded skies, The wakeful bee doth wing her flight, And to the purple heather flies.

There in the rich and nectared heath She finds the sweetest honey store; Though oft her burden sinking b'neath, She ever comes to gather more.

The humming of her drowsy song The while she darts from flower to flower, Floats in the air the bright day long, Till even's calm and silent hour.

And if we might attend her home, And trace her steps as she alights, Might peer into the hidden comb, Surprised we should behold the sights.

Upon the many waxen walls A multitude of toiling bees, All crowded in their narrow halls, Yet moving to and fro with ease.

Here making comb of purest white, There cleaning cells now old and dark, Bee workers working day and night Within their busy, teeming ark.

Whilst others bring the harvest sweet From distant moors, and leas, and fells, Or pollen, stored above their feet,
To feed their offspring in the cells;

Distinguished by his larger form We quickly mark the lazy drone, Of all the thousands in a swarm An idle bee he is alone.

These brown capped cells, with ease we spy, Contain the grub, or sealed brood, Those mealy-looking ones close by Are filled with pollen or bee food.

If eyes are sharp there may be seen, Most likely where the brood is near, Her majesty, the mother queen, Surrounded by her subjects dear.

Unlike the workers, short in wing, In body long, in colour light, Dissimilar in head, and sting; This is the queen who meets our sight.

Moral.

Ye little insects of the hive, In love, and industry, and art, Ye show in life how we should strive Most manfully to act our part. OSWIN B. HEMY.

In order to make a pound of honey, the bee has to collect the sugar that is lodged infinitesimally in two and a half millions of flowers—a fitting image of the infinite number of individual acts and efforts of the will in the way of goodness by which the sweet graces of the Christian character are finally acquired and matured.

Echoes from the Nives.

Limerick, August 14th.—I drove some bees last week. Some of the skeps weighed 66 lbs.; out of ten the average was 48 lbs. On the whole it has been a good year for bees in these parts, though we have now no blossoms; everything is burned, still honey is coming in, and driven bees are working out combs.—Ălba.

Broadstairs, Kent, August 15th.—The season is over now, or nearly so, though the drones are still tolerated—a fortnight later than last year. Swarms have been plentiful in the neighbourhood. I have succeeded in preventing my hives swarming, or, to be more accurate, have not caught them in the act. The chief honey flow came on with a rush, and lasted from 1st to 20th June. At one time late fruit bloom, sycamore, and white clover, were on together, and the bees would not look at a good patch of Limnanthes provided for their express benefit. Then came a period of comparative rest, until about 21st July, and even now a little honey is still coming in. Garden flowers seem to be of little practical value for honey, but are very useful as a sort of 'honey barometer.' If the bee-keeper noticeth the bees turning up their noses at a nice clump of borage he rejoiceth, and ordereth his honey bottles; but when he findeth many bees and few blossoms in his garden, then countermandeth he the honey bottles and procureth a store of sugar. I find Simmins's plan of placing starters in front of combination hives a very good one for preventing swarming, but the bees seem to prefer building them out to working in the sections if honey is scarce.—T. W. OETZMANN.

Chilton, near Thane, Oxon, August 15th.—The honey harvest of 1887 is over. It began late, with a bad spring for bees, and finished about the 15th of July here. The order of the day now is rob, rob from morning till night, there being a great many more bees in the parish than my own. The season has not been up to the average; the limes which abound here being quite a failure, some of them not opening at all. Swarms very few. My returns being-from twelve hives, six frames, six skeps,—three swarms, 350 lbs. of honey, all sorts included. One word as to wasps. I do not agree with one of your correspondents who say they are harmless insects. We are regularly infested with them here, nests in some places within a yard or two of each other; no sort of fruit can rest for them, and if you open a door or window the room is full directly. They carry off the dead bees from under my hives wholesale to their nests, besides robbing the hives and killing the live ones.—H. W. Perkins.

Appleby, near Doncaster.—A correspondent writing from Malvern Links wants to know how Lincolnshire bee-keepers manage to take honey by cwts., as he puts it, asking for information as to number of hives, &c. Like him, I have six hives of the common black bees and three years' experience. This year's result is over six cwts. of honey, including about 300 sections, the rest extracted; a record which might have been nearly, if not quite, doubled had it been worth while to do so, which, with honey at its present price, it was not. The way it is done is very simple, it is merely by the use of Cowan's hives and following the very clear instructions as to their working given in Mr. Cowan's Bee-keepers' Guide. I started with those abominations called Combination hives, but a few weeks' experience and the perusal of the above-named work speedily convinced me of the bad start that had been made, and I began again, discarding the old hives and substituting Cowan's as fast as I could make them. If your correspondent will go and do likewise no doubt the same success will attend his efforts. Black bees, too, seem to the writer good enough; he knows nothing about foreign bees, having had no experience of them, and for the matter of that only three years of any kind, but looking at the state of his hives during the past season he has come to the con-clusion that if any bees are more prolific than the black they must be very prolific indeed, and would want hives six feet high. -H. Dumaneso (Colonel).

Hill Cottage, Sidmonth, August 6th.—There are more wasps' nests in this neighbourhood this season than I ever saw at any time. I have destroyed a great many and shall destroy more.—W. F. H. Majendie.

NOTICES TO CORRESPONDENTS & INQUIRERS.

Letters or queries asking for addresses of manufacturers or correspondents, or where appliances can be purchased, or replies giving such information, can only be inserted as advertisements. The space devoted to letters, queries, and replies, is meant for the general good of beckeepers, and not for advertisements. We wish our Correspondents to bear in mind that, as it is necessary for us to go to press in advance of the date of issue, queries cannot always be replied to in the issue immediately following the receipt of their communication.

All queries forwarded will be attended to, and those only of personal interest will be answered in this column.

H. C.—Weight in proportion to Comb Surface.—See 'Useful Hints,' p. 354.

A. Oxley.—Microscope.—There are many excellent works on the use of the microscope. We can especially recommend Practical Microscopy, by G. E. Davies (7s. 6d.); and Preparation and Mounting of Microscopic Objects, 2s. 6d., by Thomas Davies. Both of these works are published by W. H. Allen, Waterloo Place.

R. Auld.—Unsealed Sections.—You cannot keep unsealed sections until next year. During the present hot summer there is no fear of the honey fermenting after extraction. Allow it to stand in an open vessel for a few days, in a warm room, and skim a small quantity from the surface, when the remainder may be put into glass or other jars and sealed down.

A. P. J.—1. Honey.—The sample of honey is of superior flavour. Speaking generally, we think such honey ought to realise 1s. retail and 8d. wholesale; but it altogether depends on the market it is taken to. 2. Black Honey.— The prevalence of honeydew from aphides is the cause of the dark colour of the honey. Keep Italians, or other Eastern races; amongst many hundreds of sections worked by these bees, we have not an ounce of dark

J. W. P.-1. Rate of Flight of Bees.—There is a difficulty in calculating the rapidity of the flight of bees. Their presumed directness of flight, as indicated by the term bee-line,' is to be accepted with some modification; and refers more especially to the line adopted by them when returning from the fields laden with honey and pollen, as it saves both time and labour. But their mode of flight is 'to skim along in extended sweeps, alternately curving to the right and left.' An instance is given by a traveller of a humble bee accompanying a railway carriage proceeding at the rate of twenty miles an hour, though the wind was contrary, not merely with the same rapidity, but even greater, as it not unfrequently flew to and fro about the carriage, or described zig-zag lines in its flight. The aerial motions of a hive-bee are more leisurely; and they may be estimated to be at the rate of seventeen miles an hour. 2. Distance of Flight .-The general extent of the excursions of bees for forage is a mile. Huber says half a league, which, as a German league is our miles, would be two miles; but this is not borne out hy his own practical observations. In B.B. J., vol. xiv., p. 120, there is an anthentic instance given of Italian bees being found on the heather 23 miles from their hives, and at 983 feet higher elevation; and we have even read of them being seen twice that distance.

T. Nixon.—Dry Sugar.—1. Dry sugar left in the hive during winter is not beneficial for the bees. All feeding for the winter should be completed by the end of September. Towards spring dry feeding may be resorted to in preference to syrup. The sample of sugar is very good, and would be found useful for the purpose of dry sugar feeding at the proper time. 2. Queenless Colony.—Most likely, as there is almost sure to be a colony having drones somewhere near. 3. Pitched Paper for Quilts.—No; use American cloth, having as little smell as possible. The smell of pitch is obnoxious to bees. 4. It is not used for the purpose. You can buy the paper already prepared at a nominal price. It is kept in stock by all good paperhangers; they use it as a first coating for damp walls. 5. Sugar Bags.—These answer the purpose very well. We should place eight or ten thicknesses.

E. Shotter.—I. Becs.—The bees forwarded are hybrids with very slight indications of foreign admixture. so-called black bees have acquired their special black shiny appearance through having lost their pubescence either from old age or disease; but they are not a different variety from the others. 2. Black bees.—'The handful of black bees, headed by a good queen,' have very probably contracted the disease called Bacillus depillis, or Gaytoni, and are gradually dwindling. 3. A Pound of Bees.—If your pound of bees consist of driven bees, we are afruid that you will not be able to rear them into a stock; but if the bees are of a cast of that weight with care they will pass through the winter, and in the spring may be raised into a useful stock.

J. J. H.—Foul Brood.—Presuming that you gave your bees the Cheshire Cure you would have great difficulty in getting them to take it at this season of the year if there is any amount of honey in the hive. Another disadvantage is that some of the honey is capped over and would be used in feeding the larvæ next spring. In this honey the germs of the disease lay dormant; therefore if you cured them now upon this honey being used you would have the disease again next year. Phenol will without cure 'foul brood' if the queen is not affected. By taking them to the moors in their present condition you would be committing a great injustice to your fellow bee-keepers whose hees are there; in fact, it is in a great measure owing to this description of carelessness—we might use a stronger expression—that the disease is spread abroad. Your best plan is to place the bees of both colonies in a well-ventilated box for twenty-four hours, then into a clean hive upon foundation, feeding them as fast as possible on syrup and the Cheshire Cure; it is rather late in the season for this: the combs of the affected hives to be melted down and the honey either boiled or destroyed, preferably the latter. If you use your hives again, and there is no reason why you should not, thoroughly saturate them inside and out with carbolic acid solution. This should be made by mixing together equal quantities of Calvert's No. 5 and glycerine, three ounces of each; then pour two quarts of boiling water upon it, stirring well. Do not let this solution get upon your hands, or it will cauterise them. Expose the hives to the air until the smell has passed off. Burn the old frames and quilts, as these can be easily replaced

F. Jewell.—Observatory Hives.—Unless the hives were seen by us it would be impossible to give an opinion. So much depends upon the 'get-up' of the hive; the condition and building of the combs, also the quantity and quality of the bees. No doubt the judges gave their awards in proper order to the hives whose relative qualities—taking the above as their standard—ranked foremost.

G. Hudson.—I. Dees near House.—It is not likely that the position prevented their working. 2. Moving half a mile.—Wait until November and then you may move the bees without loss. 3. Earthen Pans for Honey.—Honey will keep better in an earthen pan than in any other vessel; paper will do to tie down with.

Young Beginner.—I. Extracting.—After extracting from four out of ten frames place two of the emptied combs in the middle of the others and feed gently until the end of this month, then rapidly for a fortnight, or until sufficient stores are sealed. 2. Robbers.—Having contracted the entrance the bees will be able to repel attacks, and the dead bees which you see are the strangers who are trying to rob.

ALBA.—I. Honey and Pollen.—If you pass honey and pollen through a patent honey squeezer, the former will be tainted by the latter. 2. Obstinate Honey.—Cut the comb into cubes and place in a conical bag before the fire, and the honey will exude.

RECEIVED from Mr. H. W. Perkins, Chilton, near Thame, Oxon, a bottle of extracted honey. We beg to thank him for trouble taken in forwarding it. The honey was of an excellent quality, and of good consistency and flavour.

Bee Swaeming Extraordinary.—A swarm of bees took possession of the shop of Messrs. Thos. Fraser & Son, High Street, Dunbar, on Tuesday morning, July 19, and by their presence caused not a little inconvenience to the immates, as well as temporary stoppage to trade. Two skeps were soon filled and taken out, still the shop swarmed with bees for the remainder of the day.

Show Announcements.

Giving Name and Address of Secretary, Date and Place of Show, Date of Closing Entries. Terms: Three Insertions and under, Two Shillings and Sixpence; additional insertions, Sixpence each. No charge made to Associations whose Shows are announced in our general Advertising Columns.

Two Hundredweight Sugar for Feeding Bees, pure Cane, 20s. per cwt., 11s. 56 lbs. Address Hon Sec., Northants B. K. Association, St. James', Northampton. Λ 83

BEE TENT for Hire. Apply Hon. Sec., Northampton. Bee-keepers' Association, St. James', Northampton.

WANTED. — Becs. Three lots. Vigorous Queens. Weight 5 lbs. each. Address B., Ivedon Cottage, Springfield Road, Kingston-on-Thames.

DRIVEN BEES, 1s. per lb. Packing extra. A district where Foul Brood is nnknown. Address E. Garner, Broom, near Biggleswade, Beds.

TOCKS OF BEES.—Have to Sell for an old Cottager, now too feeble to manage Apiary, 12 large, well-made Straw Hives, full of Honey and Bees, 12s. 6d. each, or £7 the lot. Address S. S. Goldsmith, Boxworth Rectory, St. Ives, Hunts,

A DVERTISER will give 1s. per lb. for Driven Bees, safely packed. Address Douglas Cooper, Normanton, Derby.

TAKE NOTICE.—A rotten bad Stock of Bees in Barframe Hive (Abbotts') to be sold Cheap. Price £1 5s., or as much more as the Purchaser likes to fork out. Address W. Ruhl, Swanmore, Bishops Waltham.

INTRACTOR WANTED.—Exchange ninety-eight 3d. numbers Journal of Horticulture from Aug. 1884 to 1886, December or offers in Bee Furniture. Addres W. Hunkin, Poole, Dorset.

OR SALE.—British Bee Journal, half-bound. What offers? Extractor or Bee Furniture. Address W. Hunkin, Poole, Dorset.

POR SALE.—Six Strong Heavy Stocks of Bees 12s. each. Cash offers invited for Honey in 1 lb. sections. Address Maltson, Covenham, near Louth, Lincolnshire. a 91

Price 11. per stock. Address X., Offenham, Evesham,

AGIC LANTERN SLIDES for Sale on Natural History of Bees. 34 Slides $3\frac{1}{4} \times 3\frac{1}{4}$, 20s. Address J. H. Atkins, Naturalist, Dunmanway, Cork.

WANTED Prime Quality I lb. Sections Honey. Address stating price to White, c/o W. T. Joyce, Farnborough, Hants.

AX EXTRACTOR (Blow's) for Sale, as Good as New. Cost 15s. Will take 7s. 6d. Address A. Wood, Esq., Bellwood, Ripon.

AYNOR EXTRACTORS.—A few last year's make of I we machines at 21s, to clear out. Greatly improved for present season. See British Bee Journal for July 28. Address W. P. Meadows, Syston, Leicester.

THREE RAYNOR REVERSIBLE 30s. EXTRACTORS for Sale, Meadows' make, price 25s. each, or 24s. each if the lot are taken.

MARKETING HONEY.

That is the very thing we want to know about! It has been said we are a nation of shopkeepers; that is daily getting less true of us, as we are fast becoming, if we have not already attained to the position,—a nation of costermongers. The question now is, not what a certain thing cost to produce, but what will it fetch. Honey is no exception to this rule. The trouble of 'raising' it, with many, is a small thing compared with the trouble of disposing of it after it is raised. You can rush off to the Honey Company of course, as many did in the fall of '85, to the benefit of its shareholders and the injury of your pockets, but if you want a good price you must take a little trouble, and, what is by no means a small factor in the business, use your wits.

This is a day of 'putting on the market.' Look at your match-boxes, go and buy a farthing's worth of pins; turn where you will, from artists' colours to Nubian blacking, or from Yorkshire relish to Pears' soap, the package looks as if it cost the largest half of the money. The British Honey Company was not slow to take the hint, and Mr. Woodley soon followed suit, so that if we want show-cases for section honey, we have them already provided to our hands; and what I want to press upon you is, if you wish to get a good price for your honey, you must resort to some such device to secure it.

Your first aim must be to make a name by always putting up your goods in the same style, which will in time become a kind of trade-mark. If it is extracted honey, always use the same shape and size of bottle, even to the style of your screw cover, and the colour of the string you use to tie down your parchment if you use the 'tie-down' bottles. The same rule applies to the sections, you must use the same kind of fancy boxes, or, if you prefer to 'dress' your sections yourself, as I told you last year I do mine (see page 407 of last Vol.), you must always keep to the same style, and perhaps it may be beneficial to use only one colour paper. For labels you cannot be too neat. Have your own

distinctive mark by all means, but do not attempt to copy the Canadian lobster tin labels.

There is another matter which is of far more importance, it is *cleanliness*. Let everything go out of your hands as if fingers had never touched it; let the wood of your sections be as white and spotless as when they left the planing machine; clean off every speck of propolis; and last, and most important of all, so fix your foundation, be it whole sheets or only guides, so that when it is cut out of the section and laid on a dish preparatory to going on the table, there is not a long, dirty patch of something indescribable to mar the appearance of the luscious slab of honey, and bring discredit to your fair fame. These remarks may seem frivolous, but allow me to assure you they are no mean items on the narrow and thorny road to success.

If there are any local gentry in your neighbourhood, try to induce them to buy. If they only take a small sample, do not be discouraged; if it is what it should be, they will come again. As to price, do not open your mouth too extra wide; if you do, Nemesis will be on your track, and that market will be spoilt for you for ever. Now go to a respectable grocer, or chemist, or Italian warehouseman; do not ask him to buy, but ask him to sell for you. Offer him twenty per cent discount on what he disposes of, you to keep up his stock to a certain amount as he disposes of it, and he to pay you for what he has sold on the first of every month. Give him to understand he need not sell the showcases, but keep the sections in them as a protection, and if any of his customers prefer to take eases, they will be the price of the cases extra. If he is a tradesman with whom you can profitably deal, and you can take his groceries instead of money, all well and good; but that is a matter for your personal consideration. After a season of this arrangement, you will most likely find he will prefer to buy of you, and run his own risks, and get what discount he chooses to fix, but your great point is to get him to start. The more respectable his customers, and the more prominent his business position, the greater your chance of success, and the larger the discount probably he will require.

This is no new fancy eliminated from 'A E.'s' cranky brain, but has been successfully worked for the past three years under the eyes of—AMATEUR EXPERT.

METEOROLOGICAL OBSERVATIONS FOR JULY.

The summary of meteorological observations at Hodsock Priory, Worksop, Notts, has been sent to us by Mr. Joseph Mallenger. During July the mean temperature was 63.8°. Maximum on the 3rd, 85°; minimum on the 6th, 37.7°. Maximum in the sun on the 15th, 139.2; minimum on grass on the 18th, 31.5°. Mean temperature of air at 9 a.m. 66.7°. Mean temperature of the soil 1 foot deep, 63.5°. Total duration of sunshine in month, 228 hours, or 44 per cent of possible duration; no sunless day. Total rainfall, 146 inch. Rain fell on ten days. Average velocity of wind, 8.3 miles per hour. Velocity exceeded 400 miles on one day, and fell short of 100 miles on five days. Approximate averages for July—Mean temperature, 612; rainfall, 2:36 inches. Sinshine (ten years) 163 hours. A very bright, warm, and rather dry month. The mean temperature is higher than any previous year since 1876. Sunshine more than any of the previous six years. Rainfall small, but not exceptionally so; coming, however, after a very dry June, the deficiency was more noticeable. During the past six months only 6 inches of rain have fallen, as compared with an average for the period of $11\frac{1}{3}$ inches.—Journal of Horticulture.

ASSOCIATIONS.

ABERDARE FLOWER SHOW.

The show of honey which was held in connexion with the above show on August 18 was a distinct improvement on last year both in quantity and quality. Nearly half a ton was staged, and with few exceptions was put up in a much more attractive form than it was last year. The section honey shown by Mr. Guy, of Cardiff, was a capital exhibit, the sections being well filled and even in

appearance.

In the class for the largest collection of extracted honey the prizes were taken by some very good honey, mostly white clover, but it would be advisable if the committee could see their way to defining the class more strictly, as the judges had to decide between the merits of two exhibits, one containing 300 bottles of dark-coloured honey, which had already begun to granulate, and a much smaller exhibit of some sixty bottles of first-class white clover honey. The rules defined 'largest and best,' but the judges were unanimous in awarding the prize to the best rather than to the largest.

In the class for twelve I-lb. sections there was no difficulty in awarding the prize to Mrs. Price, as her sections were very much superior to any of the other ten exhibits. In the class for twelve I-lb. bottles Mrs. Price was again successful. The second prize was awarded to Mr.T. W. Rake, but it was pointed out to the judges after the prizes were awarded that there was some dust in the honey, due probably to the bottles not having been properly cleaned; but the honey was so superior in tha our to all the others except the one which was highly commended, that even if the judges had perceived the defect it was so slight that its position in the prize list would not have been altered.

During the afternoon manipulations took place in the bee-tent, and the modern system of bee-keeping was

explained to large and attentive audiences.

Two candidates were examined for third-class expert's certificates, and W. W. Williams, 14 High Street, Newport, passed a highly-satisfactory examination, his driving and manipulation being extremely good. The other candidate passed in driving, but failed to find the queen until some time had elapsed.

It would be an advantage if the rules for examinations were not quite so strict, as this candidate was as well qualified to act as expert as many whom I have passed. There always must be a certain amount of luck in examinations. One candidate may find the queen on the first comb he picks up, while another may have to look

through nearly all the combs until she is found. As the examinations are held all through the country, and the Education sub-Committee have not them under their immediate control, rules, no doubt, must be made; but it would be an advantage in those cases where the examiner was satisfied with the knowledge of the candidate, even if he had not passed according to the regulations, to refer the matter for the decision of the Educational sub-Committee.

The following is the prize-list:—Class I. For the largest and best collection of super honey: 1, W. Gay, Cardiff; 2, James Lewis, J.P. II. Ditto, extracted, in I-lb. or 2-lb. bottles: 1, G. H. Rake, Ysenborwen; 2, E. Richards, Talyillyn. IH. Twelve I-lb. sections: 1, Mrs. Price, St. David's Vicarage, Brecon; 2, Miss Price, Brecon. IV. Twelve I-lb. bottles extracted: 1, Mrs. Price; 2, G. H. Rake; H.C., Miss Price. V. Best samples of beeswax, not less than 2 lbs.: 1, Mrs. Price; 2, Miss Price. VI. Best kephive of bees within a radius of three miles: 1, James Lewis, J.P.; 2, D. P. Davis, Commercial Street, Aberdare. The judges were Mr. Thomas, Ysenborwen, and—Geo, Walker, Wimbledon.

WELLINGTON (SOMERSET) COTTAGE GARDEN SOCIETY.

The above Society held its annual meeting at the Town-hall, Wellington, Somerset, on Friday, August 6th. The hall was tastefully adorned with flags, and the arrangement of the cottagers' exhibits was very creditable and effective. Besides the flowers and vegetables there was an exhibition of honey. Though not very large, we were pleased to see it as indicating the interest taken by the cottagers in that part of the country in this industry; and though small, there being but six exhibits, we have hopes that it may be increased on some future occasion. Most of the exhibitors had made use of large bell-glasses for having their surplus stored in, but happily this is a plan now becoming obsolete in this country, thanks to the efforts of the British Bee-keepers' Association and its many branches scattered throughout the shires. Combs worked in bell-glasses have to be cut in pieces before they can be used, whereas the same weight of honey stored in a crate of sections is available for use at any moment without damage or mess, as could be seen by the specimens on the table. There were some fine diagrams and a set of beautiful Italian plates exhibited, illustrating the anatomy and physiology of the honey bee; also several small glass cases containing specimens of various kinds of comb, queen-cells, &c., the society being indebted to Mr. C. Tite, Shutes House, for this part of the honey exhibition. But it was evident that the local bee-keepers have yet much to learn, and that there is a fine field open in the neighbourhood for a new branch of the Somerset County Bee-keepers' Association, when the honorary Secretary (Rev. C. G. Anderson, of Otterhampton, Bridgwater) can spare time to set it afloat. Two excellent bar-frame hives were sent to the show by Mr. Edward Pyne, hive-maker, Yeovil. They were admirably made, well finished, and contained the latest improvements. Moreover, one of them was offered at a price that will meet the requirements of intelligent cottagers, for whom bee-keeping in the rural districts offers a source of much pleasure and profit.

SOMERSET COUNTY BEE-KEEPERS' ASSOCIATION AT TAUNTON FLOWER SHOW.

The twentieth annual show of the Taunton Deane Horticultural and Floricultural Society was held on Thursday, the 11th inst., in Vivary Park, Taunton, and notwithstanding the dryness of the season the exhibits in all departments were of extraordinary excellence. The interest manifested in the exhibition by the inhabitants of the town and county showed no falling off, and throughout the day the Park was visited by several

thousand people.

The exhibition of hives, honey, &c., was a great advance on previous years, both in the number and the quality of exhibits. The principal exhibitors of apicultural appliances were Messrs. Abbott Bros., of Southall, who sent a collection containing almost every article that bee-keepers can require, or fancy they require. Messrs Abbott's articles were good in quality, reasonable in price, and admirably arranged. Next to them came Mr. E. J. Butt, of Barnstaple, with a smaller but useful collection, which took second prize. Mr. C. Lewis, of Taunton, sent a number of cheap plain hives, but not for competition. Mr. Edwin Pyne, hive-maker, of Yeovil, also sent two excellent hives, one for well-to-do amateurs and the other for cottagers. The show of honey was also large and good. The chief exhibitor was the Rev. H. F. S. Gurney, of Stoke St. Gregory, one of the principal bee-masters in Somerset; but the most attractive exhibit was that sent by Mr. William Peirce, of North Petherton, a charming collection of comb and run honey, admirably put up. The increased number of exhibitors in this department must be most cheering to the Rev. C. G. Anderson, the honorary secretary of the Somerset Bee-keepers' Association, who has laboured most assiduously for years past to popularise bee-keeping in the county, and to Mr. W. B. Maynard, the zealous secretary of the local branch of the Association. A very interesting and attractive feature of the bee show was the observatory hives. Messrs. Abbott Brothers took the lead here again with a splendid and novel hive, containing six frames stocked with the beautiful Italian bees. The Rev. C. G. Anderson was second with a welleonstructed observatory of the ordinary type, but containing many improvements and several most interesting features. Altogether the bee and honey department was most attractive, and the large tent devoted to it was erowded with spectators. The manipulations were held in a separate tent and were conducted by Mr. John Ayres, of Southall, the Rev. C. G. Anderson giving the descriptive lectures and answering numerous questions.

The following is the prize list:—

Honey, &c.—Best collection of honey-comb and run, from one apiary—I, W. Peirce, Bridgwater; 2, Rev. H. F. S. Gurney, Stoke St. Gregory; 3, Miss E. J. Elliott, Taunton. For the best exhibit of sectional super honey. each section not to exceed three lbs. in weight, the total weight of each entry not to be less than twelve lbs.-1, Rev. H. F. S. Gurney; 2, Miss Elliott; 3, Henry Perry, Williton. For the best glass super of honey—I, W. Hawkes, Newberry; 2, W. W. Jones, Williton. For the best straw super of honey-1, J. Taylor; 2, E. Cattle. For the best exhibition of run or extracted honey in glasses, each glass not to exceed three lbs. in weight-1, William Peirce; 2, J. E. Heydon. Best observatory hive with a complete stock of live bees, all combs to be visible on both sides-1. Abbott Brothers; 2, Rev. C. G. Anderson.

Offered by the Somerset Bee-keepers' Association.— Best and most complete collection of hives and bee-keepers' appliances—1, Abbott Brothers: 2, E. J. Butt, Barnstaple. Best stock of bees in straw skep for manipulating combs not to be less than two years old-1, H. Riddles, Staplegrove;

2, F. Jewell, Bridgwater.

MAER (STAFFORDSHIRE) FETE AND HONEY SHOW.

This, the first show at Maer, proved to be a decided success, both in the number and quality of the exhibits, especially in Classes II. and IV., which were very good throughout, and this success ought to be an incentive to future efforts in the same direction.

The work of judging was entrusted to the Rev. G. R. Bailey, of Madeley, Staffordshire, a gentleman who takes a lively interest in matters of this kind. Mr.

J. R. Critchlow, Hon. Sec., being an exhibitor; Mr. Bilton, a member of the fete committee, was appointed steward to accompany the judge in making his awards and attaching prize cards. Mr. Bailey, finding it a difficult task to finally decide some of the awards, as some of the exhibits were so near in quality, called in the assistance of Mr. Rollins, expert to the S. B. K. A., and their awards gave general satisfaction. Mr. Critehlow's exhibit included section displaying the letters 'S. V. R. 7," he also stagel 'J. R. C. Pure Honey, but not for competition. The Steward and Hon. Sec. of the show are to be complimented upon the admirable manner in which the arrangements were carried out. The S. B. K. A.'s bee-tent, in which Mr. Rollins, the expert, manipulated bees, was a centre of attraction during the afternoon and evening.

The following are the list of awards:-

Class I.—For the best twelve I-lb. or six 2-lb. sections: 1. J. R. Critchlow, Maer Farm; 2, H. Wood, Lichfield; 3, S. B. Fox, Maer. V. H. C., Mrs. Vawdrey, Maer Vicarage.

Class II.—For the best exhibition of I2 lbs. of run or extracted honey in glass jars: 1, E. Clowes, Blackbrook; 2, G. Arkinstall, Whitmore; 3, E. S. Hinchliffe, Mucklestone. V. H. C., T. Bailey, Whitmore; and Jos. Thompstone, Shortwood; and the judge commended the whole class, which consisted of fifteen exhibits.

Class III.—For the best exhibition of not less than 2 lbs., nor more than 5 lbs. of pure beeswax: I, J. R. Critchlow: 2, Edward Clowes, Milton; 3, T. Bailey,

Whitmore.

Class IV.—For the best exhibition of honey in any form not to exceed $\frac{3}{4}$ ewt. in weight: I, and silver medal of S. B. K. A., E. Clowes, Blackbrook; 2, and bronze medal, S. B. Fox, Maer; 3, J. R. Critchlow. V. H. C., II. Wood, Lichfield, and G. Arkinstall, Whitmore.

Correspondence.

The Editor does not hold himself responsible for the opinions expressed

The Editor does not hold himself responsible for the opinions expressed by his correspondents. No attention will be taken of anonymous communications, and correspondents are requested to write on one side of the paper only, and give their real names and addresses, not necessarily for publication, but as a guarantee of good faith. Plustrations should be drawn on separate pieces of paper.

Communications relating to the literary department, reports of Associations, Shows, Meetings, Echoes, Queries, Books for Review, &c., must be addressed only to 'The Editor of the 'British Bee Journal,' clo Messys. Strangenays and Sons, Tower Street, Cumbridge Circus, W.C.' All business communications relating to Advertisements, &c., must be addressed to Mr. J. Huckle, Kings Langley, Herts (see 2nd page of Advertisements).

**** In order to facilitate reference, Correspondents, when speaking of any letter or query previously inserted, will oblige by mentioning the number of the letter, as well as the page on which it appears.

LINCOLNSHIRE BEE-KEEPERS' ASSOCIATION.

[1198.] In reply to report of the above in Journal of 28th July, page 322, I am exceedingly sorry that the Association is in such a ruined state, as it has in the past been productive of much good. For some years the members in this district, which at one time numbered about seventy, have been falling off, for the simple reason they wanted to know what they were contributing to.

I am not aware of any report since 1880, and at the present I only know of two members left. I enclose the rules, scarcely any of which have been carried out for years, and at the present time I only know of one officer left (the Honorary Secretary). There are some beekeepers in this district with a good knowledge of their work, who are doing their best in the advancement of apiculture and who are ready at any time to as-ist in the formation of a new Association upon sound principles. I shall be glad to know the feeling of the other districts upon the subject. I may say we have a gentleman of alluence and ability in this district, who, I think, might be prevailed upon to act as Secretary in the formation of

a new Association with the assistance of the B.B.K.A. —NORTH LINCOLNSHIRE.

[We think it would be a great misfortune if so good an Association as the Lincolnshire were suffered to lapse. According to the rules sent us, there has been no Association for several years. We should think there would be no difficulty in re-constructing the Association. Write to the Secretary of the B. B. K. A., who, we feel assured, would be pleased to assist in so useful a work.—Ed.]

· THE HONEY CROP AND PRICES.

[1199.] This is the heading of a few lines in *The American Bee Journal* of August the 10th, which I think may with advantage be copied into the *B. B. J.*, that your readers may see that we may reasonably hope to get a fair price for the very small 'honey crop' harvested in the United Kingdom, as the market is not likely to be glutted with new honey from the United States or from Canada, where the crop is also very short.

'We have several times cautioned those having any honey to sell to hold back for the advance in prices, which must surely come very soon. In reference to this matter, Mr. S. F. Newman, of Norwalk, O., writes as follows:—"The honey crop in this section is almost an entire failure. Probably about one-tenth of a crop has been gathered. There is no question as to the advance in price. It certainly will reach 20 cents within sixty days." What little hope there was for a fall crop is daily dwindling. The extremely hot and dry weather has 'burnt up' almost everything, and all crops are suffering, and prices of every crop are advancing. Do not sell any honey until the end of September, is the best advice that can be given. Really, this year's crop of honey is but little, if any, more than will be required for winter stores for the bees, if used for that purpose. Prices should be doubled at least within two months.

In the same number of the A.B.J. there are reports

from different States, as follows:-

'No Surplus Honey.—E. Liston, Virgil City, Mo., on July 26, 1887, says: "In this part of the country the surplus honey crop for 1887 is a ruineus quantity. Unless it is extremely favourable for fall production, it will be as nearly a failure as we have had for eighteen years."

Half a Crop from Basswood.—Edmund R. Buller, Campbellsport, Ont., on July 26, 1887, says: "Bees have done very poorly here this season. Clover and basswood have not produced more than half a crop, owing to dry, hot weather. Basswood trees were loaded with bloom, yet many of them were scarcely touched by the bees. There will be very little fall honey if we do not get more rain soon."

'No Honey, &c.—V. W. Keeney, Shirland, Ills., on August I, 1887, says: "I have not taken one pound of honey from forty colonies, and had only one swarm. I have been waiting for some time to see the 'big' reports come in, but everybody seems to be quiet this season. There is no honey in this part of Illinois, and a good prospect to feed the bees and all other stock soon."

As there does not seem to be any fear of foreign competition, those who have honey to dispose of should hold for fair prices, and not rush the honey into the market all at once to their own disadvantage.—John M.

HOOKER.

LEE'S SECTIONS.

[1200.] I beg to send you herewith one of Lee's Patent Sections, that you may see the perfect way in which it is filled without pop-holes. I obtained a few of these sections through the kindness of a friend, and they were put on the hive quite the tail-end of the white clover harvest, and before the major part of the heather came into bloom.

The one sent is a fair sample. The ready way the

sections were put together, and full sheets of foundation fixed, was quite a treat, after the old way of fixing with melted wax. I am sure one trial will be sufficient to satisfy any practical bee-keeper of their superiority over all others, if they can be obtained at a reasonable cost. Had I used these sections exclusively, the superior appearance and uniformity of the comb and rapidity with which it was built out would have very considerably increased my receipts.—WM. Soar, The Apiary, Chobham, near Woking, Survey.

[The sample received fully bears out the above statement. It is perfectly even, and pop-holes are absent. The honey was most delicious. We had on Saturday last the pleasure of meeting Mr. Lee at the Exhibition of the Middlesex B.K.A. at Southgate. He had with him some beautiful specimens of one and two-pound sections, worked out in his new sections; they were from the apiary of the Rev. G. Raynor, of Maldon, Essex. These were simply perfect in colour and evenness, and with no pop-holes. Mr. Lee speaks very hopefully of his ability to produce his sections at a cost which will enable him to compete with those imported from America.—Ep.]

EFFECTS OF A STING.

[1201.] A few days ago my wife was stung on her head by a bee, and in a very few minutes she felt a fearful irritation like nettle-rash from head to foot, and then commenced to swell, especially about the neck and face, and then followed faint and sickness, which continued for some hours. Will you kindly tell me what is the best treatment in such cases? I may say she is fond of a few stings, but has never had such serious effects before.—W. Elfred.

[A case like the above is, happily, not very common among bee-keepers. It is known in medical language as *Urticavia*, or nettle-rash, and often follows from eating shell-fish, cucumbers, mushrooms. &c. The recipe of a lotion which may be used with advantage if the nettlerash appear will be found in vol. xiii. p. 235. The other portion of your letter will be forwarded to the Secretary of the British Honey Company.—Ep.]

BIRDS, REPTILES, AND BEES.

[1202.] It has been for some time rather a vexed question as to whether the graceful-flighted swallow is an enemy to our busy little labourers, the bees. Having now a good opportunity of noticing the behaviour of various birds in their attentions, or not, to bees, I have come to the conclusion that swallows cannot be placed in the category as apicides-excuse the coining of this word. My apiary is situated in a meadow adjoining the garden, and separated by a quickset hedge; it is railed off from this meadow by a wire fence, the top wire of which is barbed in order to prevent the curiosity of the cows leading them to a too close aequaintance with the hives. Upon these wires sometimes as many as four or five thy-catchers (Muscicapa grisola) sit waiting for their prey. I shall procure some of them, and examine their erops. The red-backed shrike (Lanius collurio) sits on the posts, and, I am strongly of opinion, impales my bees on the barbs of the wires, as in two instances I have found the abdomens of workers so situated. But it is more particularly to the swallow tribe that I have given my attention. I had failed to notice any act on their part that would lead me to suppose any damage might be done by them to the bees, and now, so far from supposing such to be the ease. I find that the bees themselves are obnoxious to the swallows. Being a dull, eloudy morning, I stood watching a party of swallows, both chimney swallows (Hirundines rustica) and house martins (*Hirundines urbica*), hawking around over my hives. The morning was favourable for observation on account of the absence of any glare of light, so that their

motions could be followed with ease as they swooped over head or anon glided along close to the ground over the meadow. Not a single bee did they catch; numbers were flying around; but guess my surprise when I saw the bees 'go for' the swallows. Their attacks were skilfully avoided: sometimes two bees would follow a single swallow round and round, but seemingly unable to overtake it in its swift aerial flight. The swallows evidently disliked the bees attentions, as they frequently avoided them by doubling away from the point of attack. This continued for some ten minutes, until at last the swallows took their departure, evidently dissatisfied with their reception. I noticed the same thing occur with a starling (Sturnus vulgaris), two bees chasing it as it flew across the apiary; they may have thought it was a swallow, but the starling never deviated from its course, evidently taking little notice of its irritable pursuers. Although there are numerous tits (Parus major, P. caruleus, P. caudatus, and occasionally P. ater), I have not seen one attempt the life of a bee; but no doubt, when other food gets short, they will commence their depredations: any eaught actually at this work will have short shrift given them. Toads are exceptionally numerous, but although many of my alighting-boards touch the ground, I have not yet seen any at their, I know, favourite occupation—licking up the bees. These batrachians are of great use in a garden, watching under a broad leaf or stone for any unwary insect that may happen to pass by; and so until I see special ones watching my bee-hives I let them rest in peace. One fat gentleman has become quite tame, and will scarcely move without being poked along, his favourite spot being under the door-step of my office. Sometimes he will venture to invade its precincts, but although there may be several bees crawling near he has not in my presence tasted one.-W. B. Webster, Binfield, Berks.

FOUL BROOD-DEAD BROOD.

[1203.] Again and again this subject crops up, and one hears of whole districts plagued with the dreaded malady. Dreaded, I say, because it is now and ever will be a dark cloud hanging over our industry, when we consider what a number of bee-keepers there are who cannot, or do not care to take the trouble to put a stop to it.

Was not Mr. Cheshire's remedy to drive the scourge from all apiaries? and did we not hail his discoveries with rejoicing? Yet why is it so few have been able to cure by the phenol treatment, and others report that it is of no use? The present state of things shows that either the treatment is not carried out as Mr. Cheshire has advised, or else that he himself overlooked some factor which gave him an advantage; while his followers have been unable to grasp the entire subject in consequence of this one point not being brought before their notice. The fact is, my esteemed friend does appear to have overlooked a matter of the greatest importance which gave him a decided advantage over those who attempt to follow him.

It will be remembered that Mr. Cheshire had a very badly diseased hive provided for experiment, and it is in just such a state that many allow their hives to get before they become aware of the trouble. But note this: there were very few bees and no queen. And what did Mr. Cheshire do? He gave them a young healthy queen and two frames of clean brood. Why, reader, here was health to start with, and then by feeding constantly with medicated syrup, the operator would have it all his own

The healthy bees would have little trouble in removing the disinfected foul brood, as I am aware from the fact that under certain conditions the original inhabitants will clear out the filth without it being disinfected. During my own experience some ten or twelve

years since, I found that a populous colony would throw out every vestige of diseased brood if the queen were removed. I have also found since, where any bees happened to be bought having the disease, that by removing the queen and inserting a cell from clean stock, on the point of hatching, every particle of the putrid matter has been removed by the time the young queen was ready to breed; the disease again appearing, but with less virulence, until medicine was given.

It will be readily seen, therefore, that where a bad case will not give way all the time the original queen is allowed to continue, a change to a young and vigorous mother will impart energy and determination to the workers, and then Cheshire's remedy will never fail.

Where the bees are so reduced as to be unfit for broadrearing, of course they are not worth the addition of a new queen and more bees or brood, but should be immediately smothered, and the combs burned or reduced to wax. On the other hand, it will probably be found that when a stock is not very badly infected, the feeding of phenolated syrup, or its injection into the cells when the bees will not take it, will be found effectual without removing the queen. Another point which appears to have escaped notice is that all sealed honey must be uncapped and likewise disinfected, or the disease is likely to reappear from time to time. Where there is much sealed honey, uncap a portion only at a time, and if possible do not contaminate the extractor.

What is done should be done thoroughly, and experiments left to be carried out by those who can afford the time, and have nothing to fear from risk of infection.

Mr. Ward of Highgate, when visiting my apiary, stated that he failed to cure with phenol until the original queens were removed from his infected hives, and others from clean stock inserted. Notwithstanding, therefore, that Mr. Cheshire considered it a great disadvantage to have received his diseased hive without a queen, it was the one thing that ensured success, in that he gave a healthy queen as well as clean brood.

It would appear therefore, that when a queen is badly diseased, the phenol treatment does not renovate her impaired constitution. The workers probably are cured by taking the medicated food: but just here is the point: Does the queen, or does she not, receive the phenol in the food prepared for her by the workers. Perhaps Mr. Cheshire will pursue his investigations farther, and benefit us all by giving some definite information upon

That phenol is a cure for foul brood is certain, that it gives health to the workers appears equally true, and that in future it will prove effectual in every case, I feel convinced, if the queen is superseded when the disease does not at first give way.

Dead Brood.

That foul brood is often confused with simple dead brood I am well aware. The latter I have observed oceasionally, and have never allowed it in any way to interfere with necessary manipulations, such as uniting, queen-raising, &c., as I have no fear of communicating disease. At present I am unaware of any cause for this, unless it be weakness of the queen, as by inserting a fresh one, all is cleared out, while no more is found, and no medicine is necessary.

HOW TO DISTINGUISH BETWEEN THE TWO.

In some respects the two are similar, much of the larvæ turning rotten, and of a dark colour, while the bees seem unable to remove such as is in that state until the weak queen is taken away. Nevertheless, some of the matter being placed under the microscope, Mr. Cheshire was unable to find the slightest trace of

But that every bee-keeper may decide for himself without the aid of a microscope which is the genuine foul

brood and which not, I will show how I have always been able to detect the difference. With simple dead brood, while some may appear like the foul disease, much of the older brood dries up to a white cinder, in many cases retaining its original form, which I have never found to occur when genuine foul brood is present. Chilled brood can be distinguished from the more serious malady in like manner.—S. SIMMINS.

THOUGHTS ON PASSING TOPICS.

[1204.] Wasps.—You said you would like to hear from different parts as to the scarcity, or otherwise, of wasps. I write to tell you that my prophecy, published in the Journal, has been fully verified here, for they have appeared in thousands. My honey-shed swarms with them, although bees do not seem able to force an entry. I have just heard that a person who gets his livelihood by catching eels in the river has taken no less than 150 rasps nests within the last few days. In dry weather when worms are scarce he uses the larvæ of the wasps to bait his wicker baskets. So much for the scarcity of queen-wasps in the spring.

Extracting from Brood Combs.—I expected this barbarous method had been given up long ago, but I see it still advocated in the Journal. Your readers should bear in mind that the 'liquid' extracted from brood combs is not honey—it is a mixture of honey and water, and perhaps a little pollen, and is just the sort of substance to ferment and waste good honey; besides when it is remembered where the water is procured—i.e., from old manure-heaps, stagnant ponds, by the sides of sewers, &c.—it is not pleasant to think of adding such a mixture to good ripe sealed honey. Again, the practice is always fraught with danger to the brood if to nothing else, and those who have not plenty of honey without extracting from brood combs should give up keeping bees or adopt a better system of management.

bees or adopt a better system of management.

Inverting Supers, &c.—Where are the advocates of inverting supers? Come, 'Amateur Expert,' please let us have your experiences. If the system has not answered in such a grand season as this it most assuredly never will answer. Where, too, are the supporters of the Heddon hive? Are they, too, going to keep silent after such a splendid summer in which to make trial?—F. Boyes, Beverley, 16th August.

BACILLUS MINOR.

[1205.] I am somewhat in a difficulty, and should much like the aid of your experience in a case of diseased brood. I had a nearly pure Ligurian swarm from a neighbour on 27th June. It was hived as usual in a bar-frame hive, and on 16th July I determined to raise a couple of young queens from the brood by exchange of frames. I did not notice anything wrong then, but might easily have passed it, as I suspected nothing. On about 30th July when dividing the artificial swarm most of the brood had hatched, and I noticed a good many cells, say five per cent, had greyish grubs, dead and about a quarter the normal size. I am not sure whether the cells had been capped or not, but fancy they had. There was no bad smell, and the bees seemed in no hurry to clear them out. The two young queens hatched out, and were flying on 5th August. On the 9th August I took away the frames coming originally from the swarm. The dead grubs were not all gone. They had turned black and had no bad smell.

Now, it is about these two young queens (on six and three frames respectively) that I want your advice. I examined the old swarm on 1st August, and finding the brood similarly diseased I cut out a piece and sent it on to Mr. Cheshire, but have heard nothing yet. On the 8th I availed myself of chance assistance and destroyed the old swarm and brood, brimstoned it, and buried it, in

fact. It seemed a pity. What would you have done? The thing that decided me was Mr. 'Useful Hints' saying there was no cure for *Bacillus minor*, which it seemed to resemble.

Thus I have destroyed all trace of the swarm except the two young queens and the few Ligurians that hatched out of the two brood frames.

Now, the question is whether, supposing the first brood from the young queens is healthy, would it be liable at a later date to become diseased? Apologising for troubling you at this length.—Brimstoner, Broadstairs, 15th August.

[We certainly think the dead larvæ had not been 'sealed over,' since the death of these at two or three days old is one particular symptom of the disease, but there is a total absence of putrid pupæ under pierced caps, as in Bacillus major alvei. We advise you to notice carefully whether the larvæ from the two young queens show any sign of the disease before deciding upon a future course. We certainly have been unsuccessful in applying remedies, except in one instance, where we have effected a cure by feeding upon phenolised syrup, spraying the brood-combs with the same, and in a day or two afterwards blowing the dust of finely pulverised coffee over them. This colony, although much reduced in numbers, continued to produce healthy brood afterwards, and there has been no recurrence of the disease.

As a precautionary measure insert a lump of camphor in each live to prevent the spreading of the disease, if it should appear, by robbing. Robbers will not enter a hive where a strong seent of camphor pervades the interior, and the Germans assert that the spores of Bacillus cannot exist in a camphorated atmosphere. We hope Mr. Cheshire will soon be able to report on the disease.—Ed.]

HONEY BY HUNDREDWEIGHTS IN LINCOLNSHIRE.

[1206.] Your correspondent, 'A Member of the Worcestershire Bee-keepers' Association, in last week's 'Echoes, asks a very reasonable question of us here, and I echo him, but first, by my hearty congratulations on his success this year of having obtained from his six stocks one and a half hundredweight of honey, presuming he has left them ample store (say another hundredweight) for the coming winter. Very good, Worcestershire, and, may I say, keep to your old English bees. I wish I could give a more complete answer from Lincolnshire to 'W.'s' question, but I may state it is no uncommon occurrence with us to have a surplus of half a hundredweight per stock, and this where ten to twenty stocks are kept, well managed. Here I would repeat the oft-repeated advice in the Journal, that to get good results stocks must be large at the time of honey gathering. I have before me as I write this a statement that Mr. Gillfin, of Grantham, has just taken one hundredweight of honey from a single stock, and has left them sufficient store for winter. I think his apiary consists of two stocks. I myself extracted, early in July, one and a half hundredweight from four stocks, and hope in a few days to take another half hundredweight, and still leave ample store. Mr. Blankey, of Denton, wrote me, July 6th, that he had taken from his best stock 106 lbs., and hoped to get 50 lbs. more by end of month. His other five stocks were doing nearly as well. At our Spalding Show, Mr. Hufton and Mr. Pocklington, of Cowbit, jointly staged about eight hundredweight; their apiary consists (speaking from memory) of twenty-six stocks. Mr. Truss, of Bainton Heath, staged over five hundredweight; his apiary, in June, numbered twenty stocks, seven of which were very indifferent. Mr. Thorpe, of Swineshead, staged a little under five hundredweight, I don't know the extent of his apiary this year, but it's

August 25, 1887.]

very large, I believe. I would remark that, in the case of the last four named gentlemen, these weights by no means represent the full, and may be taken as only showing the weight of honey taken from a portion of their stocks for our Show. I hope to be able at the close of the honey harvest to obtain more information from others of our large apiarians as to their average yield (Mrs. Brown, of Whaplode, to wit, with her thirty stocks), when I will communicate further. Lincolnshire is, doubtless, a favoured county for producing honey, and that of a very superior quality; hence we have so large a number of bee-keepers, with such extensive apiaries, and yet increasing, and I hope will continue.—R. R. Godfrey, August 13th.

A WORD FOR WASPS.

[1207.] I am sorry to see the constant reference to wasp-destroying in the Bee Journal. If wasps interfered with bees, there might be some excuse, but as they do not, but are rather an advantage than otherwise, I do see on what grounds the 'humane' bee-keeper can defend wasp-killing. Wasps prey chiefly on insects, many of which are harmful to bees. I have seen wasps, for instance, carrying off the larvæ of moths from the neighbourhood of hives. I have never seen or heard of wasps doing any damage whatever to hives. People hate wasps because, if one comes near them, they are frightened, and spit or strike, and very properly get stung. After this they go howling to the Bee Journal. and accuse an insect, which is at least as valuable as bees are, of all manner of crimes. Of course, if a skepowner chooses to leave a hive full of honey, but empty of bees, out till September or October, there may be robbing, but who ever heard of wasps destroying a strong lot in fifteen minutes, as is quite possible with robber bees?

I should like to ask 'Perseverando' if he can manage without a veil? I have not found stings about the eyo cease to swell, and the consequent annoyance is great. Bees will often fly at your face when you do not get a sting in the hand.—W. M.

BEST TIME FOR MANIPULATIONS.

[1208.] In your article last week on 'Vicious Bees, you say, "Have we not recommended in the columns of this Journal ad nauseam to manipulate during the honey season only, on fine days, and between the hours of ten and three?' It is true that this advice has frequently been given, and it may be that when hives are kept in shade these hours are the best, though I must say that in hot weather I should not have thought they would be, and hot weather is common during the honey season. But probably many bec-keepers like myself have no shady situation suitable for their hives, and do not care to go to the trouble and expense of putting an awning over them. Now, my experience is that it is far better to manipulate hives in the evening than with the blaze of a June or July sun upon them. I should be very glad if other beebeepers would kindly state if their experience coincides with mine. — Henry Chenevix, Blackrock, Dublin, August 22nd.

GLAMORGANSHIRE AGRICULTURAL SHOW.

[1209.] Your correspondent in the reports of the above show regrets that the judging did not give general satisfaction, which, I think, is too much to expect, as it is impossible for every exhibitor to take the first prize; and we still have people who, no matter what quality honey they happen to possess, think that because it is theirs it must be the best honey in the show.

My reasons for awarding the prize as I did, were that

the two samples (six bottles of each) were equal in colour and far superior in flavour to the second prize honey.

Your correspondent named a committee to 'discuss this matter and establish a judging standard.' I had the privilege of meeting one of those gentlemen named at a recent show, where Mr. E. J. Gibbins' honey was staged for exhibition and passed unnoticed by the judge, and in conversation about the report in the Journal I said, 'There is the honey on the stage now:' his reply was, 'If there were five prizes for extracted honey here to-day that sample would not have taken even the fifth.' After that I leave your readers to judge me right or

There is another matter I wish to refer to with your permission. 'Welsh Novice' was kind enough to send, in the shape of 'another complaint,' a graphic description of misdoings in the bee-tent, taking care to colour it to suit himself. The skep with broken combs had been repeatedly driven; it was a two-day show, and the time referred to was the afternoon of the second day, the skep was rotten, and the combs completely broke away from it, the other skep, which was a good one and contained a fair quantity of Lees when brought to the show and had been successfully driven on the previous day, was queenless. I found the dead queen and a number of dead bees in front of the hive in the morning. There had been a number of bees from the neighbourhood the previous evening robbing the skeps, and caused much fighting till the occupants of the skep had dwindled down to about one-third. As soon as I saw the state of the skep in the morning I concluded it would be next to useless to attempt driving it. Most of this had been explained to 'Welsh Novice,' but it did not suit his purpose to state the facts. I could not get other bees to drive, so had to do the best I could under the circumstances. I feel very much obliged to 'Welsh Novice' for his kind 'endeavour to show the lecturer wherein he erred,' but it does seem to me a roundabout way of showing it; if he had been more anxious to do me good than harm he had ample opportunity in the show grounds. - W. GAY, 4 Flora Street, Cathays, Cardiff.

[We are obliged to our correspondent for the previous statement, and sympathise with him in his difficulty of doing his duty under the circumstances mentioned. As both parties have had an opportunity of giving their version of the matter, we trust the controversy will now cease. We have received several other letters on the above subject.—Ep.]

MONKEYING WITH BEES-SWARMING.

[1210.] The ubiquitous Star reporter was strolling along a country road last Wednesday. He sat down on a mossy stone, first spreading his handkerchief carefully over it, drank in the ethereal beauty of the scene, inhaled the breeze laden with incense stolen from closing blossoms, and listened to nature's harmonies rising all around. A frog, with a grunt of disgust, plunged into the brook, and the reporter smote himself. 'Hang the mosquitoes!' he said, and, rising, had walked onward a few paces, when he was startled by an uncouth figure sitting on the fence of a farm-house, which was dimly visible through the trees in the gathering dusk.

The figure was sitting with his elbows on his knees, and its face in its hands, which were incased in large fur gloves. Stocking legs covered the arm from wrist to elbow, while a black veil hung over the dilapidated hat, after the coy fashion of Castilian dames. As the reporter drew near, it sat creet and shyly raised its veil. Then, in a voice which extreme dejection seemed to have robbed of surprise, and which seemed familiar somehow, it said, 'Good evening, Mr. Blank.'

Looking closer the reporter recognised with astonish-

ment the lineaments of one whom in former days he had known as a policeman in New York,—it was solely in the way of business, that is, newspaper business, that the reporter had made the acquaintance of the guardian of the peace!

'Why, McFinney, how do you do? What's the matter? Small-pox?' exclaimed the reporter, as he saw the red swellings covering Mr. McFinney's face, and the

hand that had been ungloved to clasp his own.

'Bees, said McFinney, laconically.
'Ah! So you are keeping bees? Very intelligent,

interesting little creatures, I have heard.'

'Young man, said the veiled ex-policeman, earnestly, 'my advice to those about to monkey with bees is -Don't. I've been at 'em for two days now, and I find 'em something too intelligent; they can find a hole in a veil so quick it makes you dizzy. And interesting! They're like a detective story; when they hump up and get a focus on you, you want to finish 'em.'

Mr. McFinney smiled feebly at his humorous conceit, and, laying his hand on the reporter's arm, continued con-

'You know all the books say bee-keeping is such a nice, clean, pleasant business. So my wife thought she'd like to try it. She said she wanted some profit off the farm, and bees wouldn't make any trouble, but would just go to work and make honey and money for us, and we wouldn't have to hoe 'em, nor milk 'em, nor weed 'em, nor churn 'em, nor nothing, but just let them set in the sun and work. One of the neighbours wanted to sell some, and we bought a dozen swarms and set 'em over there.' (Mr. McFinney indicated the place with his thumb.) 'A little book came with 'em that told how to work 'em.

'Well, yesterday my wife thought they'd been making honey for home consumption long enough, and said I must put in some honey-boxes. I went to my son Melville—he was making a fish-pole—and told him to put 'em in; he said he was too busy to fool with bees, so I had to do it. I am afraid of bees and snakes. The book says "to proceed boldly." I proceeded boldly, and took off a cover, but the bees came out,—and I went away. The book said "if one were timid to wear veil and gloves," -so I put on this rig; but it makes a man want to dodge when he sees a dozen just outside making for his eyes. The book said "to blow a little smoke into the hive to quiet the bees;" but the very first time I tried that the bees got as mad as the — as mad, concluded Mr. McFinney, mildly.

'They went for me on all sides. Luckily, I remembered that the book said, "If persistently assailed, retreat to the shade;" and I retreated to the shade. But I got a few boxes in. By-and-by my wife came out, and said and I retreated to the shade. But I got the way to manage bees was not to be afraid of them. Some bees came out and argued with her, and she went back for a veil. We tried a few more, and slapped them in boxes in a way that made the interesting and intelligent creatures swear like blue blazes, till pretty soon a colony swarmed out, and my wife said, "I must be getting back to my work." I thought I would, too, for quite a few had taken up their quarters in my ear. My wife bragged that she put the boxes in, any way. This morning I went out and found the cover on cornerwise, and the bees just red-hot and boiling over because the boxes were in bottom side up, and one of the glasses was stove in. I told my wife that taking eare of bees was nice girl's work, and we'd leave it to Jenny when she got home from school.

Mr. McFinney paused.

'Have they swarmed any yet?' the reporter asked,

sympathetically.

An ominous light gleamed in Mr. McFinney's eye. He had evidently been touched in a tender point, but he answered gently:—'Yes, they swarmed to-day. Yes, I think they swarmed this morning. I was hilling the

corn when my wife blew the horn for me, and I went down to the house. It was about nine o'clock. My wife said the bees were swarming, and she had a hive, and a sheet, and a brush, and some sweetened water ready. Way up in the tip-top of an apple-tree there were a lot of bees making an awful circus about a big black bunch that hung from a limb, and when I looked at it I saw it was one crawling mass of bees." My wife said, "Go up a ladder and knock them into a basket, and let it down." So when they had all settled I climbed up the ladder, but I thought it might soothe them to sprinkle some of the sweetened water on them; and when I came down I found that the puppy had drank it and tipped over the hive, and chewed up the sheet, and hid the basket. Well, we got 'em all ready again, and then I went up and sprinkled the bees, and came down and got the basket and a long-handled egg-beater.

' What?' said the reporter.

'It was a patent thing that we couldn't ever make work, and Mrs. McFinney thought I could poke them off the branch with it. I couldn't get near enough on the ladder, so I climbed up in the tree and held the basket under the swarm, and scraped them into the I don't believe the water had soothed them much; they hissed just like snakes when they fell into the basket, and my wife made me nervous; she kept telling me I was smashing them against the limb. Then I began to let the basket down, but it turned over in the air, and they all came out and flew most every way, but chiefly my way. They seemed to think it was all my fault. One "gentle Italian worker" got under my veil and shut up my eye.'

The reporter had noticed the peculiar expression

given to Mr. McFinney's face by the mishap.

'Pretty soon,' he went on, 'they all went back to the same place; and just exactly the same thing happened over again; only this time the whole swarm went for me, and I tumbled out of the tree. I hit the hive as I came down, and hurt my shoulder some, and the sweetened water got all over my hair. My wife said she didn't see what was the idea in tipping the basket over every time. They flew into another tree this time, and we set up the hive, and I got up in the tree and sawed off the limb. It was a big limb, up in the top again, and my wife was to steady it with a pitchfork as it fell. Well, she missed it, and the fork scraped off every blamed hee. They doubled up and turned all colours, they were so mad: but, finally, they flew off again, and we were pretty tired and had our dinner.

'After dinner I went out again and found then on a lot of little twigs. I picked them off and laid them in front of the hive, and kind of brushed 'em along toward it. After awhile they all went in, and then after awhile they all eame out. They crawled all over the hive, and Mr. Jordan, the man I bought them of, came up and looked at em with me. He said he didn't see what they were doing on the outside of the hive. They stayed there so long I got kind of tired of seeing them crawl over each other and make faces at me, and I said, "I guess I'll brush 'em off into the sheet." Mr. Jordan put on his hat and said, "I guess I won't stay, then." So I brushed 'em into a sheet, and they all flew up and lighted on a fence over our swamp. I jammed my hat on. and I said to myself, "Thomas McFinney, don't let it be said that you couldn't collar a swarm of bees; and Melville and me went down there. We spread the sheet over the hummocks in the bog and set the hive on it. Melville had on his gum boots, so he waded in and dummed 'em into the sheet. About a quart fell into the water and drowned. They sissed when they touched the water, as though they were red-hot. But the rest were so tired that pretty soon they crawled into the hive, and we've put it in place. I hope they won't come out again to-morrow, said Mr. McFinney, not very hopefully. 'I told my wife that it needs a younger man than me to

gallop and climb and swim after her bees, and a more active.' Mr. McFinney felt of his shoulder tenderly, and, taking off his hat and veil, passed his fingers through his sticky hair.—New York Sun, July 27th.

Echoes from the Hives.

Auckland House, Brondesbury, N.W., August 22.—This season in my district has been worse than last year. At tirst it began well with the hawthorns, &c.. but the white elover was a failure and the limes almost entirely so. I have taken about half what I did last year and my neighbours have taken nothing as yet. I have an equally bad report from Mill Hill, Highgate, and Harrow Weald.— T. F. L.

NOTICES TO CORRESPONDENTS & INQUIRERS.

Letters or queries asking for addresses of manufacturers or correspondents, or where appliances can be purchased, or replies giving such information, can only be inserted as advertisements. The space devoted to letters, queries, and replies, is meant for the general good of bee-keepers, and not for advertisements. We wish our Correspondents to bear in mind that, as it is necessary for us to go to press in advance of the date of issue, queries cannot always be replied to in the issue immediately following the receipt of their communication.

All queries forwarded will be attended to, and those only of personal interest will be answered in this column.

J. S. C.—We can recommend Bec-Pasturage, by Mr. Henry Dobbie, Thickthorn, near Norwich, which deals with the propagation and cultivation of honey and pollen produeing trees, shrubs, and plants.

- R. E. C.—New Zealand Bee-keeping.—We are not aware that any standard frame has yet been adopted in New Zealand. The British Standard and the Langstroth frames $(17\frac{3}{8} \times 9\frac{1}{8})$ are those chiefly in use there. You will find that the New Zealand bee-keepers are in no way behind those in this country. The annual produce of the honey crop in that eolony is from 300 to 400 tons, fully half of which is produced in Auckland Province. The success of apieulture in New Zealand is in a great measure due to the zeal and energy of Mr. J. C. Firth, of Manamata. He has secured the services of Mr. Hopkins, the wellknown apiarist, and author of the well-compiled work on apiculture in New Zealand, and has established several apiaries in his neighbourhood, fitted with all the latest improvements for manufacturing bee-applianees and purifying wax. The hives in Manamataabout 200 in number—average a product of 100 lbs. per hive. The honey produced is of a very high quality. Its price last season ruled rather low: the best comb honey was 6d. per pound in 1-lb. sections; extracted honey, in bulk and tins, $2\frac{1}{4}d$. to $4\frac{1}{2}d$.: strained honey, 2d. per pound (wholesale). 2.—Taking English Combs.— We should recommend you to dispose of your combs before your departure, and not to encumber yourself with them.
- Mrs. Graham.—Bees in Box-hive.—As you are desirous of starting the bar-frame system it would be as well to transfer the combs from the box to frames. This is not a difficult job. Having quieted the bees by smoking them the box can be broken open, the combs cut out and tied in to the frames with tapes, the frames placed in the hive and the bees brushed on to them. If not disposed to treat them thus now they may be left until the spring, when a swarm may be hived in a bar-frame hive and the combs transferred afterwards.
- F. G.—1. Earwigs.—These do not eat honey or do any harm in a hive, they simply go there for warmth and dryness.

 2. Fermented Syrup.—This is very bad for bees. If stored now and used for food in winter it would certainly eause dysentery. Add a little solution of salicylic acid to the syrup. 3. Roofs.—You should have pitched the outsides not the insides. If you now pitch the outsides no harm will be done by the pitch inside.

Bee-keeper.—The sample of sngar forwarded will answer your purpose for making syrup.

E. W. - 'Honcy Dew,' alias 'Aphidean Exercta.'-1. The American view is that as winter food it most certainly produces dysentery. We should hesitate to winter bees

upon it. 2. We prefer granulated sugar syrup, salieylised, for winter stores - supplied in early autumn, of course—to this nauseous compound. 3. You may safely feed bees upon it at spring. When bees are breeding fast, and working actively in the fields, it loses its deleterious effect.

JUBILEE DESIGNS.

In our number for July 7, we mentioned the specimen of honey-comb forming the word 'Jubilee,' the work of the bees of Mr. Alsford, of Blandford, which was so perfect that it drew forth high commendation from all who saw it at the time. This has been presented by Mr. Alsford to Her Majesty the Queen at Osborne, through the influence of the mayor (Mr. J. W. Luff), who secured a personal interview for the owner with Sir Henry Ponsonby. On Thursday last Mr. Alsford received the following communication: --

'Osborne, August 23rd, 1887.

'Sir Henry Ponsonby is commanded by the Queen to thank Mr. Alsford for the Jubilee Honeycomb which he has presented to Her Majesty.'

LORD SUDELEY'S PLANTATIONS.

It is my good fortune to be located for a while in a village nestling at the foot of the Cotswolds, not far from the famous Vale of Evesham. Some little distance beyond a field of forty odd acres facing the house in which I am staying trees rise in rich profusion; amid these the spire of a church and a mansion of more than ordinary size and beauty arrest the attention, while a mile or two farther the Cotswolds form a semicircle, cutting us off apparently on one side from all communieation with the outer world. The spire that forms so striking an object in the landscape is the spire of Toddington Chnrch; the mansion is the residence of Lord Sindle street form a portion of his famous plantations. Among these I was kindly permitted to wander a few days since, nor did I omit to pay a visit to the apiary of 200 hives under the charge of that genial and canny Scot, Mr. John White.

I wish some of those who despair of the future of agriculture in England would visit these plantations. Here on heavy clay and poor soil, which some time since eonld searcely be let at 30s, per acre, may now be seen fruit trees (especially plums and apples) intermingled with currents (black and red), strawberries, gooseberries, and raspberries. Such raspberry canes I never saw before, and I was glad to learn from the foreman who accompanied me that the crops, especially raspberries, had been splendid and that no difficulty had been experienced in selling the produce at remunerative prices.

The jam-factory in the centre of the plantations takes a portion, but only a portion, and by no means the whole, of the produce. Every year fresh plantations are made, and more than 500 acres have now been taken up. The rateable value of the land has of course been raised, in some parts to 4l. per acre, and a very large number of men and women are employed throughout the year in cultivating the ground and in picking the fruit, as well as in preparing and packing the jam. I could not but regret that Lord Sudeley's useful example has not been followed more elsewhere. Even at Evesham, the centre of the plum and of the fruit district, no factory has been started, though, of course, you are told there has been 'a talk about it.' As a consequence, when there is a glut of fruit, it becomes unsaleable and so is wasted. Yet a factory does not require much capital or skill, and one would have supposed that self-interest would have induced the parties concerned to start some-

thing of the kind.

You, however, Mr. Editor, will remark that I have forgotten John White, and have left him with the bees! Well, after wandering amid a 'plot' of 250 acres, I was glad to greet the veteran and to find him at work among bis friends. He had heard of my intended visit, and had specially reserved a swarm for me to hive! A hunger swarm had visited the apiary and, after various vagaries, had settled on a hedge adjoining his hives. So, thanks to the kindness of Mr. White, I had the pleasure of hiving a swarm in Lord Sudeley's plantations. It was pleasant news to learn that he, too, had had a very good harvest, the best he had ever known. We discussed different points. The earbolic sheet he has not tried; I have tried it personally for some months and have scarcely used a smoker. But the smoker is not superseded. My household complain that some of the honey from my hives is distinctly tainted with carbolic flavour. I have, too, recently found in the examination of candidates for the third-class certificates that some of them fail to subdue their bees before driving, because they have ceased to use the smoker. The hands of one candidate were recently pierced with stings in a manner which I never saw equalled, partly because he had beeome quite unaccustomed to the use of the smoker. Mr. White uses one with a larger furnace than is commonly employed. This smoker (as many are aware) does not need the attention which the smaller size requires, and will continue alight for a long time. He is not an advo-cate for dry-sugar feeding. He prefers to make his syrup as much like honey as he can. For my own part, when I feed on syrup, I always put salicylic solution with it, and was never troubled with foul brood to any extent. For the last year I have tried the dry-sugar system, and must admit that it saves a vast amount of trouble, nor does it induce 'robbing' as syrup sometimes does. But the fact that it is possible to mix salicylic solution

in the one but scarcely in the other seems a point in favour of syrup feeding. I am, too, inclined to think that it stimulates breeding more than dry-sugar feeding. Perhaps some of your correspondents will discuss this and the other points I may raise. I was sorry, but not surprised, to learn that Mr. White is troubled with foul brood. It appears to give him considerable trouble, but not much anxiety. I had suggested isolation or the 'stamping out' of disease by the destruction of the hives affected with this pest, but he declines to destroy his bees in this fashion. He has used phenol extensively, and believes in it as a cure. Instead of a petty 'spraydiffuser,' he prefers to use a small can with a narrow spout, and to pour the phenoled syrup over around the infected combs. He admits that the time consumed in repeating this process from day to day until something like a cure is effected is considerable; but he thinks that patience and perseverance have their reward in this as in other things. He showed me a hive that had been 'a bad case,' as he said, where this method had been tried. The bees were very fairly numerous, and there were very few infected cells; the brood, however, was as scarce as were the showers in the month of July. While looking over the frames the queen appeared, and at his request \tilde{I} caught her, as she was evidently unfit for future work, being small in size and her wings imperfect. To bring a fresh queen and to place her in a pipe-cover cage was the work of a few minutes, for John White, like a wise man, has all that he requires close at hand, and several surplus queens were ready for use in the shed attached to the apiary. While we were carefully examining this hive, au unpleasant sensation behind led me to suppose that some bee had found a weak point and had assailed it! Turning round I discovered that my enemy was—a Scotch thistle! John White could not forget his native land, and so had allowed this invader to live and thrive amid his hives. Yet the sunshine on his face shows that he is no 'exile from Erin,' no Highlander bewailing his fate in sad solitude on the shore of some Western lake, for is not his 'gude' wife with him to assist him in extracting the liquid sweets day after day from the loaded combs of his two hundred hives? While we were enjoying the joke of the Scotch thistle, he informed me that some years since, when he met Mr. Cowan at the Grantham Show, Mr. Cowan had invited him to cross the border once more, and return with him to the land of the heather. Happily, for the success of Lord Sudeley's apiary, John White declined. He assured me that the sections were going off as fast as he could wish, and that but little of last year's harvest remained unsold. The honcy was obtained chiefly from the raspberries, and the returns from these (as I was informed by my guide through the plantations) had been very large. Indeed, the pickers were still at work upon them the day I was there (August 22nd). Thus the bees had done good to the raspberries, and the raspberries by their returns in honey and in fruit had done substantial service, let us hope, to Lord Sudeley as well as to our friend John White.—E. Bartrum, Berkhamsted, Herts.

AMONGST THE CO-OPERATORS.

On Tuesday the 23rd, I was amongst the co-operators. Bee-keepers are enthusiasts, but in the matter of enthusiasm the co-operators out-Herod Herod. But their enthusiasm is intensely practical, they have not only organized stores where their members can purchase the necessaries of life at wholesale prices, but they also manufacture largely on co-operative principles as well. The display of wearing apparel, shoes, articles of common use in the household, hardware, and coals, was very good indeed. Added to this there was a good show of flowers, fruit, and vegetables in the Conservatory of the Royal Horticultural Society; and considering the number and value of the prizes, and that exhibitors must be members of the Co-operative Society, there was a very creditable

display of honey.

What memories the great Conservatory called up! Of honey shows unparalleled; of crushing, good-tempered holiday throngs; of keen, but good-natured rivalry, and of bronze medals!

'Still o'er these seenes my memory waits And fondly broods with miser care.

Outside in the gardens desolation reigned supreme; there was a band—the boys from the Duke of York's School—the band kiosks are amongst the things of the past, but the little fellows played splendidly, especially considering there were few to listen and none to applaud. The large masts from which the electric lamps flashed so brilliantly last year stood like grim sentinels keeping guard over a scene of spoliation and death, but 'their

lamps were gone out.

The British Honey Company, and Messrs. Abbott and Neighbour, each had a stall in a most out-of-the-way place. The appliances as collections were sufficient for a much larger exhibition, and were not so large as frequently, to give novices the idea that bee-keeping requires a lot of money to start. Mr. A. Neighbour had a splendid observatory hive of Italians on show, they have been in Regent Street for the past two months, but had honey unsealed that they had gathered within the past few days. The wonder is where did they get it from? There was also another wonder, but this time it was on Messrs. Abbott's stall; it was their 'Gayton' hive. Well made, of good material, a hive good enough for keeping bees in, if their owner happened to have a sack full of money and was at a loss to know what to invest it in. But I don't love broad-shouldered

The honey entered for competition was staged in the Conservatory, the appliances should have been there too, as there was ample room and to spare. The lot that won the first prize was 'raised' by a good bee-keeper, he is unknown to me, but workmanship is an unfailing test of ability. It was well put up, a different kind of paper would have still improved the sections, and the run honey had not been in the bottles sufficiently long to allow the air-bubbles to rise out of it. These remarks are not intended as fault-finding, but as hints for whoever cares to profit hy. The owner of the second prize lot had bottled his earlier, and I judge only lost the first on the score of bulk. Mr. Ebenezer McNaily sent a nice lot, his sections were very fair, packed in Woodley's cases they looked neat, but were staged lying down; a position fatal to section honey. His heather honey in bottles (Ah, the aroma of it!) was clouded with wax, and for looks the 'get-up' of his run honey was put out of it by the prize-winners! His 'Victoria Jubilee' device in comb honey I was pleased to see, doubtless it would have been better worked had the season been different. There was another lot that took my attention, it had the notoriety of being the dirtiest lot of sections I ever saw. I cannot conceive who will buy them.

A few others as well as myself attended by invitation hoping to teach the co-operators to profit by the cooperation of Apis mellifica, but there was a big meeting and a startling resolution to pass that is intended to greatly affect the brotherhood of man, consequently all the enthusiasts rushed off to that. We were left to gossip together on bees and their owners, the band wasted its sweetness on the desert air of the Royal Horticultural Gardens, and I fear bee-keeping was not advanced much.

But I am told this is only a beginning, it is intended this show shall be annual. Their Secretary certainly lacks neither courtesy, energy, nor enthusiasm. operators, above all people, should be bee-keepers on principle, perhaps bee-keepers on the same score should be co-operators. I am not one of the clan, but the afternoon was spent amongst them with some pleasure and profit by—Amateur Expert.

USEFUL HINTS.

Weather.—Heat and drought still prevail in our immediate neighbourhood, and the copious and refreshing showers with which other districts have been favoured have avoided ours. Still, the slight rains and heavy dews prevailing of late have revived the herbage, which is putting on a greener shade, and the second crops of red clover are affording superior pasturage for our Eastern races, which leave no petal unvisited in search of the precious nectar, while the blacks amuse themselves by flifting from flower to flower, and kissing all buds that are pretty and sweet.

But the income—alas! like many other incomes—is small indeed, and the exposure of refuse comb, intermixed with pollen, and a flavour of honey, causes intense excitement in the apiary and is quickly covered by raiding and ravenous wasps, by which our hives are vigorously attacked, so much so, indeed, that the hive-entrances have all been reduced to a passage-way for one or two bees only, and now dead wasps beneath the alighting-

boards are plentiful enough.

Preventing Robbing is of the utmost importance, especially in the larger apiaries, since if once it becomes established it is a matter of the greatest difficulty, if not of impossibility, to check it. The eye of the beemaster should ever be upon his apiary. Every colony—its history, strength, queen, and all else relating to it should, without written memoranda, be at his fingers' ends—figuratively, we mean, yet without figures, and not literally, or he might become the victim of-well, we will not say how many thousand stings.

A beemaster who loves bis bees will never be long absent from his apiary which will ever be his maxima cura, and will demand his attention at all times. True, there are many whose daily calling summons them away from Arcadian delights; but even so, the true bee-master will devote a few minutes, morning and evening, to visiting his hives, and by so doing will forestal many an

evil.

Roofs and Hives.—Let all roofs and outer cases of hives be rendered water-proof before the autumnal storms are on us. No better time than the present for stopping chinks (of which plenty will be found after a long dry season) and tarring exteriors.

FEEDING also must be carried on vigorously where required, and all feeders should be filled at night and

securely covered.

SPACE BENEATH FRAMES has occupied considerable attention of late. It has always been held as a sound axiom in apiculture that 'If a greater space than onefourth or three-eighths of an inch be allowed between the sides or bottom-bars of frames and the walls or floor of the hive that the bees will build comb in such space." In 'Useful Hints,' vol. xv., p. 308, B. B. J., we related the results of several experiments made by ourselves in this direction, e.g., 'Experimentally we have allowed to several newly-hived swarms two inches beneath the frames, and have not contracted the hives. As we expected, the bees have confined themselves to the frames, building out the combs on full sheets of foundation, and adding no brace combs below.' These were first swarms, each containing about 4 lbs. of bees, and the hives twelve Association standard frames, or equivalent thereto. On p. 354, also, in reference to Lee's frames, we stated our belief that all combs would have been attached (built down) to the bottom-bar if one or two inches had been allowed between frames and floor-board -i.e., instead of the half-inch which we always give, in preference to one-fourth or three-eighths of an inch, allowing for sagging of the frames. In many cases where three-eighths of an inch have been allowed we have found the bottom bar touching the floor-board, and firmly propolised thereto.

It has been objected that the 'Editorial note' appended

to Mr. Robinson's letter on 'Vicious Bees' (1187), p. 359, sanctions a quarter inch space, and that our advice is contradictory. Now, the 'Editorial' states that it was a mistake to raise the hive half an inch for ventilation (when a quarter of an inch would have been sufficient), thus giving an inch space below the frames, which in this particular case, of an over-crowded hive, would be certain to induce comb-building below the frames, the great error of crowding a large swarm into a small hive having previously been committed. 'Circumstances alter cases,' as our old copyslip fifty years ago taught us, and we certainly see nothing contradictory

We should certainly hesitate to recommend hives to be built with a space of two inches beneath the frames, but we find by experience that when that, or even greater space, is allowed, during the winter months, the bottom ventilation is more perfect, and, consequently, the interior of the hive is kept dry, healthy, and entirely free from damp or mouldiness. And this plan can be put to the test by simply inserting between hive and floor-board an 'eke' of the dimensions of the hive, and from two to four inches in depth, when placing the bees

in winter quarters.

TIMES FOR MANIPULATION.—With regard to Mr. Chenevix's letter (1208), p. 373. There are plenty of days during the honey season, when bees are busily at work, that are by no means too hot for manipulation, and we have always found operations on such days far more pleasant and easy of performance during hours of flight than in the evening, with over-crowded hives, while every bee is at home, and at times clusters lying outside. In the former case, the bees at home are the nurse-bees, young and harmless, and the ease and despatch with which a hive can be thoroughly examined while two-thirds of its population are absent, the queen interviewed, queen-cells cut out or inserted, frames exchanged, and almost every other operation performed, contrast very favourably with the latter case, when bees of all ages are at home, and ready to do battle on the slightest provocation, even if no crushing of bees take place—and consequent emission of sting-poison, so provocative of anger to all races of bees-which few, even skilful manipulators, can avoid under such circumstances. We continue, therefore, strongly to recommend to beginners and the inexperienced manipulation during flight hours, when honey is being stored; but at other times, especially when there is danger of robbing, in the morning or evening—provided always that manipulation is necessary. The less of it the better, so long as colonies are strong and healthy. See 'U. II.,' present vol., p. 308.

PARALLEL versus RIGHT-ANGLED FRAMES.—On this subject we will not enter upon the arguments for or against since it has been thoroughly ventilated in past volumes of the Journal. We are strong advocates of perfect ventilation of hives, at all seasons of the year, and our point is that this cannot well be attained on the 'parallel' or 'hot' system. Combination, and many other hives, have parallel frames, and are better adapted for back and side than for 'top storage,' and admit of twofold expansion—towards front and back. All our experience is in favour of 'top storage' as being also in accordance with the instinct of the bee, and we maintain that the honey stored above the brood-nest is of better quality, more free from intermixture with pollen, less liable to the deposition of eggs and brood, and more abundant in quantity, than when stored at the back or on the sides. This plan of right-angled frames and 'top storage' in modern parlance is designated the 'tiering-up system,' and is almost universally practised by other nations; and although we should be extremely sorry to ignore the views of some of our foremost English apiarists, yet we cannot shut our eyes to the fact that the 'parallel system' and side storage are utterly condemned by American apiarists, almost to a

man, and the system finds little favour in Germany and other parts of the European Continent. If parallel frames and expansive hives have any advantage over the other system, it is in this, that they are better adapted to prevent natural swarming. And yet the advocates of the latter tell us that by piling hive upon hive (i.e., doubling) and super upon super, we many prevent swarming altogether. Here again there must ever be varying opinions. Let each man be fully persuaded in his own mind. Prove all things. IIold fast that which is good,—the Divine utterance, as applying to hely things, may well apply here also.

things, may well apply here also.

EXTRACTING. — We have just received from Mr. Meadows one of his latest improved 'Raynor Extractors,' which is doing its work admirably, throwing out honey of so great a density that our old extractor would not separate at all from the combs, and withal so portable, light, and easily taken to pieces for cleaning, or renewal of its parts, that nothing is left to be desired. We do not remember honey of so great density at any period of our experience. Except for colour, aroma, and

flavour, it resembles heather honey.

Sections should be removed without delay, where neglected hitherto, and the honey extracted from those unsealed. Some of our later sections, worked on Mr. Simmins's plan, without separators and in his skeleton folding frames, are beautifully even, and, save for loopholes at the corners, might almost compete with those worked on Mr. Lee's plan. We consider that greater advance in sections, and their crates and cases, has been made of late than in any other apicultural articles; and he who would keep pace with the times, and present his honey in the best and most tempting manner to the eyes of the purchaser, must by no means neglect these late improvements, which, to be of real use, should be obtainable in any quantity without difficulty, and at very moderate prices.

'DEAD BROOD,'-Speaking of Mr. Simmins reminds us of his interesting letter (1203) on 'Foul Brood and Dead Brood, published in our last issue. On one point therein stated we must, however, join issue with him, viz., his supposition that 'dead brood'-which we are inclined to place in the same category as Bacillus minormay arise from 'weakness of the queen.' This is contrary to our experience. Weakness, whether from age or otherwise, causes a paucity of eggs, and consequent dwindling of the colony, but we have never found it productive of diseased larvæ, which we are inclined to believe arises principally, if not entirely, from bacilli. We are the more inclined to this opinion because in several instances in which we have changed the queen of an infected colony, superseding her by a young and vigorous queen, the disease has been in no way checked, but has continued its usual course. however, soon to obtain more light on this important subject, convinced, as we are, that almost all the diseases to which bees are liable, are too often classed under the one head of foul brood.

ASSOCIATIONS.

MIDDLESEX BEE-KEEPERS' ASSOCIATION. N.E. Provincial Honey Show.

A most successful exhibition of honey and bee-keeping appliances was held at Southgate on Saturday, the 20th Aug., in the conservatory and grounds of P. P. Hasluck, Esq., of the Wilderness. The amount of practical support afforded to the scheme by Mr. Hasluck from the moment of its first inception till the close of the show, fully guaranteed the success of the venture.

The Middlesex B.K.A., in their annual report for 1885, deplored the absence of members in the N.E. corner of the county. Now this district is gaining members at a pace which bids fair to place it in a position to compare favourably with the rest of the county. The unfortunate

crop of bricks and mortar is, however, fast circumscribing the available honey area.

The locale of the Southgate Show was charming in the extreme; indeed, the wonder is that such a thorough country retreat is still to be found within such a short distance of London. The schedule of prizes offered was an excellent one for a first attempt, and the judges placed the awards as follows:—

Class I. For twelve 2-lb. sections of comb honey: no exhibits. II. For twelve 1-lb. sections of comb honey: 1, Mr. Bolton, Southgate, 20s.; 2, Mr. Willan, Tottenham, 10s. III. For 24 lbs. extracted honey in 1-lb. glass jars: 1. Mr. English, Tottenham, 20s.; 2, Mr. W. M. Graham, Edmonton, 10s.; 3, Mr. Willan, eertificate. IV. For 12 lbs. extracted honey in 1-lb. glass jars: 1, Mr. Bolton, 20s.; 2, Mr. English, 10s.; 3, Mr. Hasluck, certificate. V. Straw super: no exhibit. VI. Collection of hives and bee-furniture most applicable to bee-keeping; no two articles to be alike; real utility to be taken into account in deciding: 1 and 2 divided between Messrs. Abbott and Mr. S. J. Baldwin, 15s. each. VII. Sample of foundation, viz., 3 lbs. thick and 3 lbs. thin (section) to be made in the presence of the judges. 1, Abbott Brothers, 20s.; 2, Mr. Baldwin, 10s. VIII. For 12 lbs. extracted honey in reputed 1-lb. glass jars (subject to the rules of the B.B.K.A., this being the class competing for the county medals of the year): 1, Mr. Fewtrell, Reading, Berks (ineligible for Medal); 2, Mr. Bolton, Southgate, Silver Medal; 3, Mr. Hasluck, Southgate, Bronze Medal.

Special Prizes for Southgate District only.
M.B.K.A. Members' Class.

Six 1-lb. sections: 1, Mr. Deakin, 15s.; 2, Mr. Bolton, 10s. Twelve 1-lb. sections: 1, Mr. Bolton, 15s. Six 1-lb. glasses extracted honey: 1, Mr. R. Clement, cup: 2, Mr. Bolton, 10s.; 3, Mr. Hasluck, 5s. Glass super: the only exhibit was a partly-finished one by Mr. Burrows. Largest exhibits among Southgate members of both section and extracted honey: 1, Mr. Bolton, 10s.

Open Class.

Six 1-lb. sections: Mr. Bolton, Six I-lb. glasses extracted honey: 1, Mr. Bolton; 2, Mrs. Davis.

The quality of the honey was fairly good, but the colour, except in one or two instances, was very dark. Making allowance for the very peculiar season through which we have just passed, the Middlesex B.K.A. are to be heartily congratulated on the vigorous determination of this district to push the interests of the Association, although year by year the chances of obtaining a good surplus of honey must decrease as the builder advances.

surplus of honey must decrease as the builder advances. The Judges, J. M. Hooker, Esq., and Mr. Expertin-chief Baldwin for honey, and J. M. Hooker, Esq., and G. Henderson, Esq., for Classes 6 and 7, gave thorough satisfaction by their award. The bee-tent was under the experienced agis of friend Baldwin, who net only performed the time-honoured driving feat, but transferred a stock from skep to frame-hive, and also introduced an Italian queen to the stock in lieu of their injured queen, much to the astonishment of some skeppists.

Five candidates attended for examination for thirdclass certificates. Four failed; the fifth was unable to complete his manipulations during daylight, and will, therefore, be taken again at an early date. Mr. Hasluck not only invited free entry to his grounds, but also kindly provided a band, which greatly enlivened the proceedings. Several showers of rain fell during the afternoon, preventing many from availing themselves of his kindness.

Another show is proposed to be held at the same place on Saturday, 25th July, 1888.

SHREWSBURY HORTICULTURAL SOCIETY.

The Annual Meeting of the above Society was held in the Quarry, Shrewsbury, on Wednesday and Thursday, August 17th and 18th. In conjunction with the show was held the annual honey fair, and exhibition of honey, hives, and bee-furniture of the Shropshire Bee-keepers' Association. The honey fair was not the least in the numerous attractions of the fête. The exhibits were both numerous and delicious. About six tons of honey were brought into the exhibition, and one ton was sold on the first day. The silver medal was won by Mr. W. G. Preece, jun. (Shrewsbury), whose practical knowledge as an apiarist enables him to bring both bees and honey to the highest perfection. Mr. Wood, of Somerfield, Wellington, also occupied a prominent position among the more successful exhibitors. In Class 6, Mr. Bradley took the bronze medal with a very pleasing novelty, the bees having made with honey the initials of the exhibitor, the word 'Bee,' and the year '1887.' In Class 7, Mr. Abbott's appliances attracted considerable notice, and gained the first prize, his 'Gayton' hive also gaining first prize for hives, being closely run by Mr. W. G. Preece, Messrs. Neighbour winning third prize. In the class for novel and useful implements, Mr. Woodley (Reading) gained the first prize with an ingeniously contrived section case, while Mr. Wilcox (Shrewsbury) was second with an improved bee-skep. In Class 13 the bees shown by Mr. Abbott were exceptionally fine. The whole of the exhibits in the cottagers' elasses were very good, and some difficulty was experienced in making the awards. The Rev. II. W. Wilcox, of Cockshutt, and Captain Nieholas Robinson, of Frankton Grange, Shrewsbury, acted as judges, and their decisions gave great satisfaction.

Honey.—For the best exhibit of comb honey in sections, to exceed 29 lbs.: Mr. W. G. Preece, jun., Shrewsbury, 1; Mr. John Bradley, Yockleton, 2. For the best 24-lb. section of comb honey: Edwin W. Jones, St. Martin, Chirk, 1; W. G. Preece, jun., 2. For the best exhibition of run honey, to exceed 29 lbs.: Mr. E. Wood, Springhill, Wellington, 1; Mr. J. Palmer, Wrockwardine, 2. For the best 24-lb. bottles of run honey, Mr. E. Wood, 1: Mr. J. Palmer, 2. 24-lb. bottles of run honey: Mr. E. Wood, 1; Mr. J. Palmer, 2. For the best exhibition of honey in the comb, in any kind of super: Mr. A. Bealc, Rea Place, Meole Brace, 1. For any novelty of honey of practical interest calculated to advance bee-keeping: Mr. J. Bradley, 1.

APPLIANCES, HIVES, &c .- For the best hive suitable for modern bee-keeping: Messrs. Abbott Bros., Southall, 1; Mr. W. G. Preece, 2; extra prize, Messrs. Neighbonr & Sons, 127 High Holborn, London. For the best hive, being the bonê-jîde work of an amateur: Mr. W. G. Preece, jun., 1, Mr. John Palmer, 2. For the best collection of apiarian applianees: Messrs. Abbott Bros. 1; Mr. Whittingham, Haughmond View, Shrewsbury, 2. For the best section-rack: Messrs. Abbott Bros. For the best 1-lb, sample of super foundation: Messrs. Abbott Bros. For the best new and useful invention calculated to advance bee-keeping: Mr. A. D. Woodley, Reading, 1; h. c. Mr. John Wilcox, 27 Castle

Foregate, Shrewsbury.

-For the best exhibition of live bees, of any pure race, with queen, to be properly secured in an observatory hive: Messrs. Abbott Bros., 1; Miss M. E. Eyton, Leaton,

Wrockwardine, 2.

Cottagers' Classes.—For the best exhibition of not less than 12 lbs. of comb honey: Mrs. S. Withers, Marchamley; Mr. H. Tatton, Petton Lodge; and Mr. John Walford, Grinshill; equal. For the best exhibition of not less than 12 lbs. of run honey: Mr. H. Tatton, Petton Lodge, 1; Mr. Mark Sutton, Harmer Hill, and Mr. John Walford, Grimshill, 2. For the best exhibition of honey in any form: Mr. Mark Sutton, 1; Mr. John Badger, Belle Vue, 2. For the best hive suitable for modern bee-keeping, the work of a bonâ-tide cottager, not being a carpenter, joiner, or wheelwright: Mr. J. Bradley, 1.

NORTH-EAST OF IRELAND BEE-KEEPERS' ASSOCIATION.

ANNUAL SHOW.

Judging by the dimensions, quality, and comprehensiveness of the exhibition which, under the auspices of the above Association, was held on Friday, August 19, in the Y.M.C.A. Hall, Wellington Place, Belfast, beckeeping in the North of Ireland is rapidly developing. True, as compared with England and Scotland, we are as yet only in the elements of the science of apiculture, but with such able and energetic pioneers as the Rev. II. W. Lett, Mr. Paul M'Henry, Mr. William R. Orr, and Mr. W. Lonsdale, to prepare the way, a few years will see Ulster well onward in the march of progress in this as in other respects. The show, which is the fourth held by this Society, was by far the best ever held in this country, and the attendance was good. The hall, although on the small side, was admirably adapted for the exhibition, and the exhibits were all very good. A very fine photograph of an arch of bee-hives, erected by Mr. W. R. Orr, Strabane, was much admired, and bore testimony to this gentleman's enterprise and ingenuity; while the 'Crown design' exhibited by him was universally admired, as were the designs 'Victoria' and 'Jubilee' of Messrs. M'Nally. There was every evidence that humane bee-culture is going forward in the North of Ireland, and hope the friendly visit of the Messrs. M'Nally, Robertson, Abbott, and others, will serve to stimulate our local apiarians to renewed efforts, and that we shall have some Irish exhibits well to the front in the sister countries. The display of Mr. Abbott, from Dublin, was very deservedly admired, as was that of Messrs. A. Cross, Bryce, & Co., of Belfast. All that could possibly be required was to be had at these stands. There were 104 entries staged. The show was a success. Mr. Thomas M'Henry's exhibit of 200 lbs. of I-lb. sections was very good, and staged in very fine condition. In the run honey there were all shades of colour, and the quality of the class was pronounced by the judges to be extra good, all the exhibits being of fine quality.

Much of its success is undoubtedly due to the energy and forethought of the hon, secretary and treasurer, Messrs. Paul M'Henry and Samuel Cunningham. The judges were as follows:—Bees, hives, and appliances: Rev. H. W. Lett, M.A., Aghaderg Glebe; Mr. W. Ditty, Newtownards. Honey: Mr. A. Morris, Knockbreda Park, Belfast; Mr. A. B. Johnston, Brick Hall, Killy-

The following is the prize list:—

Bees.—Class I. For the best observatory hive: 1, and special presented by Messrs. A. Cross, Bryce, & Co., Belfast, W. R. Orr; 2, William Lonsdale.

HONEY.-Class II. For the best super of comb honey (not being sectional), the super to be of wood, straw, or of wood in combination with glass or straw: 1, and special prize presented by Mr. W. Lonsdale, Lurgan, Rev. J. Hunt, 50 lbs.; 2, W. Lonsdale; 3, Isaiah J. M'Cabe, 20 lbs. Very highly commended, Rev. J. Hunt, 20 lbs.—III. For the best glass super of honey: 1 (presented by Rev. James Hunt, Parkgate), John Rainey, 30 lbs.; 2, John Rainey, 18 lbs.; 3, Edward Smith.—IV. For the best twelve one-pound sections of comb honey: 1 (presented by Messrs. Malcolmson Brothers, Belfast), W. and J. D. M'Nally; 2, Rev. H. W. Lett; 3, W. and J. D. M'Nally.—V. For the best six 2-lb. sections of comb honey: 1, Thomas Moore; 2, W. and J. D. M'Nally; 3, James Lewis.—VI. For the best twelve 1-lb. or six 2-lb. glass jars of extracted or rnn honey: 1 (presented by Messrs. Forster, Green, and Co., Limited, Belfast), George Turner; 2, T. G. Barlow; 3, Alexander Turkington. Very highly commended, Rev. J. Hunt, W. Edmund Best, W. and J. D. M'Nally, and William Lonsdale.—VII. For the largest and best exhibit of comb honey from one bee garden: I (presented by Messrs. E. and W. Pim, High Street, Belfast), Thomas M'Henry, scetions 200 lbs.—VIII. For the best ornamental design in comb honey: I, W. R. Orr; 2, W. and J. D. M'Nally.

WAX.—Class IX. For the largest and best exhibit of bees-wax, being produce of exhibitor's own bees: 1, William

Lonsdale; 2, W. R. Orr; 3, Rev. R. D. Knox. Hives.—Class X. For the best frame-hive: 1, silver medal (presented by W. M'Causland, Esq.), Abbott Brothers, 'Universal Doubling Hive;' 2, Abbott Brothers, 'Combina-

tion Hive;' 3, William Lousdale, 'Irish Jubilee Hive.' Very highly commended, W. R. Orr, 'Irish Jubilee Hive.' -XI. For the best and most complete bar-frame hive, and price not to exceed 10s., unpainted: 1, William Lonsdale, 'Morgan's Cottage Hive;' 2, Abbott Brothers, 'Economic Hive;' 3, Morgan and Son, 'Morgan's Cottage Hive.'—XII. For the best and cheapest straw hive: 1, William Lonsdale, straw hive, complete; 2, Abbott Brothers, straw hive complete.—XIII. For the best two crates of sections, price not to exceed 3s. 6d.: 1, Abbott Brothers, divisible super; 2. William Lonsdale, 'Belfast Jubilee;' 3, Abbott Brothers, Economic super.—XIV. For the best collection of appliances: 1, Abbott Brothers, hive and super, feeder, smoker, veil; 2, Abbott Brothers, hive, veil, smoker, feeder. Very highly commended, Alex. Cross, Bryce, and Co. No. 3 'Morgan' bar-frame hive.

WINCHCOMBE AND SUDELEY FLOWER SHOW.

The Winchcombe and Sudeley Flower Show was held on the 17th Aug. in the grounds adjoining Sudeley Castle, and the gardens were kindly thrown open for

visitors by Mrs. Dent.

The honey class showed a great improvement both in quantity and quality, and in the manner in which it was put up. Judge for honey, Mr. C. Marshall, jun., Cheltenham. Awards:—*Honey*.—Six 1-lb. sections of honey—I, Lord Sudeley; 2, Mrs. Jaynes, Warmington Grange; 3, D. Sheppard, Park Farm. Super of honey (non-sectional)—I, Lord Sudeley; 2, C. Staite. Run or extracted honey—I, D. Sheppard; 2, W. Harris, Winchcombe; 3, W. J. Smith, Beckford. Cottagers' Class.—Honey in the comb-2, John New, Gretton. Extracted honey-1, John New.

ABERDARE SHOW.—A CORRECTION.

In Dr. Walker's report of the result of the examination for experts' certificates, held at the above show, through a mistake the address was given as W. W. Williams, 14 High Street, Newport; it should have been W. Williams, 14 High Street, Caerleon, Monmouth.

Correspondence.

The Editor does not hold himself responsible for the opinions expressed by his correspondents. No attention will be taken of anonymous communications, and correspondents are requested to write on one side of the paper only, and give their real names and addresses, not necessarily for publication, but as a guarantee of good faith. Illustrations should be drawn on separate pieces of paper.

Communications relating to the literary department, reports of Associations, Shows, Meetings, Echoes, Queries, Books for Review, &c., must be addressed only to "The Editor of the "British Bee Journal," elo Messys. Strangeways and Sons, Tower Street, Cambridge Circus, W.C.' All business communications relating to Advertisements, &c., must be addressed to Mr. J. Huckle, Kings Langley, Herts (see 2nd page of Advertisements).

***In order to facilitate reference, Correspondents, when speaking of any letter or query previously inserted, will oblige by mentioning the number of the letter, as well as the page on which it appears.

IN THE HUT.

'To-morrow to fresh woods and pastures new.'

[1211.] My heading this week is doubly misleading. In the first place, the hut is now deserted and left to be used at the sweet will of such earwigs as may find in its old hay-stuffed seats a nice warm home during the coming chilly autumn nights—left to the wood-lice, spiders, centipedes, and damp; for we have gone amongst the heather, and when we return the early closing movement will have come into operation amongst the huttites. Our smoke-offerings and oblations will be paid at the fireside—by the cosy ingle neuk—in preference to the influenza-laden air of the fairy glen. In the second place, we sought fresh fields of forage fully a fortnight ago, and it is to-morrow we go to inspect the workings of our little black slaves in the dark recesses of their honey mines. Solomon tells us not to boast of tomorrow, for we know not what a day may bring forth; and one almost trembles at an absolute decision, with a falling barometer and copious showers, which, however welcome to us here, who for months have had our taps cut off all day except between 9 and 11 a.m., do not make the heart bound with glee at the thought of wading knee-deep through wet ling. Besides, we each take little huttites with us, worthy little scions, whom we wish to be bee-masters in their day. Little pitchers these, with wide ears! Truly it is worth all the hother and cost of the trip to see the young scamps romp about in the sunlight, just 1000 feet above sea level — now gorging on bilberries, then on hard-boiled eggs, qualifying all with copious draughts of new milk.

'Ah, happy years! once more, who would not be a boy!' if only for our stomach's sake, as Paul said unto Timothy. Fully fledged huttites, by the way, follow

Paul.

Such of our readers as haven't seen it, I commend to the bee-keepers a Jubilee joke in the shape of the following advertisement on the last leaf but one of B. B. J., Aug. 18th. It is as follows:— Take notice. A rotten bad stock of Bees in Bar-frame Hive, to be sold Cheap. Price 11. 5s., or as much more as the purchaser likes to fork out.

There is some formic acid being slung about in place of ink somewhere, I ween. I don't think it is the Ruhl, but the exception, for Swanmore bee-keepers to sting thus. It's one more than enough.

Let me introduce E. Garner to Douglas Cooper on the same page. The one wants, and the other wants to sell,

driven bees at the same price per lb.

What fun if the swarm of bees in the Dunbar shop turned out to be those particular bees of Mr. Clark's,-

> The bees which nothing can quell, Antenna-less bees, without smell (Or scent organs rather) a cell Of a queen-grub I'd heartily wel-Come at Horsforth.

'L. Y. D.' makes a chaste answer about being 'caught in the act.' His remarks are far more easily understanded of the people after his explanation; but what must we say about the 'July 4th' oration on p. 299? Read it again, dear reader, and mark well, as a treat, the following:—'What is to be done? Happy thought, the hydropult!' Had one huttite 1 know been there the writer of the lines would have had the contents of the squirt instead of the bees. We are reminded of the pastor's sons who had to stay at home to watch for swarms. Did they not take a bucketful of water and a garden syringe, some long pipes, and a jug of ale? And did not they use the syringe every time the bees showed signs of swarming? Again I quote, 'There is still some water in the pond, though the pump in the yard is dry.' Pity about the pump being dry, but what must be done to him who suggests the alternative, the pond? 'A sudden thought strikes me, let us swear an eternal friendship. The Rovers.

Let us all think of this when we find the contents of our inkpots becoming acidulated.

Joke.—Formic acid cannot be truly classed amongst the acids, for is it not an ant-acid (Formica, an ant)?

I notice this month's l'Apiculteur gives honey as a remedy for warts. The warts are to be touched with honey two or three times a-day. X-Tractor.

A VISIT TO MR. F. REED'S APIARY, PORTSLADE, BRIGHTON.

[1212.] To the north-west of Brighton lies the picturesque village of Old Portslade, in one of the nooks on the sonthern slope of the famed Southdown Hills. We arrived at the station and took our way through the quaint village street, and came to the noted bitter-ale brewery of the Mcssrs. Dudney, and out into a deep valley, heautifully wooded, and, passing through the well-arranged grounds of a very luxuriant fruit and vegetable garden, could not but admire the quiet and pcaceful scene presented to our view, while the blue smoke emerging from among the lofty trees recalled the lines—

'I knew by the smoke that so gracefully curled
Above the broad elms that a cottage stood near,
And I said in my heart, "If there's peace in the world,
A heart that is humble might hope for it here."

For, delightfully situated amid the gardens and orchards, we came upon the residence of the proprietor, Mr. Wilhiam Reed, and here met the genial owner of the apiary we had come to inspect. In apparently delightful confusion, 'far from the madding crowd,' were the various colonies of busy workers forming the 'Stonereigh Apiary' of Mr. Frank Reed, whom we found busily engaged among the industrious denizens. Truly, this seemed a bces' paradise. Sheltered completely from the northeast blast, and protected from the south-west gales, we could scarcely imagine a more suitable locality for an apiary, while around were the open fields, within easy distance the thyme-decked hills, with fruit-trees close at hand, and the thought struck us as to how much the splendid crops with which these were laden were owing to the fertilising labours of the industrious workers of the apiary. Donning our veils, we were soon deeply occupied in investigating the various mysteries and appliances belonging to the science of modern bee-culture. As the different processes of the art were brought under our notice in the lucid and practical manner in which they were, you would hardly wonder at our surprise, especially when the ease and confidence with each was carried on among the thousands of bees around us. Whether familiarity in this science, like some others, breeds contempt we know not, but each stage of manipulation was carried on by Mr. Reed with the greatest abandon. Here we saw the process of queen-raising, there the building up of weak colonies into strong stocks, there brood was inspected, frames of cells were offered for our inspection, the egg of an hour's age, grubs of a few days, the partially developed pupa, and the young bee just perfectly emerged, and in a few hours to take its place among its fellow-workers; drones and queens were brought under notice in due course, then the wonderful manipulation of that important process, queen-raising, was explained and illustrated. Queens were taken from hives for direct insertion into others for the introduction of new strains, others were enclosed in those curious little cages for transmission by post, drone-combs were transferred from one colony to another; the status of others was examined with reference to capabilities for the winter period, and notes made as to the requirements, to be attended to at an early opportunity. Now we were invited to see—what shall we call them-slabs? Yes, that is the most fitting name, slabs of the brightest honey we ever saw. We could fancy the shades of our Saxon forefathers stalking among the luscious stores which furnished the materials of their favourite beverage, for here seemed enough to supply the wants of Valhalla. Honey of Hybla never possessed richer flavour, more delicate aroma, or golden tint than that submitted to us. We have sampled specimens from all parts of the world, but Sussex can hold its own against all comers for aroma, flavour, body, and hue. The tint most prevalent we observed to be that of the finest wheaten straw. Having given the greater portion of our limited time to the various processes and appliances, we looked round again at the various palaces of industry and their occupants. Specimens of almost every kind of hive were to be seen, and their special features were pointed out; after considering the whole under review, we came to the conclusion that for all general purposes nothing better could be wished for than Simmins' Economic Hive. One, a special observatory hive by Rusbridge, must not be passed by in silence, as by it many of the mysterious habits of those wonderful insects may be made more plain to the ordinary student of the apiary. Sections, too, of a very manageable kind constitute part of the economy of this system, when we recall to mind the old cottage system of the straw hive, and recollect that, at this time of year, what holocausts of bees were offered in order to obtain the results of their labour, we cannot but admire and rejoice that among the many advances in scientific labour few have made more and practical progress during Her Majesty's fifty years' reign than that of the apiary. And now, as to the varieties of bees forming the myriads flying around us in every direction. We find this hive contains a variety known as black; keen, sharp, energetic little fellows they are. Here we come upon Ligurians, hard workers, with their bright hands. Now we arrive at a colony of hybrids, black and Ligurian. These have a more robust form, and from the weight of their storeswe tested several—are evidently good workers; but what have we here? What beautiful, glossy, gentle creatures these appear to be. Our obliging friend informs us these are the noted Carniolan hees, and truly for beauty, physique, and working capabilities, these must be considered the hees of the future. Our friend tells us they are the best winterers, a most important point, early swarmers; one of the first swarms this present season in this neighbourhood being from a Carniolan hive in May, and as for their working capabilities they are facile princeps. We had ocular demonstration of their energy and perseverance; even now they seemed as full of vigour as in the height of summer, and were storing pollen in vast quantities for spring use, while the honey produced is of the highest class for grain, body, aroma, and quantity. We could still write on, on this littleknown apiary, telling of the valuable work that is being most assiduously carried on in the most unobtrusive manner, and we feel convinced that more real progress in the science of apiculture is being made here than in many more pretentious establishments. We are sure that should any of our readers feel disposed to pay a visit to the Stonereigh Apiary, Portslade, they would receive a most cordial welcome from our respected friend, Mr. Frank Reed, and not regret the time spent in looking into some of the mysteries of 'the little busy bee.'-E. New, Southwick, August 18.

EXTRACTING FROM BROOD COMBS (1204).

[1213.] I would like to say a few words on Mr. F. Boyes's 'thought' on extracting honey from brood combs, which he calls a barbarous method. Now I have had some experience in extracting honey. I have extracted over 600 lbs. this year and have been awarded three first prizes for it, and shall be glad to forward a sample of it to any analyst for his opinion, for I feel certain it will not be found 'liquid' or containing any of the dirty water that he speaks of, for I don't believe that hees are such fools as to visit such places as 'manure-heaps, stagnant ponds,' &c., if there is good water within three miles of them; and if they did visit such places and carry such stuff into their hives and mix it with honey I should be greatly afraid of some disease arising from its use. And then I find it is necessary to use the extractor freely; when there is a honey glut to give space for the queen to lay, or if not the stock will soon dwindle away. There will be very little honey got in sections or otherwise, and there will be a very poor stock for wintering mostly old bees, and as to injuring the brood it never does, no matter what stage it is in, if the extractor is a good one and used with caution. I therefore cannot think how Mr. Boyes can put such 'thoughts' into the Journal, unless it is to run down pure extracted honey and leave our market open for adulterated foreign honey —G. T.

REMOVING MIDDLE SECTIONS.

[1214.] Will you allow me space to put myself right on the record? Not that I want to pick any quarrel with your correspondents, for I hold it as one of the foolish things to allow feelings of jealousy because we happen to be on opposite sides of 'the big pond,' and I look with interest for the weekly visits of the B.B.J., glad to learn all I can therefrom. We be brethren.

On page 312, B.B.J., Mr. F. Boyes objects to my

removing the middle sections as soon as they are sealed. I am not sure that Mr. Boyes' objections are valid, for, although I do not practise it, I am told that one of our most intelligent bec-keepers does practise it and with good success, as a crop of over 30,000 lbs. in a single season can testify. But Mr. Boyes merely quotes from your interesting correspondent, 'Amateur Expert,' whom I must hold responsible for getting things a little out of

'A. E. says, I use 'the Heddon slat honey-board as a queen-excluder.' I use it solely to prevent building of brace combs between the sections and the top bar of the brood frames. Without it my queens do not go into sections, and if they did the slat honey-board would be no hindrance, as the passage-ways through it are three-

eighths of an inch.
Then 'A. E.' proceeds to say, I take 'the middle sections away as soon as filled, putting the outside ones into the centre of the crate to be finished.' My good friend, 'A. E.,' how could you have understood me as saving anything of the kind? Let me quote just what I did say:— When a super is filled, or so nearly filled that only the outer sections lack a little of being finished, it is taken off and the unfinished sections of several such supers are put into a super to be put back on a hive for the bees to finish.' Don't you see that's almost the opposite of what you say? In strictness I should have used the word 'finished' or 'sealed' instead of the word 'filled,' as the sections are all entirely lilled with honey when I take off the super, there being only a little lacking in the scaling of the outside sections.

Of course all Yankees brag, so please allow me to

brag of my honey-crop this year. From 363 colonies, spring count, I have taken about 300 lbs. of honey, or about 13 oz. per colony. How much I must feed for winter I don't yet know-Drouth.-C. C. MILLER,

Marengo, M'Henry Co., Ill., Aug. 11.

WASPS INJURIOUS TO BEES.

[1215.] I cannot agree with your correspondent (1207) 'W. M. (query, 'Wasp-Master) when he asserts that wasps do not interfere with bees. My experience (see Brilish Bee Journal for 15th Jan., 1885) and that of many bee-keeping friends is that wasps plunder every hive into which they can force an entrance. An acquaintance of mine in the next county more than once lost every stock of bees in her garden through wasps. They were legion about those hives, late and early, till every drop of honey was gone, and every bee dead. This happened some years ago, and those wasps or their descendants have not changed, for since I began to write this, a letter has come from that lady, in which she laments regarding her bees, 'We are persecuted with

wasps,' which I quite understand.
If 'W. M.' has 'never seen or heard of wasps doing any damage whatever to hives,' his experience and reading must be extremely limited. I am no novice in bee-keeping, unless nearly forty years is reckoned such, and I am not afraid of wasps. I do not 'get frightened, and spit and strike' one when it comes near me, but I keep them down all I can because of the harm I have witnessed them doing to bees. And, by the way, my bees have been doing extremely well, though wasps are scarce on my globe; and I have not this season had a single cell polluted with 'aphidal excrement,' which

should have been the case if it is true that wasps benefit bee-keepers by consuming 'green flies.' excellent scavengers, they clear off all sorts of garbage, but they do not benefit our stacks of grain, and we keep them down. Cockroaches are also adepts in clearing up waste and refuse about kitchens, but they can increase inconveniently, and they do attack jam, bread, and other eatables not intended for their defectation. According to 'W. M.'s reasoning, no rat or cockroach should be killed, they should be allowed to multiply, and do as they please, because their place in nature is to devour offal. But no 'R. M.' (Rat-Master), or 'C. M.' (Cockroach-Master), will make a disciple of me, no more than 'W. M.' about his pets, the wasps.

I have just read in a Dublin newspaper of this week of the enormous number of 430 wasps' nests beng taken and destroyed inside the last four weeks within a short distance of Longford. Now I should greatly like to know if the 'wasp-keeper' to whom I alluded in my communication above referred to, is still alive and pursuing his craze in that county, and it would also be interesting to know on what terms the bees and wasps stand in the same district; whether there are many bees, and whether there has been a good yield of honey

this year?

The case adduced by 'W. M.' of a skep-owner leaving 'a hive full of honey, but empty of bees, out till September or October, is one that I can scarcely think ever occurs in practical bee-keeping. Surely a hive full of honey out of which the bees have been sulphuredwhich is the only condition I can suppose—would be stored indoors if unsold.

I may tell 'W. M.' that I do not use a veil, and when I am occasionally stung, and it happens very rarely, I do not experience any swelling or other inconvenience, but then I am told by my family that I am thoroughly

inoculated—sting-proof.

Having answered 'Wasp-Master,' I wish to ask him, How long has he been observing the habits of bees and wasps, and how many stocks of bees has he of his own?

-H. W. Lett, M.A., Aghadery Glebe, Loughbrickland, Co. Down.

PARALLEL v, RIGHT-ANGLED FRAMES.

[1216.] This is a question that I hope all bec-keepers will give their experiences on. I have been at the trade in earnest the last five years, but have not seen one skep with the combs at right angles to the entrance this season, and I have seen over more than a hundred of them. This locality has never had foul brood in it that I know of, and the frames are mostly all parallel to the entrance, and the floor-board is clear of the frames half an inch, with a quarter of an inch bee space round the ends, and we have the satisfaction that the snow does not take the bees out to die in winter, as they do in the right-angled frames. I think it would not be difficult to find a better theory for foul brood than parallel frames. The bee in her natural state does not pay attention to angles of any sort. They build where most convenient. Although I have not seen one skep with the combs at right angles with the entrance this season, I have seen them, and at other angles besides.—N. P., Lochhill, August 22.

On the position of the hives depends the range of the combs. Our contention is, that if a hive is placed perfectly horizontal, in almost every case a swarm of average size will build its combs from back to front. This we have proved in many hundreds of instances, both in skeps and box-hives. Bees, of course, cannot build combs contrary to the force of gravitation. If a skep or box-hive, having neither foundation nor frames, be placed horizontally and then slightly raised, say, from half inch to an inch at the back, the bees will always

build from back to front.—ED.]

RIGHT-ANGLED AND PARALLEL FRAMES.

[I217.] I was pleased to see your correspondent's ('E. Musgrove') letter in your *Journal* of the 18th inst., as I have myself fancied that the parallel are not so good as the right-augled frames, owing, I presumed, to the ventilation not being so perfect.

I am about to build a hive which, I trust, will obviate this difficulty, viz., to give a space between the frames and the floor-board of ene inch at the back of hive, descending to two inches in the front, thus giving a sloping floor-board. By the extra space I hope to secure efficient ventilation, thus assisting, I hope, in keeping down foul-brood, and by the sloping floor-board to help the bees in removing refuse from their hives.

I believe it is generally acknowledged that the extra space is beneficial for wintering, but that it is doubtful whether comb will not be built in the extra space during the summer; yet even with the experience I have had I find in summer that even with Lee's frames—with comb foundation filled in to bottom bar of frames—the bees actually remove about half an inch of the lower portion of foundation, thus making a space exceeding one inch. Why do they do this if they object, as stated by many bee-keepers—to an extra space at the bottom of hive?

I shall be glad to hear of the experiences of any of your readers on the subject, as I am only a novice, this being my second year at bee-keeping. I may mention that, as I work on Simmins' non-swarming system, and have found it up to the present satisfactory, I do not care to take to the frames at right-angles to the entrance.—J. T. Pattison, Chelmsford Road, Woodford.

BEST TIME FOR MANIPULATIONS.

[1218.] Regarding the above subject, according to my experience, I consider that in the honey season when the bees are working is the best time for examining a hive, whether in the shade or not, especially a very strong hive, as a considerable number of the bees are away foraging, and a hive can be examined much quicker and easier than in the morning or evening when they are all at home. But now when the honey season is about over it would be risky to open a hive during the middle of the day, as it would be sure to cause less or more robbing; therefore I find the evening the best time, as the bees very soon get settled after the manipulation, whereas if done in the morning it causes a commotion about the hive during the day, and is likely to attract robbers.—G. T.

BEST TIME FOR MANIPULATIONS.

[1219.] I have examined hives, comb after comb, inserted frames of comb and foundation, cut out superfluous queen-cells, put on crates of sections—this past season I had as many as five on one hive, and I always place the first empty one next the frames—taken off sections and crates at all hours of the day, and I decidedly prefer to do so on fine days during the honey season between the hours of ten and twelve o'clock, when a large proportion of the bees are afield. And I may tell Mr. Chenevix that my hives are not all shaded, only one enjoying that advantage, and a very great advantage I certainly found it during the summer of 1887.—H. W. Lett, M.A., Aghaderg Glebe, Loughbrickland, Co. Down.

THANKS, AND A REQUEST.

[1220.] I beg to thank Colonel Dumaresq and Mr. R. R. Godfrey for their kindness in answering my inquiry. Also to say I think such explanations and advice as they give are calculated to encourage all inexperienced bee-keepers; and if Colonel Dumaresq will be kind enough in your next to give us a little of his experience about foreign bees (as I own I know nothing

about them) and how to commence operations so as to start with them, and if now is the time, or wait till spring of next year, or any other advice he can give, it will be esteemed a favour by—Member Worcestershire B.K.A.

HONEY YIELD—LEE'S SECTIONS—BEES IN THUNDERSTORM.

[1221.] It may interest some of your readers to supplement my letter, No. 1136. The hive there mentioned has given me to the end of July 83 lbs. of very fine sections - in fact, I have not had honey of such good quality since the great comet year. expect to take a few more sections on Monday, as I have been away from home for a month, and left a few half-finished sections in the hope that they might be completed. Of course, the yield is nothing very marvellous, though decidedly good for this very dry season, with an entire absence of warm, damp, honey-producing nights. Having only just restarted my apiary here on a very small scale, I know too little of the neighbourhood to gauge the amount of honey to be obtained, but fancy that very large returns may be expected. I have used Lee's sections largely, and am entirely satisfied with them, and shall probably use no others next year. Did any one note how exceedingly vicious bees were on the day of the thunderstorm, ten days ago? It was an excellent opportunity to test 'apifuge.'—A. G. RADCLIFFE, Fonthill, East Grinstead, Sussex, August 27th.

TIME FOR MANIPULATING—INOCULATION, &c.

[1222.] In answer to Mr. Chenevix in your number of this date I must say that my experience is in harmony with his and contrary to your own. Throughout the hot weather my bees attacked me invariably if meddled with between ten and five; after seven they could usually be handled with impunity, but when very hot a later hour had to be chosen.

The alleged 'inoculation' of stings I believe to be a delusion. Last year I took a stray stock of hees out of my roof. I had first to put up a scaffold and to remove the slates at about forty feet from the ground. When the nest was opened my smoker suddenly gave out and refused te work. My bee-veil I was obliged to lend to a friend who volunteered to help me. The stock was a strong one—I daresay there were 30,000 bees—and I believe that every bee except the queen and two others left its sting in my skin; the two others stung my friend. When the job was over I appeared as if I had begun to turn into a hedgehog. During the present summer I have been stung on an average about twice aday for three months; yet I am not inoculated. I don't find that the stings hurt less than formerly. I think they hurt more.

I have no doubt that the inoculation theory has arisen from the fact that the pain from bee-stings varies very much with different stings. Nine stings out of every ten hurt very little, but the tenth is a fine test for self-control. If you can stand that without howling you are a stoic. Now, when a man first begins to manipulate bees his want of skill brings him a good many stings, and among these are sure to be some of the severer kind, and his natural funk leads him to exaggerate the severity of the stings that he gets. As he becomes used to the business he gets but few stings, and as nine out of ten of those don't hurt much, he thinks he is getting inoculated; but only let him wait. The tenth sting is sure to come, and then see what he says about inoculation!

As I am writing to you, let me mention other topics. I cannot see the value of wired foundation. I have extracted this year a number of combs that were foundation three weeks before, and have had no breakages and no trouble of any kind.

I do not agree with Mr. Boyes's objections to extracting from brood combs. If done with ordinary care it does no harm whatever to the brood, and the honey is absolutely indistinguishable from that in other combs; in fact, as the outside combs are brood-combs one week and honey-combs the next, it would be hard to make out a difference between brood-comb honey and honey-comb honey.

Wasps are very numerous here and do not appear to

do any harm.

Bee-keepers should not be too ready to assume that a stock is queenless. I examined this week a stock covering sixteen frames, in which there was not a particle of brood in any stage, and there were numerous drones, all other stocks having killed their drones a month ago. I gave them a frame of eggs and a pint of syrup, and next day no queen-cell was begun, and there were eggs on two other frames.

To estimate the amount of honey that should be left for wintering by the superficial area of sealed comb is most misleading, since some sealed combs are two and a quarter inches thick and some not more than threequarters of an inch. The former will weigh five pounds

and the latter less than one.

I have all my hives made the same pattern and same size, thus every roof and stand fits every hive, and every hive body will double any other.—C. A. M., August 25th.

[We advise inquirers and correspondents according to our own experience, and not from theory. Opinions will always differ, and if in the honey season any, contrary to our advice, find that they can manipulate better in the evening than during the hours of flight, by all means let them do so; or if they find unwired foundation equally as good as wired, let them use it. But if any are anxious to become sting-proof we certainly do not advise them to persevere in the attempt to the extent of receiving 30,000 stings in the course of one operation, since we fear to many constitutions such a course might prove fatal!—Ed.]

NEPETA.—LIMNANTHES.—SUNFLOWERS.

[1223.] If your readers will turn to page 301, No. 1154, they will there see that in consequence of many of our bee-keeping friends failing to strike the cuttings of Nepeta Mussini, 1 promised to strike a large quantity, and when ready, to offer them to those who would like to test the value of the same, and I beg to say that I have now a goodly number ready of nicely rooted and strong plants, and some with a little bloom upon them. But it must not be understood that my position in life will admit of me sending them on the same terms as I sent out the cuttings, so, in justice to myself, I must put a price upon them, and I have inserted an advertisement in this issue. I have plenty of limnanthes seed, and shall be pleased to send some to any who would like a little. It is now quite time to sow the seed, and plant out when ready. I sow the seed in rows two feet apart, and thin out the plants to the same distance in the rows, and they completely cover the ground, and do much better than when I have left them closer together.

I am sorry to say that I cannot offer any more borage seed at present, as the green linnets have laid upon it so very closely, and taken nearly all the seed away long before it has been ready to cut for seed. I am glad to say that it does not appear to interfere with the blooming of the plants. I have still large masses of bloom, both borage and Nepeta Mussini. The latter is still, and has been, one mass of bloom ever since the middle of June, and this will continue until the frosts come and put a great check upon it, but it does not kill the plants, as they are perfectly hardy, and the older

Just a word in reference to sunflowers. It may appear

they get the stronger they grow each year.

strange to some for me to say that I never can find any bees visiting them, although there are many of them grown near, and the bees fly right over them to get what I suppose they like better. This may be accounted for by the difference in the soil in different localities.—C. H. W., Aylesford, Maidstone.

VENTILATION.

[1224.] It seems to me that bees cannot have too much ventilation by the entrance at any season except when robbing is going on. I have, therefore, cut away part of the entrance slides, and nailed on perforated zinc. Why should not all ontrance-slides be thus made of perforated zinc? They are of no use except to prevent robbing. Ten or twelve inches of entrance is surely best when robbing is not going on. A simple plan (by which a dozen may be made in a few minutes), is to take two sides of an old section, plane the edges, to make them the right depth, cut the piece of zinc, and nail about an inch of it between the two pieces of wood by a single French nail, which, of course, must be turned down and hammered in at the back. No other nail is required.—L. Williams, Wheatley, Ocon.

P.S.—There are many wasps in this neighbourhood.

DOES BEE-KEEPING PAY THE COTTAGER?

[1225.] I found and hived a swarm of bees (vagrants) the second week in June on six frames of worked-out comb, and added four frames of comb as the bees required them, and when the ten frames were well covered I put on a crate of twenty-one sections and left them to do their work in peace, which they seemed to do with great energy; but judge of my surprise on Saturday, when I thought of taking off sections partly filled at the least, to find them empty, and only about two inches across the top of each frame with sealed honey, and the hive full of bees and nearly all the combs with some brood in all stages in them. So much for the vagrants.

I then hoped to find better results from the only hive I saved through last winter out of eighteen stocks, the result is the seven frames are well covered with bees and a little honey at the top of each frame, and brood in all stages in the frames, but a frame with six sections fixed in it, placed behind excluder-zinc at the back of the hive, was empty. This stock was fed in the spring on scaled honey; I did not expect much from this stock, as it was a lot of last year's driven bees and the queen was hatched in June, 1886. I may say four of the stocks which died in the winter were in straw skeps, the rest in bar-frame hives, and they did not die of starvation, as frames in all the hives, except two, contained scaled stores after they were dead; also each of the skeps had scaled stores after they were dead.

Nine queens that died were hatched in 1886, four in

1885, and four in 1884.

The eighteen stocks had about 2 cwt. of sugar given them in thick syrup in the autumn, and no honey was taken from any of them last year.

I have plenty of clean and empty worked-out combs and empty hives (my own make), but no honey, so I think I may reasonably ask does bee-keeping pay—A COTTAGER?

INDIAN BEES.

There are four species of honey-producing bees in the Wynaud. The largest (Apis, Sp.?) builds, as a rule, on the inaccessible ledges of precipices, preferring such as overhang rivers; also on the largest trees in the forest, preferring those that are isolated, and have numerous horizontal limbs. Such trees, as Bombax malabarica, Mangifera indica, Ficus, &c., are usually preferred, and

the colonies return to them year after year without fail. Such trees and precipices are known as 'Burrays,' and used to be the property of Kurumber 'Hadis' (villagers), each Hadi possessing a certain number of Burrays. Such Burrays are now the property of Government, except where they are situated in private lands. There are two crops in the year, in May and November, and the honey and wax are gathered when the nights are dark, i.e., just before ammavassi, or new moon. combs are usually built, when on the ledges of precipiees, facing the north-east, to avoid the blow of the south-west monsoon. The comb is semi-globular near its attachment to the rock, and $2\frac{1}{2}$ feet to its junction with the lower half, in which are contained the larvæ. The pollen, which is the principal food of the latter, and is generally known as bee-bread, is deposited in the cells at the junction of the upper and lower portions. The queen and drone-cells are generally to be found near the edge of the comb. A fortnight after the larvæ attain their full development, and appear as imagos, the colony splits into two—the parent and infant colonies separate, and seek other trees and fresh pastures. The number of colonies that seek a Burray in a season depend entirely on the season and the amount of flowering trees in the neighbourhood. The bees, when they desert the tree and comb of the season, do not make their way to the nearest Burray, but frequently travel for a week or ten days to distances of over a hundred miles, even crossing such mountain-chains as the Nilgiris in their migrations.

The best honey-producing flower of Southern India is the *Strobilanthes*, which not only forms the principal undergrowth of the Sholas, both temperate and tropical, but spread over the grassy slopes of the higher elevations.

There are an immense number of species in this genus, and they almost all flower once in seven years, dying down entirely, and afterwards a fresh growth springs up from seed. Whenever any species of Strobilanthes flowers, colonies of bees migrate from all parts of the eountry to feast on the honey, and rear their young broods. At such times honey becomes plentiful and cheap, and as the *Strobilanthes* honey is of the finest quality and flavour, even rivalling that from the famous Mount Hymettus, it is eagerly sought after by the Todas of the Nilgiri hills, and in fact all the aboriginal tribes. The year 1879 was such a season for honey that it sold at the rate of 4 annas per imperial pint, whereas its usual price is from 8 to 10 annas. This honey in the cold climate of the Nilgiris crystallises in from a fortnight to three weeks, when the flavour becomes richer and finer. In the Wynaad, as soon as the moon has waned sufficiently, great preparations are made to take the boney. Bamboo and rattan ladders are constructed. These are sometimes of astonishing length, and at nightfall, after 9 p.m. (for the bees do not go to bed till then, as you will find to your cost if you disturb them), the Jain (honey) Kurumbers proceed to the Burray, and having erected their ladders if they have to climb upwards, or suspended their cane ladders if downwards, arm themselves with torches and knives, and sever the combs from the rock or branch. The drowsy bees, meanwhile roused by the glare of the torches, desert the combs and buzz aimlessly about, alighting in thousands on the rocks and branches about, and even on the persons of those engaged in taking the combs, but never attempt to sting, unless crushed or hurt. The combs are then lowered down in baskets, the Kurumbers feasting on the larvæ, which taste something like cream, whilst the fish which swarm in thousands when the hives are built over a river bave a glorious feed on the grubs and bees that fall into the water and float helplessly down stream. The upper portion of the combs containing the honey is detached and thrown into a coarse canvas bag, which is squeezed with a tourniquet,

the honey flowing into a copper caldron, in which it is afterwards boiled to prevent fermentation. The wax is boiled separately in water and then strained; it is afterwards melted and moulded into sheets, which, being exposed to the sun to bleach, are remelted into blocks of a hundredweight each. To attempt to interfere with these bees during the day is madness, and many a sportsman and traveller has barely escaped with his life after doing so. Indeed it is no light punishment to be assaulted by the countless hosts of infuriated bees that attack you on the slightest provocation; and it is only necessary to light a cheroot, and sometimes even merely to go near them, to draw down their vengeance on your head. Nothing can then be done but to hasten to the nearest pool of water, and leave nothing visible but your nose above it. I could give numerous instances of men, cattle, horses, and even fowls and pigeons, being killed by those bees; but I have no space for such in this letter. These bees, however, will not attempt to sting you unless they have stores of honey and their young to guard, for it must be remembered that the insect sacrifiees its life when it stings you in the defence of its hive and young; the sting being so constructed that the poison-bag is torn out of the body when the bee tries to withdraw the sting from the skin in which it is firmly

The next species of bee which I am now going to describe is about half an inch in length, and of a dark-brown colour, the abdomen ringed with pale yellow. The thorax is generally infested with a minute parasitical insect. It forms its combs in the hollows of trees and rocks, and sometimes in hollow caves of the termite nests, which are so abundant in the Wynaad. Unlike the first-mentioned species, its combs are of nearly the same thickness throughout, i.e., nearly three-quarter of an inch between each row.

The honey is superior to that manufactured by the cliff-bee, and thicker, but is occasionally poisonous when the honey is collected from such plants as the various species of Lobelia. It is then aerid to the taste, and, if swallowed, produces nausea and violent purging.

This bee I believe to be identical with European species, and more like the Ligurian variety. In Coorg it is domesticated, and the hives, made of the hollowed-out trunks of trees, are placed near houses; but the Coorgs have no notion of collecting the surplus honey by such contrivances as bell-glasses, &c., as they do in

apiaries at home.

On the Nilgiris I have tried numerous experiments, and succeeded admirably. There is no reason why apiculture should not be successfully carried on at Ootacamund, and other highlands in Southern India. I found that an ordinary beer-cask, placed in a warm and sheltered situation, made the best hive; a small board nailed on near the bung-hole serves for the bees to alight on when leaving and entering their hives. When the swarm has been thoroughly established, i.e., when two or three other swarms have increased the strength of the parent stock, bell-glasses can be placed on the top of the eask over holes bored for the purpose, and removed from time to time, as they are filled by the industrious little workers below. When bees have ample space to work in, queens are rarely or never bred; it is only when the accommodation proves insufficient in the hole in which a wild swarm takes up its abode, that the young swarm has to look out for a fresh home, accompanied, of course, by its young queen. The Todas on the hills, when they take a hive, invariably block up the hole with two or three stones. This is done because these bees object to too much light. Residents on the hills are frequently annoyed by swarms settling in the tiled roofs of their houses, and stinging children and servants. This could easily be prevented by providing proper bives for them. Half-a-dozen empty casks would be immediately tenanted, and the honey could be turned to account.

In April and May, when the iron-wood (Mesua ferrea) blossoms, this honey is abundant, and of the most delicious aroma and flavour. Bees are very peculiar in their likes and dislikes, and, while they will allow one person to plunder their hoards without hurt, will violently sting others. It is difficult to explain this peculiar power which the bee-masters and bee-kings at home exhibit, but one of their great secrets undoubtedly is to treat the bees gently.—The Asian.

Echoes from the Hives.

Waterhouses, Co. Durham, August 23rd.—I never knew wasps so numerous as they are this year; we find them in nests every few yards as we pass along the roads. Last night, in returning from work at dusk I came upon three men taking some nests in order to get the grub for eage birds; they did not find much grub, and one of them said they had taken them too soon; if they had been a week or two later they would have been full of grub.—J. F.

Ringstead, Thrapston, Aug. 29.—The honey season in this district is now over, and most of the surplus honey taken up. It has been a very good one, and the honey is ex-cellent in quality. I wintered thirteen colonies, and have taken over 800 lbs. of honey, and am now leaving sixteen for the coming winter amply provided for without feeding. I work on the storifying system, and leave the two bottom boxes for the bees to winter in. I generally find the bottom one to contain nothing but empty combs at the end of the season, and the one above to be pretty well filled with honey; and with honey at its present price I find it pays me better to leave the two, instead of crowding the bees into the bottom box and then have the trouble to feed them up. My best colony was wintered so last year on eighteen frames; it has given me over 100 lbs. of honey this summer, and I have left it again to winter on eighteen frames, the top box filled with honey and the bottom one with empty combs. - John Bull.

QUERY.

[1226.] Can any reader of the B. B. J. kindly furnish me with a recipe for making a good honey beverage; quantity required, say 1 doz. 11 pint bottles?—J. J. Chinnick.

NOTICES TO CORRESPONDENTS & INQUIRERS.

Letters or queries asking for addresses of manufacturers or correspon-Letters or queries asking for addresses of manufacturers or correspondents, or where appliances can be purchased, or replies giving such information, can only be inserted as advertisements. The space devoted to letters, queries, and replies, is meant for the general good beckeepers, and not for advertisements. We wish our Correspondents to bear in mind that, as it is necessary for us to go to press in advance of the date of issue, queries cannot always be replied to in the issue immediately following the receipt of their communication.

All queries forwarded will be attended to, and those only of personal interest will be answered in this column.

All queries forwarded will be attended interest will be answered in this column.

- James Houston. Borgue Honey. The high repute of Borgue honey has reached us. The samples from Borgue and the adjacent parish, Twynholm, Kirkcudbrightshire, well sustain its high character: from its flavour we should say that it had been gathered from wild thyme, from its appearance from sea-lavender (Statice limonium); but we should require to know some further particulars as to the time when it was gathered, &c., before we could speak with precision as to the plant from which it was produced. We received last year from a village on the coast of North Yorkshire a sample of honey similar in appearance, though not equal to the Borgue in flavour. It is desirable that some hotanist of either parish should look into his local flora, where he will find Borgue the habitat of the plant of which our correspondent is in quest.
- J. Fenwick,—Wasps.—We have in previous numbers given information respecting the natural history of wasps. These have much in common with hive bees. live in communities. Each community consists of queen, workers, and drones. They do not swarm in the summer, however (as your informant asserts), like hive bees. All the community-queen, with workers, drones, and brood -die off at the first attacks of winter. The only

survivors are the young queen-wasps, who, after lying in a dormant state during the winter, are revivified by the beams of the vernal sun, and then forthwith proceed to carry forward the economy of wasp-life.

Lascelles Carr.—Novice's Metal Corners.—1. These may be procured from Messrs. Neighbour or most of the dealers in bee appliances. For the reasons stated in Guide-Book, pp. 33, 34, we adhere to them in practice. 2. Absence of Distance Guides.—In our pamphlet on Doubling and Storifying, recently published, speaking of the Cowan Hive, we say, 'There is a very important feature in this hive, and one to which we in a great measure attribute our uniform success. It is that our frames have neither distance-guides, pins, nor projecting shoulders, and that we can bring them closer together or put them farther apart as we wish without any difficulty.

R. E. C.—New Zealand.—1. Having so strong a preference for Abbott's broad-shouldered frames, there can be no objection to your taking with you a supply; but we have no doubt that you will find in the colony every appliance that experience has found suitable to the elimate.—2. Four years ago Mr. Firth started a bee journal called The New Zealand and Australian Bee Journal; it was edited by Mr. J. C. Hopkins. It did good service in its time, and considerably promoted the cause of bee-keeping in the colony; but, as it never paid its way, it was discontinued at the end of the second year, and incorporated with the New Zealand Farmer, Bee and Poultry Farmer. Since the 1st of July of the present year, the Bee Johnnal has been resuscitated under the name of the Australasian Bee Journal, which is devoted exclusively to the interests of bee-keepers and bee-keeping throughout Australasia. It is published monthly by Messrs, Hopkins, Hayr, & Co. The subscription to the British Bee Journal, post free to New Zealand, is 10s. 10d., forwarded fortnightly.

H. W. Wise. - Italians or Hybrids? - Of the six specimens sent one is black, two have one, and the remaining three have two yellow bands. If the offspring of the same mother they are hybrids.

M. E. K.—Fermented Honey.—Do not feed your bees upon it, or you will surely produce dysentery. Yes, a damp store-room, where the honey is kept in closed wood case, would be very likely to cause fermentation. Earthenware or tin arc the best receptacles for keeping honey in bulk. Very much depends upon the honey being perfectly ripened and sealed in the hives before extracting. Thin, unsealed honey, invariably ferments. We advise you to use it for culinary purposes.

J. C. Binder.—Temporature for Keeping Comb-honey.—By experience we have found a temperature of from 65° to 80° Fahr, best for this purpose. Our sections are placed on shelves, with small spaces between the sections, in dark, well-ventilated closets, at a temperature varying from 65° to 70° Fahr., and, care being taken to keep them free from dust, we find them fresh and free from granulation, as a rule, the following spring. But much depends on the plants from which the honey is collected. A temperature of 100° Fahr, is too high.

Tipperary Subscriber.—Preservation of Honey.—The keeping properties of honey depend much upon the bloom from which it is gathered. Fruit, hawthorn, and white clover honey keeps best, and is less liable to granulation than that collected from most other bloom. Mustard, turnip, and the brassica tribes produce honey which quickly granulates. Sections should be well ripened and well sealed on the hives, and after removal should be kept in a dark, dry, well-ventilated room at a temperature of 65° or 70° Fahr. See answer to 'J. C. Binder.

E S. A. Gougn.—Larender Water—Peppermint,—Lavender water is not as satisfactory as peppermint for the purpose, but there is little choice in the matter if the essence, and not the oil, be used. Pour a little flavoured syrup between the frames of both lots after having given them a good smoking.

Gerald Tatham.—Moving* al Uniting.—The hives can be moved any time during the cold season, choosing a day when no bees are flying. If you really wish to unite—a process which should give you a grand return of honeyit would be best to wait till next March or beginning of April. You should set your hives in pairs when you

move them so that when united there will be less disturbance of locality.

W. T. Cadness.—The expert of the district has kindly promised to call upon you and advise.

Exhibitor, Northampton.—Judging Honey.—You seem to entirely ignore the fact that there are different degrees of gravity, flavour, and translucence in honey, and seem only to look at the subject from an onlooker's point of view, viz., appearance. This is quite a secondary consideration; if otherwise, heather honey—the most expensive description—would have to remain quite amongst the lowest grades. Ask a North Countryman's opinion; he will tell you that light elover-' flower honey,' he calls it—is not worth a rap, and yet you would desire to see this same honey placed in a prominent position, simply because it was lighter in colour. As a point in judging, flavour is of the ntmost importance as well as consistency. Some light-coloured honey tastes as so much sugar syrup, but, being light-coloured, you would give it a place among the prizes; we should pass it and give the prize to a goodflavoured exhibit although dark.

JUBILEE, 1887.—It always gives us pleasure to report the Shows of Associations. We published the report of your Show as it reached us.

W. J.—The raw sugar, of which we have received a sample, will be found serviceable for dry-sugar feeding. Please refer to former numbers for the proper time when dry-sugar feeding should be beneficially resorted to.

J. H. L.—Driving Bees from Box Hives.—You may remove the box, from which drive the bees; return the bees to the frame-hive, and after putting excluder over a hole in the quilt, replace the box. The queen will thus be below, and as the brood hatches out of the box the cells will be filled with honey, if you have heather or other forage near you. Of course, if you take the honey you will have to feed them up, but this we would not recommend as you would lose the young brood, Breaking up the boxes and transferring the tender combs would mean a messy operation with honey and brood, and likely to start robbing. We should think if the two casts have filled ten frames they have not done badly. Try and prevent so much swarming next season by giving room in advance of requirements, and squeezing (not cutting out) queen-cells.

Your Correspondent,—We prefer that you communicate privately with the gentleman mentioned in your letter,

S. A. B.—The bees sent are English black bees.

LEIGESTERSHIRE AMATEUR,—Remove the bees from the heather when the pasturage is over.

W. C. N.—The parasite on the bees was the Braula cæca, or the bee-louse. These are not desirable companions, but they will die off as the season advances.

Co. Limerick.—1. Pollen-clogged Combs. As you say the honey has been removed from the combs you wish to store away, it is evident only a probably small percentage of the cells is clogged with pollen. Do not melt them up, the bees will clean them out in spring.—2. Bitter Honey. Quite likely the bitter taste proceeds from pollen becoming mixed with it in extracting. Honey being grape sugar cannot be other than sweet per se.

G. G.—Utilising Heather Honey.—By cutting the combs to pieces and squeezing them either by a fruit squeezer or in a cloth, you of course destroy the value of the foundation on which they have been built. The plan you propose of cutting the honey in the cells off close to the midrib, giving that to the bees to lick up, is the best. You may then squeeze as much as you can out of the cuttings, and by using a wax extractor the honey will run first, and then the wax, and so you will recover both with as little loss as possible. If you had not extracted the clover honey when the heather came on, but put on sections, you would have had these filled with the heather instead of the frames in the stock hive.

H. W. P.—Moving a Hive a Short Distance.—Wait until November or longer if the weather is fine and open. You may move it with safety at one operation when the weather is too cold for the bees to fly. Place a board against the entrance to call the attention of the bees when the first fine day occurs and cause them to mark down the new spot.

Received from 'G. T.,' Co. Donegal, a sample bottle of honey. We have a very high opinion of the qualities of this honey. It was of good consistency and colour. It possessed an agreeable flavour. There was a certain piquancy of taste about it which added to its pleasantness. One word of caution as to packing. Though packed in brown corrugated paper, we noticed on delivery that there had been considerable oozing in transit, and on removing the surroundings we found the bottle broken, and consequently almost all the honey was lost.

Received, from Mr. W. Elfred, a bottle of honey from his apiary in Warwickshire. The honey was clear in colour, rich in quality, and of a good consistency. It ought to fetch a good price in the market. We thank him for trouble taken in forwarding it.

Communications to the Editor to be addressed 'Strangeways' Printing Office, Tower Street, Cambridge Circus, W.C.

[No. 272. Vol. XV.]

SEPTEMBER 8, 1887.

[PUBLISHED WEEKLY.]

Editorial, Notices, &c.

FOUL BROOD.

In our correspondence columns we publish two letters of considerable interest on this vexata questio. Mr. Ward's experiment, through a course of years, would seem to prove that the disease depends entirely upon the queen, and is in accordance with Mr. Simmins' views.

On the other hand, the 'Man of Kent,' in agreement with the compiler of 'Useful Hints,' when experimenting on diseased stocks, finds that healthy queens introduced to such stocks soon become diseased themselves. It is the old, old story, Quot homines tot sententiae. Whether our views on any particular subject are formed from practical experiments, or whether the latter are undertaken in order to prove the former correct, quite unconsciously to ourselves, no doubt, there is a decided bias one way or the other. 'Man of Kent' has solved the problem to his own satisfaction, almost with an à fortiori, to the effect that there is no truth in the 'germ theory.' Now what is the germ theory of disease? If asked briefly to define it, we should say that it is 'the theory which supposes the cause of epidemic and contagions maladies to be due to the agency of specific small germs, different germs giving rise to different diseases.'

We certainly hesitate to pronounce the lifelong researches of such men as Professors Cohn, Kock, Pasteur, Tyndall, and many others, as utterly worthless, and the theory deduced therefrom as unworthy of credit. Assuredly the microscope is a great power amongst us in this nineteenth century; and when we consider that the blood of patients suffering from scarlet fever and containing bacteria being injected into the veins of rabbits, a feverish disease, which proves fatal, is immediately set up, we more than hesitate to proclaim our disbelief in the germ theory. This is one only of numerous instances, still more convincing, which might be adduced in proof of this germ theory. The experiments of Drs. Ferrier and Sanderson show that bacteria do not nominally exist in the fluids and tissues of the body, but that their presence in the animal fluids may be traced to external surface

contamination. How can it well be doubted, then, that if a healthy queen be introduced into a diseased hive, she must, almost of necessity, contract the disease arising from bacilli? Dr. Beale tells us that extreme dryness will not destroy bacteria, and that they will withstand a temperature far below freezing-point, and, indeed, that they are not destroyed by a degree of heat which is fatal to every other living organism. Professor Tyndall has shown that, in one experiment, heating for a quarter of an hour at 230° Fahr. was insufficient to destroy them, while in another five minutes exposure of an atmosphere containing them to the incandescence of the voltaic current failed to kill them.

Now of bacteria the bacillus is the *most* tenacious of life. If, therefore, as microscopists seem to agree, bacillus is the cause of foul brood, we can no longer wonder at the difficulty of eradicating it. And since the germs, or spores, exist in the densely-packed pollen, in the cells, in the exuviæ, in wax, in propolis, and in what not, how shall a diseased hive be disinfected? Dzierzon recommends two years'

exposure to the atmosphere!

Now, so far as our knowledge at present extends, i.e., according to our present light, stamping out by reducing to ashes every contaminated hive, comb, or other article, and destruction of the diseased bees, would seem to be the only safe plan of dealing with this dire pest, which is already decimating our apiaries, and bids fair, if strenuous means are not adopted, to stamp out English apiculture itself at no very distant date. Has Mr. Cheshire no word of comfort for us? Why is he silent so long? In our opinion the fell disease will never be conquered by change of queens, phenol, salicylic acid, nor by any other known remedy. Our advice would therefore be 'Stamp it out, as the Rinderpest of apiculture.'*

We recommend the perusal of an article on this subject entitled 'The Creatures we Breathe,' by Dr. Percy Frankland, published in the August number of the *Nineteenth Century*.

^{*} Should, however, our advice as above given be not carried out to the letter, and the hive be spared from the general destruction, let it be disinfected with a solution of carbolic acid, mixed in the proportion of three ounces of acid (Calvert's No. 5) to a quart of water. First mix the acid with an equal quantity of glycerine, and add the water hot, continually stirring same.

FOREIGN GLEANINGS.

British inventions seem to be well appreciated on the Continent, according to the *Revue Internationale*, which notices in its May number Neighbour's new section case, of which it gives an ample description accompanied by an illustration. Webster's fumigator is also both praised and described in a leading article entitled 'Chit-chat.'

The Editor also does us the honour of quoting our recent utterances respecting Grimshaw's Apifuge, and appends the result of his own experiments with it. He says:—'A certain number of testimonials have already appeared confirming the good opinion formed of it, and our own trials of it on our most vicious colonies permit us to add ours to theirs; it is wonderful (merveilleux).'

In the July number, M. Bertrand, the editor, devotes a special article to 'L'Apifuge Grimshaw,' which we have pleasure in translating:—

'We have continued our experiments with this new agent, and are more and more astounded with its efficacy. Having received a visit from several pupils who were desirous of seeing how we proceed in taking honey, we, in the first place, attacked a stock of Cyprians which had entirely filled three storeys. Putting on one side a little pardonable amour propre in one's profession, the hive was well chosen for such a demonstration, for this race is not always easy to handle; we were, however, soon compelled to discontinue, although protected by a veil and armed with a smoker (which, by the way, we only used after having vainly tried to operate without smoke, as is recommended with Cyprians). The bees were not slow in stinging us atrociously on the hands and . . . elsewhere; we were absolutely covered by bees, which introduced themselves at every possible point in our clothing. As they began to get very excited, attacking the assistants and even persons a considerable distance away in the garden, we closed the hive in order to resume the demonstration on other colonies less evilly disposed. The next morning we determined to be quits with our Cyprians by other means, and had recourse to Apifuge, with which we perfumed our hands and veil. Not the least excitement was produced, and we were able to take away 166 lbs. of surplus honey which the hive contained, without interrupting their working and without experiencing a single sting. One poor bee, squeezed against a frame, stung a finger, but we felt no pain from it. Apifuge is thus, in addition, an excellent remedy for stings, as we have since then been able to test and verify by renewing our experiments with this object in view; a drop of the liquid applied to the part which has been stung immediately soothes the pain. Several people have complained in the British Bee Journal of having had marks on their hands after having used apifuge; we have observed nothing of the kind, although we, with several colleagues, have submitted to numerous experiments. The only fault we have to find with Mr. Grimshaw's magnificent discovery is that the liquid is too dear, and from all we hear there is little hope that the price can be much reduced, the substances which enter into its composition being so costly. Here is what one bee-keeper says:—"I have tried Grimshaw's apifuge with the best success. I made two transfers from old hives into bar-frames without receiving a single sting; it is really marvellous, as you say, and I recommend all bee-keepers to use it without the least fear. To me, who am a novice, it is very encouraging, for I make my debût as an old soldier, who does not fear the enemy because he has never been wounded. -J. Obiols Amigo, Barcelona, July 19th, 1887."

In EApiculteur (editor, M. Hamet) Apifuge is considered of such importance that copious translations

from our columns are given for the guidance and instruction of French bee-keepers.

In 'Gleanings' Mr. A. I. Root speaks in somewhat qualified terms respecting Apifuge. After trying in vain to get stung by manipulating a hive of Cyprians, he came to the conclusion that had the bees been inclined to sting they would have done so—'apifuge or no apifuge.' The fact, however, remains the same, that he experimented on a vicious colony without being stung.

We notice also a contribution to the columns of the *Revue Internationale* from our valued correspondent Mr. W. B. Webster, besides another from M. Woiblet, recommending honey-water as a cure for warts. Altogether, it is pleasing to find beekeeping assume such a good-humoured international aspect in which British discoveries play so important a part, and receive such courteous consideration.

With regard to Mr. Grimshaw's Apifuge, which has been so highly spoken of by advanced foreign bee-keepers, we own that it has caused us much surprise,—we may say disappointment,—that this agent does not appear to have received any recognition of its virtues at the hands of the judges of the shows held during the past season. not whether this is to be accounted for by the manner in which it has been staged, or whether there has been a difficulty arising from the inability of the judges in testing its efficacy. There can be no doubt that the arrival by Mr. Grimshaw of the value of Apifuge must have involved much thought and been the result of many experiments. And we feel sure that it would have been encouraging to him to have had his endeavours to assist beekeepers in some degree acknowledged. During the past season the opportunities of ascertaining its capabilities have been very numerous, and a host of bee-keepers, both at home and abroad, are ready to testify to the comfort and confidence they have derived from its use in the manipulation of their bees, and to the alleviation of the stings they may have received. We are loth to believe that this is a case where the prophet is without honour in his own country; for we are well aware that the number of those who have benefited from the discovery of Mr. Grimshaw is very large, and would be pleased to express their gratitude to him for the same; and we are sure that if bees had voices they too would join in the loud acclamation.

MANIPULATING.

The present is the worst of all seasons of the year for manipulating. To the inexperienced and timid beekeeper manipulation is never attended with malloyed pleasure; certainly there is always a very large amount of pleasure to be found in examining a colony of bees, in turning the comb up so that the light illuminates the cells to their very bottoms, and reveals the tiny eggs so securely cemented in their places, or to watch the grubs from their first stages of life on to the time when they become ferocious-looking, burly fellows, almost too big for their habitation; or if we turn from them to the adult bees, and notice the effect the smoke and the sudden letting in of light has had upon them, how interesting to watch them standing with heads and thorax thrust into the cells lapping up the food that

they may be prepared for an emergency in case their home is about to be broken up. Here we see several rushing about to find a cell containing unsealed stores which have not already been taken possession of, while every now and again we behold one which has been fortunate enough to get fully gorged, readily giving up of her abundance to a less fortunate neighbour who has none, and in the midst of all this commotion we spot her majesty careering along with undignified haste and gait, scarcely knowing what to do under the bewildering circumstances with which she is surrounded.

At other times, especially on balmy, bright days in early summer, examination does not produce such a panic. A few will be gorging at the open cells, certainly, but the greater number will be quietly moving about, touching their neighbours with their antenne to assure themselves that all is well. Here and there a bee will raise its wings with a sharp, peculiar 'whint,' as if intending to take wing, but, suddenly altering its mind, will, perhaps, career around on its legs and remain with wings unfolded and unhooked looking somewhat ruffled and untidy, while her majesty may be seen going about her duties in the ordinary way, examining each cell, and depositing the tiny egg in each that she finds

prepared to receive it.

To those of the fraternity who are lovers of natureand which of us is not?—such sights are pleasant, and are apt to make one linger even longer than is sometimes well for the bees themselves. But our meditations are often liable to be somewhat distracted by the fear of being at any moment called upon to endure pain. A recent correspondent in the Journal seems to entertain the idea that some of the old veterans are inoculated so as to be exempt from pain. I have yet to find the beekeeper who has attained to that happy state. A sting causes me as intense pain as ever it did, but the pain is of much shorter duration, and, not being attended with swelling, as in our early bee-keeping days, one is saved the pain and soreness consequent on the inflammation and swelling; but as to pain, my potentiality of pain is great,-greater when I become conscious that my pen has inflicted pain on a brother bee-keeper than it is when a vicious bee has stung me so as to draw blood, and far more enduring.

If all the bees would keep to their combs and not take to their wings it would be a great comfort to those of us who are timid. Or even if those on the wing would alight on something else and not the operator it would be a great boon. The inquisitive way they have of buzzing around one is a trying ordeal to one's nerves, but the instant they alight on one's bare flesh the anticipation of what will probably follow is too much for timid human nature. The skin is drawn up, the muscles are contracted; the bee feels the ground thus agitated under its feet, and whereas probably it would have con-tented itself with a 'nip' with its mandibles, it now inflicts its sting, raises a cry by vibrating its wings while in the act, a strong odour of formic acid, a commotion amongst the bees, a dozen or more to the rescue, and a bad time to follow for the poor unfortunate operator. The greatest factor in successful manipulation is a cool head and steady nerves. The next is 'bee-quieters.' You first must be quiet, and then quiet the bees. I never used the carbolic cloth; I confess it freely without an apology. We have very recently heard what Dr. Bartrum has to say about it. I have heard a score good bee-men confess the same thing. My chief reason for not using it is example. I am 'godfather' to several bee-keepers who, I am certain, would taint their honey with carbolic if they used it, and use it they would if I only set them the example. My next is my reputation; it would not answer my purpose to sell one section with a suspicion of a taint of carbolic about it. The carbolic fumigator is all right under ordinary circumstances, but 'breathing' it on them fails to subdue them after ex-

tracting time, when robbers are more numerous than honest bees, wasps are on the alert, and many of the bees themselves are getting old, gouty, and cross. 'Apifuge' is a very useful article; the bees are sensitive to the taste and smell of it; but the last three or four weeks it has failed to intimidate them. It is still useful, as it helps to increase the confidence of many, and to touch a newly-stung spot with it helps to allay the pain and dispel the strong scent of formic acid.

There is nothing to beat smoke. I keep my smoker clean, see that the hole in the nozzle is large, and use brown paper for fuel. I use a coarse, rough kind, well dry, the fumes of which will make you cough if you happen to inhale them, and make the bees stop to clean their compound eyes and antennæ when a cloud of it has been puffed at them. I have long ceased to puff into the entrance, except in very special cases, but simply keep them down from the top until they are fully gorged. Give them time, and enough of it. The chief difficulty recently has been to get them gorged, mainly because there is little or no unsealed honey in the hives at which the bees can get to sip. Many of my combs, except a few cells at the bottom edge, are one slab of sealed stores; on such the bees refuse to cluster, preferring the walls and floor-board of the hives; other combs from which I have extracted are cleaned up and put tidy, and all the stores packed away and sealed over. The impossibility of getting bees to gorge with combs in such a state must be apparent to the merest tire. Under ordinary circumstances manipulation would be at an end until early in October, when they would be packed and put into winter quarters, but during the past three weeks I have been introducing several queens, and consequently the old ones had to be caught and removed, and the young ones had to be examined to see that they were secure and laying. Of course, daytime and good light were necessary for all this. Robbers and wasps were a great nuisance; the guards were too strong for either to force an entrance in front, but while I have had one frame in my hands I have seen as many as three or four wasps enter the hive. But the point of most interest to you will be how to successfully gorge the bees. Here is my plan. Get some thin syrup, make it slightly warm, put it into a clean oil-feeder used for oiling machinery. If you upset the feeder it will not spill. If you have not one (they cost only one shilling), borrow the wife's teapot. Don't ask for it, but take it, aud ask permission when you bring it back; it sometimes saves trouble and disappointment. Now lift the quilt just a little so as to expose not more than two bars, give a puff of smoke, and gently pour a little of the syrup along the edge of one of the combs, replace the quilt, and turn up the other side of it, and treat that side of the hive as you did the first. Use the syrup sparingly, as if you use too much it will run out at the entrance, and robbing will ensue at a pace to alarm you. While the bees are lapping up the syrup you have poured into the hive, give them a slight puff of smoke occasionally to keep them on the gorge, and to prevent them from storing it in the cells. Give them a little time, so that all may get their fill, and then proceed to uncover as usual, keeping the quilt over as much of the hive as you can, so as to keep out as many robbers as possible; and if you are not able to manipulate with greater comfort, it will be a matter of surprise to -AMATEUR EXPERT.

STATISTICS WANTED.

Mr. J. Bertram, author of the *The Harvest of the Sea*, is desirous, for literary purposes, to have information as to the honey-harvest of the past season. Will the secretaries of County Bee-keepers' Associations, and others, render him what assistance may be in their power by forwarding to us statistics of the honey-yield in their respective counties?

ASSOCIATIONS.

LANCASHIRE AND CHESHIRE BEE-KEEPERS' ASSOCIATION.

The annual exhibition of bees, hives, and honey, in connexion with the Royal Manchester, Liverpool, and North Lancashire Society, was held at Manchester on

August 31st and three following days.

The weather was anything but what could have been desired for the occasion. From the first day of the show to the last there were heavy storms of wind and rain, and the manipulations with the bees had to be abandoned entirely on Friday, the continuous wind and rain rendering it quite impossible. The soil, being of clay, was worked up into a state of mud similar to that which most bee-keepers will recollect at Kilburn in 1879. Notwithstanding the weather, the tents containing the exhibits of hives and honey received a greater patronage than any other part of the show, although the visitors had to go through the sticky mud halfway up their boots; such was the interest taken in modern bee-keeping by the people of Lancashire and Cheshire. The honey exhibited was, taken as a whole, the best we have seen at any exhibition this year. It was bright and uniform in colour, of good consistency, and fully keeps up the credit of Lancashire and Cheshire obtained in the Counties' Competition held at the Colonial Exhibition last year, as one of the best honey-producing distriets of England.

In the class 'for the best exhibition of honey from one apiary, in quantity not less than one hundredweight,' the second prize was given to Mr. W. Broughton Carr for an exhibit of 370 pounds of honey, placed on the same trophy as was used by the Lancashire and Cheshire Association at South Kensington. The honey was equal, if not superior, to that then staged. It now consisted of 265 one-pound glass bottles, I2 two-pound ditto, and 162 half-pound ditto. There were also 45 one-pound sections, which were not unpacked until after the judging. The first prize was awarded to Mr. Wood, of Lichfield, for I13 pound bottles, 55 half-pound ditto, 45 pound seetions, and 6 two-pound sections, weighing 197 pounds alto-gether. We did not taste this honey, but in appearance it was cloudy and darker than that to which the second prize was awarded; and it is difficult to understand how the judges arrived at their decision, when, in addition to the weight, the appearance of that awarded second place was so superior. Considerable surprise, and we fear some dissatisfaction, was expressed at the award in this We have been told that the judges considered that there ought to have been some sections staged, and it was a pity, as Mr. W. Broughton Carr had forty-five pound sections there. This was not done, although the class simply says, 'For the best exhibition of honey,' not honey in the comb.

In the class 'For the best comb honey,' the sections of Mr. Wood, to which the first prize was awarded, were very good indeed, and well deserved their position.

For the best extracted honey there were twenty-one entries, all good in appearance and of good consistence, principally clover honey, with the exception of that of Mr. Woodley, which was awarded first prize, and that of Mr. J. M. Hooker, awarded fourth, both of which, we understand, were sainfoin honey, having quite a distinct flavour to clover.

There was no competition in the best and largest collection of hives. Messrs. Abbott had a large quantity of goods and were awarded a prize, which their large exhibit deserved.

In the class for the best and most complete hives we saw several old friends, but there was nothing new. There was nothing special in class for observatory hives.

In the class for new inventions Mr. James Lee exhibited his patent devetailed system of hive, frame, and section construction. He also had two pairs of

section crates containing his sections, one of which was invertible, being held together in a most secure, perfect manner, and not left to the uncertain support of a screw, as is the case of most crates of this kind. The other consists of hanging frames which will hold three $4^1_1 \times 4^1_2$ sections or two sections $4^1_1 \times 6^1_2$, or these frames can be filled with full sheets of foundation when working for extracted honey. This exhibit attracted more attention than anything in the show, the crates of sections all being claimed as soon as staged, and disappointment was expressed by many that they could not purchase them. The silver modal of the Lancashire and Cheshire Association was awarded to Mr. James Lee.

The following is a list of the awards:-

For the best and largest and most complete collection of hives and appliances: 1, Abbott Brothers, Southall. For the best and most complete frame-hive for general use in an apiary: 1, Abbott Brothers; 2, W. P. Meadows, Syston, Leieester. For the best and most complete storifying frame-hive: 1, Abbott Brothers; 2, A. F. Hutchings, St. Mary Cray, Kent. For the best observatory hive, to be exhibited stocked with bees (English or foreign) and their queen, all combs to be visible on both sides: 1, E. G. Parker, Bloomfield Lane, Altrincham; 2, John Nicholson, Viearage Lane, Bowdon. For the best exhibition of honey from one apiary, in quantity not tess than 1 cwt.: 1, H. Wood, Paradise, Lichfield; 2, W. Bronghton Carr, Higher Bebington; 3, W. E. Little, Eastgate Row, Chester; H.C., William Wright, Partington, Cheshire. For the best comb honey in sections (from 12 to 20 lbs. in weight): 1, H. Wood; 2, William Woodley, World's End, Newbury, Berks; 3, H. T. Gibbs, Bebington, Cheshire. For the best extracted honey in glass jars (from 12 to 20 lbs. in weight): 1, William Woodley; 2, F. W. Durnsford, Frodsham, Cheshire; 3, Robert Dean, Mollington Hall, Chester; 4, John M. Hooker, 76 Tyrwhitt Road, St. John's, London, S.E.; 5, W. E. Little; 6, H. T. Gibbs. Novelties and useful inventions connected with bee-appliances: Silver medal, James Lee, 43 Glycena Road, Lavender Hill, London, S.W.

The exhibition was under the able and energetic management of Wm. Lees McClure, Esq., the Hon. Sec., assisted by our old friend and experienced bee-keeper, Wm. Broughton Carr, who presided in the bee-tent, lecturing from time to time and manipulating in a quiet and finished style, to the wonder and amazement of many.

The Judges were Dr. Walker, Mr. W. Carr, of Newton Heath, and Mr. Fred. Carr.

STAFFORDSHIRE BEE-KEEPERS' ASSOCIA-

shugborough.

The Staffordshire Bee-keepers' Associations offered their silver and bronze medals for competition in connexion with special prizes for honey given by the Trent Valley Horticultural Society at the Annual Show of that Society, held at Shugborough on Monday, Angust Ist (Bank Holiday). The bee-tent of the Staffordshire B. K. A. was in attendance, where the modern system of driving and managing bees was illustrated at intervals during the day by Mr. A. W. Rollins, of Stourbridge, the Association's expert. The awards in the honey class were as follows:—Twenty-four sections of honey-comb: I and silver medal, Mr. H. Wood, Paradise, Lichfield; 2 and bronze medal, Mr. E. Clowes, Milton, Stoke-on-Trent.

STONE.

The Staffordshire Bee-keepers' Associations offered their silver and bronze medals for competition in connexion with special prizes given by the Stone Horticultural Society at the Amual Show of that Society, held at Darlaston Park, Stone, on Thursday, August 11th. The Rev. G. R. Bailey, of Madeley, Newcastle, officiated as judge, and the awards were as follows:—Twenty-four sections of honey-comb: 1 and silver medal, 11. Wood,

Paradise, Lichfield; 2 and bronze medal, J. R. Critchlow, Maer, Newcastle. Stock bees exhibited in a straw skep: 1, J. R. Critchlow, Maer, Newcastle; 2, E. Clowes, Blackbrook, Newcastle. After the show had been thrown open to the public, the committee and judges adjourned to a separate tent, where luncheon was provided, and the Rev. G. R. Bailey being called upon to respond on behalf of the Staffordshire bee-keepers, he observed that the season opened well for bee-keepers, but unfortunately the long drought had marred the exhibition. Nevertheless, there had been some excellent honey shown, and he had experienced much difficulty in deciding between the produce of the first and second prize-takers and the 'highly commended.' The gentleman who had gained the first prize that day won the third prize at the Royal show a few weeks ago.

WILTS BEE-KEEPERS' ASSOCIATION.

The Wilts County Show was held on the lawn at Crane Lodge, Salisbury, in connexion with a bazaar in aid of the Diocesan 'Church House,' on August 16 and 17. Showers and a heavy thunderstorm prevented much work being done in the bee-tent, and the attendance was very small.

The funds of the Association being very low there was little to tempt manufacturers in the way of prizes, but there was a good display of remarkably fine honey staged on the stand which gained fifth prize last year at South Kensington. The silver medal of the Bee-keepers' Association (it will be seen by the prize list) fell this year to a cottager, and the judge had a difficult task in assigning the awards, the quality of the honey being so uniformly good, though the finish of the sections in many cases was below the mark.

The following is the prize list:-

Class I. For best bar-frame hive, complete, price not to exceed 11. 1s.: A. D. Woodley, Reading, first-class certificate.—II. Best bar-frame hive, complete, price 15s.: A. D. Woodley, first-class certificate.—III. Best collection of bee furniture: Rev. W. E. Burkitt, first-class certificate.—IV. For new and useful inventions or articles made from honey: 1, W. Killick, Sandburst, for wax extractor; 2, A. D. Woodley, for tin section boxes; 3, W. B. Webster, Binfield, for carbolic fumigator. (N.B.—In Classes I., II., III., IV., only certificates of merit were offered.)—Honex (open to members of W.B.K.A. only): V. For best 12 lbs. in sections and 12 lbs. extracted honey: 1, J. Giles, Cowesfield (a cottager), silver medal of B.B.K.A.; 2, E. C. Snelgrove, Sutton Parva, certificate of W.B.K.A.; Rev. W. E. Burkitt, highly commended.—VI. For best twelve 1-lb. sections: 1, Rev. W. E. Burkitt, bronze medal, B. B. K.A.; 2, E. C. Snelgrove, first-class certificate of W. B. K. A.; 3, W. E. Brown, Stratford-sub-Castle, second-class certificate of W. B. K. A.—VII. Best 12 lbs. extracted honey; 1, Rev. W. E. Burkitt, certificate of B. B. K. A.; 2, E. C. Snelgrove, first-class certificate of W. B. K. A.; highly commended, Mr. A. Godding, Brimslade, second class certificate of W. B. K. A.—VIII. Best non-sectional super: 1, Mr. W. Hawkes, Newbury; 2 and 3, not awarded.—IX. Best beeswax, not less than 5 lbs.: 1, Mr. A. Godding; 2, E. C. Snelgrove; 3, Thomas Giles.—(Open to cottagers only): X. For best made straw skeps, 1, H. Huish, Watney, Devizes (price 1s. 9d.); 2 and 3, not awarded. Honey.—XII. Best 12 lbs. in sections: 1, G. Newport, Oxenwood, a bar-frame hive stocked with bees, given by Rev. H. Trotter; 2, Thomas Giles, certificate of W. B. K. A.—XIV. Best beeswax, not less than 5 lbs.: N. B.—Merged in Class IX., there not being enough entries in either alone.—XV. Best old stock of bees in skep: 1, G. Newman, a bar-frame hive worth 10s.; 2, Thomas Giles, 5s.

Rev. Dr. Bartrum was appointed judge by the B. B. K. A. He reported that he had never seen better

cottagers' exhibits in the honey classes; adding, they would have done credit to any bee-master.

On August I9 the bee-tent, in charge of the Rev.W.E. Burkitt, formed a new feature at a Cottage-garden Show held at Purton, near Swindon. Here the weather was perfect and the attendance very satisfactory, and several new members will be secured.—W. E. Burkitt, Hon. Sec.

FORFAR BEE-KEEPERS' SOCIETY.

Annual Exhibition.

The seventh annual exhibition of the Forfar Bee-keepers' Society took place in the Town Hall on Saturday, August 17th, and was by far the most successful, from every point of view, ever held by the Society, a new feature being a competition in industrial work open to Burgh School Liberty.

to Burgh School children.

The hall was visited by large numbers during the afternoon, and in the evening it was crowded. The exhibition was worthy of all the patronage bestowed upon it, and the Society are to be congratulated on its success. For the first time at the Society's show there was a good display of heather honey, both run and in comb. The sections were extremely good, fine in colour and well forward as to finish, and the early season alone has enabled the Society to have this class of honey at their show. The specimens of wax were all of very fine quality and colour. There were two nests of humble bees and two observatory hives to add to the attractions, and much curiosity was manifested by many of the visitors in endeavouring to single out the queen-bee in the observatories from amongst her numerous subjects. The following is the prize list:—

Bees, Honey, &c.—Display of honey, the produce of one apiary, weight not under 40 lbs.:—1, A. Patullo; 2, W. Neave; 3, D. W. Soutar and J. Saddler, equal. Best set of sections, heather, under 16 lbs. (sections not over 2 lbs. each:—1, D. W. Soutar; 2, W. Black; 3, A. Patullo; Best eight 2-lb. sections:—1, D. W. Soutar; 2, A. Patullo; 3, W. Black. Best ten 1½-lb. sections:—1, D. W. Soutar; 2, A. Patullo; 3, D. Pearson. Best twelve 1-lb. sections, clover:—1, A. Patullo; 2, Dr. Kydd; 3, A. L. Fenton. Best single super, in wood or glass, or both:—1, A. Patullo; 2, A. Stewart; 3, Dr. Kydd. Best straw super, clover:—1, Jas. Whitton; 2, W. Neave; 3, A. Rennie, sen. Best straw super, heather:—1, A. Patullo. Best 6 lbs. runhoney in show glass, clover:—1, J. Saddler; 2, A. Stewart; 3, K. Skeene; 4, D. Pearson. Best 6 lbs. runhoney in show glass, heather:—1, A. Patullo; 2, W. Neave; 3, D. W. Soutar. Best 6 lbs. run-honey in show glass;—1, A Sturrock; 2, T. Michie; 3, W. Black. Best display of runhoney in 1-lb., aud, or, 2-lb, jars, weight not under 10 lbs. nor over 15 lbs.;—1, A. L. Fenton; 2, A. Rennie, jun.; 3, A. Stewart. Best 2 lbs. wax:—1, A. Patullo; 2, A. L. Fenton; 3, J. Saddler. Best observatory hive:—1, J. Saddler; 2, D. W. Soutar. Bar-frame hive:—1, D. Sc Cuthbert; 2, J. Herald, jun. Humble bees:—1, J. Dorward; 2, J. Herald,

Much praise is due to the Secretary, Mr. James Saddler, High Street, Forfar, for his management of the show, and for his energy in the conduct of the affairs of the Society.

FLORAL AND HORTICULTURAL EXHIBITION AT AMBLESIDE.

The honey show in connexion with the Hawkshead and district Bee-keepers' Association was held in the ante-rooms of the Pavilion on Wednesday, and much interest was manifested in the product of the busy bees by the numerous visitors who paid a visit thereto. The entries this year were a more numerous and better class. The number of entries in the schedule were fifty-one, against about forty last year, though all the entries were

not forthcoming. Mr. Jas. Wrigley, junior, of Holbeck, was the jndge. The awards were as follows:—

Honey.—A: Super of honey, the super to be of wood, glass, straw, or wood in combination with glass or straw— 1, 1, Postlethwaite, 15s.; 2, J. Robinson, 12s. 6d.; 3, W. Carter, 7s. 6d. B: Bar or bar-framed super, to contain not less than five combs—I, W. D. Heelis, 15s.; 2, Jas. Postlethwaite, 12s. 6d.; 3, J. Rogerson, 7s. 6d.; highly commended, B. Townson. C: Twelve 1 lb. sections—I, J. N. Fell, 15s.; 2, T. Bell, 10s.; 3, Mrs. T. Walker (Cunsey), 5s. D: Three 1 b. sections—1, J. N. Fell, 10s.; 2, Miss Fell, 5s.; 3, J. N. Fell, 2s. 6-t; highly commended, Alf. Horrax and Jas. Postlethwaite. E: Six $1\frac{1}{2}$ lb. sections—1, Jas. Postlethwaite, 15s.; 2, Isaac Postlethwaite, 10s. F: Straw-hive of honey, not being a super-2, John Burrow, 5s.

CRAVEN AGRICULTURAL SHOW.

Bee-keeping in the Craven district of the West Riding of Yorkshire has made rapid strides during the present year, and the increased interest in the subject was further extended by an exhibition of honey, bees, and appliances, which took place at the Craven Agricultural Society's show, held at Shipton on Friday last, August 26th. Early in the present year it was felt desirable by several local bee-keepers that a local branch of the Yorkshire County Bee-keepers' Association should be formed in the district. Mr. James Dodgson, who was a member of the Association, took the matter in hand, and induced the County Association to countenance a branch for Craven, as the district was too remote to be worked from headquarters. He then called a meeting, which was held at Shipton in March, and it was manimously decided to form such an Association for the Craven district. The Rev. A. P. Howes, of The Rectory, Bolton Abbey, was appointed President, and Mr. James Dodgson Honorary Secretary. Since then, under the able management of Mr. Dodgsen, the branch has made rapid strides, and has done much good work, the number of members now exceeding twenty.

It was by reason of the representations of the branch that the Craven Agricultural Society were induced to offer prizes for honey and bee appliances this year, and being an entirely new thing in the district, the exhibition attracted more than usual attention from the public. Prizes were offered for run or extracted honey, for honeycomb, and for the best collection of bee appliances, and the competition in each of the three classes was much more keen than was anticipated. The judges were the Rev. A. P. Howes, The Rectory, Bolton Abbey, and the Rev. J. Kemble, The Vicarage, Coniston Cold.

There were fifteen entries in the three classes, including a very well-arranged collection of hives and appliances shown by Mr. W. Dixon, of Leeds. Mr. Dixon deservedly took first prize in this class, and also in the class for extracted honey. He also took first in the class for sections, although our correspondent thought that those shown by Mr. John Grundage, of Cononly, were better filled.

The exhibits were very tastefully arranged on the field, and were visited by crowds of people throughout the day. The success of the venture must have been very gratifying to Mr. Dodgson and the others who had laboured so assiduously.

A variety of manipulations, such as bee-driving, &c., took place in a tent during the show, Mr. T. H. Varley, of Addingham, undertaking the driving, &c., and Mr. Dodgson and others gave explanatory lectures at intervals.

Altogether the exhibition was a great success, and will doubtless lead to a considerable extension next year. The following was the prize list:—

Best comb honey in sections-1, W. Dixon, Leeds; 2, T. H. Varley, Addingham. Best twelve glass jars of extracted honey-1, W. Dixon, Leeds; 2, S. Metcalfe, Carleton. Best collection of hives and appliances-1, W. Dixon, Leeds; 2, A. C. Jemeison, York.

Correspondence.

The Editor does not hold himself responsible for the opinions expressed by his correspondents. No attention will be taken of anonymous com-munications, and correspondents are requested to write on one side of the paper only, and give their real names and addresses, not necessarily

the paper only, and give their real names and addresses, not necessarily for publication, but as a guarantee of good faith. Illustrations should be drawn on separate pieces of paper.

Communications relating to the literary department, reports of Associations, Shows, Meetings, Echoes, Queries, Books for Review, &c., must be addressed only to 'The Editor of the 'British Beo Journal,' ofo Messys. Strangeways and Sons, Tower Street, Cambridge Circus, W. C.' All business communications relating to Advertisements, &c., must be addressed to Mr. J. Huckle, Kings Langley, Herts (see 2nd page of Advertisements).

*** In order to facilitate reference, Correspondents, when speaking of any letter or query previously inserted, will oblige by mentioning the number of the letter, as well as the page on which it appears.

RE FOUL BROOD.

[1227.] I am very glad to find that Mr. S. Simmins has acted on my advice (given twelve months ago), and after practical experience he is able to confirm my statement, viz., that in order to render the 'Cheshire' cure certain in its effects it is necessary to remove the diseased queen and substitute a healthy one. This, he now states, will 'never fail' to effect a cure, and will prove effectual in 'every case.' Such confirmation coming from one so well qualified to give it is highly gratifying to me, and I sincerely hope it will not be passed over by those who are afflicted with the foul-brood disease.

The advice, which I have given on several occasions in the Journal, is founded on a long and painful experience, dating as far back as 1869, and is the result of numberless experimental efforts. I laboured from 1869 to 1876 to overcome the disease, which was imported into my apiary by a stock of Ligurians supplied to me by the late Mr. Woodbury, of Exeter, but at the end of that time it overcame me, for I had to destroy the remnants of thirty-two stocks, which had been from time to time recruited with healthy swarms from six different counties. I tried every system advocated at that time, but never once succeeded in destroying it, and at last I destroyed every particle of bee-furniture, combs, and bees, and

gave up bee-keeping for two years.

I started again in 1878 with two healthy stocks, from

which in 1885 I possessed twenty-two, when the disease again made its appearance, and when discovered it had already attacked five hives. Well, at this time, and as a result of my own observations, I had an idea that the whole difficulty rested with the queen-although the advice given in the Journal was on no account to remove the queen, but stimulate her to renewed exertions by feeding-so I began operations by removing four of the queens from the affected hives and substituting healthy ones; at the same time I placed a bottle of medicated syrup (of the Cheshire quality) on every hive in the apiary. I also sprayed the combs in all the five diseased stocks from time to time, and the four with healthy queens soon recovered and became free from any trace of the disease, but the fifth grew worse under the same treatment; so to prove my theory I removed this queen also, and placed her in a strong, healthy stock, which speedily became a mass of corruption, while that from which she had been taken yielded to the 'cure.' I again repeated this operation with a like result. At last I destroyed her too, and speedily all my stocks became healthy and strong under the Cheshire treatment. I noticed that from the time I began feeding with phenolated syrup the disease never spread beyond the five stocks originally attacked, although the whole twentytwo are confined to a space of forty feet square. But I went beyond this, for I placed some medicated syrup in a number of combs taken out of the diseased hives, and allowed the whole apiary to help themselves freely, to the extent of 60 lbs. weight of sugar syrup, and I have not been able to discover a single trace of the disease

I also placed ten badly diseased combs in an empty

hive after spraying them with phenol syrup, and placed a natural swarm in this hive, fed it liberally with the same syrup, to the extent of 25 lbs., and they are now perfectly healthy, thus proving to my own satisfaction that the only reliable plan of curing the disease was a timely removal of the queen and the substitution of a healthy queen, which, as Mr. Simmius points out, is really the exact process described by Mr. Cheshire in the account which that gentleman gave of his discovery to the British Bee-keepers' Association, in 1884.

It is true he also described how after inoculating several healthy stocks and adding to others diseased combs of a disgusting nature, and after the disease had got ahead, he quickly destroyed it and made the stocks perfectly sound again; but in none of these cases is it shown that the queen was diseased—and herein lies the

pith of the subject.

In August, 1884, Mr. Cheshire wrote:

'Bacillus alvei is now understood and its method of treatment made so easy that he who suffers from it badly will in the near future rather deserve censure than pity.

'Some, sad over losses and rampant disease, with Job's comforters calling to them to burn their hives and burn their combs, and kill their queens, and start anew, will, I trust, soon be thankful and cheerful in learning that my method will save everything with the sole exception arising from the infection of the queen. In any case in which this may be suspected, and the queen replaced by a second, the removed one would be a treasure to me for dissection purposes.'

So that Mr. C. never expected that phenol would cure the disease if the queen was in fault.

And again he wrote, November 15th, 1884, when two failures of his cure were reported:—

'With regard to Mr. Johnston, I can only say that he may, or may not, have acted as I describe, for I am totally ignorant of what Mr. Blow provides and what advice he gives; but "Questioner" may have a diseased queen.'

And although Mr. Hart (page 379 of the Journal), under date November 1st, 1884, gave an account of three perfect cures simply by removing the queen and substituting a healthy one, Mr. Cheshire never seems to have realised the importance and necessity for this, and never seems to have made it a sine quá non of his cure—although he seems to have known it—and consequently, here we are, after four years with a perfect remedy in our hands, still struggling with the disease, while it is ever destroying and spreading from one part of the country to another, simply and solely because we will not use the remedy properly. Why, there has never been a case reported of failure with the Cheshire cure after removing the queen and substituting a healthy one! And yet bee-keepers are still asking in utter despair, What shall we do to be free from disease?

We cannot tell (when a stock is diseased) at what stage the queen is attacked, or indeed whether she is attacked at all; a stock may be for a considerable time diseased, and yet the queen may be free, in which case the phenol will surely cure it, and this will account for some cures being reported by the phenolated syrup alone; but by far the greater number of reported cases are failures, hence we are driven to the conclusion that there are two distinct conditions of a diseased stock-first, that in which the disease has attacked the brood alone, and probably some of the bees too; and second, that in which the hacilli have entered into the organs of the queen. Therefore it is obvious that the first step to a certain and sure cure is to remove the queen and immediately spray the combs, so that in introducing the healthy successor there shall be no risk of her contamination—because the vapour of phenol alone will destroy the disease, and every bee in the hive is dosed by licking the syrup from the combs, so that (in the words of Mr. Simmins) here is health and life to start with. Of course it is a mistake to suppose that the disease yields to the treatment as quickly as would appear from these notes; and a little patience is necessary to go over the combs carefully at intervals of about two weeks, spraying wherever a few cells appear to be tainted. But if this is done, the disease can with ease and certainty be effectually stamped out.

I believe that when the queen is attacked no amount of phenol will cure her without killing her. I have repeatedly shaken all the bees from a diseased stock into an empty box and kept them without food for fortyeight hours and longer, then shaken them out again into another new and empty box and fed liberally with phenol, and also with salicylic syrup, and the first batch of brood from the pure white comb has always been badly diseased, and after repeating this operation with the same bees the result has been the same; and other bee-keepers have done likewise. I am aware that many cases have been reported where the disease has been destroyed, or died out, under the Cheshire treatment without destroying or removing the queen; but apart from the chance of the queen being healthy, in none of these has it been proved that the old queen survived; and as the phenol will undoubtedly destroy the disease in the broad (for many healthy young bees are hatched from a diseased queen while under treatment) it is probable that a young queen has replaced the old one in some of those cases. I know that this is raising a most difficult problem, but I suspect it will ultimately be found that the grafting of the drone on the queen has something to do with the case, and like friend Simmins I also anxiously await more light from our esteemed friend Cheshire. - Thos. F. Ward, Church House,

Highgate, Middlesev, August 27th.
P.S.—Next spring I intend to try queen-rearing from a diseased mother. I think it will throw light on the

subject.

[Mr. Ward is very desirous that we should give insertion to his formula. We have much pleasure in acceding to his request, and we would be speak the best attention of bee-keepers thereto. We print in full Mr. Cheshire's directions for using his solution.—LD.]

Cure for Foul Brood.

Destroy the queen, and substitute a healthy one, then use the Cheshire remedy:—

'Completely empty the bottle of remedy into a measured pint of water. Stir or shake until all oily deposit has disappeared, using nothing that is not perfectly clean. Rinse the bottle and keep it as a measure. Empty the fluid made into another bottle of sufficient size, carefully cork it, and label it "Foul-brood Solution."

'Reduce your infected stock to the number of frames it can use, putting those removed on the other side of the dummy, and feed the bees daily with a syrup prepared in the usual way with about 3 lbs. of sugar to a quart of water, and medicated thus:—After the syrup is cooled, to each pint of it, as required, add one small bottleful (the measure) of foul-brood solution, and shake up. Give this syrup by pouring it into the empty cells of the brood-nest, and encourage breeding as much as possible by warm covering and attention. By no means remove the queen from the stock, except upon the ground that she is herself badly infected, when she should, if possible, be immediately replaced by a healthy mother.

'In early spring and late autumn, when little or no honey is coming in, this amount of foul-brood solution will be sufficient for a pint and a half of syrup, and bees may take this from the food bottle in the ordinary way; but if they refuse to do so, it must be poured into their combs. In wintering up, give medicated cake, made in the ordinary manner; but into every 3 lbs. of which has been carefully stirred during its thickeniug whilst cooling, one measure (the small bottleful) of "Foul-brood Solution."

The combs remaining at the back of the dummy during treatment of a severe case will probably smell badly; if so, spray them with water to each ‡ pint of which one small bottle of foul-brood solution has been added; but on no

account spray the combs the bees are using; add these combs to the stock one by one as the bees increase in numbers, and while they are being added, continue the treatment. Take as far as practicable honey from the bees, and this honey thinned and medicated may be used instead of symp. It may hasten the cure to uncap the bad cells, but it is not necessary. The worst cases, if there be only bees sufficient to raise brood, will soon yield to this treatment .- F. R. Cheshire.'

FOUL BROOD AGAIN.

[1228.] Friend 'Ward' wants to know how I have fared this year with the dire pest. I am happy to say that I have not got so much of it as I had last year at this time, but still too much. I cannot agree to the advice he has given to 'West Kent' as a means of curing foul brood, because I have tried it and found it useless; as soon as you put another queen into the hive it will soon be as bad as ever, even supposing you do use a tonic in your food and give them plenty of disinfectant outside. My advice to him would be to get another hive, put half sheets of comb-foundation in the bars, remove the old hive, and place this one at the same spot. Then examine the old hive and find the bar containing the queen, shake the bees down in front of the new hive and let them run in (having previously put a board sloping up to the entrance), when you have safely seen the queen go in, serve the other bars the same, and then if honey is not coming in freely feed them slowly with syrup containing salicylic acid. I have not tried phenol since last year, but I believe in salicylic as a preventative, but not as a cure unless you destroy your combs. I don't believe in the germ theory and that the queen lays diseased eggs, and I will tell you the reason why

presently.

Now for my experience of foul broad this year. I examined the whole of my hives on the 10th of March and found they did not want feeding, and no appearance of foul brood visible then. Did not open the hives again until the 12th of April. I then commenced to feed a few of my hives-what I shall call No. 1 being one of them. This hive had about 5 lbs. of medicated syrup during the month of April. On the 8th of May the bees in this hive began to throw out dead drone grubs; and as I had given them another bottle of food on the 6th I was rather puzzled to know the eause of it, as this was one of my best hives last year and I knew it to contain a young queen. I opened the hive on the 9th, and judge of my surprise to find foul broad was the cause. Having a clean hive by me I decided to turn the bees into it, and destroy the old combs and disinfect the hive for future This was done on the 12th, and I have not seen any foul brood in that hive yet, and I have examined it any rott brood in that hive yet, and I have examined a very carefully several times since, especially on the 17th of this present month, August. It had about 5 lbs. more syrup after the change. I then put a crate of twenty-one sections upon it on the 16th of June, but they did but very little to them. I have taken about 10 lbs. of the brood shall shall of the bire and shall shall of the bire and shall sha 10 lbs. of honey from the body of the hive and shall give it a few lbs. of syrup in exchange-medicated, of course. Having a queenless hive I thought I would try and see how much of the broad these foul-broady bars would hatch out, and 1 don't believe that five percent hatched out, so you may guess that it was rather bad-

where is the germ theory in this case?

Now for No. 2. This hive had about 6 lbs, of medicated syrup between the 2nd of May and the 6th of June, but it had then got foul brood so bad that I then served it the same as No. 1, and 1 have not seen any foul brood in the present hive, and I have given it a good over-hauling, the same as No. 1 — in this case I at once destroyed the remaining brood by fumigating it

with brimstone.

Now for No. 3. This hive I found queenless on the

25th of July, 1886. I gave it a frame of brood taken from No. 2, from which they raised a queen and she was laying freely in September, as I was feeding it to induce her to lay, and it went into winter quarters well provided with young bees and a good stock of medicated

syrup sealed up.

I did not begin to feed this hive until the 2nd of May, as it had got plenty of sealed food. As it was not increasing in bees so fast as I wished, I put a feeder upon it, and it had about 8 lbs. of syrup during the month of May and a crate of sections on the 10th of June. As they did not go to work in the sections and got weaker in bees, and knowing that the frame of brood from which this queen was raised was taken out of No. 2 hive, I suspected foul brood was the cause, which turned out to be true. On the 16th of July I served this hive the same as the other two, putting the bees into a makeshift hive upon half-sheets of foundation. On the 4th of August I transferred them into a regular hive, and the broad then was as clean as ever I wish to see any, and they had had nothing only what they had collected outside the hive. I have since been feeding them upon medicated syrup. I gave it a thorough examination on the 17th of August and still no signs of foul brood, but the young bees are

getting quite strong. Now for the only hive that I knew to contain foul brood. This hive was made up of condemned bees on the 13th of September, 1886, and put on combs that had been taken out of foul-broody hives, and, as I thought, had been thoroughly disinfected, both by fumigation by brimstone and being washed over with carbolic acid. I thought it looked a pity to destroy them as they were sheets of foundation barely worked out, they were fed on syrup containing salicylic acid. And as it contained a young queen it gained upon some of the other hives at a rapid rate, and had a crate of sections put upon it on the 16th of June and started working in them at once, and then decreased in bees as rapidly as they had got strong just previously. That the bees were not affected with fond brood when put into the hive, I feel certain, as they came from a district where it is not known. The only way that I can account for their getting the disease, is from the pollen stowed in the combs, as there was but very little honey in them, any one that has had foul brood must have noticed the large amount of pollen stored in them. And it is my firm belief that it is almost impossible to disinfect it. And I have made up my mind to destroy all combs that have the slightest suspicion of being affected. This hive will be served the same as the others have been at the first opportunity. I am still of the same opinion as I was last year, that straw hives do not have foul brood the same as barframes do. I could mention several instances that have come to my knowledge this season of their missing it, and bar-frame hives being eaten up by the pest not a hundred yards apart. I do not write this because I am a skeppist, as I have not get a single lot of bees in a skep. I believe foul brood will knock the bee fever out of any one but a downright enthusiast.

I think Mr. Simmins has given a very good explanation of the reason of Mr. Cheshire being able to cure his hive of all dire pest, although I cannot agree with him as regards the queens. Another thing, he says, Be careful not to contaminate the extractor, and so say I, as I sometimes think that that was the means of my getting the disease, the extractor having been used in an infected district.

And now, Mr. Editor, a few words and I have done for this time. Have any of your readers ever tried camphor us a cure for foul brood or as a preventative of robbing, as it is so often recommended in the Journal, because 1 think if ever any one gave camphor a fair trial I did last year; and didn't my bees rob, -- I rather fancy they did, and I let several lots die out with plenty of campher in the hive. I should like

for John Hounson, when he sees this article, to give his present experience of camphor as a cure of foul brood, as he once wrote saying that he had cured a hive with it.—Man of Kent, August 30.

BACILLUS MINOR.

[1229.] Whilst tendering my thanks for your advice on this subject in the Journal of 25th ult. I am sorry to say both the young queens raised from the affected swarm are now similarly diseased. The brood in each case showing the ominous dead grubs, of which I am certain many have been capped over and been since unsealed by the bees, as they exist in all stages. Some, apparently fifteen or sixteen days old, are partly uncapped, though not discoloured. Others again, more developed than at eight days old, appearing, as Mr. Simmins says, 'like a white cinder,' and at the bottom of the cell as though a bee had packed it down like pollen.

If this disease and the dead brood of which Mr. Simmins writes are the same, it clearly is not very contagious, or his apiary would have been decimated long ago.

In my case all traces of infected comb and brood were removed before the young queens began to lay, thus seeming to class the disease as congenital. This brings up the question as to whether disinfection of hives and frames is necessary. How should it be done if neither phenol nor salicylic acid are able to cure the disease? I am in doubt how to treat the two affected lots whether to brimstone them like the original swarm, or unite and give a healthy queen. Driven bees are so cheap now that it seems a pity to risk anything. The smallest editorial advice will be thankfully received by

The result is what we feared. If the case were our own we should cremate both colonies and all belonging to them—hives, quilts, &c. At this late season cure is very doubtful. If you wish to experiment we should say add a strong lot of driven bees to each colony and feed copiously on phenolised syrup. One of our own diseased colonies is now rapidly improving under the Cheshire treatment.-ED.

'BIRDS, REPTILES, AND BEES.'

[1230.] With respect to Mr. Webster's remarks on 'Birds, Reptiles, and Bees' (1202), p. 370, I can fully corroborate his opinion that swallows and martins are not destructive to bees. My apiary is situated near the house, and the buildings adjoining afford splendid opportunity for chimney swallows and house martins to build their nests, especially the latter. Before I commenced bee-keeping, a few years ago, the martins seemed to take a particular fancy to the whole building, and nests increased year by year, until they were almost looked upon as a nuisance, and many muddy tenements were ruthlessly destroyed, yet not without a touch of inward sorrow. My colonies of course increased in due time, and doubts and fears filled my mind as to the possible destruction of some hundreds, I might have imagined thousands, of my little winged pets. The bees, however, soon proved themselves masters of the situation, and instead of being chased and devoured by the feathered tribe the tables were turned. The martins were attacked, and followed by sometimes five or six bees at a time until lost to view. I was unable to prove that the bees overtook and stung the martins, but the latter, finding their quarters not quite so peaceful and comfortable as they anticipated, quietly but gradually deserted the place. It is now a rare thing to find a martin building its nest, unless in some remote part of the building entirely away from the hives. As a matter of fact, no nest has been completed this year or last. Starlings have, however, for the first time bred this year, but on the opposite side of the building to that occupied by the bees, and neither appeared to have interfered with the other. About three years since, in the month of October I believe, my wife and self watched two tits fly from the trees to a convenient perch just in front of the hives, then suddenly swoop down on the ground, and in an instant pick up a dead bee, and as quickly fly away about fifteen yards to devour the parts most palatable. This was repeated several times, and indeed they were quite welcome to carcases, but in no instance were live bees

enticed from their hives and caught.

Now, a word for the toads. These have oftentimes been captured for the purpose of ridding the garden of insects, and snug little retreats placed for them to hide in, and I have actually put them in front of the hives and watched for any depredations, but failed. Perhaps they were not hungry, or shy. Others may record quite different experiences, but on reading the Journal 1 could not help being struck with the similarity of Mr. Webster's observations and my own.—A. G. F., Denham,

REPLY TO DR. C. C. MILLER. [1214.]

[1231.] I am extremely sorry to have placed anything on record about the Doctor's practice that is not correct. As to the 'honey-board and queen-excluder,' from what our Canadian friends had shown us last year, and from what I have read about them in Transatlantic bee journals, associated with the worthy names of Heddon, Dr. Tinker, and G. M. Doolittle, I was under the impression the Heddon honey-board was always fitted with strips of excluder-zinc in the $\frac{3}{8}$ spaces, and so mentioned Dr. Miller as using it amongst others, knowing it would be of interest to British bee-keepers to know who uses a queenexcluder and who does not. Dr. Miller will readily see, I am sure, how easily I slipped into that error. But this usage in America is amongst the minute points, of which there are many, that we hope to be able to inquire about when the *chief* comes home.

As to removing middle sections, I 'own up' and beg

pardon. I have nothing to say except that I am a big dunce. The fact was, it was done late, after a hot, tiring day. I was anxious to get it off by that post to be in time for that number of the British Bee Journal, and had to abbreviate it twice to compress it into a space sufficiently small for me to hope our sub-chief would be able to find room for it. I wish my confreres would have read it in extenso. But all this is a lame excuse for

slovenliness.

It may interest the Doctor to know the practice of removing sections I attributed to him is what I follow myself. With regard to the incident, I am like the fellow who, when told his wife had recently died, said he 'was glad and sorry both.' I am sorry, as I have already said, but I will rejoice if the Doctor, having once broken the ice, may be induced to do so often, for the sake of good fellowship. He would have thought 'we be brethren' had he seen the thousands of the 'Stars and Stripes' that floated all over our dear old land during the Jubilee side by side with our own dear old flag

'That has braved for a thousand years The battle and the breeze.'

Dr. Miller's last word is pathetic—' Drouth'—he has my sincerest sympathy. I hope next season he will have a rattling good crop, get a good price for it, be able to enjoy a good long holiday with the money, and come and pay British bee-keepers a visit. How does this suggestion suit you, Doctor?—AMATEUR EXPERT.

INOCULATION, ETC.

[1232.] 'C. A. M.,' in his letter, No. 1222, says that the alleged inoculation is a delusion, basing his con-

clusion, apparently, on the very untenable ground that he has been stung on the average twice a-day during the last three months. For the information of 'C. A. M.' allow me to tell him that I have, during the last eight years, had a larger average number of stings than he mentions, but it is only in the last two years that I have been completely inoculated, and all I now feel when stung is a similar sensation to that of a needle just pricking the skin. 'C. A. M.' cannot surely be in earnest about the 30,000 stings, for it seems to me no ordinary person could escape serious consequences from receiving that number at one time. Your correspondent also says that he does not see the use of wired foundation; but having used, experimentally, one hundred frames this summer, and found them of very great advantage, I shall in future always use it.

In regard to the best time for manipulation, it is undoubtedly preferable to do so during the honey season while the old bees are away, as it can usually be done then without the aid of a veil; but at this season of the year it is almost imperative to do it either in the morning or evening, or robbing is sure to be the result. I have tried the use of Webster's fumigator this season, and can speak very favourably of it, but as the autumn advances I find nothing to equal the spray diffuser.—

J. T. Harveyson, Finchley, September 3rd,

HONEY BY THE HUNDREDWEIGHT. (1206.)

[1233.] R. R. Godfrey's Lincolnshire must be a wonderful county for honey. I have kept bees for over twenty years, but have never realised more than half a hundredweight from one hive, while a dozen others did little or nothing. I have laid out over 50% in my apiary for about eighty stocks. Last year I wintered thirty-two. One died, leaving brood sealed and about 15 lbs. of honey; three others lost their queens, all being young queens; three others I had to destroy, having what is described in the E. E. J. as Eacillus minor. This left me with only twenty-five stocks. I have made up the original number by swarms, and taken about one hundred and fifty 1-lb. sections and extracted about one hundred lbs. beside, which if I sell at present prices of 6d. for sections and 5d. per lb. extracted, will just bring me about 5d. 17s. Then I must pay carriage and risk all damage. I have devoted one half of my time to my bees, and had to purchase sections, frames, foundations, &c., which involved an outlay of about 4/. I have then left about Il. 17s. for my time, &c.

Now the question is 'Does bee-farming pay?' From my experience I think it does not. If we may judge from the last twelvo months' decline in the price of honey, it will be much lower in another year. 'Why does it not pay, and why are prices so low?' Doubtless one reason is because we have what I call a 'honey ring,' or the middle man of capital, who, like the corn-factor, stands between the producer and consumer, taking the lion's share of the profits without much labour. This may be clearly seen by reference to the British Honey Company's Report (annual) which appeared in this Journal a few weeks since, where they netted a profit of over 40 per cent. Then add to that the working expenses of the company, such as rent, gas, stationery, clerk's salary, &c., it would probably make another 20 or 30 per cent on the outlay, which might to a large extent go into the pockets of bee-keepers, if Bee-keepers Associations were efficiently organised for the benefit of its members. We have our county B.K.A. and our parent British B. K. A., but I ask (at the present time) what practical benefit are any of them to bee-keepers generally, whether members or non-members. I have been a member for years, but I receive no benefit in any way. We have splendid muchinery if it was properly worked. All our county associations are affiliated with the parent society; how easy would it be, therefore, for

the parent society to engage a good business man for two or three months at this season of the year, at salary and commission, to work London and some of our large towns, taking orders from grocers and others who come directly into contact with the consumer, thus cutting off the middle man-the great evil, or curse, of the English producer. Members of all Associations would be glad to pay double their subscriptions if they could only be thus benefited. Orders could be sent direct to county secretaries nearest to where the orders are obtained, or to the parent society, whose secretary, for a certain consideration, would send on the orders to their members, who, in order to avail themselves of such benefits, should in good time send in to their secretary the amount of honey they have for disposal, then such member could send off his honey direct to the house as required, thus bringing the consumer and producer into more immediate contact. Of course there are minor details to be worked out, which can be very easily done when confronted by such practical benefit. I hope some others will be interested in this scheme, and will endeavour to move the 'powers that be' in this or a similar direction.—SHER-BORNE, Dorset.

BUMPING A SUCCESS.

[1234.] Could you spare me space in your valuable Journal to relate my first experience in bumping? friend of mine at Sunbury invited me to drive his bees, and as I was told that he usually smothered them I accepted the invitation readily. He had thirteen stocks, six of which were this year's swarms. I arrived at Sunbury about 2.30 p.m. and found all the skeps on a single stand about four inches apart and wasps flying in and out without much opposition. The wind being rather high I found a quiet, sheltered corner, made a table of a couple of old wheelbarrows and laid all my appliances near at hand. I set to work by smoking a three-year-old stock and carrying it to my impromptu table, and as I was desirous of reserving the queen I commenced by driving—an operation that took me about twenty-five minutes. I next carried the bees to their original stand, and for practice bumped the skep with the combs. Each comb broke off beautifully, close up to the crown, and brushing off the remaining stragglers I carried the honey into the house. The next stock I did not drive at all, but bumped it at once after removing the pieces of wood that were fixed across the combs. Again I had the pleasure of seeing every comb break off close to the crown. This hive only took me ten minutes.

After this I bumped three more; one an old stock and two this year's swarms. Each one took on the average about twenty minutes. I had most trouble with the swarms, the combs being so tender, and even breaking while I brushed the bees off; but hardly any were smothered by the running honey, as all the combs when

bumped broke off likewise close to the crown.

When the bees had all clustered (a performance which I greatly helped by sprinkling the floor-boards with some weak carbolic acid solution) I united two lots by throwing them both into one skep and from thence into my boxes (14 \times 9 \times 8½ inches inside measurement), which I had prepared and brought with me; then tied them down with canvas and carried them safely home.

I should like to mention that the only instructions which I followed were those given in an excellent article in the Journal of August 18, and I would recommend them to any bee-keeper about to try bumping, feeling sure that if he would follow the instructions as closely as I did he would derive the same satisfaction and be as thankful as-Dulwich Novice,

BUMPING A FAILURE.

[1235.] I cannot make 'bumping' answer. Last year I gave it a trial on a rather warm evening; after turning a skep up and carrying it a little way from the stand I gave it a couple of bumps, which completely broke the combs away from the skep. Then commenced my troubles. The combs were heavy with honey and so soft that they would hardly bear lifting, to say nothing

about being covered with bees.

One piece after another was taken out, and the bees swept into an empty skep, but most of them returned and settled in the bumped one, making as pretty a mess of bees and honey in the crown of the skep as any one could wish to see. The result of the whole performance was that I had wasted more time in clearing the bees out of the skep than would have sufficed for drumming two, got plenty of stings by crushing the bees in handling the combs, and thoroughly roused the occupants of ten other skeps, besides losing half the bees. I drummed the remaining five hives.

This season I tried it again, and with almost worse results; the queen and a lot of bees were bumped (crushed) to death. Will some one who is successful with humping kindly say how the combs and bees are to be handled without the prospect of being stung and losing part of the bees? We were drumming during the thunderstorm mentioned in 1221, we found the bees just about mad,—and so did the pony.—Canterburian.

[Please refer to previous communication, and read over again our articles on 'Condemned Bees' in Nos. for

August 4 and 11.—ED.]

WASPS.

[1236.] Very few queen-wasps visible in the spring, but great numbers of wasps on the wing now. I catch quantities in wide-mouthed bottles (Eno's fruit-salt bottles) suspended at the back of my hives, and one-third filled with a thin mixture of treacle and water—bees never go near it, it is too coarse food for them, I suppose.—BEESWING.

WASPS AGAIN.

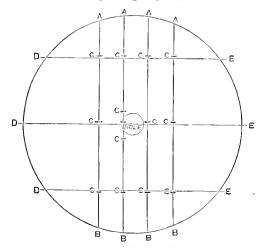

[1237.] 'W. M.,' 1207, page 373, says, among other strange things, that 'wasps are as valuable as bees.' Perhaps he keeps an 'apiary' of wasps. May I ask him to kindly favour the readers of your valuable Journal with a balance-sheet of his net profits arising from them and also from his bees, i.e., the same number of each, 'hives and nests?' I find wasps very troublesome in my apiary—never found them so numerous in my bee-house. At this moment he may see about a quart of those (to me) good-for-nothing pests lying in a heap, which I have killed in one week. 'W. M.' says they do not hurt bees. Then my experience is a great mistake, for I have seen wasps get on one corner of the alighting-board and watch for an opportunity, then pounce upon a bee. A tuzzle ensues, both falling on the ground; in an instant the wasp is up again in the same place, and repeats the same thing, but the bee never rose again. This went on for a considerable time, when I had to leave them for a week. I narrowed the entrance as much as possible, which was all I could do; but when I returned there was not a bee left, and the honey nearly all gone, the wasps being in possession of what was a moderately strong colony and stores to have kept them through the winter. 'W. M.': Did the wasps destroy the colonyor what?—M. A. S.

HONEY DEW AND FOREIGN BEES.

[1238.] I have seen the statement once or twice in the B. B. J., that foreign races of bees do not gather honeydew, and shall be glad to know if other bee-keepers have found this to be true; for I purchased a stock of pure Ligurians three years ago, and they brought in a great quantity of honey-dew; now my bees are all hybrids, and they all bring in honey-dew. I should be very grateful if any one will tell me how to avoid the nuisance.—Beeswing.

FASTENING FOUNDATION IN SKEPS.

[1239.] It is rather difficult for me to explain the way I fasten 'foundation' in skeps. I will do my best to make it as plain and simple as possible. Take a skep (flat top) on the knee and draw chalk lines $1\frac{1}{2}$ inches apart, either parallel or at right angles to the entrance (A to B), just to show the way the combs are to run; cross each line at right angles (at c) in three or more

places, each + shows where the wires are to come through. Then take some fine brass wire, cut to the proper length, and with a strong darning-needle, or bradawl, put the two ends through the skep, beth ends coming through in or about the +. When all the wires are in, put the first three right and the foundation hetween them; take a small button, or bit of wood, with two holes in it, put the two ends of the wire through the button-holes, press the button to touch the comb, and at the same time draw the wire straight and twist. Do not cut the ends off, I shall make use of them yet. With each wire do the same. To secure the combs at the bottom, put three sticks through the hive walls (from D to E) across the bottom of the combs; take the wire ends not cut off and twist them around these sticks. I think that a few half-sheets are preferable to whole ones as a trial.

My only objection to this plan is annoyance in taking the honey, but I trust that some one will improve on this.—CYMRO BACH.

WORK FOR THE BRITISH B. K. A.

[1240.] There is not the demand for honey that there ought to be, and I think the Association much to blame for not by any means in its power trying to foster a taste for honey among the purchasing public. There are thousands, aye, millions, who have not yet tasted honey—who know it ouly by name, and but want their attention called to it.

The B. K. A. would do well to copy the tactics of the Vegetarian Society, which does not leave a stone unturned to further its objects. Letters to daily newspapers from members who are well up, setting forth the virtues and different uses honey may be put to, getting the right side of editors to admit a short article—this gave the jam trade a great spurt a few years since — are within the scope of the B. K. A.—LANCASHIRE.

NOT FINDING THE QUEEN.

[1241.] I notice in your report of Aberdare Show mentior is made of one of the candidates failing in finding the queen for some time, but that he was as well

qualified to act as expert as many whom the examiner had passed. It seems to me that a candidate not being fortunate in finding the queen quickly does not pass his examination to satisfaction. Now, Sir, I cannot help thinking this a rather hard case. I will explain why I

think so by giving my own experience.

On one occasion I commenced to examine one of my hives, which contained nine frames. I took one, two frames, and hung them on a stand I use for the purpose, and then took out the hives one by one, examining each as I took them out, and put them into the hive separate from the others, so that the queen could not get on to the one I was putting in; but I failed to find her until I came to the frame on the stand which I had taken second from the hive, and there I found her in looking the second time over them. On other occasions I have found the queen, sometimes on the second, third, or fourth frames.

On one occasion this summer I did not find her until I took out the eighth frame, and when I did find her she was nearly at the bottom, between one of the side bars and the end of comb. Therefore I think if a candidate does all his other work to the satisfaction of the examiner, and can pick out the queen when he does find her, he ought to pass.—J. F., Durham.

EFFECTS OF STINGS.

[1242.] Not long after we commenced bee-keeping my wife got a sting on the head, which produced the same effects as that mentioned by W. Elfred, on p. 370 (1201). I was operating once on a hive with bare hands, and some bees were creeping over them. I thought I would drive them off with a puff of smoke, but as soon as I gave one puff one of them stung me on the back of the wrist, striking a vein; the pain was severe, and in twenty-four hours my arm to my shoulder was as thick as my leg. My hand was three times as thick as the natural size, and I could just move my finger-ends.

I was doing some work inside my bee-house once this summer when a bee stung me under the right ear on the jugular vein. It caused very severe pain and a sensation in my head, throat, and chest, as though 1 had got a very severe cold—a difficulty in breathing, so much so that I had to walk the floor for breath. The nettle-rash also came ont all over my body; these, accompanied by high fevered sensation, continued for two or three hours, and then followed swelling in my throat, inside and out-ide, down to my chest, which continued to increase for over twenty-four bours. It is generally four or five days before swelling settles down, the fevered feeling only passing away in proportion with the swelling.

Two or three weeks ago my eldest daughter, a girl of fifteen, was stung on the back of the neck with a wasp, and in the evening with a bee on a vein in her throat. I pulled the beesting out as soon as I could. She complained of suffering severe pain; but, strange to say, the effects of both stings passed away in a short time, without swelling the least, what can be the reason of the different effect on different persons? She appears to be bee-proof, to begin with, but I do not think I will ever

become so.—J. F., Durham.

EXTRACTING FROM BROOD COMBS. (1213.)

[1243.] Your correspondent 'G. T.' states 'he does not believe that bees are such fools as to visit such places as manure-heaps, stagnant ponds, &c., if there is good water within three miles of them.' All I can say is whether he believes it or not it is an undoubted fact, and he must use his eyesight more. 'There are none so blind as those who won't see.' Well, if he has extracted 600 pounds of honey this year, he does not say it is from brood-combs. I could extract that quantity from my hives to-morrow if I cared to do so, but then I should have to give them syrup. But that is not the

point. I say when combs contain unsealed brood, it is surrounded with a thin, watery liquid which is not pure honey. He then goes on to say, 'I find it necessary to use the extractor freely when there is a honey glut to give space for the queen to lay, or if not the stock will soon dwindle away. There will be very little honey got in sections or otherwise, and there will be a very poor stock for wintering, mostly old bees.' Surely he has been reading this in regard to skeps; it has no application to modern bar-frame expansible hives, in fact it is pure nonsense. Whoever heard before that it was necessary to extract the honey from the combs to make the bees fill the sections? And lastly, his insinuation that I wrote 'to run down pure extracted honey, and leave our market open for adulterated foreign honey,' I treat with the contempt which it deserves.—F. Boxes, Beverley, Sept. 5th.

JUDGING HONEY.

[1244.] I would not trouble you on this subject, especially after your note at the foot of letter 1200, but for a recent decision in the same place, but by different judges. I take a deep interest in the Glamorganshire B.K.A., and would remind those members who feel aggrieved that as yet the Society is in its infancy, and requires careful nursing and attention, and such letters as have appeared in the Bee Journal tend really to injure its prosperity and influence; and my plea for referring to the subject is that the Committee of the B.B.K.A. will see the urgent necessity of providing some rules and regulations for the guidance of judges.

In the Journal, August 25th, page 368, you give a report of the Aberdare Flower Show. The report states that for 'The largest and best exhibit of extracted honey in bottles,'-please note that it is largest and best, and not best and largest,—the first prize was awarded to sixty bottles of clover honey; the second-the report omits this, to forty or fifty hottles—passing over an exhibit of three hundred! and why? Because the honey was of a dark colour (gathered from the raspberry cane, Dr. Walker thought) and because granulation had set in. Now, sir, I would ask, is it to go forth that elover honey is five times of more value than that of the raspberry cane? Ought granulated honey to be passed over at shows? Ought colour—or is colour to be preferred to flavour? Or supposing both are equal in flavour, would colour score five points to one in such an exhibition? If such judges as Dr. Walker and another give such decisions, one cannot wonder that a third-class expert will fail to give satisfaction. Let us hope that before another season definite rules will be given by the B.B.K.A. to experts, and to—ONE WHO WISHES TO LEARN.

Wases.—Very plentiful in the north. The easiest way to destroy them is to roll a piece of rag together about the size of one's finger, saturate it with tarpentine, place the rag in the hole leading to the nest, and cover it with soil to keep the air out. This should be done about six o'clock at night. Nothing further is required, but if the nest is dug out next day every wasp will be found dead. They can be destroyed in this way in all places where the air can be excluded.—G. Garner $(J.\ of\ H.)$.

Echoes from the Hives.

Richmond, Surrey, September 2nd.—Honey barvest all over in this district. Have not done quite so well this year as last, but must not grumble. One new beginner in Kingston has had about 30 lbs. for his first crop. Have had the pleasure of helping to start two friends in beekeeping last week. Have introduced two young queens successfully by the direct method, and have made one strong nucleus lot headed by young queen. Bees are going into winter quarters welt stored with provisious. Looking at it all around we are going ahead.—H. Crawley.

Rowley Avenue, Stafford.—I have five bar-frame hives, of which at the beginning of the season four were fairly strong and one weak; from the four strong ones I have obtained about 340 lbs., an average of 85 lbs. a-hive, and from the fifth about 10 lbs., a total of 350 lbs. from five hives, an average of 70 lbs. a-hive.—H. J. Bostock (Graphic).

The Mall House, Lismore, August 27.—The honey season is over here, and as far as I am concerned has been a very prosperous one. I began badly: during a long absence from home in cold spring weather several stocks died out from queenlessless, so I began with ten bar-frame hives and four skeps. One bar-frame hive more lest its queen and gave me only half-a-dozen sections, and one skep that I inverted and supered with sections only gave me a dozen perfect ones. My other hives did right well, however, and I got 442 perfect sections and 431 lbs. of run honey. The inverted skeps, worked with queen-excluder and supered with bars, were really a first-rate investment. I inverted them early in June. Let no one try to do so without passing sticks through the combs from side to side a few days before. I quite agree with Mr. Chenevix about working at an apiary in the evening. All my work, with two exceptions, has been done after six o'clock this season. exceptions are hiving swarms and removing sections. have found great comfort as to the latter by taking the racks of sections off the hives (with a little smoke) at about nine or ten o'clock in the morning. I carry the rack to an empty hive in the shade, remove the cover, and substitute a carbolic-sprayed cloth. About two or three o'clock in the afternoon, or later if convenient, I remove and store the sections, now free of bees, who have made their way out of the door of the hive and flown home. The ventilators of the hive being stopped with paper the door is the only light space, and for it the bees make to find their exit. Many friends have adopted this plan and speak very well of it. Timid or inexperienced persons find section-taking a formidable business and quite dread the process. My bees, though some little distance from the moors, brought in the fine weather such a lot of heather honey that I have scarcely any autumn feeding to do .- F. W. C.

Cahir, Tipperary.—Seeing many people are giving the results of their bee-keeping experiences, a few words from a beginner may not be out of place. I started bee-keeping by getting a swarm end of July 1885, when every one said it was useless to commence. I put them in a bar-frame hive, and fed them well all the autumn and spring. Last year I had two swarms from the stock, and took also over 30 lbs. of honey, besides taking some from the swarms. This year I took from the first swarm I had last year 63 lbs. in supers on June 24th, and 40 lbs. August 3rd, and I also took a frame of 5 lbs. a few days age, 108 in all, besides leaving them about 40 lbs. for winter use, The other swarm produced 42 lbs. on June 22nd, and 30 lbs. August 1st, and from the old parent stock I took 65 lbs. I consider this very successful for a beginner to get 245 lbs. from three stocks. We had a particularly good honey crop here in June, but end of season very poor. I expect each hive has from 40 to 50 lbs. of honey on the frames still. S. E. M. C.

NOTICES TO CORRESPONDENTS & INQUIRERS.

Letters or querics asking for addresses of manufacturers or correspondents, or where appliances can be purchased, or replics giving such information, can only be inserted as advertisements. The space devoted to letters, queries, and replies, is meant for the general good of bee-keepers, and not for advertisements. We wish our Correspondents to bear in mind that, as it is necessary for us to go to press in advance of the date of issue, queries cannot always be replied to in the issue immediately following the receipt of their communication.

Beeswing.—Carbolised Sheet.—The recipe given by the Rev. G. Raynor for quieting bees in preference to smoke is—
' 1½ oz. Çalvert's No. 5 carbolic acid.

 $1\frac{1}{2}$ oz. glycerine, 1 quart of warm water.

The acid and glycerine to be well mixed before adding the water, and the bottle to be well shaken before using.' A piece of calico, or preferably 'cheese-cloth,' sufficiently large to cover the top of the hive should be steeped in this solution, wrung out dry, and spread over the hive on the removal of the quilt, when every bee will quickly disappear below, and manipulation may be slowly and quietly performed without annoyance from the bees. The

same plan is effectual in driving the bees out of section cases. From unsealed sections bees often refuse to budge, but a little blowing through the strainer will always dislodge them. All our sections are thus removed, and we have never experienced the slightest scent or flavour of the carbolic acid attaching to the comb or honey. This unpleasant result occurs only to bunglers, who either use too strong a solution or do not wring out the carbolised sheet sufficiently dry, and so besprinkle the comb honey with the solution, and charge the evil result of their own stupidity on those who recommend the process. The strength of the solution quickly passes away, as the acid evaporates when exposed to the air. The bottle, therefore, should be kept tightly corked, or the effect on the bees will be nil.

C. B.—Treacle is not good wintering food for bees.

G. J. D. Barnes.—Moring Hives.—You may move the hives with safety when the weather is too cold for the bees to fly. When the first fine day arrives, place a bough or board against the entrance, so that the bees may note their new location.

E. A. S.—1. Uniting.—On a fine day take out the combs that have fallen into the hives, shake or brush off the bees before the entrance of the hive with which you propose to unite it, piece and straighten the combs, and tie them with tapes into the frames, the bees will soon fasten them properly.

2. Driving.—Bees may in fine weather be driven from skeps and united with the small colonies in bar-frame hives.

3. Little Wonder Extractor.—In a small apiary the Little Wonder Extractor will be found of great service.

Beginner.—Read carefully Modern Bee-keeping and Cowan's Guide-book. Prepare your hives during winter, and commence operations earnestly in spring. Purchase swarms in May. 2. Simmins' Union Hive.—An account of this hive will be found in No. 244, p. 85. 3. It will save you much trouble if by the end of this month you provide sufficient stores to last your bees till next spring. You might then use, if necessary, Mr. Simmins' dry sugar feeders.

- J. S. L.—Foul Brood.—The comb is badly infected with Bac. Alvei. If the bees are strong enough to work out foundation, could they not be built up like condemned bees? It is too late for any one with little experience of the matter to begin treatment. The suggestion that dirty water causes foul brood I do not think tenable, but it has not been proved to be incorrect. We do not as yet know of any natural habitat for this particular bacillus but the body of the bee.—F. C.
- L. S. J.—Foul Brood.—The comb sent is affected with foul brood. You may supersede the queen and feed with phenolated syrup. When spring arrives continue such feeding without intermission until the brood appear quite healthy. In the case of any one having only a single colony we should advise the destruction of same and a fresh commencement. After destroying bees, combs, quilts, and frames, disinfect the hive with a solution of carbolic acid mixed in the proportion of three ounces of acid (Calvert's, No. 5) to a quart of water. First mix the acid with an equal quantity of glycerine and add the water hot, continually stirring same.
- C. A. J.—Please refer to replies to 'J. S. L.' and 'L. S. J.' and our editorial.
- F. W. C .- Mr. Lee's address is 43 Glycena Road, S.W.
- F. J.—Observatory hives and Judging.—We consider that no judge should adjudicate at a show in which he is a competitive exhibitor; if such is allowed there will sure to be unpleasantnesses arise. As we before stated, our opinion cannot be definitely given upon the merits of an exhibit that we have never seen, but from your description we should have given the preference to No. 3. Certainly not to No. 1, as, according to your description, they were in an abnormal condition having two queens. Even if bees have only recently been removed from a bar-frame to an observatory hive it would not debar the exhibitor from taking a prize; in fact, many are so exhibited.

Received from J. J. W. Currie, Dalbeattie, a piece of honey-comb. The honey was of a high quality, and of excellent colour and consistency. We should be pleased to know how it had been produced.

[No. 273. Vol. XV.]

SEPTEMBER 15, 1887.

PUBLISHED WEEKLY.

Editorial, Notices, &c.

THE CLOSE OF THE SEASON.

For many weeks—we may say even from the middle of July—the honey season of this the year of Jubilee has closed, with the exception of those distriets which rejoice in the vicinity of heaths. The honey harvest this year came prematurely and unexpectedly to a close. In common with gardeners and all others who depend on the productions of the soil, bee-keepers have had many difficulties to contend with during the past season. A lingering winter, and a long cold spring, and a summer which will be memorable for its absence of rain, have proved adverse to the production of plants on which the bees depend for their store and sustenance; yet notwithstanding these drawbacks we are in a position to say that the honey yield of the year has proved a fair average one. We cannot assert that the season has been good throughout the kingdom, yet the production of honey in some parts has been very great. In many counties of England and Wales the honey yield has been large and full of encouragement; at the Shrewsbury Show about six tons of honey were staged. In Scotland, more especially in Northern Dumfriesshire, the honey harvest of the year is said to have 'risen to a position of real importance among the agricultural events of the season.' In Ireland, too, the reports of the harvest and the quality of the honey are most en-The earnestness with which the shows couraging. have been conducted declares that the bec-keepers in Ireland have thrown off their former lethargy, and in their new-found self-reliance and fresh energy have determined to avail themselves of the great honey resources of their country, and to walk abreast of their brethren in England and Scotland. There is a future before Irish bee-keepers, and we hope to see their exhibits in the open classes in Great Britain in the coming year.

Many old bee-keepers in some districts assert that the present season has been the most fruitful in their experience, and the month of June the finest thirty days of honey-gathering they have ever known. At the same time we have had from sundry places low and doleful accounts of the honey yield, more especially from Middlesex and Kent. But taking the country as a whole, the retrospect

of the season is encouraging and should lead successful bee-keepers to look joyfully forward, while those who have not been specially favoured need not be discouraged, but see Hope yet beckoning them onward with the prospect of a brighter future.

The season for the bee and honey exhibitions has, also, well-nigh run its course. From week to week we have announced a list of shows; these have now come and gone; honorary secretaries have performed their arduous task, and we hope that the results have been satisfactory. The enthusiasm evoked by these shows in previous years has been well sustained in this. We are not able perhaps to point to exhibitions having been honoured by the presence of royalty, as we were last year at the Norwich and the Hampshire, nor have we any show to compare in grandeur or in magnitude with the great metropolitan exhibition at South Kensington; but we consider that good, honest, and hearty work has been achieved without 'the pomp and circumstance' of brilliant patronage. We have this year fought in the shade, but success has followed our efforts; the march of bee-keeping, both in Great Britain and in Ireland, has been onward. The good seed has been sown broadcast in many a town and many a hamlet, and the result, if we faint not, will be seen in after days. By these shows, by the display of the necessary appliances, and by the results of work in solid sections and translucent bottles of honey, the significance and intent of them have been well kept in view, viz., the promotion of beekeeping; the obtaining a market for honey when produced; the making known the virtues of honey as food and medicine; the creation of a new industry whereby the labourer and the artisan may be benefited; and the setting before the cottager a more interesting and fascinating pursuit, which will rouse his intellect, elevate his mind, and introduce a refining motive to his existence superior to the low and often-debasing temptations by which he is surrounded, and impart a freshness and energy into his dullened life. Exhibitions are essentially didactic. Who can tell the extent of the benefit which may be conferred on the advocate of the skep as he listens to the lecturer showing by voice and hand a more excellent way of keeping bees; and, while listening, he resolves to abjure his old system, and be more on a level with those bee-keepers of whose success he had heard and whose results he had

seen? Before this he was in darkness, he had perhaps never seen a queen,—scarcely believed that such a thing was in existence. But with his eyes he sees her,—he is convinced of his mistake in adhering to his antiquated methods; a new revelation dawns before him, and he departs from the exhibition with new hopes and fresh resolves.

But exhibitions prove of service not alone to the cottager, but also to the farmer. The union of apiculture with the old and well-established pursuits of Agriculture and Horticulture has been well exemplified in those exhibitions which have beeu held during the past season. By far the larger number of bee-keepers' shows have been held in connexion with the County Agricultural Associations, and the bee-keeping department on these oceasions has not been the least attractive part of those shows. Bee-farms have been established in various parts of the country; farmers are recognising in bee-keeping a valuable auxiliary. It is pleasing to find that the majority of the Agricultural Societies are taking the recognised County Beekeepers' Associations under their wings, and it must be gratifying to witness the warm interest that is taken in the bee department by the farmers, their wives and daughters, and the public generally. Many intelligent farmers have added bee-keeping to the other occupations of the farm; and when we remember that the annual amount paid to the foreigner for honey and wax is not less than 133,425l., we may well think seriously whether in these depressed and depressing times it is not possible to produce them at home rather than to allow the flowers 'to waste their sweetness in the desert air.' The fruit-grower and the seedgrower and the farmer will find their crops improved and increased to a very much greater extent by their keeping bees.

SUNFLOWERS, BEES, AND OTHER INSECTS.

These showy, æsthetic, and truly handsome flowers are recommended to be grown by bee-keepers as late pollen-producers, though we question very much, if grewn for this alone, whether the game would he worth the candle. But if poultry be kept, we would distinctly urge you to have a patch somewhere in the garden where they will hide or beautify au old wall or fence. The flowers may be used in house decorations if the beekeeper can find in his heart to be so extravagant; the pollen will materially assist in rearing brood, strong and prepared for a successful wintering; then, when autumn concludes, there is a magnificent harvest of seed for the poultry, which is well appreciated by them, and gives a good return to their owner as fattening food.

The sunflower is not, as is generally supposed, a single flower, but is a conglomeration of hundreds of small ones crowded together into a head, the outer ones (those bearing the golden yellow blades) being barren, and named 'florets of the ray,' their raison d'être being to attract insects to the flower for cross-fertilisation purposes. The more numerous inconspicuous flowers are grouped tegether in a central mass, and are called 'florets of the disc;' in short, the disc is the dark centre and the ray the petals of the flower. Taking

the ray as being simply a colour bait for insects, we will next consider the true perfect flowers—the disc floretsthose flowers which have within them perfect organs of reproduction. The table, or placenta, on which these are fixed continuing to grow, forces the outer florets further apart by pressure from the centre, where they are so densely packed together, immature, and unexpanded, that insects can find no passage-way amongst the flower-tubes, as they can amongst the older ones, now bearing at the base of each a seed, protected by a hard extine skin, proof against the attacks of earwigs and others. When we observe the beautiful symmetry of the convoluted lines in which the florets are arranged, amongst which are roaming earwigs, we at once see the ntility of their bodies being so supple, bent as they are the shape of the letter S. Here in these thickets, hitherto almost impervious to their attacks, they move about with ease and hide from their enemies. The outside florets, maturing first, leave a protecting stockade or fence, consisting of the anthers which are pushed up and out of the florets by a loug stalk or filament, the cases of pollen open and shed their contents, so that thrips or other small insects which are roaming about may carry it on their bodies from one sunflower to another. Passing in imagination through this stockade of filaments as a predatory insect might, let us see what steps the flower takes to preserve the unexpanded, juicy, tender florets within from its attack. Scattered about on the surface (a corrugated tableland) we notice minute drops of what appear like nectar, and wonder how it is none of the numerous insect visitors seem to eare for it, and leave it intact. If we taste it or rub it between finger and thumb, we shall find it to be a beautiful aromatic, resinous compound, very fluid and sticky-the very worst thing for any insect except as a sort of propolis, the very best protective for the plant—water and weatherproof, and so disgustingly bitter that our insects do well to leave it alone. Honey is contained in the flower-tubes, but these are so deep that they are only accessible to insects having unusually long tongues, or which are able to creep bodily down. Thus does Nature's chemistry provide the sunflower, amongst her myriad others, with substances both attractive and repellent, for friend or foe, according to its own or their requirements; these diverse compounds, so tetally at variance, being found close to each other on the flower, and evidently secreted out of the same sap by a similar type of cells.

USEFUL HINTS.

Weather.—The rains have descended at last, and the meadows have again put on their verdure, but few are the flowers, and, with the exception of that 'rare old plant, the ivy green,' there is no pasturage for our bees at this late period.

Wasps.—Nights have been frosty, and days too cold for bees to fly, but wasps can bear a much lower temperature than bees, and have paid constant visits to hives whose guards have retired within to avoid the chilling cold. To strong colonies these marauders do little harm, but many a weak one has perished under

their persistent attacks.

Ronning, and Carbolic Solution.—In dull, cold weather, at this time of year, when bees are flying little, a cloth steeped in carbolic solution, wrung out dry, and laid upon the alighting-board, will cheek the attacks of robhers and wasps. Renewed every morning it is as good a preventive as we have tried. In bright weather, when bees fly freely, and have a decided penchant for robbing, the cloth should be sprinkled, or sprayed, several times daily with fresh solution. If these precautions are carefully carried out there is no colony in existence that can rob or destroy another, however weak it may be. One caution we would add, viz., never to use the ordinary crude carbolic acid,

usually retailed by the ehemists, but ask for 'Calvert's No. 5,' and use it for all purposes connected with bees and hives, except for mixing with food. The unpurified, crude article might, likely enough, contaminate sections if used carelessly in their removal, but of this we have no experience since we always use 'Calvert's' purified. By means of it we have removed thousands of sections during the last two or three years, and have never heard a single complaint of any contamination being conveyed thereby. But of sections being flavoured with smoke, and spoiled by the filthy fluid dropping from the smoker, we have often heard complaints, and have suffered ourselves. Our sections, too,—without any 'self-praise,' which we are aware 'is no recommendation,—are pretty well known to all the best judges in this county. Again we repeat that under our 'Heading' nothing is recommended to others that we have not ourselves proved, and let any one who doubts refrain from making use of our 'Hints.'

Manipulations should be performed as sparingly as possible. The less bees are disturbed after the middle of September the better. Manipulate in the evening only. Do it quickly and quietly by using the carbolised strainer, which by one motion may be drawn over the frames as the quilt is drawn off. Turn back the strainer sufficiently to take out the first frame or division board, and thus proceed until the operation is completed.

Drone Comb has been built in several of our hives on worker foundation; notably, one hive has about half its cells drone, and this was one of our best swarms which has given us over 90 lbs. of comb-honey. In several cases where we did not fill the centre frames with foundation, leaving about a quarter of the space to be filled up by the bees according to their instinct, drone-comb has been built without an exception. We are not quite sure that it is wise to endeavour to deprive the bees of that which nature so strongly demands, and it would, perhaps, be wise to allow a small portion of drone-comb in every hive. In hives most productive of comb-honey, whether in sections or otherwise, we have always noticed abundant drones.

QUEEN INTRODUCTION should be finished as soon as possible. We have introduced successfully on Mr. Simmins's plan, but in one instance had an encasement and were obliged to cage the rescued queen. At this season, when there is no income, and when robbing is rife, we prefer the cage for a certainty. During a copious honey-flow introduction is easier and more certain. The cage we prefer is the enlarged and improved 'pipe-cover,' manufactured for us in Germany, and a specimen of which we shall be happy to present to any friend wishing to try it. Since using this cage we have no experience of the loss of a queen.

WINTER PREPARATION must now be thought of. The colonies undisturbed after the middle of this month always winter best. Floor-boards should be cleanly scraped, winter quilts placed over frames, and, as soon as the danger of robbing is over, entrances should be opened to summer width, say 6in. × \(\frac{3}{8}\)in.—just sufficiently deep to exclude a mouse.

Before giving the winter quilts the tops of the frames should be scraped clean from propolis. Here, again, the carbolised sheet will drive the smoker out of the field. With the small spatula as a scraper and the sheet one person alone can finish off a hive as quickly as two with the smoker, since two hands are required for using the scraper to advantage, and a continuous stream of smoke to keep the bees in check. No weak colonies should be kept; although by careful attention such often pass through the winter successfully they rarely pay for the extra trouble given. Such colonies, however, with a young queen at their head, may be built up by the addition of condemned bees and early copious feeding into strong stocks. When it is desired to put this into practice there must be no delay.

FEEDING should now be completed as speedily as possible. From ten to twelve pounds of granulated white cane sugar to five pints of water, boiled gently for two or three minutes, will form a good syrup for autumn feeding which will not granulate. For quick feeding, Mr. Neighbour advertises a very useful feeder, which holds twenty pounds of syrup, and is called the 'Canadian feeder.' The principle of this feeder is decidedly good, and, its material being wood only, there can be no injurious action upon the food, as in many metal feeders.

CLEARING-UP.—All articles for summer use should at once be thoroughly cleaned, dried, and stored for use another season, such as spare hives, section-cases, extractors, and all things appertaining thereto. Discarded combs should be melted, and the apiary and honeyrooms made neat and tidy for the winter. Let all operations be pushed forward and nothing left until next month which can be done now.

ASSOCIATIONS.

STAFFORDSHIRE BEE-KEEPERS' ASSOCIATION.

This Association held its Annual Exhibition at Burslem on September 7th and 8th, with that of the Staffordshire Agricultural Society. The site selected for the joint exhibitions was conveniently near the railway station and the town on the road from Burslem to Smallthorne.

Burslem is situated in the very midst of the Potteries and the large iron-works of Staffordshire, and is essentially a part of the Black Country. We were, therefore, naturally surprised to see such an exhibition of honey as was displayed, but were reminded that the rich valley of the Trent (as fine a tract of land as any in the midland counties) was in close proximity, and that it was surrounded by an excellent agricultural district containing rich pasturage, from which the clover honey was obtained.

As is usually the case at all agricultural shows, the bee-tent and exhibition of hives, bees, and honey, attracted a very large proportion of the visitors. All of these appeared to be much interested, and expressed themselves surprised at the progress modern bee-keeping had made during the last few years, and the different appearance of the honey, now clear and bright, and free from the dull and cloudy look it was wont to have in old times. The bees were then smothered, and the whole tainted with sulphur, the honey-combs, bee-bread, larvæ, and young bees, were all smashed up together and put into a cloth before the fire to strain, and the thick stuff, the result of all this, was called and accepted as pure honey.

We were sorry to learn that the Staffordshire Agri-

cultural Society does not give nearly so much assistance to the County Bee-keepers' Association as is generally the case with most of the leading agricultural societies of England where the shows are held in conjunction. They simply give the privilege of holding the show within the enclosed ground, and print the list of entries, &c., in the catalogue. The Bee-keepers' Association provides and pays for the tents in which to place the exhibits, and finds the whole of the prizes. The Agricultural Society do not even give an entry-pass to each exhibitor. This is most illiberal and unusual, and surely would be altered in future if properly represented to them. The Staffordshire Bee-keepers' Association is one of the largest of the affiliated County Associations, numbering, according to the report for 1886, 484 members. The Association has been thoroughly well organized. The county is divided into some eighteen or nineteen districts, and a considerable amount of energy is shown

throughout. Staffordshire is to be congratulated on the

position taken, and the useful work that is being done by

this Association. We have seen the honey exhibited at several of the leading shows this year, and had considered that the quality of the honey shown both by the Lancashire and Cheshire bee-keepers at Manchester was the best, but now that we have been to Burslem we have altered our opinion, and have no hesitation in saying that both for quantity and quality Staffordshire stands second to none.

In Class 3, for twelve best I-lb. sections, there were nine entries, a very fair class for the year. Mr. H. Wood, of Lichfield, was awarded first for the same sections that he took first in the open class at Manchester. In Class 4, for the best 12 lbs. of extracted honey, there were twenty-four entries. This was without exception the most even class of the kind in appearance that we have seen. There was not a single entry that was not good, and the task of selecting the three best must have been a difficult and unenviable one. We understand, however, that the exhibitors were satisfied with the awards which were made, after the time and pains taken to arrive at a decision. The majority of the honey was gathered principally, if not entirely, from clover. Class 8 for bees-wax there were 13 entries, most of them very good. The first went to Mr. J. Handley, a fine sample evidently from virgin comb. In awarding second place we understand that two adjoining entries were judged as one, being nearly similar in colour, and the number of one exhibit being covered by a piece of wax, this being found out some time after, equal second prizes were awarded to both, but this did not seem to satisfy the irate exhibitor. The most attractive exhibits were those shown in Class 9, for the best exhibition of honey in any form. Mr. II. Wood was again to the fore, exhibiting the same trophy for which he took first at Manchester, but somewhat differently filled, containing 174 lbs. of extracted honey and 73 lbs. of comb honey, at the base was a Jubilee device in comb honey, consisting of a crown, with the letters 'V.R.' one on either side, with 1837 and 1887 underneath: this was in addition to the weight given.

The trophy exhibited by Mr. J. R. Critchlow obtained second place, it was surmounted with a royal device, and contained 150 lbs, of extracted and 108 lbs, of comb honey, it was a very good second. Mr. Elihu Clowes took third with a trophy containing 134 lbs. of extracted and 61 lbs. of comb honey. All the seven exhibits in this class were good. The comb honey of Edward Richards, a cottager, consisting of two large bell-glasses and 2 lb. sections, together about 50 lbs. was as good comb-honey as we have seen this year, and 15 lbs. of extracted. In quality the whole was superior to anything in its class, but the much larger quantities of the other exhibitors (who were farmers), left no question as to where the prizes must go. Much credit, however, is due to Edward Richards for his skill and management in producing such excellent comb-honey. Class 10 was for the best exhibition of honey in any form made by bees belonging to an artisan or agricultural labourer in the county of Stafford, offered by A. II. Heath, Esq., Madeley Manor, the hon. sec. of the Association. There were nine entries: first was awarded to D. Mitchell, of Hanley, for a handsome trophy of comb and extracted honey; the second was awarded to S. B. Fox, Maer, Newcastle, for 57 lbs. of comb and 58 lbs, of extracted honey; the third to William Green, Great Bangley, Tamworth. Edward Richards exhibited some nicely filled 2-lb. sections in this class; and had he not divided his honey by entering in Class 9 as well as in Class 10, he would have stood a good chance of a prize in this class.

In Class I, Messrs. Abbott Bros, with a large collection of appliances took first, and Mr. A. W. Rollins took second with a very creditable collection, though not so large as that awarded first prize. We think that an improvement might be made in this class and a larger competition insured if the items to be exhibited were specified

in the same way as was done by the B. B. K. A. in the schedule prepared for Bury St. Edmunds; the cost to the exhibitors would be less, and the heuefit to the public would be greater, as those things only that were necessary would be then exhibited, and the judges would have only to take quality and not quantity into their consideration.

The following is the list of awards:-

Class 1.—For the best and most complete collection of hives and bee furniture most applicable to modern beekeeping. (Open to all England) Offered by the Staffordshire Beekeepers' Association. First prize, 21.; second, 11.; third, 10s. 1, Messrs. Abbott Bros., Southall, London; 2, Mr. A. W. Rollins, 65 Hagley Street, Stourbridge.

Class 2.—For the best and most complete bar-framed hive without supers, price to be taken into consideration. (Open to all England.) Offered by the Staffordshire Beekeepers' Association. First prize, 15s.; second, 7s. 6d.; third, 2s. 6d 1, 3, and highly commended, Messrs. Abbott Bros., Southall, London; 2, Mr. Thomas B. Blow, Welwyn, Herts.

Class 3.—For the best exhibition of twelve 1lb. sections of comb honey, in crate. Offered by the Staffordshire Beekeepers' Association. First prize, 10s, and silver medal of the Staffordshire Beekeepers' Association; second, 7s. 6d, and bronze medal of ditto; third, 5s. 1, Mr. Henry Wood, Paradise, Lichfield; 2, Mr. John R. Critchlow, Macr Farm, Neweastle; 3, Mr. S. B. Fox, Macr, Neweastle.

Class 4.—For the best exhibition of 12 lbs. of run or extracted honey, in glass jars. Offered by the Staffordshire Bee-keepers' Association. First prize, 10s. and silver medal of Staffordshire Bee-keepers' Association; second, 7s. 6d. and bronze medal of ditto; third, 5s.; fourth, 2s. 6d. 1, Mr. James S. Lawton, Swan Terrace, Woore, Newcastle; 2, Mr. John Handley, Fazeley, Tamworth; 3, Mr. S. B. Fox, Maer, Newcastle; 4, Mr. Elihu Clowes, Black Brook, Newcastle. Highly commended, Mr. Thomas Bailey, Baldwins Gate, Whitmore, Newcastle; Mr. Fred Jolly, Milton, Stoke-on-Trent; and Mr. Edward Richards, Wrottesley Lodge, Wrottesley, Wolverhampton.

Class 5.—For the best stock of bees exhibited in a straw skep. Offered by the Staffordshire Bee-keepers' Association. First prize, 1l.; second, 10s.; third, 5s. 1, Mr. Elihu Clowes, Black Brook, Newcastle; 2, Mr. John R. Critchlow, Maer Farm, Newcastle; 3, Mr. Henry Wood, Paradise, Lichfield; highly commended, Mr. James S. Lawton, Swan Terrace, Woore, Newcastle.

Class 6.—For the best specimen of bees of any race, exhibited with their queen in an observatory hive. (Open to all England.) Offered by the Staffordshire Bee-keepers' Association. First prize, 15s.; second, 7s. 6d. 1, Messrs. Abbott Bros., Southall, London; 2, Mr. Geo. Farrington, Smallthorne, Stoke-on-Trent.

Smallthorne, Stoke-on-Trent.
Class 7.—For the cheapest, neatest, and best super for harvesting honey in the comb, in a saleable form. (Open to all England.) Offered by the Staffordshire Bee-keepers' Association. First prize, 7s. 6l.; second, 2s. 6d. 1, Mr. Charles Redshaw, South Wigton, Leicester; 2, and highly commended, Messrs. Abbott Bros., Southall, London; highly commended, Mr. A. W. Rollins, 65 Hagley Street, Stourbridge; and Mr. T. B. Blow, Welwyn, Herts.

Class 8.—For the best exhibition of not less than 2 lb, nor more than 5 lb, of pure bees' wax. Offered by the Staffordshire Bee-keepers' Association. First prize, 5s.; second, 2s. 6d. 1, Mr. John Handley, Fazeley, Tamworth; 2 equal, Mr. Thomas Bond, Hilderstone, Stone, and Mr. E. Clowes, Hole House Farm, Milton, Stoke-on-Trent; highly commended, Mr. S. B. Fox, Maer, Newcastle, and Mr. Elihu Clowes, Black Brook, Newcastle.

Class 9.—For the best exhibition of honey, in any form. Offered by the Staffordshire Bec-keepers' Association. First prize, 10s.; second, 5s.; third, 2s. 6d. 1, Mr. Henry Wood, Paradise, Lichfield; 2, Mr. J. R. Critchlow, Maer Farm, Newcastle; 3, Mr. Elihu Clowes, Black Brook, Newcastle; highly commended, Mr. T. F. Hulme, Trentham, and Mr. E. Clowes, Hole House Farm, Milton, Stoke-on-Trent.

Class 10.—For the best exhibition of honey, in any form, made by bees belonging to an artizan or agricultural labourer in the county of Stafford. Offered by Mr. A. H. Heath, Madeley Manor. First prize, 11.; second, 10s.; third, 2s. 6d. 1, D. Mitchell, 34 Boundary Street, Hanley;

2, S. B. Fox, Maer, Newcastle; 3, William Green, Drayton Bassett, Great Bangley, Tamworth.

Mr. Jas. Lee exhibited, not for competition, a section crate complete, showing his patent dovetailed system of construction, also one in the flat which could be put together without nails—these were, we understand, purchased by the hon, see, and the assistant hon, see.

We are informed four candidates were examined for third-class certificates as experts and two of these, Mr. John Beach, Burntwood, Lichfield, and Mr. Frederick Wilshaw, Cheddleton, have passed. The other two we are teld failed, the weather being most unfavourable to the manipulation of bees, but another time under more favourable circumstances no doubt they will both pass, being old bee-keepers having considerable experience in the handling of bees.

Mr. John M. Hooker was the judge and examiner of experts. The superintendence of the Bee Department devolved upon the Rev. G. R. Bailey, the assistant honsecretary. The show was a great success; the bee-tent, as usual, being a great attraction; and under the able guidance of A. H. Heath, Esq., the hensec, (son-in-law of the late Rev. H. R. Peel), the Staffordshire Bee-keepers' Association will continue to increase the numbers of its members and its usefulness in the county.

HANTS AND ISLE OF WIGHT BEE-KEEPERS' ASSOCIATION.

HIGHCLIFF SHOW, SEPTEMBER 8, 1887.

The last show of the year held by this Association came off at Higheliff last Thursday and was as usual attended with considerable success. As many of our readers will remember, Higheliff is the southern seat of Louisa, Marchioness of Waterford, who has done so much for the Hants B. K. A., and it is situated on the sea-coast near Christchurch, overlooking 'the Needles' and the Isle of Wight. Indeed, apart from the interest attaching to a Honey Show, the view from the grounds where the show is held is amply sufficient to repay anyone travelling in that direction; and as the weather was all that could be desired for the occasion everyone was in the best possible humour for assisting in lending interest to the occasion. If we are to gauge the work done by the Hants B.K.A. by this show alone there is ample testimony that it has not lived in vain. When the first Higheliff Show was held some five years ago, if we except the specimen exhibits of Mr. Bellairs (which were then described by an incredulous bee-keeper of the old stamp as artificial bogus honey), there was nothing to be seen but a few dishes of comb honey cut from skeps and some bottles of an opaque substance which passed for honey at that time, but now-a-days would run the risk of being classed as 'unfit for human consumption.' But year by year intelligent men of the new type have been taking up the matter, so that to-day, or rather last Thursday, the cottagers mustered in strong force and united in producing an exhibition which would do credit to the cause anywhere in the country. In consequence of what we will hope is only a passing attack of the prevailing epidemic amongst Bee-keepers' Associations, the symptoms of which are shortness of cash and general anemia, the prize schedule was considerably curtailed from that issued last year, nevertheless the entries numbered close upon fifty.

There were five classes, amongst which prizes were offered for the best wasp's ne.t, which drew forth nine entries and proved one of the most interesting features of the show. In this class the first prize fell to Mr. J. Hiscock, who exhibited the most perfect nest we have ever seen, and worthy of any museum. It measured about fifteen inches in diameter, was enclosed in a glassbox 'hive' into which it had been transferred about two months previously, and consequently was in full working

order and fully equipped with live wasps. The second prize was carried off by G. Manning, son of the gardener at Higheliff, for a fine nest under a large bell-glass, and the third prize by a promising young bee-keeper, Harry Stephens, who, we understand, braved many stings in order to obtain an uninjured specimen.

Mr. J. Edgell was awarded a special prize in this class for exhibiting a nest peopled apparently by nothing but queen-wasps, of which there were scores. There was, unfortunately, no 'authority' present who could positively affirm that they were queen-wasps pure and simple, many people believing that it was a real hornets' nest; but this latter theory was somewhat upset by the fact that the nest had been dug out of an old bank by the exhibitor without any protection to arms or face! We think the Bee Journal would largely increase its usefulness if it devoted articles now and then to the life-history of wasps, ants, wax-moths, earwigs, and other insects affecting bee-keepers, quoting the best authorities, for there is a vast amount of ignorance on the subject, and it is very desirable matters should be cleared up. The writer of this article, an old and practised bee-keeper, has never seen so many wasps about his home as this year has produced, yet his honey-crop is amongst the best, and the wasps do not molest the hives. He has even encouraged two nests close to the hives! But this en passant.

For the bronze medal, &c. (Class I) the first prize was awarded Mr. Allen Broom for some extremely fine and well-flavoured sections; second prize to Mr. Arthur Stephens, and third prize to Mr. J. Hiscock. In Class 2, for the best 12 lbs. of super honey in sections not exceeding 1 lb. each, the first prize fell to Mr. Ambrose Pearce, of Christchurch, second to Allen Broom, third to Arthur Stephens, and fourth to Harry Stephens. In Class 3, for the best 12 lbs. of extracted honey, first prize given by the hon, sec. of the county, there was a very keen competition, the number of entries amounting to sixteen. There were many shades of colour, some remarkable bettles of a light amber colour calling forth much interest. These proved to be pure holly honey, gathered in the New Forest when there was no other bloom for miles, of a very distinct smell and piquant taste. There is no doubt as a fashionable colour they took precedence, but when compared for flavour with the notorious Christchurch darker honey they had to take a lower seat. Ultimately, the first prize was allotted to Mr. Arthur Stephens of Newtown, second to Harry Stephens of the same village, and third to Mrs. Burgess of Hinton, whilst Messrs. Pearce and Smooker had an h.c. attached to their exhibits. In the Bees-wax Class, P. C. William Burgess was again to the fore, and it would puzzle any bee-keeper in all England to beat him, Arthur Stephens came second, and Mrs. Burgess third.

The distribution of prizes by Lady Waterford in the Great Hall of Highchiff followed, after a lecture by Mr. Bellairs, her ladyship remarking how much pleasure it gave her to see the Show growing in importance from year to year, whilst expressing a hope that the high standard of excellence now attained might be maintained by succeeding good seasons.

WROCKWARDINE BEE CLUB.

The annual show of the above club took place in the Boys' schoolroom at Wrockwardine. The number and quality of the exhibits reflected great credit upon the skill and energy of the members of this young and flourishing association, which has recently succeeded in passing five of its members through the third-class examination for experts certificates under the B.B.K.A. Competition was especially keen in the cottagers' classes. The exhibit of the club appliances was a centre of attraction to the visitors, as also were the exhibits of live bees in observatory hives. Mr. W. G. Preece, jun., of

Shrewsbury, well known as a successful exhibitor, acted as judge. Too much praise cannot be given to the hon. sec., Miss M. E. Eyton of Leaton, for her efforts on behalf of the club, and no doubt the present exhibition must have been to her a great source of pleasure.

Appended is the prize list:—

Open to Club Members.—Best 12 1-lb. sections—Mr. John Palmer (Wrockwardine) 1. Best 12 1-lb. bottles—Mr. Fryer (Overley), 1; Mr. John Palmer, 2; Mr. H. Brooks (Leaton), b. c. Best and most complete hive for general use—Mr. John Palmer, 1. Open to Cottage Members only.—Best 6 1-lb. sections—Mr. James Shuker (Allscott), 1; Mr. R. Grainger (Allscott), 2; Mr. John Shuker (Allscott), 3. Best 6 1-lb. bottles—Mr. James Shuker, 1; Mr. John Shuker and Mr. R. Grainger equal, 2; Mr. T. C. Clarke (Overley) and Mr. H. Brookes (Leaton), equal, 3; Mr. H. Shuker, h. c. Best exhibit of honey, not less than 24 lbs., half run, half eomb—Mr. John Shuker, 1. Open to all Comers.—Best 12 1-lb. sections—Mr. John Palmer, 1. Best 12 1-lb. bottles—Mr. John Falmer, 1; Mr. John Shuker, 2.

HEREFORD HONEY FAIR.

On Wednesday, September 8th, the Herefordshire Beekeepers' Association held their fourth annual fair in the county town. A large space was appropriated in the Market house, the counters forming an oblong enclosure. About thirty-five cwt. of honey was staged by some thirty bee-keepers. The average price for extracted boney was about 10d. per pound in bottles—comb honey same price. There were several inquiries for run honey in bulk that could not be attended to, owing to the fact of nearly the whole of the honey being in I-lb. bottles. A number of people visited the fair, but most of them 'came out for to see' not to buy, the consequence being half the amount of honey remaining unsold. The half the amount of honey remaining unsold. arrangements were in the hands of the hon. secretary, Mr. Watkins, and were everything that could be desired. The Association also offered prizes and medals for exhibits of honey. The judges were the Rev. F. S. Stooke-Vaughan, Wallington Heath; Rev. James Oakeley, Hereford; and Dr. T. A. Chapman, Burghill. The following is the result of their awards:-

Class 1.—For the best exhibit of honey, not exceeding 200 lbs.—I, bronze medal of the B.B.K.A., and (given by the President, Mr. James Rankin, M.P.) 11., H. Bridgewater, Linton; 2, 15s., Rev. G. Herbert, Llangarren; 3, 10s., Thomas Charles, Caerswall, Much Marcle, Eight entries. Class 2.—For the best twelve 1-lb. jars of clear extracted honey—1, certificate, and (given by the President) 15s., Rev. J. F. Marillier, Much Dewchurch; 2, 10s., Alfred Watkins, Hereford; 3, 5s., W. Smith, Thingehill. Twentyfour entries. Class 3 .- For the best twelve 1-lb. jars of extracted honey, candied or partially candied-1, certificate and 10s., Rev. G. Herbert, Llangarren; 2, 7s. 6d., Mrs. Chelwick, Clun; 3, 5s., W. Smith, Thingehill. Fifteen entries. Class 4.—For the best twelve '1 lb.' (two inches wide), or sixteen '1 lb.' (less than two inches wide), or six '2 lb.' sections of comb boney 1 silver and 1 lb.' as sections of comb boney 1 silver and 1 lb.' sections of comb honey-1, silver medal of the B. B. K. A., and (given by the President) 15s., F. Lewis, Pembridge; 2, 10s., Mr. Meadham, Huntington; 3, 5s., T. Pritchard, Clun. Seventeen entries. Class 5.—For the best single super of honey, not being a sectional super-1, certificate and 10s., W. Tompkins, Burghill; 2, 5s., J. Vale, Burghill; commended, Miss Parry, Marden. Six entries. Class 6.—For the best exhibit of honey in any shape shown by a bona fide cottager, a member of the H. B. K. A.—1, certificate, and (given by the President) 15s., W. Tomkins, Burghill; 2 (given by Mrs. Glynn), 10s., F. Lewis, Pembridge; 3, 5s., W. Smith, Thingehill. Four entries.

WATERFORD HORTICULTURAL SOCIETY.

A Bee and Honey Show was held on the 6th of July in connexion with the Waterford Horticultural Society's Show, in the Rink, Waterford.

The Irish Association Bee Tent was lent for the

occasion, and lectures and manipulations given by Messrs. Francis Jones and W. E. K. Duffin.

Messrs. R. White and Co., of Limerick, exhibited a fine Cowan storifying hive, and a number of appliances, and Mr. Snow an excellent amateur's hive. An exhibit by Mr. W. E. K. Duflin consisted of different extracted honeys of several years, and comb and extracted honey made up in several modes for sale or exhibit, also sweetmeats, cakes, &c., made with honey. Mr. W. Andrews exhibited 'Arnold's Soap' for cleaning propolis from the hands. The honey exhibits were not numerous, but in comb honey they were of unusual excellence.

For the best twenty-one 1-lb. sections:—1, Francis Jones; 2, Miss Currey; 3, Miss Bolton; highly commended, Francis Jones. For the best twelve 1-lb. bottles of extracted honey:—1, Miss Currey; 2, F. G. Barlow; 3, J. Barr. Cottagers' Classes.—For the best super, not sections:—No first prize awarded; 2, P. Shelly. For the best twelve 1-lb. sections:—1, P. Shelly; no second prize awarded.

EXAMINATION.

An examination for third-class experts was held at Leaton, Wrockwardine, near Wellington, Salop, in the apiary of Miss M. E. Eyton, on August 29th and 30th. Six candidates presented themselves, of whom five were successful. The manipulation was exceptionally good, all the candidates showing great neatness in handling the frames and catching the queen, due to the fact that they had been carefully 'coached' for the examination by Miss Eyton. The following are the names and addresses of the successful candidates:—Miss M. F. Eyton, Leaton, Wrockwardine, near Wellington, Salop; Henry Brooks, Wellington, Salop; John Palmer, Wellington, Salop; Thomas Shuker, Admaston, Wellington; James Shuker, Allscott, Wellington.—Geo. Walker, Jun., Wimbledon.

STATISTICS.

W. Lees M'Clure, Esq., Hon. Sec. of the Lancashire and Cheshire B.K.A., writes:—'Our Association is not yet sufficiently spread throughout the two counties to give reliable information about the honey yield. Our experts are now on their tours, and, when completed, I will gladly give you the best information that lies in my power, but it will take some years to get reliable and complete statistics.'

TWO ENGLISH QUEENS.

THE LESS TO THE GREATER.

My velvet robe of state is brown and yellow,
My throne an apple bough, you peopled hive,
My subject world—great Queen, and sweet yoke-fellow,
To hum thy praise our nation is alive,

With busy murmurs in the snulight mellow,
Mid heather blooms, whence we our wealth derive.

That queens love honey is a saying olden,
Then come and feast upon our perfumed store;

Bring thou thy robe of state and sceptre golden, Thy royal sister queen will kneel before Thy mightier sway, and will her fiefs embolden

A nation's welcome at thy feet to pour. They for thine enemies shall guard their stings, But fan thee gently with their myriad wings.

Sissells.

Honey-Lemonade.—Make it in the usual way, using honey instead of sugar; nothing can be used as a summer beverage that is more grateful and refreshing. Try it. Many thousands of pounds of honey may be used in this way, and all the users be benefited.

CINNAMON OIL.—I have tried everything for hee-stings, and I have found that pure einnamon oil is the best thing I have ever tried. Two drops of einnamon oil will keep it from swelling.—D. E. BARKER (A. B. J.).

Correspondence.

The Editor does not hold himself responsible for the opinions expressed by his correspondents. No attention will be taken of anonymous communications, and correspondents are requested to write on one side of the paper only, and give their real names and addresses, not necessarily for publication, but as a guarantee of good faith. Illustrations should be drawn on separate pieces of paper.

Communications relating to the literary department, reports of Associations, Shows, Meetings, Echoes, Queries, Books for Review, &c., must be addressed only to 'The Editors of the 'British Bee Journal,'' c/o Messrs. Strangeways and Sons, Tower Street, Cambridge Circus, W.C.' All business communications relating to Advertisements, &c., must be addressed to Mr. J. Huckle, Kings Langley, Herts (see 2nd page of Advertisements).

***In order to facilitate reference, Correspondents, when speaking of any letter or query previously inserted, will oblige by mentioning the number of the letter, as well as the page on which it appears.

OUR HONEY IMPORTS.

The value of honey imported into the United Kingdom during the month of August, 1887, amounted to 2001. [From a return furnished by the Principal of the Statistical Department of Her Majesty's Customs to E. II. Bellairs, Wingfield House, near Christchurch.

DEAD BROOD.

[1245.] In 'Useful Hints' of the 1st inst. exception is taken by the worthy writer to a portion of the letter which appeared in the previous week's issue from the pen of Mr. S. Simmins, in which Mr. S. is made to say that dead brood is a sign of 'weakness in the queen,' but Mr. 'U. H.' affirms that it owes its origin to bacilli. If it is the latter, unless curative measures are taken, the stock, in all reasonable calculations, would still be affected. But I take it that in Mr. S.'s case it is not so. I have on several occasions, notably in four instances this season, had the same experience as Mr. S., which I think will bear out his ideas as being the most feasible. I will take the case of a single stock having an imported queen. This queen had been confined longer than usual in her travelling box (fifteen days), and was introduced last autumn. Noticing this last spring that things did not seem to be in the most flourishing condition, I made an examination and found dozens of larvæ dead in their cells. This continued for some weeks until the warm weather set in; it then suddenly disappeared. I accounted for this by the fact that the queen had recovered from her indisposition on the advent of such weather as she had been accustomed to in sunny Italy. In two other instances the same results were experienced, but the queens in these cases had not been confined for so long a period (according to my knowledge). The number of eggs laid were about on a par with other imported queens, but I had to add brood in order to keep the hives crowded, or should have thought that it might have been chilled, although too patchy. In the third instance it occurred in a lot of driven bees. In this case they were over a week in confinement last season, and were also very close pushed for stores during the winter. Why should not queens lay eggs, some of which have less vitality than others? Birds frequently do so. In mammals, after the dam has been subjected to any extraordinary privation, some of the young brought forth will have little or no vitality, and yet others of the same birth are well and strong. With the above facts before me I think there is little doubt that all dead brood—excepting chilled—do not contain bacilli. Let ns hope they don't.

Bees and Manure-heaps.—If Mr. Boyes will provide his bees with plenty of salt and water very few of them will visit manure-heaps. I trust that his opponent G. T.' will soon give up the practice of extracting from brood-combs, or rather from combs containing brood, not on account of the quality of the honey, but for the welfare of the brood.

Wasps.—I wish 'W.M.' would come and collect all

the wasps around my location. He is welcome to them even if they are such 'useful critters.

Honey Dew.—'Beeswing' will find that foreign races of bees will collect the excreta of aphides as readily as the down-trodden blacks. Scarcely any has been collected in this district during the last scason, although we were ten weeks without rain, and very little dew.-W. B. Webster, Binfield, Berks.

EXTRACTING FROM BROOD-COMBS.

[1246.] With one or two exceptions, I have made an absolute rule for myself not (outside my late official duties) to write to the Bee Journal on any subject, and certainly not on controversial points, feeling that my limited bee experience does not yet justify my protruding my views on the English bee world; but I have been drawn from my rule by a late letter of Mr. F. Boyes, on the subject of extracting from brood-comb, which has hurt my feelings, I must own, very much. To start with, quite irrespective of this special subject, Mr. Boyes has a peculiar way of his own of stating his views which always grates harshly on my ear. When a man makes a new, or even disputes an old, important statement on any science, it is usual to do so with some degree of Quite unintentionally, I hope, Mr. Boyes writes as if no one else could be right except himself, and that once he has stated what he believes to be fact, that fact (?) must be law from henceforth. I honestly hope I have misconstrued him, and hope to get a good basting from him next week. I will own for his benefit, in writing his reply, that a letter of his, early this year or late last year,—I forget the exact date,—has prejudiced me slightly against his writings. I am open to correction.

To return to my special point, when I read the letter in question (1204), I made up my mind to wait and see whether some one better able than myself would take him in hand in the next issne, September Ist. On reading 'G. T.' on the vexed point (1213) I thought I would

try also.

To start, therefore, I would ask for details of Mr. Boyes' chemical analysis of the honey from which he makes his statement, as I presume he has some grounds for it. If, as I suspect, he has not tested honey from brood (or other) combs for impurities such as would be found if there were traces of the nitrites which would be found in manure-water, I would be really grateful to him if he would, even at this late date, take a broodcomb containing honey, extract, and either experiment on it himself or get a friend to do so. To test analytically for nitrites, which are always present in all sewage water or water which contains urea (CON₂ H₄) is a very elaborate process, and requires chemical skill. However, since urea is found to take up elements of water and form ammonium carbonate, this by oxidation is converted into nitrous acids. To test for the presence of nitrous acid is a very simple process, and may be done by any one as follows: Add to the honey to be tested a little potassium iodide, acidify with a few drops of acetic acid, and add a little starch. Shut this mixture up in a dark capboard, and let it stand for fifteen minutes. If nitrous acids are present the liquid will turn blue.

I do, and always have, extracted from brood-combs, and believe it to be distinctly beneficial if done carefully. My honey (mea sententia) is second to none in purity, colour, and flavour; and though I rarely taste it myself, it is eaten regularly by a judge who would soon detect any vile stuff tasting of urea and manure-water. I am away from the use of a chemical laboratory at present, but at some future time I will try and go deeper into the subject which affects the interests of bee-keepers more than appears at first sight.

Next, set the chemistry of the question aside, and allow for an instant that bees while collecting honey also collect and STORE water in their brood-combs. What

are we faced with at once? Evidently, I think, that we may never extract from a comb which has ever contained brood. Because even if there is no brood at present in the comb, and all liquid has been evaporated or extracted and cleaned out by the bees, traces of solid nitrites cannot fail to remain, which would probably be taken into solution or su-pension again when placed in contact with a liquid. Even if that is too broad a statement, it would, by Mr. Boyes' argument, be daugerous to extract from a comb containing honey, but from which all the season's brood has hatched out; and of these combs I always have a large number, in upper especially, and also lower storeys. I admit that bees do visit queer places, manure-heaps, pig-styes, &c., but I have always thought that they were only attracted there by their powerful sense of smell, and that unless absolutely reduced to water starvation, left all foul places as empty as they came. I have no definite proof on either side.

I have said my say, and now withdraw for wiser pens than mine to do fierce battle in the interests of pure English, Scotch, Irish, and Welsh honey. The only reason that I know of for not extracting from broodcombs is the possible injury done thereby to the eggs and brood. I have watched very carefully and am decidedly of the opinion that with care no injury is done to the brood, and, except an odd one, eggs stay in their places. The argument that I would not like to have been put in a machine and whirled round when an infant is manifestly a joke, and dees not compare with present circumstances. This was gravely suggested in my presence lately, and was considered as final by the meeting.—Walter J. Stanford, Lucan, Co. Dublin.

EXTRACTING FROM BROOD-COMBS (1243).

[1247.] I may tell Mr. Boyes that it was from the brood-combs I extracted my honey, although he should have understood so from my letter; and I may also tell him for his edification that I finished extracting on the 3rd ult., and could now extract nearly 600 lbs. more, but it would not be as good honey as the first, and intend to let the bees winter on it. In his letter (1204) he says the 'liquid' extracted from brood-combs is not honey, no word of unsealed brood, or larva, as I should name it, containing the liquid, but the whole of the brood-combs, as I understood it, and so it reads—and as to the extractor taking it from the larvae it is doubtful if used with caution.

He quite misunderstands my meaning about using the extractor freely. Whoever heard or read of using the extractor on skeps? I never did (it would have been well for the skepists if it could have been done this year, especially with swarms, as will be seen next spring). What I meant to convey was that the bees, as the cells become vacant, fill them with honey, leaving no room for the queen to lay, as she should do at least 1000 eggs a-day during the busy season to keep up the strength of the hive. The consequence is there are not sufficient young bees to take the place of those that die from different causes, which are considerable, and the hive is therefore getting weaker instead of stronger. By using the extractor the queen can lay up to her standard, as my hives prove, which are overflowing with bees, and shall winter on the eight frames, Langstroth size. I never said it was necessary to extract from the combs to make the bees fill the sections, and I consider it all nonsense on his part to have understood me writing such a thing.—G. T., September 10th.

TIME FOR MANIPULATION,—INOCULATION,— THIRTY THOUSAND STINGS.

[1248.] If you will kindly allow me space, I should like to say a word in answer to 'C. A. M.' (1222). I think it makes but little difference at what time of the

day a hive is manipulated during warm weather if it is done with care and without any quick motion of the hands. I believe they notice that more in the bright sunlight than in the evening, as in the sun the shadows from our hands pass in varied motions on and off the top of the hive; this my experience teaches me they dislike. I think if 'C.A.M.,' another season, does as I have done, shade the hive during manipulation by simply fixing a small sheet on two long stakes in front of the hive in such a position as to stop the sun's rays from the hive, he would save himself from so many of those much-dreaded tenth stings, and thus save himself a deal of harding

Now with regard to the alleged in culation theory, our friend thinks it all a delusion. I find that a bee's sting affects one person differently to what it does others, and different stings will vary in severity and effect on one person. A great deal depends upon the part we are stung; if on a vein, or a part where our skin is thin, the effect would be more; also, our health at the time rules it considerably. I find with myself that the stings affect me less as the season advances. With some it may be different; but still I should be slow to say that others' experience, though differing from my own, is all a delusion.

No doubt 'C.A.M.' speaks from experience. He says, 'his natural funk leads him to exaggerate the severity of the stings that he gets.' It must be the case with himself and his tenth-sting theory, and when he was taking the bees from the roof, when he says he received about thirty thousand stings, perhaps about thirty were exaggeratively multiplied into that number; for if he actually received anything like that number—and, according to his tenth-sting theory, I should not have cared to have been near the locality at the time—the howling must have been awful.

With regard to calculating the winter stores by the superficial area of sealed stores, it is my plan, though it may be most misleading. But I should be sorry to see some of my combs two and a quarter inches thick and others only three-quarters. I think I should set to work with my kinfe in the early season, and teach my friends to keep their combs more regular.—A. G. Andrews, Rose Cottage, Haughley, Suffolk.

PARALLEL I. RIGHT-ANGLED FRAMES.

[1249.] The above subject being now under discussion, perhaps you will allow me to say a word. I have kept bees on both systems (cold and warm so called) for some few years, and have now about equal numbers of each. For the summer I do not think it makes the least difference what system is practised as regards the production of honey. My best hive (which gave me over 100 lbs. of honey) was on the warm system, and my next best was on the cold. But for winter I prefer the cold, though I know that will be contrary to a good many bee-keepers' advice. Last winter I lost the first two seams of bees in three of my hives on the warm system. They were starved to death though they had plenty of honey at the back of the hive, but the cold being so long without a warm spell between they could not get at it. I put them in winter quarters on ten frames, but as the weather got colder the bees got closer together, so that they only covered seven frames in the depth of winter. In the early spring I found the three last frames full of sealed honey, and the two first frames full of dead bees without a bit of honey in. Now, the bees on the cold system came through the winter in prime condition. They, like the bees on the warm system, wintered in the front part of the hive, but instead of occupying six or seven frames they occupied the front part of all the frames, so that they had access to all their stores without leaving the frames they were on. I do not think it necessary to cut passage-ways in the combs when you have the frames at right angles. I have never found it so.

As regards foul brood, I cannot say anything on that; I have never seen it.—John Bull, Ringstead.

P.S.—All new hives I get will be on the cold system.

STARTING A BEE-FARM.

[1250.] With your permission, I shall be very pleased if some of our veteran and much-esteemed bee-masters will kindly reply to the following—perhaps unusual—

questions, viz.:

I. What would be a fair number of strong stocks with which to start a bee-farm as a means of earning a living -i.e. by which an income of 30s, to 40s, per week could be secured—assuming the average price of honey sold to be 6d. per lb.?

2. What outlay would be required?

3. What breed of bees, all things considered?

4. When is the best time to commence?

Those who will take the trouble to answer the above will kindly accept the most sincere thanks of -A Welsh Bee-Keeper, September 8th.

[Will some of our bee-masters kindly reply to above? —Ed.]

A NOVICE DRIVING BEES BY CANDLE-LIGHT.

(Extracts from a letter to a friend.)

[1251.] My hive is now completed and inhabited, newly painted green, and looks quite creditable for an amateur. The hive I have made out of old timber that I had, $14\frac{1}{2} \times 15\frac{1}{2}$ inches inside, like the one on p. 95, in the sixpenny book (Baldwin's Dublin hive), with a moveable floor. I am really pleased with it. 1 wrote to Abbott's for No. 1 foundation for eight frames, and put it in. I replied to an advertisement in the Bee Journal and received at 10.45 last night, from Biggleswade, Bedfordshire, 5 lbs. of bees, and, I suppose, queen or queens amongst them, at 1s. per lb., and packing 6d., viz., 5s. 6d.—I shall also have to pay carriage, about Is.

We had gone to bed, having given them up for the night, but when I had got nicely to sleep there was a rap-rap at the shop-door, it wakened me, and I went to look out at the window; and I saw a gentleman standing with a box. I said, 'The bees were come!' and pulled on my trousers and received them from the station-master; he said I was to open it and let them have their liberty in the cellar: this, of course, by way of a joke. I was excited. A constant hum roared in the box, which denoted abundance of life. It was very dark and had been raining very heavily, and eleven o'clock at night, what was I to do? They had travelled all day, and were enclosed in a wood box about 15 by 12 by 8 in. deep, $\frac{1}{2}$ in. stuff, with a 2 by $\frac{1}{2}$ in. hole in one side covered with perforated zinc, to prevent the bees' exit. Now I had to decide what to do. I thought it best, as they had been confined so long, to release them. So I got corduroy, syrup, &c., all ready, and went into the garden with Frank, taking matches and candle. There was a strong wind, and we had no lantern, and the candle was blown out scores of times and as often relit. I determined first to try and drive the bees from the box into the hive, and nailed three pieces of wood together, forming a sort of tunnel between the box and hive to drive the bees through, so that they could not escape. I scarcely durst pull the zinc away from the hole of the box: I had the idea just at the moment they would rush out, because there was so much commotion inside. The sides of the box were covered with sprigbit holes. I set the corduroy on fire and blew the smoke into the box as well as I could, and drummed the box, both myself and Frank, for threequarters of an hour; but all to no purpose, -not a bee went into the hive. I thought 'This will never do, I must

try another plan.' All at once it came to my mind—'Spoonful them.' I thought I would open the hox-lid just a bit—all was quiet. I opened a little further—still all was quiet. Finally, I lifted the lid altogether; there the bees were, clustered on the under side two or three inches thick—all was quiet. I lifted it gently on to the hive, having first extracted two frames from the eight, and thus leaving a gap. Frank gave me the spoon, and I pushed them all off as well as I could in the dark and intermittent candle-light. I then took the box and did the same with it-waited a few minutes, put back the two frames after they had spread a bit in the hive. I then began to collect the stragglers as well as circumstances would permit. All at once Frank says, 'There's one creeping up my leg!' 'Oh, never mind it, if it does not sting.' 'It has got higher up now!' 'Well, never mind it.' 'It's got on my back, now it's stinging me;' and there was a yelp, I can tell you. 'Go into the house.' He told his mother there were half-a-dozen on his back, his mother could only find one, but there was a red point where the sting had entered. I had the veil on and a pair of kid gloves, and did not receive a single sting.

This morning I was up early to see how they were getting on. I found a very few bees about that had been killed in the dark, and a few clusters about the size of an egg here and there dripping with wet-it rained terribly fast after we left them at night-I got them on the spoon and placed them on the quilt near the syrup bottle to revive; and at noon I found they had all disappeared except about half-a-dozen dead ones. At noon the syrup had all gone out of the bottle; about threequarters of a pound. Some I had given them the previous night had run off the floor-hoard on to the ground, and about 100 or 200 bees were busy sipping it. They seemed to be quite settled, and all getting on right.

I send you herewith a sample bee. Is it not a strange experience for a start?—fancy the rapping at dead of night three-quarters of an hour from 12 to 12.45! I have not seen the queen, I suppose she will be there. Will she be fecundated already?—J. F.

HIVE-MAKING.

[1252.] I have read with very great interest the differentarticles on the making of hives, manipulating them, introducing queens, and the various systems of managing bee-hives generally.

After a careful study of these matters I cannot help coming to the conclusion that the majority, and more especially the labouring class, cannot avail themselves of one-half of the requisites of bee-culture as laid down.

One writer recently stated, and very correctly, that a labourer had not the time at his disposal; neither has he, sir, the tools and money to carry out all that is recommended; and except some cheaper, easier, and more simple method can be introduced, bee-culture amongst cottagers must go on very much in the old style. Some three years ago I bought *Modern Bee-keeping*, in which (page 21) very useful and simple instructions are given in making hives. This led me to make my own hives, and any one can do the same with very few tools and little expense. Many cottagers are very fair carpenters, as I have every reason to know from experience, and they, as a rule, possess the tools—a saw, hammer, gimlet, plane, and screw-driver. Now for my hive.

I get from the grocers a corn-beef box-one that holds six tins, I4 lbs. each. The box (this is obtained for 3d. or 4d.) measures $14\frac{1}{2} \times 14 \times 14$ inside. I cut down front and back level with inside, just to hold standard frame, and being fourteen inches deep it admits of frame and sections on top. I lay a piece of zinc over both ends where the frames rest, and let it wrap over slightly in the hive. This box takes eight standard frames (broadshoulder), but I am obliged to saw just a bit off each end of frame; metal ends would answer well here, I think. To finish the hive, I use the best parts of the top and bottom of the box for a hinged flap, which, let down, affords a small table when manipulating; raised and fastened, it secures the sections and helds the frames firmly. The nails I take out of the top and bottom of box I use to make sides a little more secure. I putty, and paint two coats. During the winter I cover with unbleached calieo, and over it a pillow filled with very small bits of paper, a covering both warm, dry, and clean, and further within the reach of all. The little ones, as in my case, can, and delight in tearing up bits of paper for 'pillows.' Of course, I make an outer covering; and here again I am indebted to your small work (page 26).

Here is a hive, sir, for less than one shilling, that any labourer can make. I know that objections will be made against its size, &c.; but I have used and worked it for

the last three years.—E. T.

WASPS,

[1253.] In these days we ought to be surprised at nothing, but your correspondent 'W. M. must have surprised most bee-keepers, both amateur and professional, by his defence of wasps. I am only an amateur of a few years' experience, but so far as I know there is not a greater pest to the apiary than 'W.M.'s' favourites. True, these insects are very beautiful, and from 'W.M.'s' point of view very interesting. What can more interest a lover of bees than to see these beautiful, harmless insects glide gracefully along the alighting-board, till, reaching the entrance, they get repulsed once, twice, or even the third or fourth time, and then, with perseverance worthy of a professional burglar, at last find the doorway unguarded, and proceed to plunder right and left -bees, brood, honey, they don't care what—and, after disabling a few bees, who have eventually to be carried out corpses, fight their way out, only to repeat the precess, I am afraid to say how many times a-day. As to their destroying aphides, they may do so, but, like the sparrows and tits, they have got so demoralised that green dy and red spider have it their own way while the fruit and the poor bees have to suffer. These harmless insects, too, have another good point: they are early risers (they get up about two hours sooner than bees and retire an hour or two later), and, unless it is a very strong stock, they make sad havor while the bees are more or less dormant. I killed (I hope for 'W. M.'s' forgiveness) three hundred and twenty of these beautiful and harmless insects as they were *leaving* one hive. True, they may have been in search of the larvæ of moths. but evidently they didn't know one from the other, as several met their death with bee larvæ in their jaws. If the Yankee advertisement which appeared some time since offering a reward for making outdoor life agreeable to mosquitoes were slightly altered, I believe most beekeepers would gladly subscribe to reward him who would make ontside an apiary' life agreeable to those harmless insects versus daylight robbers—wasps.—C. HONEY.

WASPS-VEILS-STINGS.

[1254.] Your correspondent 'W.M.' (No. 1207) asks 'on what grounds the humane bee-keeper can defend wasp-killing,' as he has never seen or heard of wasps 'doing any damage whatever to hives.' I should like to express my belief in his assertion, but at the same time state my opinion from observations that wasps, though doing no injury to hives, yet do a great amount of harm to the contents thereof, namely, to the bees, hency, and comb, which, according to my ideas, is a matter of far greater moment. This year especially I have noticed wasps fighting with and killing bees on the flight-boards of my hives, possibly made more desperate by the lack of ripe fallen fruit in my garden; and on examining the

other day a cottager's skep, which two months since had been occupied by a moderately strong stock of bees, and finding no bees, no honey, broken combs, and a small colony of wasps, I do not wonder at the humane beekeeper defending and adopting wasp-killing, although they may be in other respects, as 'W. M.' says, as valuable as bees. I don't mean of course to assert positively that the entire destruction of the above stock and spoliation of its stores were attributable to wasps, but the hive having occupied a nice sheltered spot, and, as I have said, been fairly tenanted, and as numerous wasps had latterly been seen busily engaged thereabout, I cannot help sharing in the owner's belief that 'most of the mischief was owing to them wasps.'

With regard to 'W. M.'s' inquiry if I can manage

without a veil, I reply that though daily manipulating veilless I never so attempt any of the major operations, and so far have not once been stung on the eye. I have however, been stung several times on various parts of my body, but not felt any inconvenience therefrom. That some stings hurt more than others I know, but, in forming my opinion as to inoculation or otherwise, do not look to the actual pain suffered at the time of infliction, but to the after results. And when I find that though when stung a blister may rise, giving pain, yet in a few moments it disappears without the application of any so-called remedy, and all pain ceases, I cannot but believe in inoculation, and deem myself inoculated

not with standing.

'1222's' humorous experiences 'up a scaffold.' By the way, if not giving him too much trouble, should like to ask what ultimately became of the queen, the sole survivor of the 'strong stock,' for it is evident from his letter that she alone survived the horrors of that dreadful day. Let me refer to his letter for particulars: 'The stock was a strong one (I daresay there were 30,000 bees), and I believe that every bee except the queen and two others left its sting in my skin; the two others stung my friend.' On reading these words I could not help thinking (without casting any reflection on '1222's' pluck) that long before his skin had received the 29,997 stings he probably had acted as 'W. M. 'says wasp-haters do act, and had received the punishment the same writer declares such conduct deserves. And then the question arose in my mind, could it be possible that having innocently, and possibly blindly, carried home the queen in solitary grandeur (her two companions having paid the penalty for interfering with his friend's 'skin') and placed her in a hive discovered, on losing his 'hedgehog-like' appearance, that she and her followers were not, attributed his loss to the wasps? I make no assertion, but simply state the question as it arose in my mind,-Perseverando.

DEAD WASPS.

[1255.] Since reading your article on wasps, in B. B. J., I have given time and attention to them and find that single-handed the bees have no chance. This week I discovered between two hives I have on one stand a small mound of dead wasps, numbering near two hundred. Now, the bees must have carried them there, but could it be from one or both hives. Perhaps some bee-keeper will enlighten me.—Member Worcestershire B. K. A.

BEES INVADING SHOP.

[1256.] Your lively correspondent 'X-tractor' is wrong. The bees which invaded the Dunbar shop were, I believe, the property of an old gentleman who lives just across the street. Curiously enough, that was the third time a swarm from the same owner had tried to make a home in that shop. Could it be the same queen who has yearly coveted this place? Queen records not being kept by this bee-keeper, I have been unable to find out.

What does 'X-tractor' mean by the—poetry, shall I call it? Does he want a queen? Sorry that I have too few for myself.—G. D. Clark, Kirklandhill, Dunbar, September 4th.

BUMPING.

[1257.] On the subject of 'bumping' I should like to say that I found it quite a success. I bumped seven lots this year in the time I took to drive three last year, taking less than ten minutes per hive, as against five and twenty last year. There were several hives with combs very soft and heavy with honey, but I think that with care, and a little working backwards and forwards of course, these can be fished out with less mess than is made by cutting ont the combs after driving, which is a very nasty business. Besides, there is the delightful 'tit-bit,' the crash! How pleasant to dash the hive of bees on the ground and hear the buzz of alarm and consternation that follows. I may say that I also followed the explicit instructions given in the B. B. J. for August 11 (not 18), for which I was very greatful as they came just in time, and I had never before heard of humping, which, I think, ought to supersede 'driving' altogether.—A Learner.

BUMPING A FAILURE.

[1258.] If folk only take half your advice instead of the whole they must not wonder at failure. Bumping a hive containing tender new comb and on a hot evening is, to say the least, a great risk, which I would not run, With old combs I can generally get through six stocks in an hour. For removing heavy combs I use a thin piece of hoard, with a handle screwed on (across the grain) on which to lift out the combs, and one for the middle and the other for outside combs would be better. I think it would be better still if made of tin with a stiff wire round the edge and to form the handle.—W. E. Burkitt, Witts Bee-keepers' Association, Buttermere Rectory, Hungerford.

FASTENING COMBS IN SKEPS.

[1259.] I do this by cutting ordinary top bars with saw cuts to the required length, put in the foundation, and fasten in the bars with a few wire nails, and tie them with wire through the top of the hive at proper distances.—W. E. BURKITT.

JUDGING HONEY.—A JUDGE APPRECIATED.

[1260.] By your kind permission I should like to say a few words on the judging which took place at the North Staffordshire County Show, held at Burslem on the 7th and 8th inst.

Being one of the exhibitors, it was my privilege to be present, and thinking it not rude on my part to notice the whole proceedings and gain what information I could from the remarks of the judge on the various exhibits, and as I stood by I remarked to a friend what a tedions and unpleasant position it was to be placed in; but I must say he exercised the greatest patience and care in making the awards. I have not sent this because I was one of the fortunate in gaining the first prize and the silver medal, but as I think Mr. Hooker deserves great praise for the judicions manner in which he performed his duty, and I return him my sincere thanks for the same.—

James S. Lauton, Swan Terrace, Woore, Newcastle, Staff.

HONEY BY THE HUNDREDWEIGHT.

[1261.] I hope no one will be discouraged by reading the letter signed 'Sherborne, Dorset.' In the first place, he tells us he has realised 56 lbs. from one hive; then whose fault was it the others were such a failure? I am afraid he has not followed our friend Cowan upon general management in The Bee-keepers' Guide page 125, &c. Some of our friends fail in having more stocks than they can attend to. I find twelve to fifteen stocks to take up all my spare time, and I have found by following the Cowan essay and 'Useful Hints' in our valuable Journal the best results. This year my bees have done well (not better than last year). I have taken from one stock of twelve frames over 130 lbs., chiefly 1-lb. sections; another 130 lbs., chiefly 2-lb.; another over 100 lbs., one swarm over 50 lbs., No. 2 swarm over 40 lbs., chiefly 1-lb. sections; altogether the bees have paid for the labour bestowed. I don't know what stock pays so well with such an outlay of capital. Now respecting the price of honey last year, I commenced the season with extracted (which I pass through a flannel bag) at 1s. 1-lb. jars, sections 15d. a pound, 3 lbs. 2s. 6d., sold about three dozen sections at the finish of the season at 10s, a dozen; and if, as 'Sherborne' says, it would be easy to find a good business man to find a market for honey, my advice is, use all your influence in trying to keep on the work of the Association to which you belong to pay for such a man. Our Association unfortunately has gone to the had, and I should only be too glad to assist in the formation of another, as 'North Lincoln' says, upon sound principles. I have been waiting and hoping to see a reply to 'North Lincoln's' from some of our more experienced bee-keepers in Lincoln, Boston, Grantham, Louth, Spaiding, &c., as we all know the great benefit an association is to the labouring classes when properly worked.—N. E. LINCOLNSHIRE.

ARNOLD'S SOAP.

[1262.] Every bee-keeper has experienced the difficulty of getting his hands clean from propolis after working with his bees. I have tried everything with indifferent success, until I was presented with a bottle of 'Arnold's Soap' to try its cleansing powers; I tried it on propolised hands, and, like other illustrious personages, 'since using it I have used no other.' The propolis disappears almost instantaneously, and saves much time and ill-temper, and leaves the hands really clean and unstained.—D. E. L.

CARBOLIC ACID—APIFUGE.

[1263.] Referring to 'Amateur Expert's' letter in last Journal (page 393), I don't think he need be a bit afraid of earbolic tainting his sections if used carefully, which of course he would do. I have been using it for the past season or two, and find it far hefore smoke or apifuge. If I want to take off a crate of sections I damp a cloth with the carbolic solution and throw it over the crate for a few minutes, when nearly all the bees go down. By merely doing this it cannot touch the honey, and how could it taint it? Some party ('A Lanarkshire Bee-keeper,') advised putting carbolic papers down between the sections, but I think that a dangerous plan and likely to taint the honey.

I have given the apifuge a fair trial; there is no doubt there is some virtue in it, but it won't prevent bees stinging if inclined. If it was cheaper, and that we could use more of it, it might; but while so expensive as it is at present we cannot do that unless we have plenty of money to pay for it. To be really useful it should be about 1s. 6d. a pint instead of 1s. 6d. for a tablespoonful

as it is .- A COTTAGER.

ASSOCIATIONS AND MEMBERS' HONEY.

[1264.] With reference to the suggestion made this week by 'Sherborne,' Dorset, that Associatious should assist their members in the sale of their honey, I may mention

that this is done by the Irish Bee-keepers' Association. We have established a depôt in Dublin where, by the agency of a good business firm, the honey of our members is sold to 'grocers and others who come directly into contact with the consumer.' A commission of five per cent paid to the business firm and charged to members is the only share of the profits taken in this case by the 'middle men.' So far we have sold during the present year nearly 2000 sections, besides some extracted honey in bottles. As regards prices, there was a short period—about a fortnight—when the market was flooded with sections, and we could not obtain more than the price complained of by Sherborne, viz., 6d.; but now, and during the first half of the year, the price has been substantially higher than this. With reference to extracted honey, we have not had any of it sent unbottled. Probably we could not obtain more for it in that form than 'Sherborne' does. But in bottles, after deducting $1\frac{1}{2}d$. for bottle, &c., the prices obtained leave considerably more than 5d. a pound for the honey. HENRY CHENEVIX, Hon. Sec. I.B.K.A., Blackrock, Dublin.

LANCASHIRE AND CHESHIRE BEE-KEEPERS' ASSOCIATION.

[1265.] In your report of the above, in your issue of the British Bee Journal for September Sth, I noticed there is an inaccuracy as to the quantity of honey said to be staged by me in the class for the best exhibit from one apiary in quantity not less than one hundredweight, as in addition to the quantity named in your report I also staged in this exhibit a device in honey-comb, representing a V. R. with a crown in the centre, and the figures 1837-1887 underneath. This device alone gained a bronze medal as second prize at the recent Caledonian Society's show held at Perth, such prize being awarded in a competition of eight exhibits in the same class. Regarding the question as to whether extracted honey only, or a collection of both comb and extracted, was intended by the schedule of prizes to be shown in this class, and your emphasis on the word 'Honey,' printed in italics in your report, I would point out that before making my entries for the show, I wrote the hon, sec., Wm. Lees McClure, Esq., for information as to what should be shown in this class, and he replied. 'Both comb and extracted; honey in any form.' This, I think, should confirm the decisions of the judges.

Echoes from the Hives.

'Honey Cott,' Weston, Leamington, September 12th, 1887. -During the month just passed I have been very busy of an evening driving bees, and making them up into stocks, by giving them combs ready built and feeding them up; some that I took a month ago have been breeding well, and are in first-rate order. After getting the bees home of an evening if I have any brood, which I get sometimes, I tie it in frames and place in the centre of temporary hives which hold about seven or eight frames, though usually I only place about two combs on each side of the one with brood, I then place them on a board on the ground and raise the front of hive up about I! inches, also putting another board up to the other, and get the hive with bees and give it a good smack on each side with both hands and the bees fall out on the board and soon run in. If there are not bees enough to make a good stock I pitch another lot on to them, so that in running in they always unite peaceably; then, first thing in the morning, I place them in their proper place and feed at once, so that there is no fear of their turning out as poverty swarms. I should like to give my opinion against bumping, except in regard to casts that have not more than half filled their hives with combs. I know that people would not want me to take their bees if I messed up the bees with honey, &c. as some do, whereas people send and ask me to drive their bees, because they have had it done

satisfactorily year after year, the young queens from easts and old stocks that have swarmed I look after, so as far as possible to only save the young queens. The bees now keep at home to protect themselves against robbers, either bees or wasps, while of the latter they lay on the ground in front of the entrances showing that the bees are masters of the situation. I cannot understand the wasps killing whole stocks, except they are queenless or the entrances much too large. While stocks are in proper order I never fear damage from the wasps; fortunately I got most of my sections taken off and extracting done before they became so numerous.

Haworth, Keighley.-Our report is as follows:-Started year under gloomy prospects, very cold and wet, until end of May. Vegetation was kept back, so that when June and better weather came all was out at once, viz., bilberries, sycamore, hawthorn, and fruit trees—bloom in abundance. Bees then did well; but owing to cold May, hives were not ready for it. By end of June all was over in this section. Fields were cut and bee pasturage reduced. Increase plentiful—never did better better in the time; but, owing to hot, dry weather, instead of bees forging ahead, they gradually consumed stores, and when taken to the moors in August, about the 7th, there was not a pound to spare (none had been taken). For three weeks after bloom was out nothing was done off it, on account of dryness and frosty nights. Rain came; we had then five days in which the bees worked marvellonsly; every space was filled up in next to no time, and our hearts rejoiced, -when suddenly the weather broke, and it has been rain ever since. Now all is over except the rain, which continues to descend. All we have to depend on here is the ling bloom; if that fails, we fail likewise. Straw skeps are chiefly used. Myself and one friend have bar-frames—I thirteen, he twenty. He has been a beekeeper these last forty years, and his report is, 'If all was reckoned up, I am 100% debtor to eash just now.' a poor district for bee-keeping, and my friend's private opinion of it is as follows: 'Noo wan reete i' ther heads would keep bees i' this cuntry.' Wasps are becoming a nuisance, they are so plentiful; no fear of their dying out just yet. They are also plentiful, even to a seourge, in two places more I can mention. Cannot give weight of honey yet, but consider average about 20 lbs. a hive surplus.—G. Robinson.

Kirklandhill, Dunbar, September 4th.—This year has not been such a good one with me, owing to the drought completely spoiling the pastures about here. I commenced the year with three Stewarton and five frame hives. From them 1 got 240 lbs, of comb-honey and three swarms; also a lot of comb unfinished. The sections used were one and a half inch, and have not been by any means a success. Though no separators were used the combs were capped straight enough, but there were as many, if not more, popholes in narrow sections as in wide. Wasps are very plentifnl, and doing immense damage to bees, frnit, &c. seem to be two kinds of wasps; one is smaller than the common, and very dark yellow on the first two rings. Can anyone tell me if they have been noticed before? I forgot to say that my bees have not been to the heather this year. -G. D. CLARK.

NOTICES TO CORRESPONDENTS & INQUIRERS

Letters or queries asking for addresses of manufacturers or correspondents, or where appliances can be purchased, or replies giving such information, can only be inserted as advertisements. The space devoted to letters, queries, and replies, is meant for the general good of beckeepers, and not for advertisements. We wish our Correspondents to bear in mind that, as it is necessary for us to go to press in advance of the date of issue, queries cannot always be replied to in the issue immediately following the receipt of their communication.

All queries forwarded will be uttended to, and those only of personal interest will be missared in this column.

interest will be answered in this column.

Agnes Thomson.—Transferring.—We advise you to keep your bees as they are until next senson, and then to take a swarm and place it in the frame-hive. It is too late to transfer now, except by an experienced apiarist. You do not state the size of the octagonal hive. If it weighs about 25 lbs. gross you may remove the upper box of honey for your own use.

G. T .- Casting out Young Bees .- This not infrequently happens from nuclei. In some cases it is caused by the very young bees being 'crowded out' by their rather older brethren in the middle of the day, when such fly and cannot return. We have also seen the old bees turn them out, but not in very large quantities; in such cases we have always supposed, that through some physiclogical failing or weakness of the mother, these are the weaklings of the hive.

T. H., Pinxton.—Your post-eard suggests a number of topics for us to write upon; we shall be happy to gratify your wishes to the extent of our limits in subsequent

Fearful,'—Foul Brood.—The piece of comb forwarded is so small that a positive opinion can hardly be given, although we are very strongly of opinion that it has come from a stock so affected.

Aps.—Condemned Bees.—When driving two skeps, with the object of uniting the colonies there is no necessity to scent them. One can be driven, and the hive containing them placed over the second stock, and these bees driven in with the others, they will unite peaceably. Either of the queens can be caught as the bees ascend, or they can be allowed to settle their own differences. We are strongly averse to putting condemned bees upon foundation only, as the labour of drawing it out exhausts the bees so that by spring very few will be fit for work. If given frames of comb they will make good colonies for next season. They should be driven and put in the hive at once, feeding them continuously and as fast as possible.

Subscriber.—See reply to 'Aps.'

T. T. M.—Syrup for winter food made from crystallised pearl sugar would be preferable to that made from sample forwarded.

- G.H.—1. Salicylic Acid Solution.—Salicylic acid 1 oz.; soda borax 1 ez.; water 4 pints. Salicylic acid will prove a preservative of syrup. 2. Autumn Food.—White lump sugar, 10 lbs.; water, 5 pints; vinegar, 1 oz.; salicylic solution (as above), 1 oz.; salt, ½ oz. 3. Carbolic Sheet Recipe,—1½ oz. Calvert's No. 5 carbolic acid; 1½ oz. of glycerine; 1 quart of warm water. The acid and glycerine to be well mixed before adding the water, and the bettle to be well shaken before using. The piece of calico should be steeped in the solution, wrung dry, and spread over the hive on the removal of the quilt.
- G. Robinson.—Our reports bear testimony to the large honey yield in some parts of the north of England. If bee-keepers who have been so fortunate as to have had a large harvest of honey would postpone selling it for some months, the price realised would be much higher than it is at present.

Beeswing.—Lee's Sections.—Mr. Lee is at present engaged in a series of experiments as to the best method of using his sections. It will therefore he desirable to postpone the reply to your questions for a few weeks, when we will take an opportunity of recurring to them, and giving the information in a more complete form than it is possible to do at present.

INQUIRER.—Position of Hires.—The position of hives very much depends on the surroundings. A south or southeasterly aspect is desirable; but the presence of hills, valleys, plantations, trees, hedges, walls, &c., would require the bee-keeper to modify it accordingly. There need be no hard-and-fast rule adhered to in this matter.

H. Lander.—Winter Passages.—These are very important, and should not be omitted, as without some such means of bees passing from comb to comb there is much danger of colonies perishing. The simplest and the most rapid method is to raise the comb, and resting it between two others, to make the required passage with the cutter or a pen-knife, and permit the exsected portion to drop between the combs on to the floor-board; the bees will clear it up without attracting the attention of outer bees. The method suggested by you for dispensing with winter passages is similar to the contrivance known to bee-keepers as 'Hill's device.' This consists of a number of curved strips of wood nailed to a crosspiece. When laid on to the tops of the frames it keeps the quilt up so as to allow the bees passage beneath it. It has the advantage of not disfiguring the combs, as winter passages are said by some to do; the latter are considered to be the more efficient.

Received from Mr. W. J. Green, Sudbury, Suffolk, circular with description of his 'Improved Imperial Bar-frame Hive,' a model of which was shown at the last quarterly conversazione of the B.B.K.A.

Received from Mr. J. M. Hooker a sample box of honeydrops, manufactured from his own honey. Exhibited at the Manchester Show, Stand 492, Section 2. The drops have a distinct flavour of honey, and are worthy of appreciation.

Secretaries of County Associations are requested to note that the next Quarterly Meeting of County Representatives will take place on October 19th. Notices of Motions for this Meeting should reach the Secretary of the B. B. K. A. by Wednesday next, the 21st inst.

HONEY-DEW.

Dr. Dzierzon, in his apicultural instructions to bee-keepers for the present month (September), says, 'In heath districts the bees may in favourable weather still have some pasture till towards the middle of September, otherwise they can only gather honey where honey-dew has formed, which this month is not rare on pines. But this generally brings the stocks more loss than profit; and the honey that is carried in itself is of bad quality, and is often the cause of dysentery when a long and dreary winter ensues.'—Rational Bee-keeping, p. 302. It may not, therefore, be inopportune at the present time if we endeavour to discuss the history, nature, and character of honey-dew, this being a question of the deepest importance to beekeepers, as the presence of this so-called 'honeydew' too often spoils the legitimate honey which has been gathered, frequently blights the prospect of their harvest, and disturbs their tempers.

To us moderns honey-dew is generally interpreted as 'a sweet saccharine substance found on the leaves of trees and other shrubs in small drops like dew. Two substances have been called by this nameone secreted from the plants, and the other deposited by a small insect called the aphis, or vine-fretter.' But to the ancients the substance to which they gave the name of 'honey-dew' had a very different and a much more highly exalted meaning. Honey-dew is an old-world term; it is a combination of two words indicative of sweetness and freshness. It was conjectured to be the purest nectar, which was distilled from the air in some miraculous manner. A spirit of poetry is called forth by the lofty virtues attributed to it. It sends ns back to the time when the world was young—to the golden age—to the times of the Naïads and the Dryads, the Fauns and the Satyrs, when

'Jove once more, as erst the Poets told, Drips down each verd'rous robe a shower of gold,'—when the hardy oaks, as Virgil has it, 'perspired the dewy honey' (et quercus sudabunt roscida mella),

or, as Ovid sings, 'The yellow honey dropt from the green oak' (Flavaque de viridi stillabant ilice mella.) The poets at all times speak in rapturous

terms of the excellency of honey-dew, they sing of the aërii mellis cælestia dona ('the heavenly gifts of ethereal honey'); and the matter-of-fact philosopher Pliny appears to be in great doubt as to his designation of honey-dew, 'whether it is the perspiration of heaven, a certain saliva of the stars, or the moisture of the air purging itself.'—Nat. Hist. 1, xi. c. 12.

Passing, by a leap, from the poetic and classic period, and following the history of honey-dew to after-times, we find the idea of the ancients that honey-dew is a deposition from the surrounding atmosphere continued to rule in the minds of bee-keepers for many centuries. We cannot, in our survey, find it in our hearts to pass by 'the father of English apiarians' (Dr. Butler), and we therefore consult him to ascertain the interpretation of honey-dew in his day and generation. We find in his Feminine Monarchie an estimation of it quite as enthusiastic as that of the poets sixteen hundred years before his time. He says:—

'It is purest nectar coming from above, which Almighty God doth miraculously distil out of the air. If conjecture might be admitted, I would judge it to be the very quintessence of all the sweetness of the earth drawn up as other dews in vapour into the lowest region of the air by the exceeding and continued heat of the sun, and then concrete and condensated by the nightly cold into this most sweet and sovereign nectar, which thence doth descend unto the earth in a dew, or small drizzling rain. . . The hotter and drver the summer is the greater and more frequent are the honey-dews; cold and wet weather is unkind for them; much rain at any time, as coming from a higher region, washeth away that which is already elevated, and in the end it dissolveth them quite. . They may happen at any time of the day, but for the most part in the morning, before it be light.

One of the acutest observers of nature, Gilbert White of Selborne, writing about 180 years later, makes no advance in the elucidation of the nature of honey-dew. Writing on June 4, 1783, he says, 'Vast honey-dews this week. The reason of them seems to be that in hot days the effluvia of flowers are drawn up by a brisk evaporation, and then in the night fall down with the dews, with which they are entangled.' We are the more surprised at this theory of honey-dew, as he complains in another portion of his work that the honey-dews were so frequent as to deface and destroy the beauties of his garden. His honeysuckles, which were one week the sweetest and the loveliest objects that the

eye could behold, became the next the most loathsome, being enveloped in a viscous substance and 'loaded with black aphides or smother-flies.'

Dr. Evans, the poet, and author of the *Bees*, as we would naturally suppose, clings to the poetic aspect of honey-dew; but, unfortunately for his ideas, his lot was east in an inquiring age, the world had grown older, and the eyes of science had peered into the areana of Nature and exhibited facts in all their prosaic truthfulness. After saying that honey-dew should be compared to the temporary and wholesome sweats excited by severe exercise or excessive heat, he, with a mental wrench, with which we feel inclined to sympathise, says:—

'In a much greater number of instances the honey-dew appears to arise from a distinct cause—the attack of the aphides, or vine-fretters, which, instead of jaws like the locust, are provided with a hollow pointed proboscis, folded under the breast when the animal is not feeding. With this instrument they puncture the now turgid vessels of the leaf, leaf-stalk, or bark; greedily suck their contents, and expel them nearly unchanged, so that, however fabulous it may appear, they may literally be said to void a liquid sugar. The superior size of the Aphis salicis enables us to perceive, on looking stedfastly at a group of these insects feeding on the bark of the willow, some of whom elevate their bodies, and emit a transparent substance in the form of a small shower. They may also be seen distinctly, with a strong magnifier, on the leaves of the hazel, lime, &c., but invariably on their inferior surface, piercing the vessels, and expelling the honey-dew from their hinder parts with considerable force; and which might be received on paper or any other intermediate substance, the leaves below being in that case unstained. . . . Future inquiries must decide this question.

Inquirers were close at hand. Mr. Curtis, in the sixth volume of the *Transactions of the Linnean Society*, informs us that the honey-dew is an excrementitious matter voided by the aphis, or vinefretter, an insect which he regards as the cause of what are called 'blights.' He states that he never in a single instance observed honey-dew without its being accompanied with aphides.

Dr. Kirby, in his *Introduction to Entomology*, discourages the theory of honey-dew being a morbid exudation of the saccharine juices of plants.

'It may be,' he says, 'possible, but I may observe that in the course of more than thirty years, which I have attended to this subject, I have never met with any honey-dew which did not seem to be clearly referable to aphides as its origin; though, from the circumstance of their having been all swept away by the attacks of their natural enemies and other causes, while their saccharine excretion remains on the leaves for weeks on a dry time, and after having been moistened by a slight dew may have every appearance of being a recent morbid exudation, and may, even after very copious dews, fall on the ground.'

Most persons nowadays are ready to adopt the conclusion of Dr. Kirby. It is very rare that plants secrete any amount of saccharine liquid; but it is generally conceded that honey-dew is a deposit from aphides, and therefore we are prepared to agree with Dr. Dzierzon when he says that 'honey-dew' is an unsuitable name, and that it should be called 'aphis-honey.'

We propose to return to this subject in a subsequent number.

En Memoriam.

MR. DUNCAN STEWART.

It gives us much pain to find it incumbent upon us to chronicle the decease of one of the most active members of the British Bee-keepers' Association and of the British Honey Company,—Mr. Duncan Stewart, which sad event occurred on the 12th September, at Harthill Hall, Bakewell, Derbyshire, whither he had gone to spend his holidays. Mr. Stewart was in his sixty-third year.

Mr. Stewart was for many years a Taxing Master of the High Court of Justice in Bankruptcy, and Receiver in Insolvency cases.

Mr. Stewart became a member of the B.B.K.A. in the year 1875; and on the late Rev. H. R. Peel taking office as Hon. Secretary, in the year 1878, he was elected as a member of the newly-formed Committee. In the year 1879 the Committee was reduced to nine members, and the system of election by voting papers as now followed came into force. Mr. Stewart was a candidate on this occasion, but failed to obtain a seat either in this or the following year. He was elected again on the Committee in 1881 by a substantial number of votes, and continued to hold his seat until the close of last year, when he retired from the Committee owing to an increased pressure of work in his profession. On the occasion of his retirement he looked forward to taking an active part in the Association's work at some future time.

Until the end of 1883 Mr. Stewart resided at Knockholt in Kent, whither he removed to Harcourt Terrace, Kensington. He has been one of the most hard-working members of the Committee. Residing in London, he always expressed himself as being bound to take a large share of the 'burden and heat of the day' by serving on sub-committees. He was extremely liberal towards all objects promoted by the Association, and never failed to add his name to its various subscription lists. His legal knowledge was of considerable benefit to the Association; and it, and bee-keepers generally, have lost one of their best friends.

Mr. Stewart took a warm interest in the great national Apiarian Exhibition in 1886 which was held in South Kensington in connexion with the Indian and Colonial Exhibition, and devoted much time to the preliminary inquiries and the subsequent arrangements. His heart was in this matter, and in a great measure bee-keepers are indebted to him for having worked out the details of an enterprise which proved so creditable to the British bee-keeping industry. At the Conference of bee-keepers that was held on August 4th an interesting paper by him was read on 'The Honey Market.'

On the occasion of the exhibition of Canadian honey he took much interest in the welcome that was accorded to the Canadian delegates.

At the formation of the British Honey Company he very heartily co-operated with the late Rev. H. R. Peel and others in their endeavours to place prominently before the British public the virtues of British honey. For some time past he has acted as Chairman of that Company, and to the last he has laboured assiduously to promote its interests.

The loss of so active, liberal, and intelligent a member

The loss of so active, liberal, and intelligent a member of our community is, indeed, greatly to be lamented; and we trust that his bright example may incite many to

follow in his footsteps.

ASSOCIATIONS.

HEREFORD HONEY FAIR.

REPORT BY THE JUDGES OF THE HEREFORD HONEY FAIR, SEPTEMBER 7TH, 1887.

The quality of the honey in all the exhibits was almost all that could be desired with very few exceptions, contrasting in a marked manner with the honey of the two previous seasons, when, and especially in 1885, very little honey was not more or less dark from honey-dew. The dark samples this year were of a rich and not a smoky tint, and almost certainly owed their colour to the class of flowers from which they were

gathered.

In Class I, there were six competitions—a seventh entry, which seemed equal or superior to any of the others, was withdrawn from the notice of the judges, being disqualified by having the name of the exhibitor on each item. The first prize went to an exhibit which consisted entirely of 1-lb. parcels; the honey appeared to be of excellent quality, was very neatly put up, and there were six varieties of parcels. The second prize went to an exhibit which was not quite so neatly presented, and was seen, perhaps, to disadvantage, heing rather crowded: it contained six varieties of parcels, including a fine series of 2-lb. sections. The third prize was taken by an exhibit very neatly placed on the stand and the parcels neatly got up; there were only two forms of parcels, and some of the extracted honey was rather dark. The other exhibits were not without merits.

In Class II., for extracted honey (clear), were twenty-four entries, and almost all were of superior quality. The exhibit taking the first prize was of extreme brilliancy and clearness, being distinctly before any of the others in this respect; it was also rich in colour, of good, thick consistence, and excellent flavour. The judges found less than the usual difficulty in placing this first. The second was only hehind the first in clearness, and was of a much lighter tint—a high-class clover honey. The third was more like the first in general character, and was selected from two others with difficulty. The bronze medal of the B.B.K.A. was accorded to this class as being altogether very excellent. The first prize taken in Class I., to whom it ought to have gone, being disqualified to receive it. [The first prize honey in this class was extracted from standard frames in top storey and strained through flannel; the second prize lot extracted from shallow frames in top storey and not strained; several lots passed over were extracted from sections. A. W.]

In Class III. were fifteen entries (extracted honey partially or wholly candied). Much difficulty was felt in weighing the comparative merit of samples carefully candied, and others only slightly so. The first prize went to a partially-candied sample. The second to a very white and completely candied sample; and the third to a partially candied honey. The judges were, if anywhere, not so confident as to their judgment being sound in this

class as in the others.

In Class IV. were seventeen exhibits, the majority of very excellent quality. The first prize went to twelve 1-lb. sections, of great transparency, well finished, and sufficiently thickly capped to have a nice white appearance without being propolised or otherwise injured in appearance by being left too long on the hive—the prize-taker is a cottager. The second went to six very perfect 2-lb. sections, in which the only defect was a faint smear or two of propolis. The third was accorded to an excellent sample of 1-lb. sections.

In Class V. were six entries. One was a very handsome piece of comh, but was really a frame out of a frame-hive, and not strictly a super. Another was a hell-glass well filled with excellent comb-honey. There

were also two boxes and one miniature skep, these were all well filled and with excellent comb; each, however, had some discoloured comb in the centre, either from the bees travelling over it, or, possibly, from its having at one time contained a little brood. These seemed the most satisfactory supers, and as their merits were otherwise very even, the first and second prize went to the two heaviest.

In Class VI., for cottagers, were four entries, though one was a very nominal one, the other three were excellent. The first prize was taken by one that exceeded the second as the second did the third, in extent, in variety of parcels, and, to some extent, in neatness of packing and display; in each the honey seemed of excellent quality, as in the other classes.

The judges acted as hee-keepers of experience, and not as chemical experts. The time allowed for the work in hand showed that no more than this was expected; but nothing came to their notice to suggest that any more critical examination than they accorded it was required

by any sample of honey exhibited.

SCOTCH EXHIBIT OF HONEY.

A fine exhibit of honey was staged on Wednesday, 7th September, in St. Andrew's Hall, Glasgow, in connexion with the Glasgow and West of Scotland Horticultural Society's Autumn Show, the exhibitors being Messrs. William and John D. McNally of Glenluce and Springburn, whose names are well known in the beekeeping world of the present day. These gentlemen exhibited a stand containing seven cwt. of honey taken from the bees in various forms. The sections looked just perfect, were well filled and of good colour, and were certainly shown to best advantage in Woodley's new section cases. In the centre of the stand were the words built in honeycomb by the hees 'God Save our Queen,' which was greatly admired by the public, and many were the conjectures as to how it was done. At either end of the stand were two observatory hives shown in full working order, stocked with various races of bees. We would compliment the Messrs. McNally on their method of placing their honey before the public, and are pleased to hear that they find ready purchasers for it at a remunerative price.

Honey-dew.—A writer in a Suffolk newspaper says that some singular results of the hot weather through which we have passed were to be seen even on the dust-laden hedgerows in the shape of suspended drops of transparent honey-dew. The leaves of the lime and other trees are sticky and glossy with the abundance of the same product. It is a grand time for the bees and ants, and other honey-loving insects by day, and for the moths by night. To an entomologist a lime-tree is naturally 'sugared' for him. He has only to wait with his lantern (or use that of the moon), and his captures may be made by scores. It is years since such a manufacture of natural honey was made; perhaps not since the long hot summer of 1868. The appearance of this product always goes with hot summer weather.

A Honse Attacked by Wasps.—On the evening of the 14th inst., Dr. Proudfoot, Kirkcaldy, had been visiting a patient in the neighbourhood of Dunnikier, and, along with his coachman, was driving home, when the horse, travelling in the middle of the road, trod on a wasps' nest, and was immediately attacked by the insects. Becoming greatly irritated, the animal kicked furiously, and both the doctor and his coachman were thrown from the carriage, the former being severely cut about the head and face. The vehicle was broken to pieces.

A GRIZZLY BEAR AND THE BEES: SCENE IN A CALIFORNIAN APIARY.—The Hutchinson brothers have a large apiary up at Victor Tejunga, says the Los Angeles (Calif.) Express. It is an isolated place, far

from real estate booms and the hauuts of men. But it is a good place for bees, and there, as a rule, they toil unmolested except by their owners, the Hutchinson boys. The country is romantic. The quiet life of the little rural retreat was turned into the greatest excitement last Thursday night. While the Hutchinsons were asleep, and dreaming of the great sums of money they would make this season, a stranger entered the camp. He was not slow in making his presence felt and heard. The sleepers were suddenly awakened by sounds that suggested a small cyclone raging among the bees. One of the men got up, looked out of the window, and what was his consternation and terror to see the faint outlines of a huge, brown-coloured mouster npsetting the bee-hives, and working destruction with property that required the toil and economy of a number of years to accumulate. The surprised spectator hastened to his brother's bedside, and told what was going on in the apiary. The two rushed out, one taking his rifle. The bear was evidently hungry, for he made savage lunges at the boxes filled with delicious honey. He would take a few mouthfuls out of one frame, and then go for another. The Hutchinson boys concluded that if they did not act on the instant the bear would soon leave them without an occupation. The gun was levelled and diseharged. The ball found its way through the thick hide of bruin back of the left shoulder. It was evidently almost a 'centre shot,' for the animal fell. But he remained on the ground but a second. He arose, enraged with pain, and made frantic plunges at the nearest hives. Meanwhile the men advanced a little. The bear caught sight of them and made a rush at them. When within twenty feet of where they stood, his progress was arrested by another leaden messenger. It struck a vital part, and once more the huge bear fell. This time he did not get up. A third ball was put into his side, Upon examination it was which caused his death. found to be a grizzly cub about two thirds grown. Next day he was dressed and weighed. The scales tipped at 700 lbs. This is the second or third bear ever killed or seen in that section.

Correspondence.

The Editor does not hold himself responsible for the opinions expressed by his correspondents. No attention will be taken of anonymous communications, and correspondents are requested to write on one side of the paper only, and give their real names and addresses, not necessarily for publication, but as a guarantee of good faith. Illustrations should be drawn on separate pieces of paper.

Communications relating to the literary department, reports of Associations, Shows, Meetings, Echoes, Queries, Books for Review, &c., must be addressed only to "The Editor of the "British Bee Journal," of Messrs, Strangeways and Sons, Tower Street, Cambridge Circus, W.C.' All business communications, relating to Advertisements, &c., must be addressed to Mr. J. Huckle, Kings Langley, Herts (see 2nd page of Advertisements).

** In order to facilitate reference, Correspondents, when speaking of any letter or query previously inserted, will oblige by mentioning the number of the letter, as well as the page on which it appears.

FOUL BROOD AND PROFITABLE BEE-KEEPING.

[1266.] I have read with great interest all that has been said in your Journal upon the subject of foul broad, and your leading article in a previous number induces me to give my experience of this fearful sconrge to beekeepers, and tell how, two and a half years ago, I exterminated it in this neighbourhood by doing just what you now advise.

In the early days of March, I885, I found that one of my seven bar-frame hives was suffering from what I believed to be foul brood, and on a piece of the infected comb being submitted to Mr. Cheshire for examination he confirmed my fears. I at once got half-a-dozen bottles of phenol from Messrs. Neighbour & Son, prepared specially for the Cheshire cure, and after having taken away

as far as possible all the bees' stores of honey, commenced to feed my seven stocks with syrup prepared exactly according to Mr. Cheshire's printed instructions. The bees would not take the phenolated syrup from a feeder, so I had to pour it into empty combs and place them at the back of the hive; and so I persevered for nine weeks, day after day physicking my seven hives; but I was disappointed to find that not only did I not cure the hive first infected, but the disease spread to the six othersne doubt by my carrying the germs upon my hands in manipulation.

The phenol at once checked the disease, and the hives became very strong, but a few infected cells constantly appeared in every brood-comb, and when honey began to come in they got worse and worse. I then decided to destroy the bees, frames, quilts, &c., and disinfect the hives, feeders, and smoker. In order to thoroughly accomplish the latter, I had a tin box made large enough to contain a complete hive, and filled it with a strong solution of carbolic acid and water, and then soaked each hive in this solution for two hours. After this the feeders, smoker, &c., were treated in the same way, and then the tin box was filled with clean water, a fire lighted under it, and each of the hives immersed and boiled for ten minutes,

The next thing was to prevent the new swarms, which I intended getting, being infected by other bees in the neighbourhood, which I knew were diseased. Although a busy man with little time to spare, I decided to take a couple of days' holiday, and visit all the bee-keepers in the neighbourhood, and see what could be done to stamp out the enemy. During those two days I believe I examined every hive for miles around, and at three places found foul brood; and, after explaining the disease and its effect to the owners, induced them to let me destroy the infected stocks and burn the hives, two of which were straw skeps. Since then I have not been able to find a case of foul brood in our neighbourhood except a doubtful one, and the old woman who owned this skep allowed it to be at once destroyed.

I believe such action as I took to be the only way to stamp out foul brood. My experience and that of others is that phenol checks the disease but does not cure it, and that healthy stocks soon become infected if there is any communication in any way between them and an infected stock. I should have mentioned that I put the stock first infected into a clean hive before giving it phenolated syrup, and shortly afterwards I did the same for the other six. I used a great many bottles of phenol -the exact number I do not recollect, but I think about a dozen and a half-so in every way I gave the cure a fair chance.

I notice also, in your issue of September 8th, a complaint from 'Sherborne, Dorset,' of the unprofitableness of bee-keeping. I don't wonder at his complaint, if he seriously thinks that the results he has mentioned are anything like as good as those obtained by moderately successful bee-keepers. I do not know of a district outside large towns where intelligent bee-keeping upon modern principles could yield such a poor harvest. depend here upon white clover and other wild flowers, having no heather, and I can with confidence count upon 100 lbs. of run-honey per hive, after leaving enough for winter stores. Last year I averaged 127 lbs, per hive, and I have not used any sugar for spring or autumn feeding for three years, except for stocks made up of driven bees. Of course I prevent swarming, and take eare to have young queens at the head of each colouy, and I give each hive from thirty-eight to forty frames of standard size.

To be really successful with bees, as with all other pursuits, one must devote time, thought, and study—an hour before breakfast every fine morning during May, June, and July, with your busy little labourers will be conducive to your health, and if you are moderately

skilled do all that is necessary or at all desirable for a dozen stocks; and if you don't get 9 cwt. of honey there will be something wrong iu your management. If you have leisure during the day so much the better, but many, like myself, are engaged in business almost all and every day.—J. H. Rogers, Glyncoed, Llanelly.

FOUL BROOD.

[1267.] In my last communication on the above subject I promised to give the results of the treatment of a stock with phenol belonging to a friend. I am sorry to have to report that it was a failure, although I cannot myself consider it absolutely so, as, in cousequence of the very cold and wet weather we had just at that time, it was impossible to open the hive regularly, as, the bees refusing to take it freely from the feeder, it was essential to do. It will, perhaps, be remembered that in my last letter I expressed the opinion that it was to the use of phenol in the spray-diffuser to which I owed freedom from disease in my apiary; but unfortunately for me, shortly after writing that letter, I had to alter that opinion, for on June 3rd I found the disease in two stocks, and immediately commenced to treat with phenol. Both hives rapidly improved, and one of them gave me a crate of sections, and is now one of my best colonies. The other hive, which was rather a weaker one, while they were being treated made several attempts at queen-raising, but the cells were cut down as soon as discovered, for being only a small colony I did not want them to swarm; but such was evidently not their intention, for having left one queen-cell to see what they would do, the young queen was hatched and the old one destroyed, although, on turning to my register, I find she was only hatched on July 12th, 1885, and was to all appearances quite healthy. I should say that the young queen was not hatched until all signs of the disease had disappeared, so that I could not suspect the old one of being diseased. The stock being the only small one I had was used for exhibition purposes at our local flower show, at which I had the valuable assistance of 'Amateur Expert,' who could answer for the entire absence of any signs of disease.

I now come to what is to me a peculiar case, for examining on May 28th a stock which had been transferred, I found what appeared to be chilled brood, but. being undecided which it was, I cut out a small piece of comb and forwarded it to Mr. Cheshire, but unfortunately I got no report from him. I waited just over a week before I reopened the hive, and when I did so there was no mistaking what was the matter with them, for several of the frames were one mass of putrid matter which could be smelt some distance off, and the bees seemed to have lost all life and energy. The stock was a good strong one, but having the other two colonies on hand I hesitated whether to destroy or try to cure them, but decided to do the latter; so I put on a slow feeder, and fed for three weeks with phenolated syrup, keeping during that time the entrance and ground in front of the hive frequently sprayed with carbolic acid, after which the feeder was removed, and the hive left untouched until August 20th, when it was again opened, and after a careful examination only two cells containing any signs of disease could be found, whilst in the frames in which breeding was going on the brood was without exception quite healthy, and to the best of my belief with the same queen as before.

The result of my observations certainly does not to me point in the same direction as Mr. Ward's, given in a recent issue, although there must be a certain amount of suspicion attaching to the second case mentioned. Mr. Ward seems to overlook the fact that Mr. Cheshire distinctly says the queen must be removed if there is reasonable ground for believing her to be infected and a healthy one substituted ere a cure can be effected. I

quite agree with Mr. Ward as to the difficulty we have to say whether a queen is diseased or not, and it would no doubt be to our advantage in the majority of cases to at once give a young healthy queen, that is, if we do not, Mr. Editor, carry out your good advice and immediately stamp out the disease by destroying the stock as soon as it appears. I am happy to be able to report that at present I do not know of a case of the disease in this neighbourhood; but should it break out again in the spring, in spite of all precautions, I shall make short work of it, for unless one has plenty of time to spare I do not consider the risk and the labour involved worth the object aimed at.—J. T. HARVEYSON, Finchley, September 15th.

NOT FINDING QUEEN.

[1268.] Mr. Edditar, I beant much of a skolard, but I do read your Journal every week as I do keep hees, and I do get a good bit of honey, and I had 3 cwt. this year, all from bar-frame hives, but I do agree with your letter (1241) in this week's Journal about finding the queen. I do now a mans who do keep a lot of bees, an do drive bees in autumn for hisself, an do rear his own queens, and o mind bees for other peoples, an he do try for sertificate for expert, but because he could not find the queen in time he could not get sertificate. The mans who zamined him did ask him not one question about bees, but told him he must come again because he cudn't find queen. Why didn't the zaminer ask him what he knew about bee-keeping an then he could see what he knew? Is finding the queen everything in bee-keeping? If so, let our zaminers for third-class expert, as soon as the queen is found, give the candidate a sertificate as expert whether he knows anything about bee-keeping or not.—Tam Shon Catti.

NOT FINDING THE QUEEN.

[1269.] I was very pleased to see an article in the B. B. J. of the 8th inst. on the above subject. I have always been greatly surprised that the B. B. K. Association should make the finding of the queen a test to the examination of an expert, whereas the examiners must know that it is generally a matter of chauce. At the Royal Agricultural Show at York I noticed that Mr. S. Baldwin, expert-in-chief, failed to find the queen until he had driven all the bees out of the hive; he afterwards discovered her among the driven bees. I then asked him if he considered the finding of the queen a fair test at the examination for an expert's certificate. I forget what his answer was, but I believe he turned it off, as the question was not one of practical utility. Why not allow the examiner, who must be a practical man, to base his decision on the way the candidate performs the operation? Under the present system it is possible for any muff to find the queen immediately, while the expert-in-chief might fail.—ICARDUS, Kirk Merrington.

BUMPING.—HONEY BY THE HUNDRED-WEIGHT.

[1270.] Last year I reported my single attempt at bumping a failure. Subsequently discovering the cause I promised myself another trial during this season. About a fortnight ago I went to secure a couple of lots of condemned bees, and proceeded to drive the first in the ordinary way. It was a late swarm and had not half filled the skep with comb. The result was that instead of leaving the skep the bees merely ascended just above the partially built out combs, and then promenaded very decorously round and round the skep. Not without a little trepidation I resolved on bumping. Complete success! Owner of skep immensely pleased. Myself ditto. I have since bumped thirteen other lots, and

with such satisfaction as to determine to confine myself to this method in future.

One very great advantage that I find in bumping is that I can do without my smoker. That provoking article is now for sale. Except for driving purposes, I had ceased to use it in my manipulations. Its place in my apiary is taken by the carbolised cloth. This is how I use the latter in bumping: I stand behind the skep and lay the cloth in folds on the floor-board across the entrance. I now take hold of the uppermost edge of the cloth and bring it half way around the edge of the skep. Still keeping hold of it I turn up the skep, and thus get the cloth to fall over it. I then blow through the cloth and allow it to remain on two or three minutes, after which the bees are pretty sure to be in manageable condition. Of course the cloth comes into contact with the combs, consequently I take special care to wring the cloth dry. I bump before removing the cloth.

I confess that there is a drawback in this method to those who, like myself, intend, at some date in the distant future, to venture on an examination for third-class expert. Owing to want of practice, I fear that in that eminently satisfactory test of expertness, bee-driving, I shall be found 'not in it.'

I wish, sir, that, for the well-being of the unsuccessful ones, you would suppress all reports which record a yield of 100 pounds and upwards per hive. The amount of evil they do is incalculable. The effect of them on those who are only able to secure twenty, thirty, or forty pounds per hive, is not at all inspiriting. The 100-pounders are not, I suppose, one per cent of the subscribers to the British Bee Journal, and yet these one per cent are allowed, through the columns of the Journal, to stir up any amount of bad blood in the breasts of the ninety-nine per cent. Every Thursday these reports make about 10,000 otherwise well-disposed persons jealous, morose, savage, and highly dangerous—dangerous to themselves and to the country. Could you not act on my suggestion?

My three best hives have yielded me about forty pounds per hive—all they contained. I console myself by believing that the return would have been greater had I been able to pay more attention to them and had Glamorganshire been favoured with a little rain during the summer. I hope to goodness that I shall not see a hundredweight report from Glamorganshire this season.—Welsh Novice.

[Please refer to advice given by J. H. Rogers on a preceding page, and it may be that at a future time you may arrive at the coveted weight.—Ep.]

A FAMOUS IRISH BEE-KEEPER.

[1271.] Perhaps one of the most advanced Irish beekeepers we have is our friend Mr. William Ditty, of Newtownards.

Visiting the North-east of Ireland's annual show of bees, &c., held on 19th August, in the Y.M.C.A. Hall, Wellington Street, Belfast, I made the acquaintance of Mr. Ditty, who was acting in the capacity of a judge; and having a day or two to spend in Ireland, I resolved to visit Mr. Ditty's apiary, along with another noted Scotch bee-keeper, Mr. William McNally, of Glenluce, Scotland, who was exhibiting some goods at the Belfast Show. Leaving by rail I reached Newtownards on the 20th, a beautiful day with bright sunshine overhead. Making some inquiries, I learned from a friend that Mr. Ditty was head-cashier in Lord Londonderry's Estate Office, where I found him. After a friendly greeting, he asked leave off for a time, and we proceeded to his house and apiary a mile from the town, and gleaned in a brief way his success in bee-keeping. Mr. Ditty is a young man, about twenty-seven years of age, and resides with his grandfather, his parents both dying left him an orphan at a very early age. He entered the office of Lord Londonderry as boy clerk, and after eleven

years' faithful service now holds his present high position. He is a most enthusiastic bee-keeper, and has between twenty and thirty stock hives, and a dezen or so of nncleus bives. His bees are mostly of foreign strain, and his hebby is working for extracted honey. The apiary is neat and well arranged, and the hives, which are of the frame type, are all his own manufacture, and I may add reflect great credit on Mr. Ditty. The locality abounds with sufficient natural flowers for the bees, and yields large quantities of honey, Mr. Ditty's hives this season giving him an average from sixty to eighty pounds per hive. He is not a timid bee-keeper, and manages his bees entirely without smoke. After a rather quick run over the apiary we retired to the workshop where all the appliances, &c., are to be seen in great variety. After partaking of a substantial dinner we made for the station and received a sample of honey-wine made by Mr. Ditty in 1885, which was really excellent. Altogether my first visit amongst the Irish bee-keepers will not soon be forgotten. I wish him continued success, and hope to have the privilege of visiting his apiary again, meantime -Au

NORTH-EAST OF IRELAND BEE-KEEPERS' ASSOCIATION.

[1272.] Being an exhibitor at the above show this season I must urge my protest against a practice that should not occur in any well-managed association. The grievance I refer to is this: all the exhibitors' names are known to the indges while they are awarding the prizes, and this should not be the case. On the prize list and schedule every competitor's name is printed with the number of his exhibit, &c., which is supplied to the judges and the public previous to judging, price 2d. per copy. This arrangement is very good were they withheld from both judges and the public until the prizes were awarded. I hope the hon, secretary will see to putting this matter right by another year.—John D. McNally.

REMOVING MIDDLE SECTIONS.—(1214.)

[1273.] I should be sorry to think that Dr. C. C. Miller believes the bump of combativeness to be so largely developed in the Journal's correspondents that it was necessary to commence his letter by stating that he did not want to pick a quarrel with any of them,—no, not a bit of it. I am sure he did not think that, and I am equally sure he will believe me when I state that I have no feelings of jealousy whatever in bee matters, being at all times anxious and willing to impart any of my experiences to any one and every one who cares to know them.

When I stated in the Journal that I did not think our American cousins could give us much start in bee-culture I in no way wished to infer that there was anything but friendly rivalry between us, but merely to point out that, judging from the extracts given by 'Amateur Expert,' the systems adopted in America were, in my opinion, no advance upon those practised in this country and from time to time put forth in the Journal; and I still think so.

In bee-culture, as in most other pursuits, there must ever be differences of opinion as to the best road to success by reason of the very nature of the circumstances under which bees are kept and the ever-varying conditions of soil, climate, and flora, immediately surrounding the apiary. Dr. Miller knows as well as I do that the fact he mentions of one bee-keeper taking 30,000 lbs. of honey in a season by adopting one method, in no way proves that more and in better condition would not have been taken by some other method.

All I wished to say was that I considered the taking away of the middle sections before the others were completed was not a step in advance, but the reverse. I think I gave my reasons, viz, that it was a great waste

of time; it broke up the cluster of bees when combbuilding; the sections were not so fully completed and sealed, and the sealings were thinner and the sections more liable to 'weep,' and, altogether, it gave a great deal of unnecessary labour, both to the operator and the hees. I am now glad to see that Dr. Miller does not follow the plan but adopts a more advanced system. I read with great regret that Dr. M. had had such a universally poor honey season, but hope there has been yet time to make up a little.—F. Boyes.

DARK HONEY.

[1274.] I have no reason to complain of the quantity of honey my bees have gathered this year, but should have been more pleased if it had not been so dark; some of it more like old-fashioned treacle, nearly black, such as I knew in my school days; the flavour is very good, but the colour is not appreciated. Now, if it is possible by any means to improve the colour I shall be very glad to do so, and shall feel greatly obliged if you can tell me the best way to go to work to accomplish it. It is the general complaint in this neighbourhood; mine, I think, is not a singular case. I have a large super on each of my hives weighing about twenty-four lbs. of good colour and another on the top of that, same weight, and the honey is dark indeed; the top one was nearly filled when I put the other on below it. The dark is so thick that I am obliged to set the pan in hot water to strain it. By advising how to remedy the same I shall feel greatly obliged.-G. R., Diss.

[By boiling the glasses or jars containing the honey in water, the colour will be slightly modified.—Ep.]

JUDGING.

[1275.] The complaints made from time to time in the B.B.J. of mistakes,—unpardonable mistakes, in judging honey, point to a real grievance demanding prompt removal. The other day a couple of gardeners were instructed to 'look' over the honey and award prizes after they had finished the vegetables, &c. And they actually had the assurance to do so. Now, without for one moment insinuating that they were actuated by any other motive than that of heing obliging, yet I cannot but think they, and others 'of such ilk,' might derive great benefit from meditating on two old cautionary proverbs, viz., 'Let no cobbler go beyond his last,' and 'Fools rush in where angels fear to tread.' But, seriously, what would they feel and say if two bee experts were appointed to decide the merits of their choice productions? The vials of wrath poured out, and justly, too, upon the devoted heads of the poor bee-masters would be worse than all the formic acid of all the most vicious bees. In the particular instance that prompted these remarks, the judges were certainly befooled by the case, for they not only did not taste the honey, they never even removed the case; and a splendidly-worked lot of sections in a sober case had to submit to the indignity of being ticketed 'second.' Let the County Bee-keepers' Associations look to this matter, and without being impertment, suggest fair conditions of competition, and offer to supply properly qualified judges at a regular scale of remuneration.—FAIRPLAY.

A BARROWFUL OF SLABS OF HONEY.

[1276.] I have been waiting for some time to see a bit of advice in the Journal to the humble bee-keeper—the poor labourer who cannot dip his hand into his pocket and send off for expensive hives, apifuge, scrapers, and the thousand and one articles which you are told, if you buy them, make bee-keeping a success, but which in reality make it an expensive hobby. I have, about two months ago, with the aid of a friend, taken two lots of

bees with their honey. In one of them we took out a barrowful of solid slabs of honeycomb, two feet deep, out of an old flue in a peach wall. It was an eye-opener for me, I assure you,—here was simplicity itself, and with such results and such delicious honey. Acting on the hint thus given me by Nature herself, I intend to build a brick hive for a few pence to super at the side, and one to super at the top. My supers are made—for I have used them this year—at a cost of sixpence. I take a two-dozen canned fruit or salmon box, costing twopence at the grocer's, put in two false ends, and the thing is done; cover the frames up with the usual packing, and on the top a roofing slate; these I have used successfully as ekes and supers for flat-topped skeps. Going back to our exploit with the stocks in the wall, our weapons of warfare were a smoker charged with hrown paper, a pint of carbolic acid costing ninepence: of this we used about a wine-glassful in half a gallon of water, and a whitewash brush to sprinkle it on the wall. I might add that the bees were successfully transferred, together with the brood-combs, into hives, and are doing well.—A LANCASHIRE BEE-KEEPER.

EXTRACTING FROM BROOD-COMBS. (1204.)

[1277.] It is quite clear that some of your correspondents have misunderstood my remarks on this subject. I will, therefore, with your permission, Mr. Editor, endeayour to put myself right with them.

Now, when I wrote 'Extracting from Brood-Combs I imagined—foolishly, no doubt—that 'brood-combs would be understood to mean combs containing brood. Such a thought never entered my mind as that it would be taken to mean all combs which had at some time or other been bred in. But so it has been, and I must here disclaim any intention of implying that honey extracted from such combs was not pure in the ordinary sense; indeed, I thought it generally admitted that such combs were tougher and better than new ones for extracting nurposes.

Reverting to the letter of 'G. T.' respecting the liquid extracted from combs containing unsealed larvæ, I can only repeat that I have often found in close proximity to msealed brood a thin, watery liquid, which, on giving a little shake of the comb to dislodge an odd bee or two, has flown out like so much water. This I have looked upon (probably erroneously) as a thin preparation of honey and water placed there by the bees for feeding purposes. Whether I am right or wrong in this supposition, it is clear that if this preparation be extracted and mixed with honey such a mixture cannot be pure honey, and, as I stated at first, the watery element was likely to ferment and spoil good ripe honey.

I had not the remotest idea that in mentioning the source from whence the 'water' was drawn anyone would suppose that I was trying to run down extracted honey. My object was solely to give a limit to the inexperienced lest they should spoil the quality of their honey by mixing with it a highly fermentable substance and to discourage the too close extracting of honey from hives, and especially from combs containing broad, because I had seen nothing but bad results attending such practices. I have found that when hives were in a prosperous condition with abundance of brood there was always plenty of unsealed and unripe, or thin honey; and if this be wanting much of the brood never reaches maturity, but either dies or is destroyed, the juices extracted and the skins ejected or carried away by the bees. It is probable that this unsealed, watery honey is not only necessary food for the larva, but also helps materially towards keeping up that moist atmosphere in which the brood seems so much to prosper. I therefore think that the too close extracting from broad-combs is anything but judicious; if we extract too much honey from a hive we must either give it back again or destroy

its prosperity, but I do not for one moment wish to force my opinion on others; if they think otherwise, by all means let them follow their own opinions. Kindly remember that when I state brood-combs I do not mean combs which have been bred in the year before and placed in a doubling box on the top of the hive proper, but combs in the broad-nest which are being used for breeding purposes and if these get filled with honey so that there is no room for the queen to lay, as 'G. T.' argnes, then I say there is mismanagement somewhere. The instinct of the bees is to store honey above the broodnest, and so long as the sections or doubling combs are properly attended to there is no fear of the queen being crowded out below, especially if she be a vigorous one

laying I000 eggs a-day.

And now, G. T., I have done with this subject, but one word ere we part. I never heard of any one extracting from skeps, what I said was that his remarks about the queen being crowded out and having no cells in which to lay her eggs applied only to skeps and not to expansible bar-frame hives.—F. BOYES.

P.S. I do not consider that 'G. T.'s' hives are by any means strong ones if he can winter them on eight frames.

MEMS BY 'WOODLEIGH.'

[1278.] Carbolised Cloths.--The varied reports respecting carbolised cloths for work in the apiary are on par with other mundane affairs, some succeed and some fail. Having used the cloths all through the season without a smatch of carbolic flavour, or even a taint strong enough to be detected by the keenest olfactory nerves, I may be pardoned for laying my modus operandi before my brother apiarians. Mix in a basin a few drops of acid in water, then well saturate your cloths (of, say, calico, about the size of your quilts), then wring them as dry as you can, so that you have no dropping; roll back your cover from section-crate, letting your carbelised cloth take its place, then gently raise same and blow a little smoke in; prise it with screwdriver or strong knife to break the propolised joint, and then let your other carbolised cloth cover your bottom crate or the frames, as the case may be; brush off the bees from bottom of crate with a feather and proceed to remove your sections, shaking the few remaining bees into an empty skep, and throw same on the alighting-board. I generally take the crate of sections to a quiet part of the garden to remove them, so that I am not troubled with other bees; and if they get a scent after a few crates have been taken off, I go to another corner, quite away, and proceed as before. I find the carbolised cloths save a great number of bees, as it is impossible to take off and change position of crates without crushing some; but with the cloths they are simply driven down out of the way, and it does not interfere with the ordinary routine of their work; and I always like to start on the job about nine o'clock in the morning, and get done by two or three in the afternoon. And, again, the cloths are capital things when extracting to prevent robbing during the time you have your hives open. Remove your quilts with a jerk, and spread your carbolised cloth in its place; then blow some smoke in under it, and the two agents will soon start the accustomed hum, when the bees will begin to look after No. 1. I find cotton rag or touchwood good fuel for smokers, the only objection to the wood is that small coals will sometimes get into the bellows and burn holes where they are not wanted.

Bumping.—I am sorry for the failure of our 'Canterbury friend with bumping. I think he bumped too hard, and smashed the combs. I find in the new stocks the combs break off at the hive better than in old stocks, where with every care they will sometimes break half to three quarters of an inch from the hive; and if the operator is not quick at the job some of the bees get into the running honey. If 'Canterburian' smokes his hives a few minutes before he begins, then turn them up on a table or bucket, give some smart raps to break side attachments of the combs, then bump in direction of arrow in the illustration given in B. B. J. early last month, he will find, if the combs are built straight across, that they will all break off well; then brush your bees off with feather into an empty skep, putting your combs into a vessel, with a cloth to cover over to keep flying bees from the honey, then return your hive to its original place, first shaking your driven bees back into it, if no honey is left; but if there is any honey at crown of hive, shake your bees on the stool and turn the hive over, and, if possible, leave them till night, when you will find them clustered in the top of the skep like a new swarm.

Position of Combs.—I have paid particular attention to the position of combs built in skeps, and some I find parallel, some with combs towards the entrance, and some mixed, and others in a crescent or concave shape, with ends of centre combs converging towards the entrance, so that I do not find any particular style in vogue with the industrious little architects, and nature gives us no guide as to the proper position of our modern frames. For convenience in manipulating the Combination hive is par excellence, and, as far as my experience goes, my bees are as healthy in one as the other, and I have a number of hives on both parallel and right-angled principles, also a few with the old wood crown-boards, in which bees winter as well as those in chaff-cushions, and come out in spring in better condition; but I must add, they are well covered with chaff and wraps over the crown-boards.—Woodleigh.

Echoes from the Bives.

Aldridge, Walsall, Sept 10th.—The last season, although almost deprived of its chief stay, the white clover, in consequence of the drought, must be classed as good. Spring was very backward, May being an especially trying month. But, then, it is not always May, and Jnne 4th initiated such a spell of tropical weather as has not been experienced here since 1868; not the proverbial English summer of three fine days and a thunderstorm, but for fifty-four days there was not rain enough to lay the dust. Hawthorn very late, white clover very early, and beans, eame in together, and by July 20th honey-gathering had quite ceased with me. Nevertheless, a highest yield of 56 lbs. for one stock is for the black country very good. Showers have now refreshed the thirsty land, and stocks seem in a fair state for winter. The season has been one of constant work and anxiety; now, however, we may rest and be thankful,—especially the latter.—Edw. Joberns.

Whitehaven, 12th September.—I started last year (August 5th) with a second swarm. Did the usual autumn and spring feeding. On June 22nd I got a strong swarm off; on June 27, July 5th, and 29th, took off twenty-one 1-lb. boxes on each date. Took first prize for honey at a local Sent both swarm and stock up to heather and have taken twenty-one boxes off each, the swarm being now very heavy. I have nine hars in each hive. What I want to know is, Are nine too many for my bees to winter on? Never having seen the inside of a hive until I got my own

you will see that I am very much amateur.—J. A. Jackson. [Confine, by means of division-boards, the number of frames covered by the bees.]

Springholm, Dalbeattie, September 12.—I was agreeably surprised to see in the Journal what a good opinion you had of the piece of honey-comb I forwarded to you. You will be pleased to hear that bee-keeping in its improved form is getting to be very popular in the stewartry, many having been induced to join the ranks through what they saw and heard at the Horticultural Society's Show at Dumfries last year and also at the local flower shows since then. The honey barvest here has been (with me at least) a partial failure owing to the dry season, which fairly burned up the clover and other pasturage, although from

our local papers I see that they have been very successful in the border counties of Scotland, one bee-keeper having taken as much as 7 lbs. per day off one live for I forget how many days together. That, I think, was pretty fair, and as the bee-keeper was 'a wearer of the cloth,' we cannot suspect him of drawing the long bow. I have driven a good few skeps for cottagers this year, and find that the yield is about an average one, though in some cases the bees seemed to he 'living from hand to mouth.' I may mention that I started bee-keeping about three years ago with a hive of driven bees, which I drove moself, never having seen driving done before, and now my stock consists of ten frame-hives and two skeps, hesides a few hives of driven ones of this year. I make all my own hives and appliances except sections, and find that it pays to do so, as the carriage would be no trifle in this part of the country. The way I was first induced to start bee-keeping may perhaps amuse you, and show how infectious the bee fever is. A neighbour of mine who kept bees in skeps had seen a frame-hive somewhere, and wished to have one, but did not know how to get it, as we have no hive-dealers here; so having seen an article on hive-making in a magazine, I offered to make him one, which I did satisfactorily I hope. Having got his hive, he was not much better, as he knew nothing about managing bees in it, so I got the most of that work to do till he got used to it; and from working with the bees I of course canght the bee fever, and could not rest till I had bees of my own, which have given me a great deal of pleasure in managing them, a fair quantity of honey, and last but not least a large amount of stings; iu fact I have got so many stings from my own and other people's bees that I am quite inoculated, although I see one of your correspondents thinks that inoculation is a farce. Such has not been the case with me at any rate, as when I started hee-keeping first, if I got stung the effects lasted for nearly a week, and now I can get ten or a dozen at once, and in ten minutes I could not show you where I had been stung. Looks frather like being inoculated, doesn't it? I may mention that I have taken the Journal from the first, and attribute to it the success which I have had. Besides the information which it contains, I like the amusing contributions of some of your correspondents, and trust that you and they may long be spared to furnish us with information and amusement combined.—John J. W. Currie,

NOTICES TO CORRESPONDENTS & INQUIRERS

Letters or queries asking for addresses of manufacturers or correspon-Letters or queries asking for addresses of manufacturers or correspondents, or where appliances can be purchased, or replies giving such information, can only be inserted as advertisements. The space devoted to letters, queries, and replies, is meant for the general good of beckeepers, and not for advertisements. We wish our Correspondents to bear in mind that, as it is necessary for us to go to press in advance of the date of issue, queries cannot always be replied to in the issue immediately following the receipt of their communication.

All queries forwarded will be attended to, and those only of personal interest will be answered in this column.

R. G.—Dead Queen.—I received a dead queen reminding me of one Clarence who was drowned in a butt of liquor he much loved, for she was swimming in about \(\frac{1}{4} \) oz. of housy, intended no doubt to prevent her fainting by the way. The other morning a queen came with four workers, and about 1 oz. of dry moist sugar, in a box 4 ins. square and 3 ins. deep with thirty or forty bradawl holes in the lid. The owner was no doubt a believer in dry sugar feeding, but a bulkhead should have been inserted in the box to keep the cargo from rolling over the passengers, as excessive generosity had smothered them in sweetness. Queens come with three or four attendants in a metal vesta box more safely than in these huge packages. Airholes are not required, and the better the outside packing the less likely is crushing. It is not pleasant to mess delicate and valuable appliances with sticky fingers, and how can they be kept clean unless bee-keepers send more wisely? The queen first mentioned I dissected as well as circumstances permitted and found several bacilli, but these, though showing that she came from a contaminated stock did not prove her diseased, as in the general clamminess the bacilli may have been transferred from the outside of the body. My address is Rosemont, Bromley, Kent, and bee-keepers forgetting this are putting me to considerable expense for the redirection of my letters and packages. In future all misdirected ones must be refused.—F. C.

- J. D. M.—Will you please thoughtfully discuss some of the subjects suggested by you?
- J. Brown.—The sprig of heather forwarded is the Calluna vulgaris. It is the best of all British heaths for honey secretion. It is a great favourite with all races of hees.
- INQUIRER.—Mead.—We reprint two recipes for mead as requested. 1. From Mr. E. Thompson of Brigg:— To every gallon of water put 41 lbs. of honey, to which add 1 oz. of giuger, in pieces, and 1 oz. of hops, tied in a bag, to about 5 or 6 gallons. Boil and skim it an hour. Let it stand till cold, then put it into casks, with a pint of brandy to every 6 gallons. N.B.—No yeast must touch it. 2. Take a gallon of honey and 8 gallons of water, and boil it well, till it comes to 6 gallons; then pour it into a large vessel of earthenware, let it stand till it is almost cold, and then pour into it a little yeast to work it. When it has worked a while, put it into a rum cask, and stop it close. Let it stand two months, then hottle it off, and put into every bottle two cloves and a little lemon-peel. (This receipt is almost one hundred years old.) There are many others to be found in previous numbers of the Journal.

THOMAS CROSS.—Salicylic Acid.—The drug used in salicylic acid is crystals, but they will not dissolve in water, therefore a solutive must be added. This is found in soda borax. Mix equal parts of the acid and borax, then add the water. Half an ounce each of salicylic acid and soda borax to a quart of water; half an ounce of this solution to every five pounds of sugar used in making the syrup.

MIDLANDER.—Driven Bees without Queen.—The queens have got killed. It is of no use the bees raising queens, as it is almost an impossibility of their being fertilised. You must either unite them to another lot having a queeu or introduce one to them, first destroying the queen-cells. If this is done more than eleven days after the first cell was seen, you will have to remove the virgin queen, as by that time one will have left the cell. Feed until they have 30 lbs. of syrnp stored.

Subscriber.—Uniting Condemned Bees to Bar-frame Hive.-The manner in which you conducted this was correct, presuming that you removed the bees from the bar-frame hive, of which you say nothing. The bees ought to have been removed from the bar-frame hive, then mixed with the driven bees, and then run in at the entrance of the hive, the combs of which ought to have been replaced in the hive before doing so. We have never had them fight after so doing. The next time you had better scent both lots with syrup having a few drops of essence of peppermint mixed with it,

R. Glasgow.—The comb sent was affected with foul brood.

- E. Field.—Dead Brood.—So far as we can judge from the specimens sent, there is no disease. The pupe have failed to develope into perfect nymphs, probably from heing chilled when the change of weather occurred. Continue to feed on syrup medicated with salicylic acid or phenol according to recipes.
- X. Y. Z .- Orange-coloured Sections .- From your description, we are juclined to think that the section-honey has been collected from mustard or rape, but we never knew these plants to cause a bitter taste in the honey. It is possible that if the dandelion is plentiful in your neighbourhood, the bitter flavour may come from it, but we have no experience of such a result.
- R. J. S. and Beeswing.—Carbolic Solution.—We have not found the solution, of the strength recommended, to blister the hands, but we are rather thick-skinned-not to say pachydermatous-and we can well understand that the case delicate hands of a lady might suffer. But in such a why not use a lemon-squeezer, or a press of some kind, instead of the hands, for wringing the carbolise cloth?
- E. C.—We are averse to insert letters affecting the decisions of judges at shows. Some exhibitors must necessarily be disappointed. We should advise that the grounds of your dissatisfaction with the verdict of the judge be laid before the hon, secretary and the local committee, who would take a greater interest in the matter than the general body of bee-keepers.

^{*}_* We are obliged to postpone the replies to several queries till next issue,

HONEY-DEW.

'Fresh from their Summer sleep, on airy wing, Forced thro' each oozy pore the Sap-floods spring, And, as gray dawn or evening tints the ray, Twine pearls or liquid rubies round the spray. Nor scorn ye now, fond elves, the foliage sear, When the light Aphids, arm'd with puny spear, Probe each emulgent vein till bright below, Like falling stars, clear drops of nectar glow; And, roll'd along the glade in billowy streams, To the rapt eye a sea of amber beams.'

Evans, The Bees, III., 570-579.

In our last number we endeavoured to trace the history of honey-dew from primitive times to the present day; and that which struck us most in our review was the great difference in the appreciation of honey-dew by the ancients and by the moderns. By the former it was extelled in the loftiest terms, as 'the heavenly gift of ethereal honey,' 'the saliva of the stars,' 'the quintessence of all the sweetness of the earth,' and 'the purest nectar coming from above; while by the moderns it is regarded as 'the excrementitious product of aphides,' 'aphidean excreta,' 'black aphidian honey,' &c. No more entire subversion of the meaning of a term can be conceived. The supramundane superlatives have resolved themselves into the lowest of positives. But 'with regard to tastes there is no disputing.'

Honey-dew is not, however, always spoken of in such disparaging terms, and it is doubtful whether those that apply them have acquired sufficient entomological acquaintance with the peculiar organisms of aphides to justify them in their application; and it is a question whether, when they have arrived at that knowledge, they will not desire to modify the

opinion they now entertain of it. While the great majority of these who have studied the physiology of aphides accept the conclusions of Mr. Curtis and Dr. Kirby as to the production of honey-dew as given in our last number, yet many other observers maintain that it is of vegetable origin. Dr. Hooker endorses Liebig's opinion, that honey-dew must not be ascribed to the agency of aphides. The Abbé Boussier de Sauvage thinks that the secretion may have both a vegetable and an insect origin. Mr. H. Doubleday considers the dropsical appearance of currant-leaves due to a disease which causes the transpiration of a

fluid from the pores. M. Boussingault denies that the saccharine matter on lime-leaves is the produce of aphides. His analysis of honey-dew is—Cane-sugar, 48.86; sucre interverti, 28.59; glucose, 22.55 = 100. But this analysis has not been accepted by Dr. Gunning, of Amsterdam, who states that it principally consisted of cane-sugar, and not of grapesugar or glucose. Mr. Buckton, than whom no one has paid such attention to aphides, is very much of opinion that the honey-dew found on leaves is of aphis origin.*

Let us turn now to the opinions of bee-keepers

as to the taste of honey-dew.

Mr. W. Carr of Newton Heath, Manchester, says, 'The linden tree produces a great quantity of honey-This fluid is scarcely inferior to honey in sweetness, but is of a dark colour.' Mr. Cowan, in the discussion on Mr. Griffin's lecture on 'Honey and Wax,' says that 'honey-dew is not altogether valueless, and that from the pine has a peculiar flavour, which is not at all disagreeable.' Langstroth, as a representative of American bee-keepers, says that honey-dew 'though seldom light-coloured, is generally of a good quality.' A bottle of honeydew was forwarded to us about two years ago; it was characterised by the party sending it as 'abominable stuff'-'as black aphidian honey, almost the colour of ink.' This we gave away, and the report of the recipient was that it was very palatable, that he had relished it very much, and was sorry when it was exhausted.

Mr. Griffin, on the occasion of the above-mentioned lecture, had among the samples which he had brought for the illustration of his lecture one of honey-dew, which had been gathered by bees in 1884 at Hungerford from the aphides of the oak. He states as his opinion:—'Raised to a high temperature, almost black, most disagreeable to the palate, and of strong odour; 'a second sample, like to the preceding, but left to crystallise, 'had become a mottled brown, much resembling marble.' Mr. Griffin described honey-dew as 'a viscid transparent substance as sweet as honey itself."

Whatever difference of opinion there may be as to the origin of honey-dew, there can be no disputation as to the large quantity of it that is sometimes found; and the evidence with regard to this is very ample, and the circumstances under which

^{*} Monograph of British Aphides. By G. B. Buckton, vol. i, p. 43.

it is found, fully bear out the idea of Virgil as to roscida mella (dewy honey), and that of Dr. Butler when describing it as 'descending unto the earth as a dew, or small drizzling rain.'

Mr. Knight (writing towards the end of the last century) once observed a shower of honey-dew descending in innumerable small globules near one of his oak-trees. He cut off one of the branches, took it into his house, and, holding it in a stream of light admitted through a small opening, distinctly saw the aphides ejecting the fluid from their bodies with considerable force.

Mr. W. Carr thus states his experience:

'On July 21st, 1876, I was in Leek churchyard, around which, more than fifty years since, were planted rows of linden trees, and underneath these trees the flags were wet over with honey-dew, and I observed a shower of honey-dew descending in innumerable small globules, and extending beyond the trees, the leaves of which were covered with aphides salicis. My clothes soon began to be sticky with honey, so I called a friend that lives near, and told him to put some buckets under the trees, as it was a land really flowing with honey. The happy humming noise of the bees could be heard at a considerable distance from the trees, sometimes nearly equal in loudness to the united hum of swarming.'

Mr. Garratt, Mr. Dobbie, and others (B. B. J., vol. 13, pp. 166, 256) bear similar testimony to the large amount of honey-dew deposited by aphides.

What the locusts are in warm climates, aphides are in cooler ones. It is said that locusts fly in such numbers as to intercept the sunbeams, and to darken whole countries as they pass from one region to another, wasting large districts. The same tendency to shift their quarters in countless numbers is to be noted in the aphides. Gilbert White, of Selborne, says:—

'About three o'clock in the afternoon of the 1st of August, 1785, the people of the village of Selborne were surprised by a shower of aphides or smother-flies, which fell in those parts. Those that walked in the street at that juncture found themselves covered with these insects, which settled also upon the hedges and in the gardens, blackening all the vegetables where they alighted. These armies, he observes, were then, no doubt, in a state of emigration, and shifting their quarters, and might have come from the great hop plantations of Kent or Sussex, the wind being all that day in the east. They were observed at the same time in great clouds about Farnham, and all along the vale from Farnham to Alton.'

Dr. Kirby had a similar experience:—

'An emigration of these flies I once witnessed, to my great annoyance, when travelling later in the year, in the Isle of Ely. The air was so full of them, that they were incessantly flying into my eyes, nostrils, &c., and my clothes were covered by them. And in 1814, in the autumn, the aphides were so abundant for a few days in the vicinity of Ipswich, as to be noticed with surprise by the most incarious observers; as they were September 26th and 27th, 1836, at Hull, where, as the local newspapers stated, such swarms filled the air that it was impossible to walk with comfort from their entering the eyes and month at every step; and on the same days they were equally numerous at York and Derby.'

There is so much of interest in the life-history of these producers of honey-dew that we find we must postpone our continuation of it to a subsequent number.

USEFUL HINTS.

Weather.—Autumn weather, on the whole, is proving favourable to the bees. Easterly winds and cold nights prevent too much excitement and long fruitless flights, but occasional hours of sunshine encourage cleansing flights and a gradual preparation for the winter's rest, which ought, in well-regulated apiaries, to commence at once.

Wintering.—Strong celonies, with plenty of sealed stores and winter coverings, ought to be disturbed no more until March winds or April showers harbinger the summer's flowers, and, let us hope, another bounteous honey-flow. As regards winter quilts, our hives are covered with enamel sheet, which is already propolised, and will not again be disturbed. Over this is placed several thicknesses of carpet, and upon all a flat straw cover, with a couple of bricks to keep all tight. When wasps have disappeared, plenty of bottom ventilation will be given, and all colonies, having abundance of sealed honey, are already in winter quarters, and will, we

trust, soon be in a state of semi-hibernation.

QUEEN Introduction.—It has been impossible to write instructions for the use of the improved pipe-cover queen-cage to all who have applied for specimen cages. A few hints, therefore, may prove acceptable. Our own practice is to remove the queen which is to be superseded about noon on a fine day, and on the same evening, when the bees will have discovered their loss, to cage the new queen in the brood-nest. The division-board and an outside frame are removed first, in order to obtain plenty of space for manipulation, and the frame on which we intend to cage the queen, containing hatching brood and sealed honey, is raised, and one end again lowered into the hive until the end of its top-bar rests upon the hive-side, and the opposite end of the bottom-bar on the other side. This plan sets both hands at liberty for action, and gives full command of the comb. The alien queen, having previously been kept in solitary confinement for half-an-hour under the cage placed on a card in a warm room to avoid chilling, is now carried to the raised comb, and the bees are removed by a dry carbolised feather from the spot which the cage is to occupy, between brood and sealed honey. The cage, upon its card, is placed upon this spot, the card carefully withdrawn, and the cage screwed down to the midrib of the comb, allowing room enough for the queen to move freely around. The frame is then lowered into its proper position, the remaining frames closed up, one by one, and the hive left in its normal state until the next evening-twenty-four hours-when it is again opened and the comb on which the queen is caged is raised as before. If the bees are thickly clustered upon the cage in shape of a solid ball, evidently intent upon mischief, the hive is closed and allowed to remain in statu quo for twentyfour hours longer. But if, on the other hand, the bees appear well disposed towards the imprisoned queen, offering her food through the bars of her cage, she may gently be set free by turning the cage slightly aside, and allowing her to walk out upon the comb. If she is allowed to proceed and food is offered, the hive may be quietly closed, and on the following morning an examination may be made to see that all is right. If, however, on setting free, the queen is seized by the wings or legs, and an angry knot of bees begin to surround her, stopping her progress, she must at once be rescued and caged for another twentyfour hours. A carbolised feather, wiped clear of the solution, will drive away the evil-disposed bees, when the cage can be slipped over the queen, and again pressed down to the midrib. We always enclose within the cage two or three cells of capped honey, so that the queen can feed herself, and the bees are induced to feed her also, while gathering up the honey from the bleeding comb. If the above directions are carried out quietly, without hurry or excitement, success will be all but certain. We successfully release the queen after twelve hours' con-

finement. Before attempting the release it is best to look over the brood-combs, and carefully to notice whether any queen-cells have been commenced. cut them out, and close the hive, without attempting to set free the queen, or the probability is that she will be encased and destroyed. It is best to get queens intro-duced by the end of this month, but if the weather continues fine introduction may be continued until the middle or end of October.

Dead Brood.—In regard to Mr. Webster's apologia for Mr. Simmins's theory of 'dead brood,' we should only be too pleased to believe the theory correct, but, unfortunately, our experience is dead against it. We can hardly compare bees and poultry, since the fecundation of the eggs and other conditions differ so widely. With the exception of chilled brood we have never met with dead brood in a fairly populous colony, save from disease, but we admit that our experience has been principally with queens raised under the natural swarming impulse. But whether dead brood may be attributed to an imperfect or to a diseased queen we hope shortly for a report which will set the question at rest. That more than one kind of bacillus attacks our bees is a question beyond dispute, and that the dead brood in question will be found to be caused by bacillus we have little doubt.

TRANSFERRING STORES AND WINTER PASSAGES.-Where winter preparations have not been completed it will be advantageous to remove from strong colonies combs containing much pollen. Such may be given to condemned bees which have built their own combs, but have had no opportunity of collecting pollen. Sealed combs of honey also may be removed from the outside of strong colonies having more than sufficient winter store and given to weaker ones. Winter passages are a decided advantage, enabling the bees in cold weather to pass freely from comb to comb. Combs of sealed honey stored in a dry warm closet will be found of great use as food at spring.

South Aspect.—Whether the combs of the hive range from back to front, or parallel with the entrance, let the aspect of your hives be south. Then the cluster of bees will be on the south side of their hive over the entrance, and they will have far greater inducement to take cleansing flights during sunny days in the winter months than if the aspect had been in any other direction. For this reason we prefer the parallel combs to be close up to the front or entrance side of the hive, without any intervening space or porch as recommended by some. Our plan has always been to encourage flight during winter in suitable weather as much as possible, since nothing more conduces to healthy wintering than occasional cleansing flights.

FECUNDATION IN CONFINEMENT.—In the American Bee Journal of the 7th inst., Mr. W. N. M'Lain gives the results of varied experiments in controlling the fecundation of queens, both by natural and artificial methods, carried on during the last two or three years. His most important point is, that a portion only of the drones produced in a hive have the power of procreation, and that this power is conferred by the workers by means of a particular kind of food, just as in the case of queens. Also that fertile drones are found in greater abundance in hives affected with the swarming fever than in others, and he makes the remarkable statement that not more than 5 or 10 per cent of the drones produced are capable of procreation. We recommend the perusal of Mr. M'Lain's important and interesting paper to those of our readers who take an interest in the subject; since our space will not admit of long extracts, suffice it to say, that, by his most ingenious artificial method he succeeded in fecundating queens which proved, upon trial, as prolific as any queen he possessed. In experimenting by natural methods he made use of a house 10 feet by 16 feet, and 8 feet high, partly covered on

the sides with wire-cloth, a wire-covered sash in the gable, and large screen wire-covered doors in each end. In this house he placed his hives, and succeeded in pro-curing the fecundation of three out of six queens. This is undoubtedly a decided step in advance, and Mr. M'Lain is sanguine of complete success. The subject is one of the greatest importance, and almost the only problem which remains unsolved in apiculture.

FOUNDATION FIXER.—In American apicultural circles also a new machine for fixing foundation is thus described:—'It is an automatic, self-lubricating machine for fastening comb foundation into section boxes for surplus honey, as used by bee-keepers. The task heretofore has been a slow and tedious one, owing to the want of a machine that would do the work expeditiously. This machine will fully satisfy the want. It will do the work of any ten machines ever invented in a given time. Though simply constructed it is a marvel of ingenuity, and all apiarists cannot fail to appreciate it upon examination. A patent will be obtained, and the manufacture of the machines will be commenced at once.

We trust that Mr. Lee will lose no time in bringing out his patent machine for producing sections in which full sheets of foundation are fixed while putting the sections together, and which process obviates the necessity for the use of a foundation-fixer at all. The American machine, we suppose, merely fixes a strip of foundation on one side of the section, and can never successfully compete with Lee's method.

TIN SECTION-CASES.

As will be seen from our advertising columns, Mr. A. D. Woodley has disposed of his interest in the Tin Section-cases, brought out by him this year, to the British Bee-keepers' Stores, now removed to larger and more convenient premises at 6 George Yard, Fenchurch Street, E.C. These cases have taken several prizes during the late season, and by their neatness and cleanness have proved of great service to bee-keepers in the disposal of their sections.

ASSOCIATIONS.

BRITISH BEE-KEEPERS' ASSOCIATION.

A meeting of the Committee was held at 105 Jermyn Street, on Wednesday, September 21st. Present: The Hon. and Rev. H. Bligh (in the chair), Dr. Bartrum, the Rev. F. S. Sclater, Capt. Bush, Capt. Campbell, H. Jonas, J. M. Hooker, Dr. Walker, W. O'B. Glennie, Treasurer, and the Secretary. The minutes of the last meeting were read and confirmed. The Finance Committee presented their report, recommending the payment of certain bills, also a statement of assets and liabilities of the Association. The Secretary reported that he had made application for the outstanding subscriptions, and that several had already been sent in.

It was unanimously resolved that the Chairman be requested to express their sorrow on account of the sad loss the Association had sustained in the death of Mr. Duncan Stewart, and to express the sympathy of the members with Mrs. Stewart and other members of the family in their heavy bereavement.

The Examinations Committee reported that the certificates gained by the third-class candidates during the past season had been duly signed and would be forwarded to the respective Secretaries of the County Associations.

It was resolved that the second-class examinations

should take place on Saturday, November 12th.

The Secretary reported that he had received a letter from Mr. S. Corneil, of Canada, together with a newly invented machine for fixing foundation on sections. It was

resolved that Mr. Hooker be requested to give the machine a practical trial and report the result at the next quarterly meeting, to take place on October 21st.

The following is the list of successful candidates at the third-class examination held during the past season:-

Berkshire M. Whittle, Wantage.	
Derbyshire Thos. Austin, Alvaston.	
,, W. Coxon, Ambaston.	
R Skorman Swanwick	
I I Shipman Acharar	
B Rawson Soleton	
Essex J. G. Cheek, Braintree.	
Gloucestershire J. White, Toddington.	
A I Brown Bradley	
G Naveman Gloucester	
R Woodward Charlton Ki	nos
// TNT TNT 1 (7 11)	ug.
Kent W. Blake, Collingwood T. Badcock, Gravesend.	
Lancashire W. Drinkall, Lancaster.	
W. Liddell,	
Leicestershire A. II. Windsor, Netherseale	٥.
Monmouthshire W. Williams, Caerleon.	
Northumberland T. Hedley, Hexham.	
Staffordshire J. Beech, Burntwood.	
" F. Wilshaw, Cheddleton.	
Shropshire Miss M. E. Eyton, Leaton.	
" H. Brooks, Wrockwardine.	
" J. Palmer, "	
" T. Shuker, Advaston.	
" J. Shuker, Allscott.	
er en	

Any of the above, or candidates who have gained third-class certificates in previous years, and being desirous of competing for a second-class certificate at the next examination, fixed to take place on Saturday, the 12th day of November next, should give immediate notice to the Secretary of their County Association.

MIDDLESEX BEE-KEEPERS' ASSOCIATION.

A Quarterly Committee was held at 107 Jermyn Street, W., on Wednesday, the 21st inst. Present-Hon. and Rev. H. Bligh (in the chair), Major Fair, Dr. Raynor, Messrs. Jonas, Hasluck, Graham, and English. A cordial vote of thanks was given to Mr. Hasluck for his courtesy in placing his grounds at the service of the M. B. K. A. for their show on 20th August. Resolved that the expert's tour in the N. E. Province be undertaken by Mr. S. J. Baldwin. A statistical return was considered and referred to a sub-committee to be printed and circulated. The subject of winter lectures was under consideration.

Correspondence.

The Editor does not hold himself responsible for the opinions expressed by his correspondents. No attention will be taken of anonymous communications, and correspondents are requested to write on one side of the paper only, and give their real names and addresses, not necessarily for publication, but as a guarantee of good faith. Illustrations should be drawn on separate pieces of paper.

Communications relating to the literary department, reports of Associations, Shows, Meetings, Echoes, Queries, Books for Review, Ec., must be addressed only to 'The Editor of the 'British Bee Journal,' c'o Messys. Strangeways and Sons, Tower Street, Cambridge Circus, W.C.' All business communications relating to Advertisements, &c., must be addressed to Mr. J. Huckle, Kings Langley, Herts (see 2nd page of Advertisements).

2nd page of Advertisaments).

*• In order to facilitate reference, Correspondents, when speaking of any letter or query previously inserted, will oblige by mentioning the number of the letter, as well as the page on which it appears.

PARALLEL v. RIGHT-ANGLE FRAMES.

[1279.] Dogmatism is, I trust, no part of my nature, but if there is one thing more than another that makes me feel at all inclined to be dogmatic it is the question of parallel v. right-angle frames. I must own that I 'go in' for parallel frames; not that it is for any idea

that I think the bees do better upon this principle or that they do worse, but simply that the frames in this position are much easier to handle, the hive can be manipulated with greater comfort. There is, as a rule, greater space in the hive which is useful for a variety of purposes; there is also economy of space: but that it makes any difference in the honey yield I consider a fallacy, or that the health of the bees suffers in consequence is another fallacy. Often have I smiled at the expressed ideas of some that the system known as the 'hot' is a canse of 'foul brood.' Am 1 not dogmatic? Well, let ns examine the above assertions in as dispassionate and unbiassed a manner as possible. In the first place, Does it make any difference in the honey yield? My best hive this season was on the 'hot' system, but one hive stands for nothing. I find on tallying the whole of the apiary that this question is 'six to one and half-a-dozen the other; there is not the slightest difference, just as I have found before. I daresay that I have as many skeps pass through my hands as most bee-keepers, and for some years have given this question a deal of observation, the results of which are as follows. The positions of the combs built are as often one way as the other, that is, if the angle is accurately gauged; but on account of there being a much larger number of angles within a circumference and its centre than these two, I find that more combs by far are built augleways than any other, also a great number are built at several different angles in a

single hive.

Many, I know, will say that their experience is the reverse, and as the thought just strikes me at this moment I will run out to the apiary and look at six skeps I have there. Unfortunately, for this question, I have just now only that number in this apiary. . . . I have done so, and find eight different angles represented, but the majority is in favour of the parallel or 'hot' system. This is the result: No. 1 hive within one degree of parallel. No. 2 at an angle of 45°. No. 3 at an angle of 50°. No. 4 has three different angles. No. 5 exactly parallel. No. 6 within five degrees of right angle. I must own that I did not expect to find such a result in favour of the parallel system as the prior portion of my letter shows. The next assertion I make is that the frames are much easier to handle. I don't think that any experienced bee-keeper will negative this. In handling such frames your hands need not move over the tops of the frames at all, the hive being manipulated from the back—the correct position. In handling frames on the 'cold' system you cannot lift any frames from the back without passing your hand over the whole extent of the uncovered portion of the hive; this, as is well known, is inadvisable, therefore the manipulator to prevent it must stand at the side, if there is any room between the hives. This is a consideration in cramped positions. Such a position as I saw at Llanrwst, where one of the most advanced of Welsh bee-keepers (Mr. Berry) is obliged to keep his hives within three inches of each other. A hive on the 'cold' system has the space-if any--unoccupied by frames, divided into two; there is, therefore, unless the hive is—shall I call it?—abnormally large, much less room to place extracted combs or sections to be cleared out behind the dummyboard. With parallel frames this space is all in one place at the back. I find it very convenient to keep any little adjunct belonging to that particular hive, for clearing out combs without disturbing the interior, and moving frames well away from those contiguous when examining for anything. In using a hive on the 'cold' system as a nucleus it will be found very awayard, as the two or three frames used with the two divisionboards will not extend the whole length of the entrance. You, therefore, have a number of the bees entering on each nuoccupied side of the division-board and getting into the roof, thus losing themselves; it also gives a

better opportunity to robbers-much feared in nuclei-

as even with contracting entrances you cannot entirely surmount this defect; but with a hive on the 'hot' system there cannot be but one entrance direct into the

hive, even if you have only one frame.

The chief advantage claimed for the 'cold' system is that better ventilation is afforded. This may be true with those frames directly opposite the entrance, four in number, but those on each side of these four are as badly off (?) as those on the 'hot' system, but with entrances extending the whole width of the hive this will not apply. If there is so very much difference in the amount of ventilation, which I question, so must there be a greater variation of temperature within the hive, cold nights will be more visibly felt, and warm days likewise. The latter is of little importance, as this the bees can easily reduce. The question of ventilation is, I think, very much of a myth, yet the results of these two systems devolve entirely upon it. I have heard the opinion given that according to the position of the hives, whether the entrances be towards the north, south-east, or west, so will the combs be built. I must really negative this. Just examine a few and see whether there is any knowledge of the cardinal points expressed in the building of natural combs by the bees.

The opinion I have expressed can be summed up in a very few words: that there is no perceptible difference to the bees which system is adopted, but to the beekeeper the parallel is the most advantageous. These are not the results of observations made upon one, two, or three hives, but extended over a very wide area of naturally and artificially built combs.—W. B. Webster,

Binfield, Berks.

EXTRACTING FROM BROOD COMBS (1246.)

[1280.] My thanks are due to your Irish correspondent, 'Walter J. Stanford,' for his notice of my remarks on this subject, and also for his candour in confessing that his mind is prejudiced against me; this admission on his part involves a principle which, if universally carried out, could lead to nothing but the worst results, and to me it seems somewhat extraordinary that he should have put forth such a doctrine in the Journal. His principle is this, that because a correspondent has written a letter to the Journal, perhaps a year ago, which contains something he disapproves of, so henceforth his mind is prejudiced against that person, and ever afterwards his writings are to be looked upon with disfavour. Surely this is, to say the least, most unfair and irrational, and I do hope no other readers are imbued with the same sentiment. 'W. J. S.' states that 'Mr. Boyes writes as if no one else could be right but himself, and that once he has stated what he believes to be fact, that fact (?) must be law henceforth.'

I was not aware that I had ever been guilty of assuming any such spirit of dogmatism, and if I have, it certainly has not been intentional; but to be candid, I must admit that when I have stated what I have proved to be a fact I have endeavoured to uphold my opinion. This is one of the primary tenets of scientific men to maintain what they believe to be fact until it is upset, and if it really be a fact, that truth is law henceforth; and so long as I write to the Journal, I shall endeavour to do so—it is open to 'W. J. S.' as well as to every one else-to dispute me, and when they bring sound argument to bear on the subject I do not complain; but I do object to have facts opposed by theory, or perhaps nonsense, or worse, abuse. Now let me point out an example arising out of this very subject under discussion.

I advance what my eyes have seen, viz., bees drinking at manure-heaps, &c., and it is also a fact well known to many bee-keepers—careful observers; it is, therefore, an incontrovertible fact, a truth. How is it confronted? as follows by 'W. J. S.':—'I admit that bees visit queer places, manure-heaps, pigstyes, &c., but I have always thought that they were attracted there by their powerful

sense of smell, and that unless absolutely reduced to water starvation, left all foul places as they came.' Here then is simply a case of inaccurate observation; but does any one suppose that my fact is in any way altered by such negative evidence as this? no scientific man would for one moment admit it. How then does my other opponent, 'G. T.,' meet my fact? He states:-'I do not believe that bees are such fools as to visit such places as manure-heaps, &c., if there is good water within three Can any one wonder when facts are met miles of them." in this way that people sometimes write rather strongly

on this point?
'W. J. S.' asks me for my chemical analysis of the honey from which I have made my statement. I have none; common-sense has been my guide in this as all other bee matters, nor do I see the necessity for a chemical analysis. I watch bees drinking at manureheaps, &c., and they fly direct to their hives, that is sufficient for me. I can readily guess that if I analyse the contents of that hive I shall find it there. I am, however, very much obliged to 'W. J. S.' for his remarks regarding analysing honey, but I am sufficiently acquainted with the subject for my purpose. But why try to make a mountain out of a molehill, 'W. J. S.'? And do not, please, raise up any metaphorical monster in my name. What evidence have you that 'after all ammonial liquid has been extracted and cleaned out by the bees, traces of solid nitrates cannot fail to remain, and would be taken into solution on suspension again when placed in contact with a liquid'—would it not depend on the density of that liquid? and would not the quantity be so infinitesimally small that the liquid would be, for all practical purposes, unaltered?

If you are going on a line of argument of this kind I shall, in spite of your assertion that your honey is second to none in purity, colour, and flavour, yes-I shall not only deny that it is pure, but I shall deny there is such a thing as pure honey. But all this is beside the question, and is a bugbear of your own raising. The point is whether it is beneficial or otherwise to extract from brood-combs? My contention is that if there be feeding larvæ in these combs there is usually unsealed honey and food in close proximity to it, which

is not pure honey.

One word more and I have done. I regret exceedingly that my letter on extracting from brood-comb has hurt his feelings very much.' I fear he is a little too sensitive on the point, and this may have led him to view the subject in such a terrible aspect. I hope this letter will soothe his mind and help towards his speedy recovery. I can assure him there is nothing to be alarmed at. But what about my feelings? what must they be, when he calls upon English, Scotch, Irish, and Welsh bee-keepers 'to do fierce battle' against me ! Well, well, I hope I shall get over it; I think I shall. I have too good an opinion of them to believe they will hurt me much, or that they will find me guilty of trying to do bee-keeping an injury.—F. Boyes.

DRONE-COMB.

[1281.] As a constant reader of your Journal I have had much pleasure and profit from your 'Useful Hints, though I have not always agreed with the author. But

who are always right?

On p. 407, Mr. 'U. H.' put forth some meditations on the above topic, and there, I think, he is certainly wrong. He speaks of drone-comb as if this was built by the bees with the intention to rear drones, but I think that this is very seldom the case. Drone-comb is generally built by the bees as store-comb, because it is cheaper and easier to build than worker-comb. If you give a swarm some frames with empty worker-comb, but also some empty frames, or such with foundation only half-way down, the bees will not build out the empty

room with worker-comb, even if it is in the centre of the hive, but with drone-comb. This is a common case, and nothing to be wondered at, as Mr. 'U. H.' seems to believe. The cause of the building of drone-comb is in this case evident, viz., in the empty worker-comb given to the family the queen has at first room enough fer depositing her worker eggs, so the bees fill out the empty room in some of the frames with the intention to use them for honey. Try to put a swarm in a hive in which the frames have only narrow starters, and the bees will build all worker-comb as long as the queen is able to follow them with her egg-laying. But try then, after, say, eight days, to put only a couple of frames with empty worker-comb in the centre of the hive, and then the bees instantly will begin to build drone-comb. Is this because 'Nature now demands drones?' No, most certainly not. It is only because the queen now suddenly gets room enough for her worker eggs, and then the bees will build for storing honey. So you see it is always the bee-keeper's own fault if he gets dronecomb when he wants worker-comb.

To get worker-comb built, it is only necessary either to manage so that the queen constantly is in want of cells for egg-laying, or to till out all the empty frames to the bottom bar with good foundation. Mr. 'U. II.' speaks of drone-comb being built on worker foundation, but then I am sure it has been bad foundation. Some years ago I had often the same result, but now I have better foundation with cells of the right size, and since I used this foundation I have never seen drone-comb built on worker foundation in my hives.

That a strong colony in the summer ought to have some drones, there I agree with Mr. 'U. H.,' but for this the bees always will find room enough without the help of the bee-keeper.—HANS ERSLEY, Kalundborg, Denmark, Editor of the 'Danish Bee Journal.'

RE FOUL BROOD.

[1282.] I think the result of Mr. J. T. Harveyson's observations points to the fact that none of his queens were diseased, and in this lies the difference between his case and mine. I should be the last to advise the destruction of a healthy queen knowingly. Will Mr. II. kindly direct me to that observation of Mr. Cheshire which I overlooked, viz., where he 'distinctly says the queen must be removed if there is reasonable ground for believing her to be infected, and a healthy one substituted, ere a cure can be effected?' I was not aware that Mr. Cheshire ever laid it down as a rule that in bad cases it was better to remove the queen. What I want to encourage is the destruction of every queen on suspicion, for Mr. Harveyson shows how easy it is to cure the disease if the queen is not diseased, without destroying the combs as recommended by the 'Man of Kent;' and although a good many healthy queens may be destroyed by acting on my advice, still I compare the disease to a house on fire, the sooner it is out the better. Mr. Cheshire does not approve of feeding healthy stocks with medicated syrup as a preventative; but in my case I am convinced it saved the apiary from attack, and that is why I recommend it. I heartily congratulate Mr. II. on his success.—Thos. F. WARD, Highgate, September 23rd.

FOUL BROOD AGAIN.

[1283.] Come, friend Ward, you have made a very great mistake this time when you say that you are glad to find that Mr. Simmins, having acted upon your advice, given to him twelve months ago, can now from practical experience confirm your statement as to the Cheshire cure of foul brood being certain if the diseased queen is removed and a healthy one substituted. I cannot find one word in his communication in which he says he has had any practical experience of foul brood during the

last twelve months. But we have it from 'W. Hollier' (II70), page 334, that he has not had any experience of it since he has been at Rottingdean, and it is five years ago since Mr. Hollier made his first journey there, but he tells him that he thinks the Cheshire cure will prove effectual (if) you only requeen as well.

Now only fancy a breeder of queens for sale, like Mr. Simmins, saying that he has been experimenting with foul brood. I wonder who would buy queens from him? Not I, for one. Mr. Simmins is far too shrewd a man for that, but he does say that he had experience of it some ten or twelve years ago, and that he starved it out, which I should imagine is a very similar process to what I am recommending.

Again, Mr. F. Cheshire, in reply to inquirer, 'J. S. L.,' page 403, recommends the turning out system if the bees are strong enough to work out foundation.

Will Mr. Ward give us a little more information as regards his treatment of his five infected stocks in 1885, the date of his first finding out that he had got foul brood, and the date of his putting the swarm upon the affected combs, &c.? If Mr. Ward has got his apiary elear of foul brood, I certainly should not advise him to try breeding from a diseased queen, if he can make sure of getting one; but how is he going to prove that he has got a diseased queen unless he has her killed and dissected?

It does not appear to me to be a disease of the mature bee, but only of the grubs, principally just before they are sealed over in the cells. If the queen gets the disease, how is it that it does not kill her? I have known hives dwindle down to a mere handful of bees, and yet the queen appears to be as lively as ever, even depositing two and three eggs in one cell, but there have not been enough nurse-bees in the hive to attend to them.

There is no mistake but what the fell disease is travelling in the wake of the bar-frame hive at a rapid rate. Since writing last I have been in conversation with two bee-keepers, owning about forty hives between them, and the one having the largest quantity wants to sell out through having got the disease, and yet this man did well with his bees in the old straw skeps.—Man of Kent, September 19.

CURING FOUL BROOD.

[1284.] In reply to 'Man of Kent' (1228) as to my present experience of camphor as a cure for foul brood, I have not tried it on but one stock this year, and that at a friend's some distance from here. When, after three weeks, I examined the same stock, there was no difference. There was a lot of disease, but also some healthy brood hatching out as before; so I thought of trying phenol, but, for all that, it did not cure it, so I concluded that the queeu was diseased. But the stock that I eured two years ago that 'Man of Kent' speaks of I have now. The same queen has been in up to a week ago, when I replaced her with a young one. I have taken from this hive this year nine bars full of brood to double another, and 12 lbs. of honey, besides having enough for the winter. As for 'Man of Kent' not finding skeps with foul bread, I can assure him I have found five this season—one at a farmhouse quite half a mile from any bar-frame hives. This and two others were so weak when I found them I was told to de as I liked, so I made a fire and burned the lot—bees, comb, hives, and all. I have cured one other bar-hive with phenol this year; two others, not my own, would not yield to anything. Last year I cured two by fumigation with salicylic acid-turning a small bull's-eye lantern into a fumigator by fitting a chimney to it, turning into mouth of hive, feeding as directed in Mr. Cownn's Guide-book, and using sweet oil instead of spirit for lamp. - John Hounson, Leigh, Tunbridge, Sept. 19th.

A USEFUL ASSOCIATION.

[1285.] One frequently reads in your columns the complaints of bee-keepers who cannot find profitable markets for their honey. 'Sherborne, Dorset,' sees little use in associations so long as nothing is done to bring the members into direct communication with retailers. So do I. I think this question of the sale of honey is perhaps the most important one for consideration just now, for, after all, bee-keeping, in the majority of cases, ceases to be attractive when it ceases to be profitable. What advantage can one derive from abundance of sections, and abundance of stings also, if he has to sell his honey at 5d. a-pound, except, perhaps, the satisfaction of knowing that some one—the middleman most likely—secures a profit?

I should like, with 'Sherborne,' to see the middleman no more, and I am glad to let your English Associations know that in Ireland our Association is of real use to its members in this respect—the profitable sale of their honey. I sent all my sections to the Association this summer, and the secretary secured 10d. per pound for me, when section honey was being retailed in Dublin at 6d. Not only does the Association bring us into direct communication with the retailer, but with the best retailers, and all this for 5 per ceut. Your English Associations would do well to take a hint even from Ireland, where, as you say, 'bee-keepers have thrown off their former lethargy!'—J. Garven Digges, Lough

BUMPING.

[1286.] On the subject of bumping I must say I have been still more successful this year. As regards stings especially, from fourteen stocks I have not received more than twenty stings. One stock of hybrids gave me more than all the rest put together. I use a Clark's smoker charged with touchwood; when filled I pour a little neat carbolic acid on top before lighting; the bees seemed so much quieter. In three lots some of the combs broke off about half an inch from the top, but I had no trouble with them; by the time I was ready to transfer to my own skeps the little honey left was all cleared up. One lot, a cast, hived late in July, about three parts full of comb, two inches of honey at top; the rest was full of honey-dew, which when bumped came out like water, causing a lump of bees, the size of a quart measure, to be in the skep after the combs were removed. I swept them into another skep, tying them up till the next day to see if they would recover or not. When I opened them the next evening they were all right and lively enough. 'Canterburian' must try again. I had a similar case two years ago in August, when it was very hot weather, and a swarm of the same year; I gave a warning at the time. This year I have bumped some in August, but it was cooler weather at the time.—J. H. L. K.

STARTING A BEE-FARM.

[1287.] Replying to your request for information for a correspondent starting a bee farm, I greatly doubt if, with honey at 6d. per lb., 'and which will be probably lower,' he would clear the amount per annum he states with one farm, as fifty strong stocks are sufficient for an ordinary district, and they would not, after deducting expenses, clear more than 15s. each.

'A Welsh Bee-keeper' should carefully consider before adopting a hive pattern. If storifying, a short box; if longitudinal, a long oue; and each has infinite surroundings. Have Association frames; black bees at first; buy them in skeps in the spring, and transfer them, using frames filled with comb foundation and feed liberally at first, or bny at a small cost of those clearing

out. I have adopted the long twenty-frame hive, and advised Mr. Brown of Swinehead to do the same, as they, for utility, convenience, and cost, compare favourably with storifying hives. I am selling hives at 3s. each that I recently bought of a noted apiariau, and they cost him 10s. each—' Irish fourteen-framed ones'—and he more than once lost nearly half his bees.

than once lost nearly half his bees.

In consequence of the difficulty of selling honey, Mr. Brown has sold me his apiary and bee-gear. Fifty hives (new) with bees and appliances would cost from 70l. to 80l. I have no 'axe to grind' beyond getting rid of my honey, and if 'Welsh Bee-keeper' will send me a stamped envelope I will give him more particulars.—ROBERT

THORPE, Swineshed, Lincolnshire.

STARTING A BEE-FARM.

[1288.] Press of work has prevented me from saying a few words until now in reply to 'A Welsh Beekeeper' (1250). The above heading recalled to my memory some pleasant recollections which seven years ago occupied my thoughts. On one occasion, when spending an afternoon with the late Mr. Pettigrew, of straw-skep fame, I put a question to him much the same as now asked, viz. 'Do you think any one could make a living off bee-keeping?' His reply to me was, he had no doubt but a man could make a living off bee-keeping provided he had a good district and every opportunity; but, he said, should two bad seasons follow in succession, he would require 'a nest-egg to fall back upon.' To proceed, then, to answer briefly 'A Welsh Bee-keeper,' let me take the questions up seriatim.

I. Bee-farming as a means of earning a living can only be done by a limited number. Any one aspiring to this position ought to be favoured with the undermentioned conditions. He must be a practical beekeeper, live in a good district for honey, roll up his sleeves, and able to do the heavy part of the work, and find a good market for his produce. To earn a weekly income of 30s. to 40s., I would say one would require to have 160 hives and do all the work of managing, with the assistance of a smart youth, except perhaps during the swarming season, when an additional hand would be useful. During the winter months the youth's services

can be done without.

The average price quoted for honey, 6d. per lb., would not pay; the lowest price I think any bee-keeper would find remunerative is 6d. per lb. for extracted, and 9d. per lb. for comb honey. Speaking from experience there are several ways to the bee-keeper for improving his income. I find this year that to produce the finest heather honey, that I realised 4d. per lb. above the current price of clover and flower honey. Creating a good market for honey and keeping it up will help greatly to improve the bee-keeper's income.

2. The outlay required to start a bee-farm, say, in spring, on a scale as above mentioned, might be put at 180% for a complete outfit. Here, again, the bee-keeper could lessen this sum if able to do his own hive-making

and section-crates during the winter months.

3. The best breed of bees, all things considered, are the blacks; for honey-producing there is no other breed can excel them.

4. The best time to commence is in the spring; it may cost a little more for stocks then, but the risk of winter is over, and the possibility of a return of money is draw-

ing nearer.

If 'A Welsh Bee-keeper' resolves on starting a beefarm I would advise him to count the cost; he should be an adept in the art, and not attempt too much to start with, beginning with a few hives would be the better way if he has all to learn. For my own part I have every confidence that a living can be made, when in case of bad seasons 'a nest-egg is there to fall back upon.'

I have only expressed my opinions here as working expressly for honey, keeping out of view the selling of stocks and swarms, &c. - WILLIAM Mc NALLY, Glenluce, Sept. 24th.

BEE-KEEPING IN THE ISLE OF MAN.

[1289.] About the middle of August I crossed over from Liverpool and set foot on the Isle of Man for the first time. Having only a few days at my disposal, and desiring to make the acquaintance of some of the resident bee-keepers and see as much of the island as possible, I took up my quarters at Douglas, as the most convenient centre. The town was very full of visitors; it was therefore an unfavourable time of the year to call upon those engaged in business. However, I visited several bee-keepers on the outskirts of the town, and found most of the bees in bar-frame hives; they were principally the native bee, some few had introduced the Ligurian, the hybrids following as a natural consequence. The drought had cut the season short; the honey harvest, therefore, was scarcely equal to the average. The honey was very good; I only saw one sample on the island approaching a dark colour.

Ramsey and the district around appear to be advancing rapidly in modern bee-keeping. I generally find where there are one or two intelligent bee-keepers who are willing to give advice and assist others, there bee-keeping is sure to advance. Ramsey is thus favoured in Mr. E. C. Kerr and Mr. Harry Corlett. Mr. Kerr was from home taking his holidays, but I saw his apiary. Hives and everything about the place conveyed the idea that he was in touch with the times, and in advance of many bee-keepers. Mr. H. Corlett is a good practical apiarist, and willing to impart his knowledge to others. Consequently Ramsey and district have made considerable progress. I was informed that bar-frame hives had increased upwards of fifty per cent in the locality during the past twelve months. Mr. Corlett being a builder, he manufactures hives. &c. I have not seen better hives sent out by anyone than those of his make that I came across in different apiaries. The worst hives I saw on the island, to my surprise, were from English makers. Mr. C. keeps about twenty stocks, consisting of Ligurians, hybrids, and native bees. He thinks the native bee will bear favourable comparison with either Ligurian or hybrid. The honey I saw from his apiary was good in colour, flavour, and substance. His average this year was about 50 lbs. per hive, some hives touching close upon 100 sections. Clover is the principal source. In the country where cottagers have several stocks I found they were trying one or two barframe hives.

I consider the Isle of Man a good place for keeping bees; the climate is favourable and the pasturage good, the bees winter well and come out strong in the spring ready for the early honey, and foul brood is unknown on the island.

Sections were generally of a good colour, the sealing on some very thick, but I did not see half-a-dozen well filled on the island; neither did I see a single shop where honey was exhibited for sale in a tempting form. The influx of visitors to Douglas is so great that I should see no difficulty of retailing in Douglas all the honey produced on the island if I had one small window in the principal street.

A Bee-keepers' Association, with an expert to make one or two visits during the year, would be a great boon to the cottagers and small bee-keepers on the island,— L. Wren, Lowestoft.

NORTH-EAST OF IRELAND BEE-KEEPERS' ASSOCIATION.

[1290.] With reference to 'Mr. John D. M'Nally's' complaint (1272) about the judges at this show, I think he is in error in supposing that they knew the respective ownerships of the entries before and while they were judging them; and so far as our department is concerned I know he is. I am sure Mr. M'Nally-whose acquaintance I was much pleased to make at the Belfast show is actuated by the best of motives, and writes in the interest of all honest-minded bee-keepers, even though his 'Protest' savours of dissatisfaction and hints at nnfairness.

Now, at the show in question, I, together with Mr. Ditty, of Newtownards, acted as judge of hives and appliances, and I saw no catalogue or any other list of the exhibitors, and knew not who owned the articles we were engaged on, except what I might guess at, till we had completed our task. Mr. Ditty took the greatest pains in co-operating with me, and though we did not quite agree on every minute point, I can safely say I have never had a more conscientious or painstaking judge to work with.—H. W. Lett, M.A., Aghaderg Glebe, Loughbrickland, Co. Down.

THE CO-OPERATIVE FLOWER AND HONEY

[1291.] In your issue of September 1st, page 378, your correspondent, 'Amateur Expert,' has been visiting the Co-operative Flower and Honey Show, held at South Kensington on Tuesday, 23rd August. I must protest against the criticism regarding the Scotch exhibit of honey; and being the exhibitor myself I wish to prove to the readers of your valuable Journal, that 'A. E.' has no knowledge of what he writes about. In the first place, permit me to say, the exhibitor of the nice lot of sections, designs, and run honey, was John D. McNally, Manager of Cowlairs Co-operative Society, Glasgow, and not Ebenezer McNally, as 'A. E.' reports.

Coming to the run honey, the exhibit was entirely flower honey, and granulated, and did not contain an

ounce of heather, as he asserts.

My section honey, which has been awarded first prize at Perth, Belfast, Rutherglen, &c., this season, goes to prove that it is of the finest quality. This, I trust, will show your readers that the Scotch honey, though not awarded a prize, was a splendid sample. And my heather honey was not clouded with wax because I had none there; all the same, I have heather honey, which I can boast of, and if 'A. E.' will supply me with his name and address, I will forward him a sample for criticism, and at the same time will let you have one also, Mr. Editor; and I have no fear to await the result of your criticism, which I shall be pleased to see in the pages of the Bee Journal.

I have always admired 'Amateur Expert' as a writer,

and do still, but sometimes I think his 'hard knocks' are uncalled for, and should not be allowed to pass unchallenged.—John D. McNally, Springburn, Glasgow,

September 14th.

[We visited the Co-operative Show held at South Kensington, and can assure our correspondent that his name was not attached to the exhibit, but that of 'Ebenezer McNally,' as 'A. E.' states. The mistake does not lie with 'A. E.'—ED.]

A PROPOSITION FOR HUMBLE BEES.

[1292.] Dear Mr. Editor,—I think the two main things why we cannot keep workers and queens of humblebees through winter are, first, the cold, and, secondly, a short supply of food. Now if, during the summer, we took a nest and transferred their brood and honey-combs to small square frames (already made), tying them in with string, we could feed up during the autumn; and then as winter came on caulk the entrance up (leaving air-holes) and transfer the lot into an attic or some warm place. I fancy by so doing the workers would not seem so inclined to die as they do now.

I am going to try the experiment. I have saved all the old combs of five or six lots of bees, and have strung them into small frames (sections with shoulders would do).

I have been an observer of humble-bees for about three years, and this is my great experiment, viz., to keep workers and queens alive until spring. Any assistance or advice will be very welcome. — DARCY GRIMSHAW, Horsforth, near Leeds.

Echoes from the Bives.

Leigh, Kent.—Wasps are numerous this year, very few queens to be seen in the spring. On an estate here last year, the workmen caught over three thousand in April and May, very few nests in the summer, only three or four to be found. This spring about ninety queens were caught, now there are a number of nests being destroyed.

Grantham, September 20th.—Not having seen a report from my immediate neighbourhood, I may say that we have had a splendid honey harvest here; from five stocks I obtained about 476 lbs. of comb and extracted honey of excellent quality, and have increased two, making a total of seven to winter; other bee-keepers have done well also in this district. My best stock (doubled according to Mr. Cowan's instructions) gave 146 lbs. and left eight combs in brood-nest untouched!—N, P.

Springholm, Dalbeattie, September 24th.—According to promise I give you the result of taking my bees to the heather. I took three stocks to the moors at the end of July and left them till last week, and the amount of heather honey which I took off the three was 12 lbs. The only reason I can give for their doing so little is the bad weather which we had here when the heather was in bloom. At any rate, I am afraid I have got enough of migratory bee-keeping, as I do not think I will venture to try it again.—I. C.

[In the previous communication of 'J.C.' there is a mistake; for Horticultural Society read Highland Society.]

NOTICES TO CORRESPONDENTS & INQUIRERS.

- A. M. Tainted Honey. After removing the section-cases by means of the carbolised sheet, the sections should have been taken out separately, one by one, in some shady corner of the garden; and the few adhering bees, brushed off with a feather, would have returned to the hive. Using smoke after removing the sections was the great mistake. The best plan will be to nucap the soiled sections and pass them through the extractor. If they were all sealed you will thus obtain good liquid honey free from taint. Any unsealed ones may be given as food to the bees.
- A Beginner.—Unsealed Honey.—1. Yes. If any combs contain unsealed honey—unless they contain brood also—pass them through the extractor. Unsealed honey quickly becomes acid, and causes dysentery and destruction to the bees during the winter and early spring months.

 2. If sufficient section cases are given, by 'tiering up,' as more room is required, a ten-frame hive is large enough for a prolific queen, especially if the outside frames are kept free from honey by extracting when required. Bottom ventilation will usually prevent swarming. It is well, however, to have hives large enough to take twelve standard frames.
- N. P., Grantham.—Broodless Colonies.—On the cessation of the honey-flow, queens often cease to lay for a time. In a strong, healthy colony, however, there ought to be brood in various stages in September. Probably you overlooked the queens. Examine again, very carefully, and if the hives are really queenless introduce queens immediately. It is not likely that colonies which cover nine standard frames are queenless, but if they were so drones would be found—and probably in abundance—in such colonies. The bees, from some whim or other, may have changed their queens.
- Novitas.—1. Queen producing Diminutive Bees.—From her producing both drones and workers in worker-cells, and the workers even being diminutive, it is clear that she is not fit, and should be superseded. 2. United Bees

fighting.—You should have shaken all the bees off the combs, mixed them with the driven bees, and allowed the whole to re-enter the hive of combs. This is better that trying to seent hoth lots. 3. Bees refusing to raise Queen.—There is most likely a queen existing, although you failed to find her. We have this year noticed drones existing unusually late in hives undoubtedly possessing queens.

Lady P.—Honey from unsealed Sections fermented. — If there is merely a layer of thin and frothy liquid on the top of the jars, and the remainder solid and good, by carefully skimming off the thin part, the solid will be good food either for human beings or bees. If the whole mass is frothy, it must be melted down, brought to nearly the boiling point and skimmed when it will be fit for food, but will have lost much of its aroma. After boiling it will keep for a long time.

J. W.—Honey candying qaickly.—The cause is the source from which the bees have collected the honey. That from rape, mustard, and plants of the same genus, candies almost immediately after extraction. The honey which you say does not candy is probably from clover. The difference has nothing to do with the systems of beeleastic.

keeping.

APS.—Honey difficult to Extract.—Heather honey cannot be extracted, and the supposed white clover is most likely sufficiently mixed with heather to render its extraction difficult. The best way to get the honey is, to shave off the cells from each side of the comb, as near the midrib as possible, give the combs for the bees to lick np, and preserve to give in the spring to be rebuilt. The shavings containing the honey may be squeezed first, and the wax melted afterwards, when the remaining honey will

Separate.
FEARPUL.—Foul Brood.—The comb sent is affected with the disease now known by the name of bacillus minor. It is a severe case.

D. P. and Corwen .- Foul-broody.

- T. Huck.—Doubtful. We have known bees so peculiar that it would be difficult to verify the fact that any individual bee worked for three hours only. Whenever we open a hive we generally find many ready to commence work; probably they are on the next 'shift,' that is, to shift the intruder. Personally, we have seldom three hours to spare to note the time bees work. The onus probandi rests with the writer of the paragraph.
- R. R. Reed.—The combs will, if well wrapped in paper to exclude wax-moth, keep through the winter at a moderate temperature, and will prove serviceable in spring, Exposure in a warm room when about to be used would be desirable.
- F. J.—Wetted Sections.—This may possibly be a case where the sections have been left on the hive too long, and the dampness, if not sticky, be the condensed moisture of the hive.
- T. Welham.—Pine-wood.—The resinous odour of the pine-wood attracted the bees, and they would use the little resin they could obtain as propolis. Neither the smell nor taste would make them drunk. In fact they would not taste it.
- J. M., Glasgow.—The sugar would be more snitable for making syrup than for dry sugar feeding. For the former purpose we should call it 'third-rate.'
- A STRANGER.—There are no shows in London at present. Your object would be attained by a visit to Messrs. Abbott Bros.' establishment at Southall, Middlesex, which is not far from your present residence.
- J. H. S.—The parasite noticed by you is the Braula cæca. It will most probably die off as the season advances.
- J. M. B.—Queenlessness.—Very few drones are flying about now. The late presence of drones indicates queenlessness. It would be desirable to overhaul your hive, and ascertain if the queen be present.

BEES AND ESSENCE OF LEMON.—The Postmaster-General in his last report states that a post-office in Gloucestershire was in a state of siege for a fortnight by bees attracted by a leakage from a tin of essence of lemon

Editorial, Hotices, &c.

MR. COWAN'S VISIT TO AMERICA.

The reception that has been accorded to Mrs. and Mr. Cowan during their visit to Canada and the United States has been most cordial; and bears strong testimony to the good-will that subsists between bee-keepers on both sides of the Atlantic. In acknowledgment of kindnesses received, the following has been forwarded by Mr. Cowan for insertion in the Bee Journal:—

We think it only right, in justice to the kindness we have received from our many Canadian and American friends here, to send a few lines to the *Bee Journal* to mention the warm, hearty welcome we have everywhere received, having been guests in several families for days.

We have, throughout our journey, been treated with the greatest hospitality and consideration, and shall ever remember with pleasure our coming over to this New World—so wonderful in its growth and spirit of progress. We shall carry away with us pleasant recollections, many of which appear later on in thep ages of the Journal. Suffice it now to say, we are anxious to state this at once that our friends here may see how much we have appreciated their kindness. We leave New York in the Umbria, which is to sail on the 1st October.

HONEY-DEW: ITS PRODUCERS.

In our last issue we mentioned the large amount of honey-dew which, especially in dry summers, was to be found on, and falling from, the leaves of certain trees,* and also the extraordinary migrations of aphides, or plant-lice. We purpose now to attempt a slight sketch of the physiology and life of the producers of honey-dew; and we feel assured that it will be found one of the most wonderful histories of the entomological world.

Those who have studied the history and economy of the hive-bee will find those of the aphis equally elaborate; and as with bees the students thereof are continually making new and unex-

pected discoveries, so those who have endeavoured to probe the arcana of the life of the aphides find themselves ever coming in contact with new questions to engage their attention,—questions which they have not been able satisfactorily to answer. Among the most interesting phenomena connected with the aphides may be mentioned—the injuries they inflict upon plants and trees, their singular migrations, their almost incredible numerical increase, their processes of reproduction, the enemies they have to contend against and their defences against these enemies, and their relations with ants, who so tenderly nurse and cherish them.

The name 'Aphis'* was given to this class of insects by Linneus; and the minds of many naturalists have been much exercised to account for his selection of the word, and many ingenious suggestions have been put forth for its determination. Among these suggestions, the readiest seems to be that the word is derived from the Greek ἀφαημι, in its sense of emitto ('I emit'); having a reference to the very peculiar office of the unique organs known as 'nectaries' or 'cornicles,' from which is ejected the substance to which we give the name of honey-dew.

It is scarcely within the province of a periodical devoted to a special purpose like the *Bee Journal*, to enter into a recondite or scientific history of the physiology of this insect, or to enumerate the numerous varieties of it. Buckton, in his *Monograph*, describes several hundred tribes; and almost every tree—the rose, the apple, the lime, the oak, the beech, the sycamore, &c.—has its special aphis; and some trees have several varieties. The aphides assume different colours according to the plaut upon which they feed. That on the rose is green; that on the bean is black; and that on the apple takes a kind of cottony appearance, called 'American blight.'

The bee-keeper, however, is specially interested in the two organisms of the aphis concerned in the production of honey-dew. These are the rostrum or proboscis,† which pierces and sucks the juice, and the two ducts on the posterior part of the abdomen through which is ejaculated the substance.

+ By some called haustellum, from haurio, 'I drain' or 'suck.'

^{*} M. Boussingault states that in Switzerland the aphides almost kill the trees; and so exhaust them of sap that a single sick tree may produce as much as three kilogrammes (about 6\frac{1}{2} pounds) of sweet substance elaborated from the juice.—Buckton, vol. iii. p. 36.

^{*} Class Insecta; sub-class Haustellata; order Hemiptera; sub-order Homoptera.

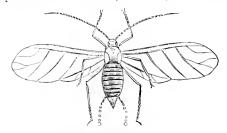

The proboscis is an elongation of the *labium* (or lower lip), which is modified into a three-jointed sheath, inside which are three sharp-pointed laneets, which have a backward and a forward motion. This suctorial organ is folded on the breast: by its means the insect pierces the skin, and extracts the juices of the leaves or the roots of plants which form its nourishment. The length of the proboscis varies in different kinds, some being very short, and others quite as long as the insect itself: it is also found disproportionately long in the young of some of the aphides. By means of this organ the juices are drawn into the mouth by a kind of pumping movement, similar to that noticed in the proboscis of the bee.

The function of the nectaries or cornicles is to give off, as the result of the suction of the proboseis, the drops which gradually accumulate at the ends of the tubes. Sometimes, as we have mentioned, these drops fall on the grass saturating with the treacle-like substance the ground, at other times on the leaves, and so choking the stomata, or leaf-pores, and thereby preventing the natural respiration performed by these pores. The nectaries vary much in form and size. In some they attain half the size of the aphis; in others they are very small; while in others they are altogether wanting. There is considerable difference in opinion as to the part these nectaries play in the economy of the The opinion that of late has prevailed is that they have some connexion with the respira-C. Morren considers them to be tory organs. nothing more than prolonged stomata, i.e. the apertures leading to the tracheal or respiratory system; and he states 'that a considerable lacing of tracheæ may be seen to start from the points at which the cornicles enter the integument.' Also, he asserts, 'that the air replaces the liquid which is ejaculated from these tubes, and that the bubbles so often to be seen within their cavities are evidences of the regurgitation of air.' Morren points out at the bases of the cornicles a gland to which he ascribes the secretion of the usually sweet liquid known as honey-dew, and which he regards as the first nourishing fluid provided for the young aphis. The same naturalist also puts forth the singular idea that there is some similarity between the Aphides and Mammifers, as he maintains that he has frequently seen the young suck the secretion from the tips of the cornicles of the mother.

By the proboscis of the aphis the soft under skin of the leaf is pierced, and the juice pumped out and eventually ejected by the cornicles. The leaves are ever forming starch, which is converted into sugar. It is quite possible that the juice in its passage through the body of the aphis may undergo some change, even as we know that the nectar drawn by the bee from flowers into the honey-sacs is in some degree changed in its qualities. It is doubtful to what extent the juice sucked up by the aphis passes through the alimentary system. This still requires elucidation.

Accompanying this we have given an illustration of an aphis, fifty times magnified,—the Aphis vastatrix or A. dianthi. C. Morren noticed the first

advent of this insect into Belgium, and he states that the countless swarms that spread over that country in September and October, in 1834, came over the

sea from England. He says that the clouds of aphides obscured the light of day, and covered the pavements of the streets. To this insect was at one time ascribed the potato disease, but further research has proved that this was not the ease, but that it was eaused by a small insect which fed upon the roots.

If we look at the under-leaf of (say) a rose where the aphides love to congregate, we shall find it infested with these insects. The majority of them will be found wingless, but some few are winged, and it is somewhat of a mystery how these latter come there. Aphides are produced from eggs, or are born alive, under certain conditions. The aphides in spring are the product from the eggs of the pre-They pass through some changes, ceding autumn. and they moult four times. The first brood are wingless, and are all females, and being wingless are imperfect females. The second generation is a counterpart of the first, and so on during the summer, to the tenth (or as some naturalists say, the eleventh) generation, without the intervention of a male. The last generation, however, consists of perfect insects—males and females—all winged. These latter are fecundated, and this renewed condition of life suffices for the next ten (or eleven) generations. The females now lay their eggs in autumn, and this closes the year's story.

Not being subject to the usual law of metamorphosis, aphides increase in an astonishing manner. Réaumur calculates that each aphis produces ninety young ones. She lives to see five generations; and if we multiply ninety by ninety four times over we shall find that it amounts to 5,904,000,000; and if the increase were allowed to go on unchecked for a single season it would be found that one aphis would produce a quintillion of aphides. One mathematician has made a calculation that if the generations were continued 300 days, the progeny would fill the universe, land and sea, so that there would not be room for any creatures but themselves. Professor Huxley makes a singular calculation. Assuming an aphis to weigh $\frac{1}{1000}$ grain, and a stout man 285 lbs., the tenth brood of one aphis would be equal in matter to more than 500,000,000 of such men, i.e. to more than the whole population of China.

Let us be thankful that there is a law of compensation which steps in and keeps these pests under subjection.

In our next we may consider the enemies of the aphides,

CANADA.

TOBONTO INDUSTRIAL EXHIBITION.

The Toronto Industrial Exhibition is the leading annual exhibition in Canada. The Association recognise the importance of apiculture, and have for the last seven years given a very large sum of money in prizes, hesides medals and diplomas. A large space is also granted for exhibition purposes, and Toronto has from year to year the largest display of honey and bee-keepers' supplies on the American Continent. There were about 40,000 lbs. of honey in the building at the commencement of the show, divided amongst a number of exhibitors, amongst which were:-

	Extracted.	Comb.
D. A. Jones, Becton	10,000 lbs.	
Ira Orois, Whithy	3400	2800 lbs.
Martin Emigh, Holbrook		1600
G. Deadman, Brussels		1500
G. B. Hodgins, Hornings Mills	800	600
Jacob Alpaugh, St. Thomas	1500	2000
R. H. Smith, Bracebridge	300	100
A. G. Willows, Carlingford	2150	
Wm. Goodger, Woodstock	700	700
R. F. Holterman, Brantford	1000	1400
E. Thompson, Burgessville	300	500
Jno. Davidson, Uxbridge	200	2000
H. J. Howie, Eden	400	400

The honey was put up in a neat and attractive manner, and a large quantity was sold during the show. The principal exhibitors of appliances were D. A. Jones & Co. and Messrs. Goold & Co.

During the exhibition a special meeting of the Ontario Bee-keepers' Association was held in the exhibition grounds, at 7 p.m., on Thursday, Sept. 16. Owing to the illness of the president of the association Mr. J. B. Hall of Woodstock occupied the chair. The occasion of the special meeting was the presence amongst them of Mr. Thos. Wm. Cowan of England and Mr. Ivar Young of Christiania, Norway. The meeting was a very large one, and many prominent bee-keepers from distant parts of Canada were present, thus showing the desire all felt to meet with these prominent bee-keepers from foreign lands. Owing to the fact that our Canadian hee-keepers had last year visited England, and there partook of the hospitality of British bee-keepers, and made the acquaintance of Mr. Cowan, the feeling of kindly interest towards Mr. Cowan was if possible greater than that towards Mr. Young. Before the formal opening of the meeting many examined, under Mr. Cowan's microscope, mountings of the different parts of the bee; these were examined by all with the greatest interest, and were very instructive. The meeting was called to order by the Vicepresident. A communication was then received from President Pettit explaining that illness prevented his presence. Vice-president Hall then mentioned the reason of this meeting, and called upon Mr. McKnight to read an address to Mr. Cowan on behalf of the Ontario beekeepers, which was as follows:-

'To Thomas William Cowan, Esq.:

'Dear Sir,—On behalf of the bee-keepers of Ontario we bid you and Mrs. Cowan welcome to Canada. As chairman of the British Bee-keepers' Association, we recognise in you the representative of a body of philanthropic gentlemen who devote much of their time to the promotion of apicultural knowledge among the artisan and labouring classes of your

own country.

'We are not ignorant of the good work you have accomplished. We know you have been instrumental in inducing thousands of your countrymen to embark in the fascinating work of bee-keeping, and thus spend their leisure hours in healthful, profitable employment. The fact that the Association of which you are the chairman (with its affiliated branches) numbers some ten thousand members attests the success of your labours. We sincerely hope that you and your associates may be long spared to prosecute the good work so well organized and so skilfully conducted.

'As proprietor and editor-in-chief of the British Bee Journal you are better known to the apicultural world than most of your countrymen. Your published works on scientific and practical bee-keeping have won for you a name and a fame far beyond your own sea-girt home. We rejoice in the opportunity this visit affords us of making a closer and more personal acquaintance with you.

'We indulge the hope that your present visit to the United States and Canada, and your personal intercourse with the leading bee-keepers of both countries will increase your zeal in the good work of teaching men the means and methods whereby the earth may be made to yield its increase of delicious and healthful nectar, which abounds in the flora in the fields and in the forests of most countries. The extent to which the honey industry may be developed is as yet but little understood, and he who labours to make it better known is certainly doing as much for mankind as he who makes two blades of grass grow where but one flourished before.

' We are especially pleased that you so timed your visit to Toronto as to be able to witness the display of Canada's industrial products now on exhibition here. A careful examination of these will help you to form a just estimate of what the people of this young country have accomplished within the present generation, and give you an idea of the resources of the Dominion. It will serve to prove to you that Canadians are not drones in this hive of British colomists, and mayhap inspire you with the common faith of our countrymen that

> " "If our past has records few In battle song or story, Our future rises fair to view, Gleaming with morning's youthful dew And bright with coming glory."

'Accept this trifle as a slight, but tangible expression of respect and esteem for you, as a man and a brother beekeeper, we wish you and Mrs. Cowan a pleasant time while you remain on this side of the Atlantic and a safe return to your home and family beyond the seas.

R. McKnight, Chairman Reception Committee, W. Couse, Secretary. Toronto, Sept. 15, 1887.'

A gold-headed walking-stick was also presented to Mr. Cowan bearing this inscription :— To Thos. Wm. Cowan, Esq., Chairman B.B.K.A. Presented by the Bee-keepers of Ontario in commemoration of his visit to Canada, 1887.

Mr. Young was then presented, in a humorous but fitting manner, with a meerschaum pipe and case.

Mr. Cowan expressed his thanks to the bee-keepers of Ontario for the address and walking-stick, and for the very kindly and warm manner in which be and Mrs. Cowan had been received by all everywhere on this continent. He then gave at some length the working of the British Bee-keepers' Association. They aimed at getting many to enter into bee-keeping and to keep a few colonies. The method of advertising honey by circulars creating a market was entered into. The examining of experts and their duties were described, their shows and a number of ideas were given to Canadians, which might be made useful in the advancement of bee-keeping in Canada.

Mr. Young then rose to acknowledge the reception he had met with. Although an entire stranger to all personally, and until lately known to few even by reputation, such a presentation had been been entirely unexpected. He trusted that ideas might be exchanged between Norway and America to the advantage to all.

He had found his visit profitable.

BRITISH BEE-KEEPERS' ASSOCIATION.

Syllabus of Subjects of Examination for the Secondclass Examinations to take place on Saturday, Nov. 12:

- 1. Natural history of the honey-bee, including class, order, family, genus, species, varieties, &c.
 - 2. Anatomy and physiology of honey-bee, including

transformations, eggs, larvæ, pupa, imago stage, &c., queens, drones, neuters, &c.

3. Products of bees, their origin and functions.

4. Swarming-its causes, objects, method, and varieties, with explanation of operations and uses, prevention, &c.

5. The apiary—its care and management, inclusive of various styles of hives, houses, varieties of bees most desirable; economy, purchasing, &c.; transferring, feeding, and feeders; queen-rearing, nuclei, increasing colonies, dividing, doubling, queen introduction, various cages for and methods of, &c.

6. Extractors—varieties, uses, methods, and opera-

tions, &c.

7. Handling bees or manipulating—full description of

various methods; varieties of smokers, &c.

8. Comb-foundation—varieties of and manner of fixing in broad-frames and supers or sections of all kinds; machines for making, &c.

Honey-plants and trees, or bee flora—most valuable

kinds, and seasons of blooming.

10. Wintering bees, various systems, both at home and abroad, with their advantages or disadvantages.

II. Difficulties of bee-keeping - robbing, diseases,

remedies, enemies, &c.

12. Calendar of operations for each month of the year, with any short terse axiom you would lay down for general success.

The books recommended are:—1. Modern Bee-keeping. 2. The British Bee-keeper's Guide-book (1s. 6d.). 3. Cook's Manual of the Apiary. 4. Root's A B C of Bee-culture.

Every information respecting the examination may be obtained upon application to the Secretary of the British Bee-keepers' Association, J. Huckle, Kings Langley, Herts. Intending competitors must give one month's notice at least to the Secretary of their County Association.

DERBYSHIRE BEE-KEEPERS ASSOCIATION.

The annual exhibition of bees, honey, and appliances, under the management of the Derbyshire Bee-keepers Association, was held on September 14 and 15, and fully proved the great progress which bee-culture has made in recent years, but particularly during the last twelve months. There were twelve entries for bees, sixty-eight for honey, twenty-one for wax, and twenty-four hives, supers, collections, and extractors, besides which there were fourteen entries for bee-manipulation, and five for expert examinations, making the total number of entries 144, which was about fifty per cent more than usual. The honey staged was large in quantity, and much of it was of great excellence as regards quality. Mr. Wood, Paradise, of Lichfield, again produced a fine trophy, while the specimens of honey sent by Mr. Glover, of Rodsley, near Ashbourn, Rev. N. Gresley, of Netherseal, near Ashby-de-la-Zouch, and Mr. A. Simpson, of Mansfield Woodhouse, were of the finest flavour and quality. The hives and appliances were a very interesting feature. In this department Mr. Handby and Messrs, Cooper again entered the lists for excellence, and the judges had some difficulty in deciding upon the merits of their exhibits. The arrangements reflect great credit on the secretary, Mr. W. T. Atkins, of Derby, who seems to have devoted his whole energies to promoting the success of the Association. The judges were Mr. T. Blow, Welwyn, Herts, and Mr. E. C. Walton, Muskham, Newark.

Bees.—For the best stock of bees of any race in observatory lives: 1, Mr. W. Handby, Hasland; 2, Mr. T. W. Jones, Etwall; 3, Mr. T. M. Bryan, and Mr. J. Dickenson, Clay Cross. For the best exhibit of sections, not less than 12 lbs.: 1, Mr. A. Simpson, Mansfield Woodhouse; 2, II. Wood, Liehfield; 3, II. Glover, Rodsley; 4, W. Handby. The best exhibit of honey: 1, II. Wood; 2, Mrs. Foster, Brailsford; 3, T. Anstin, Alvaston; 4, Rev. N. Gresley,

Netherseal Rectory; h. c. E. Toom, Etwall. The best run honey, not less than 12 lbs.: 1, H. Glover; 2, A. Simpson; 3, H. Wood; 4, Mr. I. Stone, Cubley Carr; 5, J. Pearson, Lea, Cromford.

BEES-WAX.—Not less than 1 lb.: 1, Mrs. Foster; 2, J. J.

Shipman, Ashover.

COTTAGERS' CLASSES.—For the best run honey, 6 lbs. at least: 1, R. Bridges, Harstoft; 2, E. Toon, Etwall; 3, Mrs. C. Hunnybun, Stanton Lees; 4, H. Bramley, Old Tupton; 5, J. Stevens, Breadsall. For best exhibit of comb honey not less than 6 lbs.: 1, J. Rowland, Holbrook; 2. Mrs. Foster; 3, R. Bailey, Derby; 4, T. Wilson, Ashover. For best bees-wax, not less than half-pound: 1, Mrs. Foster; 2, R. Bridges; h.c. G. Waterfield, Shottle. For the best frame-hive, not to exceed 15s.: 1, W. Handby; 2, B. Skirmer, Swanwick. For best frame-hive, not to exceed 10s. 6d.: 1, W. Handby; 2, B. Skirmer. For the best hive made by a cottager, the work of an amateur, price not to exceed 5s.: 1, G. W. Foster. For the best super: 1, Messrs. D. and A. Cooper, Derby. For the best collection of hives and bee-furniture: 1, W. Handby; 2, Messrs. D. and A. Cooper. For the best honey extractor. Equal firsts, prizes divided, W. Handby, and Messrs. D. and A. Cooper.

BEE DRIVING COMPETITION.-1, Mr. G. Waterfield, of Shottle, Belper; 2, Mr. T. Austiu, Alvaston; 3, Mr. Joseph

Rowland, Holbrook; 4, Mr. D. Cooper, Derby.

Five entries were made for the examination for third-class expert certificates, Mr. T. B. Blow, Welwyn, Herts, being the examiner.

All passed in a very creditable and satisfactory manner.

Correspondence.

The Editor does not hold himself responsible for the opinions expressed by his correspondents. No attention will be taken of anonymous communications, and correspondents are requested to write on one side of the paper only, and give their real names and addresses, not necessarily for publication, but as a guarantee of good faith. Illustrations should be drawn on separate pieces of paper.

Communications relating to the literary department, reports of Associations, Shows, Meetings, Echoes, Queries, Books for Review, Ec., must be addressed only to 'The Editors of the 'British Bee Journal,' c/o Messys. Strangeways and Sms, Tower Street, Cambridge Circus, W.C.' All business communications relating to Advertisements, &c., must be addressed to Mr. J. Huckle, Kings Langley, Herts (see 2nd page of Advertisements).

**In order to facilitate reference, Correspondents, when speaking of any letter or querg previously inserted, will oblige by mentioning the number of the letter, as well as the page on which it appears.

STARTING A BEE-FARM.

[1203.] Seeing that neither yourself nor any other of our able bee-masters and bee-farmers, have troubled to answer your correspondent, 'A Welsh Bee-keeper's" question (p. 413, September 15th), I will assume the task; for I do think it would be a most lamentable, and damning, coincidence, after so much has been preached by our leaders on this great question of beekeeping and bee-farming, that any one seeking advice should be given the opportunity of remarking he had been sent empty away. In advancing my views, I need scarcely hint to a 'W. B. K.' the importance of his weighing well my statements. I assure him my best thoughts have been given to this question, and I trust he may find them helpful in arriving at what he desires. Assuming 'W.B.K.' has a good knowledge of beekeeping and the practical working of an apiary, is not lacking in confidence and steadiness in manipulations, is prepared for some heavy work, and blessed with a stout heart to meet troubles and disappointments (for such do come at times), has good prospects of a ready market for honey, then I do not hesitate to say he may embark in his proposed engagement advantageously. 'W. B. K.' makes no remark upon his locality and his surroundings, I will therefore conclude he has fully satisfied himself as to its suitableness for the establishment of a large apiary, and would hesitate before

^{*} Our correspondent must have overlooked the valuable communications on this subject from Mr. Thorpe and Mr. W. McNally in previous number, -ED,

proceeding with even a thought of starting a bee-farm unless favoured with ample common for forage for his bees. And I would here venture to suggest to 'W.B.K.' that he build up his apiary by degrees, starting with forty stocks the first season, increasing them as opportunity offers for favourable purchase until 140 stocks are placed. He would thus gather much valuable knowledge at the early stage of his business, which should better enable him to work successfully a more extensive apiary. The very many and varied little matters that constantly crop up force upon the bee-keeper the fact that close observation is of the greatest importance. It not unfrequently happens that what would be done in a particular case one time circumstances may make it undesirable to work in the same way another.

Iu passing, I may just refer to hives. And here we have a very knotty question; of course every maker thinks he sells the best hives, and many, very many indeed, are the varied principles of their workings, each and all are so admirably constructed that no bees can fail to prosper in them and secure a bounteous yield of honey, if only given a trial! A good, well-made bar-frame hive, simple in its construction, and adapted for the storifying system, purchased from a rehable maker, is the hive I have taken as my guide. I disapprove of home-made hives as a rule; I have rarely seen any such which please me, and I make bold to assert that any one commencing a large apiary will find it the wisest and best policy to purchase substantial, well-made, accurately-fitted, new hives. I must not be understood to ignore straw-hives; if such are used, let them be of a large size with a flat top and capable of supering, for they would be found very useful and not without profit.

Coming now to bees. Here, again, we have much diversity of opinion, and from experienced men too. For myself I lean to our old blacks, and for a cross, Ligurian and black; I have found both do well, and less trouble in manipulating than some of the other breeds; if convenient it might be of some advantage to place, at a distance of (say) two miles from any other bees five stocks of pure Ligurians.

Respecting the price of honey, as I have so often expressed my views as to a paying average price to the beekeeper, I will only repeat that if 9d. per lb., or more, for good honey cannot be obtained, I would not advise any one to go into bee-keeping as a business alone. By the way, I observe that a strong tendency at the present time, and especially after this grand harvest, is to run down price; and it is not to be wondered at that the timid give way to the benefit of the trader. I have noticed at our fairs and shows persons standing side by side with honey exhibits of equally good quality; one will sell fifty or more I-lb. jars at 10d. and 1s. each, whilst the other would only sell a dozen or two at 8d. or 9d. each: here, then, steps in the tact and judgment of the vendor.

To commence bee-keeping to the extent under consideration, and, indeed, with any one starting, the best time is the spring, and with swarms of 5 or 6 lbs. weight if possible. Stocks that have wintered well, having plenty of bees, and are healthy, may often be met with reasonable by looking round amongst skeppists. The plant, hives, and all requisites, should be prepared during the early months of the year, to be in readiness. Better purchases can be made when trade is quiet than when all is bustle and driving, as will be the case later on in the season.

Having made the foregoing somewhat lengthy remarks (though unasked for), I consider it well to make them as showing in a measure the lines upon which I bave worked, to assist me in arriving at such conclusions as would warrant me making a statement upon so important a question that should not be deceptive or misleading.

The following will, I hope, show what may fairly be looked for from a bee-farm consisting of 140 stocks, under

competent management, with a capital of 300l., allowing that the average price of honey be 9d. per lb.:—

	£	s.	d.

MEMS BY 'WOODLEIGH,'

[1294.] Work for B.B.K.A.—No doubt our friends would be very grateful, after having taught them a trade -how to produce honey. We also still progress in philanthropy, and sell their produce for them at good pricessimply discover a market for them at a good price, and introduce the retailer to them for 1s., 2s. 6d., or 5s. per annum, as the case may be. Allow me to inform our friend that the members of the committee of the British B.K.A. are far worthier of having a monument erected in their memory than many I have seen have had the honour bestowed on them in my peregrinations in various parts of the kingdom. Take, for instance, the journeys per rail; the valued hours spent in working out the aims; the time spent in reading up and applying the knowledge gained, proving this and rejecting that as unnecessary; busy brains evolving new ideas and putting the same into practice, and pouring out acquired knowledge free as water in the early volumes of our Journal-and for what? Simply love of humanity, in the hope of bettering the condition of the poor cottager. Then 'Sherborne' follows snit, and thinks County Associations should exist for the sale of honey. I think—in fact, I

know-his county sec. (most likely hon. sec.) will do all in his power to place him in communication with purchasers, but retailers are not in the habit of writing hon, secs, for honey: there may be exceptions, but it is not the rule. Then, another point (and, my friend, it is a grand point), how you put up your honey for sale, Some sections I have seen have looked as though they had been turned out of a cobbler's shop, covered with scraps of wax, rather than out of the laboratory of nature-clean, v iblemished. And again, of bottles containing nature's choicest elixir, I have seen them—even in competition (at least, staged as such) for prizes! with the scum and particles of wax still floating, and forming a veritable crust over the honey. I pity the poor hon, sec. who has to push such produce as that, Still, I admit there is room for advance, and I trust that our British Honey Company will launch out in a new direction, emulate old-established commercial houses and undertakings, and place samples in the hands of old commercial travellers for sale on commission. Here is a system of intercourse, with ramifications extending to almost every village and hamlet in the kingdom. Then, again, a very considerable item of expense in the mode of putting up sections by the Honey Company is the use of cardboard boxes. I am positive that sections can be glazed both sides with strips of gummed or glued paper at sixpence per dozen on a large scale, which would be a saving of a penny on each section, thereby enabling the Company to give the producer one shilling per dozen more for his sections instead of putting it in the hands of German box-makers. Another item, and a larger one than putting up sections, is the expense and nuisance of the bottling of honey. Now I do hope the Honey Company will sell bottles at a cheap rate in the original packages only, and I believe that a good screw-cap bottle could be sold at about 16s, or 16s, 6d, per gross. Then if bee-keepers did not want so many as a gross, they could club together—co-operate—and send; and a good tie-over bottle at 10s. 6d. per gross. Here would be another penny added to the price of honey, instead of going into the dealer's pocket. Another point is that the bottles should be the correct size to hold one pound of honey. Some I have seen this season and tested hold only fourteen ounces, others nineteen ounces; in one ease the public are cheated, in the other dissatisfied if the bottles are not filled, and to fill same and sell as a pound means giving away a large percentage of your

honey (to a grateful public?)
On reference to B. B. J. I find it was Mr. Musgraye (1197) who reintroduced the question relative to the correct position of frames. In answer to same on its bearing on the foul-brood question, I cannot see how the position of frames in a bee-hive can influence the propagation or retardation of foul brood in my own apiaries. I have hives on both principles, though all new hives during past five years have been made on the so-called warm or parallel system, and I find my bees as healthy and as vigorous as those in the hives with frame-ends toward entrance. Is it not written in the chronicles of apiculture that foul brood often makes its appearance in an apiary shortly after the introduction of foreign races of bees into said apiary or district? Very probably you may get the infection from some enthusiastic bee-keeper who goes in for all and sundry in the bee world, not omitting the latest discovered strain of Apis mellifica in some out-of-the-way nook on the sunny slopes of the Alps, proving that the germs must be brought into the hive and not created by any particular kind of hive or position of frame. No doubt at some future time when apiculture comes to be recognised as one of the sources of the wealth of the country, we shall get restrictions as to the indiscriminate importations of foreign bees irrespective of their freedom from disease or not, as at present practised.

Then another prolific source of propagation of foul

brood is by the visits of careless experts, who after they have visited an apiary in which they have found the pest still continue their visits without properly disinfecting their appliances and themselves. As regards proper disinfecting I do not profess to be able to give instructions; if empty hives require two years' exposure to kill the germs maybe the woollen garments of the expert would require more; but I do think an expert should discontinue his visits to other apiaries after he has examined and manipulated the hives in any apiary having foul brood. The mistaken kindness of associations in lending appliances, such as extractors travelling from apiary to apiary, possibly carrying the germs of bacillus in them and spreading it far and wide, is another cause; but mapping the counties out into districts, I am happy to say, has curtailed the danger from travelling appliances. Still, there is another and a greater chance of contagion, that is, by purchase of stocks, swarms, or driven bees from infected districts. The only remedy I can see for this danger would be the issue of a map by the B. B. J. indicating by red colonring the infected districts, leaving the other parts white with simply the names of the counties and a few of the most important towns marked.

Those harmless, inoffensive creatures yelept wasps, of which 'W. M.' speaks in such high terms of praise in a previous number, must be of very different habits to wasps in my own neighbourhood, or 'W. M.' (glad his initials were not two 'W's') must have championed their cause without any investigation or observation of their propensities or habits of thieving, as to their not clearing out hives in twenty minutes, --perhaps not, but I know from experience they can carry off a pretty good quantity of some things in a short time. I remember some years since—I think in '63 or '64—the wasps carried off during a Sunday over thirty pounds of sugar left in a grocer's sugar-mill. 'W. M.' may think, perhaps, the bees had a share of the plunder, but when the store-room window was closed on the Monday, the besiegers were wasps only, proving who the thieves were, so that they were not flycatching or going in quest of larvæ on that particular day; and to think of 'W. M.' asserting that wasps are as valuable as bees, why, bees have done more in the economy of nature for the benefit of mankind than any other insect in existence.

As many of our bee-keeping fraternity may not be able to get the soap mentioned a short time, I may mention that methylated spirit procurable at any chemist or oilshop is an effectual solvent for propolis and other stains on the hands, applied with a bit of rag or sponge.

The writer of 1242 must have a novel style of arithmetic if he can manage to crowd into 'less than one shilling' the following articles enumerated in his letter, viz., corned beef box 4d, strips of zinc say 1d, eight frames presumably Abbott's, at $2\frac{1}{2}d$, 1s, 8d, putty and paint at least 4d., (paintseller to lend a brush?) $1\frac{1}{2}$ yards of unbleached calico say $4\frac{1}{2}d$: he says, of course, 'there is an outer covering,' costing, no doubt, another 1s, with paint and putty, our friend should have said a few shillings, 'not less than one shilling.'

Was it a printer's error that the initials to a recent letter was 'C. A. M.', surely it should have been 'C. R. A. M.' re the 30,000 stings, or must we excuse him and think well after the first thirty stings his mind was confused, or that the mistake may have occurred through blindness from the swelling, and he could not see or remember how many cyphers he added after the figure 3. Is the colony of stingless bees still in existence?—WOODLEIGH.

BEES AND MANURE-HEAPS.

[1295.] Bees, we know, are possessed with a very acute sense of smell, and as 'W. J. S.' presumes, this exquisite sense attracts them to the vicinity of manurcheaps. Why such should be the attraction, I am sure I

do not know. I feel confident that if my olfactory nerves were much more sensitive than they are, it would cause me to give such places a 'wider berth.' Bees do visit these places, but in very small numbers. The question is, why do they visit them? Mr. Boyes says, 'to drink of the liquid found there,' and further states that 'my eyes have seen bees drinking at manure-heaps,' &c. It is also a fact well known by many bee-keepers—careful observers: it is therefore an incontrovertible fact, a truth. The italics are mine.

Now, Mr. B., don't think that I am going to absolutely negative your assertion, but simply to ask you to notice a little more carefully, and then I think you will agree with what I am going to write. We must jam just a little ehemistry into this controversy, but I will put it into as simple a language as I possibly can. The bee ou alighting proceeds to the edge of the liquid just where it meets the straw or other vegetable substance, or more correctly speaking, on the line of efflorescence; and it is upon this line, the point where evaporation takes place, that the bee's attentions are specially directed. We shall there find that just at this point hippuric acid is formed; that is, an acid contained in the urine of horses or beasts, as its name denotes. The starch contained in the vegetable substances with which it comes in contact, is acted upon by the acid, and thus formswhat?—glueose—sugar. After this a reaction takes place into which we need not inquire.

Now all this sounds very strange, but, nevertheless, it is true as far as the chemistry of decomposing animal excreta is at the present understood; but this is in a very unsatisfactory condition, and very little is known by chemists about the subject, so that everything above may not be the correct theory although it looks very much like it. Well, now don't turn up your nose at honey, because there is just nothing in all this: the amount obtained is so infinitesimal that it would have no effect upon the bulk in the hive, even if this substance were taken without any preparation and placed in the cells; but such is not the case, as after being swallowed by the bee it goes through another transformation, and no doubt comes forth as very good honey. We manure our gardens and enjoy the proceeds, and yet these cabbages, potatoes, &c., have all partially been formed from what has been put in the ground, but by certain chemical changes the same has been rendered fit for human consumption. So it is with the bees and what they collect. We do not eat the manure-heaps when we eat the honey, but only what through chemical reaction has been rendered fit for our use. In the case of honey this reaction takes place in the air—in our sight. In the case of vegetables it takes place in the groundout of our sight, the true cause of any seeming disgust.

Now with regard to larval food (not honey alone but a mixture), being stored in the cells before being fed to the bees; this is without doubt an error. Unripe honey will be found stored there, but not prepared larval food; this is a material partially digested by the nurse-bee and fed direct to the larvæ. Kindly refer to B. B. J., page 185, April 28, 1887. I have never found prepared larval food stored in the combs contiguous to the larval cells; it has always been unripe honey, the same as stored in any other part of the hive in unsealed cells. The only prepared food found is that minute drop with which the egg is surrounded just before and after it hatches.—W. B. Webster, Binfield, Berks.

FOUL BROOD.

[1296.] Having noticed the correspondence for some time past re foul brood, I should like to give my first experience of it.

About April this year I discovered that five of my stocks were infected, although when they were packed for the winter there was no sign of it. I immediately placed a small piece of camphor under the frames in

each hive, two of them I treated according to Mr. Cheshire's directions, i.e. reduced to number of frames bees could cover and extracted all honey that was possible, and poured phenolated syrup into combs every evening, feeding also with phenolated syrap. I also forwarded a piece of comb with brood to Mr. Cheshire, who wrote me that it was undoubtedly foul broad. I carried out this treatment for about four or five weeks, when, becoming rather disheartened at no improvement taking place, I drove them from the hive into two swarm-boxes, destroyed all the combs and frames and fed with phenolated syrup for five days and then hived them both in one hive on frames with starters of foundation only, but unfortunately they had the misfortune to lose both queens, as I did not take the trouble to remove one of them; but one of my other stocks having a sealed queen-cell I cut it out and inserted in the stock, which was duly hatched and fertilised and is going on all right with no sign whatever of any disease; and I may add that all trace of the disease has entirely disappeared out of the other three hives, although nothing was done with the exception of the camphor being placed under the frames, and they now appear to be my strongest stocks. Since I have become acquainted with the disease, instead of using the smoker I have substituted a spray-diffuser with Calvert's carbolic acid No. 5 diluted. - F. Hughes, Long Lane, Finchley.

EXTRACTING FROM BROOD COMBS.

[1297.] It seems a pity that there should be any squabbling on this subject. Apparently the original writer referred to extracting from combs in which there is unsealed brood, a practice which for various reasons seems to be undesirable. That bees do go to unsavoury places there can be no doubt. I have often seen them in a pig-stye, and have also seen them in a railway station urinal. Probably, as one of your correspondents suggests, they may be in search of salt which might be supplied to them in a cleaner form.

With regard to drone-comb, that bees will have it I have found on more than one occasion. Once, when I had without thought given full sheets of worker foundation, the hees worked it all out but half of the outside of one of the outer sheets, this they made quite smooth, and started a drone-comb from the top at an angle. Another time, under the same circumstances, they made a piece of drone-comb on the dummy at the back. I took this off, cut away a corner of the last comb and inserted the drone-comb, they joined it in neatly, and then were quite satisfied.—J. W. N.

A NOVICE'S EXPERIENCE IN BEE-KEEPING.

[I298.] My experience only dates back to last year. My hives stand within 200 yards of the shafts of one of the largest collieries in the county of Durham, and I was told it was folly to dream of keeping bees in so smoky a district. Last year, 1886, I had one stock which I purchased about three miles away from here (there are no hives nearer to mine than about one and a half miles); it was weak in numbers and yielded that year about 28 lbs. honey in sections and a frame about 5 lbs. In August 1886, I bought a hybrid stock on six frames, they came by rail, and I won't forget the transferring of the frames from that bex into the hive I had for them. They are perfect demons those hybrids. At the commencement of this season I worked both lots up by giving sheets of foundation till No. I had nine frames (all it would hold) and No. 2, ten frames. On June 15th I bought a swarm and put it into a hive of my own make. I gave it six full sheets and two strips of foundation, afterwards adding two frames of full sheets, in all ten frames: this is No. 3 hive. Results-from No. I I have taken ninety-six good 11b. sections and a frame of 5 lbs.,

from No. 2, 52 lbs. in sections. I have not moved any of their ten frames, nor shall do so till later. They are all solid so far as I can see: these are the demons. They made the best sections—just solid slabs. From the swarm No. 3 I have obtained thirty-one splendid sections and two frames, each over 5 lbs. weight, and they are left with eight frames nearly all solid. In fact, I was thinking of taking two frames from them in the front, so as to leave them on six.

On July Ist No. 2 hive swarmed, they had on a crate three parts full. I raised it, put an empty one beneath, and put them back in the evening; I did not want to increase the stocks of this race. I took my first sections

off on July 7th from No. 1 hive.

On September 10th I drove ten skeps for a gentleman I had made some frame-hives for, one of these was still empty. I fixed six frames with some of the comb out of skeps and put the bees out of four skeps into the frame-hive; the other six skeps of bees I brought away in two skeps and put them into two frame-hives, each on two frames of comb, and four sheets foundation feeding with syrup regularly since. I drove the ten skeps in two and a half hours, and had them to carry forty yards without floor-hoards, these being fixtures. I never saw a hee attempt to sting. The gentleman and his family had not seen any driving before, always nsed the sulphur pit, and they were delighted. They have given up the skep. This, Sir, is my record up to the present, and I have to thank your Journal and the useful work Modern Beekeeping for the little I have learnt.

I have tried various new articles, such as apifuge and carbolic acid, but have not had experience enough to

give an opinion.-T. T. M.

HONEY BY THE POUND.

[1299.] Having given a report of the heavy yields of honey obtained by the more advanced bee-keepers in some of the districts of Lincolnshire, which yields were secured under what may be considered at the present day ordinary management, I now enclose you a report of the light yields of honey, obtained under what I will style extraordinary management by inconvincibles. I beg, Mr. Editor, you will not suppress this report, even at a risk of its doing incalculable evil by your publishing it; but if you should consider its publication might be the means of driving ten thousand otherwise well-disposed persons into such a state as to render them eligible only for Hanwell Ah! ah! sup- no, don't suppress it, please, let it go, not to Hanwell (might tell the door-keeper at that establishment to be prepared for a rush), but to press, away from page 424 for the present.

I report the following as the results of the honey harvest by some of our genuine old skeppists. During the early part of last month I visited in villages eleven beekeepers, whose total stocks together numbered seventy-eight, all in straw skeps of the small dome-top make, except three or four which were large and flat-topped. The bees consisted of old stocks, swarms, and casts. Out of the number I drove thirty-six stocks, which yielded a total, as near as I am able to state, of 390 lbs., an average of a little under eleven lbs. per stock. The heaviest of the lot gave seventeen lbs. of honey, the lightest gave $6\frac{1}{2}$ lbs. only. The whole of the hives had more or less of brood in them; the combs built cross-way of entrance,

or verging that way in nearly every hive.

Returning again to page 424, I would ask Mr. 'W. N.' how this report snits. He has the opportunity of reading a heavy-weight report and a light-weight report, himself having furnished a mid-weight one. 'W. N.' speaks of suppressing reports of the good takes of honey. Allow me to ask him to glance through a report from 'A Lancashire Bee-keeper' (page 425), 'A Barrow-load of Solid Slabs of Honey-comb.' Here's an eye-opener for him. Only follow nature's simplicity itself: a few old

bricks, and here's a hive for 'nawt,' and honey by the barrow-load. Would 'W. N.' desire that such an interesting report as this should be suppressed?—R. R. Godfrey, Grantham.

HONEY BY THE HUNDREDWEIGHT.

[1300.] I find by the last issue of the British Bee Journal that I am not the only one who does not get the coveted boon, as per 'Welch Novice' (1270), but friend J. H. Rogers (1266) lets out the grand secret. He says that he can with confidence count upon 100 pounds per hive.' But how does he do it? Hear what he says: 'Of course I prevent swarming, and take care to have young queens' (the italics are mine) 'at the head of each colony, and I give each hive thirty-eight to forty frames of standard size.' Here he has four ordinary colonies rolled into one enormous hive, at least 4 ft. 6 in. long, unless he works on the tiering system, and then he produces 100 pounds of run honey; and, I say, a very small yield after all, only amounting to 25 pounds per ordinary hive when divided into four. He says he does not feed except for stocks made up of driven bees. Now I would like to ask my friend Mr. Rogers two or three questions. Suppose he gets a new stock of bees from driven bees, or from a new swarm or swarms, how many swarms or lots of driven bees would be put into this monster hive in order to well cover forty frames? Would he be certain there would not be more than one queen preserved among such a vast quantity of bees? Queens are supposed to fight a duel when they meet in one hive, but I think in this case their chance of meeting in such a hive is very small. But suppose Mr. R. starts with only one swarm, with one young queen, would she be likely to fill such a hive with bees, and produce 100 pounds of honey the first season? I say no, she would not; but by putting three or four swarms together, he might. Then, I maintain, it is not the work of one swarm or hive, but the united work of three or four hives or swarms. Another question. Does Mr. R. winter his bees on forty frames, or even twenty? If so, how many frames will they cover by the middle of April? Will they cover six frames? Hence, if there is only one queen, the (to me) impossibility of one queen filling with bees such a hive in time for the honey-flow. I may not be in the happy possession of the necessary moderate skill or intelligence for the successful management of bees, therefore I would be most thankful if Mr. Rogers would kindly answer my questions, and oblige an unsuccessful brother hee-keeper.

From my experience I believe there is often more than one queen in one hive at the same time during the honey-flow. This season I hived a new swarm early in June; the next day another swarm went into the same hive; in the evening I put another hive on the top of it, which was immediately taken possession of; they went to work with a will, and in about seven or eight days they nearly filled the both hives,—being Taylor's observatory,—when they swarmed again (which swarm I lost). I let them remain until they had again well filled the hives with bees; 1, about a month since, divided them, putting the one with the most bees on a new stand and quite another aspect. I expected, of course, to see a great commotion in a short time with one of the lots, but, to my surprise, they took it very quietly, and so have remained, only some of the old bees went back to

the old stand.

A friend of mine wintered two stocks in one hive with two entrances. In the spring he stopped up one entrance and removed the division-board, leaving them to run together without smoke or in any way disturbing them. They blended together without any fighting whatever, and jointly soon filled the hive with bees, giving a good harvest of honey, but still less than 100 pounds. The hive with one queen could not have filled it in the time. I, therefore, am of opinion that where

we see those large yields of honey from apparently one hive, it is the result of three, four, or perhaps more, swarms united together, hence the production of not one hive but many, properly speaking.

I attribute the smallness of my honey harvest to the long drought. The white clover with us, as well as many other sources of honey, were completely burnt up

before one half became properly developed.

I have been anxiously waiting to see if some one had any plan to propose for the better sale of honey without the *middle man*, but as yet no one has ventured to propose a plan except our Irish friend, which is a good one. I think the B.B.K.A. should move in this matter.— Sherborne, *Dorset*.

HIVE-MAKING.

[1301.] Seeing a letter in last week's British Bee Journal, re above, I though I would give the particulars of my own experiments to those of your readers whose pockets—like my own—are somewhat shallow and light. I bought a current-box from the grocer's, which was 2 ft. 6 in. long, 11 in. deep, and 13 in. wide (inch wood), at a cost of 3d. Finding the width inconvenient, I bought another box for 2d., called, I believe, a pineapple box, anyhow, branded on one side were the words, 'Pine-apple, preserved in syrup.' This was 18 in. long, 11 in deep, and 14 in wide (inch wood). I also bought an egg-box—these can be had for 6d.—and thought myself well stocked with material, at any rate for making a first-class hive. I now took the current and pine-apple boxes, knocked out the ends of both, carefully taking out all nails, and nailed the sides of the pineapple one to the sides of the currant one. This gave me a hox 2 ft. 6 in. by 18 in. I then took one 9-in. beard off egg-box, which gave me the two inner walls, nailed them $14\frac{1}{2}$ in. apart in the above-named box, which finished body of hive. Now for the floor-board and roof. I found on examining the wood I had left there was plenty to make a moveable floor-board, porch, and a span-roof deep enough to hold a doubling box or two crates of sections. To cover the roof well for winter I painted one coat, then tacked on cheap calico, over which I put two or three good coats of paint. This has made it quite proof against wind and tide. Thus I have a good hive, helding twenty-two frames, a doubling box, or four crates of twenty-one 1-lb. sections (two inches deep and two in length), for the sum of about 1s. 6d.

I began bee-keeping September 21st, 1886, with one hive; I have now tive, three made up of driven bees this year, one an artificial swarm from first hive, so that I begin to feel myself a real live bee-keeper.—CHARLES

Howes, Ayleston Park, Leicester.

SUPERS LEFT ON BAR-FRAMES.

[1302.] When reading your 'Useful Hints,' that no super should be left upon the bar-frames during the winter I have often wished that the writer had said why it ought not to be done. Suppose a crate of unfinished sections remained upon the frames, what injury to the bees would possibly occur? Warmth must certainly be one result.

Are not the following 'hints' conflicting? viz.,' the second crops of red clover are affording superior pasturage for our Eastern races, which leave no petal unvisited in search of the precious nectar,' and 'sections should be removed without delay, and the honey extracted from those unsealed.' If bees were gathering 'the precious nectar' on the 1st inst., why should not they be permitted to deposit the article in the cells prepared for that purpose?

My simplicity, it is probable, will create a smile—you won't ridicule me I know—please remember I am only

-An Aged Amateur.

P. S. I have great pleasure in being able to add that I

saved a colony from a violent death a few evenings ago. Wholesale apiarian murder has been perpetrated in my neighbourhood within the past few weeks, eleven stocks in one place, nine in another, and many, many other groups have gone down the sulphur pit. A friend gave me permission to drive one let on condition that he witnessed the operation. I succeeded in driving out a quantity weighing in the aggregate more than two pounds, which I had the additional pleasure of seeing enter the 'Ark (hive) of safety' on the following morning there to feast on the sweet contents of a bar-frame that I had taken out of an adjacent hive.

NOTICES TO CORRESPONDENTS & INQUIRERS.

Letters or queries asking for addresses of manufacturers or correspondents, or where appliances can be purchased, or replies giving such information, can only be inserted as advertisements. The space devoted to letters, queries, and replies, is meant for the general good of beckeepers, and not for advertisements. We wish our Correspondents to bear in mind that, as it is necessary for us to go to press in advance of the date of issue, queries cannot always be replied to in the issue immediately following the receipt of their communication.

- R. Williams.—Bees lying out.—It is unusual for bees to cluster outside the hive so late in the season as the end of September. Warm weather, small hives, and large colonies, may be the cause. Some bees, especially the black race, will lie out in large clusters on the alighting-boards to defend themselves when attacked by wasps or raiding bees.
- J. S. Webb.—Drones, Queens, &c.—1. It is the general opinion that drones produced by an Italian queen impurely fecundated, are pure Italians. 2. It is thought best to rear queens from a mother in her second year because she is then in her prime, and surrounded by a larger colony than in her first year; both points being of great importance in producing a strong, healthy progeny.
- A BEGINNER.—Foul Brood.—The comb sent is affected with 'foul brood.' It is not a bad case, but bad enough to advise the destruction of the stock, if, as you say, there are no other cases in the neighbourhood. Fill the empty combs referred to with a weak solution of carbolic acid, and then allow it to drain out completely, putting them away m a warm place for future use. The combs can be filled by plunging them in the solution, frames and all.
- RICHARD WILLIAMS.—Diseased Brood.—We are very much of opinion that you have the disease known by the name of Bacillus minor; but before giving a definite answer we should prefer to see the comb, or a portion of it, untouched. If you have any more hives, examine them and report their condition. Do this before you touch the stock supposed to be diseased.
- G. H. Richardson.—1. Bees Utilising Wax.—It is well known that bees will utilise wax, even after it has been rendered into blocks. The very fact of their drawing out foundation into combs is an argument in support of this. We have been frequently annoyed when drying sheets of foundation, after passing through the wet rollers of the machine, at their visits, when they would gnaw the edges and fly off with the spoil. It is a most unusual thing for them to fill up the under part of the feeder. This, no doubt, arose from the circumstance that there was considerable—too much—room between the top bars of the frames and the bottom of the feeder. Thanks for photograph. 2. Bees with White Backs.—The white pollen on the backs of the bees is from the giant balsams, which are now in full bloom. When collecting this they will get as dusty as millers; the pollen on their backs they are unable to remove effectually, and so fly forth with it on.

ERRATA.—P. 423, in letter 'Not finding the Queen,' line 7, for York read Norwich.
P. 432, Third-class Certificates—for B. Skerman read B. Skirmer.

The Co-operative Flower and Honey Show.—Mr. W. Broomhall, secretary to the above show, writes as follows:
—'Mr. John D. McNally has requested me to put the matter of the ownership of the Scotch exhibit of honey at this show right. The entry was made in his name, but how the error in the name upon the card arose I cannot explain.'

[PUBLISHED WEEKLY.]

Editorial. Motices. &c.

BRITISH BEE-KEEPERS' ASSOCIATION.

The usual October Meetings will take place at 105 Jermyn Street on Wednesday evening next, October 19th.

The Meeting of County Representatives will take place at 4.30. Secretaries of County Associations are requested to advise their representatives of this meeting.

The Quarterly Conversazione will commence at six o'clock. Members wishing to introduce subjects for discussion, or to submit new inventions and improvements relating to bee-culture, are requested to communicate with the Secretary without delay. This meeting will no doubt prove an interesting one, as Mr. Cowan who has just returned from visiting the United States, and having inspected some of the largest apiaries in the world, hopes to be present.

HONEY-DEW: ITS PRODUCERS.

In our last issue we noticed the enormous fecundity Bee-keepers, not desiring that the of the aphides. genuine produce of their bees should be contaminated by honey-dew, have especial cause for rejoicing that there are many insects whose life-mission appears to be the reduction and destruction of aphides. Stormy weather and heavy showers sweep them away like-

wise by myriads.

The foremost of these insect enemies is the lady-bird. or lady-cow (Coccinella septempunctata). As the locusteating thrush is always to be found accompanying the locust so does this insect seem ever to be in pursuit of the aphides. The food of the lady-bird appears to be almost exclusively the bodies of these insects. In the Journal of Horticulture of September 22, 1887, a correspondent dating from Whitcroft, Pershore, writes:-'On Saturday last about half-past three in the afternoon we had a great swarm of lady-birds, thousands upon thousands; we could distinctly hear the noise of their flight. Is it usual for them to move in such large Have they been seen elsewhere?' can be no doubt that these visitants were in quest of the aphides which commit such devastation in the hop-

Mr. Buckton, in his Monograph of Aphides, says of

lady-hirds:—'The marvellous voracity of lady-birds is shown equally in their larval and their winged condition. The former stage may be commonly seen throughout early summer as slaty-grey or brown six-footed creatures, covered with tufted tubercles, and provided with mandibles efficient both for holding and sucking out the juices of their victims. In some years the imagos are wonderfully numerous, and when they take wing, form vast swarms, which travel great distances. By their sudden appearance in a district they often raise popular astonishment. In the year 1869 such a cloud passed over a large part of Kent, Sussex, and Surrey, alighting on the footways of Maidstone, Guildford, and Midhurst, and making it difficult to avoid crushing hundreds under foot. In the autumn the perfect insect often enters houses for hybernation, and clusters of many hundreds may be seen in crannies and under the ceilings, and in the angles of the walls of houses within the hop districts. These clusters sometimes are so large that a half-pint measure would not contain them. Although the coccinella is not restricted to the hop aphis for its food, it frequently follows its migrations, and travels on the same winds. It is also a valuable visitor to the apple orchard, and destroys thousands of *Aphis mali* and *Aphis pruni*. Whilst feeding the aphis is seized by the lady-bird near the back, and the liquid contents are quickly sucked out of the abdomen, about one minute being required for this process. The aphis is held and manipulated by the jaws and palpi of the coccinella, and the devouring operation proceeds, amidst the struggles of the victims, from the tail to the thorax, which parts, together with the head and legs, are finally rejected.

The special aphis which falls thus a victim of the lady-bird is the Phorodon humuli, and the ravages committed by these insects on hops are very great. It is stated that in the year 1802 the excise duty paid on hops of the previous year fell from 100,000l. to 14,000l., and this falling off was ascribed entirely to the ravages of this insect. In 1833 it is stated that the duty paid for hops when 'the fly' was absent amounted to half-a-million.

It is very fortunate that in most countries the children take lady-birds under their protection. In France they are considered sacred to the Virgin, and are called Vaches à Dieu, Bêtes de la Vierge, &c., and in this country the frequent mention of lady-birds in our juvenile ballads insures them kind treatment from young people. The hop-growers are fully sensible of the value of the services of these insects, as they hire boys to prevent the birds from destroying them.

Besides the Coccinella, there are other aphidivorous insects which subsist on aphides. There is a beautiful genus of winged flies (Hemerobius), their wings resembling the finest lace, the larvæ of which are such voracious devourers of the aphides that Réaumur has named them 'the lions of the aphides.' When among the aphides they are like wolves in a sheep-fold, and the ravages they make among them are very great. It takes

them only half-a-minute to suck the largest aphis, and there is one species which clothe themselves with the spoils of their helpless victims. Many species of the Syrphide are also very destructive to the aphides. Their grubs are armed with a singular mandible, furnished with a kind of trident with three points, and with these they transfix their prey. Dr. Kirby says:—'They may often be seen laid at their ease under a leaf or upon a twig, environed by such hosts of aphides that they can devour hundreds without changing their station; and their silly, helpless prey, who are provided with no means of defence, so far from thinking of escaping, frequently walk over the backs of their enemy, and put themselves in his way. When disposed to feed, he fixes himself by his tail, and, being blind, gropes about on every side, as the Cyclops did for Ulysses and his companions, till he touches one, which he immediately transfixes with his trident, elevates into the air, that he may not be disturbed by its struggles, and soon devours. The havoc which these grubs make amongst the aphides is astonishing. It was only last week that I observed the top of every young shoot of the currant-trees in my garden curled up by myriads of these insects. On examining them this day, not an individual remained, but beneath each leaf are three or four full-fed larvæ of aphidivorous flies, surrounded with heaps of the skins of the slain, the trophies of their successful warfare; and the young shoots, whose progress has been entirely checked by the absorption of sap, are again expanding vigorously.

There is also a small ichnenmon-fly (Ophion luteum), which alights on the body of the aphis, and deposits an egg in it; the wounded victim then separates from its companions and dries up, having the larva within it.

It only now remains for us to describe the singular re-lationship of aphides and ants. In all accounts of honeydew it is agreed that bees and ants are very fond of it. The loves of the ants and aphides have long been celebrated. Wherever the latter are found there will the former be seen very busy; the object of their presence is to suck the saccharine juice which exudes from the nectaries. When the ants are at hand, they watch the moment when the aphides eject the fluid and at once suck it down. It is also said that the ants have the power of making the aphides yield the nectar at pleasure, or we might say 'milking them.' Linnaeus says, 'The ant ascends the tree that it may milk its cows, the aphides, not kill them.' When they do so, they use their antennæ for fingers; with these they pat the abdomen of the aphis on each side alternately and rapidly, and after the drop has been obtained they pass on to another aphis. P. Huber, who studied the habits of ants for many years, has told us some almost incredible stories of the treatment of aphides by ants. He says that a certain kind of ants regard the aphides as their special property, and are ready to fight for their possession, and that the Aphides radicum—which derive their sustenance from the roots of plants and grass—are kept in large numbers in the nest of the yellow ant (Formica flura), so that there may be always at hand a plentiful supply of food, these aphides and their eggs sharing the solicitude of the ants equally with their own eggs and young.

Strange as these statements are, such are the wonderful instincts of ants that it does not behave us to regard them as incredible, seeing they are given as the result of patient research by scientific investigators. Mr. Backton, in commenting on the above phenomena, says:—'It will be unwise to put limits to the peculiar phases of insect economy. Extraordinary ingenuity and unexpected habits are continually pressing on the observation of the entomologist. Perhaps the only safe conclusion arrived at with reference to aphis and formica [ant] is, that the latter is a considerable sugar consumer, and that like man it also is a fosterer of pets and favourites.'

Reverting to honey-dew, we find that many curative

virtues are ascribed to it. In some parts of Italy the villagers collect it from the elm-tree, and it is used for dressing wounds under the name of Olia di S. Giovanni (the oil of St. John). The knowledge of the healing qualities of honey-dew is not confined to Italy. Bonnet says that both physicians and ants rush to aphides for their secretion—'of which medicine use is made.' Mr. Cooke, in the Entomological Magazine, says that 'the liquid found in the pseudo-galls of the elm is, under the name of "Ean d'orme," collected in France, and is supposed to be a cure for sore eyes. After the galls are dried, a balsamic residuum is found within them, which, under the name of "Baume d'ornean," has some reputation for diseases of the chest.'*

It would be very desirable if the intelligent analyst of the British Bee-keepers' Association (Mr. Otto Hehner) would undertake an analysis of honey-dew. We should thus be able to judge whether its component parts are as bad as represented by some bee-keepers. The analysis that we have given from M. Boussingault has been questioned by another eminent chemist, and therefore cannot be pronounced to be satisfactory.

Our observations on honey-dew and its producers have extended considerably beyond our intention when we selected the subject for comment; but our apology is that one part has so insensibly led to another that we have found ourselves compelled to treat it more fully than we had originally intended.

CANADA.

We are enabled, by the aid of the Canadian Bee Journal, to give a fuller report of the remarks of Mr. Cowan on the occasion of the presentation of the address and walking-stick by the Ontario bee-keepers at the Toronto Exhibition, than that of last week.

In replying to the address Mr. Cowan stated that when he received the invitation to visit Toronto, he had no idea of being made the recipient of any souvenir at the hands of the bee-keepers; he had found much pleasure in the visit, both to himself and Mrs. Cowan, and the present moment found him unable to express his feelings. He felt that British bee-keepers would accept the souvenir and address as a mark of esteem to themselves. Until now he had had no idea of the extent of Canada's resources; in 1862 Canada had sent a fair exhibition to England, but that of last year had been a great improvement. He was very much struck with the products he had here seen on exhibit, particularly was he pleased with that of the Great North-west. In the honey department he found a magnificent display of honey; the exhibits were made by but few exhibitors but on a large scale.

Speaking of the British Bee-keepers' Association, he explained that it was a philanthropic society whose desire was to get as many cottagers and others in moderate circumstances into the business as possible—they wanted everybody to keep bees-the society was formed as a means of bettering the condition of the working classes. The Association distributed thousands of circulars explaining the uses of honey as food. The Canadian commissioners did a great deal last year in popularising honey among the masses. The Canadian system of selling 'honey on a stick 'did not commend itself to him. England would not copy them in that respect. The B.B.K.A. endeavoured to get as much wealth and as many great people in their ranks as possible. The President of the Association was the Baroness Burdett Coutts, a lady far famed for her philanthropy and liberality. The Vice-Presidents were members of the Royal Family and the principal nobility in the land. The head centre of the Society was in London, and the counties were generally taken as dis-

^{*} Buckton, vol. i. p. 44.

tricts. The Lord-Lieutenants of the counties were generally chosen as presidents of the county associations. Each of the branch societies was represented in the London Association by two delegates, and there were at present forty-two branches. The head association meets the delegates once every quarter, when all the business relating to the county branches was considered. counties were again divided into sub-districts, and over these were appointed local advisers. All the shows are held under the auspices and rules of the head association. When branch associations are to be organized, lecturers are sent out to explain the advantages of bee-keeping, and circulars are distributed explaining 'how bee-keeping may be commenced' and the cost. After the local association is formed and they comply with the conditions, showing that their new organization is in good standing, the central board receives the application, and if everything is satisfactory the new society is taken in and 'affiliated.' Experts are appointed by the central hoard, after examination, in three classes—a third-class expert is usually a good practical bee-keeper; a second class must be further advanced, while the examination of a first-class expert was very severe, and required a thoroughly practical and theoretical as well as scientific knowledge of the business. The duties of the experts are to visit each fall and spring all the bee-keepers who desire their services in the district for which they are appointed—this is all done free of charge. The time allotted to each bee-keeper is three-quarters of an hour; if more time is requested by the owner of the bees, a small extra fee is charged.

Before closing, he said that he desired to say that the Ontario Commissioners did their work wonderfully well at the Colonial Exhibition. Britons had tried to do their duty, but failed, because they could not entice them to leave their work. The delegates said their object was to sell honey, and sell it they did. He (Mr. Cowan) would return to England with very pleasant recollections of his visit. He had one weakness, and that was to possess: a walking-stick from any countries he was visiting, and he had just been suggesting to Mrs. Cowan that he should have to get one before returning. There was nothing he would have preferred more, and the stick would always remind him of the happy time they had spent in Canada, and it would be handed down to future

generations as an article of much interest.

Amidst much applause, Mr. Cowan sat down, and was followed by Mr. Young, who begged to be excused from more than expressing his heartfelt thanks to the association for his kindly reception. He assured those present that should any of them ever visit Norway, he and his brother bee-keepers would be only too glad to show them hospitality. He would never forget his visit to Canada, and he would carry home many pleasing re-

collections of his trip.

Mr. Allen Pringle was then called on by the chairman and he expressed his pleasure at being present. He was just recovering from the most severe illness of his life, and he had strained a point to be present. He had been grievously disappointed that he had been unable to receive Mr. Cowan after extending the invitation and having him (Mr. C.) go so much out of his way to accept it. He felt that there was room for much improvement in their own association. It was a good thing to encourage everybody to keep bees, though there were those who were inclined to keep the art within the select few. As to their stage of advancement as bee-keepers, he felt that Canada was equal to Britain, in fact, she was, in his opinion, equal to any country in the world. After some further remarks by Mr. Pringle, he was followed by the Rev. W. F. Clarke, who said: 'It affords me great pleasure to join with my fellow bee-keepers of the Province of Ontario, in welcoming our visitors from the mother-land, and from remoter Norway. I am especially glad to have the opportunity of uniting in expressions of

esteem and gratitude with which we all regard our friend—for such he has truly proved himself—Mr. T. W. Cowan. We have learnt from our commissioners to the Colonial and Indian Exhibition, with what unwearied kindness he laboured to promote their personal comfort and the success of their mission to England, and we all say from our very heart, "Thanks, a thousand thanks." I would have liked the inscription on the cane to have recorded our gratitude, but though the engraver has done wonders with the space at his disposal, it was not possible to include all of which we wish our little present to remind him. Let me emphasize our thanks as the very first thing he is to remember when he picks up or looks at his "walking-stick," which we all hope he may live to carry for many, many, happy, useful years. Mr. Cowan's address is fruitful of points on which I should like to touch, did time permit. I think we may take a leaf or two out of English apiculture to advantage. The plan of sending round experts to give private instruction and public lectures on practical bee-keeping, is one that we shall be wise to copy. Our English brethren, we have heard, do not encourage making a specialty of bee-keep-They believe in spreading it all over the country, and interesting the masses and the millions in keeping bees. So do I. During all the years that I have been at work in the promotion of this pursuit both by tongue and pen, I have sought to popularise it, and especially to induce farmers to go into it on a limited scale, in connexion with other branches of husbandry. Bee-keeping is a branch of agriculture, and bees belong properly to the live-stock of the farm. I believe too that the logic of events will bring round this state of things. Our specialists have suffered much during the two bad seasons just passed, and must surely begin to see that it is not wise to put all their eggs into one basket. Moreover, in large apiaries, it is terrible when foul brood breaks out, and it is far less likely to spread when bees are kept in small apiaries widely scattered. This kind of bee-keeping also renders it far less easy to over-stock a bee-range. Our American brethren, some of them at least, are inclined to invoke the protection of law on behalf of specialists, but it does seem a rather hard thing to forbid people from going into this fascinating pursuit in a small way because a monopolist has acquired exclusive territorial rights. I cannot think this style of bee-keeping likely to be that of the future, but rather that the English method in this particular will become increasingly equivalent. With best respects and kindest wishes on behalf of our visitors I beg to conclude these few imperfect remarks.

Some remarks were then made by Messrs. Jones, Corneil, McKnight, Clendenning and Emigh, all expressive of their pleasure at meeting Messrs. Cowan and

Young.

Mr. Cowan also spoke, at length, respecting the extent of the bee-pasturage, compared it with that of the old country, and recommended a more extended development of the home market.

USEFUL HINTS.

WEATHER.—Again we are favoured with fine, mild weather, and bees are flying freely, and carrying home loads of pollen. Several of our colonies are breeding more extensively than we like at this late period; and numerous drones are on the wing, notably Italians and Cyprians, so that with brilliant sunshine, as we write, several late-hatched queens will have an opportunity of mating.

Late Fecundation.—If snitable autumnal weather a fine, bright October could be depended upon, we see no reason why fecundation should not be as successful now as earlier in the season. Indeed, we have on several occasions had queens fertilised in October which proved to be of more than average fertility. Three years ago we procured the pure fertilisation of an Italian queen on November 6th. This queen we still possess, and she has proved herself a prolific mother. This we consider an exceptional case, as also is that of a Cyprian queen which mated on the thirty-first day of her age, and proved a good mother. One great advantage of late fecundation is that a queen may be mated with a drone of any selected race with much greater certainty than at an earlier period of the year, when ordinary drones are most abundant.

Winter Preparations should be completed as soon as possible. On this subject we may refer our readers to former 'Hints,' but we wish to reiterate the advice to keep none but strong colonies for wintering, unless it be a few well-stored nuclei for supplying queens, which are often required at spring. Contraction of hives and union of weak colonies may still be effected during fine weather. We do not, as a rule, recommend the wintering of colonies which cover less than eight standard frames. Upon these frames the bees should be crowded, by means of division-boards, and well covered by warm quilts, chaff-cushions, or section-cases filled with chaff, or cork-dust. As before stated, we cover with enamel sheets, warm quilts, and straw covers capping the whole. Under this treatment some fifty colonies passed through the last winter, severe as it was, in perfect health, and without a single loss, but with entrances at summer width.

Syrup-feeding should have been completed ere this; but where it has been neglected, it may still be carried on during fine weather. In a cottagers' manual, lately issued, we find in the monthly calendar of operations, under the heading 'September,' 'Rest and be thankful.' For that important month no other advice is offered. But going on to October, we are advised to 'commence feeding early in the month, and under November 'to finish feeding early in the month.' These directions are contrary to our preconceived ideas in modern times, and we fear that the cottager who complies with them, in case of a cold October, will find his weak colonies, which required food in the antumn, requiring none at spring.

CLEARING UP AND STOWING AWAY.—During the present month the only work requiring attention should be a thorough cleaning, drying (where necessary), and storing of all apiarian appliances. Extractors, especially, should be thoroughly washed, cleaned, and dried, before being put aside for the winter. The same rule applies to all utensils used for honey or wax. The apiary should be rendered neat and tidy; and a little sawdust, or sand, scattered around the hives will tend to preserve bee-life. Combs of sealed honey, which have been removed from colonies having more than sufficient, must be wrapped in paper and stored in dry and warm rooms or closets to be ready for spring use, in preference to feeding with

Uniting.—Unions of weak colonies, weather permitting, may still be made, if neglected hitherto, and queens may still be introduced. But to all we say, Get these operations performed as soon as possible, and do not attempt them at all in unsuitable weather. Better it is to forego them than to ruin colonies by manipulation in cold, wet, and stormy weather.

Roofs.—Especially be careful to ascertain that all hive-roofs are water-proof, and all stands sound and firm.

Observatory Hives.—Let frames and bees be transferred at once from observatory to well-made wooden hives, and securely packed, as advised above, for winter. It is almost certain death to colonies to attempt to carry them through the winter in glass hives.

Entrances. — As soon as robbing and wasps have disappeared open the entrances of the hives. These should not be less than six inches in width and 3 in. in depth. Healthy ventilation and dry hives will thus be secured; and, having attended to all these suggestions, then, we say, ' Rest and be thankful.'

OUR CENSORS AND MENTORS, - Although, in the space allowed to us, we are unable to enter into controversy or to assign a reason for every scrap of advice given, nevertheless we are always willing to explain any apparent discrepancy, or any view to which exception may be taken when advanced in our department. Ou the other hand, we will not hold ourselves liable to answer trivial exceptions, put forth for the sake of leading up to controversy, or from other motives which we have no desire now to investigate. If our experience in apiculture, together with the daily practical work in a large apiary, conducted on modern principles, is insufficient to qualify us for giving advice; or if we have failed to display sufficient rovg—to use a very expressive term—in our contributions to the Journal, we are more than willing to lay down our pen and to make room for others to take our place, of whom, we are perfectly well aware, there are sufficiently well-qualified candidates.

But, after digression, to the point.

HANS ERSLEV AND DRONE COMB.—First, as regards the building of drone-comb. We were pleased to see the Danish editor's, Hans Erslev's, remarks on this subject. Our short statement was not intended to advance any theory on the building of drone-comb, and we made no wonderment of the case related, as Hans Erslev seems to suppose. For nearly half a century we have been fully aware of the propensity of the bees to build drone-comb for the storage of honey. This, however, is almost always placed outside the broad-nest, and usually as remote as possible from it. In the oldfashioned supers, drone-comb was the rule and not the exception, and during the present season many of our sections, supplied with full sheets of the finest thin worker foundation, were filled with drone-comb built thereon, and stored with the finest quality of honey. But the peculiarity of the case we related was this: that the lower halves of all the combs consisted of dronecomb, built upon the most perfect worker foundation of which we have any experience, which we have used extensively for several years, which hitherto has been built into perfectly beautiful worker-comb, and of which one dealer alone relates that he sold in one year in this country about 50,000 lbs. weight; and he is not the maker, neither has he more interest in the sale of this foundation than of any other. So much for the quality of the foundation of which Hans Erslev says, I am sure it was bad foundation. That the drone-comb in the central frames in the case related was not built for storage was proved by its being filled with droue brood. The queen (a favourite) is in her prime, the drones have all been destroyed, and the hive has a large population of Italian workers. It is no difficult matter for the bees to cut away the slightly raised wall-bases of workercells on the flat-bottomed foundation, leaving the flat septum intact, and to build thereon drone-cells. In a cottager's skep a few weeks ago we met with a case precisely similar, except that no foundation was given. Here, too, the lower halves of the combs consisted entirely of drone-comb, and the upper halves were well stored with honey.

An Aged Amateur regrets that in the 'Useful Hints' of September 1st we admit 'that no super should be left upon the bar-frames during winter," and also regrets that we did not say 'why it ought not to be done.' In the first place, 'Aged Amateur' should quote us correctly. The whole advice on this subject consists of a few words, viz., 'sections should be removed without delay where neglected hitherto, and the honey extracted from those unsealed.' The word 'winter' is not mentioned. However, our advice certainly is that no sections should be allowed to remain on the hives during winter, and for a good reason. If they contain unsealed honey it will quickly ferment, become acidulated, and

cause dysentery. If the honey is sealed it will granulate and become very like lumps of ice. And lastly, but by no means the least evil, the section-case will cause dissipation of the heat ascending from the bees below, and condensation will take place and cause the moisture to descend upon the combs and bees, rendering the whole damp, mouldy, and thoroughly unhealthy, and during long and severe frost the inner sides of the case will be covered with sheets of ice. Therefore we say, 'Remove your section-cases, and contract your hives for the winter, allowing as many combs only as the bees can fairly cover, and place over the frames woollen quilts, chaff-trays, &c. Again, we never use the word 'bar-frame' or 'bar-frame hive.' Frame and frame-hive we think amply sufficient to describe what is meant. A frame is a frame without the prefix bar, the meaning of which we should be sorry to be asked to define. But 'Aged Anateur' charges us, moreover, with making conflicting statements — which, we suppose, means contradictory because we advised the removal of sections, without delay, on September 1; while at the same time we asserted that our Eastern races were collecting honey from red clover, and wittily (witlessly?) remarks, 'If the bees were gathering the precious nectar on the lst September, why should not they be permitted to deposit it in the cells prepared for that purpose?' Could anyone really be so simple-minded as to suppose that we recommend the removal of sections while they were rapidly being filled? Like 'An Aged Amateur,' we are on the 'down-hill of life,' but not yet, we trust, in our dotage. So we allowed our sections to remain, and subsequently removed many of them beautifully filled with luscious nectar collected from our red clover fields by our Eastern races. But since, perhaps, not one British bee-keeper in a thousand keeps the Eastern races (and in our experience black bees do not gather nectar from red clover), and since, owing to the long-continued drought in most districts, there was no red clover to be rifled of its nectar—ours being an exceptionally strong loamy soil which retains its moisture longer than most soils, our second crops of red clover were productive of nectar—and since, also, the honey-flow in most districts had ceased long before the first September, and we write for the masses, the beginners, and the ignorant, therefore we advised the removal of sections on September 1. Our contemporary, The Bee-keepers' Record, in its current number of October 1, p. 200, remarks: 'We hear, more often than many suppose, of surplus honey being "still on the hives" so late as October. Why it should be so, in the face of our constantly-repeated advice to the contrary, we do not know, except it be that some of our readers are too busily occupied in other ways to pay any attention to their bees at this season. This, it need hardly be said, is not sensible bee-keeping, and is sure to end in failure.' So that, although we have not practised what we preached to others, yet, in giving the advice, we have sinned in good company. We write thus simply to give a reason for the advice offered to those who need it, and not from any expectation or desire of influencing skilled apiarists like the 'Aged Amateur,' who will no doubt continue to keep his supers on the 'bar-frames' through the winter months.

A Mouse in a Bee-Hive,—While packing hives up for the winter at Shipley Glen, Saltaire, I came across the skeleton of a monse in a straw hive. The creature had managed to creep in, but it had no sooner entered than Mousy was stung to death, and the bees, unable to carry off the carcass, carefully removed and conveyed outside the hair, the skin, and flesh, leaving the skeleton neatly picked. The parts of the mouse they could not reach were neatly sealed with wax from the air, and there was not the least particle of smell in the remains of the little quadruped. -WM. DIXON, Belmont House, Beckett Street, Leeds, October 4th.

Correspondence.

The Editor does not hold himself responsible for the opinions expressed by his correspondents. No attention will be taken of anonymous communications, and correspondents are requested to write on one side of the paper only, and give their real names and addresses, not necessarily for publication, but as a guarantee of good faith. Illustrations should be drawn on separate pieces of paper.

Communications relating to the literary department, reports of Associations, Shows, Meetings, Echoes, Queries, Books for Review, &c., must be addressed only to "The Editors of the "British Beo Journal," c/o Messrs. Strangeways and Sons, Tower Street, Cambridge Circus, W.C.' All business communications relating to Advertisements, &c., must be addressed to Mr. J. Huckler, Kings Langley, Herts (see 2nd page of Advertisements).

**In order to facilitate reference, Correspondents, when speaking of any letter or query previously inserted, will oblige by mentioning the number of the letter, as well as the page on which it appears.

OUR HONEY IMPORTS.

The total value of honey imported into the United Kingdom during the month of September 1887 amounted to 2002. (From a return furnished by the Statistical Department H. M. Customs to E. H. Bellairs, Wingfield House, Christchurch.)

HONEY YIELD—YOUNG QUEENS—HIVES.

[1303.] I notice in your issue of October 6th that 'Sherborne' (1300) asks me a few questions, and I will briefly answer them. In saying that I took care to have 'young queens at the head of each colony' I did not mean that I had more than one queen in a hive, and regret that I misled 'Sherborne.' He says that as I prevent swarming and give thirty-eight or forty frames to each hive I have 'four ordinary colonies rolled into one enormous hive.' Of course if he expects to quadruple the number of his colonies every season, and only allows a colony ten frames, he must not expect much surplus honey.

In reply to 'Sherborne's' question as to how many stocks of driven bees or swarms I put into one hive, it entirely depends upon the number of bees in each stock or swarm. In one case this autumn I put the driven bees from four small skeps into one ten-frame hive, and a few days later I drove those from a very large skep and obtained enough bees from it to cover ten frames, and did not, therefore, unite any others to them.

It would be only waste of winter stores to put into one hive sufficient bees to cover forty frames as mentioned by 'Sherborne.'

In reference to what he says about queens, I always inquire from the owner the age of the queens, and when driving destroy the old ones, allowing the young ones to fight for the throne. 'Sherborne' need not have any fear that more than one queen will be left alive when stocks or swarms are united. He asks whether if I start with a swarm the queen would be likely to fill with bees a hive of forty frames the first season. I certainly think not, but have never tried; and he must bear in mind that it is one thing for bees to fill a hive of forty frames and another for them to require that number to entirely prevent swarming and get the largest possible honey yield.

'Sherborne' also asks upon how many frames I winter my bees? As a rule ten, never less, and rarely more than twelve. He also asks whether a stock which only covers six frames by the middle of April, would require forty frames at the time of the honey flow? I should say they would not; but with such backward stocks one cannot expect good results. Twelve frames at least ought to be thickly covered with bees by the end of April and twenty by the end of May.

The hives I employ are of two kinds—long ones with twenty frames, upon which I place a doubling box long enough to hold twenty more; and short hives with twelve frames, and two doubling boxes containing

fourteen frames each. When I put on doubling boxes I always put empty combs or foundations in the lower section of the hive, so that the bees pass them when going in and out. It is by adopting this principle, and very carefully shading the hives and giving a great deal of ventilation that I have for the last four years entirely prevented swarming. To allow the sun to strike upon a hive in the summer is most injurious in many ways.

I have not for several years worked sections, as I have not the necessary time, but have given my attention to perfecting the most simple and practical plan for those who are from home during the day to obtain the best possible results in run honey. As to selling honey I cannot say anything, as I give mine away, or let it be sold at bazaars for charities, and my only object in keeping half-a-dozen hives is the pleasure I derive from studying the habits of insects, especially bees, and my desire to induce the working classes and farmers to make some use of the hundreds of tons of honey that are yearly wasted for want of bees to collect it. I have had to do with bees for about thirty years, and have, I think, read every book upon apiculture printed in the English language, and the more I study the question the more I feel that we do not get anything like the best results obtainable from our bees. I do not at all despair of ultimately getting 200 lbs. of run honey per stock taking the average of seasons, though we have no heather to give us a second crop of honey-yielding flowers, hut we must be as careful to breed our queens from the best parents as florists or farmers are to raise their plants or cattle from the best obtainable strain. Until one has studied this point one can have no idea of the enormous difference in the quantity of surplus honey obtained from a stock, the bees of which are the children of a really first-rate young queen and one in which the queen is only of average quality.—J. H. Rogers, Glyncoed, Llanelly.

RE FOUL BROOD AGAIN.

[1304.] I suppose I must reply to the 'Man of Kent,' as he may consider me discourteous. He says I have made a very great mistake in supposing Mr. Simmins condescended to act on my advice, because he cannot find one word in his communication in which he says he has had any practical experience of foul brood during the last twelve months, and indeed it is proved on the evidence of Mr. Hollier that he has not experienced it during the last five years. When, then, did Mr. Simmins use the Cheshire remedy? It was given to the world three years ago. He must have paid me even a greater compliment, and accepted my ipse divit without any other proof than is contained in Mr. Cheshire's original observations, and written an article giving emphatic approval and confirmation of my advice without any trial whatever; and this, from such a 'shrewd man,' is beyond all expectation. But why should the 'Man of Kent' refuse to buy queens of any breeder of queens who had been known to have foul brood? Does he not in the same letter tell us that it is not a disease of the matured bee, but only of the grubs? And 'if the queen gets the disease, how is it that it does not kill her?' I should have thought he would have been anxious to prove the consistency of his arguments, and rushed off to Rottingdean and said, '1 understand, Mr. Simmins, you have experienced foul broad; I want some of your queens to show how lightly I value the popular error. Please ensure them coming from badly diseased stocks, for I wish to prove it is only a disease of the grubs after all.' This would have been noble conduct on his part, it would also have proved how to tell a diseased queen, and have given Mr. Simmins the opportunity of expressing his regret at being unable to comply with his request, and advising him to send off to 'friend Ward' for the needful queens, who doubtless had them, although he said he had stamped out the disease. But like the boy who wrote up 'No Popery! he runs away from Mr. Simmins on the bare suspicion of foul brood, because he sells queens, and yet he does not believe the disease affects queens at all. It is useless to argue with a man who dishelieves everything except that the disease is caused through the use of bar-frame hives, and that it can be cured by simply taking away the combs.

I do not submit a proposition for argnment, but I state a fact, and opinions are worthless in presence of fact. What I say now ought to have been said by Mr. Cheshire three years ago, just as it is said by Mr. Cheshire three years ago, just as it is said by Mr. Simmins. I go further, and say that with our present knowledge of the disease, so long as only one diseased queen exists in an apiary, or in a locality, the disease cannot be kept down. I do not say an attack of the disease cannot be cured without removing the queen, or by other means than the Cheshire remedy, but I do say when all other means have failed this will succeed. I believe it is the missing link in the chain of evidence against the fearful criminal, and it will take the 'Man of Kent' (or any other man) all his time to upset it.

Here are full directions for curing a diseased stock which has defied all other means, viz., a stock with a

diseased queen:—
1st. Take out all the combs and wash the hive with medicated syrup of the Cheshire standard, taking care to wet every part of the inside; then return the combs, limiting them to the number which the bees will cover. 2nd. Next day spray the combs well with the syrup, shaking the bees off each comb for this purpose. A good drenching is desirable. Do not spare the unsealed brood, but do the work thoroughly, keeping the syrup off the bees. Return the combs as they are thus treated, and cover up, not too close. 3rd. Next day remove the queen (and send her to Mr. Cheshire), introducing a healthy one the same evening, and next morning put on the bottle of syrup, feeding briskly at first. After five or six days examine the combs closely, and where the grubs have a slightly yellow and sickly appearance, force them out with a syringe charged with the syrup. A good one for this purpose is made of an indiarubber ball and about two inches of a tobacco-pipe for a nozzle. Place the end of the pipe to the cell and squeeze vigorously. This should be repeated at intervals of a few days until the cure is completed.

I also recommend placing a bottle of syrup on every healthy hive in the apiary during the above operations as a preventative of infection. Of course it is understood that all syrup used is of the Cheshire standard.

According to my own knowledge and experience this will 'never fuil,' and I regret to say my experience of foul brood has been very long and extensive.—Thos. F. Ward, Church House, Highgate, 3rd October.

P.S.—I should not think of attempting the cure of any diseased stock between September and March.

FOUL BROOD, &c.

[1305.] I am only a new subscriber to your Journal, but I have learnt a lot by reading it in a little time, especially about foul brood; I never heard of it before taking your Journal. I was rather surprised when I read the last paragraph in the 'Man of Kent's' letter last week,—that the fell disease is travelling in the wake of the bar-frame hive, and it set me thinking if I was doing a wise trick in casting away my skeps and taking to the bar-frames. I should like him to explain the why and the wherefore. Does he think it is because there is too much draught in the bar-frame? because, if so, nothing would be more easy than to make a bar-frame as free from draught as a straw skep. He cannot think they are too close, as no frame-hive could be closer than an old skep with the top bunged up and the side propolised fast to the floor-board. Come, friend, 'Man

of Kent,' to use your own words, I think you are on the wrong track this time; we shall have to look somewhere else for the cause of foul brood. My grandfather kept bees in wood hives, 'not bar-frames,' and he died without ever dreaming of foul brood. I should think the disease has been imported into this country, not in barframe hives, but in or on queens and their attendants.

It would be a good thing if 'Man of Kent' would try and get the man with the diseased stocks to destroy them, and not help to spread the disease by perhaps selling them to a new beginner, and very likely they may go into a district at present clear of disease; it would not be a very nice thing to do. I have heard it said that a Yorkshireman would sell his stepmother if he could make sixpence out of her, but I never heard of one who had foul brood and tried to sell it to some one else.

I should like to ask your numerous readers if they have ever known of a wasp's nest being attacked with foul brood. I took one this year that certainly contained rotten brood. I wanted the larvæ for my birds, so I put on my veil and dug it out. The wasps seemed to he very listless, and there was scarce a grub in the nest that was not rotten, and the smell was fearful, so I put the whole lot back and filled up the hole with soil. Could bacillus minor be the cause of this?— Yorkshireman.

TAKING AWAY DISEASED QUEEN.—FOUL BROOD.

[1306.] In reply to Mr. Ward's query as to where he can find the statement of Mr. Cheshire's, to the effect that a queen must be removed if infected with Bacillus alvei ere a cure can be effected, I would refer him to Bees and Bee-keeping, volume 2, page 567, line 11, which reads, 'Where the queen is diseased probably no treatment will be efficacious until she has been replaced .-J. T. Harveyson, Finchley, October 5.

THE SECRETION OF NECTAR.

[1307.] The secretion of nectar by flowers is a subject of considerable importance and interest to bee-keepers, and also to botanists; but whilst the former concentrates his interest on its production from a financial point, the latter restricts his interest on scientific grounds. The chemist also has something to say with respect to its composition, hs tells us that it is starch converted into a variety of sugar, flavoured with the aroma peculiar to the species of flower from which it is gathered.

This conversion of starch into sugar or nectar cannot be manufactured artificially by the chemist, as he is unable to impart the all-important quality aroma. This alone can be accomplished by Nature in her own grand laboratory. The domain of Botany has charge of the organs that produce this sugary liquid; therefore, if we appeal to any student in this department of science he will gladly show us the secreting glands, which are situated at the base of the petals or on the disk of flowers; he will further tell us, if we are so inquisitive, that Nature's object in placing them so low down at the further part of the flower is to compel her winged agents of cross-fertilisation to more effectually perform their important mission.

If the nectar-secreting glands were placed on the ontside of flowers instead of the inside, cross-fertilisation, which is so important, in fact necessary, would be reduced to a minimum. The varied methods—how Nature employs her insect agents, how special flowers can only be fertilised by special insects, how the different parts of a flower occupy different positions, according to maturity or age of any individual flowers—is a vast and extensive field of inquiry.

While our bees are thus gathering us the sweets of the

earth, they are, with the same effort, unknown to them, — and, indeed, unknown to thousands of ourselves — accomplishing another work, the importance of which we could more fully appreciate if one could possess St. Patrick's magic-wand, and banish the little innocents from the land.

The bee-keeper, however, is most concerned about the production of nectar, rather than the benefits his bees do to the fruit and seed grower and to Nature. It is essentially an £ s. d. question, or, at least, a good surplus per hive with him; he knows the exact time, within a few days, when the queen of all honey-secreting flowers (white clover) commences to bloom and to elaborate material for his supers, and he has all in readiness for the few weeks' 'honey-flow,' viz., colonies of gigantic strength, and supers waiting to be filled. Still, it sometimes happens that even hives at this boiling point fail to obtain more than they are able to live upon from day to day. Many bee-keepers, too, are at a loss to know the reason why certain high-class bee flowers fail to secrete honey with them. Climate, soil, altitude, individually or combined, are the great factors in determining the secretion of honey without the requisite degree of moisture, and the chemical food required by any particular plant, -the sun might give us his warmth and light for ever without producing the all-important nectar. I may venture to assert that one day's rain in early June of the present year would have increased the general honey-yield in England at least fifty per cent. We had most brilliant sunshine and warm, balmy nights, but no rain, consequently honey-yielding plants were prematurely ripened, and, in many instances, the flowers were scorched before they had time to open their buds.

In a subsequent paper I hope to give the merits of a few plants that have been under my observation, with a view of testing their honey values. Hy. Dobbie, Thickthorn, Norwich, Oct. 7.

ONE HUNDRED POUNDS PER HIVE,

[1308.] May I venture to give my small experience in support of Mr. Rogers' 100-lb. theory? In 1886 I bought a swarm, sometime about middle of June, and put them into a hive containing fourteen frames. When full I put on two section-boxes; the result was I took about sixty lbs. of honey during the season. This year the same hive, with the aid of a doubling-box same size as the body of the hive and without section-boxes, has produced certainly not less than 100 lbs., and I do not think I should be wrong to say 112 lbs. It is now the best hive in my apiary (numbering six), having abundance of bees and stores left for wintering. I can say positively that there is only one queen, as there has never been a queen-cell made in the hive. I have also a driven lot put into hive September 1886 which has produced sixty lbs. this season. I am only a bee-keeper of two years' standing, so do not consider myself an authority, but should be inclined to say that seventy-five per cent of the hives made are too small.—R. SUTTON, Ruddington, Nottingham, October 7.

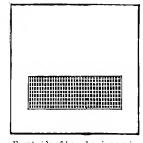

HONEY BY THE HUNDREDWEIGHT (1300).

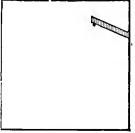

[1309.] Your correspondent 'Sherborne, Dorset,' is evidently not yet quite ready to believe if it is possible to get the above weight of honey from an ordinary stock of hees in an ordinary hive. With your permission I will give my results this season. I should perhaps say, first, this is only my third year as a bee-keeper, therefore I am yet but a novice. I commenced the season with seven stooks in fairly good condition and from which I have had three swarms. As I live nearly a mile from my apiary I tried to prevent swarming as much as possible, and therefore worked on the tiering principle. Most of my hives hold twelve standard frames in the

body. These I never disturb during a honey flow, and above I worked two and in some cases three crates of sections. On the 13th August I had taken 523 lbs. of extracted and comh honey from my seven stocks, and I then took them to the moors, and since they came back have taken over 100 lbs. more from them, leaving each hive not less than thirty lbs. to winter on. Although this is not an average of one cwt. per hive, it will, I think, be conceded a fair average, especially when the distance I am away from the bees is taken into account. I have not the slightest doubt that a competent bee-keeper residing in this locality could in an ordinary season count upon and get 100 lbs. per hive with as much confidence as 'J. II. Rogers.' I may add that from my best hive (Ligurians) I have taken 118 lbs.—C. A.

AN IRISH WASP-TRAP.

[1310.] Take an ordinary box with lid (which screw down), cut a piece (say, eight inches long by three inches wide) out of the front side, cover this opening with wire gauze or glass (wire gauze is best, as it allows smell to attract wasps); now make a hole in one end, three-quarters of an inch in diameter, and insert a tube, made either of wire gauze or perforated zinc, abont six inches long. The hole should be about six inches from underside of lid, so as to allow the tube to incline upwards, drive a nail under upper end of tube to prevent

Front side of box showing position of window, covered with wire gauze on inside.

End of box showing tube inside resting on nail.

it falling down. This trap has been most successful with me when bottles were not noticed. Insert any extracted comb or pieces of comb inside hox as a bait. Strange to say, I have not had one single bee enter, although my trap stands in front of hives, and is at time of writing stocked with at least a 7-lb. swarm (?) of wasps, which I would gladly exchange with our friend who is fond of them for some of his bees, to replace two hives of mine killed out by the 'yellow demons.' The same box, if made large enough, will answer well for clearing supers by pushing tube outside. 'Waspie' can surely get all he wants with a few of these, for which no patent right is asked.—Co. Wexford.

CURE OF FOUL BROOD.

[1311.] I can most fully sympathise with bee-keepers who are troubled with foul brood, and should rejoice to hear that it was completely eradicated in every apiary in the country. Some years ago I was troubled with it in my apiary, and only succeeded in curing it by destroying all my hives, section-cases, &c., and isolating the bees. Last year it appeared again, and I determined to try another plan, and I am happy to say that I think it has been completely successful. The disease appeared in two hives in June, the very height of the honey season, when section-cases were on, and the bees seemed full of activity. Most vexing! What was to be done? First of all, I placed a lump of camphor in each hive, both infected and non-infected. This I have renewed ever since, and imagine that it has prevented the spread

of the disease, for it has not spread beyond those two Then I tried fumigation with thyme, but it appeared to have no effect whatever. I then tried fumigation with salicylic acid, fumigating the hives thoroughly about every third evening. This seemed to check the disease, and to cure it so far as the slightly affected and open cells were concerned, but to leave untouched the very bad and closed ones. I then removed some of the worst frames—they were very bad—and opening all the suspicious cells of the other frames, poured into them and around them a liberal supply of syrup medicated with Cheshire's cure. I did this a second time after about a week's interval, continuing also the fumigation with salicylic acid, and soon had the satisfaction of seeing that all trace of the disease had completely disappeared. Early this spring I changed the hives, using the previously infected ones after simply painting them twice with salicylic acid, but boiling the section crates, &c. used on those hives with strong carbolic acid. No sign of the disease has appeared all this year, although it has existed all the time in the immediate neighbourhood, and on a recent examination of every frame in my hives I could not see the slightest trace of it. I may mention that I dethroned one of the queens, but left the other, and the result was that the colony presided over by the new queen was so feeble in the spring that I was obliged to unite it to another, but the one with the old queen was so strong that it gave me one of the largest swarms that I have seen. I should be glad to hear whether any other bee-keepers have tried the same plan-viz., Cheshire's cure, salicylic acid, fumigation, and camphor combined, and whether it has been equally successful with them. The disease is so vexing, disappointing, and disastrous, that any remedy seems worth a thorough trial.

Heddon's hive has not succeeded well with me so far. I could not induce the bees to go up through the zinc excluder when I separated the brood-nest, except to hatch out the brood in the upper half. Perhaps in a better season they might have been more obliging, but as the drought came on they got into a bad humour.

Grimshaw's Apifuge I have found most useful. It has enabled me to discard gloves, and to handle the bees much more comfortably.—Sussex Rector.

THE PLATELAYER'S REPORT.

[1312.] Just a line to tell of my success this season. In spring I commenced with fourteen stocks. Made an artificial swarm of the whole of the flying bees of one stock, and placed brood-combs in an upper storey on top of another strong colony. At one time this lot was made up of four storeys altogether—forty-two frames; but, unfortunately, the queen would persist in laying eggs in the four centre combs throughout the whole pile, by that means causing a vast amount of labour in securing the harvest.

Now for results. My best hive was the Stewarton, from which I secured 60 lbs.; my worst, thirty-six 1-lb. sections,-altogether from the thirteen colonies 580 lbs., viz., 250 sections, 270 extracted, and the 60 lhs. from the Stewarton before mentioned. My increase in stocks is one natural swarm, which was returned to the old hive after having removed all the brood-combs save two. The removed combs, nine in number, were split up into three nuclei; the queens hatched, and became fertilised in due course, and are now amongst the best stocks I have. It has been my good fortune to escape foul brood so far. Until this autumn I had never seen it, now it is within a half-dozen miles of me, introduced into the neighbourhood by the beautiful Italians (not frame-hives, perhaps 'Man of Kent' will please note). I could give another instance of the dire disease being given-1 was going to say, perhaps sold would be better -with a straw skep of the interesting foreigners.

Viewing the above facts, I do not feel disposed to change my stock, like a recent correspondent. After handling a great many stocks of bees, I do not think the English hee is easily beaten. I know many advanced hee-keepers advocate Eastern races, but much is in management. To cite a case in point: An enthusiastic bee-keeper, perhaps the owner of twenty stocks, is fired with the ambition to outdo his bee-keeping neighbours. He sends off for a queen of one of the fancy races. In due course she arrives, and is introduced to the best stock which he possesses. Every attention must be paid to this particular hive, and often the remaining nineteen are wholly or partially neglected. At the end of the season the happy owner is loud in praise of the new variety; and no wonder, seeing one guinea was paid for the queen, and gold must be looked after. Season No. 2 comes round, the thing is old now, and if you ask then how about your fancy races, where are your Syrians, Cyprians, Carniolans, &c.? echo answers, Where are they? At least, when I have asked such a question that has been the experience of-PLATELAYER, Ruckinge, Ashford, Kent, September 30th.

SEAM OF BEES.

[1313.] There is an expression used in last week's B. B. J. by 'John Bull' (1249) which sounds very unfamiliar in connexion with bees. He says, 'I lost two seams of hees.' Is it already a technically common word, or is it an adaptation of 'John Bull's' own? I should never have guessed its meaning had I not by chance seen the Italian word so closely resembling it when abroad this summer. It was in a high Swiss valley, whither an Italian bee-keeper had sent up his pile of box-hives for the in-gathering of the honey-harvest. On every one of these boxes was the word seme, followed by a number, or date, or state and age of queen. This Italian word means a seed, race, or progeny, and would surely answer to our word stock. This, therefore, is only a case of resemblance of words and not of derivation, I know, because seam meaning weight or measure, according to Webster, has its Italian parallel in salma or soma, and all are derived from the Greek σαγμα.

It may interest many of your readers to hear that this new art of bee-keeping is being steadily fostered and developed by Italians just over the borders of Switzerland, and genuine honey can be confidently expected to oust the glucose mixture in a few years.—F. H., Kent.

[The meaning of the word 'seam' as used by 'John Bull' is the cluster between two frames.—Ed.]

Echoes from the Bives.

Keswick, Cumberland, Oct. 8.—After our long and beautiful summer we are having a splendid autumn, up till this morning when all the mountains were covered with snow almost to the bottom; I do not remember such a heavy fall so early before. Up to the middle of the past week bees have been doing a little, almost daily gathering some pollen and working on borage, of which I have still a splendid crop in full bloom. Bees in this neighbourhood have done exceedingly well the past season by those that have adopted the bar-frame system, but with the old system many of them have only had a very moderate time of it. Through their bees being so late in swarming they did not get their hives furnished with combs before they were prevented from doing further work through the drought; but with those that are working their hees on the modern principle, where they were properly managed in the early part of the season, they were ready to do business at the first opportunity; that was when fruit and other trees came into bloom. Betwixt them and clover no time was lost. On the eve of our great Jubilee Day I took for the first time over twenty pounds of section honey; this is very early for this district. After that I took more or less almost daily till the drought put a stop to further labour. All then came to a standstill for at least three weeks. In some hives breeding was almost stopped owing to the food supply being closed. Heather came into bloom before July was out; I was then able to reap a second harvest of over one hundred pounds, besides a number of unfinished sections. The weather broke long before the heather was exhausted. I might have done much better if I had taken my bees to the heather. As it is they have to make a flight of close on two miles. These long flights I find are very injurious to the bees, as they diminish in numbers daily, so much so, at the close of the season there are far too few to go into winter quarters.—R. Philipson.

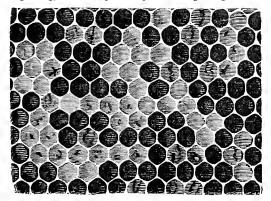

Stocket, Aberdeen, Oct. 7.—The season has been, although short, very good. The flow commenced in the early part of June and ended on 2nd July. My highest record is 74 lbs. extracted, and next 68 lbs. principally sections. My average is 45 lbs. per stock. Honey has been very cheap this year. For extracted I have got 6d. and 7d. per lb., and for sections 7d. and 8d. Extracted honey demands the readier sale, and with so little difference in price is more profitable than sections. The honey is not of such good quality as last year, as the flow began earlier, so that the clover was mixed with sycamore and fruit blossom.—A. Cadenhead.

NOTICES TO CORRESPONDENTS & INQUIRERS.

Letters or queries asking for addresses of manufacturers or correspondents, or where appliances can be purchased, or replies giving such information, can only be inserted as advertisements. The space devoted to letters, queries, and replies, is meant for the general good of bee-keepers, and not for advertisements. We wish our Correspondents to bear in mind that, as it is necessary for us to go to press in advance of the date of issue, queries cannot always be replied to in the issue immediately following the receipt of their communication.

- S. White.—Granulated Honey.—The reason of your honey becoming candied was extracting it before it was ripe. It is always best to extract none but scaled combs, unless it is ripened artificially, and even then the honey loses its aroma and fine flavour. A low temperature will cause any honey to congeal, and there is positively no difference in the tendency to granulation between skep honey and that in frame-hives, whether it he taken by murderons brimstone or hy the extractor, so we hope you will not return to the murder system.
- H. G. Sturoes.—Foreign Bees.—Scattered throughout the pages of past volumes of the B. B. J. will be found the fullest information respecting the foreign races of bees which have been introduced into this country, but there is no work or pamphlet which treats entirely on this subject. Mr. Blow's pamphlet, entitled Among the Queen Raisers, may give you some information. The races most cultivated here are Italians, Cyprians, Syrians, and Carniolans; hut the opinions as to their merits differ widely, even amongst the most practical and skilled apiarists. The palm, however, is generally awarded to the Italians for 'all-round' qualities. The Cyprians are very prolific and excellent workers, and the Carniolans have come very much into favour of late.
- G. G.—Heating Honey.—Submitting honey to a temperature of 150° or 200° Fahr. will generally prevent subsequent granulation, but it destroys the rich natural flavour and aroma of the honey. When honey has granulated in the comb the application of heat is the only way to liquefy it. We do not think there would be a large sale in this country for Professor Cook's heating apparatus.
- H. R.—Ventilation.—During the two previous winters the use of enamelied cloth over the frames has been well tested, and in the spring when the hives so treated were examined the hees were found perfectly healthy, and the hives free from damp or mould. Upward ventilation, though advised by many apiarists, appears to be in opposition to the instinct of the bee, seeing the use of propolis prevents it. In using the enamelled cloth, the summer entrances are left open the full width.
- S. J. Stevens.—Foul Brood.—This disease is caused by a bacillus, to which has been given the name of Bacillus alvei. It is not only a disease of the brood, but of the mature bees, and sometimes of the queen. When the cells are examined they will be found indented and pierced, and containing a putrid, sticky, coffee-coloured substance, which sends forth a most disagreeable smell,

which may be perceived at some distance from the hive. The disease is most infectious, and it is the worst the beekeeper has to contend against. It requires all the bee-keeper's attention to eradicate it and prevent its future appearance. Many bee-keepers stamp it out by the destruction of hives, frames, bees, &c., infected. For the various proposed modes of curing foul brood, refer to Cowan's Guide Book, pp. 138, 139. We insert a woodengraving, which may assist you in recognising it:

H. C.—The comb is decidedly affected with foul brood bacillus alvei. If the queens are from the diseased stock I should be greatly obliged by them, but they would be of service in any case.—F. C.

W. M.—The queen, much dried and somewhat crushed, is not in favourable condition for determining the points asked, but clearly she is young, and apparently a ' black.'-F. C.

A. J. B.—Bacillus alvei of the usual type.—F. C.

J. Davies, Pullheli.—Freeding.—Put thick thatch on the roof, see that it is fastened securely. Try the syrup as suggested, but put small sticks on the muslin as an additional safeguard. It would be advisable to give them a cake of candy in any convenient vessel. For the other thirteen try syrup as long as the weather remains open. Pack them close and warm. The less cold they have to combat against, the less food they require. Put one or two cakes of candy under the quilt; it was recently described in this Journal. If they are short of stores, replenish candy at the carliest period the weather will allow of. Give flour-candy in the spring to encourage early breeding.

Excelsion.—If we inserted your letter in the Journal we should have preferred seeing your signature attached to it, and not a nom dc plume. We consider the old Lincolnshire Bee-keepers' Association to be defunct, and we should rejoice with you to see a flourishing Association in a county where 'honey can be stored by the cwt.' As to the matter of personal pecuniary responsibility this should be settled by those locally interested in it.

Ignoramus.—Feeding.—See reply to J. Davies.

Subschiber.—The piece of comb forwarded is badly affected with foul brood. Refer to the communications of 'T. F. Ward ' and ' Sussex Rector ' in this issue.

A CONSTANT READER. - There ought to be from twenty to twenty five pounds of food to last the bees until the return of spring.—The feeding should be discontinued as early as possible.—The arrangement suggested for the position of frames during winter can be adopted.

Editorial, Hotices, &c.

THE FLAVOURS OF HONEY.

We are frequently asked to say what plant honey has been gathered from which bears some peculiar pronounced flavour, sometimes agreeable, sometimes the reverse; at times so intensely sweet as almost to be objectionable, or so bitter as to be compared to marmalade made from Seville oranges.

Sometimes this is no light task when we remember how easily in chemistry, by almost infinitesimal additions, the taste, smell, and other distinguishing characteristics of various substances, may be totally altered. Simple degrees of intensity even will do this. Nearly every disagreeable odour if sufficiently attenuated or diluted is thus rendered agreeable, or at least its objectionableness is removed; and, per contra, if we concentrate or condense almost any delightful odour we have, it is at once robbed of its charm and produces in all probability only a feeling of disgust. Poisons diluted become our most valuable medicines, and our concentrated plant essences become most virulent deadly poisons.

These arguments apply equally to odour and flavour, taste and smell. We know some of the most bewitching perfumes to us are an abomination to some other animals, and that they are attracted by the (to them) delicious exhalations from what is (to us) only abominable carrion.

We cannot, somehow, divest our minds of the fact that taste and odour are as one, for it is rare indeed to find them part company. In nine cases out of ten, what a substance tastes of it smells of, and vice versā. Besides, the organs of taste and smell if not precisely (as we believe them) one and the same, are so similar and sympathetic that if one be disordered the other is also: in cases of catarrh the taste and smell sense is inactive and do not return until the trouble shows signs of passing away.

The dictum that we possess the five senses distinct as such, must now be taken cum grano.

The chemistry that is worked out in the dark little laboratory of the bee is even now nearly a hidden science in spite of the rapid strides made in recent years by our analysts in deciding what are the various changes undergone by its saccharine contents from the time it is gathered as nectar from the flower, to its crystallisation beneath the

capping of the ripened store. Cane sugar converted into grape sugar; nectar into glucose; dextrose v, levulose; these do not touch in any way the most important point of all, that quality which gives to honey its characteristic charm and enables us to distinguish the honey-jar from the treaclepot, which makes our honey a wholesome, toothsome delicacy of direct service as a medicine as well as a food (not unlike tomatoes amongst esculents); in effect, the only quality which gives it the stamp as 'food for the gods.' Honey ceases to be such when its flavour is gone. Take oxygen from the atmosphere, and, to our mind, you symbolise the gap made in honey by robbing it of flavour. Nectar is scented by the chemistry of the plantcell, and this distinctive aroma is preserved by the chemistry of the bee in the honey-cell. We thus obtain large quantities of honey having an unmistakable sign of its origin in its flavour, its taste and smell; but only is this the case where flowers bloom in such preponderating profusion of one single species, as are instanced by the clover of June and July, or the heather of Angust and September.

In the earlier and later seasons there is a gathering from 'all the flowers,' and then our honey has simply that peculiar 'twang' (on the palate, we erroneously say) which brands it as honey and not syrup.

If we, with our coarse methods, could but have twenty or thirty thousand messengers, each one bringing in the usual bee-load (one-third of a drop), each load being gathered, as bees do gather, from one kind of flower only, for ripening, keeping, and other chemical reasons—other insects, which do not lay by stores for winter, are not so particular—and, it may be, perhaps from a dozen different kinds of flowers by the bees of the same stock, we should get the common and usual flavour of honey, i.e. the mixed perfumes of flora.

If chemistry did not appear to us ignorant mortals as a fickle, inconstant science, full of surprises where constancy and regularity are expected, the perfumer could provide us with the 'triple extrait' of honey quite easily were that 'a consummation devoutly to be wished,' though those who used such scent would perhaps have more attention paid them than agreeable, by our bees, especially when in country residence.

Now, let one class of flower in bloom even

slightly predominate in the neighbourhood of an ap iary, and the basis flavour is at once so altered that the honey acquires a taste in which even the predominating component cannot be recognised by our comparatively coarse faculties, and it is only as this particular component becomes proportionately excessive that the flavour and source of the honey can be recognised.

If half-filled sections of clover honey be filled up at the heather, we obtain a honey quite distinct and superior to that of either of the components. When cells filled with clover, and others with hawthorn, are extracted (for we believe there is yet a distinction kept, i.e., it is not stored promiscuously), the mixture gives us quite a new And so it is through all the many changes and combinations which may be rung on our flower-bells ad infinitum, quite new and marvellous taste-puzzles are elaborated. strong permeating perfume be introduced, such as peppermint or thyme, and even the all-discriminating bee would be puzzled to tell the origin of the honey, let alone the palate of the honey-editor. Let us remember, first, that the smell of a flower is the taste of the nectar and of the honey in nearly overy case, and that there is as stringent and accurate a law in the effects produced by mixing these as in the mixing of oxygen and carbon into a poisonous gas, oxygen and hydrogen into water, or oxygen and nitrogen into air. Harmonious combinations are made by the musician according to well-known laws; they are made by the artist by similar rules, and the perfumer still, according to the same theory, blends primary bases into secondary and tertiary compounds, which are tetally distinct from their separate component parts, these being unrecognisable. So with our honey and bees. It may be that as we now have bee-gardens kept distinct for the raising of separate varieties of bees, we may in time, by judicious selection and cross-breeding, arrive at a bee of allround excellence, an early-and-late working race, a good breeder and winterer, having little disposition to sting. We may have fields planted with bee-flowers, coming successively into bloom (with the accuracy of the floral clock which enabled our botanical forefathers to tell the hour of the day), from which we may obtain honey of distinctive prononcé flavour, and blend these at our pleasure.

A VISIT ON BEE BUSINESS IN MID WALES.

An invitation from the leading bee-keepers in the districts of Caersws, Glanyrajon, Glanclywedog, Llanidloes, and Tref Eglwys, in Montgomeryshire, gave me an opportunity to see for myself how bees and beemen pursued their business in Wales. I left Holme Apiary on Monday, August 22nd, en route for Llanidloes, vid Rugby, Lichfield, and Shrewsbury. From the latter place our speed of travel slackened. Slowly as we travelled, even so the shadow of night was falling; and it was but the outline of hill-tops, gleams of lamplight from elevated houses, with now and then the bark of the shepherd dog, which told us we were in the midst of Welsh homes, hills, and scenery. Our changing place for Llanidloes was Moat Lane End Junction; but my Welsh companions, when queried as to changing place,

conveyed the intelligence to me,—'You change at Mortal End, sir!' 'I judge we do!' was my remark; 'but to near the "mortal end" so well and strong, amid such company, and the prospect of continuing one's journey with bees to boot, is what I had never hoped for.' This caused some merriment, and made a north-country fellow-passenger feel he knew me a bit; and didn't we begin bees in earnest? When Moat Lane was reached, then in all probability the Mortal End of our beechat ended, as he changed for one direction and I for another.

At Llanidloes I was soon under the hospitable shelter of friend Roberts's roof-tree, and after a frugal meal I took me to rest. 'Up with the lark in the morning,' and I had a chance from my elevated bedroom to look out into the street below and from thence to the hillsides; but here I felt my vision sadly imprisoned, insomuch that I sat me down and wrote to the 'best queen' in Holme of my safe arrival, and said that I felt in a great big hole, with but a few houses and people to keep me company. Breakfasting, I was serenaded, first with vocal, and then with instrumental music by wandering minstrels. The vocal from two male persons, whose voices, like their stature, were of great capacity, and from the hollow sounds there appeared but little inside either. My heart was good to give the men a meal, if only to get a little hetter music; but the time had arrived for my departure, by pony trap, to Tref Eglwys. The road thither took us over a hill-top ere we gained much distance on our journey. When on the summit it struck me, 'Aren't these Welsh bees mountaineers indeed?' and when I saw their products on the show tables of Caersws and Llanidloes, and again in the apiary of Mr. Nicholas Bennett, of Glanyrafon (here handling the natives), I was convinced that for vigour and fit and finish of work, the black bee of Wales can hold its own against all comers. As, too, the bees in this apiary have a history of two centuries, as also have others I know of, how much does it speak for crossing and interchanging blood by art in bees when natural laws have handed down in these districts Dame Nature's faultless

But here I must stay, or I shall find myself on the hill-top of controversy, and forget Llanidloes hills. Here the pines gave a fragrance to the morning air, and the remembrance of the puny hills of Huntingdonshire provoked a strange contrast with the vision before me.

Arriving at Tref Eglwys, our friend Mr. T. Bonner Chambers was out to meet and give a hearty welcome, Ilaving refreshed the inner man we drove to see bee friends at Caersws, and give a look at the apiaries of Messrs. Francis and Evans. Here, in both, the sad mistake of bar-frames crossing hive entrances was apparent.

Caersws (once the site of castles) lies in as fine and fertile a valley as ever Welsh hills could surround. Here the bee can roam and find a meal, and man can roam also until he wants one. Does he choose he can fill his mind with knowledge, inspecting earthworks and trenchexcavations, wrought by Roman warriors, now in the sleep of death, maybe beneath one's very feet. Night found us back to Tref Eglwys, and early next morning we were on our way to Llanidloes show. Here our bee tent (an ordinary one) was pitched for the company, and the bee-man and his charge had but the canopy of heaven for a covering, his inside audience seeing how things were going on through the partly-netted ontside walls of the tent. I say inside audience, for no sooner had bee-driving commenced than many boys were crowding around, evidently feeling that the nearer the beeman the more seems they would be. Didn't I feel grateful that in the shape of large, heavy boots I was bearing more leather than necessary without that of the boys; still these boys gave strong hope of many a Welsh bee-master, and best proof of the genuineness of our pro-

ceedings, for the suspicious look which many an elder betrayed as to 'doctoring' and 'mystic' salve was dispelled when the bees on wing paid each and all outside a friendly visit. It was amusing to see the lads look at me ere they ventured to give the bee his 'removal order' from the tip of their ear, nose, or chin, evidently feeling that the finger of removal was more in danger than the part the bee was parading. Gradually the timidity of men folk,-aye, and of women too, was broken, and the hot tent soon emptying, friends Humphreys and Jones were manipulating and your humble servant talking bees (not spelling bees this time) to a host of persons in the very same tent where Noah caught the bee he introduced to his specimen house of all creation.

The honey exhibited, as before noted, was of a very high class, the sections of Mr. T. B. Chambers especially so. The run honeys were extremely good, and deserving of particular notice were those of Miss Amy Roberts and of Messrs. Humphreys and Jones. This latter reminds me of the good old Welsh name and its many bearers, and how from using it I felt I was about to be lawlessly mobbed! Wanting help with a hive I sang out to the last-named gentleman, 'Mr. Jones, please give me a lift!' A stirring of the air caused me to look up from my stooping posture, and, behold! some fourteen or fifteen able-bodied men were confronting me. 'Sure, men, and what is it troubles you?' I greeted them; when my apprehensions were relieved by one Mr. Jones Evans saying: 'All right, Mr. Howard, you have all the Joneses of these hill-sides to pick from!' There heing little to choose, I took the first Jones to hand, and, fulfilling my request, returned to the fold, and I heartily thanked them all for their prompt attention. The day passed off in goodwill and general happiness, the competing choirs and all were tuneful, save, perhaps, a slide trombone in the brass band. This operator evidently must have plugged his ears for the occasion, or his head would have felt as mine did, about to receive the last screw-up from the Raitt honey-press. Still do not let me convey the idea that the Welsh are unmusical; far from it. Here, without accompaniment, I heard mixed choirs, and choirs of men voices only, give forth earth's sweetest melodies. At early morn, and nightfall too, it was charming to hear from sons of toil, plaintive as well as joyous, concerted strains, given forth from many a vale.

The Llanidloes show over, our return to Tref Eglwys was uneventful, save from the fact, as Pat would say, 'Down these hills it is impossible to ride in an empty From this you may gather that in Wales, what with the up-and-down hill, a five-mile drive means a combination of walk and ride. Around Llanidloes, indeed (the highest town in Wales), the former is far preferable. Thursday was spent in visiting many apiaries, all of which were capable of improve-ment. Still, I prophesy that when the Jones family get well and truly practised in modern apiculture, even onr Cheshire veteraus may haul down their flag at Colonial and national competitions.

On Friday I attended Caersws show, where everything in horticulture from a tiny cork-bound carrot to the choicest orchid; in 'Canine culture,' from a ten-ounce pet to one of $1\frac{1}{2}$ cwt.; in apiculture, from the queenbee's egg to the grandest sectional honey, and many a

promising beeman was to be seen.

As the brass hand here was more attuned, so were my bee thoughts, and as a consequence I felt more satisfied with the lecture which I gave. My remarks were well kept in mind by my audience; I was freely questioned, and I think a lasting impression and good results inevitable. Friends Humphreys and Jones here found me out, and as we took up the skep hives sent for manipulation, some of the contents came out sharp end first apparently, and as friend Jones removed one morsel, which was doing the 'Channel Tunnel' down

his shirt-collar, he remarked, 'They have picked them for us to-day, Mr. Howard.' However, the carholic spray and a feed of syrup soon brought peace to the troubled world, causing one who had not seen the quieting process to ask in what manner bees were trained to this performance. The place of the Observatory hive at this show was the scene near which many a quaint idea of bees was to be heard. For example, said one man, 'Now here be the ones (workers) which blows thems' eggs. This one (the drone) blows his eggs, but the one which blows the queen's eggs my old woman or I has ne'er seen yet.' Again, quietly, and the two alone, one lady remarks to the other, 'Lizzy, if here aint bees spinning honey!' The exhibits were here much a repetition of those at Llanidloes, but, as usual, dissatisfaction was given in the judging to one or more who were the unhappy possessors of beautifully clarified and coloured honey, but which could not score one point for consistency. Much credit is due to Messrs. Francis and Jones, of Caersws, for giving their time and services in making the honey and bee departments a grand

Tref Eglwys being my centre, we (Mr. and Mrs. Chambers and I) homeward turned, and on Saturday morning we made our way to the apiary of Mr. Nicholas Bennett, J.P., at Glanyrafon. Here the bees have a history which many a house would be proud of. These hees have conserved all their good old ways-aye, and their had ones too—but (which is rapidly going on) the introduction of them to bar-framed castles may give them more respect for the feelings of others. Heather honey was being freely gathered by these bees, each hill abounding far and near with this valuable late secreting

bee-pasture.

At Glanyrafon the day was well and profitably spent, and was crowned with the hospitality ever and anon shown me by all. I am shy at telling the small hours at which we took our departure from our noble host, but suffice it to say we were not prevented attending Church services morning and evening. One service was in my mother tongue; the other in that of Brother Jones. The latter to me was none too edifying, but set me wondering how the parson kept his teeth when uttering such language.

Monday morning brought with it a letter from my 'best queen' calling me homeward, and I had to disregard much persuasion and entreaty to stay yet longer. I shall, however, bear in mind for many a day to come a visit on bee business in Mid Wales.—John

Howard, Holme, near Peterborough.

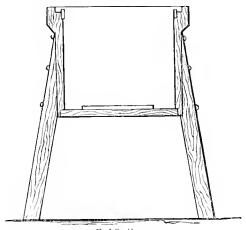

IRISH BEE-KEEPERS' ASSOCIATION.

STANDARD HIVE.

At the meeting of the Committee on the 4th inst. it was resolved that the standard hive of the Irish Bee-keepers' Association should follow the description given below. It was also resolved that any Dublin hivemaker constructing hives on this pattern, and undertaking to do so under the official supervision of members of the Committee, be entitled to style himself Hive-maker to the Irish Bee-keepers' Association. The limitation to Dublin is necessary in order to make the supervision above-mentioned practicable.

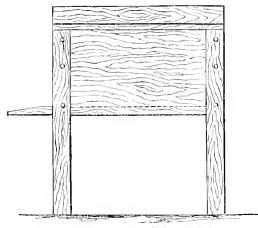

Description of the Standard Hive.—(A large portion of this description had previously been approved and appeared in the B.B.J. for July 14.) The length of top-bar to be 16 in. out to out, width $\frac{\pi}{2}$ in., thickness $\frac{2}{8}$ in., sides $\frac{1}{4} \times \frac{7}{8}$ in., outside measurement of frame $\frac{1}{8}$ $\frac{1}{2} \times 14$ in. The top-bar of the frame to be what is known as open-ended, with screw-distance keeper l in. in length, and $\frac{5}{10}$ in, across the eye, outside measurements, the eye screws to be inserted immediately over side-bars. The runners to be of hard wood, not exceeding $\frac{1}{10}$ in bearing. The hive to be 22 in long, $14\frac{1}{2}$ in

wide, and 91 in. deep from top of frame to floor-board inside. Walls, if single, to be of \(\frac{3}{4} \) in. wood, with a strip of wood at the top to cover the ends of the frames, and $10\frac{1}{2}$ in, deep. If double, these details may be varied where necessary. The floor to be of 1-in, timber, planed

End Section.

on both sides, nailed to rabbet in the sides, and, if joined, to be tongued and grooved. The roof to be sufficiently deep to admit of a second tier of frames being placed over the brood-frames. The hive to be sent out with one layer of canvas, two layers of jute carpeting, and two layers of flannel, or their equivalent, and to be supplied with one close-fitting division-hoard. The door to be 9 in. wide, and fitted with effective entrance slides.

Side Elevation. Scale, 1 inch to the foot.

Peculiarly-Shaped Cells,—We have now before us about one dozen different specimens of comb that have been cut out. These vary in size from four inches square to half the size of an ordinary comb. In these pieces there are a large number of cells of almost every imaginable shape, some obtong, a few tiexagonal, and some V-shaped; some have three sides, the ordinary hexagonal shape, the other three made with two forming a V running off to a sharp point; some are formed somewhat like a V, then others are as perfectly square as the bees could make them, and not a few are triangular; some are five-sided, some are nearly round, some heart-shaped, in fact we could hardly think of a shape that might not be found in some of the pieces. The square cells are in perfect rows two inches in width, and six or more in length, nearly all perfectly square. Most of these different cells had brood in them, and we have not been able to detect any difference between he bees hatched in these peculiar-shaped cells and those hatched in the ordinary ones. - Canadian Bee Journal.

Correspondence.

The Editor does not hold himself responsible for the opinions expressed by his correspondents. No attention will be taken of anonymous communications, and correspondents are requested to write on one side of the paper only, and give their real names and addresses, not necessarily for publication, but as a guarantee of good faith. Illustrations should be drawn on separate pieces of paper.

Communications relating to the literary department, reports of Associations, Shows, Meetings, Echoes, Queries, Books for Review, Ec., must be addressed only to 'The Editor of the 'British Bee Journal,'' clo Messics. Strangeways and Sons, Tower Street, Cambridge Circus, W.C.' All business communications relating to Advertisements, &c., must be addressed to Mr. J. Huckler, Kings Langley, Herts (see 2nd page of Advertisements).

** In order to facilitate reference, Correspondents, when speaking of any letter or query previously inserted, will oblige by mentioning the number of the letter, as well as the page on which it appears.

WHAT CONSTITUTES A GOOD STOCK?

[1314.] One and all are interested in this question, and many will be glad to know what a really genuine colony should be, as well as how to obtain such. Considering that you keep bees solely for the production of honey, it is understood that you desire only strong stocks, and also must be aware that to make bees pay, your stocks must all be in good condition. In a general way this is obtained, (1), by keeping only young queens; (2), by uniting in the autumn; (3), by supplying any deficiency of stores soon after surplus receptacles are removed; (4), warm covering above the frames at all times; and lastly, thorough veutilation in winter without draught through the brood-nest. Here we have the whole question in a nutshell, but a few remarks upon each subject may be found interesting.

Young Queens.—Many object to the trouble of

changing queens, and consider it unnecessary; but their reasoning is influenced by the thought of that little trouble, for, as a matter of fact, stocks can only be kept in generally good condition year after year by the help of young queens. A queen is the life and soul of the hive, and those colonies only do well that are in possession of a queen all the time, but that stock does best which has a young one, as the bees partake of her own energy and do better in consequence. Mr. Cowan and others have long shown the necessity of deposing queens that have worked two seasons, but I prefer to keep them only one year. The best results will always be found with queens raised at the end of July, superseding them in August of the following year. Such queens carry their colonies through winter and build up in spring in a manner that is perfectly astonishing. queens do not breed after September unless the manner of feeding is at fault.

Uniting in Autumn.—This is far better than waiting till spring, as little good can then be done with weak colonies still further reduced by the cold of winter. A good queen at the head of a strong colony in autumn will give a stock the following spring worth half-a-dozen weaker lots. Instead of being reduced in number the opening of the new season will find her colony even stronger than before winter; whereas, instead of the apiarist uniting by twos in antumn, if left till spring, some of the weaker lots will have died out, while a larger number will have to be united. It need hardly be stated that young queens should be reserved in preference to those older, and in any case of uniting fighting seldom occurs if the condemned queens are removed the day before the union takes place. In any case all but the one queen should be first removed.

Deficiency of Stores.—When supers are removed very often the bees have little left below. They have plenty of broad, and this is the time to give what more food will be wanted, so that enough more young bees will be produced to compensate for the consequent exhaustion. Do not by any means wait till the bees, linding themselves running short of food, cease breeding, or the wear and tear caused by late storing will be very detrimental.

Warm Covering.—It is most important that the frames be carefully covered with warm material at all times, or the development of the brood-nest will be seriously retarded, and the first batches of brood generally produced from the turn of days, so necessary to give the colony a good start, will be found wanting.

Ventilation in Winter.—This matter is of the first

importance, though too frequently omitted. Thorough ventilation can be provided in several ways, but whatever plan may be followed it is imperative that there be plenty of room below the frames, as I have pointed out upon former occasions. For my own part 1 prefer a deep comb, or, with the standard frame, an empty chamber under the stock hive. A space of $\frac{3}{5}$ in, between the floor-board and bottom rail of the frames is little enough, but a circular hole of 2-in. diameter provided in the centre of the floor-board will be found very beneficial. Failing this, an extra shallow rim can be placed under the hive, or strips of wood may be placed under the frame ends, giving a clear space below that all refuse, dead bees, &c., may fall away from the combs, giving a Where perous free passage for bees and fresh air. covering is preferred above the frames, giving a gradual change of air, the entrance may be small, but with nonporous clothing the flight-hole must be at least six inches wide for very strong colonies, otherwise the excess of moisture cannot be disposed of. Where the form of the hive permits, I have found no better way for giving a thorough change of air than the following: Place all the combs (with bees) at the end furthest from the entrance, with or without a dummy on that side next the vacant space; but if the dummy is used, it must not be tight-fitting, and should hang just as an ordinary frame. Cover the frames with warm material, porons or otherwise, and let there be a clear, open space from the entrance to the roof. Here we have a thorough change of air in front of but not through, the broodnest, and not a particle of mildew is ever found upon the combs.

A colony to be really profitable should cover not less than ten frames in August, having had a succession of young bees throughout the season, and, if required, its full compliment of food given before breeding declines, with a young queen from good stock supplied early in the above month. To be on the safe side, the novice cannot do better than put all his colonies in this condition during August, uniting where necessary to gain the required strength. Do not say that you cannot afford to thus reduce your stock; you certainly cannot afford to do otherwise.—Sam. Simmins.

RE FOUL BROOD.

[1315.] I am much obliged to Mr. Harveyson for pointing out the passage in Mr. Cheshire's new book, but as I have not yet seen that book it could hardly be said I had overlooked the fact, and as the whole subject has special reference to what Mr. Cheshire advised three years ago I do not exactly see the force of the remark; still it is gratifying to know Mr. Cheshire at last advises a timely removal of the queen whenever there is reasonable ground for believing her to be infected, which I consider is always the case, and as this was the only cloudy part of his advice in August, 1884, since which time the disease has spread in every direction. I hope the future will not find us looking for more 'reasonable ground' than the very fact of the disease being present supplies, but at once and immediately requeening as a first step to effecting a speedy and certain cure.-THOMAS F. WARD, Church House, Highgate, October 15.

EXTRACTING FROM BROOD-COMBS.

[1316.] The position taken up by Mr. Boyes, that it is not advisable to extract from combs containing broad,

is a perfectly tenable one. He says by doing so we get what we certainly do not want—our honey contaminated with a thin watery substance which flies out readier than honey, this stuff being brood-food. Yet, in my opinion, he is entirely wrong in giving manure-heaps, stagnant ponds, the sides of sewers, &c., as the sources whence bees obtain this substance. Let us compose and console ourselves with the knowledge that if our bees gathered by the pouch-full such chemicals as are there found, they would, in all probability, die ere they reached home, let alone stored it. To ascertain that they cannot bear it in bulk, let any one wet a part of the hand with it and then approach the hand to a hive-door, and if he wants a few cheap stings he will not be sent empty

Mr. W. B. Webster is 'warm' (as we used to say at guessing games) when he suggests the bees presence at manure-heaps is accounted for by them requiring hippuric acid for use in honey conversion, this acid being there in plenty. This is very near, if not a portion of, the true solution of the question. If the bee fed on starch granules, it might go in for storing crystals of hippuric acid, somewhat after the dry-sugar feeding principle. Uric acid might be a better term, seeing that uric is found in animal, and hippuric in human liquid excreta; thus, so to speak, reversing their ordinary positions. If these acids be revolting to contemplate, I may say they can both be artificially made by the chemist. Hippuric will be secreted by all animals which have benzoic acid given them-benzoic, the ancient product of the fragrant aromatic gum-benzoic; benzoic, from which is prepared the delightful essence of bitter almonds, so much used for flavouring. There should be nothing repulsive or objectionable in contemplating these two acids, nor even the manure-heap or sewer-drain itself, so long as such a view remains imaginative, especially when I remind you that our fathers had to trust to the excrements of the camel for the ammonia they required in medicine,—the almost indispensable ammonia,—and that the sources whence musk and civet are obtained are still more objectionable. Again, when the liquid portion of manure is left to itself a certain bacterium (Micrococcus urea, Pasteur) sets up ammoniacal fermentation, this resulting in urea changing its form into carbonate of ammonia, one of the most valuable of medicines. Let us then, figuratively, approach the manure-heap without any feeling of disgust, and recognise in it a storehouse of essential elements required for plant-life, and readily transposed by them into food for man. It is rich in pure chemicals, which are only offensive when in an aggregate or conglomerate form, such as nitrates, phosphates, sulphates, and alkalies. We no more expect bees to carry quantities of liquid manure into their hives (and they do not), than we expect the 'maters' of the mammalia to fill their stomachs with salt, chemicals, or medicine, storing the same, and feeding their young upon it.

When we reflect that the honey-bee does not waste the contents of superfluous eggs laid by the mother-bee, and also stores aphidian honey-ourselves also eating with relish those omnivorous cannibals, the duck and pig, refraining at the same time from examining minutely the ripe cheese, pâté de foie gras, caviare, venison, or game—we ought not to be prudish if our bees visit their chemists' shops, and occasionally the stagnant pool. Let us think a little about the origin of the innocent egg and harmless milk (which is a most ready vehicle for zymotic germs), and our honey is purity itself by comparison. Examine the action of Torula cerevisice (yeast), in the preparation of the staff of life, and we recoil; dig up celery, or onions, gather mushrooms at dusk, and the phosphorescent manure sends apparently living, gleaming threads in all directions, these do not increase our appetite for the food. Why the very vegetables absolutely taste of some manures, and these have to be avoided by the gardener. Examine your lettuce and

watercress under the hand magnifier, and you will 'pass,' -−as Mark Twain did.

Now animals (bees as well as men) require a series of salts and chemicals, to be used in assimilating nutritious substances, amongst which may be named salts of potash, soda, lime, magnesia, iron, mauganese, gum, pectin, sugar, substances analogous to fibrin, albumen, and gelatine; phosphoric, acetic, sulphuric, hydrochloric, and fluoric acids, and others. Honey itself * contains, besides sugar, gum, wax, mucilage, extractive matters, acids, and peculiar flavours. Mr. Cheshire tells us:-'Honey under natural conditions in the hive always contains nitrogenous matter in small amount, or is associated with it; but when honey is replaced by sugar, pure and simple, the absolute absence of albuminoids affects the bee prejudicially;' he truly adds that the arrangement of nature is the right one. Trouessart also says:—'In animals, gastric, pancreatic, and intestinal digestion, together with other changes connected with nutrition and assimilation, which take place in the blood and in all the organs, may be considered as true fermentations.' Pasteur follows this up by laying down the law that three things are necessary for the development of the ferment—nitrogen in a soluble condition, phosphoric acid, and a hydrocarbon capable of fermentation (such as grape sugar). Otto Hehner, the analyst of our Association, informs us that the bee requires water, nitrogenous matters, mineral substances, and carbonaceous materials, for the sustenance and growth of its body. How then are we to expect it to keep itself healthy and thriving,—how, indeed, is it to live at all, if we wish to prohibit it (supposing we could) from taking up such chemical substances as are necessary to it, guided as it is by a never-failing hand into unerring accuracy? Such infinitesimal quantities taken from nature's laboratory, depend upon it, are practically pure and totally in-

appreciable to us.

We presume that by the aid of an alkaline salivary secretion the bee converts nectar into honey; can we then deny its access to alkalies? How, again, is it to elaborate the brood-food and the so-called royal jelly, if we refuse it the necessary sulphates, phosphates, and nitrates? True, pollen-grains contain these, but evidently not in sufficient quantity, or the bee would not have recourse to what have been considered objectionable sources; pollen-grains, so necessary to the bee for broodfood, also contain starch granules, and these cannot be changed without the aid of powerful chemistry in the economy of the bee. If we watch bees drinking on the moors, we notice them give distinct preference to water trickling from decaying sphagnum and mosses. We frow know why. In short, we may take any article of ood (and its producer), examine it under the microscope, or touch it with the chemist's wand, and we shall find our honey and our bees have a decided advantage, so far as purity and cleanliness are concerned. For my part, I think we have no business to adulterate our honey when extracting, by using combs containing worms and maggots (for these are but plain English names for broad) floating in or saturated with a maternal secretion or preparation only intended for its food when in a larval condition. I am of opinion we should decidedly avoid broody combs, if not for our own then for the sake of the broad itself; and I hope I have shown that we can safely trust the worker to gather, convert, ripen, and seal for us only such honey as is well fitted for food, chemically pure, scrupulously clean, and faultless to a

WINTER STOCKS.

degree. -R. A. H. G., Horsforth, n. Leeds,

[1317.] In this week's Journal J. H. Rogers (1303) says he never winters stocks that have not sufficient bees

* Smith.

to cover ten frames. I feel sure he would confer a boon on many bee-keepers besides myself if he will tell us how he manages to keep up the population to that extent. I have had fifteen years' experience, but can never get mine to cover more than seven or eight combs at the end of September, however strong they may have been during the summer. I once heard Mr. Baldwin say that he never met with a stock that he could not crowd on to six or seven frames in the autumn. There has been a good deal of talk lately about the position of frames, whether those at right angles or those same way as entrance are best. So far as honey-producing goes I find no difference, but for wintering I much prefer those same way as entrance. Last winter I lost only one stock out of an apiary of ninety, and they were all on the Combination system—Abbott's wide shoulders; there are no better frames produced. I have driven newards of fifty skeps this autumn, and not one contained over 24 pounds of bees, more under two pounds than over. My experience is that a stock which covers well six frames by the middle of April is a pretty good one.

I can safely say that this district is free from foul broad,

-James Gilbert, Stamford,

NORTH-EAST OF IRELAND BEE-KEEPERS' ASSOCIATION.

ANNUAL SHOW,

[1318.] Referring to Mr. J. D. McNally's letter in your issue of 22nd September, protesting against so-called irregularities at our late show, with your kind permission I will put the matter as it occurred. The judges were supplied with books containing only numbers and which can be produced and were duly signed and returned to me. The hon. trensurer, Mr. S. Cunningham, had charge of the catalogues, and did not get them from printer until a short time before opening of the exhibition. He informs me they were not on sale until after judging was completed. There were two catalogues (proof copies) for use of Mr. Cunningham and myself in staging, and we no doubt acted indiscreetly in allowing Mr. McNally's brother the use of one of them for a few minutes to check over his entries. Beyond this I am not aware of any irregularity. I think Mr. McNally's grievance is, like a good many of the 'Irish' ones now aired before the public, mostly imaginary. I do not think any of the gentlemen who acted as judges would have used a named catalogue, even had it been at their disposal. The office-bearers of the Association have only their spare time to devote to the furtherance of its objects and cannot be expected to have it as 'well managed' as if they were in the bee business. I regret very much that any exhibitor should feel he had suffered injustice, and trust the explanation will be satisfactory. Apologising for trespassing on your valuable space. PAUL M'HENRY, Hon. Secretary, Belfast, October 15.

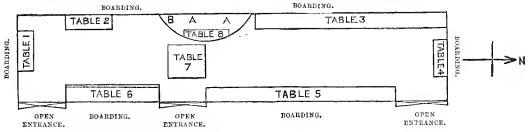

I only to-day saw Mr. J. D. McNally's letter in your paper of the 22nd September, and hope you will kindly insert this reply. He must be mistaken as to the names of exhibitors being in the hands of the judges when forming their decision. I made all the arrangements about the catalogues and had them sent to me direct from the printers, and the parcel was unopened till the awards were made. Only two proofs had been previously struck off, which Mr. McHenry (hon, secretary) and I necessarily had for the guidance of ourselves and assistants in arranging the exhibits in the hall; and one of them was lent to Mr. McNally for arranging his own exhibits, but the judges could not have seen or have had any access to these. They had merely books without any names till after their duties were performed and their decisions made.—Samuel Cunningham, Glencairn, Belfast, October 14,

MANIPULATING TENT AT THE MANCHESTER SHOW.

[1319.] At this show, instead of the manipulating tent being erected separately in the ground, netting was stretched in a half-moon shape in the centre of the shedding appropriated to honey and bee appliances, and the canvas roof thrown back that the bees might get a clear flight from the manipulator, the hives to be manipulated upon being kept outside the hoarding, in which a small door was placed to enable the manipulator to take the hives in and out as required. At the time of the Manchester show the weather was very stormy, and when not actually raining, all agreed it would have been impossible with the high wind to manipulate bees successfully in the ordinary manipulating tent, whereas under the shedding the audience were well protected, and the manipulator could do his work with comparative comfort. Ten hives of bees were on the ground during the time of the show (four days), and still no bees were seen on the honey displayed for competition or sale. The carriage of the manipulating tent in large counties is a serious item, and the manipulations being in a separate tent many visitors to a show miss the time the manipulations are going on. The question is, can a way be devised so that manipulations could be managed in the tent or shedding used at ordinary shows, a piece of netting being hung round the manipulator to prevent any chance-accident from bees stinging the visitors? I take it in all cases it would be necessary to have an opening in the roof above the manipulator.

It is hoped the ground-plan here given will make the method adopted sufficiently plain to the reader.—

WM. LEES MCCLURE, Prescot.

WHERE DO BEES GET WATER?

[1320.] With respect to the sources from which bees obtain the necessary moisture, some of the numerous friends who have kept up a long correspondence on the subject in the B. B. Journal may not have had an opportunity of observing that Nature has provided a supply for them in the most convenient situation that is possible, which is the drops of water invariably hanging below the foam of the frog-hopper, and it is also used by the solitary mason-wasp for mixing up the mortar that it requires for building its nest or nests, and moths also avail themselves of the same source of supply, and most probably butterflies and other insects; and as this is obtainable through a considerable part of the summer, upon almost every yard of the ground, over what to them would be otherwise waterless districts, and is the most abundant in the hottest weather, it can only be regarded as one of the many forcible illustrations of the perfect economy of nature.—S. C. K.

BEE-KEEPING IN IRELAND,

[1321.] A Correspondent from Leitrim writes as follows:—'A word about this part of the country might interest you. It is certainly a splendid place for beekeeping, abounding with floral beauties on which the bees delight. They are all this week working as in midsummer on the ivy. We have to the south of us two or three himdred acres of heather; to the north-east and west of us, thousands of acres of pasture land abounding with clover (chiefly white), intermixed with numerous honeyproducing trees and shrubs, such as the wild raspherry, the bramble, laurel, and giant rose, with plenty of lime and sycamore, hazel and willow within easy reach, and standing in the midst of a garden of fruit trees, leaving out the garden and trees. The whole country for miles and miles is beautifully wooded. But, alas! there is not hardly a bee to store the honey. I can easily count the hee-keepers within five miles on either side of me on my one hand. Four years ago there were only two. The people in those parts seem innocent of any means of industry, their only hobby is the agitator, the potatoes, and the rent. You can form your own opinion.

'Our hest hive this season gave us 160 I-lb. sections

 $4\frac{1}{4} \times 4\frac{1}{4} \times 1\frac{2}{4}$, four bee-ways worked without dividers. Our worst, 40, superseded its queen in April or early in May (black bees). I consider 160 lbs. without reckoning what they may have in the hive, which I feel sure will amount to 30 or 40 lhs. at least, is very good for blacks or any other bee.

'In justice to your Journal I must say that I could not get anything like that but for the knowledge I derived

from its pages for the two years.'

COTTAGERS' APIARY COMPETITION.

[1322.] To those readers of the British Bee Journal who are interested in the working of county bee-keeping associations the following narrative will be of interest. The Association for the county of Kent is fortunate in having for its Local Honorary Secretary, at Hawkhurst, Miss F. Herschel, who, since her acceptance of the appointment, has never ceased to labour indefatigably to bring her district into a high state of efficiency. In this work she has had the encouragement and assistance of her brother, Sir William Herschel, Bart., and it should also be stated, that of Capt. H. S. Swiney, her predecessor in office. Early in the present year the idea was formed of instituting a Cottagers' Apiary Competition, and this being submitted to the Executive of the Association, hy whom it was approved, plans were formed for carrying it into practice. At the outset it was felt that the rules which should govern the competition should be as few and simple as possible, and that the order of merit

should be decided chiefly upon the general management and condition of the apiary and surroundings, regard being, of course, had to the amount of produce and number of hives kept. The object in view was to create a greater interest on the part of cottagers in the pursuit of bee-keeping, and to induce the class to utilise for their immediate advantage the benefits which the Association endeavours to place within their reach. To ordinary observation there is nothing to suggest that Hawkhurst possesses any special features favourable to bee-keeping, therefore, the results attained by the competitors attest to the fact of the great superiority of the modern system over that which is fast being superseded, and to the enlightened interest of those who engaged in the competition.

The competition was arranged to commence in the month of June and terminate on the 31st of August, but owing to the inability of the three gentlemen appointed to judge to meet before, it was protracted until the 8th of September. The task of judging was undertaken by Mr. A. J. Pratt of Tenterden, Mr. E. G. Tye of Cranbrook, and Mr. J. Garratt, the hon. secretary of the Kent B. K. A. The work of inspection and judging was performed under most favourable conditions of weather, the day being so fine and warm that no risk in closely and thoroughly examining each hive was involved.

The two first-named judges were on entirely new ground, and therefore were altogether unacquainted with the capabilities of the competing parties, and it was with no little surprise and pleasure that they found themselves in most instances face to face with the most complete proofs of the ability of farm-labonrers, and other cottagers, to grasp the principles which by many have been thought to be far above their comprehension. By the thoughtful kindness of Miss F. Herschel, the judges were rapidly driven from apiary to apiary, and accomplished to their own satisfaction the task assigned to them.

The first prize (given by Sir W. Herschel) was awarded to Mr. James Hicks, agricultural labourer; second prize (given by the Kent B. K. A.) to Frederick Reed, of similar occupation; and the third prize (given by Capt. Swiney) to John Collins, of no occupation, but who owing to an affliction to his legs, had to perform all the work of manipulating and hive-making seated in a wheel-chair.

From the appended tabulated statement the individual results may be easily seen and compared. That they reflect very great credit upon each and all concerned cannot be gainsaid, and it is hoped that so useful and successful an experiment may in the future be productive of many more like competitions in the same and other counties.—J. G.

MEMS. BY WOODLEIGH.

[1323.] Propagating Foul Brood.—In addition to the various ways in which the pest may be propagated (vide former 'Mems.'), I would point out to bee-keepers another probable source of infection rendered possible by the new labour-saving solar and steaming wax-extractors. Now if combs from hives reeking with foul brood are put into these extractors and the wax extracted from same, we know that the temperature at which wax melts would not be high enough to destroy the germs of bacilli, and consequently the foundation made from infected wax must carry the germs with it wherever it goes.

'Man of Kent' (1283) asserts that foul brood is following the wake of bar-frame hives with rapid strides. I do not doubt his assertion; but why is it thus? Simply because of the many opportunities for its propagation and introduction into bar-frame hives in comparison with the straw skep. The skep is simply a beenest left unmolested till the sulphur-pit puts an end to the majority of the colonies at 'taking time,' and the few instances in which foul brood has appeared in skep apiaries may always be traced to the introduction of modern hives into the district.

Yet one more possible means of infection, though I recount it with some trepidation, and that is by the circulation of the B. B. J. If it is handled by a bee-keeper who has been manipulating foul-broody stocks of bees, may he not unwittingly transmit the germs to the next on the list, who, ou receiving the Journal, finds he has neglected doing something in the apiary, lays down the paper, and sets about the 'doing,' and possibly the infection is transmitted to another apiary?

Extracting from Brood Combs.—I am glad Mr. Boyes has answered 'W.J.S.' I should have endorsed Mr. B.'s views when his letter first appeared, but considered Mr. B. quite capable of taking his own part. I may add that any practical bee-keeper who works or cares for the well-being of his bees would never under ordinary circumstances extract from combs containing brood in all stages. I have this season, in a few instances, extracted from combs containing a small patch of capped brood, and, to prevent injury to the brood, laid a piece of flannel over the brood to prevent the capping being crushed by the wire of extracting-cage while revolving in the extractor, but that was from brood-comb clogged with honey to give breeding space. Bee-keepers who extract from combs containing eggs, larvæ, &c., must, as Mr. Boyes says, extract the prepared food, the thin, watery honey, also the eggs and larvæ.

Bees and Manure Heaps or Drains.—I beg to endorse what Mr. Boyes says as to bees drinking from the oozing shish that exudes from manure-heaps; and although one correspondent says bees are not such fools as to visit such places if they have water within three miles, I can assure him that bees do visit such places with an abundant supply of both good water and also a supply of diluted sodium.

Starting a Bee-farm.—The two replies to 'A. W. B.' in last week's Journal are both from practical men, and now this week's from Mr. Godfrey, giving an estimate of the probable cost of the enterprise, has covered all the ground, so that I have burnt a rather long letter in reply, and will only say a few words on the subject. I myself a few years ago had an idea of starting a bee-farm as a means of livelihood, but on giving the matter mature consideration, and looking at the large number of hivemakers who were then (and are still) sending out great numbers of hives in all directions, not to mention the number of home-made ones, I reasoned that the thing must of necessity be soon overdone, and prices go down for the produce of the bee-keeper; and present prices are proving my surmises right, and in 1887 I am glad I did not embark in the farm of 1882. My experience has taught me that bee-keeping in England would not pay to take up with it alone; but if 'A. W. B.' has any trade

or calling, he may work a fair-sized apiary as an auxiliary, and derive a profit from it. I have no doubt that in the near future we may have to accept a lower price for honey than at present. The American and Canadian crops of honey this season are both very short, but another season it is probable they may have a good crop, and then the competition would be keen, as the freight per steam ship is a nominal sum when compared to what our English railways charge us for carriage of honey, and the public have little, if any, more predilection for English honey than they have for bread made of English corn in preference to foreign.

ON BROOD-COVERS.

By Pastor Schönfeld of Tentschel.

In No. 3 of the Nordlinger Bienenzeitung for 1884, Dr. von Planta communicated the results of a microscopic and chemical examination to which brood-covers of bees had been subjected by him. The microscopic examination which Professor Schröter of Zürich made of the broad-covers submitted to him, showed that they consist of a 'granular substance, cemented together by wax and mixed with whole and crushed grains of pollen of different plants.' The chemical examination of the brood-covers by Dr. von Planta showed that 100 parts by weight of air-dried brood-covers contain-

57.60 per cent of wax, " matter (pollen and pollenhusks) insoluble in boiling ether, " water.

From this Dr. von Planta thought himself justified in expressing the conjecture that the bees mix with the wax they use to close the brood-cells both whole pollengrains and pollen-husks ejected by workers, in order to make the covers more porous and better fitted to receive

the necessary supply of air.

The editor of the Nördlinger Bienenzeitung, as well as the majority of bee-keepers, rejoiced at this discovery, which they looked upon as a welcome addition to our knowledge of bees. Dr. Dzierzon, however, soon raised objections. He did not, it is true, bring forward any scientific counter-proof, and did not even submit the brood-covers to examination, nor did he state positively how the matter really stands. Neither are the conjectures which he starts such as to stand the test. For when he states—Nördlinger Bienenzeitung, 1885, page 26—that the larva may, perhaps, impregnate the cover with its saliva or some exudation and add to it by pressing against it some remains of the food, supplied, perhaps, in excess, we at once feel the weakness of the attempt to get rid of the difficulty. Besides, this supposition is in contradiction to every microscopic examination made, as the pollen and the pollen-husks are found in horizontal and perpendicular sections of the covers, firmly embedded in the mass, as well as on the surface of the covers, where the larvæ cannot possibly get at them; and when Dr. Dzierzon lately called von Planta's discovery a mistake because, as he alleges, bees cannot eject pollen, he is equally mistaken in this supposition.

At the same time, the doubts of Dzierzon, who is so great an authority, will have unsettled again the opinions of many bee-keepers as to the nature of broodcovers. I have, therefore, with the consent of Dr. von Planta, subjected the question in dispute to a further examination, which has given some startling and novel

It should, in the first place, he stated that brood-covers, such as Professor Schröter and Dr. von Planta had an opportunity of examining, are doubtless in such a condition as has been described. But neither of these gentlemen being practical bee-keepers, they were obliged to operate upon the material placed before them by Mr.

Kramer, a schoolmaster of Fluntern, which consisted exclusively of coffee-coloured brood-covers. They were thus unable to test the matter thoroughly, and this has led them to draw conclusions which are incorrect.

In dark-coloured wax-combs of all shades not only the brood-covers but also the honey cell covers, the edges of the cells, the cell walls, and cell foundations, are all more or less mixed with pollen and the husks of pollen. Every wax comb which has been used only once for breeding, and every small piece of new comb which has been constructed partly of old material, shows, in addition to whole pollen-grains, numerous fragments and cells of pollen. From a wax-comb made by the bees in June, 1886, the lower part of which I shortened about 10 c.m. last antumn, I took a small piece about the middle of May this year, after the bees had completely renewed the portion of the comb cut away. Three days later, when the bees had repaired the damage, I cut the same part away once more, and afterwards a third time. All the three small pieces of wax removed contained pollen and fragments of pollen, the piece built by the hees first having the largest number, and that made last containing the smallest quantity. The number of pollengrains and pollen-husks mixed with the wax is always in proportion to the colour, i.e. the age of the combs. The older the comb the less the weight of the wax it contains, and the greater the quantity of pollen and pollen-husks found in it, so that wax-combs of an almost black appearance contain much less than 50 per cent of real wax (coffee-coloured comb, 57.60 per cent), a fact which every practical bee-keeper will have realised in melting down old comb.

Nay, more than this, not even wax newly made and worked up into cells or cell-covers is absolutely pure. It is true it does not contain any husks and fragments of pollen, but often a surprisingly large number of whole pollen-grains. In order to procure absolutely pure wax I put a swarm which issued on 3rd June into a new hive without any guide-combs, but almost every small piece of wax the size of a poppy grain which I cut off the end of the newly-made comb contained whole pollengrains. A few only of the slides I prepared showed wax in an entirely pure state. I then caught a few comb-maxing bees, and with a needle drew forth the small wax-scales from between the rings of their abdomen. On examining these I found that out of fifteen scales four only were entirely pure wax, the remainder containing from four and five to thirty whole pollen-

grains, (To be coninued.)

Echoes from the Pives.

Scotten Street, Wyc, Kent, Oct. 17.—Seeing no report from my neighbourhood, I am glad to say I have had a splendid season this year for honey, which has been the best year I have had. I have three bar-frame hives, and from one hive I have taken forty 1-lb. sections, and one sectional super weighing twenty lbs., and about thirty lbs. of extracted, and from the other two I have taken nearly the same, which I think you will consider very good for a young beginner. I may say that I have worked my hives upon your storifying system, which I have found a success. I enclose you a sample of my extracted honey, and shall be glad to see your report upon it in the Bee Journal.—H. HEAD.

[We are very pleased to receive such an cheering report from your district. The accompanying sample of honey is of excellent quality, and of clear colour. It would command a good price in the market.—Ep.]

Honey Cott, Weston, Leamington.—Have packed all stocks np nicely for winter, with the exception of two lots of driven bees that I only took about a week ago, but to which I gave combs ready built; I have shut them up pretty close and fed them with a bottle of warm syrup every night, and which they carry down and store below. We have had

some very severe frosts the last few nights, but the sun is quite hot to-day (noon), and the bees are taking advantage of it, to have a good fly, in fact it seems just like summer, there are so many out and about. As I have run rather short of hives, I have been putting driven bees in half-inch and three-quarter hives; having packed the tops well and put roofs on, I expect I shall get them through all right, also I set them in pairs, so that in the spring I can take one of the queens away and join the one to the other, and thus make good strong stocks.—John Walton.

NOTICES TO CORRESPONDENTS & INQUIRERS.

Letters or queries asking for addresses of manufacturers or correspondents, or where appliances can be purchased, or replies giving such information, can only be inserted as advertisements. The space devoted to letters, queries, and replies, is meant for the general good of bee-keepers, and not for advertisements. We wish our Correspondents to bear in mind that, as it is necessary for us to go to press in advance of the date of issue, queries cannot always be replied to in the issue immediately following the receipt of their communication.

All queries forwarded will be attended to, and those only of personal interest will be answered in this column.

T. S.—Becs Dying.—The only eause we can assign for the great mortality in your colony, judging from your description, is an attack of Bacillus Gaytoni. Taking advantage of the first fine, warm day, transfer combs and bees to a clean, dry hive, and feed with phenolated syrup according to Mr. Cheshire's recipe. Cover up warmly, and give plenty of air by enlarging the entrance of the hive. Since the bees are reduced so much in number, unless you can unite them to another colony, changing the queen, it is doubtful whether they will survive the winter.

R. W.-Foul Brood.-The comb sent is not affected with the virulent form of 'foul brood,' Bacillus alvei, but by another type, ealled Bacillus minor. Feed up, in the

spring, with phenolated syrup.

T. D. S.—1. Canadian Bee-Freder.—There is no occasion to remove the Canadian bee-feeder when refilling. All that is needful is to bring ean or other vessel with syrup, and pour in at the receptaele specially reserved for the purpose. The lid has to be pushed aside so as to get at the opening referred to. 2. The amount of syrup given will

T. Jenkinson.—The contents of your letter merit, and will

receive, our best consideration.

SHEREORNE, Dorset.—Your letter is based upon a fallacy. The shareholders in the British Honey Company have never received any dividend.

Subscriber.—Re Foul Brood.—T. F. Ward writes in reference to a question of 'Subscriber' respecting P.S. to Mr. Ward's last letter:— In reply I should say all depends upon the strength of the affected stock, whether to destroy it or not; if a weak one I should say yes, but if a good strong stock, say, eight or ten frames covered, then it might be worth while risking a healthy queen, but the process is a wet one, and he eannot at this season continue the necessary examinations, nor could the bees seal over the medieated syrup. If it is a strong stock with plenty of food, and a healthy queen can be obtained early next year, say March, the combs might be sprayed now, the queen removed, and let it pass the winter without a queen (as many others do); but circumstances alone must be the guide now, as it is not possible to follow the rule, and if there are other hives situated near there would always be the danger of infection through robbing. Unless I knew the whole eircumstances I could not say yes or no.

Communications to the Editor to be addressed 'Strangeways' Printing Office, Tower Street, Cambridge Circus, W.C.

[No. 279. Vol. XV.]

OCTOBER 27, 1887.

[PUBLISHED WEEKLY.]

Editorial, Hotices, &c.

NEW INVENTIONS.

One of the most interesting features of the Quarterly Conversazione is the exhibition of new things in the way of hee-appliances, &c., which are explained to the visitors present, and a free discussion as to their value takes place. At this meeting Mr. Godman of St. Alhans exhibited an improved machine for making brood-comb foundation with a natural base. In most of the machines there is frequently a difficulty in getting the front edge of the sheet of foundation to leave the indentations in the rollers, and recourse has to be had to a quill to get the wax out of the same before you can get sufficient through the machine that you can take hold of. In Mr. Godman's machine the rollers are kept sufficiently open to allow the front edge of the wax-sheet to be passed through until you can take a firm hold of it, when, by the pressure of a lever the rollers are brought into close gear, and the foundation is wound through in a satisfactory manner. This machine (an illustration of which will be found in our advertising columns) is strong and well made, and is an improvement on any we have seen.

Mr. Godman also exhibited some frames with metal ends, which are made in pairs, so that the frames can be either $1\frac{1}{2}$ inches from centre to centre, or by turning the alternate frames end for end they will be $1\frac{1}{4}$ inches from centre to centre at the option of the manipulator, so that whichever width it is desired to have the combs apart the exact distance is correctly kept. These ends obtained a medal at Newcastle, and are as useful as any in the market.

Mr. Lee exhibited some samples of his patent sections, most beautifully made by a model of a machine it is intended to use for making. The ingenious and perfect way in which the dovetailed grooves were cut was shown by the great exactness of the work done in the specimens exhibited. In some of the parts so beautifully had the grooves been made that the piece cut to form the groove actually remained in its position as if it had not been operated on, but with the point of a knife being pressed on it, the strip came out whole, to the surprise of those who saw it. We understood Mr. Lee to say that sections of this kind will be ready for the trade and customers by the end of January. Mr. Lee has made some sections of a size that can be used in the old crates.

some of which he exhibited in a crate. He had also examples of section cases, each frame holding three 1-lb. sections. Seven of these frames complete the tier, and are securely held in position by a simple and novel method, so that, if desired, they can readily be inverted. Mr. Lee exhibited another crate containing seven hanging frames, each holding two 2-lb. sections. Some fine samples of comb-honey in the new sectious were exhibited, having been filled in the apiary of the Rev. Geo. Raynor, and some from the apiary of Mr. F. Palmer, Sunninghill, Berks, in the section cases and The sections were well filled frames noticed above. to the edges, and were free from popholes, the wood of the section being clean and free from propolis. Great interest appeared to be taken in Mr. Lee's exhibits, which were carefully examined and freely criticised, and many very favourable opinions were expressed by those present, many of whom were old and experienced beekeepers. The crates, cases, frames, and sections, are all put together without glue or nails, and we hope shortly to give in the B.B.J. a more detailed description of these useful inventions.

A machine for fixing foundation in sections was exhibited, the invention of Mr. Aplaugh of Canada, made by Mr. Corneil and his son, and kindly sent by that gentleman as a present to the B.B.K.A. Mr. Cowan, who had seen a similar machine worked by the inventor, explained it, and fixed several pieces of foundation in a very satisfactory way. It is somewhat difficult to describe the machine so as to make it intelligible without a drawing. It consists of a frame about fifteen inches square at the base and about twelve inches high; about half way up there is a stage, on which the pieces of sections are placed; in front of this is a metal plate, about four inches square, slightly bent towards the piece of section to be operated on, which it rests nearly in the centre. The stage has a back to it so arranged that half of the piece of the section can pass under, the back forming a support for the newly fixed foundation as it passes along from the metal. Opposite to the metal there is an arrangement for pushing up a sliding back in line with the fixed back, this being the same width as the metal. Underneath a paraffin lamp is placed for the purpose of heating the metal plate, so that the edge of the foundation is melted when placed upon it. With the assistance of a thin piece of wood the foundation is then quickly slid from the heated plate on to the top piece of section, and is kept upright by the sliding back; this is now slipped back, and the next piece of section pushed into position; and in so doing the one just operated on is passed along the stage, and by the time it gets to the end the foundation is firmly fixed, the wax edge having had time to cool. This machine is suited for fixing foundation in four-piece sections only, which have to be put together after the foundation is fixed.

The meeting passed a vote of thanks to Mr. Corneil for his kindness in sending the machine, which was exceedingly well made, and quite a novelty.

BRITISH BEE-KEEPERS' ASSOCIATION.

Meeting of the Committee, held at 105 Jermyn Street on Wednesday, October 19th; present, T. W. Cowan (in the chair), Hon, and Rev. H. Bligh, Rev. Dr. Bartrum, Rev. F. T. Scott, the Rev. G. Raynor, the Rev. F. S. Sclater, Captain Oampbell, J. M. Hooker, H. Jonas, and the Secretary. Letters were read from the Rev. F. G. Jenyns, Captain Bush, and the Treasurer, regretting their inability to be present.

Communications were considered: (1), From the Derby Association, in reference to the award of the Association's Silver Medal to an exhibitor residing outside the boundary, as defined by the Derby Association. The Secretary was instructed to inform the Secretary of the Derby Association that the Committee were unable to award the medal under the circumstances. It was further resolved that the question of boundaries should be considered with the Connty Representatives.

(2), From Mr. J. P. Sambels, suggesting that the Association should forward a complete set of the Association's publications to the Ontario Bee-keepers' Association. Resolved that the Secretary do forward the publications as suggested, and to express the best thanks of the Committee to Mr. Sambels for his suggestion.

The prize-schedule for the Royal Agricultural Show to be held at Nottingham in July next, as prepared by the Exhibition Committee, was considered and approved.

QUARTERLY MEETING OF COUNTY REPRSENTATIVES.

Present: Rev. E. K. Clay (Bucks), W. Lees McClure (Luncashire and Cheshire), Rev. W. E. Burkitt (Wilts), Messrs. Graham and Rayner (Middlesex), F. H. Meggy (Essex), W. B. Webster (Berks). Mr. McClure suggested that, inasmuch as several of the representatives travelled long distances to attend the meetings, some further facilities should be given for the representatives themselves to hold a meeting prior to their meeting with the B.B.K.A. Committee, in order that any subject to be considered might be discussed and presented to the Committee in proper form. The suggestion met with the unanimous approval of those representatives present; and the Secretary was requested to communicate with the County Secretaries and make arrangements for such meeting to be held on the date of the next Quarterly Conference in accordance with the suggestion of Mr. McClure.

The question of the disposal of honey and the advisability of the B.B.K.A. taking steps to get the current prices of honey stated in the columns of the *Bee Journal* was discussed at considerable length. Mr. Meggy, the Rev. E. K. Clay, and others, took part in the discussion, and strongly urged the Committee to use their influence with the several dealers to give quotations regularly.

Mr. McClure reported that honey was now staged continuously for sale in the Liverpool Market.

The question of awarding the medals of the B.B.K.A. at County Shows was discussed. The Committee were recommended to take into consideration the advisability of confining the competition for these medals to members of the County Association residing within the county.

QUARTERLY CONVERSAZIONE.

The last Quarterly Conversazione of the present year was held at the offices of the Royal Society for the Prevention of Cruelty to Animals on Wednesday, the 19th inst., when among the crowded audience present were the following ladies and gentlemen:—Mr. Cowan, Mr. Hooker, Captain Jonas, the Hon. and Rev. Henry and Mrs. Bligh, Miss Gayton, the Rev. Mr. Scott, the Rev. G. Raynor, Captain Campbell, Mr. Meggy, Mr. Henderson, Mr. Webster, Mr. Grimshaw, Mr. Andrews, Mr. Sambels, the Rev. W. E. Burkitt, Mr. Lyon, Mr. Garratt, the Rev.

Mr. Clay, Mr. Baldwin, Mr. Neighbour, Mr. Maclure, Mr. Crawley, Mr. Fatt, &c.

Mr. Cowan presided, and in opening the proceedings said that no special subject would be brought forward for discussion, but that there were several appliances and inventions for exhibition and examination.

The Rev. Mr. Scott suggested that as the Chairman had very recently paid a visit to North America, where he had seen many of the Canadian gentlemen who were in London last year, and had also inspected some of the largest apiaries in the world, it would be extremely interesting to the bee-keepers present if he would kindly describe the wonders he had seen, and also what kind of a reception he had met with from their brethren on the other side of the Atlantic.

The Chairman: When I came here to-day I was not prepared to make any lengthened statement respecting my journeys in North America, but as it seems to be the general wish that I should say something on this matter, I shall be very pleased to give you an outline of what I have been doing over there. It is just three months ago since we (my wife and I) started for New York. After a fair passage we landed in that city, where the After a fair passage we ranged in that city, where the thermometer registered 90°, which seemed a very high temperature on coming off the ocean. We could not therefore stay in New York, but journeyed north up the Hudson River to Albany. From there the first establishment we visited was that of Messrs. Aspinwall and Treadwell. These gentlemen are in business together as hive-manufacturers, queen-breeders, and dealers in hees. Their trade is not on a very large scale, but they do a fair amount of business. We stayed a few days with Mr. Aspinwall, who is proprietor of the Bee-keeper's Magazine, whom I found a most intelligent gentleman, fond of scientific pursuits. I found their appliances are very much the same as ours; and I may here take the opportunity of saying that throughout my wanderings in the States and Canada I noticed that most of the contrivances in use were similar to those adopted by us in Eugland. I have been enabled to carry away a few new ideas: but I feel justified in remarking that we are quite equal to our transatlantic friends as regards hive-making and all the appliances necessary in beekeeping. That which struck me most to the disadvautage of England, was our deficiency in pasturage. You would be perfectly astonished to see the thousands and thousands of acres of waste land across the water filled with an abundance of honey-yielding plants, immense quantities of honey being lost owing to the want of bees to collect it. After spending a few days with Mr. Aspinwall, he took me to see Messrs. Knickerbocker and Lock, the queen-raisers in New York State. Mr. Lock is the former editor of the American Apiculturist. These gentlemen raise queens in a way very similar to the Alley system, that is, by inserting strips of cells, and destroying every other egg. They rear the queens in the same way, but destroy two eggs for one left, and keep them in very much the same way as he does. From there I went to see the largest bee-keeper in the world, Captain Hetherington, who has 2700 hives. He has twenty apiaries, situated at distances of two or three miles apart, in a radius of twelve miles, so that the greatest distance he has to go from home is twelve miles. He and his brother manage the whole of these apiaries, having several men under them; they keep horses and carts, and are hard at work all day long and continue till evening. Business is commenced at 5 o'clock in the morning. I was there during the honrs of business and saw all the working. The men go round from hive to hive and take off crate after crate; perhaps a hive has three storeys of sections, which are promptly examined, and removed if necessary, and in this way 100 or 150 racks of sections are taken off and carried away. The sections are not removed singly, as we remove them.

Captain Hetherington produces the largest quantity of

honey in the States. He does not puff himself, and he never writes to any of the papers; in fact, one seldom sees his name appearing anywhere in connexion with honey-raising. He is one of the most advanced bee-keepers, and the largest producer of honey with the least fuss I have ever seen. He has been at this work for thirty years, always keeping a little ahead of the generality of bee-keepers. He is a good business man, and knows how to gratify the popular taste, having no difficulty in selling his honey. He uses sections the same as we do, and also separators. He says it would not answer his purpose to do without separators, as he requires every section to fit into a crate, because there is no time for delicate manipulations, he and his staff working at high pressure from early morning till late at night. Captain Hetherington drove us over to see Mr. Ellwood, who is also an advanced bee-keeper, owning 400 hives, and who goes in principally for 2-lb. sections. We also made the acquaintance of Mr. Van Deusen, who makes the beautiful flat-bottomed foundation so well known in this country. From Captain Hetherington's we went to Boston, and other places. As I before explained, we were obliged to direct our steps northward owing to the high temperature. We therefore went to Quebec, Montreal, and other places, regretting that Mr. Pringle was too ill to see us when we stopped at Napanee. At Owen Sound we spent an agreeable time with Mr. McKnight. He has 200 hives of bees, and uses sections without separators. I saw a number of his sections; they looked very nice, but some not quite so even as those that were produced with separators. I found, generally, in Canada that it was the practice to dispense with separators, while in the States they were almost invariably used. The Canadians claim to produce more honey without separators. After spending some time with Mr. Mcknight, I went with him to visit Mr. Jones, and saw his works. He is the largest manufacturer of appliances in Canada, and has a 90 horsepower engine working the machinery for the construction of these articles. I was much interested by what I saw there. The husiness is conducted on a large scale. Hives are made in pieces, and stored away by the hundreds, and are supplied to purchasers by the dozen, the score, or the gross. Cases are made up of ten hives together. In Canada bee-keepers work on a large scale, there being very few in a small way of business. They go in for it as a commercial undertaking: and, of course, taking into account the pasturage and the immense extent of their country, they can do so better than we can. While at Mr. Jones's Mr. Corneil came and invited us, and we spent a very pleasant evening together. The journey from London to Liverpool is only a question of a few hours, but travelling in America from one city to another generally occupies a great many hours. The country is not so populated as ours, and I found it necessary sometimes to make an excursion of 500 or 600 miles from one bee-farm to another. On one occasion I went nearly 1000 miles to see the establishment of one honey-producer and foundation-maker, and that was of Messrs. Dadants', of which I shall say more hereafter. After inspecting Mr. Jones's manufactory, his 400 hives, and his queen-raising arrangements, we went to Lake Superior, and from there through Michigan State to Lancing, where I stayed with Professor Cook. He does not keep bees on a large scale; he is more of a scientific bee-keeper, and tries experiments with different hives, the results of each of which are kept separate. His object is to teach entomology and bee-keeping to the agricultural students, so as to enable them to commence that pursuit on leaving the college. There are about 300 students at this Agricultural College, many of whom are interested in bees. On one afternoon Professor Cook asked me to take his class of about forty students, and I am glad to tell you that by means of my microscope 1 was enabled to show them some things they had not

seen before. They were generally well-educated and intelligent men, who, after leaving the college, go out as farmers. The time spent at the College was most agreeable, the Professor being a charming and sterling man. While there I found my way to Mr. Heddon's. He seemed to me a very intelligent gentleman, very quick to seize an idea and appreciate the experience of others. He showed me his apiaries, although he was unfortunately suffering from bee disease, which affects him in a very peculiar way, namely, by producing catarrh, so that he cannot open a hive himself without being attacked by this complaint. However, as I was there, he showed me how the hives were manipulated, the consequence being that he suffered considerably all the evening. He showed me the handling of the shallow hives, and how easy it was to find the queen. I ascertained that he brought his bees through the winter very unsuccessfully, and had lost as many as from forty to fifty per cent in wintering. We discussed the merits of the Heddon and Stewarton hives, and in the course of conversation he stated that last year was a very poor honey season, which bore out the complaint of the Canadians who were over here in 1886. I cannot remember what he said was the average produce, but it was not more than 20 lbs. a hive at any rate. I found in his district the honey season had been very bad, whilst in some parts of New York State the reverse was the fact, 60 to 80 lbs. per hive being an average yield expected; but there were other districts in which not more than 10 to 15 lbs. were obtained. One gentleman (the President of the Michigan Association) jokingly said that no one would believe I had been to the States if I returned to England without boasting about something, and he further said if I came to him I could boast I had seen the apiary where nearly 1 lb. of honey per hive had been obtained this year. From Mr. Heddon's I went to Chicago, and met an old friend, Mr. Newman, who showed me over his place, which is in the city. Unfortunately, I did not let him know when I was coming, and, consequently, he was unable to get any bee-keepers to meet me, but he was most hospitable, taking me for a five hours' drive through the city, and showing me all the lions of the place. From there I went to see Mr. Dadant. He is a Frenchman, who settled in America some years ago, and with his son carries on the business of bee-keeping. They also make a large quantity of comb foundation. Last year they turned out 70,000 lbs. of foundation, but this year not more than 50,000 lhs., as the season had been such a bad one. It is the best natural-based foundation I have seen in America. They melt about 3000 lbs. of wax at a time, and in this way are able to get the colour uniform. The foundation most in demand in America is the natural base foundation made on the Van der Voort machine. They also produce a large quantity of extracted honey, and a little comb honey. They work the extracted honey just as we do, by storifying or putting one hive on another. Their hive is a little larger than the Langstroth hive, with supers about six inches deep. These frames are used for extracting. They have 400 hives now. This year has been a very had year, they having obtained only 9000 lbs. of honey. I think the bad season is demonstrated by the fact that their issue of foundation this year has been 20,000 lbs. less than last year's. From the Dadants' I went back to Chicago, and spent a little more time at Lancing. From there we travelled on to Toledo to see Dr. Mason. He was out, but he visited me in the evening, and we had a chat about bees and other matters. I found him a very nice, agreeable gentleman, quite well up in hee matters. Mr. Cutting, Secretary of the Michigan Association, who is a very smart and energetic worker in our cause, accompanied him, and I regretted time did not permit me to stay longer to visit them. From Toledo we passed on to Medina, where we saw Mr. Root and

his son, Ernest. Mr. Root is the editor of Gleanings, and he and his son made our stay there most pleasant. They are both very intelligent and anxious to pick up information. We spent a very agreeable time at Medina. Mr. Root is a very different kind of man to what I had pictured him. He is short, thin, and seems quite worn out with work. He has worked extremely hard, and has succeeded better than any one clse on that side of the ocean in popularising beekeeping and creating a demand for appliances. He employs 150 hands making nothing but hives and appliances. Everything is turned out on a large scale. He has machinery for doing almost everything, and it was quite a treat going over his large factory and his yard. I met one or two Englishmen employed there, who seemed well satisfied with their lot. I found men hard at work when I visited the manufactory, one making the metal corners for the frames was stamping them out by a very ingenious machine for the purpose. At Mr. Root's, as I had my microscope with me, I was enabled to clear up some points respecting foul brood. He knew all about foul brood practically, but had not been able to make any close investigation of it microscopically. I must tell you that wherever I went I found the microscopes in use inferior to that I had with me. Even Professor Cook had not seen the germs themselves, although he had a mounted slide containing specimens. When I showed him the bacillus under my microscope with a one-twelfth Powell's oil immersion, he was much interested. There was no instrument in the College with such magnifying power. Mr. Root told me he had never before seen foul brood in its different stages. The disease over there is exactly similar to what we have here. From Mr. Root's we went to several other places, Niagara among the number, and afterwards met by invitation the Canadian beekeepers at a large meeting and exhibition of hives and honey in Toronto. The exact quantity of honey exhibited I cannot remember, but the figures were given in the British Bee Journal. The exhibits of two hivemanufacturers, the D. A. Jones Company and Messrs. Gould, occupied a great deal of space, but the honey was rather crowded, like the Canadian exhibit here, which militated against the attractiveness of the show. The clover and lime honeys were excellent. As regards the lime honey I think it is superior to ours, the Canadian climate being better suited for its production, but clover honey is as good here as over there. They had an extraordinary, but, to my mind, somewhat objectiouable, way of selling honey at the show. A section was cut into four pieces, and each piece offered for sale separately, five cents being charged for a quarter. You would see people distributed all over the show biting at these pieces of comb, and eating it as they walked along. By this method a large quantity of honey was got rid of, but it was not pleasant to see the people pushing about in a crowd and messing each other with the sticky substance. I expressed my opinion at the time to some of the bee-keepers, but they assured me it would be impossible to sell the honey at that exhibition on any other plan; and as the all-important object at these shows is to sell the honey, I suppose the custom is likely to coutinue. At this meeting I had the opportunity of seeing a large number of the Canadian bee-keepers. They came from districts far and wide. Mr. Young, editor of the Norwegian Bee Journal, was there at the time, and we were both very hospitably entertained by our Canadian friends. We also met Mr. Holtermann, our Canadian correspondent, Messrs. Pringle, Emigh, Alpaugh, Ilall, Rev. W. Clarke, Mr. McPherson, Mr. McKnight, Mr. Corneil, and others. I was honoured by the presentation from the bee-keepers of Ontario of an address, and also a walking-stick with a gold top, which lies here for your inspection on the table. The address has appeared in the columns of the Journal, where the walking-stick

cannot be inserted. I am glad to say that everywhere we went in Canada and the States we met with a most hospitable reception. We became on good terms at once, our co-workers over the water doing their best to make our time agreeable; they showed us everything, and our difficulty was to find sufficient time to see all there was to be seen. We might have stayed several days longer at each place, and been made most comfortable and welcome, but it was not practicable under the circumstances. At the Toronto meeting of course I was asked to say something about the B.B.K.A., and I made a special point of describing briefly the working and organization of the Association. They were very much interested to hear the record of our work and system as they have nothing of the kind over there. Their Associations are merely Associations of bee-keepers in certain districts, who meet for the purpose of talking over matters connected with their work. After the pleasant time spent at the Toronto exhibition, we went to see Mr. Hall of Woodstock, Vice-President of the Ontario Association, one of the largest Canadian honey producers. He has 400 hives, and has produced as much as 200 lbs. per hive. Of course he is not able to do that regularly, 80 to 100 lbs. being a good average. He makes bee-keeping his sole business, and depends on it entirely for a living, as many others do in America: Captain Hetherington is one, for instance; he was a Captain in the army during the rebellion. He started beekeeping, and being fond of it, made so great a success that he has managed to live sufficiently well and bring up a family on the proceeds of the business. Heddon has made bee-keeping his only means of subsistence, besides lately the editing of a local paper. He had very little money at starting. Mr. Hall was obliged to give up the business he was in owing to bad health, and took to bee-keeping as a livelihood. He is bringing up his family upon it. As a business, speaking generally, it answers very well in America. At Mr. Hall's I picked up a great many ideas, but I cannot describe everything on the spur of the moment, having seen so many different things: I shall, however, be able to enter more into detail in the Bee Journal. From Mr. Hall's I went with him to Mr. Pettitt, President of the Ontario Bee-keepers' Association. As he was not able to be present at the Toronto meeting, I thought it was only right I should go and see him, and I stayed with him from Saturday to Monday, and spent a very pleasant time there. His hives are very similar to ours, and he has adopted a frame almost the size of our standard, which he finds answers quite as well as the deep frame he had been using. He works with sections of one and three-eighths width without separators. From there Mr. Pettitt accompanied me to see two or three other bee keepers who lived between his place and St. Thomas. One of these, Mr. Alpaugh, a young man, I found to be an advanced bee-keeper, of great intelligence. He is the inventor of the machine for fixing foundation in sections, which I will show you at work here to-night, and which has been sent by Mr. Corneil. You will see it is an ingenious contrivance, but, unfortunately, I cannot show you the working of it as well as he did himself. From Mr. Pettitt's we went through New York State to Washington, and from there to Philadelphia. In Carpenter's Hall at the latter city, we met with a hearty reception. This Hall is of great historical interest, for it was there that Washington sat, and the first Congress met, and the Declaration of Independence was signed. At Philadelphia, we made the acquaintance of several scientific bec-keepers. I believe there are more scientific bee-keepers in Pennsylvania than in any other part of the States. Dr. Townsend is President of the Association. Mrs. Thomas, who goes in actively for bec-keeping there, asked if we had any lady bee-keepers in England. On my replying 'yes,' she said we ought to make more of that fact in the Bee Journal, because such notices would stimulate other ladies to undertake

the same pursuit. Although it might do in America, bee-keeping on a large scale was not suitable for ladies in England (laughter). This may appear strange, but there is, undoubtedly, a difference between the mode of life led by ladies in America and in this country. American ladies are used to hard work. In every household every lady does her share of work as much as the man does, and performs her part of the household duties. There is a great difficulty in getting servants there, and she has to do cooking, sweep the rooms, or dust the furniture. Gentlemen also assist in the household duties, sometimes cleaning the boots. You will, therefore, see that what American ladies might do ours could not. I must not forget to acknowledge our indebtedness to Dr. Townsend, Mrs. Thomas, and Mr. Arthur Todd, for their kindness. The latter gentleman took us about and showed us everything of interest in Philadelphia. It was there I met our friend, Mr. Hooker's son, who also kindly showed us about. From there we travelled back to New York, and across the ocean home. I am afraid in the foregoing remarks I have only given you a slight idea of what we saw and did and the districts we have travelled over, but the pages of the Bee Journal shall give you fuller particulars from time to time. Wherever I took my microscope it was a source of great interest and delight, and the preparations were attentively examined. I have already told you how hospitably we were received everywhere in the States and Canada. All bee-keepers seemed pleased to meet me, not only as a brother bee-keeper, but as the representative of the bee-keepers of this country. I assured them that the compliments paid to me would be appreciated by the members of our Associations here, and I can now only repeat my expression of thanks for all the kindnesses I received on the other side of the Atlantic. Our trip was a very enjoyable one, although travelling is not so easy there as here, and one becomes wearied by the long distances. Of course, my wife could not hear the fatigue of accompanying me everywhere. Accommodation is not so good there as here; sometimes, in out-of-the-way places, we have had to sleep on the floor, owing to unwelcome bed-fellows. In conclusion, let me say I shall be happy to give you any further information in my power, if you will ask me questions on any specific points.' (Loud and protracted

In reply to questions by Mr. Meggy, the Rev. Mr. Clay, Mr. Garratt, and Mr Lyon, the Chairman said that Captain Hetherington's bees were Italians, or crosses between them and black hees. Large honey-producers like the Captain raised their own queens, and did not deal with queen-raisers, because where an extensive business was done queens were wanted by the dozen. It was found by experience that Italian bees or a cross between them and black hees were best suited to the American climate, at any rate in that district. Carniolan hees were being introduced in some places, but not largely. It was the practice always to select queens from the best stocks. All the sales at the show were retail. A large quantity of honey was sold by producers to the stores in the neighbourhood. The only place where he had examined foul brood was at Mr. Root's.

Mr. Lyon asked what was the average price per lb. of honey paid to producers, because he thought, considering the market price of Canadian honey in this country, a bee-keeper over there who only had 400 hives could not

make a very good living.

The Chairman replied that the usual price was from

fourpence to eightpence per lb. Mr. Hall had a very bad season last year, but as a rule he made a good living

by bee-keeping.

In reply to the Rev. Mr. Raynor, the Chairman said that Captain Hetherington always introduced his queens by means of a cage very similar to the pipe-cover cage. The Captain said it would not pay him to practise direct introduction. He must make sure of introducing every queen successfully. He had tried the direct method, but had lost so many queens thereby that he could not afford to waste any more time by experiments. The question was governed entirely by cents and dollars, and every day was of consequence. One gentleman he (the Chairman) met who frequently tried direct introduction, and by taking the precaution to smoke the bees and the queen and thus give them all the same scent, had been successful.

In answer to Mr. Grimshaw and Mr. Garratt the Chairman said that Captain Hetherington used a different smoker to those employed here. A fire was lit in the American smoker, which sent out an immense quantity of smoke. He (the Chairman) had been present during the manipulation by Captain Hetherington. gentleman would not allow any of his friends to be present on such occasions unless veiled. A tremendous puff of smoke was blown into the sections, which caused the bees to rush down and crate after crate was removed in that way—a work occupying only a few moments. Very few bees were killed or taken away, perhaps not more than two or three. The wood used in the smoker was maple cut out into pieces about four inches long and half an inch square. Some people, like Mr. Heddon, used moistened plane-shavings mixed with dry shavings, which combination smouldered very much and gave off a considerable amount of smoke and steam. In every apiary there was always a smoker ready at hand. He (the speaker) took the opportunity of testing Mr. Grimshaw's apifuge at Messrs. Knickerbocker & Lock's. Mr. Lock put some on his face and hands when examining a hive of savage Cyprians. One bee flew direct at his face, but did not sting, at which Mr. Lock was agreeably surprised. He (the Chairman) left some of the apifuge with several persons.

In reply to Mr. Sambels, the Chairman said that sec-

tions in America were propolised late in the season just as much as here, but early in the season the honey flow there was very rapid, and they were consequently not propolised so much. Captain Hetherington considered seventy pounds per colony a very fair yield. With regard to carrying bees away on the sections he had omitted to say that every establishment had its honey house, and the windows in these were so arranged that bees taken in could get out again. In America, however, they were not so particular about destroying a few bees as we were, so long as time was saved. They do not trouble to remove the sections as carefully as we do, and with them it is of no consequence to crush a few bees. Wintering in Canada is much easier than in the States, owing to the dryness and equable temperature. The climate of the former is colder, but less changeable than that of the States. Captain Hetherington's greatest difficulty was in wintering. He moved all his hives into cellars, but his losses during the spring had been great. He had lost as many as ninety per cent some years and could not ascertain the cause. He had a house built partly above and partly below ground, which was ventilated by a pipe running a long distance under ground, the air inside the building being warmed to the temperature of the earth. That gentleman's apiaries were in New York State and occupied a very cold region; in fact, they existed in a snow belt which extended for about fifty miles north and south. The district seemed always to be visited with a larger quantity of snow than was experienced either north or

south of it for many thousands of miles. Melons would

not thrive in that belt, though they came to perfection

^{*} The above outline of Mr. Cowan's travels through the States and Canada, and his narrative of visits paid to beekeepers, were delivered without the aid of notes, and with little previous preparation, which must be his apology for any possible omissions or misstatements.

both north and south of it. In Iowa and Illinois bees can be wintered out-of-doors.

The Rev. Mr. Raynor said he thought the meeting was deeply indebted to Mr. Cowan for the very lucid and interesting description of apiculture as carried on across the Atlantic with which he had favoured them that evening, and he (Mr. Raynor) wished to express on behalf of his brethren their heartfelt thanks to the Chairman. He was glad to know that, with the exception of pasturage, bee-keepers here were in every way equal to their co-workers in America.

The Hon. and Rev. Henry Bligh seconded the motion, which, upon the suggestion of Mr. Garratt, was formu-

lated thus:-

'That this meeting expresses its best thanks to Mr. Cowan for his kind and lucid description of American Apiculture in the United States and Canada, and also desires to record its sense of the kindness and hospitality shown to him as the representative of British Beekeepers by American and Canadian bee-keepers.'

Mr. Grimshaw, in supporting the resolution, said be was very glad to know that the bacillus of foul brood seen by the Chairman was exactly like that which English bee-keepers were accustomed to. It was a comfort to think that instead of having a dozen different varieties to fight there was, probably, only one kind.

Mr. Sambels also supported the resolution, saying he was glad that Mr. Cowan had convinced the Americans that English bee-keepers were not a few decades behind He thought after the Chairman's visit they would, perhaps, adopt some such system and organiza-

tion as prevailed in this country.

The resolution having been carried, amid applause, the Chairman expressed his thanks to the members for their kindness. He said his visit to the great western Continent was quite a labour of love, and that he and Mrs. Cowan had benefited greatly by the tour, notwithstanding that the railway journeys were often very fatiguing. When at Toronto he was asked to give an opinion respecting Canadian honey, and efforts were made to induce him to commit himself on that subject, and in that connexion he was very much pressed by the persistence of interviewers. He could only confess that their clover and lime honeys were very similar to those in England. With regard to thistle honey he was rather sceptical last year, and had said he could not understand any country producing sufficient thistles to give a crop of honey; but his opinion on that point had been rudely shaken when he saw hundreds of acres of thistles. Although an Act existed against the cultivation of thistles it was not put in force. He thought his visit and the reception accorded him would have the effect of cementing the bonds of friendship between beekeepers in all three countries. He had found that some little prejudice was felt in the States against English beekeepers, who it was thought had treated the American honey dealers somewhat badly. However, a little explanation soon removed the grievance and secured the Americans' approval of the steps taken by the Association. He was quite sure their friends over the water would be gratified by the resolution just passed. (Cheers.)

After a short conversation between Mr. Garratt and the Chairman respecting Canadian thistles, Mr. Sambels proposed that a copy of the resolution should be sent to the American Bee Journal, the Canadian Bee Journal, and Gleanings, which proposition was seconded and supported by two gentlemen among the audience, and

carried unanimously.

Mr. Lyon asked whether the Chairman had any practical experience of the working of the Jones-Heddon

The Chairman said that hive was not in very general

use over there, and Mr. Heddon himself was not using it very largely.

Mr. Grimshaw and Mr. Sambels referred to the peculiar and various effects caused by the smell of honey on some persons. In answer to the latter gentleman and Mr. Lyon, the Chairman said he saw no skeps in America, bee-keepers there being too advanced for any such imperfect appliances.

Mr. Alpaugh's method of fixing foundation by means

of slit sections was then exhibited for inspection.

Mr. Garratt feared that the foundation as fixed might buckle, but the contrivance was commented on in favourable terms.

Mr. Godman's machine for embossing foundations

was also exhibited.

Mr. Baldwin said that, although the Canadians had such vast tracts of pasturage, they did not seem to have profited much by Nature's gifts, many bee-keepers in England having produced far larger yields of honey—the Chairman himself, for instance.

The Chairman said the most he had produced from one hive was 230 lbs., but then he was a bee-keeper on a small scale compared to the Americans. could not afford to devote the time and care to beemanagement as was done in Eugland.

Mr. Baldwin thought there was nothing to fear from

American competition.

Mr. Sambels said Miss Gayton was a very successful lady bee-keeper in his county, and had produced from one hive during the past season a far larger quantity of honey than any of the American yields to which the Chairman had referred.

After a few remarks from the Rev. Mr. Raynor, the Chairman said it was not fair to select the produce of one single hive as an example of the amount of honey raised here or there; an average must always be struck. Mr. Hall, of Woodstock, has obtained 400 lbs. from a single hive, and Mr. L. C. Root as many as from 400 to 500 lbs. He (Mr. Cowan) could not say that his average was 230 or 200 lbs. A certain number of years must be considered when computing an average. Captain Hetherington did not complain of from 60 lbs. to 80 lbs. average. He (the speaker) had snggested that it would be better to reduce the number of hives, and make sure of paying more attention to the management, by which means he thought an equal, if not better, yield would be obtained.

After a few words from Messrs. Sambels, Baldwin, Hooker, and Neighbour, Mr. Lee's system of dovetailing sections was shown and explained; and a bar-frame belonging to Mr. E. J. Jones, the speciality of which was that, instead of the side and bottom bars being of one piece, they were halved. In order to insert the foundation sheet, the metal ends were to be removed, and the frames would open like a book. (Further reference to articles

exhibited will be found in p. 469.)

During the remainder of the evening, the Chairman evoked much interest by exhibiting under the microscope various portions of the bee's structure, including the tongue, the semicircular comb used for cleaning the antennæ, a longitudinal section of the eye, the worker's claw and sting. He also showed some peculiarly shaped cells, which had been cut out of frames by himself in America.

USEFUL HINTS.

Weather.—The autumn weather we are now experiencing is, to our taste, simply perfection—warm, bright, bracing, dry—the day temperature much in excess of the night. Yesterday and to-day (Friday and Saturday) have been days of brilliant sunshine, without a cloud to dim their brightness, while that invigorating atmosphere, which a fine dry English autumn alone affords, prevails from day to day; while the thermometer is down to freezing point at night, the mid-day temperature in our bee-houses is 84° Fahr.—weather in which almost any operation may be performed in the apiary.

BEES BREEDING.—Several of our colonies are breeding far more extensively than we approve, and pollen, in pellets, as large as those seen in April and May, are rapidly conveyed to the hives during working hours. This occurs chiefly in colonies whose aged queens have been lately superseded by imported Italians—a result we have often before noticed. If the coming winter prove mild and open this late breeding may be an advantage, but, after eight or ten weeks of hard frost, we dread to forecast the condition of such colonies. Driblets of food during a late fine autumn will often cause breeding, but we are wintering entirely on natural stores, not an ounce of syrup having been supplied to our bees since the spring months.

CAGES AND INTRODUCTION.—In response to our offer to present queen-eages to our friends and readers, we have received numerous applications, with which it has afforded us much pleasure to comply. Will those who have received them—many of whom have desired to send value in stamps—please to accept them, their cost being a mere trifle? In future Messrs. Neighbour will keep a supply of these eages on hand. From the correspondence ensuing from our offer, we are sorry to hear of the loss of so many queens in attempts to introduce direct. Even where queens survive they are often injured by long encasement; hence our advice to the inexperienced is to avail themselves of the security offered by the cage, during the honeyless season of the year at least. With the cage we have been busily engaged in introducing queens during the last month, and have met with no loss, often leaving the queen eaged in the brood-nest for three or four days from want of time to set her free, and always finding her vigorous, healthy, and improved in appearance and condition. We have also found it a good and safe method of keeping a supernumerary queen to eage her on the confines of the brood-nest of a strong colony still possessing its own queen at large. Such queens, after a week's imprisonment, have been found well nurtured, strong, and healthy. It is a curious fact that bees will feed an alien queen when protected by the cage, which, without that protection, they would instantaneously destroy. Queen introduction at so late a period is exceptional, but the fine, brilliant weather we are now enjoying is also exceptional.

Skeps versus Foul Brood.—Were it not for the fear of that terrible pest, foul brood, we should rest perfectly contented with the condition and prospects of our apiary, but, with the scourge all around, a dreadful nightmare oppresses us and compels the use of precautionary measures. To the expressed view that colonies in skeps are less liable to foul brood than those in frame-hives, or that the disease was not in existence before the introduction of the latter, we must demur. It is more than probable that the dire disease existed in ancient times. Virgil speaks of Aristæus having lost his bees by disease—'amissis apibus morbo,' and again, 'Si vero, tristi langue-bunt corpora morbo,' (If, moreover, their bodies shall languish with a sad disease). &c. Varro, Pliny, and indeed all ancient writers on bees, treat of their diseases, our own Dryden having amplified the latter's statement,

'And crowds of dead that never must return To their loved hives, in decent pomp are borne; Their friends attend the hearse, the next relations mourn.'

Our ancient English authors treat largely, too, on the diseases of bees, and we should hesitate to affirm that foul brood has not existed in this country as long as the bees have existed. The old straw skep, without roof or cover, saturated with moisture and rotten to its core, is a meet receptacle of the spores of bacillus, and there is

scarcely the shadow of a doubt that the disease has existed here from time immemorial. And the same may be said of many other diseases, which appear now and again under novel and scientific names. So far, indeed, from the fell disease following in the wake of the framehive, we are more inclined to think that it has followed in the wake of the old straw skep and of the modern expert. Absit omen!

SALE OF HONEY.—It is a very common complaint of County Associations that there is no market for their honey. We fear there is much truth in the allegation. But taking into consideration the great depression prevailing in every branch of industry, how can we expect ours to be the one exception? Again, are the County Associations doing all that lies in their power to remedy the evil? In the sale of honey very much depends upon the style in which it is 'put upon the market'—the 'get up, as it is called. Our best dealers will purchase none but first-class honey, especially in sections: and how few of these do we see even at our shows! Very few indeed are well and evenly filled, and fewer still are worked in clean new section-boxes of snowy whiteness. More often do we find them in dingy, soiled material, propolised within and without, and the propolis left adhering. Surely there is much improvement needed in these points. Teach producers, first of all, what is meant by a really good section, and, next, teach them how to produce it and present it in proper form for the market. The same may be said of extracted honey also. Then, again, it is a great mistake to force the entire honey yield of the year upon the market at once. What should we think of the farmers if, even in these terrible times of depression, they forced the entire corn-crop of this country upon the market within three months of its ingathering? Should we not expect prices to come down? Granulation, to a great extent, may be prevented if proper means be used, just as the farmer by care and foresight can keep his corn in dry and saleable condition as long as he pleases, ready for the market whenever a favourable opportunity may offer. Try as we may, we shall never teach people to consume the entire honey crop of the year in three months, and to abstain for the remaining nine months.

PREVENTING ROBBING.—A friend informs us that he has used carbolic powder most successfully as a preventive of robbing. It is the ordinary disinfecting powder, sold in 1s. tins, with perforated lids, of which a small quantity is sprinkled on the robbers when attacking. The would-be thieves, disgusted with the scent, return to their hive only to be shunned or expelled by their sisters. Generally speaking, bees which have been in contact with carbolic acid, i.e., upon which has been sprinkled a little of the solution or powder, immediately desert their home and kindred, and are seen no more, perishing as outcasts shunned by all. If a little of the powder falls upon the guards, no great loss is sustained, as others will quickly supply their place, and the speedy check to raiding is of greater importance than the lives of a few bees.

With a press of most interesting matter for the pages of the present issue of the *Journal* our readers will kindly excuse the curtailment of our 'Hints.' For work to be performed, but which has *not* been performed, we beg to refer them to 'Hints' in our late issues.

ITALY.

In reviewing the result of the season which has just closed, the *Apicoltore* of Milan, whilst exhorting its readers to look forward to better things in future, points out that, generally speaking, all the hopes which had been placed upon an abundance of honey from the heather have been disappointed. It would appear, adds our Italian contemporary, that this honey-producer has this year followed the example of the acacia-tree, which

has been very prolific as regards blossom, but very sterile as regards honey. The editor concludes, however, by assuring his readers that the above circumstances will not be allowed to interfere with his hopefulness, particularly as this scarcity of honey has not been limited to Italy alone, but has been, on the contrary, very general both in Europe and in America as well, and he ventures, therefore, to express his conviction that his hopes in the future will be participated by all beekeepers throughout the land.

Correspondence.

IN THE HUT.

'Weaving spiders, come not here; Hence, ye long-legged spinners, hence!

[1324.] At last we have got our bees from the moors, but our best-laid schemes have gone agley, for we had fixed on to-day for depriving them of surplus stores, and here we are, kicking our heels during an incessant steeping of rain, with nothing to do but smoke and talk bec-talk. Patience, Huttites! wait; and in good time

'The musical hounds of the fairy king That hunt for the golden dew,

shall sally forth again. Wait till a fairer day, for it is not yet the time

> 'When chilling frost and nipping wind O'er earth exultant reign, And close within the hive confined The Brown Bee shall remain.

Fine days and frosty nights. The glass now drops to freezing nearly nightly, and we shall only have occasional days this month when we can open our hives. We have been driven to this delay (Oct. 15) in wintering preparations in consequence of the peculiar season on the Yorkshire moors, inasmuch as the weather broke just as the heather bloomed in full; the bees had only one week's fun, the rest of the time being what we call 'snatch days;' indeed the weather was so fickle that three weeks ago had they begun running downstairs with the contents of sections. We therefore left them later on the moors, in hopes of a change, this coming only in time to enable them to fill up and seal frames, but leaving sections unsealed. Such sections will be carefully wrapped up and put away so that we may in June get the perfection of honey—heather and hawthorn mixed; we cannot extract it to get a nice article.

Your leaders lately remind us that

" Aphidean honey " is not strained; It droppeth as the gentle rain from heaven Upon the leaves beneath.' (Ugh!)

I suppose everybody takes care to put a pencil—or some other-mark on the top of each section, either at the time of putting on or taking off section crates. When this is neglected, and they get sent away by rail, wrong way up, the jar (not the honey-jar) of the jour-ney causes leakage because of the downward pitch of the cells, or, when stored away, they bleed.

Speaking of mice in bee-hives (vide Mr. Dixon in recent issue) one huttite, last winter, found a dead mouse (inside a hive) which had eaten its way through combs, and in tightening up the frames it had evidently got nipped and jammed to death between two bottom bars. Our bees left this mouse severely alone; but then, we have such strange bees! The little beggars won't do

any wonders for us.

What, Mr. Useful Hints, surely you do not mean to punish the many for the criticisms of the few! Perish the thought that anything at present is likely to jeopardise the regular appearance of those kernels of practice judiciously flavoured with germs of theory—Useful Hints. 'No Jottings' this week neither.

There is one thing, however, which causes us to re-

joice at the close of the season, and that is, the temporary stoppage of reports from county meetings. suppose it is only a case of 'suspended animation!' They will come round again. I have often wished, when reading the full lists of prizes at various shows, that an inspiration might come over the secretary whilst writing out his report, to 'tell us a bee-tale.'

Somebody has parodied the lines quoted by Mr.

New (p. 383):-

I knew by the smoke that so gracefully eurled Above the broad brim, that a bee-man stood near, And I said, in my heart, 'If there's peace in the world, A bee, that is Humble, might hope for it here.'

By the time these lines are in print, we shall have had 'Welcome the coming' over, at the Conversazione, in hailing the return of our chief 'frae for'n pairts.' I may be branded as a greedy one, but I anticipate something 'richt guid' in your columns as a result of our Editor's

By the way, if some courteous correspondent will contribute to your columns a list of the bee-keepers in the McNally family—Christian names, and relationships—it would be of considerable value as a reference; there is such a lot of 'Please, sir, it wasn't me; it was the other boy,' that we ought to know whether the other is which or not.—X-Tractor.

AMONGST THE RED INDIANS.

[1325.] Very recently I paid a visit to 'Buffalo Bill.' It was not my first visit by any means; I was familiar with his show and the 'war-whoop' of his horde. I had gone carefully over the place, watched the process of extracting 'John Bull at the switchback railway and tobogganing slide, stood and gazed on 'Liberty' and tried to imagine myself entering New York Harbour, and admired the ice palace. I had given more than a passing look at the 'arts, manufactories, and resources of the greatest and best honey-producers in the world.' I had looked amongst the canned fruits, essences, meats and lobsters; sweet and delicious (?) drinks there were without number, but I could find no honey. Whether the American bee-keepers lack pluck, or have given up all hopes of redeeming their character on the London market, I know not; but I must confess I was greatly surprised to find them not represented, and I had turned home with the probability of not paying the show another visit; but on this particular day having to go to town I thought I would give it one more look. In town I met the terse and logical inventor of 'Apifuge,' and a hint or two was sufficient to induce him to mount a 'bus with me for the 'Wild West.' Arriving we turned into the Indian Encampment, but stillness reigned throughout the camp. The 'Hon.' we did not wish to interview; 'Buck Taylor was 'bossing' up and down showing off his flowing hair to the crowds of English girls that were about. Cowboys there were in abundance, but our thoughts were not centred on them. The Yankee ladies of the show were —we judge from appearances only—all 'at home,' but even 'little Sure-shot' herself had no charms for us; we wanted the real dusky article, male or female, we cared little which, but 'red-skins' we were in search of; and, for the time being at least, we were blind to all the charms of the 'whites.' We 'took stock' of the sable gentleman that roasts the 'pop-corn' and watched the humorous look in the corner of his eye at the end of each oft-repeated husky yell of 'S-o-u-u-c-h-! It is honey-coated!' and the bland look of disappointment when he discovered it failed to make even a muscle of our faces relax. By this time the corn commenced to burst and 'pop,' and elicited from our 'darky brother' the cry 'Look! Wonderful!' but failing even then to get a response from us he turned his back on us with disdain. Now the 'X-tractor' was brought into play in the shape of a loud whisper to myself, 'Honey-coated! pshaw!

glucose?' This had the desired effect. 'The "popcorn," ladies and gentlemen, is sweetened with granulated sugar and the best American strained honey, you cannot do better than try it; only threepence a ball the corn and twopence a bar the candy and no glucose!'

At this moment I espied a figure mocassin-shod and enveloped in a striped blanket, holding a tête-à-tête in dumb show with a flash young English lady in charge of a cigar-stall. Here was our chance. So we proceeded to first get the lady to forward our project. 'Did she like honey?' 'Not much.' 'Wonder if the Indian did;' but he meanwhile had enveloped himself still closer if possible in the folds of his blanket, so that we could only get a glimpse of his eyes and a small patch of his forehead by peeping in a way amounting to rudeness. A motion from the lady caused him to look at what we wished to show him. My companion and I both placed a piece into our mouths, the lady takes a taste to encourage him, and as a reward for our andacity our dusky friend allows us to put a nice piece of section honey into his mouth from the blade of a bone knife, and we watch the result with some amount of alarm. 'Would he tomahawk and scalp us? Should we be the cause of a sensation in the evening papers? Would the coroner have to summon twelve "good men and true" to give a true verdict about us?'
But nothing happened. The 'brave' stood erect, rolled the blanket around him so that we could not even see his eyes, swallowed the 'mel' and slowly relaxed his blanket again. At this juncture two more passed to the rear of us. These we also waylaid. 'Chippa-wah' No. 1 stood and looked; 'Chippa-wah' No. 2 gave a look, a most decisive grunt of disgust, and passed on. My versatile friend proceeded to treat 'Chippa-wah' No. 1 to a liberal helping; he took it into his mouth with a broad grin, wrapped himself up and proceeded to assimilate it. If ever I felt sorrow over feeding any one with sweets I did that poor Indian. Some of us old stagers know the effect of a good lump of strongly flavoured comb honey on our bronchial tubes. But how about a throat that is not hardened to the acids contained in honey? But the demeanour of the savage gave us no indication of what was passing through his mind, nor the amount of pain he was enduring. He simply stood erect and immovable, but he refused the offer of a second helping with a most decided grunt. But the first 'brave' who all this time stood looking on did take a second taste, and I judge by his demeanour rather liked it.

We next passed on to the encampment again. The first we sighted was a 'squaw;' she looked at our section and passed on 'dumb saucy.' The next was the tallest, finest 'brave' it was our fortune to come across, but our invitation made in 'dumb show' only drew from him a grunt more decided and scornful than we had yet got from any of the others. By this time a small crowd of sight-seers had gathered around us, which was above all things not likely to forward our project. At the door of one of the tents sat an Indian girl about five years firing off a toy pistol some one had given her. The cool way in which the small child placed on the percussion caps and listened to each consecutive report without a wink of amusement or animation lighting up her eye was a study. We tried to attract her to us, but never a move did she make. At last a jolly young fisherman up on an excursion drew from her a small cry of pleasure by offering her a penny. She dropped her pistol and ran to him with outstretched hand to take it, but the penalty was to be a 'kiss.' The child stood as erect and immovable as a statue while the smart young 'salt' imprinted a kiss on her cheek that was audible for some yards. The moment the 'chick' was released she ran into the tent and as quickly reappeared-minus the penny-to meet the sight of a biscuit being offered her by a lady. This was also taken into the tent, and no other offer being presented she sat down again intent on exhausting her box of percussion caps. As no one would

yield to our charming we at length gave it up—cigarettes, money, biscuits, gew-gaws, 'bacca, anything but 'Mel,' which seemed to be unknown to and unappreciated by them, or probably is held in disrepute by them as being gathered by the white man's 'stinging-fly, the Ahmo, the bee, the honey-maker,' which always 'swarmed before him' in his appropriation of their once happy hunting grounds. I confess I turned from these fine fellows with a sigh, not because I had failed to induce them to partake of my 'sweets' so much as when I remembered in the words of Hiawatha:—

'The westward marches
Of the unknown, crowded nations.
All the land was full of people,
Restless, struggling, toiling, striving,
Speaking many tongues, yet feeling
But one heart-beat in their bosoms.
In the woodlands rang their axes,
Smoked their towns in all the valleys,
Over all the lakes and rivers
Rushed their great canoes of thunder.

Then a darker, drearier vision
Passed before me, vague and cloud-like;
I beheld onr nations scattered,
All forgetful of my counsels,
Weakened, warring with each other;
Saw the remnants of our people
Sweeping westward, wild and woeful,
Like the cloud-rack of a tempest,
Like the withered leaves of autumn!'
AMATEUR EXPERT.

BEES AND MANURE-HEAPS.

[1326.] I am very pleased that our old friend, Mr. Grimshaw, has fallen somewhat into the views that I expressed in my letter published in the Bee Journal of the 6th inst. (1295); although he only gives me credit of being 'warm,' meaning—as expressed in the game of hideand-seek-that I am only near the mark, but have not hit right upon the correct theory, and so venturing to suggest that he has 'hit the nail right upon the head.' Well, perhaps he has wrested the honours (?) from my hand. I am sure that I am perfectly willing to give in to his superior knowledge of chemistry, knowing that I am but poor fist' at the best. Of course, we are not all born scientists in any one particular branch, it would be against all advancement in this world of multifold ideas and knowledge. I made the assertion (vide 1295), that hippuric acid $\mathrm{HC_9}$ $\mathrm{H_8}$ $\mathrm{NO_3}$ is found in the urine of horses and cattle. Yet Mr. G. asserts that hippuric is the acid contained in the human excreta and uric in cattle, thus misplacing both their positions and terms. I don't say for a moment that he is wrong; but still, I remember that when a little boy I was always taught that hippopotamus, a river-horse; hippodrome, a circus for equestrian exercises; hippophagy, eating horse-flesh; hippopathology, veterinary science; hippolith, a stone found in the stomach of a horse; hippocampus, a fish with a head like a horse, &c., were, in the first syllable, derived from the Greek word hippos, signifying a horse; perhaps my tntors were wrong and onght not to have led me to suppose that hippuric had anything to do with horses, but yet I can hardly conceive that a very formidable work on chemistry now laying before me should be wrong as well; and yet, even this informs me that hippuric acid is found in the urine of horses in quantity, but in larger quantities in that of the cows, and uric acid H2 C5 H2 N. O. in that of humans, but in each of these a faint trace can be found of both, that is to say, in humans a faint trace of hippuric, and vice versa. But still I will give in to Mr. G. Oh, by-the-by! I find that an ordinary dictionary (Nuttall's) contains the following, 'Hippuric, obtained from the urine of horses.' But still I'll give in.

Now I'm going to ask for information from Mr. G.

I always endeavour to obtain this from some one who, I think, ought to be capable of assisting me, and so in thus soliciting I expect to be fully posted up upon the following subject, thus adding one more item to my chemical knowledge, which, as I before owned, had been sorely neglected by my mentors. In Mr. G.'s letter (1316), he tells us that hippuric will be secreted by all animals which have benzoic acid given them.' My question is: Upon what food can an animal be fed in order that benzoic acid may be taken into its system with same, in quantities sufficient to form hippuric acid, which is found in every manure-heap frequented by a few bees? I own that I am in a complete fog, -I don't know. The adage says, 'Where ignorance is bliss,' &c., but I really want to be wise. But stay! perhaps they feed horses, &c. in Yorkshire upon gum-benjamin, a resin flowing from the Styrax benzoin, a tree of Sumatra.

Following up the letter, I find an astonishing misstatement has been made in confounding nitro-benzol C₆ H₅ (NO₂) or artificial essence of almonds with the benzoin products. Artificial essence of almonds is produced by the action of strong nitric acid on benzol, a liquid obtained from coal-tar, and by no means to be confounded with benzoin. Nitro-benzol cannot even be used as a flavouring ingredient on account of its rankness. It is sometimes used for scenting cheap hair-oil and soaps.

After this latter, I think I may be more than 'warm' on the subject of the cause of the visits of bees to manureheaps, and also may be correct in my assertion as to the relative positions the two controversial acids ought to be placed in.—W. B. Webster.

NOTICES TO CORRESPONDENTS & INQUIRERS.

- E. T.—1. The insects you forwarded are of the order Diptera -flies not bees. They, however, bear a great resemblance to bees. Their specific name is Eristalis fossarum. They live on the vilest garbage, and are often called 'stink flies.' 2. The sample of sugar sent is not the most suitable for dry-sngar feeding; Porto Rico is the best. This, however, should not be given till next spring.
- WILLIAM JOHNSTON.—It is not desirable to disturb your bees so late in the season. Wait till next spring, and when the hive has swarmed, twenty-one days after drive and transfer to bar-frame hive.
- W. K.—Breeding Space.—It is generally allowed by those who have experience of the various races of bees that Cyprian, Carniolan, and Italian queens are more prolific than black queens, and consequently require more breeding space, especially if natural swarms are not desired. It is not uncommon for the queens of the three former races to keep twelve standard frames well filled with brood, while, in our experience, eight or ten suffice for black queens.
- J. White.-1. Ripened Honey.-Frames of sealed honey are ripe when removed from the hive, and may be kept free from granulation if stored in a dry, warm room or closet (see answer to 'Aps'). 2. Age of Queens.—It is generally recommended that a queen should not be kept after her third year, many say after her second, and a few would supplant her after her first. We have found queens most prolific in their second year. Many, again, do not supersede queens at all, but allow the bees to decide the matter for themselves. When driving a swarm, the queen may be changed by driving the swarm into a skep, removing its queen, and shaking out the bees; the new queen being placed amongst them while running in.
- Aps.—Unscaled Sections.—As a rule it is the safest and best plan to extract the unsealed honey from unfinished sections when the honey harvest is over, as this thin unripened honey soon becomes acid, and is not suitable food either for men or bees. We have not much experience of heather honey, but believe that if the unfinished sections were placed, say, for twenty-four hours in a temperature of 90' Fahr., the honey might be extracted; when the sections, minus the greater portion of the

honey, being placed over a strong colony for a few hours on a fine day would be cleaned by the bees, and might then be stored for use next seasou. On the other hand, if kept as they are in a dry and warm room, it is likely that the honey might not granulate, and could be used, as you propose, at spring. But granulated honey is generally cleared out of the combs at spring by strong colonies, and, to say the least, is of no advantage to the bees. In the brood-chambers honey may be considered ripe when the cells are all sealed, and may then be extracted. Until such is the case, we never extract, believing that honey artificially ripened is of inferior quality.

- H. S.—1. Moving Bees.—Move them to the position required in one move, after they have been confined to their hive for a few weeks by winter weather. 2. Position of Quilt when Supering.—The quilt is to be removed entirely. 3. Storifying .- Remove top hive when full and extract, then replace under the then top hive, and when this is full work it in the same mauner. 4. Section Racks.—These are much better made with sides: iu fact, they are the only ones that can be tiered up.
- Beeswing.—We do not recommend that the queens should be superseded at the end of the first year; our experience has been that queens have been most prolific during their second year.
- W. J .- Twichbells .- We have had, we coufess, no slight difficulty in ascertaining the meaning of your local word, 'Twichbells;' we have at last satisfied ourselves that your word is equivalent to our 'earwigs.' Now as earwigs are gifted with wings, we do not think your contrivance will keep them out of your hives. They are not very agreeable neighbours to bees, but they do them little damage. They resort to hives for warmth. Earwigs are of some service in the gardens, as they destroy multitudes of smaller insects, as thrips, aphides, &c.
- INQUIRER.—Crown-boards are now obsolete. perience of bee-keepers for many years has proved some kind of quilts to be the best form of crown-cover for barframe hives. It is not necessary that the quilts should be of any special form or construction, matting, hair-cloth, flannel, carpet, &c., each has had its advocates; but it should be of some material through which the vapours of the hive can ascend and disperse. Besides the porosity of quilts, they are more easily removed, and therefore manipulation is facilitated. Bees would work up to the crown-boards, and the wrenching of these from the frames, and the consequent irritation of the bees, were something terrific. Bees can be more easily fed through quilts. Enamel cloth has of late found acceptance with many bee-keepers, the hive entrances being kept the same width in winter as iu summer.
- LLANCAIACH.—1. Presence of Drones.—The presence of drones at this time of the year would incline us to think that your hive is queenless. But before you take any proeeedings, it would be desirable to assure yourself, by ocnlar observation, of her absence or presence. As the stock appears to be strong, we should recommend that no action be taken till the spring. 2. Doubling.—Excluderzine is not used in doubling, as it has been found to interfere with the work of the bees. In storifying the ordinary entrances would be much too small for these hives, they are therefore raised one inch in front by small wooden wedges, thus allowing the bees to go in and out on three sides of the hive, and this is not found too much in the height of the season.

[PUBLISHED WEEKLY.]

Editorial, Notices, &c.

BEE-KEEPING AS A LIVELIHOOD.

A query from a correspondent has brought forth a few answers in respect to bee-keeping as a means of gaining a livelihood. We should have thought that a much larger correspondence upon the subject would have emanated from other bee-keepers who, although perhaps not entirely depending upon beekeeping for a sole support, are adding very considerably to their incomes by so doing; if so, it would be of much interest that they should give their opinions and experiences, and also the amount of honey and wax yielded from a given number of hives and their increase extending over a period of several seasons. Such a statement would be of little use unless it was compiled from the results of at least thirty stocks, as a correct computation cannot be made from apiaries of a few hives; these obtaining a much larger share of attention than could possibly be given by any bee-keeper having a much larger number under his control.

It is not our purpose to advocate anyone pursuing this industry alone, without fully weighing its advantages and disadvantages over other means of gaining what we all so earnestly desire—a competence. In reviewing the four letters that have appeared we note in two instances nothing has been alluded to with regard to the flora of the district where the would-be apiarian should establish his colonies. This without doubt is one of the most important points to be considered; a difference of quite fifty per cent in the honey production in many instances with other districts will be found. We feel quite sure that this computation is within the mark. An instance in point occurs to us at the present moment where quite a novice this season obtained 400 lbs. from four colonies, these being the whole extent of his apiary. This yield

honey yield and consequent fortune of the speculator.
Our American contemporary Gleanings, of the issue of October Ist, publishes a letter from the pen of Dr. C. C. Miller, a gentleman who now entirely depends upon honey production for a

no doubt was in the greatest measure owing to the

unexceptional honey-yielding flora of his neighbour-

hood, which we have an intimate knowledge of, and

not to any extraordinary expertness of the bee-keeper.

Such a position as this would materially affect the

maintenance, in which the question is asked: 'Should bee-keeping be made an exclusive business, or should it be pursued in conjunction with some other business?' The following very wise observation is afterwards made by the writer: 'This question can be best answered after considering some of the pursuits that may be combined with This is very true. In how few bee-keeping.' pursuits could bee-keeping be combined? venture to assert with a very small number. It could not be done to any very great extent with the farmers, as just at the busy time of haymaking the bees require the greatest attention. With the small fruit-grower it is the same; in fact, the aspect here would be much worse. Quoting the words of Dr. Miller: 'So far as my experience goes, the small fruit business requires the closest attention at the very time the bees demand it. As soon as spring has fairly opened there is work to be done at the bees, and so there is at strawberries, raspberries, &c. As the season advances the bees become more imperative in their demands, and so do the berries. In the height of the picking season when the eyes of the fruit-raiser must be everywhere to see that pickers are making good work, to settle disputes, to make sure that berries are promptly sent to their proper destination, and not allowed to lie over and spoil—at this time when the fruit-raiser, unless possessed of a very cool head, is about half crazy—the bees are alone enough to make him go distracted, when a dozen swarms may come out at once. In a word, the busy time of each comes at the same time, and what is wanted is something to occupy the leisure time of the bee-keeper.'*

We do not mean to assert that a farmer or fruitgrower could not manage, say, forty hives during the busy season; but our ideas of an apiary which shall yield a sufficiency to pay any one for their trouble and employment of capital and labour would be not less than 200 hives, and as many more as the district would support.

There are in Great Britain many men who are partially dependent upon their bees. We could name several who, in conjunction with other businesses, make bee-keeping a considerable source of income, or, as our contemporary puts it, have another business to assist bee-keeping.

^{*} Dr. Miller's letter will be found in extenso on p. 485.—ED.

The production of honey, wax, and bees alone, is our basis for these arguments, excluding queenraising as being a separate branch of the apicultural industry.

The next point that occurs to us is that of competence on the part of the apiarist. Not only must he be expert in the management of bees, but as a salesman business tact must be combined. A man may produce corn, and all he has to do is to take his samples to the nearest market-hall, when at the price fixed in this market he will have customers come to him; but with the honey-raiser this is different, he will have to make a market for his honey, and in this will depend a great measure the success of the enterprise. As Mr. Godfrey remarks in his exhaustive letter: 'Two persons standing side by side with honey exhibits of equal quality; one will sell fifty or more 1-lb. jars at 10d. and 1s. each, whilst the other would only sell a dozen or two at 8d. or 9d. each.' This is perfectly true, our experience entirely coinciding with his.

It would be giving but sorry advice to advocate a man who is capable of managing four or five colonies to invest in a hundred, as although a good bee-keeper with a few, he would most likely lose his head when surrounded with so many. Even in the practical working of an apiary, upon which so much depends, it is a very different matter to have this management subdivided to so great an extent than with perhaps a single row of stocks. We would much rather advise a gradual increase in the number of stocks kept, until the advent of twenty or thirty more into the apiary would make little or no difference to the brain-work of the honey-producer.

During this period of gradual increase a knowledge of the style of appliances and manner of working them in the most economical manner will be gained; the knowledge of such in these islands is very deficient—no doubt in this particular a 'set-off' against a further fall in the price of honey may be fairly assumed. The price expected for the honey must be less than that quoted by Mr. Godfrey. No one at the present time would pay 9d. per lb. for extracted honey in hulk; a computation of 6d. would be much nearer the mark, with 8d. for 1 lb. An average yield of 30 lbs, per colony from 150 colonies would not be sufficient to support a family; therefore an increase of stocks must be made and a consequent increase of capital. There are many points where considerable retrenchments may be made, such as depending entirely upon one's own exertions, with an oceasional help from the bee-keeper's family, which in America, where bee-keeping pays, is always obtained, the wife working as industriously in the business as the apiarist himself, winter employment in making hives, &c., for the coming season, peddling a considerable part of the productions in the winter months, when a better price can always be obtained than just after the honey season. This latter proceeding we know is considered in England by many as a little infra dig., savouring too much of the costermonger style of business; yet we cannot see anything in it that would stamp any

man otherwise than of being a very commendable character. A 'nest-egg' in the event of a very bad season, without doubt, is of very considerable importance, and should not be overlooked; here the gradual working into the honey-producing business will be of some advantage, as until a certain point is reached the bee-keeper has 'kept touch' with some other business which may tide him over his difficulties. There no doubt ought to be a deal of consideration given to this chance of a bad season, although with the great advancement that has been made of late years in apiculture the likelihood of a total failure of the honey-gathering has been reduced to a minimum. Our last season, if it had occurred ten years ago, would have been put down as a total failure. In our own district no rain fell for ten weeks, there was not a scrap of aftermath elover, yet we averaged forty pounds per colony in those hives which were run for honey.

There is one favourable circumstance that should not be overlooked, that is, the advantage that the British bee-keeper will have over his colonial and foreign rivals in the production of comb honey. is almost an impossibility to send, with safety, as ordinary goods, cases of sections, on account of their fragile character. The greatest care may be taken by the packers, huge labels describing the contents may be pasted upon the cases, but still the fact remains that it is very unwise to send such long journeys, where several transhipments are bound to take place. Our colonial friends are well aware of this circumstance, consequently they will be very chary of sending any over, the effect being that the price of this commodity will always prove remunerative to the bee-keeper, although there is a very evident tendency towards a preference for extracted honey over comb by the public.

BROOD-CELL COVERS.

BY PASTOR SCHÖNFELD OF TENTSCHEL.

(Continued from page 467.)

How is this impurity in wax, which, nobody will doubt, leaves the body of the bee in a perfectly pure state, to be accounted for? What is the origin of whole pollen-grains in newly-made wax, and of pollen-husks and fragments of pollen, in combs which have been used once for breeding? This question is easily answered, without our being obliged to have recourse to any artificial theory. It is, indeed, very natural, and we can easily understand that of the large quantity of pollen which bees carry into their hive, numerous pollen-grains are scattered about while the bees rid themselves of the pollen, or while it is pressed into the cells, while cleaning their heads, with which the pollen has been pressed into the cells, or while taking pollen from the cells for consumption, these pollen-grains becoming attached to the wax, which is kept in a soft state owing to the high temperature inside the hive, but are afterwards used up with the wax when whole cells or cell-edges are gnawed away by the bees, in order to construct cell-cappings or make use of the wax for repairs. Consequently, the greater the age of the combs, the greater also will be the quantity of pollen accumulated upon and in them. But by the pollen-grains which attach themselves to the surface of the bodies of the bees, and thus find their way into the hive, the combs become contaminated still more than by the pollen carried home by bees in small pellets

We frequently see bees returning home quite covered with pollen. Most pollen-grains carry on their surface stings or organs of attachment. As soon as such a grain comes in contact with wax, it at once becomes fixed. How little bees are able to free combs from pollen, or even from grains on the surface, is seen in each freshly-polished cell, prepared anew to receive brood, every small particle of wax being full of pollen. The fact that not even the small wax-plates from between the rings of their abdomen are free from them clearly shows how largely the body of bees itself is covered with pollen. The presence of husks and fragments of pellen-grains is also easily explained; they are, as a product of preliminary digestion, the excreta or fæces of the larvæ, which are deposited at the bottom of the cell. The larva until it becomes metamorphosed, of course, ejects no excrementitions matter, not, as people suppose, from the absence of an orifice, but because its stomach is closed by the pouch-shaped structure of its interior membrane. But as soon as the larva passes into a metamorphic state the stomach remains no longer closed, and the larva then ejects the contents of its alimentary canal together with the interior membrane of the stemach. At the bottom of every cell from which a young bee has issued, this excretion, consisting mostly of fragments of pollen, is found in such quantity that we need not be surprised that the combs in the process of being cleansed by the worker-bees are so badly contaminated with pollen-husks.

Dr. Dzierzon, therefore, is decidedly wrong in throwing doubt on the results of the investigations of Dr. Von Planta, but he is right in assuming that all cell-cappings are made of similar material, like the entire comb which carries the cells. What Dr. Von Planta observed and based his report upon is perfectly correct, but his conclusions are erroneous, as the cappings of brood-cells and honey-cells are always constructed of the same material, i.e., from wax of the same quality as the comb which contains the cells. Not even in weight or thickness do cell-cappings differ so much as Dr. Dzierzon seems to

think, as 10 brood-cell cappings weigh 9.50 milligrams, and 10 honey-cell ,, ,, 9.75

The weight of a brood-cell capping being therefore 0.950 milligram, and of a honey-cell capping, 0.975 milligram.

— Translated from Gravenhorst's 'Deutche Illustrierte Bienenzeitung,' August, 1887.

FRANCE.

In connexion with the Insect Exhibition which has lately taken place in Paris, the Apiculteur promises to give at an early date a full report for the benefit of its readers. In the meantime, however, our contemporary expresses its regret that the bee-keepers' section was not so largely represented as it should have been, coming, as it did, at the close of a good season.

According to the above-mentioned authority, it would appear that the bee-keeping section consisted of eightyfive exhibits only, contributed by some sixty odd exhibitors, although our contemporary admits that some of the so-called lots almost constituted a small exhibition of their own. Still, at the outset a larger number of contributors was anticipated. The best represented 'Départements' were the 'Yonne' and the 'Côte-d'Or.' The prizes given away were fifty in number, a summary of which will be given in an early number.

Notes Bee-keepers' Association.—The committee are working on steadily to promote the interests of bee-keepers in the county. The bee-tent has been sent and prizes given at three shows, viz. Retford, Sutton-in-Ashfield, and Farnsfield. Bee-publications are circulated monthly to all the members, and the district secretaries have been busy giving advice and assistance

to them. Messrs. Merris & Place, auctioneers, Bridlesmith Gate, Nottingham, having kindly offered the use of their auction mart to the committee it is intended to hold a honey fair there on Friday and Saturday, December 16 and 17. At this fair the silver and brenze medals and certificate of the British Bee-keepers' Association (with which the N. B. A. is affiliated) will be offered for competition. Full particulars will be advertised in due course. One of the aims of the Association is to introduce the best form of hive to bee-keepers, and to attain this hives are drawn for at the annual meeting. For the drawing next January several manufacturers and others have promised hives and appliances. Some districts of the county are without secretaries, and the committee are anxious to get ladies or gentlemen to take the posts before the end of the year, so that their names may be printed in the annual report. Lectures will be given on bee-keeping throughout the county during the winter whenever desired, application be made to the hon, secretary, Mr. F. H. K. Fisher, Farnsfield, Southwell.

How Beeswax is Made by the Bees .- It is no mere extraneous substance which needs only to be collected for use; it is a bit of individual organic home manufacture. If you examine the under surface of a cell-building worker you will find beneath the abdomen four pairs of white plates projecting from as many pockets in the incasing rings of this part of the body. These are the wax-plates made from the life-blood of the worker. Examine now with a lens one of the hinder legs. You will find that the stoutest joints are very square-shouldered at the hinge, and that the hinge is well over to one side, so that the shoulders form a pair of jaws, which open when the limb is bent and close when it is straightened. The upper jaw has a row of spines which bite on a plate on the lower jaw. With this apparatus, piercing it with these spines, the worker withdraws a wax-plate from its pocket, transfers it to the front legs, and thence to the mouth, where it is laboriously masticated with a salivary secretion. Unless it undergoes this process it lacks the ductility requisite for cell-making.—Murray's Magazine.

Uses of Honey in India.—Honey of fair quality is obtainable in most parts of India. Though not possessed of any marked medicinal proportions, it is always advisable to keep some in store, as it forms an agreeable sweetening ingredient for mixtures, is a good article in which to administer powders for children, and is one of the best substances in making pills, &c. Should it be dirty and impure, it should be 'clarified' by melting in a water bath, and straining through cloth.—A mixture of honey and distilled vinegar, or lime-juice, in equal parts, melted together by gentle heat, is an excellent adjunct to cough mixtures, and in the coughs of childhood. Diluted with an equal quantity of water, and with or without a few drops of paregoric, it forms a pleasant and useful mixture which children will readily take when they will not swallow other more nauseous medicines.—An excellent stimulant application termed Ceromel, for indolent and other ulcerations, is formed by melting together, with the aid of gentle heat, I onnce of yellow wax, and 4 ounces of clarified honey and straining. It is admirably adapted for use in hot climates, where animal fats, the basis of so many ointments, soon become rancid and unfit for medicinal use.

RUTHERGLEN HORTICULTURAL AND APIARIAN So-CIRTY.—This Society has recently presented Mr. Ebenezer McNally with a handsome marble timepiece and marble ornaments as a recognition of his valuable services during the past three years. Mr. McNally has taken a prominent part in introducing bee-culture into this locality, and the results have been of the most satisfactory nature. The 'hobby' is now getting very popular, and it is evident, in years to come, the name 'McNally' will be long remembered in connexion with this local industry. This is certainly encouragement to others who may be labouring in the same direction,

Correspondence.

The Editor does not hold himself responsible for the opinions expressed by his correspondents. No attention will be taken of anonymous communications, and correspondents are requested to write on one side of the paper only, and give their real names and addresses, not necessarily for publication, but as a guarantee of good faith. Illustrations should be drawn on separate pieces of paper.

Communications relating to the literary department, reports of Associations, Shows, Meetings, Echoes, Queries, Books for Review, fc., must be addressed only to 'The Editors of the 'British Bee Journal,' c/o Messrs. Strangeways and Sons, Tower Street, Cambridge Circus, W.C.' All business communications relating to Advertisements, &c., must be addressed to Mr. J. Huckle, Kings Langley, Herts (see 2nd page of Advertisements).

**In order to facilitate reference, Correspondents, when speaking of any letter or query previously inserted, will oblige by mentioning the number of the letter, as well as the page on which it appears.

GRANULATED HONEY.

[1327.] The time, I think, has arrived when something should be said in favour of granulated honey. By this I mean extracted or run honey not comb honey. There appears to be a widespread opinion that a jar of honey in its granulated state is not pure, that it is mixed with flour or some such ingredient, or that it is old honey. Most of us bee-keepers know that this season especially, being free from rain, and consequently a dry atmosphere, honey when extracted quickly set into a solid block in a few days. This was the case in my own apiary, whether the honey was taken from fruit or heather blossom; it set in less than eight days, and from the clover in less than fourteen days. Before proceeding further allow me, Mr. Editor, to draw your attention to the reply you favoured your correspondent 'S. White,' B. B. Journal of October 13th ult. page 457. You state there, 'The reason of your honey becoming candied was extracting it before it was ripe.' I thought at the time it was an error of the printer, and have been looking for you to contradict it ever since. This remark placed beside your specimen honey label, which you recommend in your Guide-Book, page 82, somehow don't agree. I am of opinion that every jar of honey put into the market should bear a label of this kind, which I greatly admire. Kindly allow me then to venture giving my opinion that honey must be ripe and extracted from sealed combs or it will not granulate. In frequenting the most of our leading honey shows the thought has often occurred to me, viz., how does it come that judges, when giving an award in a class for extracted honey, and there happens to be a sample of granulated honey competing with a sample of liquid honey, that almost invariably the latter takes the first place? The first time I saw the tables turned in this respect was at the Caledonian Society's Show at Edinburgh, in 1884, when Messrs. Raitt and Neighbour were the judges; and in the class for twelve jars extracted honey, the second and third prizes were awarded to the granulated samples, against perhaps fifteen in the liquid state. When I have been asked to judge at any of our honey shows, I have always placed granulated honey on equal footing with the liquid, for the simple reason that it is as difficult to produce a perfect sample of the one as the other. Suppose then briefly that we have two samples of honey, the one liquid, the other granulated (I don't like the word candied) to pass judgment on, and we take the six points usually taken by our competent judges to guide us in deciding, viz., flavour, colour, condition, uniformity, aroma, and get-up or form shown, for to guide us, I fail to see where the granulated sample should lose one point, except perhaps in colour; and I doubt very much if it should lose there, while as to condition or consistency it should more than hold its own against the liquid sample, because it ought to be already tested. I have more than once secured a first-prize jar of liquid honey, and kept it beside me to see in what form it would granulate. I have seen it after it had become set to be large-grained, a sure sign of inferior quality, and |

several times it remained liquid. I maintain then that we bee-keepers should do all in our power to uphold the granulated against the liquid honey when all other

points are equal.

Honey in its granulated state will keep for a long period of time, it is the best to send by rail or otherwise, and, so far as I have proved, is the most marketable. It is also an easier matter to transmute graunlated honey into its liquid form than vice versa. One firm which has bought nearly 1000 jars extracted honey from me this year writes that they want it all granulated, as in the liquid form it is of no use to them .- WILLIAM MCNALLY, Glenluce, Scotland.

The circumstances of S. White's honey were peculiar. Without our correspondent seeing his queries it would be impossible to form a correct judgment of the reply. The specimen honey-label refers to the purity of honey as regards its freedom from adulteration with glucose, and not to its consistency (vide context), and of this purity granulation is a proof. As a rule well-ripened honey will granulate as quickly as unripe, or, in many cases, more quickly; but granulation depends more upon the pasturage from which the honey is derived than upon its consistency. For instance, in our own apiary a few weeks ago, unsealed honey of the least possible density, when extracted from unfinished sections, granulated sooner than the most dense we ever saw, which had been extracted from well-ripened sealed comb. It is a difficult matter to compare and judge granulated honey—when shown in the same class -with liquid. We very much prefer the granulated, hut there ought to be classes for both.—ED.]

THE HONEY FLOW.—OVERSTOCKING.

[1328.] Many inquire how they are to know when honey is coming in. Examination of the hive will of course show every vacant cell being more or less occupied with the thin, newly-gathered nectar. bees, too, come in with distended bodies, falling heavily upon the flight-board. Sometimes the aroma of the incoming stores is distinctly noticeable, more particularly at evening, when many bees are ventilating at the entrance, and a perfect roar is heard throughout the apiary. Apart from this, the advanced apiarist has an instinctive feeling that honey is, or is not, being gathered. The state of the atmosphere and his knowledge of surrounding crops tell him at once what to expect.

The temperature may range anywhere from 70° to 90° in the shade, but if it continue too hot and dry for more than ten or fourteen days, the amount of honey brought in will decrease daily, unless there happens to be a succession of heavy ground crops coming along, when, the earth being shaded, moisture is still retained. A shower once in a while is beneficial, but frequent rainfalls destroy all chance of a good honey-flow, as such induce also a low temperature. Even with fair weather it sometimes happens that the temperature rules too low for the secretion of nectar; but usually, if none is stored during a fine season, it implies either that the district is poor in honey plants or there are too many colonies in one place. It is sometimes stated that honey is secreted on a larger scale by plants during thundery weather, but I have found it come in just as freely during steady fair weather, when there was no sign of thunder for weeks together; and the latter condition is certainly to be preferred to the other, as the atmosphere is often cold and unsettled after thunder.

The question of overstocking is one that has received considerable attention, though nothing satisfactory has been arrived at in regard to this matter. It may safely be said, however, that in any fairly good district one hundred colonies will each put out as much surplus as one only. But with a large number there are greater risks, and the whole cannot receive the same attention individually that would be given to a few. It will generally be found that it is not the district that is at fault, but rather that our stocks are not always ready when the first or only glut of the season occurs. Honey is seldom secreted so abundantly as when everything is bursting into new life, but it so happens at that early date it is often difficult to get the bees strong enough to do more than provide for the expanding brood-nest. When bees can be so wintered that they will come out stronger in spring than when they settled down for winter, we shall hear little more about overstocking. That this desideratum will shortly be an accomplished fact I am fully persuaded, and hope on a future occasion to give evidence to that effect.—Samuel Simmins.

'IN THE HUT.'

[1329.] In reading over the article of last week, the 27th ult., with above heading in B. B. J. I see 'X-Tractor' is very anxious to have a list of the bee-keepers in the McNally family. I have no objection in the least to furnish him with a list of them with their 'Christian names and relationships' provided he will kindly say what he wants a list of the names for. 'X-Tractor' should bear in mind that when he wants a favour of this kind through the columns of your paper it is as little as he can do to affix his signature to the request. It looks very singular when any one is asking a favour if he is afraid to disclose his name. This shooting 'frombehind-the-hedge style of business' ought to be avoided by every one pretending to write to any public paper. By way of consoling 'X-Tractor' a little, if he will extract all the articles that have been contributed to your paper from time to time by the McNally family he will see that each one has got his Christian name and surname - but not relationship-affixed thereto, If 'X-Tractor' would take my advice, and like the bee hibernate in his hut during the winter months, and not, dog-like, keep snarling from the manger against persons better informed and more practically conversant with a subject in writing of which they are not afraid to append their names. Perhaps with reviving spring he may be able also 'to tell a bee-tale,' which with his undoubted (?) ability and smatterings of Shakspearian lore will be a treat to your readers. By the way, for the guidance of 'X-Tractor,' I may say the McNally family are a dangerous lot to tackle; their name is Legion, and they are all bee-keepers .- WILLIAM MCNALLY, Glenluce, Scotland.

[We have received a letter much to the same effect as above from Mr. J. D. McNally.—Ed.]

NORTH-EAST OF IRELAND BEE-KEEPERS' ASSOCIATION.

[1330.] I have just read Messrs. McHenry and Cunningham's letters in your issue of 20th October, anent my letter which appeared in issue of 22nd September. I am sorry, in one respect, and glad in another, for bringing this Association into such prominence in the pages of the B. B. J. for irregularities. When I wrote the letter, which Mr. McHenry characterises as 'imaginary,' it was not with any selfish motive on my part; but for the common good of all concerned, and, if possible, to assist in putting matters right for another year.

Mr. McHenry must have a poor memory, or perhaps it is 'imaginary,' when he says, Mr. McNally's brother had the use of a 'proof schedule bearing the numbers, names, and character, of entries from each exhibitor, to check over his entries.' Allow me here to state, there was only the one McNally present, and that person the writer, who had entire charge, with the assistance of the

Rev. J. B. Robertson, of placing the exhibits of W. and J. D. McNally; and, further, Mr. Wm. McNally did not arrive in Belfast until the judging was over. I think Mr. McHenry will admit this statement is not 'imaginary,' but correct. Coming now to the main point at issue, on the show day, when I called to arrange my exhibit, I asked Mr. McHenry for a schedule, and I could not be supplied with any other but the one I have referred to; and I must demur to the statement that in receiving said schedule I was privileged in any way, because other exhibitors had the use of this schedule as well as myself, there being nothing else to give them. I do not for a moment insinuate that I received any injustice from the hands of Messrs. McHenry and Cunningham more than any other competitor; and it would be wrong on my part to wilfully bring any discredit on the Hon. Secretary and Treasurer of this highly-respected Association, for their kindness and hospitality to all exhibitors, and especially to those who happened not to belong to the 'Green Isle,' was everything that could be desired or looked for. At the same time, those gentlemen will admit the fact that great dissatisfaction existed at the result of awards in the 'honey classes,' and particularly so in the 'run-honey.' And it was then some competitors pointed out to me that the printed names on the schedules had something to do with the awards not giving satisfaction; but I am perfectly satisfied now, after reading Mr. McHenry's letter, that the judges were not biassed in giving their decision, and I am not to be considered writing simply for writing sake, nor smarting under the sting of defeat. The printed 'rule' that all honey 'was to be shown as taken from the bees' was ignored by many in the I-lb. section classes, and I pointed this out to the Hon. Secretary before the judges came to make the awards; but despite the fact of doing so the second prize went to a lot staged in a glass section-case, which certainly gave it an advantage over the other competitors, who acted according to the rule, and, in my opinion, should have been disqualified.

I trust this will settle the discussion, and that I shall have the honour of meeting and receiving a cordial shake of friends McHenry's and Cunningham's hands at their next annual show.—John D. McNally, Springburn, Glasgow, October 24th.

FOUL BROOD.

[1331.] The discussion on foul broad in the pages of the B. E. J., still goes on, but instead of improving the tendency is, to make confusion worse confounded. It may be a bold assertion, but it is nevertheless true, that the 'Man of Kent' is the only one that has written anything sensible on the subject, although ignorant parties have attempted to sneer at his remarks.

Mr. Ward has stuck to no particular line of action, giving phenol, salicylic acid, changing queens and comb all at one time, so that it was difficult to know what was the cause of cure or failure; and I am afraid by his recipe he wants to lead bee-keepers into a trap, that I,

and possibly he, has been led into.

It is now generally admitted that the Cheshire cure is too strong to give even in small doses, and yet he advises the spraying of all the combs with it at one time. Now what would be the result if the poor bees are forced to occupy these combs? The half of them would be killed and the brood likewise literally roasted, it would be a job to get rid of the dead ones as he advises; and would the combs he cured? No, nor never will be! And it is in them that the disease is, and not in the bees and queen, as they try to make believe. Bees as they become affected with the disease leave the hive, and the queen would do the same.

But in all my experience I have never seen a queen affected, and I have had them bred and been three years

in rotten hives, and yet when changed into clean hives, either by swarming or shaking out and starving a day or two, they were all right. I have at present ten queens that were bred into foul hives, and I know of many more, and there is not a foul cell in them at the present day.

If bee-keepers wish to get rid of this foul disease, they must resort to the old plan of swarming, and starving; and phenol, if used in small quantities, will be found of great assistance, as it will check the disease and keep it from spreading in the combs, where it undonbtedly is, and the sooner bee-keepers take that view of it the better will it be for bee-keeping.—Jas. Saddler, Hon. Sec. Forfar Bee-keepers' Society.

UNITING AND FIGHTING.

[1332.] Though amateurs cannot instruct, they can communicate information which, in an indirect manner, may be of small, if not of large, henefit to their superiors, and a consideration of this truism induces me to seek admission into the pages of the *Bee Journal* once more, with a further relation of my experiences in apiarian labours.

Since my successful operations as recorded in a recent issue of the Journal, I obtained permission to drive a colony of skep-dwellers, receiving the creatures as remuneration for my labour. As the modus operandi had been neither seen nor heard of, I became an object of special interest for a time. So successful was my work that only three bees were left in the hive. I was most courteously thanked, and asked to perform on another hive: and the third evening following I again had the gratification of performing the life-preserving process, with the like good result. As I had not another empty hive, the interval between the two operations was so short, and I had repeatedly read accounts of your correspondents having united two and more stocks. I dropped the second lot into the hive which contained those I brought home three evenings previously, first putting in another har-frame of honey, and taking out four frames, thus leaving an unoccupied one in the middle of the hive, and between two colonies. Before going to bed I heard what I supposed to be the warcry, and surely enough the fratricidal war had raged all night; they had fought like niggers, and at dawn of the morn, lo! the floor was strewn with the dead, while a heap of corpses had been deposited on the ground in front of the alighting-board.

What is the lesson I am to learn from this untoward incident? Am I to believe that the bees belonging to this part of the country are less disposed to become Socialists than are those that inhabit the more northern part, or was the non-success a result from any blunder on my part? Teach me, Mr. Editor, pray. You have

as a pupil-AN AGED AMATEUR.

[We have frequently advised that each lot of bees should be deprived of their hives, combs, and brood, and when thus separated thrown together and theroughly mixed, then run into the hive,—no fighting will take place. If it is required to unite a driven lot to a stock, the above can be done; or both lots scented, and the driven ones run into the hive containing the stock. Your first lot of bees after three days were equivalent to—a stock.—Ed.]

A CHEAP HIVE,

[1333.] In 1293 your correspondent says he disapproves of home-made hives in general. So do I. But I will give him an idea of mine, and see what he thinks of it. Being nothing but an ordinary gardener, I am not an expert in making hives or in explaining them. My hives are all made of I-in. wood, bought new for the purpose, not currant or pine-apple boxes. The boxes are all made one size, so as any storey fits the floor-board; and by having extra roofs and floor-boards, they

can be all turned into stock-hives. They are not standard size, but 15 in. long by 14 in. wide, $10\frac{1}{2}$ in. deep, all inside measurement: board I in. thick $9\frac{1}{2}$ in. deep inside—this for frames to rest on, making them I ft. in width and $9\frac{1}{2}$ in. deep: and roof or quilt over frames to come level of the outer boards. I put strips 4 in. wide and $\frac{1}{2}$ in. thick on the bettom of each box, which covers the joints or clips the floor-board. I can make one, two, or three of these storeys. There is a span roof to fit, the ends hanging over the entrance and behind, throwing the wet off on both sides.

My frames are 11 in. by 9 in. deep, top bar $12\frac{1}{2}$ in., giving $\frac{1}{2}$ in. all round, which I like, as the bees fill them quite full all round and they extract better. So you see each box holds ten frames. I generally use two storeys in summer, one in winter. My floor-hoards are fitted on legs, the entrance made in the board, and alighting-board attached. The material for one of these doublestoreyed hives costs about 4s., including paint and nails, and when properly put together will last a man's lifetime if kept painted. I put the second storey on two of these hives the last week in June, and in sixteen days I took 55 lbs. of honey from the top storey alone; one black bees, the other Ligurian. It takes 24 ft. of board, 2 lbs. of paint, I lb. of nails (3 in.), for a double-storeyed hive. I never plane anything except frames, as the rough wood holds more paint without blistering. hope 'Woodleigh' will not despise my hives, hut suggest some beneficial alteration. I think there are many that would use bar-frame hives if they had a little instruction in making that cannot afford to buy them, and would get more interested in the busy bee. -O. WILL, Clifton, Ashbourne.

BEES INJURING ROSES.—BEES BUILDING DRONE-COMB.

[1334.] The very kindly reception given me by 'Amateur Expert' and 'Mr. Boyes' makes me feel at liberty to come again. The matter of bees injuring roses has been slightly discussed in the B.B.J. I have some eighty varieties of roses which I enjoy much, but this fall the bees have spoilt my pleasure by pulling over the petals, so that searcely a bud can be found of any value, unless covered with mosquito-netting. The very dry season, I think, together with scarcity of stores in the hive has made them unusually bad.

Mr. Hans Ersler (1281) thinks bees will build dronecomb on worker foundation only when the foundation is bad. While it may be true that he has had such experience, it is equally true that I have had drone-comb built on the very best foundation, made by C. Dadant & Son, than whom I doubt if there are any better mannfacturers, and the cells were also of the right size, five to the inch. As to whether bees build drone-comb with honey-storing or drone-rearing in view I am not prepared to say. I have seen it stated that if bees are fed bountifully in the fall, and obliged to build comb in which to store it, they will invariably build, at that season of the year, worker-comb. If this be true (and the experiment could be easily tried) it is, so far, proof that bees build worker-comb as store-combs. For some years my hives have contained little drone-comb, and what little there is is not used as store-comb until late in the season, but kept for broad only, and if a hole in a comb is built full by the bees, it is almost invariably filled with drone-comb, which I have never seen used as storecomb until after it has been used for brood. This gives some ground, at least, for the belief that when bees are well supplied with worker-comb, any additional dronecomb built by them is built with drone-rearing in view.

Another item just now occurs to me. My sections are usually filled with worker foundation. If at any time a starter fills only a part of a section, the bees, I think, always fill the vacancy with drone-comb, but the queen not having ready access to lay in this drone-comb, I am

apt to find it empty, although well built out, while the worker part is promptly filled with honey. This looks as if the bees were building and holding this drone-comb for the use of the queeu rather than as store comb.—C. C. MILLER, Marengo, McHenry Co., Ill.

LADY-BIRDS.

[1335.] Some time ago I sent you an extract from the game-book of a sportsman in Switzerland. I now give you the following, anent lady-birds, from the same:—'On the 29th of December, 1820, after ascending a mountain 5000 feet in pursuit of the chamois, I discovered a large block of crystal in a bed of granite. On dislodging it, there were concealed behind it upwards of two hundred of the small insects commonly called lady-birds—by sportsmen, lady-cow. I carried some home with me; the heat of my pocket revived them. How did this feeble insect attain so great an elevation, and bow did it penetrate the rock? And why, for its retreat, did it not rather choose the comparatively mild temperature of the valley? At Glis, Switzerland.'—J. Lawson Sisson.

MY YEAR'S WORK.

[1336.] Some of your readers will remember that some time ago I promised to tell them how I got on with regard to produce of honey. It may be that some will be somewhat surprised not to see larger returns, but it will not be the case with those who are acquainted with the district for producing honey. As there is but very little white clover round about here, and it is a very rare thing to see any seeds grown, I mean such as turnips, cabbage, parsnips, radishes, &c., such as may be found in many other districts, so the bees have to depend very largely upon what is provided for them; and I find nothing so well suited for this purpose, as I have said before, as borage and Nepeta mussini, as both these plants continued to give abundance of bloom up to the 12th ult., when Mr. Sharp Frost came and sent all the borage to its mother earth. But the Nepeta mussini still continues to bloom, and the bees visit it whenever the weather permits them to fly. I am sure, Mr. Editor, yourself and many others will be pleased to hear that I have sent large numbers of the latter very favourite bee-plant to many parts of England, Scotland, and Ireland. But I must ask our friends not to send for any more plants at present, as I have but very few left, and they are rather weak, and which I should not like to send out at this late period of the year; but if all is well I will in the spring of next year strike other large quantities, and when ready communicate the same to our bee-keeping friends through the columns of the B. B. J. Now for the produce of honey, &c., for the present year. I started in the spring with seven stocks. I think it best to call them by numbers, giving each number and its produce separately:—

		_	-	-		
No. of Hive.	No. of One pound sections.	lbs. of extracted honey.	Partly filled combs in store.	Swarms.	No. of frames crowded on for the winter.	Total lbs. of honey.
$ \begin{array}{c} 1 \\ 2 \\ 3 \\ 4 \\ 5 \\ 6 \\ 7 \end{array} $	83 lbs. 50 ", 46 ", 38 ", 18 ", 17 ", 29 ",	18 lbs. 39 ,, 51 ,, 45 ,, 48 ,, 36 ,, 48 ,,	6 8 8 6 7 4 8	1 1 1 1 1 1	8 9 11 10 8 8 9	101 lbs. 89 ,, 97 ,, 83 ,, 66 ,, 53 ,, 77 ,,
	281 lbs.	285 Ibs.	47	7	63	566 lbs.

No. 1 Swarm is wintered on 7 frames; 2 on 6; 3 on 6; 4 on 7; 5 on 8; 6 on 8; 7 on 8.

Now I must confess that the above figures give me

great satisfaction, considering the district being, what I may say, not a good one for producing honey; and if those of our friends who are similarly situated, and have the laud to spare, and time to cultivate some borage and Nepeta mussini, they would greatly improve their prospects, and the quality of their honey would, I am sure, give them great satisfaction. I am sorry to say that one of my applicants for Nepeta mussini plants letter got mislaid, and only came to light last week, so he was a long time before he received the plants; but I am glad to say that I have received acknowledgment from him for the receipt of the plants; should there be any similar case, I shall be very much obliged if the parties will communicate with me, and they shall have my best attention.

Now, Mr. Editor, will you kindly answer one question, I am sorry to trouble you, but as one of our bee-keeping friends appears to be somewhat in a fog, your answer to my question might clear him of the mist. He tells me in his letter that he understood me to say, through the columns of the B. B. Journal, that I would send out one dozen of Nepeta mussini plants to any address free. I most respectfully ask you, sir, did you at any time understand me to say so? A reply at the bottom of this letter in B. B. Journal will much oblige.—C. H. W., Aylesford, Maidstone.

[Your first communication regarding Nepeta mussini appeared in our number for May 26, in which you say that you would be pleased to send a few cuttings of the plants provided a stamped and directed envelope were forwarded. In number for September 1 you inserted an advertisement, which informed the public that you were prepared to send out well-rooted and strong plants at 1s. per dozen, postage extra.—ED.]

BEE-KEEPING WITH OTHER PURSUITS.

[1337.] Should bee-keeping be made an exclusive business, or should it be pursued in conjunction with some other business? This question can be best answered after considering some of the pursuits that may be combined with bee-keeping. I am competent to speak of only a few; and if it seems really desirable that there shall be a combination perhaps others may be called out. Perhaps I may arouse Mr. G. M. Doolittle by saying that I think he has made one of the worst combinations possible in combining bee-keeping with small-fruit raising. I think there is a somewhat general impression that bee-keeping and raising small fruits go nicely together. There is this much to say in favour of it—that the man with the right taste for bee-keeping is apt to have the right taste for a fruit-raiser; and if successful at either he would be successful at the other if he should turn his attention to it.

But a business to be combined with bee-keeping should be one that would require the attention of the bee-keeper mainly at a time when his bees require no care. So far as my experience goes, the small-fruit business requires the closest attention at the very time the bees demand it. As soon as spring has fairly opened there is work to be done at the bees, and so there is at strawberries, raspberries, &c. As the season advances the bees become more imperative in their demands and so do the berries. In the height of the picking season, when the eyes of the fruit-raiser must be everywhere to see that pickers are making good work, to settle disputes, to make sure that berries are promptly sent to their proper destination, and not allowed to lie over and spoil-at this time, when the fruit-raiser, unless possessed of a very cool head, is about half crazy, the bees alone are enough to make him go distracted when a dozen swarms may come out at a time. In a word, the busy time for each comes at the same time; and what is wanted is something to occupy the leisure time of the bee-keeper.

Teaching school, I think, comes nearer to it, for the

busy time with bees comes in the summer vacation, and one with sufficient strength and the right taste might take care of quite a number of colonies without interfering with school duties. I think, however, he would in time decide as I did to give up one or the other.

Of course, there may be many special departments in which different individuals may have developed special taste and ability, where a somewhat successful combination might be made. For instance, the teacher of the old-fashioned singing-school (now unfortunately out of vegue) could take care of bees without interfering with

his 'schools,' held only on the long evenings.

But what we are after is something that may be done by almost any one with the requisite qualifications to be a good bee-keeper. I think I have heard poultry-keeping spoken of in connexion with bee-keeping. That, again, comes too much like berry-raising. When work begins to press with the bees old Biddy will be wanting to sit, and perhaps two or three hens will be sitting on one nest persistently changing from where you want them, till you feel like shutting your teeth together hard and saying, 'What does make you act so when I haven't time to fuss with you? I should just like to wring your necks for you. Yet after all this is said there remains the fact that, in at least two instances, periodicals have been published having for their specialities bee-keeping and poultry-raising. Why this, unless the two pursuits were supposed to have some special adaptation to each other?

To tell the truth, if a young man to-day were to write me, 'I have at least ordinary ability as a bee-keeper, and have decided that I must have some other pursuit to connect with bee-keeping, what shall it be?' with my present knowledge I should reply 'Keep poultry.' But I would not have any hens sitting in swarming time, nor, indeed, with flocks of little chicks wandering about trying to lose themselves in the wet grass. I have studied some little about it and taken some observations, and I think the whole business of poultry-raising might be done almost entirely when bees require little attention.

Mind you, I do not say it is best to combine at all, but if combining is done the merits of poultry-keeping deserve consideration.—C. C. MILLER, Marengo, Ills.

(American Gleanings.)

HONEY AS MEDICINE.

[1338.] The Herald of Health is high medical sanction. In answer to a question, 'Is honey wholesome?' it says 'Yes; used in moderation it is.' It then adds: 'A German teacher has lately written a work on the subject of honey and its healing properties.' While he may over-estimate its value, what he says is interesting. We quote: 'A strong influence for publishing this book was the fact that I, a sufferer from hemorrhages, already given up to despair, and at the verge of the grave, was saved by the wonderful curative powers of honey; and now, thank God, I am freed, not only from weakness of my lungs, but rejoice in the possession of perfect health. first attack, upwards of thirty years ago, powders and tea were ordered for me, which benefited me but little. I then placed but little confidence in honey which I had used occasionally, but in small quantities. Judging from my present knowledge, I believe that the honey was the only remedy that was doing me any good, and it is this that I have to thank for the gradual but sure restoration of my health.

'As my disease increased I began to use cod-liver oil, which weakened and injured my stomach so that I could hardly digest any more, and my condition became worse and worse. Again I returned to loney, when my sufferings gradually began to decrease and disappear. Besides the use of honey I took pains to preserve my breast and lungs from injury, which in my trying situation as public teacher was almost impossible. My disease being caused by my constant teaching during so many years, I gave up my profession, and honey was my only medicine, whereby I, by the simplest, safest, quickest, and pleasantest manner (for I was fond of honey) relieved the disease in my throat; and out of thankfulness I now write this book for the use and benefit of many especially for the use of those suffering from diseases of the throat and lungs.'

This German teacher is none other than Kail Gatter, from whom we quote still farther on the same subject. He says: 'In medicine, and especially in the healing of wounds, was honey, already in early times, used as a universal remedy, it yet constitutes the principal ingredient of many medical preparations, is used, with the best results, in many internal and external diseases, serves as a means for taking powders, for the preparation of

salves, and the sweetening of medicine.

'Honey modifies, promotes festering, causes gentle purging, divides and dissolves, warms, nourishes, stops pains, strengthens the tone of the stomach, carries away all superfluous moisture, and animates and strengthens the breast, nerves, and lungs. Honey is therefore to be used when suffering with a cough, hoarseness, stoppage of the lungs, shortness of breath, and especially, with the best results, in all affections of the chest.

'Many persons, afflicted with various species of cousumption, thank the use of good honey, either for the entire restoration to health, or for the mitigation of their

often painful condition of mind and body.

'Honey is also an excellent remedy for the occasional inactivity of the abdominal organs, and a means of strengthening weak nerves. For severe coughing, barley water mixed with honey and the juice of honey drank warm, is a pleasant relief. It appeases and mitigates fevers, and owing to its taste and its soothing qualities, it is used as a gargle.

'Honey can also be used with advantage in asthma, in constipation, in sore throat; promotes perspiration, lessens phlegm, and is very healing to the chest sore

from coughing.

'With old persons, the use of honey is very useful, since it produces warmth and a certain activity of the skin. For persons leading a sedentary life, and suffering from costiveness, and especially from piles, pure unadulterated honey, either mixed in their drink, used alone, or on bread, is the best and healthiest means of

'Honey has also great value as a medicine for children, and is readily partaken of by them as a choice, dainty dish. It is especially useful to children afflicted with scrofula or rickets. In difficult teething rub the gums with a mixture of honey and emulsion of quinces. the removing of worms honey has often been beneficially used, and it is often used in diseases of the mouth and throat. Honey mixed with flour, and spread on linen or leather, is a simple remedy for bringing to head or maturity, boils, &c. Also, honey mixed with flour or fried onions, serves an excellent purpose as a covering for any hard swelling, or callosity, or abscess, and often for ulcers it is mixed with turpentine, tar, and tincture of myrrh. A plaster made of unslacked lime and honey has sometimes relieved the most obstinate sciatica. If good honey is applied to inflamed wounds or boils, it lessens the drawing, quiets the pain, and produces a good festering or suppuration, undoubtedly for all wounds,'-T. B. (Farmer and Dairyman.)

TOM-TITS, WASPS, &c.

[1339.] Tom-tits.—Will some bee-keeper inform me of some method of destroying these bee-pests? I find them very destructive just now. I have been shooting them for the last month, but find they still come more numerous than ever, which reminds me of an old adage, 'that to kill one, half-a-dozen come to the funeral.' They

require some one to be always about with a gun, which (at the present price of honey) does not pay; and then no one is scarcely safe unless he has a license to carry a gun. I have heard sundry rumours afloat, coming from a farmer the other side of the hedge, wondering if I have a license to carry a gun. I do not know whether I am exempt or not on the same ground as farmers. Would some one kindly inform me? I do not use it for any other purpose, or go off the premises of the apiary. Some farmers are dreadfully nasty and jealous of their privilege.

Wasps are all gone to their winter quarters, and it is to be devoutly hoped that they will never see daylight again, except it is for the especial benefit of our waspy friend's own waspy apiary, where I hope he will keep them within his own limits under his immediate control; he is quite welcome to a monopoly, and enjoy all the benefit he can make of his waspapiary. I am sure that I do not covet, or desire any of those pets of his.

(1303.) I am personally greatly obliged to Mr. Rogers for answering so many of my questions, but he has failed to show how he manages to fill a hive of forty frames with bees and honey by the 'hundredweight.' Mr. R. winters his bees on 'ten frames,' this is one quarter of the original summer hive; this, I presume, would be done at the latest by the middle or end of September. This I can quite understand, but my query is, How many frames will they cover now, say the 1st of November, and then on to the end of February, will they cover five frames? As our Yankee friends say, I guess they will not, although they may have one of the best queens that ever lived. I fail to see, therefore, how this hive is to be filled with bees by this one queen, by the (say) middle of June, to be ready for the honey flow. This fine sunny weather the bees are out in abundance, and I find they decrease in numbers very fast, and will continue to decrease through the winter, on all such fine days of sunshine, especially if there is snow on the ground.

There is but very little if any breeding from now until March, and during the whole of that time the bees are diminishing, and, therefore, I am of opinion, from twenty or more years of experience, there is not one hive out of twenty that would cover twelve frames with bees by the end of April, if they did by the end of May. Hence, the difficulty—nay, the impossibility of covering forty frames by the end of June, without the addition of swarms, the produce of other queens: I therefore say the 100 lbs. is not the produce of one queen or hive, but many.

It is not a cause for fear with the weather there is more than one queen alive in a hive or not, but think as the success of the colony is dependent on the life of one bee, it would be much better if there were half-adozen, so as to quickly fill a forty or fifty-frame hive to produce all the more readily the 100 or 200 lbs. of honey, as some so sanguinely speak of. There may not be more than one queen left alive in an ordinary hive, or when they go into winter quarters; but who has ever proved that in a hive of forty or more frames, there are not two or more queens at the same time? It may be a new idea, but I cannot on any other hypothesis account for such rapid increase of bees, so as to cover a forty-frame hive by the end of June. Take, for instance, an ordinary hive or skep, get two swarms from it, and then unite them in one hive, and they would not cover twenty frames. I therefore ask those who have had such (to me) extraordinary yields of honey, to honestly state all the facts, i. e., to confess the addition of swarms, or deny what I presume to be the facts. The two cases I mentioned in my last prove to me that there is at times more than one queen in a large hive, at the same time each having her own colony and dominions .-SHERBORNE, Dorset.

BEES AND MANURE-HEAPS (1326).

[1340.] Your interesting and always agreeable correspondent, Mr. Webster, places me under the necessity of

inflicting upon your readers what, I fear, may be a dreary letter in defence of the position I took up, and which he attacks. I will endeavour to be as little prosy and as clear as I can. Far from wresting the honours from his hand, there seemed to me no honour in entering into the discussion, but only a probability of putting my unworthy head into a hornets' nest, so to speak, and the consequent labour of defending it. Such labour, I may say, however, becomes a pleasure when criticised by the gentleman in question.

Mr. W. says (p. 445) our bees resort to manure-heaps for the purpose of obtaining hippuric acid, i.e., an acid contained in the urine of horses or beasts. I reply (p. 463) that 'uric acid might be a better term, seeing that uric is found in animal, and hippuric in human liquid excreta, thus, so to speak, reversing their ordinary

positions.

The question before us was that of bees visiting all sorts of objectionable places, not stable or farm-yard heaps alone; 'Gentlemen' on railway platforms being named amongst the rest by one correspondent. I therefore suggested uric acid as being a better term than hippuric, a more comprehensive one, there being so many derivatives of uric (heaps of them-oxaluric, cyanuric, and what not), hippuric being one of them. Who is then to say that they collect that solely, or even that? I will give a few extracts in support of my

'Hippuric acid has been discovered in human urine by (Gregory's Org. Chem., p. 135.)

'Some hippuric acid is found in human urine under ordinary circumstances.' (Remsen's Org. Chem., p. 291.) 'Hippuric acid is a normal constituent of human urine.

(Attfield's Pharm. Chem., p. 299.)

'Hippuric acid is contained in cow's nrine 1 in 100.' (Bloxam's Chemistry, p. 621, 2.)

'Uric acid is contained in human urine 1 in 1000.' (Bloxam's Chemistry, p. 621, 2.)
'Uric acid occurs in human urine and in the urine of

carnivorous animals.' (Remsen, p. 205.)

So much for the mixed origin of both.

I am next asked, 'Upon what food can an animal be fed in order that benzoic acid may be taken into its system in quantities sufficient to form hippuric acid, which is found in every manure-heap frequented by bees?' Then comes the joke, 'Perhaps they feed horses in Yorkshire upon gum benjamin.'

This is where Mr. W. goes astray. I said, 'Hippuric will be secreted by all animals which have benzoic given

them.

In reply I will quote again:—'Dr. Alexander Ure first pointed out that benzoic acid changed uric into hippuric.' (Squire's Comp. to Brit. Pharm., p. 7.) 'The supposed conversion of benzoic into hippuric acid has been unequivocally established.' (Wm. Keller in Annalen der Chemie und Pharmacie.) 'Where horses have been worked hard their mrine contains benzoic instead of hippuric acid.' (Naquet's Princip. of Chem., p. 576.) 'Benzoic is now made from urine of herbivora.' (Ibid. 576.) 'Only fresh urine yields hippuric acid, for after putrefaction only benzoic acid can be obtained from it. Conversely, if benzoic acid be administered to an animal it makes its appearance as hippuric acid in the urine. It is remarkable that this acid can only be obtained when the animals are kept at rest, for if actively exercised the above treatment educes benzoic in place of hippuric acid.' (Bloxam, p. 622.) 'Hippuric acid is found in the urine of patients whose medicine contained benzoic acid.' (Attfield's Pharm. Chem., p. 299.) 'If benzoic acid be taken with the food it appears as hippuric in the urine.' (Remsen's Org. Chem., p. 291.)
The third paragraph of Mr. Webster's letter charges

me with making 'an astonishing misstatement in confounding nitro-benzol, or artificial essence of almonds, with the benzoin products. Artificial essence of almonds is produced by the action of strong nitric acid ou benzol, a liquid obtained from coal-tar, and by no means to be confounded with benzoin. Nitro-benzol cannot be even used as a flavouring ingredient, on account of its rankness. It is sometimes used for scenting cheap hair-oil and soaps.' The confusion is on the part of my critic, not in my statement. In the first place, I cannot find his nitro-benzol at all. There is nitro-BENZENE, having the same formula as he gives, prepared exactly as he says, but resulting in the 'essence of mirbane.' 'Its odour is like that of bitter almonds, and it is hence used in many cases instead of the latter.' (Remsen, Org. Chem., p. 259.)

In mentioning essential oil of bitter almonds, 'so much used for flavouring,' I alluded to its synonymbenzoic aldehyde. This may be made (Remsen, p. 282) by four different benzoic processes. 'Benzoin heated to redness returns to the state of benzoic aldehyde.' (Naquet, Princip. of Chem., p. 669.) 'Hydride of benzoyl, or essential oil of bitter almonds.' (Attfield, p. 273.) 'Benzoyl is the radicle of benzoic acid, or oil of bitter almonds. (Gregory, p. 128.) We have then the urine of herbivora containing uric acid, and hippuric when stallfed, this latter being excreted as benzoic acid when hard worked. We have also benzoic converted by the chemist into its aldehyde, a delicious flavouring, non-poisonous to boot, in opposition to the extracted oil. Mr. Webster will now see how correct I was in my original statement.

One word on the open question. Mr. W. pins his faith to hippuric acid alone, the gathering of which is the sole object of the bees' visits to manure-heaps. On the contrary, I make such a resort a laboratory of nature and a chemical storehouse to which they seek access according to their need for infinitesimal and chemically pure quantities of a host of substances—as I said, nitrates, phosphates, sulphates, alkalies, nitrogenous substances, and mineral matters.

We speak proudly of the chemistry of the bee as one of nature's many marvels, and its mysterious conversion of materials in the darkness of its cell; surely, then, we must allow it to be the correct judge of what it requires, and mentally permit it access to its chemicals, without experiencing either loathing and disgust.

The objections to extracting from broody combs lie not in visits to mannre-heaps and other places, but to extracting broad-pap instead of honey. R. A. H. GRIMSHAW, Horsforth.

NOTICES TO CORRESPONDENTS & INQUIRERS.

- T. RICHARDSON.—Candy.—Into a tin saucepan put about three-quarters of a pint of water, let this boil, and gradually stir in 6 lbs. of white lump sugar. Keep it boiling, and stir to prevent burning. To test when it is done, dip your finger into cold water, then into the boiling sugar, and back again into the water; if properly done it will be crisp and brittle: or drop a little on a plate, and if sets tolerably hard in cooling, it is done enough. If very sticky and soft, it must be boiled a little longer. When hard, take off the fire, and stir it till it begins to set; place paper into saucers, and pour the candy out into them. In half-an-hour it will be hard and ready for use. Great caution is requisite to prevent it from being burnt, as burnt sugar is injurious when it is fed in cold weather.
- C. H .- Pea-flour candy would be found serviceable, but great caution should be exercised in not unduly stimulating the bees at this season. Proceed as above (see T. Richardson), and as soon as it is taken off the fire stir in I lb. of pea-flour, and when setting pour into
- F. Jubb.—Draining.—We do not advise you to pierce the combs with a knitting-needle. Uncap the cells with a sharp knife, and in a warm room near the fire, lay the comb across an earthenware pan, and when the greater part of the honey has drained from both sides of the comb give the frame back for the bees to clean. Afterwards, wrap the frame and comb in paper and store it in

- a dry place. All this should have been done sooner, but it may still succeed in fine weather.
- W. J.—Wide Sections.—It is very doubtful whether bees would fill 8×6×3 inch sections 'solid,' as you term it. Probably they would build double combs, crosswise, or join section to section, foundation notwithstanding. our opinion, there is no better width for section-boxes than 2 inch. If you decide to experiment in this direction we shall be glad to hear the result.
- P.—The honey is of a fine flavour, and seems to us to taste of wild flowers, such as thyme, and probably the sweet chestnuts mentioned have also something to do with its strength of flavour.
- H. Witt.—The sample forwarded is an excellent honey. Though possessing a very strong flavour of English heather honey, it cannot be pronounced to be pure heather, as it has a perceptible admixture of honey from other plants. It would command a good price in the market.
- C. H.—As desired, your query has been forwarded to Mr. Cheshire.
- W. T. Cadness.-If you consider that there is any probability of your bees requiring more food, candy cake, made as above, can be given above the cluster. There is no occasion to disturb the bees by the removal of the dummy frame.
- H. LAMBERT. Place a cake of candy, made after the above receipt, over the cluster. It may be that you made some mistake in the manufacture of the syrup.
- Παιĉαγωγος.—The viscidity of your honey is caused by an admixture of heather honey, or it has been gathered from plants whose honey candies very quickly. As you are unable to extrude it by means of the extractor, your best way would be to shave off the cells from each side of the comb as near the mid-rib as possible, give the combs to the bees to clean out, and preserve for re-building in the spring. The shavings containing the honey may be squeezed first, and the wax melted afterwards, when the remaining honey will separate. Also see reply to F. Jubb.
- Amateur.—Making Hives. Replying to your questions would involve much labour, and occasion considerable loss of time, to any correspondent who might feel inclined to accede to your request. It would be much more to the purpose if you were to purchase, and to study, Cowan's Guide-book, where all the information you are in quest of can be obtained in an accessible form in the chapter entitled 'Hives,' page 22.

[PUBLISHED WEEKLY.]

Editorial, Aotices, &c.

ANNOUNCEMENT.

We purpose in our next and in successive numbers to give in a narrative form the experiences of a lady bee-keeper. These experiences are from the pen of Mrs. Reginald Bray, the author of Family Feats, Ten of Them, We Four, and several other works which have been favourably received by the public. Beginners in bee-keeping, especially ladies, will find this narrative both interesting and instructive, and it will 'encourage those who as yet have met with little success to continue with a good heart, feeling sure that success will await them in the end.'

APIARY COMPETITION.

In the number of the Journal for Oct. 20 we published the narrative of a Cottager's Apiary Competition which has been recently brought to a successful close at Hawkhurst in Kent. We consider so excellent a method of stirring up a friendly rivalry is calculated to do more for the cause of improved bee-keeping amongst the class concerned than anything hitherto attempted; and therefore we would do all in our power to advocate its adoption into the programme of all County Associations.

The arrangements as set forth appear to be few and simple, and applicable to any well-organized branch of a county Association. Its novelty and, at the same time, its practical utility, as a means of stimulating the desire for a better acquaintance with the numerous details of bee-keeping, irresistibly attract the attention of the rural cottager in whose interest the experiment has just now been made. The idea of the competition is probably taken from the now long-established practice of numerous horticultural societies throughout the country in awarding prizes to the cottagers who exhibit the greatest skill in the management of their home gardens. These latter have borne such excellent fruit in the shape of moral and pecuniary benefits that they bring into immediate view the possibility of awakening up to new life many of the Associations which now betray a tendency towards decline. The practical suggestions that occur to us in contemplating its extension are that the County Associations generally should institute the competitions in one or more districts of their respective counties, each year, in which moderate prizes should be offered, and this by means of a fund provided in the locality; and in cases where two or more localities are carrying out competitions a prize should be offered by the County Association itself for the benefit of the district branch which attains the highest degree of success. This might, again, be supplemented by a prize, or prizes, to be given by the British Bee-keepers' Association to the County Association which should prove itself the best entitled to receive it.

USEFUL HINTS.

Weather and Season.—Gales and heavy rainfall have ushered in the gloomy month of November. The gales, in places reaching almost to the force of hurricanes, have tried, no doubt, the stands and roofs of hives, and where precautions were not taken many a good colony has suffered or been destroyed. Now, at all events, we may consider the summer ended, and the year will be classed amongst the best, in an apicultural point of view, in this uncertain climate. We have known better honey seasons, as regards duration and quantity, but not more than one in ten; and with reference to quality, we never knew it better. Our bees are going into winter quarters well provisioned with natural stores and strong in population, affording a bright prospect for another season, since, with modern appliances and the aid of science, we may consider the wintering problem solved, and those who lose their bees have only themselves to

Four Brood,—Some one, perhaps, will exclaim, 'How about foul brood?' Ah, there's the rub! Nevertheless, nil desperandum must always be our motto; and even here we must not despair, although experience teaches in this, as in all other matters, that prevention is better than cure; and for ourselves we must confess that we place more confidence in prophylactic than in curative measures. In 'stamping out' and the liberal use of preventive measures is our chief hope. County Associations, by means of their experts, may perform a great and good work by advocating and teaching methods of prevention, and we strongly recommend the subject to the consideration of county representatives at their quarterly meetings.

REMOVING HIVES to various positions in the same apiary may now be practised with success, as well as to greater distances. It is best done in cool, dull weather, and in the evening,—quietly and with as little shaking as possible. In removing short distances, care must be taken to disguise the old position, and a board placed in front of the hive after removal, will cause the bees to mark the new locality on their first flights.

ASPECT.—We prefer a south aspect to all others for the winter months. The hives should stand clear of trees and the dripping of eaves, but should be well sheltered from N.W. to S.E. by walls, hedges, or evergreen bushes of laurel, Portugal laurels, or other hardy evergreen shrubs. Such a position is conducive to cleansing flights from lying open to every ray of sunshine, enticing forth to sanitary flight and fæcal discharge. Attention to these small matters will amply repay the labour bestewed by the improved appearance of the apiary and the vigorous health of the bees.

Enemies of the Bees, during their winter's rest, must be guarded against. Keep mice from entering the hives, by nailing perforated zinc across the entrances, leaving a small opening only for the passage of the bees. This plan causes no impediment to ventilation. Beware of the titmouse (Parus major), for on fine days, when bees are in flight, he will make many a hearty meal in the apiary, being unable to obtain insect food from other sources. If disinclined to kill, scare him from the precincts of the apiary by an occasional firing of blank cartridge. He is a timid bird, and is well aware of the danger of the gun.

WINTER PASSAGES.—Mr. Langstroth writes:—'I strongly advise every one to make winter passages for their bees. As the frames touch neither the top, bottom, nor sides of the hives, the bees have such extraordinary facilities for intercommunication that they cannot be depended upon to leave any holes in their combs.' advises:—'Late in the fall, cut with a penknifc a hole, an inch in diameter, in the centre of each comb, about one-third from the top; but if these holes are made before the bees feel the need of them, they will frequently close them.' In many hives, passages will be found through the combs, chiefly, but not always, at the upper corners. Where such do not exist, it is always our practice to follow Mr. Langstroth's advice. Failing these passage-ways, we have repeatedly known colonics to perish while in possession of abundance of sealed honey outside the broad-nest, which they were unable to reach in a cold season by passing round the side or bottom bars of the frames.

Spacing Frames.—It is too late now to open hives and cause disturbance by cutting combs, but, by taking advantage of a fine mild day, the distance between combs may be increased without injury to the bees; and this will form a substitute for winter passages by enabling them to cluster in thicker seams between the combs, and thus to keep up a higher degree of temperature, and to forage, as it were, in the 'home circle.' The quilts having been removed and replaced by a carbolised cloth wrung out dry, and the division-board, or an outside frame, being removed, strips of wood, of the length and thickness of the top bars of the frames, and a quarter inch wide, may be pushed in between the top bars, thus rendering the spaces, from centre to centre of the bars, $1\frac{3}{4}$ inch instead of the usual $1\frac{1}{2}$ inch. Our hives which were treated in this way wintered exceptionally well last season. It is very much against our principles to disturb hives so late in the season, but where due preparations have been neglected at the proper season, our readers must judge for themselves as to the desirability of performing the operation described. Certainly it should be done only in the finest weather, and no smoke must be used, or the disturbance caused will raise the temperature of the hive to such a degree—causing the bees to gorge themselves—that condensation of moisture, and consequent internal dampness, are sure to follow, causing dysentery, and leaving the last state of the colony werse than the first.

CANDY.—Syrup-feeding is no longer admissible. The insertion of a frame of sealed boney at the side of the brood-nest, or candy laid on the top of the frames beneath the quilt of those colonies which are short of stores, is the only substitute for earlier feeding that can be admitted.

Skep Coverings.—The common, well-known earthenware pan, generally used for milk, forms an excellent cover for skeps. Padding of hay, or other soft material, laid on the crown of the skep, will cause additional warmth and make the pan sit well. It is also of advantage to encircle a skep with well-twisted hay-bands. Generally speaking, in good sound skeps, when protected and kept dry, bees almost invariably winter well, and are amongst the first to show signs of activity at spring. The great mistake made by cottagers of the old school is that they cling to the old-fashioned small dome-shaped skep, in preference to the more modern flat-topped roomy one, upon which sectional, or any other kind of super can be used.

Age of Combs.—It is a question often asked—' How long is it advisable to retain combs?' We may fairly suppose that three batches of brood are hatched from the same cells—taking the brood-nest only—in every season. In five years, therefore, we shall have fifteen layers of exuviæ in these cells, provided they are not removed by the bees, which experience seems to prove they are not. The brood-cells, consequently, are much reduced in size, at this age, and the bees reared will be small in size. We have used the same combs for fifteen years, without a break, when the brood-cells became so diminutive that the bees hatched therefrom were a pigmy race, and the combs were black as Erebus, and pollen-clogged. This was before the days of foundation. With our present advantages we do not think it profitable to use combs longer than four or five years. When we consider the rapidity with which a natural swarm will convert fourdation into beautifully straight and even combs, and the vigorous breeding and work performed by such colonies, when compared with those allowed to remain upon old combs; also the quality of the honey stored, and of the bees produced, there can scarcely be room for doubt as to the disadvantage of retaining combs too long.

Dr. Butler, in his Feminine Monarchie (1609), tells us of a colony having occupied the same spot for 110 years. Their demicile was under the leads over the study of Ludovicus Vives, in Corpus Christi College, Oxford; and it is a curious fact that this college is called by its founder, in the statutes, 'The College of Bees.' Erasmus writes to its first president addressing him under the title of 'Johanni Clymundo Collegii Apum Præsidi.' took up his residence as Professor of Rhetoric in 1520, when he was welcomed by the swarm of bees, which continued in possession until 1630, when the leads being decayed were removed, and we are told that an almost incredible mass of honey was found beneath them. Vives was called in the University the 'Mellifluous Doctor,' a proof, if one were needed, of the eloquence assigned in ancient times to those to whom the bees paid particular attention, and to whom they became attached. Dr. Butler concludes his account thus:- Hew sweetly did all things then concord; when in this neat museum, newly consecrated to the Muses, the Muses' sweetest favourite was thus honoured by the Muses' birds!' 'Apes cum causa Musarum dicuntur volucres.'—VARRO.

The cells on these ancient combs must have been cut away down to the septum and renewed many a time during so lengthened a period, and the colony must have been augmented or replaced, by many an additional swarm.

THE STRUCTURE OF FLOWERS WITH REFERENCE TO INSECT AID IN THEIR FERTILISATION.

In the year 1793 Christian Conrad Sprengel published his interesting treatise on the structure of flowers with special reference to insect aid in their fertilisation. This book was almost wholly neglected for more than half a century. Nevertheless, it contains, with some fanciful ideas, the germs of the doctrine now generally held,

together with many excellent illnstrations of it. That eminent naturalist, the late Charles Darwin, published in 1862 his admirable treatise on the fertilisation of orchids by the aid of insects. Since that time a copious special literature has appeared on the subject. We may mention the names of Herman, Müller, Delpino, Hugo von Mohl, and Hildebrand, amongst Continental writers; Charles Darwin and Sir John Lubbock amongst our own countrymen; and Dr. Asa Gray and Dr. Goodale amongst our brethren across the Atlantic.

Linnæus and his immediate successors taught that the adjustments in hermaphrodite flowers were such on the whole as to secure the application of the pollen of its stamens to the stigma of its pistil or pistils. 'The present view,' to quote the words of Dr. Asa Gray, 'is that this is doubtless strictly secured in certain flowers of a moderate number of species, but never in all the flowers of any such species; that in ordinary flowers where it may commonly take place it is not universal; that in the larger number of species there is something or other in the floral structure which impedes or prevents it.' It will be gathered from this definition that some tlowers are adapted for close fertilisation, some for cross-fertilisation, some for either. Before proceeding further let me state for the information of those who have not given much attention to the construction of flowers that they consist of two kinds of organs, viz., what have been apparently called protecting organs or floral envelopes, which when of two sets are named calyx and corolla, and the essential reproductive organs which co-operate in the production of seed—the stamens and pistils.

'A complete flower,' to quote from Sir John Lubbock, 'consists of (I) an outer envelope of calyx, sometimes tubular, sometimes consisting of separate leaves called sepals; (2) an inner envelope or corolla, which is generally more or less coloured, and which like the calyx is sometimes tubular, sometimes composed of separate leaves called petals; (3) of one or more stamens, consisting of a stalk or filament, and a head or anther in which the pollen is produced; and (4) a pistil or an ovary, which is situated in the centre of the flower, and contains one or more seeds or ovules. The pistil consists of a stalk or style and a stigma, to which the pollen must find its way in order to fertilise the flower, and which in many familiar instances forms a small head at the top of the style. In some cases the style is absent, and the stigma is consequently sessile.' For our present purpose the stamen may be regarded as the fertilising organ, and the pistil as the seed-bearing organ. In an ordinary flower the pistil is surrounded by a row of stamens, and at first sight it would appear that a more simple arrangement for the reproduction of the plant could not well be contrived. The pollen would seem to be arranged to fall upon and dust the stigma of the pistil and effect what is known as close fertilisation. This does happen with some flowers, chiefly with the inconspicuous ones. It is in the largest number of flowers with a gay corolla, or which emit a sweet scent and possess honey-glands, crossfertilisation is the rule and close fertilisation the exception.

There are various contrivances in these flowers which effectually prevent self-fertilisation. In many species the stamens and pistils are situated in different flowers. Such species are named dictinous; when the stamens and pistils are situated in different flowers on the same plant the species is called monœcious; when on different plants diœcious. Delpino has classified flowers into Anemophilous (literally wind-lovers) and Entomophilous (insect-lovers), denoting wind-fertilised and insect-fertilised. It is not my purpose in this paper to treat of the former, but will observe that wind-fertilised flowers are monstly neutral or dull in colour, destitute of odour and honeyless. Pines, firs, and other Coniferæ are examples of anemophilous plants. Dr. Asa Gray observes that 'Insect fertilisable or entomophilous flowers are cor-

related with showy coloration (including white, which is most showy at dusk), odour or secretion of nectar, often by all three modes of attraction to insects combined. Some insects, moreover, visit flowers for their pollen, a highly nutritious article, and ordinarily produced in such abundance that much may be spared. The showiness of the corolla or other floral envelopes is an attractive adaptation to fertilisation, enabling blossoms to be discerned at a distance; nor do we know that fragrance or other scent, or that nectar, subserves any other uses to the flower than that of alluring insects.'

'Adaptations in the pollen of such blossoms for transportation by insects are various. Commonly the grains are slightly moist or glutinous, or roughish, or studded with projection, or strung with threads (as in *Enothera*). so as not to be readily dispersed in the air, but to have some slight coherence as well as capability of adhering to the head, limbs, or bodies of insects, especially to their rough surfaces; and in two families (Orchidaceae and Asclepiadacea) the pollen is combined in masses and with special adaptations for being transported en musse. With this the stigma is usually correlated by roughness, moisture, or glutinosity.' Sprengel was the first to discover that in many species where the stamens and pistils are situated in the same flower they do not mature at the same time; consequently the pollen cannot fertilise the stigma. Sometimes, as in the Arum, the pistil matures hefore the authers. Such plants are called proterogynous (or protogynous). In others the anthers mature before the pistil. These plants are named proterandrous (or protandrous). The familiar Arum maculatum-the common arum, or lords and ladies,-of our woods and hedges, is a good example of a proterogynous plant. The well-known green leaf encloses a central pillar which supports a number of stigmas near the base and of anthers somewhat higher. Nothing would seem easier at first sight than that the pollen of the anthers should fall on and fertilise the pistils below them. But this does not take place. The stigmas mature before the anthers, and by the time the pollen has fallen have become incapable of fertilisation. It is consequently impossible for the plant to fertilise itself. Owing to the construction of the spathe the pollen cannot be carried away by the wind. What happens is as follows: The pollen when shed drops to the bottom of the tube, where it remains secure from disturbance by wind. Small insects attracted by the showy central spadix, or the prospect of honey or shelter, enter the tube while the stigmas are mature. Above the anthers and growing from the central pillar is a fringe of hairs pointing downwards. This contrivance allows small insects to enter, but effectually prevents their exit until the stigmas have matured. After awhile the stigmas have ripened and each secretes a drop of honey, thereby rewarding the insects for their imprisonment. Then the anthers ripen and shed their poilen, which falls upon and dusts the insects. Shortly after the hairs referred to shrivel up and the insects are set free. They carry the pollen with them, and on their visit to another plant can hardly fail to deposit some of it on the stigmas. In this manner cross-fertilisation is secured. I have often noticed a large number of small insects, especially flies, safely imprisoned in the arum before the hairs have shrivelled up.

Proterandrous plants, or those in which the anthers mature before the stigmas, are much more numerous. As examples amongst the wild flowers which are to be found in this locality,* I must mention wild thyme (Thymus serpyllum), rose bay, willow herb, Epilobium angustifolium, Blue Meadow Crane's Bill (Geranium pratense), Mountain Crane's Bill (G. pyrenaicum), with many of the Umbellifera and most of the Composita. Sir John Lubbock states that most of the British wild flowers which contain both stamens and pistils are more

or less proterandrous. These are almost dependent upon the visits of insects for fertilisation. Amongst foreign plants now common in conservatories Clerodendron Thompsonii, a verbenaceous African climber, is a good example of a proterandrous plant. Its crimson corolla and bright white ealyx in combination are very conspicuous and serve to attract insects. The long filiform filaments and style, upwardly enrolled in the bud, straighten and project when the corolla opens, the stamens remain straight, but the style proceeds to curve downward and backward; the anthers discharge the pollen; the stigmas are immature and closed; and anthers effete, and the filaments recurved and rolled up spirally, while the style takes the place of the filaments, and the two stigmas now separated and receptive are in the very position occupied by the anthers the previous day. The entrance by which the proboseis of a butterfly may reach the nectar at the bottom is at the upper side of the orifice. It is impossible for the flower to self-fertilise. Λ good sized insect flying from flower to flower and plant to plant must carry pollen from one to the stigina of the other.

I cannot help calling attention to the mode in which cross-fertilisation is secured in the Blue Meadow Crane's Bill (Geranium pratense), for several reasons. This beautiful Crane's Bill, with its lovely blue corolla and elegant leaves, must be well known to all who stroll in the meadows adjoining the Avon or by the brooks in the neighbourhood of this fair city. It is especially interesting as the flower which first led Sprengel to his researches. 'In the year 1787,' writes Sir John Lubbock, 'he (Sprengel) observed that in the corolla of this species there are a number of delicate hairs, and convinced, as he says, "that the wise Author of Nature would not have created a single hair in vain," he endeavoured to ascertain the use of these hairs and satisfied himself that they served to protect the honey from rain.' Another point of interest in this flower is the spontaneous movement of the stamens and pistils. Kolreuter seems to have been the first to observe this motion in another dichogamous plant, Ruta graveolens. He supposed that the object was to bring the stamen in contact with the pistil and so ensure close fertilisation. Nature, as Sprengel pointed out, had a very different purpose to fulfil. It was to bring the stamen and pistil successively in contact with the same part of the insect's body, and so insure cross-fertilisation. When the flower first opens the stamens lie on the petals at right angles with the upright pistils. As they come to maturity they raise themselves parallel and close to the pistil, which is, however, not yet capable of fertilisation. After they have shed their pollen they return to their original position and the stigmas unfurl themselves. As the stigmas do not become mature until all the stamens have shed their pollen, G. pratense is wholly dependent upon insect aid for fertilisation. The spontaneous movement thus ensures cross-fertilisation, and indicates another of Nature's plans for bringing about the end desired by making certain insects the carriers of the pollen.—W. G. WHEATCHOFT (The Journal of Microscopy).

Foreign.

FRANCE.

We stated in our last issue that we would give the names of those who had received awards at the recent Paris Exhibition. The following is a list as given by our contemporary the Apiculteur ;-

Abeille d'honneur: M. l'Abbé Boyer for his exhibits and the formation of a bee association; M. Asset and M.

The Gold Medal of the Ministry of Agriculture; M. Gois-

Flatte, of Egriselle-le-Bocage, for his exhibits and his

First-class Medal (large size) of the Society: M. Bertrand, of Buffon; M. l'Abbé Delepine, of Boussy-Saint-Antoine; M. Kirsch, of Baigneux-less-luifs; M. Meyran, of Mesterrieux; M. Moglia, of l'Ecaille; M. Parpaite, of Carignan; M. Royer, of Pargues; M. Vaast, of Arras; and M. Vivien Joly, of Mezière-la-Grande

First-class Medal (small size): M. Raimbault, of Sens, for his straw hives; and M. Warquin, of Bellevue.

Rappel de Medaille (first class): M. Bourgeois, of Lons-le-Saunier; and M. Robert-Denis, of Vendhuille (Aisne), the latter for his artificial foundation.

Medaille de Vermeil de la Société (large size) : M.

Robert, of Casseau.

Medaille de Vermeil (small size): M. Jacquelin, of Chaville, for his exhibits, and his disinterested assistance at the bee-lectures and lessons given at Luxemburg.

Medaille de Vermeil de la Société de l'Aube; M. Joly, of Tremblay-le-Viscomte-Eure-et-Loir, for his uncapping knife.

Silver Medal of the Ministry of Agriculture: M. Gremy, of Housaye.

Silver Medal given by the Aube Bee Association: M.

Braille, of Saint-Pol.

French Agriculturists' Society Silver Medal: M. Sevalle, of Paris, particularly for his wax-melting pot.

Large Second-class Medal: M. Arpin, of Bourg-Saint-Maurice-Savoy; M. Boulangé, of Jouy-en-Josas; M. Couturier, of Juvisy; M. Droux-Albain, of Chapois; Mr. Feminias, of Mahon, Spain, for his run honey and mode of packing it; M. Holder, of Steimbourg; and M. Sartori, of Milan, Italy, for his ehromos.

Second-class Medal (small model): M. Bonhomme, of Authe; M. Meuvret Haquin, of Torigny-sur-Oreuse; and M. Petit, of Ecos.

Bronze Medal (large size) has been granted to the Central Office for the Colonies for exhibits of colonial honey and wax; also to M. Rousseaux, of Aydes, and the Rev. David, of Villabon, Cher.

The following awards were given to merchants, manu-

facturers, &c., viz.:-

Diploma of Merit: Madame Vve. Brunet, of Paris, and M. Petit, also of Paris. The former mostly for her honey pistils.

Rappel of Diploma of Merit: M. Wavelet, of Arras, Pas-de-Calais, for his Arras hearts and other items of

confectionery.

First-class Medal: M. Béal-Canonne, of Cambray, Nord, for his hydromels; and M. Coenon, of Paris, for his

Second-class Medal (large size): M. Deroy, M. Gariel, M. Lagache, M. Mignel, and M. Moriceau, all of Paris.

Second-class Medal (small size) : Messieurs Poiret frères, of Paris, for their canvas pressing honey and running honey; and Mr. Ragnin, of Sens, Yonne, for his honey barrels.

Bronze Medal (large size): M. Jay, of Paris, and Messrs. A. Menetrel & Cie., of Lille-Maizière; the former

for his perforated zine.

Besides the above there were also sundry prizes for other objects, not strictly connected with the Exhibition itself or its exhibits.

AUSTRALIA.

BLACK HONEY.

Black honey is one of the latest therapeutical novelties. It is an Australian product, the bee by which it is made having been found far in the interior of the central wilderness of that continent, feeding on the flowers of the eucalyptus-tree. The insect, which is said to be new to science, and has been given the name of Apis nigra mellifica, is very small and black. All attempts to domesticate it in Tasmania have failed, but it is said

that some success has been achieved in Algeria, in the neighbourhood of plantations of eucalyptus. The socalled honey is at ordinary temperature a somewhat transparent, syrupy, thick, homogeneous, dark orangecoloured liquid, with a peculiar odour similar to that of eucalyptus; it is very soluble in water, milk, and wines, much less in alcohol. Its fermentation is exceedingly difficult, on account of the large quantity of levulose which it contains. Its specific gravity is 1.44, and it rotates the polarised ray 22°. A thousand parts of it contain 611 6 parts of sngar, mostly levulose, 1.8 parts of ash, 215 6 parts of water, and 171 parts of various substances, comprising eucalyptol, eucalyptene, terpene, cymol, and odorous and resinous matters. When black honey is given freely to dogs, dissolved in warm milk, it produces a great reduction in the number of cardiac pulsations. Thus, in a feverish dog the pulse fell from 125 to 70 a-minute; this fall was accompanied by a lowering of the temperature 1° C. The effect lasted twenty-four hours, with a slight tendency to sleep, but with no symptoms of toxic depression. A tablespoonful given to a man, dissolved in a little warm water or milk, produced after some minutes a slight agreeable sensation of warmth throughout the body. In half an hour elimination of the active principles through the pulmonic mucous membrane commenced. The voice became clearer and sharper, and the breath perfumed. urine acquired an odour resembling that of the Cassia farnesianum, an Algerian plant, from which is prepared the perfume known as 'new-mown hay.' Dr. Caraman believes that this honey will be a valuable remedy in the treatment of bronchial catarrhs, and that it acts as a sedative to the heart like digitalis. He thinks, also, that it will be of practical value as a febrifuge, and a bactericide, e.g., in phthisis, in typhoid fever, in leucorrhea, gonorrhea, and diseases of the kidneys, bladder, and urethra, as it acts more energetically than sandal oil. If it be produced in the enormous quantities described, it ought eventually to find its way into general commerce, and be obtainable at a reasonable price .- Therapeutic Gazette, June 15, 1887.

ASSOCIATIONS.

KENT BEE-KEEPERS' ASSOCIATION.

The Council of this Association, which meets in the ordinary course four times a-year, held its October meeting on the 27th ult., at the 'Saracen's Head' hotel, Ashford. The Honorary Secretary presented a report of the chief events of the season, embracing therein the expert's spring tour, the annual show, the cottagers' apiary competition at Hawkhurst, the bee-tent engagements which had been fulfilled, and a statement of affairs generally. The Honorary Treasurer made a statement of the condition of the finances which justified the hope that the accounts at the end of the year would be in a satisfactory state.

From the Secretary's report we extract the following:—
'The Annual Show was held at Ashford on the 27th July, in conjunction with the Cottage Gardeners' Society's Exhibition. The number of entries was hardly up to the average of previous years, but the increase in the cottagers' exhibits and their largely increased bulk, spoke plainly to the attainment in a large degree of the fundamental object of the Association's existence. Miss Seely, of Woodchurch, and Mr. R. Filmer, of Ruckinge, competed for the silver and bronze medals offered by the British Beekeepers' Association, and it is gratifying to know that the lady obtained the first honours. It may be mentioned that Miss Seely has been practising bee-keeping for several seasons, and although working single-handed, has not hesitated to purchase hives and appliances of the best description, in the expectation that she would reap the return of a considerable addition to her means, mainly provided by the use of her needle. Besides the

prize above mentioned she also secured a first, second, and third in other classes. The prize list contained also the names of the following cottagers:—F. II. Cudd, six 1st and one 3rd prizes; R. Filmer, four 2nd prizes; E. Posse, one 3rd prize; G. Bishop, equal 1st prize; T. M. Spaulding, one 2nd prize. In the class for hives and appliances Mr. A. F. Hutchings, of St. Mary Cray, experiences of the control of the class for hives and appliances Mr. A. F. Hutchings, of St. Mary Cray, experiences of the class for hives and appliances Mr. A. F. Hutchings, of St. Mary Cray, experiences of the class for hives and appliances of the class for hives and the class for hiv To further hibited a large and practical collection. illustrate the advance of cottagers in scientific bee-keeping the fact should be noted that the lectures and manipulations of bees were given by Mr. Filmer, more widely known as the 'Platelayer,' who two years ago gained a third-class certificate for his proficiency in the art. The judging was performed by the Rev. Mr. Oddie and Captain Bush, members of the Committee of the British Bee-keepers' Association, who also acted as examiners of the candidates (Mr. T. Badcock and Mr. W. Blake) for third-class certificates, whom they duly passed. To those gentlemen the Association is greatly indebted not only for the time and trouble freely given, but also for the great pains and discrimination exercised in all the duties undertaken by them.'

IRISH BEE-KEEPERS' ASSOCIATION.

The committee met on the 4th inst. Present: Mr. Sproule, in the chair; Dr. O'Farrell, Mr. Gillies, and the Hon. Secretary. Mr. Campbell, on the part of Messrs. Edmondson Brothers, and Mr. J. A. Abbott, on the part of Messrs. Abbott Brothers, attended to arrange for the manufacture of the standard hive. The form in which the committee 'snext report should be issued was taken into consideration.

LECTURE ON BEE-KEEPING.—On Monday, the 31st nlt., an exceedingly interesting lecture on the 'Wonders of Bee-life' was given in Ulleskelf School for the county parish of Kirkby Wharfe, by Mr. R. A. H. Grimshaw, of Horsforth, near Leeds, one of the secretaries of the Yorkshire Bee-keepers' Association. The room was well filled, and it is to be hoped that the lecture, which was replete with practical hints as to the modern methods of bee-keeping, will leave its mark. A hearty vote of thanks was accorded to the lecturer.

How to Introduce Queens.—Near the close of the day, when there is no danger of robbers, subdue the colony with smoke, find the old queen and remove her. Have a large platform or blanket in front of the hive. Remove every comb with the bees adhering. As the last frame is taken out, shake the bees from it on the platform near the entrance, and replace the frame. Now take the second frame and shake the bees from it some distance from the entrance on the previously prepared platform; when the bees are all off, put the comb in its place in the hive, and treat the third and fourth frames in the same way, shaking the bees about three feet from the entrance. This shaking from the combs completely subdues and mixes up the bees, and canses them to exhale the peculiar scent that bees do when shaken from a limb in swarmingtime in front of a hive. When all the frames have been shaken and replaced in the hive, drop the new queen at least two feet from the entrance, and she will at once move on with the marching legions toward the entrance, and in thus mingling with the mass she at once becomes impregnated with the peculiar odour of the colony, and becomes one of them; and by her queenly sound and motions among the bees, she is at once recognised as the mother-bee, and enters the hive joyously with the rest, and at once proceeds to her work of egg-laying. A few whiffs of smoke among the moving mass will cause a more hasty entrance, and also add its scent to that of the bees. By doing this late in the afternoon or evening, everything is quiet and in working order in the morning, and there will be no trouble from other bees. I have introduced quite a number of queens in this way without a single failure.—H. H. FLICK (Bee-keeper's Magazine).

Correspondence.

The Editor does not hold himself responsible for the opinions expressed by his correspondents. No attention will be taken of anonymous communications, and correspondents are requested to write on one side of the paper only, and give their real names and addresses, not necessarily or publication, but as a guarantee of good faith. Illustrations should be drawn on separate pieces of paper.

Communications relating to the literary department, reports of Associations, Shows, Meetings, Echoes, Queries, Books for Review, fee, must be addressed only to 'The Editors of the 'British Bee Journal,' 'c/o Messrs. Strangeways and Sons, Tower Street, Cambridge Circus, W.C.' All business communications relating to Advertisements, &c., must be addressed to Mr. J. Huckle, Kings Langley, Herts (see 2nd page of Advertisements).

**In order to facilitate reference, Correspondents, when speaking of any letter or query previously inserted, will oblige by mentioning the number of the letter, as well as the page on which it appears.

BEE-KEEPING IN SOUTH AUSTRALIA.

[1341.] I promised, before leaving England, to forward an account of bee-keeping in Australia, so I will attempt

to fulfil my promise.

I arrived at the Semaphore, half an hour's railway journey from Adelaide, on the morning of the 25th of August, 1887, and soon after arriving in Adelaide was fortunate enough to make the acquaintance of Mr. F. A. Joyner, Hon. Sec. of the South Australian B.K.A., whose name I happened to see while walking along King William Street, the principal road through this pretty town. From him I learned that his Association had been in existence for three years, and he presented me with a copy of the third annual report, which showed that foul-brood was very prevalent in the neighbourhood of Adelaide.

The following table shows the results of some of the members' operations during the year ending 30th

June, 1887:--

	ing on.	Hives end of season.	Honey taken.		
Name.	Hives beginning of season.		Ex- tracted.	Comb.	Disease (if any).
			lbs.	lbs.	
A. E. Bonney	Ţ	10	240	130	None.
A Member		22	3360	210	Foul brood, Cured.
F. Bowman	6	32	Nil.	1320	None.
C. F. Clough	4 5	11	1395	590	None.
H. H. Dollman	5	13	300	200	None.
Thos. Gordon	3	5	10	25	Foul brood.
John Hill	3	2	Nil.	Nil.	None.
Frank Hill	3 5	$\frac{2}{12}$	300	Nil.	Foul brood.
H. J. James	2	5	80	85	Foul brood.
F. A. Joyner	3	11	512	107	Foul brood. Cured.
J. Miller	14	15	250	170	Foul brood.
B. Poulton	1	1 .	Nil.	Nil.	None,
J. H. Walters	5	14	890	40	Foul brood. Cured.
W. B. Randell	4	12	784	700	Foul brood.
Sam. Randell	4	12	350	25	Foul brood, Cured.
C. W. Scriven	i	3	Nil.	267	None.

By the Secretary I was introduced to Mr. A. E. Bonney, and from these two gentlemen I obtained what information I could during the twenty-four hours' stay I had in Adelaide.

I went, under Mr. Joyner's escort, to view the honeystand and bee-hive stall in the Adelaide Jubilee Exhibition, where there was a pretty exhibition of combhoney and extracted in screw-capped bottles, which would compare favourably with that exhibited at the Colonial Exhibition in quality; the honey was enclosed

in a glass case about 6 feet square.

I slept in Adelaide, and the next morning I visited Mr. Bonney's apiary, which consisted of twelve strong hives and half a dozen nuclei. It was the commencement of the season, and he was beginning queen-rearing, which he conducted on Alley's system. He told me he experienced much difficulty in obtaining purely mated queens, because, on account of the mildness of the winters, the black drones were flying as soon as those from selected hives which had been stimulated. His plan was to convey his nuclei and hive containing selected drones to the hills, some three miles from the town, where he generally sncceeded in obtaining the desired cross, though he found a fortnight was sometimes necessary before all the queens were mated, which he attributed to the fact that they have a greater

preference for drones of a different variety.

All his hives contained Langstroth frames, which is the standard adopted by the Association; the only covering to the frames was a piece of calico, the hives were single-walled and had passed through the winter in this condition, out in the open. Scarcely a week had passed during the last winter that the bees were unable to take a flight. But a great drawback to keeping bees in the Colonies is their tendency to robbing; after a few weeks' good honey-gathering the glut, perhaps, suddenly stops, and the bees commence pilfering. In consequence of the mild winters, not warm enough to afford sustenance, the bees often, if a weak stock is unprotected, attack it, and if disease is present, of course a greater destruction is the result.

Mr. Bonney and Mr. Joyner both informed me they had implicitly followed out Cheshire's remedy for foulbrood, but had not found it successful. The plan they employ is to deprive the bees of their combs, put them on sheets of foundation in a clean hive, and feed with medicated syrup or diluted honey prepared as follows:-16 grains salicylic acid, 16 grains borax, and 1 ounce water to 1 quart syrup. This they have found re-peatedly to answer well. The honey extracted from the old combs they use in this manner, after boiling it

for twenty minutes.

Most of the bees around Adelaide are crossbreds between English and Italians, though Mr. Bonney has some Cyprians which he imported from Mr. Benton. He opened a strong hive of Cyprians to show me, and they were most gentle. He uses no smoke with them, from experience; and he informed me he always found them good-tempered when pure. He, however, spoke disparagingly of them as honey-gatherers; he described them as great queen-raisers, but found them swarm but little. The cross between Cyprians and Italians he found were perfect fiends though very good honeygatherers.

The South Australians look forward with hope to obtaining pure Italian queens from Kangaroo Island. There is already an apiary started there by a Mr. John Midland, whose address is Fairfield Farm, Cape Cassim, Kangaroo Island, and another by a person unknown to me. I was sorry I had not time to visit either of these farms, but hope to hear further of them, when I will

send you an account.

The greater part of the honey raised in South Australia comes from the apiary of Messrs. Coleman and May, of Mount Barker, who own 250 hives or upwards; they have not published their returns, but the hon, secretary informed me their take for the previous year was said to be about forty tons, which would be an average of about 358 lbs. per hive, which is about the average stated in the account of their apiary given in the British Bee Journal of 15th September, This is an exceedingly good average, one not equalled by any other apiary out here; and though I do not wish to be considered incredulous I may remark that the Colonials resemble the Americans in more ways than

In Adelaide itself there are only 30,000 inhabitants; the neighbourhood is a good honey-producing country,

and the market is consequently overstocked.

The principal yield is from the gum trees—blue and white especially,—a tree called the pepper tree, the wattle, fruit trees, and wild flowers. I tasted some wattle honey, and it is very similar to that produced from the clover. The different gum honeys vary in flavour, but much resemble that gathered from the

Although several weeks pass by in the summer with-

out rain, the drought does not affect the eucalyptus trees, which blossom for a considerable period. In the report of the South Australian B.K.A. above referred to the following is contained:—'Dr. Poulton also enclosed an extract from the British Medical Journal referring to the probability of encalyptus honey becoming of eminent service in the treatment of many diseases, notably in cases of laryngeal, bronchial, pulmonary, cardial, and scrofulous affections; in typhoid and marsh fevers; in whooping-cough or infectious neurosis of the expiratory nerves; in influenza, in renal and vaginal affections, and affections of the bladder. Given on bread or in milk eucalyptus honey may be substituted with advantage for cod-liver oil as an alimentary substance.

There is just one other point I should like to remark upon. Mr. Bonney informed me that his consignments of queens sent in Benton's travelling-crates have not turned out well; he finds the old-fashioned box with small frames is the better.

My next letter will be on bee-keeping in New South

Wales.—W. G. CAMPBELL.

[It may be remembered that about four months ago we notified the departure of Mr. Campbell from England: a short time previous to which Mr. Campbell had obtained a first-class certificate for proficiency in beekeeping. We desire to thank him for the above communication, and trust it may be the precursor of many more from his pen. We also desire to assure him of our best wishes for his future welfare in the new home of his adoption.—ED.]

IN THE HUT.

'A hit, a very palpable hit.'

[1342.] In my recent peregrinations in and about our hut, I happened to tread on a thistle, when oot frae the heather McNallys spring at me 'in two places,' as the auctioneer says, and I am now requested to say for what purpose I asked for a list of the Christian names, or more particularly, the relationships, one to another, of the McNally family. Mr. William McNally seems to have taken me au sérieux, but I have no intention of imitating him in vindictive and vituperative writing; his reply reads more like an extract from United Ireland than fair criticism. My reason was given, and if Mr. W. McNally will look at my request again he will find I did not ask him for the desired information, but some courteous correspondent to supply it as a useful piece of reference. Oughtn't we to have some consideration for those who follow after, and provide them with necessary information, or whatever will they be able to make of the genealogies of the next generation of this family? The request was playfully made, but being made into an angry subject, I must contend now it was a reasonable one, and some one should supply the particulars wanted. It now becomes a painful necessity, for you see, your correspondent says, 'Their name is legion and they are all bee-keepers.' He says, 'They are a dangerous lot to If they all write like him, 'dangerous' is not the word I should select, but from what I see in the Journal from others of the family he is not a fair type, else why could he not see a joke? Has the proverbial 'surgical operation' to be performed in his case?

'If satire be my weapon, yet I'm too discreet To run a-muck, and tilt at all I meet;'

hence, I did not address myself to him personally. I was not going to pop my head out of the window and

have all the slates tumbling about my ears.

I am requested 'to extract all the articles that have been contributed to the B. B. J. from time to time by the McNally family. Heaven forbid! Why it was that very labour which caused me to close a close perusal of your columns in weariness and despair, crying out for the particulars in question. It was in this wise.

A correspondent wrote a short time ago, saying, 'Search for and read, the letters of Mr. McNally in the B,B,J. and let me know who is "Coffin Dick." I found the names in inextricable confusion. Now, by the irony of fate, we find the same

> 'Ruin upon ruin, rout on rout, Confusion worse confounded,

upon the very page (483) on which appears Mr. W. McNally's letter, i.e. confusion at the N. of Ireland show-

'Between one Dromio and another: 'Twixt John McNally and his brother.'

See also pp. 381, 421, 461, 481. Was there not also confusion about the names and exhibits at the Co-operative Exhibition (see 'A. E.' on p. 378)? They were confounded by—X-Tractor.

TO THE CLAN OF MCNALLY, JOINTLY AND SEVERALLY.

[1343.] I wish to express my regret that you have not seen your way to comply with 'X-Tractor's' request. 1 can only guess at his object in making it, but after the communications we have had recently in which your family has been interested I think it is not only desirable that we should have it, but that each of you should have a distinguishing mark as well.

If 'John' sends honey to a show 'Ebenezer' gets the credit for it, and even the secretary cannot explain why; and if 'John' goes to stage the exhibits at another show the secretary says 'William' did it, so how are we to know the one from the other should we ever have the pleasure of getting their presence at a conversazione? Then again, they seem to do a family turn all round annually at puffing each other and at lodging a protest against the judges awards; and what would be the fate of the bee-keepers of Rutherglen should they lose the services of the family is a calamity to be contemplated with alarm.

Now, Mr. Wm. McNally, the 'X' made a courteous request, when you reply to it kindly tell me which of you is 'Coffiu Dick?' I would not ask if you were only two in family, but being so many of you I fear lest I should blame the wrong. I will not put my name to this, but give you further cause for exerting your powers of discrimination as to who is—AMATEUR EXPERT.

NORTH-EAST OF IRELAND BEE-KEEPERS' ASSOCIATION.

[1344.] With reference to the Show of the North-East of Ireland Bee-keepers' As ociation about which Mr. John D. M'Nally is so greatly concerned, and whose officials he has attacked all round, you will please allow me to point out that he misleads your readers when he writes on p. 483:—'The printed "rule" that all honey "was to be shown as taken from the bees" was ignored by many in the 1-lb. section classes.'

Mr. John D. M'Nally means that no sections should have been allowed to compete unless they were Iying loose on the counter, for at the close of his last letter he points to a certain lot which like some others was contained in a plain protective or exhibition case, and from which they were easily removable by simply lifting the

glass, which I saw many visitors doing.

Now when Mr. John D. M'Nally undertook to put matters right he should have given our printed rule correctly. It reads:—'In Classes 4 and 5, sections must be exhibited as they are taken out of the hive, without being ornamented, &c., with paper or any other material, which does not touch on exhibition cases at all, but forbids the decorations that were often used to conceal rows of empty or unsealed cells in sections, and to meet which it was drawn up. And instead of there being 'many,' there was only one competitor whose sections were 'ornamented, &c., with paper,' and who told me when I was speaking to him about his mistake that it was his first appearance as an exhibitor of honey, and

that he would take care not to offend again.

Now as to glass or glazed section cases, we have found them absolutely indispensable in places where bees were flying in the neighbourhood. And at one large honey show, held this year in Ulster, at which I was present, no sections were admitted unless protected by sufficiently glazed cases. I may add that the rule was necessitated by the havoc and unpleasantness effected by bees and wasps in former years, and I have read of the same being enforced at several English shows. But perhaps our Scotch censor's experience has not embraced such a contingency.

I should not have written this letter were I not desirous to see in future years both Englishmen and Scotchmen at our shows, which Mr. John D. M'Nally's letters might prevent by making it appear that we acted unjustly and partially in our interpretation of our own rules.

I wonder when Mr. John D. M'Nally is such a stickler for rules that he did not act on Rule 18 of our show, and lodge his objections to the awards of the judges in writing with the Secretary before two o'clock on day of show, when he and all others would have obtained a hearing.

Certainly the office of judge at a honey show is not a sweet one, unless he should be a fool and give a first prize to every competitor, and when any one accepts the post he knows what he may expect. But an honorary secretary and treasurer should be exempted from such a covert attack as that conveyed in this sentence from Mr. John D. M'Nally's letter at p. 483:—'I do not for a moment insinnate that I received any injustice from the hands of Messrs. McHenry and Cunningham more than any other exhibitor.'—II. W. Lett, M.A.

A QUERY FOR THE 'CHEMISTS' (OR ALCHYMISTS?)

[1345.] The 'Fumigator' and the 'Fugio' are having a battle which smells highly of the doctor's shop.

I have a fact I want to put before our two courteous debaters 'learned in chemistry.' About four years since I saw a sample of honey that, so far as looks and consistency were concerned, was everything that may be desired. It was gathered by bees placed within 300 yards of a beautiful river; the owner was above suspicion as far as management and cleanliness were concerned; he had observed his bees visiting the outflow from the stables: but when he extracted his honey he was scarce prepared for the revelation that awaited him. It stank so unmistakably of urine that my stomach even now revolts at the bare remembrance of it, and the flavour I will say nothing about. This will rather shock some of our readers I can quite understand, but truth must always have first place.

Now friend 'X-Tractor,' whose identity is so obscure as to surpass the 'cuteness of a Scotchman—a clan of Scots in fact—even though you have given your address in full on previous occasions, how about the mysterious conversion of materials in the darkness of the bee's cell in this case? And may I be pardoned if I experience both 'loathing' and 'disgust' when I see them having 'free access to chemicals?'—AMATEUR EXPERT.

ONE HUNDRED POUNDS PER HIVE.

[1346.] Your correspondent 'Sherborne, Dorset,' seems to doubt the possibility of producing 100 lbs. from a single hive, and goes on to ask those (of whom I am one) who have written saying they have done so either to confess to having added swarms to their stocks

or to admit the presence of two or more queens at one time. I can most positively deny the former assertiou, and can only say that if the bees have managed to raise queens by the half-dozen, as 'Sherborne' would try to make out, they have also managed to eradicate all traces

of queen-cells in a most remarkable manner.

'Sherborne' seems from his own showing to be an old bee-keeper. Perhaps he can tell us to a nicety how many frames one queen can possibly fill with bees ready for the honey-season, and the limit of amount of honey HE says one queen can, through her workers, produce. He says, Who has proved that there are not more than one or two queens in a large hive at one time? might ask him, Who has proved the existence of more than one queen? I wonder if 'Sherborne' remembers the fact that hives are frequently ready for swarming early in May, and if we take into consideration the number of bees we prevent (by giving an unlimited amount of room) from leaving the hive, whether it is not fair to assume that breeding be quite as rapid for the next month as for the one previous. Thus we should have at any rate bees sufficient for two hives in one early in June, and we are told that one large stock can gather more honey than two small ones, and in the ordinary course of things these two stocks which 'Sherborne' would have made would have wanted at least 100 super boxes during the season. I cannot see that it is too much (assuming that the stock at swarming time covers ten frames, and still covers them early in June, when the swarm would cover the same, making twenty frames) to add another twenty for super room, which would have been wanted if confined to ten frames in each case. 'Sherborne' will no doubt tell me there is no allowance made for breeding of young queens. My answer will be I have quite under-stated number of frames a stock and swarm would cover in May. Might I recommend 'Sherborue' to get a hive made which cannot possibly be too small; and I, though an amateur would venture to say that an old beekeeper may 'live and learn.'-R. Sutton, Ruddington, November 4th.

UNCAPPED NYMPHS—OBSERVATIONS.

[1347.] When examining the brood-combs, the observant bee-keeper will notice, scattered over their surface, in a comparatively compact mass of capped brood, cells partly filled with honey, others filled with honey but open, and some containing honey and sealed, while others will contain pollen in greater or less quantities. At the same time the bee-keeper will observe empty cells, cells containing eggs, larvae in their various stages of development, capped brood, and 'bare-headed' nymphs, scattered here and there in combs that contain, otherwise, an unbroken mass of pollen and sealed honey.

Upon scrutinising the combs alluded to above, it will be noticed that the orifices of the cells containing the bare-headed nymphs are slightly contracted, and protrude beyond their surroundings, evincing the appearance of having been left by the nurse-bees for a future finishing touch. The nurse appear to be cocconless.

finishing touch. The pupe appear to be cocoonless.

When a cause for the 'bare-headed' phenomena is sought, the conditions and immediate surroundings in which they exist seem to call for some attention. Reasoning from effect to cause, several items present themselves for the exercise of thought as indices by which the investigator may be led to the true source of the lusus nature, for such it appears to be.

In many of the uncapped cells alluded to, the larvæ die before reaching the pupa stage, and are removed by the bees, while others reach the image stage before vitality becomes extinct, and are removed by the bees also. In some of the cells the remains of the larvæ and pupae will be found in all grades of decomposition, having the appearance and emitting the odour of foul

brood. When my attention was first drawn to the phenomena of 'bare-headed brood,' I attributed the cause to a defective development—stunted growth—the result of inefficient nursing, inadequate nourishment, lack of warmth, &c., behind which the constitutional stamina of the progenitors were entitled to a due share of consideration. One item in support of a defective development, so far as I have been able to ascertain, appears to exist in the fact before noted, that the bareheaded nymphs are cocoonless. If such is a fact it presents a very sound basis for the conclusion that a lack of vitality in the larvæ prevents them from performing a radical task—that of supplying the swaddling-bands required by nature during the transformation period.

I can recall but a few instances when I have seen many unsealed pupæ in colonies having vigorous queens, when the strength of the colony was properly divided between the duties of the brood-chamber and the supers. During the past season I hived about one-half of a medium-sized swarm on eight all-worker combs, a year old, from which the honey was extracted last fall. At the time for the brood to be capped, I found the four central combs a complete mass, one-half of which, at a fair estimate, was 'bare-headed.' My first thought, on observing the condition of the colouy, was, that the old honey adhering to the combs after extracting, had generated fonl-brood; but as I could discern no visible evidence of the disease (other than enough to nurse conjecture), I was satisfied with the theory that the numerical strength of the colony was not adequate to the prolificness of the queen. On examining the colony afterwards, I found but few 'bare-headed' nymphs, and at the present time it is among my best.

Although some of the correspondents of the American Bee Journal are inclined to infer that a cause for the 'bare-headed' phenomena may be attributed to the presence of incipient foul brood, a close observation of its various conditions has not, as yet, convinced me that it is invariably a vade mecum of the foul brood disease, although it may, in some instances, be a premonition that the germs of that malady are lurking in the organism of the occupants of the hives or their surroundings. From a short and decisive experience with foul brood five years ago, I am led to think that the disease, in its round of development, occupies a position in the list of maladies accompanying bee-life of a decidedly specific character, but it may not limit its ravages to any one species of insects.

Next to the diagnosis of the 'bare-headed' (!) phenomena, comes the influence of their presence in the combs on the profit-and-loss aspect of the question. If bare-headed nymphs develop vigorous workers, they are harmless; but if a majority of them die before maturing, and the minority survive only to make puny labourers, their presence in the hive must surely result in loss to the apiarist.

Next in order is the question of prevention or cure. As I am too much of a novice to attempt to dictate a method of correction, I will suggest a prevention only, viz., Keep all colonies vigorous!—J. F. LATHAM, (American Bee Journal.)

MR. ROGERS IN REQUEST.

[1348.] Will Mr. Rogers kindly give a young hand a few hints, when making a swarm by division how to know the right time to part the hives; also how to make the Cheshire syrup; also best way to unite weak swarms; also how to introduce a new queen; also how to get a cross breed between Italians and blacks; also size of nucleus box; also how to get or make the flour candy; also how long the queens can remain together on the nucleus box?—A New Hand.

Echoes from the Yives.

Treharris, Glamorganshire.—I have taken sixty-three sections and 7 lbs. run-honey from the hive this year. I was, until this autumn (when I started a friend in this line), the only person about here with bar-frame hives, and as I have had to learn everything by experience and from the Cottager's Handbook, until this summer, when I commenced taking in the B. B. J., I think I have done very well. I have now four hives, three of them new, and have taken 110 lbs, of honey, which I sold at 9d. per lb. runhoney, and 1s. per section.—LLANCAIACH.

Carlisle, October 22nd.—1 meddle as little as possible with my hives. In the spring all the hives are washed out with carbolic soap and water, and food in the shape of dry sugar is given if necessary; later on syrap, or aphis honey, if I have any, this is extracted and boiled when wanted with the addition of a little water to thin it, and salicylic acid solution added. Beginning the spring of this year with nine hives and two skeps, I have had 900 lbs. of honey and four swarms, about 30 lbs. of the honey was aphidean. I had also 2 lbs. of beeswax, after melting down the section-comb in which the aphidean honey had been.—Beeswing.

Chester-le-Street, October 28th.—I take my bees to the moors every August, and in reference to the question that is asked, Can moor honey be extracted? I may say I have several times tried and always failed when it has not been a mixture of home and moor honey. I find pure moor honey in sections or supers cannot be extracted by heat. The season at Muggleswick moor this year was unfortunate, the heather was excellent, indeed; you could feel a sweet smell when walking over it, but the bees had only five good working days when it was at its best, and then a very heavy thunder shower came down and it never fairly recovered after; nevertheless, those that extracted the honey from the sections before they went did very well, a common practice with us. Although I have twenty miles to go with mine I consider I am well paid with what I have got, for my hives are all full below, but the most of the sections are only half full.—W. J.

Revlin House, Donegal, November 4th.—Now that I have everything squared up for the season of 1887-such as bees put up for winter, crates and sections cleaned and stored up for another season, accumulation of comb melted into wax, and a great many other things that are necessary to be done in preparation for another year—a few words in your valuable Journal, I hope, will not be found amiss. I have put up thirty-one hives, four of which are condemned bees, and two united nuclei, and am happy to say in good condition, strong, and plenty of honey. The take in good condition, strong, and plenty of honey. of honey for the season from twenty-five hives will average about 45 lbs. from each. I had fifteen hives up at the heather, with sections ready drawn out, and hives very strong, but I did not get more than forty finished sections from all, for just as the heather was in full bloom it came on wet, and continued so at intervals for a fortnight, till the blossom was all bleached. The only advantage is, getting some honey stored in the frames, as the honeyflow is principally over in the lowlands when the heather is in bloom, but it hardly pays for the trouble. I have driven a good many condemned bees this season, and generally put the bees of about five skeps into one frame-hive. I mix them together in a box, and then empty them down in front of hive, and let them run in, and there is no fighting; but if they are united to another stock without shaking the bees off the frames in front of the hive and mixing them with the others, no matter how both lots are scented, there will be fighting, and a good many killed. I found very few bees in some skeps, especially top swarms, although full of honey, some weighing 50 lbs., which I should think was owing to the rapid honey-flow, and cells filled with honey as they were made, leaving no room for queens to lay. My apiary is about one hundred yards from the sea, which seems to be an advantage to the bees, as no doubt they are fond of salt water.—George Turner.

NOTICES TO CORRESPONDENTS & INQUIRERS.

Letters or queries asking for addresses of manufacturers or correspondents, or where appliances can be purchased, or replies giving such information, can only be inserted as advertisements. The space devoted to letters, queries, and replies, is meant for the general good of bee-keepers, and not for advertisements. We wish our Correspondents to bear in mind that, as it is necessary for us to go to press in advance of the date of issue, queries cannot always be replied to in the issue immediately following the receipt of their communication.

All queries forwarded will be attended to, and those only of personal nterest will be answered in this column.

CHILLED AND DISEASED BROOD.

Query.—Can the putrefaction of sealed larvæ resulting from a chill be distinguished, without the aid of a microscope, from the putrefaction resulting from Bacillus alvei? If so, how?—C. H.

Reply. - Chilled brood, when examined microscopically, is perfectly unlike diseased brood, the juices and tissues of the former resembling those of healthy larvæ, except that they are changing or breaking down under the action of multitudinous putrefactive germs. Healthy larvæ are loaded with fat, but with the beginning of an attack by Bacillus alvei emaciation commences, and all fat disappears by about the time of death; and somewhat later cell structure is scarcely traceable, little remaining but chitinous integuments. such as limiting membranes, tracheæ, and external skin, between which lies a dirty brownish fluid of bad but characteristic odonr, and crowded with countless spores. The distinction between the effect of fatal chill and death by disease, as presented to the unaided eye by a single larva, is too slight and uncertain to determine the case with any confidence, although the appearance and smell of the comb, as a whole, would usually be a fair guide to an experienced observer. The single larva in decaying after death by chilling loses no fat, as this part of the body is least attacked by putrefaction, but most frequently changes to a greyish or blackish colour, whilst the body becomes extremely soft, a greyish fluid escaping when the skin ruptures. In diseased conditions, a buff tone, growing darker and darker until it assumes the colour of coffee, is general, and always follows an attack of Bacillus alvei. There are, however, diseased conditions in which browning is not a characteristic.—F. Cheshire.

STANDARD FRAMES VERSUS DEEP FRAMES.

QUERY.—I think of starting on the deep-frame system in the spring. My bees are all on standard frames now. Could any one advise me the best way to start? I find in a back number one of Mr. Simmins's stocks produced 198 well-finished sections, sixty others partly filled, and the stock combs at end of season one solid block of honey. Would this be with the standard frame or the 14×14 frame?—Bert.

REPLY.-With 14 in. x 14 in. frames I have, as yet, been unable to defeat the record of about 250 lbs. mentioned by your correspondent; the same being secured with the Standard frame two years since by Mr. Luck of Felton, Northumberland, who sent me the

I have put up driven bees in autumn on Standard frames of empty combs; closed up with chaff-packed dummies; a medium entrance, and warm porous covering on top, with no direct through ventilation. They were fed carefully and had young queens. Others were made up on large frames (14 in. × 14 in.) of comb, same strength, and same food, but the combs were placed to one end of hives where the wall was only half an inch thick; at the opposite side nothing protected the comb, where was a large unoccupied space, with three 2-inch holes in the side wall, and one in the centre of the floor. Communication was quite open to the roof where was ten times the space generally allowed for ventilating; the frames were covered with porous material, and yet with all this extra ventilation and no dummies, these stocks came out five to one better than those prepared as usual on Standard frames.

As the above statement shows, the deep frame is decidedly superior for wintering, and should 'Bert' wish to adopt the larger frame, he cannot do better than transfer in April—two standard combs on end—in one large frame; working a few by the side of his standard frames for a year or two, when he will be able to tell which suits his management or locality. As the deep frame takes exactly two of the standard, there is no waste, even if he wishes to return to the standard; one and the same hive also answering for either frame .--S. SIMMINS.

Cumprian. — Bees Dead and Dying. — You should have crowded the bees on to not more than eight frames, instead of eleven; possibly through so much space being left some robbing has been going on with the usual fighting. We have had wasps visiting our apiary as lately as Saturday, the 5th inst. Did you ascertain the presence of the queen on your last examination? If you get the opportunity, reduce brood-nest to six frames, cover warmly after having removed any dead bees that may be on the floor-board. Once a-week pass a piece of bent wire through the entrance and remove any dead bees that may have accumulated. Make an inspection early in January, if a mild day occur, and feed if necessary, asking any further query you may find desirable then. Your last suggestion would make matters worse.

W. Robinson.—Death's Head Moth.—The moth forwarded is the Death's Head Moth (Acherontia atropos). It is very frequently found in potato fields, feeding on the leaves of that plant. For some reason that has not yet received a satisfactory explanation, it is allowed by the bees to enter their hives and plunder them of their honey; and though apparently it is quite defenceless, its ravages are permitted with impunity. 2. If there is aught of novelty in your management of skeps, the knowledge of which will be useful to bee-keepers, we shall be pleased, when convenient, to receive the communication from

A. E. A. Edwards.—Pollen and Honey.—There need be no apprehension of foul broad from the appearance of the piece of comb forwarded. It has the cells partially filled with pollen, with some amount of honey superposed thereon.

Communications to the Editor to be addressed 'Strangeways' Printing Office, Tower Street, Cambridge Circus, W.C.

[No. 282. Vol. XV.]

NOVEMBER 17, 1887.

[PUBLISHED WEEKLY.]

Editorial, Aotices, &c.

PARSONS AND BEES,

For many years the two have been inseparably connected in our mind; indeed, ever since we made the juvenile error of confounding Bishop Heber with our great Huber. The power of association is so strong in the human mind that when the imagination, even erroneously, connects or associates two pictures, words, or acts, years may pass away meanwhile, yet let one of these be brought into the vision of our memory and the accompanying spectre appears also.

We read MM. Erckmann-Chatrain's tales of the Vosges mountains and their inhabitants, Alsatian pictures of pastoral life, tales of the charcoalburners in the Black Forest, Pastor Dzierzon's discoveries, or Père Langstroth's classic on bees. We transfer the mental panorama into Poland or Sweden, Denmark or Norway, Switzerland or Austria; and, wherever we find our bees kept and tended, there we find the inevitable pastor accompanying them—'in my mind's eye, Horatio.' We see the mirage of boyhood's days :- a blind Swiss Bishop Huber or Heber, a stout Johnsonian parson, sitting in his bee garden, his head uplifted, and his sightless eyes 'all dark, irrecoverably dark,' as he listens to his bees passing to and fro; he tries to comprehend what they are saying to each other; what they say to him he knows.

Many of our bee-books are written by our parsons; and, perhaps, we are not wrong in saying that almost half the current bee-literature is penned by them. We are quite convinced that we owe the advances made in bee-keeping, from the hollow log, the hive of staves, the earthen tube, and the straw skep, to the scientific appliances of our own time, more to our elergymen (or, as we prefer to call them, the parsons) than to the rest of the fraternity combined.

In most rural districts, where the art has lingered and 'dragged its slow length along' (a truly living death) by reason of the crass ignorance of the bee-keeper and the pigheadedness of bee-keeping traditions, such as gave rise to the 'ken-mair-aboot-bees-than-onybody' phrase, it is the parson, whose higher cultivation and perceptive faculties placing him au courant with what is passing in the outer world of apiculture,—it is he

who takes the first plunge in modern bee-keeping and who bears the brunt in the battle of new fangled versus antiquated notions. It is the parson who persuades Farmer Hobbs (1) not to smother his bees; (2), to super skeps; (3), to drive; and, finally, to use frame-hives, artificially swarm, and the rest of it. The prime mover in elevating the moral tone of his people by lectures on bees and bee-keeping, and other subjects, the promoter and indefatigable Hon. Sec. of the County B. K. A. is none but he. If we look over the list of members of our national Association, we find over fifty of them clergymen; and at our Conversaziones we are favoured by a very fair proportion indeed of the clerical element.

Bec-keeping, as it is taught to-day, is thus greatly indebted to them individually and as a body, for the higher tone imported into it by the intelligence they bring to bear upon the science. There is a je ne sais quoi of deep, plain, practical, truthful examination and trial, 'ringing out the old, ringing in the new,' fads, about their connexion with scientific bee-keeping, that cannot fail to be distinctly elevating to all who thus come into contact with them. This elevation of tone or sentiment is contagious, and we find almost all our bee-literature pervaded by it. There is a gentlemanly and courteous treatment of opponents in theory, and of those who differ in practice amongst bee-keepers, which is conspicuous by its absence in the correspondence columns of many other journals of science. Under the beneficent influence of the parsons amongst us, we feel that, in no small degree, are we under obligations to them; our very language in argument, as well as in written controversy, is modified when we remember of whom and with whom we are disputing. Perhaps, the influences of the clerical element upon the rest of the beekeepers with whom they came into contact may be best illustrated by comparing it to that of the presence of ladies at assemblies, or to the refining, elevating effect produced by sisters amongst Vigorous and courageous as we know brothers. our brothers are, both in vivê voce discussions and with the pen, we shall in no way disparage such estimable qualities, yet, it may be, that a judicious restraint is often put upon tongue and pen when tempted to write or say something peculiarly smart and cutting, by the feeling that we should be attacking, and perhaps wounding, one who, by the

virtue of his Christian office, is precluded from putting down aught in malice and replying with an exhibition of similar spiteful or poisonous darts. We know how the namby-pambyism and conceited affectation of girls are rubbed off by daily mixing with the brethren of the family, and, though we have said so much in praise of our parsons, we cannot help thinking that, were it not for their repeated contact with their brethren, bee-keeping would degenerate into the simple pastoral pursuit it once was, instead of becoming, as it rapidly is doing by the mutual efforts of both, a flourishing industry.

So, under the benign tempering beams of the clergy of all denominations may bee-keeping continue to make rapid progress in the future, as it has done in the past years of the Queen's reign.

THE STRUCTURE OF FLOWERS WITH REFERENCE TO INSECT AID IN THEIR FERTILISATION.

(Continued from page 492.)

I will now direct attention to another very successful arrangement for promoting cross-fertilisation through the agency of insects. Probably many have noticed the primroses (Primula vulgaris) present different appearances with regard to the stamens and pistils. In some the pistil is found at the top of the tube and the stamens half way down; in others the stamens are at the top of the tube and the pistil half way down. Corresponding differences may be seen in the cowslip (P. veris), polyanthus, and auricula. This difference in the form of the flowers has long been known by the homely names of 'thrum-eyed and pin-eyed.' Plants which present these differences of form are known as heteromorphous; those which have two forms of flower, like the primrose, as dimorphous; and those which have three forms, as in Lythrum salicaria (Purple Loosestrife), as trimorphons. Sprengel, as Darwin mentions, had noticed this difference in form in Hottonia before 1793. 'Sprengel,' writes Darwin, 'with his usual sagacity adds that he does not believe the existence of the two forms to be accidental, though we cannot explain their purpose.' Trimorphism was noticed by Vaucher in 1841 and by Wirtgen in 1848. It was left to our great naturalist, Charles Darwin, to interpret in the journal of the Linnæan Society, 1862, this curious phenomenon.

Referring to dimorphism in the case of the primrose, Sir John Lubbock observes, 'An insect thrusting its proboscis down a primrose of the long-styled form would dust its proboscis at a part which, when it visited a short-styled flower, would come just opposite the head of the pistil and could not fail to deposit some of the pollen on the stigma. Conversely, an insect visiting a shortstyled plant would dust its proboscis at a part further from the top, which when the insect consequently visited a long-styled flower would again just come opposite the head of the pistil. Hence we see that by this beautiful arrangement insects must earry the pollen of the longstyled form to the short-styled, and rice versa.' Mr. Darwin has shown that much more seed is set, if pollen from the one form be placed on the pistil of the other, than if the flower be fertilised by pollen of the same form, even taken from a different plant.

This eminent naturalist, in his interesting work on the forms of flowers, after giving a minute and graphic description of trimorphism in the case of Lythrum salicaria (Purple Loosestrife), observes, 'In a state of nature the flowers are incessantly visited for their nectar by hive or other bees, various Diptera and Lepidoptera. The nectar is secreted all round the base of the ovarium,

but a passage is formed along the upper and inner side of the flower by the lateral deflection of the basal portion of the filaments; so that insects invariably alight on the projecting stamens and pistils, and insert the proboscis along the upper and inner margin of the corolla. We can now see why the ends of the stamens with their anthers and the end of the pistil with the stigma are a little upturned, so that they may be brushed by the lower hairy surfaces of the insects' bodies. The shortest stamens, which lie enclosed within the calyx of the long and mid-styled forms, can be tonched only by the proboscis and narrow chin of a bee; hence they have their ends more upturned and they are graduated in length, so as to fall into a narrow file, sure to be raked by the thin, intruding proboscis. The anthers of the longer stamens stand laterally further apart, and are more nearly on the same level, for they have to brush against

the whole length of the insect's body.

'I have found no exception to the rnle that when the stamens and pistil are bent they bend on that side of the flower which secretes nectar. . . . When nectar is secreted on all sides they bend to that side where the structure of the flower allows the easiest access to it, as in Lythrum. . . . In each of the three forms two sets of stamens correspond in length with the pistil in the other two forms. When bees suck the flowers the anthers of the longest stamens bearing the green pollen are rubbed against the abdomen and inner sides of the hind legs, as is likewise the stigma of the long-styled form. The anthers of the mid-length stamens and the stigma of the mid-styled form are rnbbed against the under side of the thorax and between the front pair of legs. And, lastly, the anthers of the shortest stamens and the stigma of the short-styled form are rubbed against the proboscis and chin, for the becs in sucking the flowers insert only the front part of their heads into the flower. On catching bees I observed much green pollen on the inner side of the hind legs and on the abdomen, and much yellow pollen on the under side of the thorax. There was also pollen on the chin, and, it may be presumed, on the proboscis, but this was difficult to observe. I had, however, independent proof that pollen is carried on the proboscis, for a small branch of a protected short-styled plant (which produced spontaneously only two capsules) was accidentally left during several days pressing against the net, and bees were seen inserting their proboscides through the meshes, and in consequence numerous capsules were formed on this one small branch. . . . It must not, however, be supposed that the bees do not get more or less dusted all over with the several kinds of pollen, for this could be seen to occur with the green pollen from the longest stamens. . . Hence insects, and chiefly bees, act both as general carriers of pollen, and as special carriers of the right

A long series of experiments proved that both kinds of pollen are nearly or quite impotent upon the stigma of the same flower, and that no ovary is fully fertilisable in any other manner than by stamens of the corresponding length. Neswa verticillata, a common lythraceous plant of the Atlantic United States, is, according to Dr. Asa Gray, similarly trimorphous. Several South African and American species of Oxalis are trimorphous, and have been investigated by Darwin and Ilildebrand with the same result as in Lythrum salicaria. Referring to trimorphism, Mr. Darwin observes in one of his valuable works as follows:—'Fritz Müller has seen in Brazil a large field many acres in extent covered with the red blossoms of one form (of an Oxalis) alone, and these did not produce a single seed. His own land is covered with the short-styled form of another species, and this is equally sterile, but when the three forms were planted near together in his garden they seeded freely.' 'All known flowers,' writes Dr. Asa Gray, 'exhibiting reciprocal dimorphism or trimorphism are entomophilous' (insect fertilisable). No such wind-fertilisable species is known. Few of them are irregular, and none very irregular: they do not occur, for instance, in *Leguminosæ*, *Labiatæ*, *Serophulariacæ*, *Orchidacæ*, &c. Nature is not prodigal, and does not endow with needless adaptations flowers which are otherwise provided for.—W. G. WHEATCROFT (*The Journal of Microscopy*).

(To be continued.)

Selected Query.

[1.]—Have you used slotted dividers between the sections, and what is your experience with them?

I have extensively used slotted dividers with four beeway sections this last season, and find that in conjunction with such sections there is a trifling advantage gained in the nicer manner in which the side cells of the comb are filled; but I consider the amount of this advantage is not sufficient to warrant advising any bee-keeper going to the expense of supplanting their present plant of dividers. They—slotted ones—are also very likely to get damaged in the hauds of any one the least careless, bending, and, with brittle metal or wood, breaking just where the slot almost meets the hollow cut out at top of divider. When propolised, they require great care in removing.—W. B. Webster.

I have had this year, in constant use, over 1000 slotted dividers between sections, and found them simply perfection. The sections were all open on four sides of different width, 1½ and 2 inches wide. The bees seemed to build out their comb up to and over the wood of section edge, and also filled more quickly than with the plain divider. I think, before judging finally, I should prefer to give them another season's trial. Care must be taken in using them, as they are very apt to cut the hands when cleaning to put away at end of season.—WM. McNally.

I prefer slotted dividers between the sections that have to be glazed, better than wood: but a space should be left at the bottom and the top for the bees to easily get to the sections, the same as in the wood dividers.— WILLIAM CARR.

Do not use separators.—Samuel Simmins.

Yes, very extensively; and found that the sections were more evenly and rapidly filled than with any other dividers.—G. J. BULLER.

Yes. If there is a space left between the sections so that the bees going through the slot in the dividers can pass along and cluster round all the sections in the case, as they can do in that illustrated on page 128 of this year's Bee Journal; or when Lee's patent sections are used, which provide passage-ways, then there is a great advantage in using slotted dividers. If the ordinary section-case is used, or the one illustrated on page 50 of the present Journal, with slotted dividers, then the bees going through the dividers, being stopped by the edges of the sections touching each other, leave more pop-holes in the sections for the purpose of clustering and passing than they would where solid dividers are used.—John M. Hooker.

Using slotted zinc-dividers last season, I obtained the centre sections with neither better fit nor finish than when using the old pattern wood divider, with the sections closely encased in crate; but the fact of centre sections always turning out the best, pointed that not in centre of crate were extra passages necessary, but that passage around outside sections would be beneficial, producing more even work throughout the whole crate, and the result in trial was as anticipated. This outside passage only is not so practicable with any section as the 13-inch for bee-way, worked without dividers; and trials as to the better methods have convinced me that bee passages,

other than around outside sections in crates of three sections wide, to be bad economy in the service of bee life for sectional honey production.—J. II. HOWARD.

I have used the slotted dividers with bees, and other sections, having passage-ways on all sides, and have found them answer perfectly, the sections produced being evenly worked and free from loop-holes at the corners. This, however, was during a copious honey-flow, when only perfect sections, as a rule, can be obtained. It is most important that the bees should have, at all times, the free communication between the sections, which slotted dividers afford.—George Raynor.

MY BEES.

By Mrs. Reginald Bray.

Author of 'Family Feats,' 'Ten of Them,' 'We Four,' &c.

'No mirth, no cheerfulness, no healthful ease, No comfortable feel in any member; No warmth, no shine, no butterflies, no Bees, November.'

CHAPTER I.—A DREAM FULFILLED.

'Have you any fancy for keeping bees?' said a kind neighbour to me one day as we were walking round the garden one summer day in June.

'Any fancy?' Why my whole heart leapt within me. 'Bees!' why it had been the desire of my life from the time I had been a little child, when I used to pore over an old book in my father's library called My Bee Book, probably quite antiquated and old-fashioned in its ideas, but to me a very fairy-land of delight.

'Because, continued my neighbour, little dreaming of the ecstasy of delight which I was concealing under a calm exterior, 'I have a number of hives at my place in the country and am thinking of sending for some, so if

you like I shall be delighted to give you some.'

I could scarcely gasp my thanks. Was the sky ever so blue before? Was the sun ever so bright? Was my life-long dream now going to be realised? I had occasionally had faint dreams of hives in sunny corners and the hum of bees among the flowers; but I knew not how to start them or where to procure a swarm. Indeed, I knew very little more than what I had gathered in the days of my childhood. Sometimes, indeed, I had remarked to my gardener that it was a pity we could not keep bees, and he being a kindred spirit fully agreed; but our garden, a lovely old-fashioned one, was in the suburbs of London. I did not know of a hive in existence in the neighbourhood, and so I had to give up the wish, which until this moment never seemed feasible.

'The only difficulty,' continued Mr. Graham, 'is that I am not fond of bees myself, and have a wholesome horror of being stung. My wife has a fancy to keep them, but I do not know whether it is possible to move them at this time of the year, nor how it is to be done.'

'I will ask Watson,' I replied; 'for he used to keep bees in the country, and understands something about them.' He was summoned to the conclave, and said that it would be possible if they were tied up in sheets at night, but it would be impossible to move them by rail.

'Very well,' said Mr. Graham: 'it is only about twelve miles; I will send one of my carts, and they shall be

driven down all the way.'

Matters were soon arranged. Watson and Mr. Graham's man were to go down by rail, and as soon as the bees had all come in from their day's work and had retired for the night they were to be tied up in sheets and transported to their new homes. The hives, of which I was to have three, were all old-fashioned straw skeps. No one had taken any interest in them for years.

The bees had come and gone at their own sweet will; queens had lived and reigned and died; swarms had gone forth to new colonies; honey had been stored and eaten by themselves alone; and now they were to be rudely

disturbed from their elysian fields and brought to the suburbs of London amid the bustle and the din of man. Poor bees!

The day came at last which I had been awaiting with

an impatience scarcely concealed.

Had we known more, I should have been very anxious, but it is a fact that sometimes 'ignorance is bliss,' and that 'fools rush in where angels fear to tread.' Happily we had not then studied the subject, and little we knew of the danger and difficulty of moving hives in the middle of summer, heavy with honey-laden comb, and weighing possibly as much as forty pounds. I have wondered since that they all came safely to hand, especially when I read how necessary it is to push wooden skewers into the sides of the hives so as to support the combs, and how this ought to be done two or three days before moving, as the bees would then make them fast, and they would not give way. Also that the hives should be turned upside down, which would cause less strain upon the comb, for if in the move the combs broke and fell, then woe betide your bees! All this and much more we knew nothing about, and our great success was mainly due to the fact that the hives were so very old that the comb was probably extremely strong and tough, and therefore stood the journey, which was made with due care at a foot's-pace.

Never shall I forget the moment when I stood in front of my three hives on their new staud in the sunniest corner of the garden facing the south. I gazed at them with a feeling of respect, for I knew not then that bees could be handled with impunity. The bees flew in and out with joyful sound, caring nothing about me (the most loyal subject of the queen-bee that surely ever existed). One garden was as good to them as another as long as flowers and nectar existed. The distance being great, there was no risk in having changed their place of abode, for beginners must remember that bees must not be moved any short distance in the summer, or they will invariably return to their old homes, and, finding their hives gone, will fall down and

die.

The bees looked most flourishing, the multitudes which hurried in and out showed that they must be very strong, and I was immediately possessed with the idea that they would be sure to swarm soon. I had heard of swarms coming out and being lost before you had time to take them. What a terrible idea! there was not an hour to be lost, they might swarm at any moment, and I had not a spare hive. I must drive instantly up to London and place myself in readiness for my swarms. The question now was, 'Where should I go?' I had never heard of the British Bee Journal, that most absorbing of all papers that has ever been brought out. I knew not even where I could purchase a hive. I looked in the Field, but of course that week no one had advertised a hive. Some one suggested Messrs. Neighbour. The very thing. I knew them by name; who does not? and, ordering the carriage, I drove hastily to Regent Street.

Next to the pleasure of the bees, I think it is to see on each side of you the various hives and appliances for beekeeping. A new world seemed opened to me as I saw the different hives,—skeps with glass windows, bar-frames, which were to me as yet a mystery, and very incomprehensible they looked with their sections and supers. Indeed, I thought that it would be impossible for me ever to understand the working of them, little knowing how extremely simple it is when you have once been

properly shown.

Accordingly I modestly contented myself with a straw skep of excellent make, and one with little windows at the side, so that I could look in and see the bees at work.

With my hive in the carriage my heart felt lighter, though sundry misgivings would come over me that

the bees might possibly have swarmed in my absence. It seemed as if they would be certain to have taken advantage of my 'being out.' Happily no such misfortune had occurred, and the bees were flying in and out with as peaceable a mind as when I had left them.

One extra treat I had provided myself with, and that was the *British Bee-keepers' Guide-book*, by Thomas Cowan, and *Modern Bee-keeping*, published by the British Bee-keepers' Association. With what feelings of delight I sat down to peruse these treasures I need not here describe.

In case, however, any of my readers have not had a like treat I will give a short description of the queen and her subjects.

First of all, we will commence with her majesty, or, as she is sometimes called, the 'mother bee,' because she alone, with some rare exceptions, lays all the eggs from which the bees are produced. It will scarcely be believed that during the spring and early summer she will lay two or three thousand eggs a-day.

It is very easy to recognise the queen, as she has a long thin body, and shorter wings than either the drone or worker-bee. Each egg is deposited in one of the cells, and in three days it hatches into a small white grnb, which is carefully fed upon a mixture of honey, pollen,

and water.

The grubs are fully grown in about five or six days, and are then sealed over in their cells by the worker bees. The grnb spins itself a cocoon in which it remains for three days, when it becomes a nymph. At the end of seven more days, or twenty-one days from the laying of the egg, it emerges a perfect bee. The queens and the drones pass through similar changes, but the queen takes only fifteen days to develope, whilst the drone takes twenty-five.

The workers are a much smaller bee than the queen. They build the comb, gather the honey, and feed the grubs, and so busy are their little lives in the summer that they only live about six weeks, so it is very necessary that the stock of bees should be constantly re-

plenished by the queen.

The drones are the males, and are produced at the beginning of the swarming season. They have no stings, and are turned out by the workers in the antumn when they are no longer required. The presence of drones in a hive is usually a sign that swarming is likely to take place.

A queen may live four or five years, but it is best to replace her when she is about two years old. The workers have it in their power to raise a queen whenever they consider it desirable, and they can even turn the grub into a queen so long as it is not more than three days old. This appears to be done by simply enlarging the cell and giving food in greater abundance. A queencell can easily be known as it projects and hangs down like a small acoru.

The more I read the more interested I became. The possible failures never entered into my head. My bees were sure to do well. They would yield me an immense quantity of honey. I should supply the whole household, and sell the remainder to my friends. Honey was 1s. 6d. a pound in those happy days; and I began to calculate how soon I should be able to pay off all expenses of extra hives that I should require, and begin to make my fortune.

I may as well remark here that my household is extremely fond of honey, and up to this date they have recklessly consumed every pound of honey that I have last.

My schoolboys suggested that it would be very nice to have some to take to Harrow, but I nipped this idea relentlessly in the bud, and murmured something about the difficulty of packing it.

I rejoiced greatly in thinking that I should no longer be dependent upon exterior sources for my honey, from which I had suffered greatly. One year a friend in Scotland gave me a delightful account of the beautiful heather honey, which, in out-of-the-way places, could be purchased for 3d. a pound if you took the whole hive. I promised to share a hive with her, and in consequence did not lay in my usual large stock of honey in the

Well! my friend came south, and I waited long and anxiously for my honey. It never came, and at last I wrote and inquired after it. It was somewhat vexatious to hear that her family had found the honey so good that

they had kept it all for themselves.

The following year I determined to do better. A sister was going to the Highlands, and I felt that npon her I could depend. She did not fail me; but, alas! the hive was sent by sea packed with a large quantity of Scotch oatmeal, and somehow—it was never discovered exactly how—the honey and the oatmeal got mixed and arrived an indescribable mash.

The next year I determined to have nothing to do with any more Scotch honey, so I bought a great quantity from the poor people in the country, and was quite satisfied though it was not Scotch honey. Unfortunately another sister went to Scotland on her wedding tour, and so temptation fell in my way once more.

Knowing my weakness for Scotland and everything Scotch, and especially heather honey, she wrote to say that the most beautiful honey was to be bought from the people there, and that the landlady of the hotel where

she was could get me any quantity.

Now I own that there was a certain interest connected with that same hotel at Rowadonan, on the shores of Loch Lomond. I had been there on my own wedding The landlady was a personal friend of mine, as she had been housekeeper to some old friends, and, above all, Scotch honey—everything Scotch—always seems to me so infinitely superior to anything else.

I could not resist, and gave a somewhat large order; and, determined that nothing should go wrong, arranged to have it sent direct to me, thinking that the low price

of the honey would make up for the carriage.

By-the-bye, I did not ask the price of the honey, taking for granted it would be about 3d. a-pound. was somewhat startled by the amount I had to pay for carriage, but the honey was first-rate, and the household showed its appreciation of it by eating it up twice as fast as usual. It gave me quite a pleasure to see how that honey was appreciated.

Then the bill came in.

I opened it; I looked at it, and I sadly shut it up again.

The worthy landlady had lived in England. She knew English prices. She would not like to charge a newly-married couple anything but the top prices.

The honey was two shillings a-pound!

That was the last Scotch honey I ever bought.

(To be continued.)

Mr. W. Couse, Secretary and Treasurer of the Ontario B.K.A., desires to acknowledge with thanks the receipt of two books forwarded by 'Amateur Expert' as an addition to their library, viz., from Dr. Bartrun a copy of his pamphlet The Stewarton Hive, and Thorley's Female Monarchy, presented by Mr. John Walton.

THE USE OF THE POSTERIOR LEGS OF THE WORKER BEE.—They aid in walking; they sustain an enormous weight when bees cluster; they gather, transfer, and carry the nitrogenous food (the pollen) and the propolis; they grasp and carry forward the delicate wax scales, and aid to clean off the pollen as the bee frees its legs of this substance when the latter is pushed off into the cells of the comb.—Professor Cook.

Correspondence.

The Editor does not hold himself responsible for the opinions expressed by his correspondents. No attention will be taken of anonymous communications, and correspondents are requested to write on one side of the paper only, and give their real names and addresses, not necessarily for publication, but as a guarantee of good faith. Illustrations should be drawn on separate pieces of paper.

Communications relating to the literary department, reports of Associations, Shows, Meetings, Echoes, Queries, Books for Review, fee, must be addressed only to 'The Editors of the 'British Bee Journal,' c/o Messys. Strangeways and Sons, Tower Street, Cambridge Circus, W.C.'. All business communications relating to Advertisements, e., must be addressed to Mr. J. Hucker, Kings Langley, Herts (see 2nd page of Advertisements)

**In order to facilitate reference, Correspondents, when speaking of any letter or query previously inserted, will oblige by mentioning the number of the letter, as well as the page on which it appears.

OUR HONEY IMPORTS.

The value of honey imported into the United Kingdom during the month of October, ISS7, amounted to 668l. [From a return furnished by the Statistical Department; II. M. Customs to E. II. Bellairs, Wingfield, Christchurch.

COMPLIMENTS TO EDITOR.

[1349.] I am pleased to hear of your safe return from Canada and America in such good health, and that you have so much enjoyed your journeyings. The marvel to me is how you have done so much, for you tell us of visiting Mr. —, and after him Mr. — hundreds of miles distant, and other bee-keepers more distant still; looked over their workshops, their apiaries, their indoors; and all this to be stored up for our benefit, and so much information about bees and bee-keeping as carried

on in those States by the leading men.

I have been greatly interested in reading your first dole of your tour and shall look for a further. You can tell as much on plants and flowers, and I hope to hear you enlarge upou the subject of bee-forage in the States you have visited. Such could not fail to interest, and so possibly draw out from the rich store-box of others here a little which might help to fill a vacuum in that of the less favoured; besides, to say the least, it would be a sweet subject, sweeter than one we have been treated to of late in the Journal. Oh! by the bye, did you go bee-hunting whilst out in the wilds—I mean real hee-hunting, out in the woods hunting for wild hees? If so, please tell us all about the sport, and if you found the hees in any way different to yours at Horsham. Now I have my pen in hand I may just remark I note your editorial, 'Bee-keeping as a livelihood, in your issue of Nov. 3, and with you'l wish bee-keepers of practical experience would, for our guidance and benefit, give us their frank opinions upon the subject, especially as to the business being a remunerative one at the quotation you give for good English honey; if they would so, I venture to predict the result of such opinions would not be your figure.

Would that I could convert you to my views as to a paying price to the producer for good English honey, but please don't continue to educate the public to look for a downward price. I question if that course is one calculated to increase the consumption. We don't eat two loaves of bread instead of one because the price is low. No, rather educate the public to the use of honey, and they will be content enough to pay a fair price for it. Pray don't think me a grumbler and a fault-finder, but I am really tempted to wish I had had the manipulation of the type for one portion of your editorial, or rather had been at the elbow of him who had, I would just have honied him up to my figure (9d.), and your sour 6d. would most certainly have appeared tail down.-R. R. Godfrey,

November 7.

WINTER PASSAGES, &c.

[1350.] In last week's 'Useful Hints' (p. 490) Mr. Langstroth's advice is quoted of cutting holes one inch in diameter for winter passages: such holes, if left intact, would, in the writer's opinion, be unsightly and wasteful. Our practice is to cut holes about half an inch in diameter; and this may easily be done with a piece of brass tube, the end slightly notched, so as to cut cleanly

when a screwing motion is imparted.

Whilst on this subject, it would be interesting to know why Eastern races, particularly Syrians and Palestines, insist on pushing up the quilt and building columns and irregular-shaped pieces of wax between it and the top of the frames, about an inch high; it is not usually from want of room, although strong colonies do it most to perfection. Another (old) method of spacing frames, and at the same time diminish the circulation of cold air, is by pushing $\frac{\pi}{4} \times \frac{\pi}{6}$ fillet of deal between the side bars of frames.

Allow me, in conclusion, to congratulate the Editor on his announcement that the pages of the *Journal* are to be enlivened by the experiences in bee-keeping of so popular an author as Mrs. Reginald Bray.—John Edex,

St. Neuts.

SUNFLOWERS, POKER LILIES, FUCHSIAS, AND BEES.

[1351.] As notes on bees and flowers are interesting to all bee-keepers as well as naturalists, I offer a few that I have set down during the autumn that has just passed. What I record may be known to some of your readers, but I have not been able to find the facts in any book on bees that I have consulted.

1. Sunflowers.—My observation of these extended to about one hundred plants in my own garden. These were all in fine bloom for nearly two months, and while they were frequented by humble bees in crowds, it was very rarely that I saw a honey bee on one of the flower-heads. I am aware that this plant is put in the lists of bee-flowers, and extolled by some for the aid it affords the bees by yielding pollen late in the year. Now I have been watching the sunflower for several years in order to settle this point, and I have come to the conclusion that it is a 'delusion' for either honey or pollen, just as much as its fabulous habit of turning its face to the sun is a

groundless poetical legend.

2. Red-hot Poker Lily.—Never before have I seen so many and such fine spikes of the bright flowers of the Tritoma uvaria—red-hot poker lily—as were in my flower garden this season. The long dry summer seems to have agreed with them, for some plants produced as many as thirty-three huge 'pokers,' and they came in succession from the end of Angust to the close of October, and all that time, early and late, my bees were at them for both honey and pollen. This lily secretes large quantities of nectar, which my bees did not allow to go to waste. In former years I noticed that this plant was a great favourite with wasps; however, as I wage a ceaseless war against the 'yellow boys' they do not get leave to carry all before them on my glebe, and consequently few were observed this year on my Tritomas.

3. Fuchsia gracilis.—There is a hedge fifty yards long composed altogether of this common fuchsia in my garden, which bloomed profusely all September and October. It was a splendid sight with the Tritomas and Sunflowers in the foreground; and which, like the 'redhot pokers,' was haunted every fine day from morning to sunset by hundreds of my bees. I had often heard it said that honey bees would not touch a fuchsia, and I once was present at a discussion over a collection of beeflowers in a honey and bee exhibition as to the fuchsia being admissible in such. But now I am convinced that this graceful and beautiful plant is one of the best autumn flowers that can be cultivated for bees. There is no plant more easily and successfully grown than this Fuchsia gracilis—more so than F. globosa, while it is fully equal to the latter in being an ornament to the garden.—H. W. Lett, M.A., Aghaderg Glebe, Lough-brickland, Co. Down.

HOW TO DO IT.

[1352.] So, 'Mr. Sherborne,' you do not believe that one queen is able to produce bees to cover forty frames and yield 100 pounds of honey in a season! Well, there are many like you; and I know to try to convince a beekeeper (as you say you are of twenty years' standing) by force of argument is hopeless. I think the better way will be to tell you how to do it, so as you may see it

with your own eyes.

I. Wintering.—You say they will not cover five frames by November 1st. I could show you them crowded on the 8th and 9th inst. and nearly 3 inches between frames. They have not got bees added, and one of them yielded 150 pounds of honey the past season, but it is not always the hive that is strongest in November that is strongest in June. But that is not telling you how to do it. First leave in more frames than they can cover and have them stored with as much food as will serve them till June. Bees that have wellstored combs always rest best and conserve their strength. Have these frames set # inches apart and place a small piece of tablet on top of them to form a roadway from frame to frame. In case of severe weather cover with a leather-cloth quilt; place a sack or tuck over it, and a good chaff-cushion over all, and take out the doors and do not touch them again until the first week of April at the earliest. But during the winter months you had better see that you have a hive suitable; mine are made of four boards one inch thick, nailed together. $14\frac{1}{2} \times 16 \times 9$ inside measure, and hold eleven frames. I got these from the saw-mill cut to size at 2d, each; four of these make a hive; they have no plinths and set on top of floor-board. Floor-board is kept up $\frac{a}{5}$ to form a doorway, and this shuts up the door of next storey when it is put on bar-wood, which I get at 6d. per 100 feet, and that makes bars for three storeys.

2. Spring.—First good day in April examine all hives and cut open some honey down the side of centre frames, and set the frames up inch between and cover all up closely again. I am presuming that you have seen brood or eggs, and if so the less they are handled in April the better. The first week of May, this is an important time, as the work of the season commences with this month (I am writing from a district where the clover comes into bloom about the third week of June), this is the time to know if hives will be ready for the clover, as they may be said to have passed the lowest point and will rapidly The test is, that they have four frames full of brood and eggs at this time; if they are young combs and not pollen-clogged they will contain about 20,000 young, which will all be hatched in three weeks; but to assist them to cover more brood we at this time shift all frames up to \frac{1}{4} inch apart, cutting down any irregularities of the comb. To admit of this, hives will now need weekly attention, cutting open honey, feeding where stores are running short (I do this by pouring syrup into the combs from a vessel with a small spout, giving a good feed at a time), and adding frames as bees can cover until we have twelve and sometimes thirteen frames into a eleven-frame hive, which will be crowded with bees and brood by the time clover comes into bloom. If 'Sherborne' will try the foregoing plan he will be astonished at what bees can do. Of course if he uses metal ends he will have to throw them away.

3. Summer.—Place a sheet of perforated zinc on top of the frames flat and put on another storey with eleven frames with comb or foundation. Still keep on chaff-cushion, and when bees have fairly commenced to worst in second storey wedge up both hives at least \(\frac{1}{2} \) inch all round. When the top storey is commenced to seal, raise it up and put another in between; and when it has began to seal put another in beneath it; and if the season is at all good you will see bees from one queen cover forty-

five frames.—Jas. Saddler, Forfar,

ONE HUNDRED POUNDS PER HIVE.

[1353.] In reply to 1346 of last issue it may interest 'R. Sutton' to know that some time ago I had a stock of cross breed (Ligurian queen crossed with black drone) bees. There were twenty combs of Standard size, fourteen of which were filled with brood at one time, and I never saw two queens at one time in this stock. I thought it rather remarkable, and I mentioned the fact to Mr. C. N. Abbott, who paid me a visit, and that gentleman informed me that he once had himself a queen which covered sixteen frames of Standard size at the same time. I cannot say how many Standard frames the same time. I cannot say how many Standard frames the brood contained in fourteen combs would cover when hatched, but suppose there would be sufficient bees in such a hive to cover forty frames in warm weather.—

Thomas F. Ward, Highgate, November 11.

WHAT BEES CAN DO.

[1354.] I take this opportunity of thanking you for your great kindness in giving us so much useful and practical information. I am sure all bee-masters feel greatly obliged by your very interesting description of your visit to Canada and the States. Our cousins seem to do things on a very large scale in bee-keeping, but I was greatly surprised at the amount of honey per hive, for, setting aside a few cases where a large crop was obtained, I think we on this side of the Atlantic should take conrage in the fact that we are not to be crushed by a greater weight than we can produce ourselves. I quite anticipate many veterans in the craft will tell us of far greater things as regards production of honey. But what we want, Mr. Editor, to make the outlook brighter is, I think, better facilities for disposing of the production of the apiary.

I should be glad if we had more in the Journal from the pen of our fathers—those who were at the christening, and have watched over, tended, and cared for the bee-keeping interest, until it has grown up to this big youth who is able to stand his ground and show as good

a front as his big brothers over the water.

I should here like to give a few facts in connexion with my own experience, if not thought to partake too much of the American, Mr. Editor. I hope they may tend to convince some who are, like Thomas of old, very hard to believe. I must say I am greatly astonished to find that any one that had had twenty years' experience with bees could write such perfect nonsense about a number of queens in the same hive at the same time. Let him listen to the following and he not unbelieving. I have taken for the last seven years an average per hive of 112 lbs. of honey, one seventh of this was combhoney, for the entire apiary (which is considered a large one)

My hives have in summer not only forty frames, but forty-two, Woodbury size. These are filled with bees, and produce the above result, without the assistance of any other hive or queen, all by the middle of July, which closes my honey season, after which time the bees make up their stores (for I never use any syrup), and I stimulate with combs of sealed food taken from the hives when reducing the hives to eight combs for winter; this I do in September. I find it no gain to have a large number of bees in the fall, for I do just as well with six combs as with eight or more. The point is a good young queen. I requeen my apiary every two years, that is, half this, the other half next.

I can open his eyes a little wider by just giving him the result of two hives this year, without any assistance from any other hive. The first hive was on forty-two frames, Woodbnry size, and had a last year's queen. It gave me 217 lbs. of extracted honey and four full combs when reduced for winter. (I believe this hive had a bushel

of bees in it at one time.) The other hive was worked for comb-honey solely on Simmins' principle. It was on sixteen frames, which I reduced to twelve, then put on the sections. This hive gave me 194 lbs. finished fit for market, and gave me three bars weighing 15 lbs. when I reduced them for winter. I would say here this hive never gave any sign of swarming. It was well shaded by a large tree, and I gave it plenty of room with crates.

I should like to give my experience with mixing bees. First, if the bees are standing near each other, push a piece of camphor in each flight-hole over night; next evening uncover the hives, lift the combs with bees from one hive and place them in the one you wish to retain, taking away all spare combs, cover up, the thing is done and not a bee lost. If you are afraid of bees you can use a little smoke, but this I seldom do in my

apiary.

To move and mix bees, put a piece of camphor in each flight-hole over night, next afternoon shake all the bees from the combs into their respective hives, cover up for a few minutes, set one of the hives where you wish it to stand; now put into it all the combs containing brood, and as many more as you wish, shake the bees from the other hive on to a board or cloth in front of the selected hive; there will not be a bee lost by fighting or by going back to the old stands any more than if they had been moved when swarmed.

This plan is very much better than drenching the bees with scented syrup, to be half lost when cold follows; and then it saves the shifting the hives a few feet every day, and may be practised any time when bees can fly.—

AN OLD BEE-MASTER.

'IN THE HUT.'—'X-TRACTOR' AND 'AMATEUR EXPERT.'

[1355.] Kindly allow me a little space in reply to your correspondents in the B.B.J. of the 10th inst., page 495, who write under the above noms-de-plume. Though the controversy does not tend to edification, nevertheless, I will not lay myself open to the charge of discourtesy by not replying even to 'X-Tractor.' Anonymous correspondents ought to be the last to request family histories and relationships from those who always append their names to contributions. If I do write decent English madorned by Shakspearian scraps, my style, I hope, savoureth not that of United Ireland. The B.B.J. is not a humorous paper, and does not go in for jokes, as 'X-Tractor' would seem to think, although his most serious communications would raise a smile on the face of an Egyptian mummy who made bee-culture his hobby four thousand years ago. As to the genealogies of the McNally family 'are they not written in the book of Jesher?' a valuable chronicle of reference, now supposed to be lost. 'X-Tractor' desired information from some courteous correspondent, ignoring my qualifications in that way, also forgetting his own deficiencies in the

Par exemple, I beg to refer your readers to page 483 of the B.B.J., misquoted by 'X-Tractor,' to which the signature is not Mr. W. McNally as he says, but that of another person. This misquotation is of a piece with his habitnal inaccuracy, intentional or otherwise. When he attempts writing again let him bear in mind that I have never written anything in these columns, or in any

other journal, against the N. of Ireland Show.

Mr. Amateur Expert, a word in your ear. You are very kind and chivalrous coming to the resone of your brother in distress, 'X-Tractor.' Your aid, though perhaps much needed, has been of little avail. The clan of McNally, jointly and severally, are individually responsible each for his own acts and sayings, and not in a corporate capacity. You need not grudge us our hard-

earned annual honours, since you have a weekly puffing all to yourself, from your confrère 'X-Tractor,' to be returned in kind.

Without trespassing further on your space, just a word of advice: when next you and 'X-Tractor' visit the Wild West to revel in the eongenial society of the Red Indians, be sure to provide yourselves with an ample supply of Apifuge and Fumigators; perhaps you will meet some 'cute Scotchman who might invest. But, 'A. E.,' I have hitherto admired your contributions not a little, though you have, unfortunately, lowered yourself in my estimation by your recent communication, which was altogether uncalled for.—WILLIAM MCNALLY, Glenluce, Scotland.

[We agree with our correspondent that 'this controversy does not tend to edification,' and therefore we consider it desirable it should now be closed.—Ed.]

A DESIDERATUM.

[.356.] I think it would be a great accommodation and advantage to many bee-keepers who occasionally run up to town if there were a sort of museum or show-room in London, where they could see all sorts of appliances and inventions new and old by many makers, especially if the person in charge was qualified to explain and give information and perhaps take orders. I see many advertisements and hear of many things which if I had an opportunity of seeing I should probably procure.

If properly managed I think it would pay well, and I am sure it would be much to the advantage of makers and inventors of really good things. Again there is a certain amount of (instructive) bee-literature. I for one would willingly pay liberally to see some of these books, though I do not care to buy many of them. If the B.B.K.A. could see their way to establish something of this sort I think they would find it a considerable element of attraction and stability. Possibly, Mr. Editer, you may think the hint worth supporting.—Knownothing.

[A library of books appertaining to bees and beekeeping has been established by the B.B.K.A., from which members of the Association have the privilege of borrowing, on application to the Librarian.—Ed.]

PREVENTING ROBBING.

[1357.] In a late issue of 'Useful Hints' carbolic powder is mentioned as a preventive of robbing. A much simpler plan is one recommended by the same writer some time ago, and which I have always found successful, viz., placing a square sheet of glass in front of the entrance, resting on the alighting-board. I have used it many times, and it has always stopped robbing at once.—L. B. BIRKETT, Westbourne, Evesworth.

BEES AND MANURE-HEAPS.

- 'And them a' doctor's saws and whittles Of a' dimensions, shapes, and metals, A' kinds o' boxes, mugs, and bottles, He's sure to hae: Their Latin names as fast he rattles As A. B. C.
- *Calces o' fossils, earths, and trees; True salmarinum o' the seas; The farima of beans and peas; He has't in plenty; Aquafortis, what ye please He can content ye.
- 'Foreby some new, uncommon weapons, Urinus spiritus of capons; Or mite-horn shavings, tilings, scrapings, Distill'd per se; Salalkali o' midge-tail clippings And mony mae,'—Burns.

[1358.] Oh, dear! more groping among musty chemical works is my lot. Well, I suppose it must be done, that matters may be put in a more ship-

shape condition, and errors corrected between me and thee. 'Naquet,' 'Attfield,' The Year Book of Pharmacy, all are here, and let me wade into their mysteries as friend Grimshaw has led the way in his almost exhaustive compilation of authorities.

Now, in the first place, it is of no consequence, for the sake of argument, what acid the bees are in search of, be it urie or hippurie, it matters not which. Mr. G. ap-peared to have confounded them. His words (letter 1316, 20th Oct.) are 'Uric acid might be a better term, seeing that uric is found in animal and hippuric in human liquid excreta.' I think it no unfair deduction that Mr. G. wrote this with the idea of correcting what he thought was a mistake of mine in stating urie to be the acid of human and hippuric of animal. Now he says he merely suggested that urie was the acid the bees were in search of; I do not see the suggestion, I merely see the statement that I have misplaced the acids, to which I know he won't mind me replying-I haven't. Mr. G. knows that it is possible to obtain from a substance, by chemical means, a body that substance in its normal condition does not contain. Hippuric acid is convertible into beuzoic acid; in fact, it is the source of much of the acid in the market. But again I would remind Mr. G. of his own words. 'Hippuric acid will be secreted by all animals that have benzoic acid given them.' This naturally provoked the question, 'Upon what food can an animal be fed in order that benzoic acid may be taken into its system with same, in quantities sufficient to form hippuric acid, which is found in every manure-heap frequented by a few bees?' The italics I now place that the question may be more fully understood; and my suggestion that in Yorkshire they may be fed on gum-benjamin.

It now appears that 'where horses are worked hard,' i.e., treated with a good allowance of stick, 'they secrete benzoic instead of hippurie,' possibly since the feverish state and raised temperature of the bladder in that ease might produce the oxidation, the statement is a quo-tation from Naquet, *Principles of Chemistry*, no other statement by any of the big-wigs of chemistry bearing upon the question has come my way; but all things are possible to him that believeth, and henceforth I will add a sufficient ash cudgel to my stock of chemical re-agents. I plead guilty to the suggestion that I imagined Mr. G. to have mistaken essence of mirbane, or, as it was called when it first appeared, artificial essence of bitter almonds, by reason of its true name, nitro-benzol, being in its last component benzol like unto benzoin. By-the-by, Mr. G. says he never heard of that name, and calls it nitro-benzene; let him turn to his Attfield at page 404, he will find 'benzol, the liquor obtained from coal-tar;' again, 'benzol by the action of strong nitric acid yields nitro-benzol C_6 H_5 (NO.2) a liquid termed from its odour artificial essence of bitter almonds, or essence of mirbane. The odour of this essence, however, is not exactly like bitter almonds, and its composition very different.' Muspratt, page 285, gives the various names for the body known as benzol, viz., benzene, benzine, phene bicarbide of hydrogen. Fownes, page 487, ealls it nitro-benzol. Year-book of Tharmacy, 1885, page 97, calls it benzol, but Mr. G. says he never heard of it under that name. I was led into this mistake, thinking that Mr. G. had confounded nitrobenzol and the benzoin products, by the loose way in which he used the term benzoic, vide his letter:-'benzoic' (?) 'the ancient product of the fragrant aromatic gum-benzoic' (?), 'benzoic' (?) 'from which is prepared the delightful essence of bitter almonds, so much used for flavouring '-in one line referring to benzoic acid, in the next line benzoic hydride, or aldehyde.

Benzoic acid HC₇ H₅ O₃, can be obtained from many diverse substances—gum-benjamin or hippunic acid in urine of the herbivora; it can be obtained from hydride

of benzoyl C₇ H₅ OII—that is, oil of hitter almonds, but it is obviously impossible to obtain oil of bitter ahuonds from benzoic acid, therefore Mr. G. should have used more care in the construction of his sentence, for he certainly implies that oil of bitter almonds or hydride of benzoyl can be obtained from benzoic acid. In his reply he says, 'we have also henzoic (sic) converted by the chemist into its aldehyde.' What does he mean? This is a repetition of the original confusion, and only tends to make the confusion worse. In conclusion, we would recommend Mr. G. to carefully weigh his words next time he writes on chemistry, and then the fog that appears to wrap his chemical communications will disappear and our poor knowledge can discern his meaning, if our brain fails to comprehend his reasoning,-W. B.

[We consider that the above subject has now been sufficiently ventilated in our pages.--Ed.]

PRICE OF HONEY.

[1359.] Being a regular reader of the Journal, I have been much interested, and sometimes amused, to read some articles respecting the price of honey. I for one am inclined to echo the sentiments of one correspondent, when he says in effect that 'if 9d. per lb. cannot be obtained it is no use as a matter of business."

Personally I have experienced no difficulty in getting 9d. per lb. wholesale and 1s. retail (customers finding their own jars, &c.) i.e., for good extracted honey. I have sold a fair quantity this year of other friends' as well as my own, and in not a single instance have I received less than 9d. per lb. for it. I know this cannot be done without some effort being made, but what business can be carried on without effort? There seems to be in some people a kind of 'human drone,' who expect all their work to be done by others, and then grumble because they cannot get on. If ever we come across these, we say to their faces, 'Serve you right, yon should try.

Now, I took up the suggestion given in the Journal a few weeks since, and have sold the greater portion of the honey I have had to neighbours and friends. The time for convincing people that honey is a valuable article to keep in the house is, to a large extent, over, and I have only to ask many to take a few pounds before getting a ready response. If every bee-keeper would work in this way there would be less running to print with the gramble about County Associations selling their honey. There is a considerable difficulty, I admit, with bee-keepers who live in 'ont-of-the-way' places; but as a rule they have some friend or friends in or near large and populons neighbourhoods, who, for a trifle as profit, would sell large quantities. I think on each article sent out containing honey a label of attractive appearance, with the name and address of produce neatly printed with rubber stamp, should be seen.

Mr. 'Useful Hints' in a previous Journal has made a very apt remark when he says 'that it is a great mistake to force honey upon the market all in one three months of the year.' I prefer to keep it, if possible, all the year round, so that I shall not have to disappoint any who ask for it at any time. People, as a rule, will rather buy from the producer than from the chemist, and the only thing which needs to be done is to circulate the faet well that you have pure honey for sale, and the difficulty of selling it is triffing.—Chas. Howes, Aylestone Park, Leicester.

HOW TO SECURE STRAIGHT COMBS.

[1360.] This is the basis of successful bee-culture, for it is impossible to handle the bees unless the combs are hanging perfectly straight in the frames, so as to be easily taken out separately.

The plan formerly in use, and indicated by Langstroth, was a bevel on the lower side of the top-bar. bevel, made in the shape of a V, was sometimes made very small, and usually succeeded tolerably. Yet it happened very often that the bees would join the comb of one frame to that of another, and when they were full of honey it was impossible to separate them without cutting the comb and causing a great deal of honey to run out, drowning bees and sometimes attracting robbers. The invention of comb foundation has finally and

for ever put an end to erooked combs wherever it is Comb foundation forces them to build combs which hang in the frames 'as straight as a board.' Indeed, it has even one advantage over natural comb, it is more regular. This was said very truly by one of our leading

bee-keepers at an Eastern convention.

There are, however, some attentions necessary in order to have the full benefit of the comb foundation in obtaining straight combs. For instance, the hives should be perfectly level from side to side, so that the foundation will not haug out of the frame, but will remain perpendicular in it until the bees have it finished and well fastened to the sides. It should also be well fastened to the centre of the top-bar. This is done by pressing the edge of it down on the under side of the bar with a knife while the wax is warm enough to be quite pliable.

When foundation is given to a strong natural swarm, it should be given sparingly, not more than two or three inches deep in each frame, for if a full sheet be given, the large numbers of the bees that will cluster on it will cause it to sag. Full sheets can be given safely to colonies which have been divided, or even to full colonies in early spring before they have attained full strength.

But in order to secure straight combs it is not abso-Intely necessary to give more than a small strip of foundation on each frame running along the full length of the frame. With such strips on each frame, and hives set perpendicular from side to side, straight combs will be secured every time. It is, however, advisable to set the hive somewhat slanting forward. This will cause the water from rain or moisture to run out of the hive, and will not prevent the combs from keeping perpendicular, since the slope will be in the length of the frames, and not across them.—C. P. DADANT, (Western Apiculturist.)

A FULL COLONY OF B'S.

B-think ere you stumble, for what may B-fall, B truthful to self, and B faithful to all;

B watchful, B ready, B open, B frank, B manly to all men, whate'er B their rank.

B calm, B retiring, B ne'er led astray, B grateful, B cautious of those who B-tray.

B careful, but yet B sure to B-stow; B temperate, B steadfast, to anger B slow.

B earnest, B truthful, B firm and B fair, B meek, and of all mis-B-haviour B-ware.

B pleasant, B patient, B fervent to all, B best if you can; but B humble withal.

B just and B generous, B honest, B wise, B mindful of time, and B certain it flies.

B hopeful, B cheerful, B happy, B kind, B busy of body, B modest of mind.

B brave, and B-ware of the sins that B-set,

B sure that no sin shall another B-get. B prudent, B liberal; of order B fond, Buy less than you need, B fore buying B-yond.

B prompt and B dutiful, still B polite,

B reverent, B quiet, B sure and B right.
B thoughtful, B thankful, whate'er may B-tide;

B trustful, B joyful, B cleanly B-side. B tender, B loving, B good and B-nign,

B-loved shalt thou B, and all else B thine. American Bee Journal.

Echoes from the Bibes.

Llangranog, Cardiganshire - I only commenced beekeeping this year, and this is my result:-I bought a skep of bees in April and transferred them into a bar-frame, tiered them in June, and have taken 23 lbs. of honey; they were a weak lot, but they have almost paid for themselves already. This is a poor honey district, as we are near the sea. All have skeps, not bar-frame hives, in this part, and the ordinary average of hency which those who have killed bees have had is under 20 lbs, per skep. Some have not been able to take honey at all this year, and many swarms were lost in the hot weather.—Cranogwen Rees.

Carno, Montgomeryshire.-I commenced this year with six bar-frame hives, made two artificial swarms in June. sold one hive, and bought a hive of Carniolan bees, which made my total number eight to commence the honey season. From them I have had at least 240 lbs, of extracted honey and thirty-six sections, also one swarm and 3 lbs. of wax. The artificial swarms and the stocks from which they were taken gave but little honey, but the Carniolans and two other hives gave the most of the quantity.-M. E. Marsu.

NOTICES TO CORRESPONDENTS & INQUIRERS.

Letters or queries asking for addresses of manufacturers or correspondents, or where appliances can be purchased, or replies giving such information, can only be inserted as advertisements. The space devoted to letters, queries, and replies, is meant for the general good of beckeepers, and not for advertisements. We wish our Correspondents to bear in mind that, as it is necessary for us to go to press in advance of the date of issue, queries cannot always be replied to in the issue immediately following the receipt of their communication.

All queries forwarded will be attended to, and those only of personal nterest will be answered in this column. Letters or queries asking for addresses of manufacturers or correspon.

M. E. Marsh.—Hive with Twenty Frames.—Under any circumstances, remove frames from upper box and place quilt on bottom frames, putting a chaff-cushion over that, taking care to press the eushion well down into the corners. It would be preferable to reduce the frames in the lower box to eight, or perhaps six, if the stock is weak, should a favourable day occur. If you have any doubts as to the bees having plenty of stores, place some candy on the frames before covering up. Add half an ounce of peaflour for every pound of sugar after the candy is removed from the fire, thus supplying nitrogenous or tissue-forming matter, of which sugar alone is very deficient.

H. W. P. - 1. Extractor conveying Foul Brood. - Undoubtedly the indiscriminate use of an extractor in a district where foul brood is prevalent must be very dangerous unless extreme care is exercised in most scrupulously scalding every portion of the extractor; adding some of Calvert's carbolic acid to the first hot water used would be advisable. Use several rinsing waters. 2. Old Honey for Spring Feeding.—The honey might be used as you suggest, but syrup is more economical, and is less likely to start robbing than honey. Why not make mead with the old honey, or use it in currant cakes instead of sugar?

Miss Cornwell.—Natural Swarm placed on Stand of Parent Stock: Parent Stock removed to a New Location.—This plan is recommended on the grounds that the parent stock thereby loses the greater part of its flying becs, who, going to the old stand, join the swarm, while the parent stock-now hatching out young queens-will not be sufficiently populous to throw a cast, and will, therefore, only allow one queen to hatch. Caution.—The parent stock should be fed gently for a week or ten days to compensate for the loss of flying bees,-recommended on p. 222 of B.B.J. for May 26th, 1887; by Hedden on p. 24 of Success in Bee-culture; and other authorities.

Bert.—1. Two Hundred and Thirty Pounds from one Hive. This amount was produced in Mid Sussex in the year 1885. 2. The frame used was the Standard frame of the B. B. K.A. 3. Both section and extracted, the latter in the greater propertion.

EAST LIMERICK.—Honey.—We are of opinion that the honey partakes of the hawthern, and that it is pure honey uncontaminated with honey-dew. The bees working at the same time on the laurels has rendered the honey

dark, but it is excellent in flavour; and if appearance were not so much a matter of consideration, it would would rank as first-class, but there is no doubt that its colour depreciates its market value.

H. Schwartz.—1. Bees short of Food at the beginning of the Year.—An unusual number of dead bees at the entrance of a hive is not a sign of starvation only. Bees short of food get too weak and sluggish to fly so frequently as strong stocks. In our apiary (fourteen hives) we have noticed that those stocks that have kept on breeding latest are those who face the worst weather for a fly, and that water seems their principal quest, which they of course required for the grubs. Many never return, and this is one of the disadvantages of late breeding. Should any of our stocks not take full advantage of a fine day in January for a flight we should expect their store of food was failing if no disease was affecting them, but an examination can be so easily and speedily made. 2. Queenless Stock placed on empty Combs building Queen-cells. — We have an abnormal queen-cell sealed, close on two inches in length, which, with several ordinary besides rudimentary ones, was built by a queenless, eggless, and grubless stock last spring. There is a tradition that bees will purloin eggs from another stock when in this forlorn condition. It seems to be a sine quâ non with bees to build a queen-cell as soon as they miss their queen. In your case they might probably be some considerable time longer before they found out they had nothing from which they could raise a queen. Then comes the plague of the fertile worker. 3. Flat-bottomed Foundation for Supers-why made so?-Flat-bottomed rolls can be made cheaper than natural-based. Should bees neglect to draw out the base it leaves the septum thinner than would be the case with natural-based. 4. Can a Swarm be safely left till evening if shaded?— No, you might not lose it, but it would be very risky. Swarms should always be hived at once. The swarm may be sometimes induced to remain clustered for a short time longer by gently spraying it with water from a syringe. The longer the bees are left the more likely are they to be led off as a vagrant swarm by their scouts.

Sherborne, Dorset .- We are of opinion that our correspendent will find his questions answered in the letters 'How to do it,' 'What bees can do,' and 'One hundred pounds per hive,' in our present issue.

J. W.—Queen-rearing.—This subject has received during the past season a considerable amount of attention. our correspondent will refer to pp. 41, 210, 281, 301, 313, 315, he will find the information he is in quest of.

[PUBLISHED WEEKLY.]

Editorial, Aotices, &c.

BRITISH BEE-KEEPERS ASSOCIATION.

In conformity with the rules as amended at the last Annual General Meeting, every candidate for the Committee must be nominated by two members of the Association; the nomination paper must also bear the signature of the nominee giving his consent to be so nominated.

Forms for nominating members will be ready in a few days. The last day for receiving nominations will be Saturday, December 31st. The retiring members of the Committee are Mr. T. W. Cowan, Hon, and Rev. H. Bligh, Rev. Dr. Bartrum, Captain Bush, Captain Campbell, W. H. Dunman, J. M. Hooker, H. Jonas, Rev. F. G. Jenyns, Rev. Geo. Oddie, Rev. G. Raynor, Rev. F. S. Sclater, Rev. F. T. Scott, Rev. J. L. Seager, and Dr. Walker.

'KEEP YOUR COLONIES STRONG.'

It has been our duty frequently to remind our readers of the absolute necessity of systematically carrying out this motto, if success is to be attained in the production of surplus honey. Applicable as this motto undoubtedly is to bee-keeping, it is equally so to our Associations, which occupy the same relation to the bee-keeper that the stock does to the bee. Union is strength, and in localities where energetic and advanced bee-keepers combine to form a District Association it is surprising to see the immense amount of good that can be done in the course of a season or two, by showing their less advanced neighbours the latest methods and most successful systems of acquiring a good surplus, even to the extent of 'honey by the hundredweight,' The common stand-point of our Associations is so entirely philanthropic that any improved system should, if the objects of the B. B. K. A. are to be attained, become common property. We are aware of the natural tendencies of Englishmen to acquire 'vested interests,' but the very raison d'être of our Society is combination for the improvement of bee-keeping. This being the case, it behoves us to consider what means may be adopted to increase the influence and usefulness of Associations. In doing so we propose to go beyond the County, and deal more especially with the District organizations.

We fear that in many cases the 'District' has been chiefly the medium for conveying the members' annual subscription to the County Secretary, and, perhaps, assisting to promote a local show of honey, &c. Now, good as shows have been, and always will be, as a means of arousing a healthy interest in bee-keeping, it is clear that the efforts of our 'Districts' must not be allowed to end there, or little permanent good will accrue; certainly not sufficient to 'keep the colonies strong.' 'Packing for winter' should be attended to by lectures, which in the majority of cases should be thoroughly plain and practical; by friendly meetings at the homes of different bee-keepers in succession, which may either partake of the informal character of a conversazione, or the more formal Mutual Improvement Society, where scientific subjects could be discussed, and elucidated by the aid of a microscope. This care would enable the colony to come out strong in the spring, when, by judicious 'feeding' in the way of itineraries by the more expert, much good could be done by hints and assistance.

We consider it incumbent on us at this point to call especial attention to the practice of many members who kindly give assistance to their neighbours without securing them as members. In cases where such non-members persistently decline to join the Association, it is a question to what extent further assistance should be rendered. The fees are so low as to be well within the reach of all, and seeing that so much has already been done by combination it behaves every member to do his best to secure fresh members, and so enable his Association to attain that success which their philanthropic aims clearly entitle them to hope for. We would here mention a plan, adopted by the Middlesex B. K. A., of asking every member to give the County Secretary a list of any bee-keepers in his neighbourhood who have not yet become members. This should result in a considerable increase during the coming season.

The idea has been recently mooted that County Secretaries should undertake the sale of the surplus honey produced in their county, which the members themselves may experience a difficulty in selling. This is an untenable proposition for many reasons. In the first place, it would entail freightage from the producer to the Secretary, which in the majority of cases would more than demolish any extra profit

which this over-honeyed official could possibly secure. One fact must be patent to all, that if producers cannot dispose of their honey locally at a fair price, they can never expect to get any one to act as County Secretary in an honorary position who will be prepared to spend a considerable portion of his time in soliciting orders, packing honey in fulfilment of same, keeping rather bulky accounts, and remitting proceeds to the various bee-keepers. Our County Secretaries are worthy of all praise for their unwearying exertions on behalf of bee-keeping, but to ask them to first teach us how to produce honey, and then to sell it for us afterwards-all gratis—shows a want of self-reliance that no beckeeper should ever exhibit.

Doubtless cases may occur where the District Secretary would be able to considerably assist the members in his district if he were duly apprised of unsold honey and bees, and also of honey and bees wanted. Frequently a successful bee-keeper develops a local connexion, enabling him to dispose of his surplus at a fair price, when, suddenly, he finds he has not half his usual quantity to sell. Two alternatives are before him, either to disappoint his customers, or buy. This is the opportunity when much time might be saved if he could obtain information from his District Secretary, enabling him to go direct to those who had honey in excess of their requirements, but did not care to look about for eustomers. Great mutual advantage would be attained by such an arrangement. The same plan as regards swarms and bee appliances would be equally useful.

In conclusion, we would recommend every member, while relying as far as possible on his own efforts, to be ever willing to listen to the experience of others, and at the same time quite ready to assist his neighbours; then, and then only, shall we be able to 'keep our colonies strong.'

USEFUL HINTS.

Weather. - Severe frosts, with snowstorms, are visiting us betimes; hence, according to the old saying — When ice before Christmas bears a goose, it never bears a duck afterwards'-we ought to expect a mild winter. Severe or mild we care not, if only we may escape such a fog as we experienced in the great City on Wednesday last. Unable to discover our whereabouts even in the now well-known and notorious Trafalgar Square, we were obliged to ask a guardian of the peace, 'Where are we?' Truly, it was with no small degree of pleasure that we said adien to our friends the Kapnodytes, and once again breathed the pure and invigorating country air.

SHADING ENTRANCES is necessary when snow lies on the ground in bright sunny weather. For this purpose a stout board should be placed in front of the entrance to prevent the bees from being enticed forth to perish in the snow. Hives should be kept clear of snow, lest by alternate thawing and freezing cold and dampness injure the bees. Let entrances also be kept open and free from snow, dead bees, and refuse, by the use occasionally of a bent wire. These small precautions conduce in no small degree to the health of our colonies.

Requisites for Wintering may be summed up under four heads:—(1.) A sufficiently large population to cover about eight standard frames at a temperature

of 60° Fahr. To produce this, breeding should not be continued later than the end of September, and may be stimulated up to that time by feeding. (2.) The space occupied by the bees must not be greater than required, whether they cover eight or ten frames, and these frames should be enclosed between stout, close-fitting divisionboards: a space of $1\frac{3}{4}$ inches from centre to centre of the frames, with winter passages in every comb, is desirable. (3.) Sufficient covering winter quilts. Whether enamel cloth or pervious woollen material be placed next the frames, it must be covered by three or four layers of soft carpet, capped either by chaff-tray or straw-cover. Abundance of bottom ventilation should be provided, especially if the frames are ranged on the 'warm system; and an entrance, extending across the entire front of the hive, and covered with perforated zinc-slides - allowing a small passage-way for the bees—will not be too large; also a space of from two to four inches beneath the frames is decidedly advantageous by keeping the hive dry and the bees healthy and vigorous. (4.) A sufficient quantity of well-ripened scaled food, preferably honey gathered in the early part of the season. But those apiarists who have extracted up to the brood-nest, and fed their bees on syrup made of granulated cane sugar according to the prescribed receipt, have no cause for anxiety if a sufficient quantity of well-sealed food has been provided, although we decidedly prefer natural stores. From 20 to 25 lbs is enough to carry a strong colony through the winter.

It is best that the sealed food should be spread over the whole of the frames, except, perhaps, that the two outside ones may be solid slabs of honey. If winter-passages have not been provided through the combs, strips of wood a half-inch thick and one inch wide may be laid across the tops of the frames, about two inches apart, to allow of the bees passing from frame to frame; but care must be taken to make the outside square complete by similar strips, to prevent the escape of heat and bees, and to cause the quilts to lie flat on the whole. As regards late breeding being necessary to provide bees for spring work, we have repeatedly proved that August and September-hatched bees are available for work up to the following April and May. It is only during severe summer labours that any industrious protégées wear themselves out in the short period of six weeks. It is not meant that these winter preparations should be made now. All should have been completed by the end of October, at latest, and now that winter has made its appearance in earnest, even if no preparations at all have been made, it is best to leave the bees entirely alone, in the state in which nature only has taught them to make provision for the winter's rest. In cases of starvation, of course, candy must be pushed under the quilts, as

advised in our last,

OUR TRANSATLANTIC BRETHREN.-In some rather caustic remarks in the 'Am.' Bee Journal, by Dr. Mason, on the subject of our late Canadian visitors pushing their sale of 'Linden honey' in the English market, at the expense of the States' so-called 'Basswood honey,' we notice the following characteristic remarks amongst other choice specimens, such as 'Wily Canadians,' Modest Englishmen, &c.:—'Is it not about time some one just slightly pricked some of the egotistical and bombastic bubbles that have been sent up by some of our cousins across the border, and other relatives on the other side of the pond.' In a note appended to Dr. Mason's letter, the editor of the A.B.J. quotes from the Lord Chief Justice of Manitoba, who is an ardent lover of bees, to the following effect:—'I think the white-clover and basswood honey is the best. There is in all the accounts published a good deal of brag, for which due allowance must be made. I find that bee-keepers over-estimate. The occupation is of an exciting character which may account for it.' Do these allegations apply to English as well as to American bee-keepers? The Lord Chief

Justice—who, we are told, is 'one of Canada's best and brightest sons'—goes on to remark on the average production of honey in Canada, which he estimates at 75 lbs. of extracted per colony, and says that—'40 lbs. per colony of comb-honey is a fair average.' What would his lordship say to the statements contained in the letter (1354) entitled, 'What Bees can do,' of our correspondent 'An Old Bee-master?' With the splendid bee-flora—as regards both quantity and quality—described by Mr. Cowan as existing in Canada and the States, are we 'modest Englishmen' to conclude that our average exceeds theirs?

While on the subject of choice diction and epithets, as applied to opponents, a few 'Hints' may prove 'nseful' to all of us. In newspaper correspondence the golden rule of doing to others as we would they should do unto us, is almost entirely ignored, except in the higher-class publications. Amongst these we are all anxious that our Journal should maintain its position. A debater, whether in print or viva voce, should be master of himself, even when assailed by insulting attacks, always patient, self-controlled, vigilant, ready, courageous, and fearless, and his temper should be faultless. A man who can justly lay claim to these qualities need fear no opponent. Always kind and courteous he will return good for evil. Alas, how few of us can reach so high a standard! Truth, and not victory over an autagonist, should ever be our one great object; and, when convinced that we are wrong, let us have sufficient courage to acknowledge our error. But, as we descend from our preaching stool, we can fancy that we hear some one exclaim, 'Physician, heal thyself,' and our reply is, 'Act up to our preaching and not to our practice—take the will for the deed, for humanum est errare.' Then again, as regards the conduct of a 'Journal,' especially our own, we hold that a 'Bee Journal' should not devote too much space to technicalities,—should be eminently practical—should contain simple illustrations of the appliances of our art, adapted to the edification of the learned and the ignorant—should abound in useful hints for the million, and its pages should be interspersed with short scientific articles for the more learned and educated of its readers. Interesting and useful queries, with their answers by practical and experienced apiarists, should be another and most useful feature of 'our Journal,' while to more simple queries the answers alone should be given. Recondite discussions on scientific subjects, with embittered correspondence on matters of little or no importance, should be altogether eschewed. And now our parable has been taken up and ended, and it will be a long time before we again trouble our readers with our views on these or kindred subjects. Far be from us the intention of casting reflections on the conduct of 'our Journal' by its esteemed Editor, sub-editor, or more prominent contributors; our only object being to point the direction in which lies, as it appears to us, the most useful course for advancing amongst all classes the great industry of apiculture which we all have at heart.

Since we are sending out to that Greater Britain, upon which the sun is said never to set, our trained and certificated experts, and since our antipodean colonies are running a very close race with the mother country in apiculture and its literature, surely we ought to set them an example of what a 'Bee Journal' ought to be.

PLANTING FOR SHELTER should now be carried on in

PLANTING FOR SHELTER should now be carried on in open weather. The Portugal laurels, laurustinus, common laurel, and other evergreen shrubs, form an excellent shelter for hives when planted on the north, north-east, and north-west sides of an apiary, and are easily kept within bounds by the use of the shears, forming also a receptacle for natural swarms, and supplying forage for the bees. For the latter purpose, the deciduous small trees meseroon and ribes are excellent. Bulbs of snowdrops and crocuses should be planted without delay. We

have a long row of the *Echinops sphærocephalus* (Globe thistle) raised from seed, promising abundance of bloom for another season. During last summer *Echinops ritro* was a great favourite with our bees.

Frames with Divided Top-Bars are said to be weaker than others, but are they really so with the addition of a couple of French nails, or small screws, through the bars after wired foundation has been inserted? We think not. At least, after some experience we have not found them so. Indeed, with the same substance as undivided bars, and with Carr's ends, we have found them equally strong.

FOUNDATION, HIVES, FRAMES, AND SECTIONS, will soon be in request; it therefore behaves supply-dealers to complete their arrangements for supplying these, whether new or old inventions, in quantity. Englishmade wired foundation is, we consider, a great desideratum; and although we are not given to prophesying, we cannot but hazard an opinion that the first English firm which produces in quantity first-class wired foundation will have gone far towards making its fortune.

And now we conclude with an easy problem for the solution of our junior readers, albeit we have known individual cases of elders of our fraternity unable to solve it. Will our editor permit practical solutions to appear in the Journal? If he consents, we shall have pleasure in offering a modern frame-hive as a prize for the best solution in verse. Here it is:—'If six tomtits kill six bees in six minutes, how many tomtits will kill one hundred bees in fifty minutes?'

[We shall be pleased if young bee-keepers would take advantage of the above kind offer, and so exercise their minds in this which is called the dull season of the year. In a subsequent note, the compiler of 'Useful Hints' states that the candidates should not be above sixteen years of age.—Ed.]

Selected Query.

[2.]—Which is the best, cheapest, and quickest way of getting a quantity of combs built out for use in extracting? Should starters be given, or full sheets of foundation?

This very much depends upon the time that the honeyflow or flows take place in any particular district. Where there are two separate harvests, the intermediate space between these seasons is a very good time to get these combs built; but where there is only one flow and the combs are desired to be used in the current season, during May is the most suitable time. This should be done in the following manner: - When the colony has been brought by stimulation to the strength of covering eleven frames, either one or two frames of foundation should be placed in the brood-nest, and a diaphragm of excluderzinc slipped in between the two outermost ones—if there is any brood in them—and the other frames, gently feeding at the same time. When the last two frames are free from brood they can be removed. I find it a disadvantage to impose too much comb-building upon a colony when a good honey yield is desired, so have rarely taken more than three combs from one colony during the season with the exception where I have run a colony expressly for comb-building. I have then run this colony in the same manner as above advised, only keeping on with it right through the season with shallow frames. I have them built standard size and then cut this out and fit into shallow frames. Whole sheets of foundation should be used wired into the frame - the combs are a deal tougher.—W. B. Webster.

The best and cheapest way of getting a quantity of spare combs ready for extracting. In autumn select a

few hives for building out spare combs, place on each a rapid autumn feeder, give frames with full sheets of foundation, allow the bees to fix the foundation in frames all round before feeding too rapid. When well attached feed copiously with syrup. As the syrup-fed frames get filled and sealed, these may be exchanged with frames of honey from other hives. While in turn the honey can be extracted from the frames and returned to the bees to clean, after which they can be laid by for next season. In laying the frames by I have rafters fitted in my honey-house overhead and spaced so as the frames will hang in position — they are always in view, and ready when wanted. — WM. McNALLY, Glenluce, Scotland.

The best, cheapest, and quickest way of getting a quantity of combs built for use in extracting, is to give a strong stock of bees frames filled with full-sheets of foundation, and then feed the bees with sngar syrup for them to secrete the wax required. By this means a very great number of combs can be made in a very short time. -William Carr, Newton Heath Apiary.

For this purpose use full sheets of foundation—one or two at a time in the centre of brood-nest while building up in spring: uncap the stores of onter combs, place them behind division-boards, and remove as emptied to be reserved for extracting. Where fewer combs are required, or the apiarist wishes to renew a portion of his surplus combs yearly, a cheaper plan is that of using starters only, no more than a quarter-inch in depth. Feed carefully in either case. Several other methods require more space than can be given to describe them here.—Samuel Simmins.

Full sheets of foundation placed in very strong stocks just before swarming.—G. J. Buller.

By lifting a frame of worker broad from the centre of a strong colony, replacing such with a frame you started only. Place your frame of brood in the centre of a storified body over the colony, adding on either side of brood a frame started with full-sheet foundation; these in place, the hive is made up, each frame carrying less depth of foundation to the outer ones, the latter to have starters about two inches deep or quarter the depth of a sheet. Colonies so treated we have found to give as good a result in extracted honey as those where entirely worked-out combs were given.—J. H. Howard, Holme, Peterborough.

Probably, by procuring as early in the month of August as possible, condemned bees from cottagers, uniting three or four colonies and placing them upon full sheets of wired foundation, copiously feeding on granulated sugar-syrup, and removing and storing the combs, as finished, and fitting up the gaps with fresh sheets of foundation.—George Raynor.

Full sheets of foundation with wired frames or use the sheets of wired foundation, thus having a good foothold to frame, the combs will stand the centrifugal action of extractor better than combs built naturally or without wire.—W. Woodley.

Bee-Farming.—The man who enters a large beefarm for a term in the hope of gaining an insight into the practical management of the same must not think all the necessary information is to be picked up simply by looking around and paying occasional visits to the apiary. On the contrary, he must make up his mind to go there to work just as any other apprentice or assistant. The daily routine must be gone through in every particular, and though some manipulations may be repeated constantly, it will be only by such close study and application that he will make himself master of the entire practical management,—S. Simmins: A Modern Bee-Farm, p. 187.

MY BEES.

BY MRS. REGINALD BRAY,

Author of 'Family Feats,' 'Ten of Them,' 'We Four,' &c. (Continued from page 503.)

CHAPTER II.—DRIVING AND TRANSFERRING,

A few days after I had received my hives, and whilst I was still waiting anxiously for my swarms, which never came (probably because they had already swarmed earlier in the season), my friend, Mrs. Graham, sent to me to say that they were expecting Mr. Joy to come and transfer their bees from the straw skeps into a bar-frame hive.

I hastened to her garden in great excitement, wondering how it was possible to move all the bees from one hive to another, and longing to be initiated into the

mysteries of bre-driving.

When I arrived I found Mr. Joy with a veil over his head, but his hands bare and his shirt-sleeves rolled up prepared for action. He was going to unite the bees from two skeps into one bar-frame. The season having advanced, it was expedient to make the hive as strong as possible.

The first thing he did was to take a smoker, with some brown paper alight in it, and puff some smoke into the entrance of the hive. This was not so much for the purpose of stupefying as for frightening them. Directly bees are frightened they run and bury their heads in the cells and gorge themselves with honey. After this (like some of the higher creation after dinner) they are in a good temper, and you can do almost anything with them.

It may be as well to remark here that it is necessary to be very careful in handling bees not to jar the frames they are on or shake them. Any sudden movement frightens them, but by gently raising the frames you may look at the bees without any fear, and even brush them back into the hive with a soft brush or wing without any risk of being stung.

Should you have the misfortune to be stung, do not roughly seize the sting and pull it out by the little bag attached to it, as this is the poison-bag, and you will only squeeze more poison into the wound. Push the sting out with your nail or the back part of a knife and put a drop of ammonia in the wound.

Whilst Mr. Joy was making his preparations I ex-

amined the bive with great interest.

It consisted of a large wooden box with an alighting board and entrance for the bees. This entrance had two little sliding doors which you could contract as much as you like, for at certain times of the year, in spring and autumn, it is necessary to close them very nearly to prevent the hive from being robbed by stranger bees.

The hive was filled inside with frames of wood, the correct standard size, which I have since learned should be '14 inches by 8½ inches, outside measurement, the top bar being 3ths of an inch thick, the side bars \(\frac{1}{4} \) of an inch, and the bottom bar 1th of an inch thick, the form

being rectangular.

The top bar of the frames rested on the top edge of the box, and a space of $1\frac{1}{2}$ inch intervened between each frame, a metal end being fixed to each in order to keep them at the proper distance. If frames are placed too far apart the bees will build combs down between them, as I once found to my cost.

All the preparations at last made, the exciting moment arrived when Mr. Joy took up the straw hive, and, turning it npside down, stood it in a pail which had been placed ready to receive it. Then rapidly taking an empty straw skep he placed it exactly over the bottom of the hive, and commenced rapping the sides of the hive hard enough to frighten the bees and make them run, but not hard enough to break the combs.

After a very short time the bees began to run up, and

he then tilted the hive back so that we were able to watch the bees running in a continuous stream from the full hive to the empty one. He told us that the queen had probably gone up, and then the bees follow very had probably gone up, and the carefully you quickly. In driving hees if you watch carefully you unin creat alarm, Inmay catch sight of her running up in great alarm. deed, it is always necessary to make sure that you have her safe, as sometimes she gets lost or left among the combs. Once in driving bees we could find her nowhere, when, on turning the hive round, she was discovered the other side, having crept through a small hole. If she had not been found our stock of bees would probably have been lost.

However, in Mr. Joy's skilful hands no misfortunes occurred, and in a short time not a bee was left in the old hive, but were all collected in the skep, which was a perfect sight, as it appeared to be half full of bees. This skep full of bees he stood on a stand until wanted, the bees all hanging clustered in the upper part. He now proceeded to take the old hive to pieces, and for the benefit of beginners I will give one piece of advice. When you come to this part of the business take the hive and comb away to some shed or outhouse, a greenhouse is a very good place. Anywhere, in fact, away from the hives you are driving, as the bees become so irritated with the unusual excitement that is going on. It is all very well for experts to do everything in the same place, but it is far better for amateurs to be on the safe side and to proceed with their work where they can feel in

safety.

The next thing to be done was to cut the combs out of the hive and transfer them into the frames, and above all to restore to them all their brood-comb. This was a a most interesting sight. He pointed out to us the brood-comb, which can easily be distinguished from the other comb, as, instead of being flat, the caps over the cells are rounded, thick, and of a darkish colour. In some of the cells you can see the eggs like a little white speck at the bottom. In other cells the white grubs in various stages curled up, and occasionally you may be fortunate to see the young bees pierce the cell and emerge a perfect bee, though very weak and pale-looking. These delicate young bees do not leave the hive for some days, as they would be too weak to gather either honey or pollen; but a working bee's life is never idle, and the moment it is hatched it becomes nurse to the young grubs, which it tenderly feeds, until it has become strong enough to take its share in the work outside the hive.

We were also shown the drone-comb, which is very much larger than the worker-comb, four of these cells measuring one inch. Both worker and drone-comb are used for storing honey when not otherwise needed. The cappings of the honey-cells consist of pure wax, but those of the brood-comb are porous, and are made of a mixture

of pollen and wax.

I have sometimes heard it remarked that the pollen which we see the bees carrying into the hives on their legs is what the wax is made of, but this is quite a mistake. This pollen, which is the fertilising dust of the flowers, is rolled by the bees into tiny balls and carried into the hives on their hind legs. This pollen is made into what is commonly called 'bee-bread,' and is used for the food of the young grubs and some of it mixed with the wax for the capping of brood-cells. That which is not used is stored away in cells and often capped over

Wax is the honey extracted from the flowers and which undergoes some change in the body of the bees. So much honey is required for the formation of the wax that it is found that it takes twenty pounds of honey to form one pound of wax. Since I have known this fact it is really an agony to see my beautiful honey-comb devoured at table. I try not to show it, but it is hard not to remind yourself as you watch it disappearing that 'the weight of comb in a hive is about two pounds.' Therefore if each pound of comb is worth twenty pounds of honey and each pound of honey is worth one shilling, what a loss is going on! and how if that delicate comb were only restored to the hive to be refilled what a saving it would be! And you begin to bless the inventor of extractors, of which more anon.

It is now time that I should return to our comb,

which is about to be fastened into the frames. For this purpose two narrow pieces of tape are taken just long enough to tie round the width of the frames. The brood comb is taken first, as it is important to get this into the new hive as soon as possible, for if it gets chilled the broad will die; for this reason bee-driving should always be done on a warm day. The piece cf comb is laid in the middle of the frame and cut with a knife as nearly to fit it as possible. If it is not large enough another piece can be cut and pressed in. The two ends of each piece of tape are brought round and tied together and the frame placed in the hive. As soon as you have got a few frames ready it is as well to put the bees into the hive, as they will cluster at once on the combs and keep the brood warm.

There are two ways of putting the bees into the hive; one is by shaking the bees in at the top. This must be done with a quick jerk, when they will all fall with a great thud into the hive, which should then be rapidly covered with the quilt. The other way is to lay a board about two feet square on a level with the floor-board. Over this lay a sheet and shake out the bees on to it, when they will proceed to run up into the hive. A little smoke may be judiciously used to guide them into the way they should go. I think this plan answers admirably on a warm sanny day, but I have seen it fail when the weather has been unfavourable and the bees have refused to run. When all the best of the comb had been transferred the same process was gone through with the second hive; but before uniting the second set of bees with the first lot they were each sprayed with

some peppermint water.

Strange to say, bees seem only to recognise one another by the scent, and though they will savagely attack strangers yet if you give them all the same scent they are as amicable as possible and never discover that they are of a different family. In uniting two hives in the manner I have described you may if you like remove one of the queens, but if you are a beginner and feel a little nervous at hunting for the queen it does not matter in the least, as the two queens will settle the matter for themselves by fighting it out, and, as is usual, the weaker one will be destroyed. It may here be remarked that queens hardly ever use their stings, they crush each other to death. It has been only known in very rare instances to sting any person. Only one case have I heard of, and that was of a man who was holding her majesty between his lips, and I suppose she resented the indignity and took her revenge

When the bees of the two hives had been united they were carefully covered over, first with a quilt of ticking cut the exact size, and then with two or three layers of bits of old carpet. It must be remembered that it is of the greatest importance to keep the hives very warm. In the centre of the quilts a small hole was cut for the purpose of feeding. It is not necessary to cut the piece right out, but make a snip on three sides so that you can

turn the piece back when you require it.

It is as well to feed driven bees at first, unless there is a good supply of honey in the comb you have put back, otherwise, as a rule, it is only necessary to feed in the autumn and spring. If bees are fed up well with syrup up to the end of October, they will have filled their combs with honey sufficient to last them till the spring. It must be remembered that if you take the honey in supers at the end of the summer you must supply the bees with food to replace that of which you bave robbed them.

In the spring the chief object of feeding is to induce the queen to begin breeding, so as to insure early swarms and a strong stock of bees. Of course it must depend a good deal on the season and the strength of your hives, but, as a rule, you may begin feeding in February. I have tried several kinds of feeders, and have at last come to the conclusion that, as usual, the simplest is the best.

The float feeders I do not recommend, the wooden float so easily gets warped, and then sticks so that it does not go down as the syrup is taken, and the bees cannot get their food. Neither do I like bottles turned upside down with muslin tied over; I have often found that the syrup drips much too fast into the hive, I daresay the fault may be mine, as I often see it recommended, but 1 only profess to be writing a book with my own experiences, and our misfortunes are often a useful lesson to our friends. I shall, therefore, describe what I have found by far the best and cheapest way of feeding.

First of all, get a piece of perforated zine about three inches square, and having turned back the bits of quilt cut and given a puff of smoke into the hole to prevent the bees popping out, place the zinc just over the hole. Then get a one-pound bottle for holding honey with a screw eap. This will not cost you fourpence, and less if you get them by the dozen. In the lid make about a dozen small holes; then fill the bottle quite full of syrup, put the cap on, and turn the bottle upside down over the perforated zine. Being almost air-tight the syrup does not drip, but is taken by the bees through the holes. The piece of zine prevents the bees coming out when you remove the bottle for refilling. In this way there is neither trouble, nor risk of being stung by the bees.

There are many other modes of feeding, one lady I know feeds with moist sugar, but, as a rule, the syrup is the best.

I have given, at the end of the chapter, the best receipts taken from Cowan's book.

Spring and Summer Food for Bees. — White lump sugar, 10 lbs.; water, 7 pints; vinegar, I oz.; salt, I oz. Boil for a few minutes,

Autumn Food. - White lump sugar, 10 lbs.; water, 5 pints; vinegar, I oz.; salt, ½ oz.

(To be continued.)

${ m ASSOCIATIONS}.$

BRITISH BEE-KEEPERS' ASSOCIATION.

Meeting of the Committee held at 105 Jermyn Street, on Wednesday, November 16th. Present, the Hon. and Rev. H. Blyth (in the chair), Dr. Bartrum, the Rev. George Raynor, Rev. F. G. Jenyns, H. Jones, Captain Campbell, J. M. Hooker, and the Secretary.

The minutes of the last meeting were read and con-

Correspondence was read from the National Co-operative Society in reference to prizes to be offered for competition in honey at the National Co-operative Flower Show to be held at the Crystal Palace in August next. Resolved, That the Association do offer a silver and bronze medal in connexion with this exhibition.

In accordance with the suggestion made at the last meeting of the county representatives, it was resolved, That the rule relating to the competition for the Association's medals at county shows be amended, and that in future they shall be open to members of the County Association residing within such districts as shall be acknowledged to belong to the County Association.

It was resolved, That the annual general meeting be held either on Wednesday, February 8th, or Wednesday, February 22nd, as most suitable to the President of the Association.

MIDDLESEX BEE-KEEPERS' ASSOCIATION.

The usual Monthly Committee Meeting was held at 105 Jermyn Street, on the 16th inst. Present-Hon. and Rev. II. Bligh in the chair, Messrs. Gunn, Graham, and English. The Secretary reported that up to date receipts, although not so large as anticipated, were in excess of expenditure. The experts reports were received and considered. About 165 members owning 776 hives were visited during the recent autumn tour. The statistical returns so far as returned were referred to Mr. Graham for tabulation. A hope was expressed that those members who had as yet failed to forward their returns to the Secretary would do so with the least possible delay.

Correspondence.

The Editor does not hold himself responsible for the opinions expressed by his correspondents. No attention will be taken of anonymous communications, and correspondents are requested to write on one side of the paper only, and give their real manes and addresses, not necessarily for publication, but as a guarantee of good faith. Illustrations should be drawn on separate pieces of paper.

Communications relating to the literary department, reports of Associations, Shows, Meetings, Echoes, Queries, Books for Review, Ec. must be addressed only to 'The Editor of the 'British Bee Journal,' 'clo Messrs. Strangeways and Sons, Tower Street, Cambridge Circus, W.C. All business communications relating to Advertisements, &c., must be addressed to Mr. J. Huckle, Kings Langley, Herts (see 2nd page of Advertisements).

** In order to facilitate reference, Correspondents, when speaking of

and page of Auvertusements).

*** In order to facilitate reference, Correspondents, when speaking of any letter or query proviously inserted, will oblige by mentioning the number of the letter, as well as the page on which it appears.

PRICE OF HONEY.

[1361.] From time to time this question crops up, and receives more or less attention from the minority. Few men have done more in developing a local market, and thus showing what can be done, than your esteemed correspondent Mr. R. R. Godfrey: but that gentleman has yet to see that honey can be produced, and that profitably, at a lower figure than he himself quotes as the limit for profitable production. I presume he places 9d. per lb. as the average, but while I am willing to admit that the recent price at which comb-honey has been sold is certainly lower than it should be, I am convinced that extracted honey can be produced profitably at less than 6d. per lb.

Bee-keepers are, in a large measure, themselves to blame for being in such a hurry to dispose of their combhoney as soon as it is off the hive. Possibly, it may be that few are prepared with a suitable room for storing it until prices advance; but, be that as it may, as soon as one begins to offer comb-honey he finds the market full, and it is long ere dealers can be persuaded that the article is really becoming scarce.

During the past season prices have ruled at about 7s. 6d. per dozen $4\frac{1}{4} \times 4\frac{1}{4}$ sections, or 9d. per lb. extracted at 0d, we get the average of $7\frac{1}{2}d$, per lb.—and I fear it will not be in our time that prices will again rise higher than those figures.

If, therefore, we accept Mr. Godfrey's proposition, all had better fall out of the business at once; and indeed such would already be the case, were his statements founded upon fact. On the other hand, we shall probably accept things as we find them, regulated by 'supply and demand, which, after all, speak the truth, look at the matter how we may. If the state of the marketwhich has tended only in one direction for several years past—places our product at a comparatively low figure, there will be found those prepared to supply and live at that rate. Greater economy, improved methods of management, planting by the acre for the double purpose of honey and hay, the larger number of stocks owned by one apiarist—will all prove important factors producing the honey-crops of the future.

I have myself, in the past, given my voice against the falling price of comb-honey, but individual effort is

powerless in the face of supply and demand. I suppose we shall be equally powerless to persuade bee-keepers to go in more largely for extracted honey, and thus help to place comb at a higher figure. It is extracted honey that will be used among the masses by the tens of tons, if only placed before them at a low figure as it can be, and will be done, at a profit. During the past ten years comb-honey has come down something like 7d. per lb., extracted only 2d.; thus showing at once which has received the larger share of attention, and as a consequence has gone down rapidly in price, until our quotations now stand lower than those of America; a fact which may well receive careful attention. I do not remember the time when I was not satisfied with 8d. per lb. in bulk for extracted, and at this day consider myself well repaid at 6d.

The Honey Company has been blamed in several quarters for having induced present low figures. Of course, they have in a large measure been the cause; but the course which they have pursued is perfectly justifiable, and of advantage to the entire community. Surely those who bitterly condemn the Company are exceedingly narrow-minded in their methods of reasoning; or, do they reason at all? Can there possibly exist the mind that fails to grasp the fact that the ten tons sold to-day at 7d. or 8d. per lb. where one cwt. was sold a few years since at one-half more, shows a state of things vastly in favour of the producer as well as the consumer, in that the whole business is rendered more reliable, as it can be carried out upon a larger scale; and the time has now come when this important branch of agriculture is recognised in all quarters as one of the great industries of the country.—S. SIMMINS.

WINTERING BEES IN CELLARS.

[1:62.] As the wintering of bees in cellars had been spoken very highly of by writers in the B. B. J. and successfully adopted in America I decided upon trying the plan myself, but so far my success has been very doubtful, and I now have to appeal for advice upon this subject through the pages of the B. B. J.

A fortnight ago I removed nine skeps and three stocks on bar-frames to an attic, which I made perfectly dark by boarding the windows up. The first week I scarcely lost a bee, but the second week the bees on the bar-frames came out by hundreds and perished on the floor of the attic. To try an experiment I removed one of the three stocks into another attic, placed the same level with the window, which I opened wide, and that part of the window I could not open I boarded up, so that the bees should not worry themselves against the glass. As soon as this stock was placed in the light the bees rushed out by hundreds through the open window, discharging very large quantities of excrementitious matter, and after a very short flight settled on and about the window and died, not a single bee returning to the hive. The bodies of the bees that left the hives were very much swollen and distended, and after settling appeared too weak to rise again. After awhile, and when I thought every bee had left the hive, I went and examined the combs, when to my astonishment I found four combs crowded with bees, and to all appearance as healthy as possible; the hive and combs were as clean as in the middle of summer. During my examination I may state not a bee left the hive, although I examined every comb thoroughly. I next removed the other two bar-frame hives into the light of day. Not more than a dozen bees from each hive went away, but they, like the others, perished almost directly. I may state the sun was shining brightly the whole of the time and through the window on to the hives. The three hives were fed with syrup and completed after they had been removed into the attic.

Now for the skeps, which are still in the darkened

attic. I have not lost a bee from any of them so far, neither have they shown that restlessness which those in the bar-frames exhibited. Each skep has its own natural stores, as I never take honey from skeps unless absolutely necessary. Mr. Cowan does not treat very exhaustively upon this subject in his Guide-book, and I want you, Mr. Editor, to give me a little advice of what you would do with the nine skeps. I don't want to lose my bees, as it would be a dead loss of about 10% to me next spring. Therefore, will you or some practical gentleman tell me whether it is advisable to let the skeps remain, or to at once remove them back on to their stands in the garden? The great loss of bees that perished in the snow last winter was the main cause of me trying this new-fangled notion.

Before concluding this long letter I would give a warning to the hon, secretary of my County Association, He had promised me a visit, and I had looked anxiously forward to that visit. He came (you will perceive he was a man of his word), 6.35 p.m. was the exact time. He departed 6.55 p.m.: he left me to eatch his train. Revenge is sweet, Mr. Editor, and the next time that hon, secretary comes to see me and has another train to catch, he'll eatch it not. I shall consider myself entitled to a few extra hours of his time, just to make up for lost ground.—Nil Desperandum, November 15.

The climate of Canada and of the Northern States of the Union, where the thermometer ranges for many weeks below zero, differs so widely from our own that the systems of wintering bees in both climates cannot well be compared. There the bees are wintered in 'cellars' which are, partly at least, below the surface of the ground, and the temperature of which ranges from 45° to 55° Fahr. The temperature of an English attic during the winter is far more variable, and the degree of moisture also differs much. A bright sun raised the temperature of your attic, aroused the bees to flight, and chilled by a cold wind they perished. Others gorged with syrup, owing to high temperature, seeking an exit in order to relieve themselves of fæces, and unable to find their hives again, perished on the floor. Those in skeps having sealed and well-ripened stores and being domiciled in well-propolised skeps were less affected by the surrounding atmosphere and had less temptation to devonr food and sally forth. Were the case our own we should on the evening of a cold day remove the framehives and the skeps very carefully without shaking to their original stands in the garden, since experience teaches that in the British climate bees winter better in the open air on summer stands than they do in cellars or darkened rooms. After removal leave the hives entirely alone until the end of February, and in bright weather when snow lies on the ground shade the entrances to prevent the bees issuing forth.—Ed.]

THE SEASON IN CANADA.—MR. COWAN'S VISIT.—MR. GRIMSHAW'S APIFUGE.

[1363.] The season of 1887 has come and gone, and has been rather an eventful one to bee-keepers as well as to the agriculturalist. The spring months were the finest and most promising we have ever had. Up till the beginning of June the prospects of an abundant yield in grain, roots, and honey, were most cheering, but a protracted drought set in and continued up till September, thus making us realise the force of Solomou's saving that 'Hope deferred maketh the heart sick.' The only province of this great Dominion that rejoices in the 'tree of life,' which is the outcome of 'desires' realised, is Manitoba, whose grain-crop is phenomenally large. The crops of the eastern provinces were literally parched up. Grain of all kinds shrunk to half their normal weight, while the root-crops fell short in nearly

like proportions. Nor were bee-men more fortunate than their agricultural neighbours. Flowers ceased to yield nectar early in July, and what promised to be one of the best honey seas is for many years past resulted in not more than half a crop, with generally a short supply for winter sustenance. But most evils bring something compensating in their train, and to beekeepers this dark cloud soon presented a silver lining in the form of a brisk demand and stiff prices for the stock they held, which in part have compensated them for the short crop. I venture to say you will hear or see little of Canadian honey in the English market this year, for our home supply is less than enough to meet our ever-increasing home consumption. The Canadian market is already bare, and many orders have to be declined because they cannot be filled. Λ like condition of things exists in the United States.

A notable incident in the history of bee-keeping in Canada this year was the presence of the two distinguished visitors who called upon us, note-book in hand. During Mr. Cowan's presence here the warning in one of Burns's pieces came fresh to my mind:—

'If there's a hole in a' your coats be sure he'll tent it, A chief's amang us tacking notes, and faith he'll prent it.'

The rough and ready way we have of doing things here did not, I fear, impress Mr. Cowan favourably. Whatever he may think of our people and their ways of doing things, of one fact I am sure he is satisfied, and that is, that we have a great country and a bright future. In bee-keeping circles doubtless he saw much to condemn, but some things are conspicuous by their absence here that are common in England, notably straw skeps and long-legged hives. I hope for the good will we bear him he will not be over-severe upon us, for we are a sensitive people and pugnacious when attacked. That we enjoyed Mr. Cowan's visit goes without saying, for Mr. Cowan is a gentleman whose company is always enjoyable. Nor did Mrs. Cowan make a less favourable impression. The readiness with which she adapted herself to our strange ways manifests her good sense. I verily believe both Mr. and Mrs. Cowan would make first-rate Canadians when once fairly initiated. I had the honour of a nice visit from them, and I hope it will not be the last.

I see Mr. Grimshaw is defending his Apifuge against all assailants. I have a bottle of it here, but have not yet tested it, and cannot speak personally of its good or bad effects, but I had an opportunity of seeing it tested for another purpose than that of keeping bees at bay. The swamps of Canada and the United States teem with mosquitoes in the spring and early summer. When Mr. Cowan visited Mr. Jones at Beeton, I accompanied him. While there we made an excursion into a neighbouring swamp in search of bee plants. Mosquitoes are especially fond of 'green' blood (we call everybody green who has lately arrived from the old country). The vicious insects 'went for' Mr. Cowan, and Mr. Cowan 'went for' the bottle of Apifuge he had in his pocket. Applying some of the contents to the wound from which the 'perky 'critter had withdrawn its long proboscis, the usual swelling did not result, whilst another wound to which he did not apply the fluid very soon developed the ordinary symptoms of local poisoning. If Apifuge proves an effective remedy for mosquito bites, there is an unlimited field of usefulness for it on this continent, for mosquitos are a terrible pest to all who have to spend their time in the woods. Surveying parties, hunting and fishing parties, &c., often smear themselves with grease, parallin, and other supposed protections, against their attacks. If Apifuge be a cure it will find a ready sale. Mr. Grimshaw may put this in his scrap-book, and three witnesses will testify to its correctness when called upon.-R. McKnighr, Owen Sound, Ontario,

TWO SEASONABLE HINTS BY MR. G. M. DOOLATTLE.

[1364.] From Gleanings, October 15th, I cull two capital hints, which, although too late to be put in practice now, yet, if recorded, may get fixed on our minds ready for use next year. The first is an easy way of getting fresh brood into our apiaries. I am sure we are remiss in this respect. We should be gainers if we exchanged swarms or queens with our friends who live a few miles from us; our bees would be more vigorous and our honey yield would be larger.

Mr. Doolittle, who has made for himself a reputation as a queen-raiser, says, this year he has sent several virgin queens to selected apiaries at a distance to get them fertilised by drones in no way connected by affinity with his own strain at home. We know how much the worker progeny takes after the drone, consequently the advantage of getting fresh blood through the drone will at once commend itself to the merest tyro, and needs no

commendation from me.

The next hint is about introducing queens late in the fall. Have you ever tried it with imported queens because the price was low, and called yourself hard names for parting with your money? This is the way Mr. Doolittle says he 'succeeds every time.' When a queen arrived, if the weather was unsuitable for opening a hive, he placed the travelling cage containing the queen on top of the queenless colony, under the quilt, to keep her warm until the weather became suitable for manipulation. Of course any other suitable place will do as well. Before proceeding to introduce her he prepares a cage of wire cloth by taking a piece of the latter article, about two-thirds the size of the frame, and cutting out a square inch at each corner. Now unravel or draw out the wires from each of the four sides for $\frac{5}{5}$ of an inch; you thus have a row of pointed wires an inch in length all round your piece of wire cloth. The four sides of the wire cloth are now bent down at right angles an inch deep; you thus have a box an inch deep without a bottom. Take a comb from the hive, clear it of bees. If the stock you wish to introduce the queen to has a queen, you must now find and remove her of course. Having done so, place your new queen on to the comb, and allow her to sip at some unsealed honey while you place this large wire cage you have prepared over her (Mr. Doolittle clips her wings first), press the points of the wire into the comb 5 of an inch, and your cage with the queen underneath it projects 3 of an inch, thus giving the queen ample opportunity of keeping out of the reach of any of the bees who may be likely to treat her rudely until she has acquired the 'taste' of the colony. Mr. Doolittle advises she should be left from four days to a week before being liberated, remarking her time is not so valuable late in the fall as in the height of the breeding season.

I like the plan, and, if necessary, should take Mr. Doolittle's closing advice, which I make my closing advice also—'Try it!'—AMATEUR EXPERT.

THE NEW SECTIONS.

[1365.] Now that the Jubilee honey season is a thing of the past, and the prudent bec-keeper is beginning to turn his attention to the next campaign, it seems to me that many of us would like to hear something about the working of the new sections. For instance, have the four-way sections been better finished than those of same dimensions having only two ways? And how do those worked without separators compare in weight, finish, and readiness of sale with sections worked with separators. My own experience is taken from a limited area, as I have only about a dozen hives.

I have used the old-fashioned section $4 \ge 4 \ge 2$ with two bee-ways only, and also a new pattern

 $4\frac{1}{4} \times 4\frac{1}{4} \times 1\frac{3}{4}$, the latter being worked without separators. Both kinds gave capital comb-honey, the thinner sections being equal or superior to the old ones in appearance and in weight, many being over a pound. But the difference is found when one comes to pack for market, indeed to handle at all; one little rub in lifting out of the case, one careless touch whilst lying exposed for admiration, and the pile for home consumption receives a new addition.

Separators for me next time, certainly. But I should like to know what the experience of others has been with regard to four-ways versus two-ways, for doubtless the latter form has superior safety in handling upon its side, even though both have been worked with separators. Is there really any practical advantage in the plan of allowing the bees access from one row to another? I am inclined to doubt it, though I should mention that my section-cases are suspended bee-space above the frames so that this arrangement itself gives the bees some choice of movement. Would those who have tried Mr. Lee's sections give us the benefit of their experience? I fancy I recollect Mr. U. II.' writing of them in high terms some time ago.—A. FRYER, Ramsey, Isle of Man.

BEE DISEASE.

[1366.] In Mr. Cowan's very interesting account of his visit to America, reported in the Journal of Oct. 27, speaking of Mr. Heddon, he says:—'the was, unfortunately, suffering from bee disease, which affects him in a very peculiar way, viz., by producing catarrh, so that he cannot open a hive himself without being attacked by this complaint.'

Now I have never heard of the 'bee disease' before, but on reading this it struck me very forcibly that I am suffering from it, and I should be glad if Mr. Cowan, or some other scientific bee-keeper who understands the subject, would give us further information about it.

I have been a bee-keeper for sixteen or seventeen years, and for the last three or four years I have suffered severely from what appears to be a violent cold in the head. Unlike an ordinary cold, it comes on suddenly without any warning, causes frequent sneezing, with continual running at the eyes and nose; sometimes it lasts only a few hours, sometimes a day or two, and during its continuance I feel more or less feverish, and very good-for-notling. We have often noticed that I am almost invariably attacked on a Saturday night, and could not account for it; but though I am amongst bees more or less almost every day during the season, Saturday is a sort of field-day on which I am usually amongst my own bees.

I consulted my doctor, and he said it was not a cold at all in the ordinary sense of the word, but was analogous to hav fever, but evidently arose from some other cause as I suffer from it throughout the year. And this makes me doubtful whether it is produced by the bees, as it certainly does not always come on after manipulating a hive, whilst it comes on sometimes when I am away from home and have had nothing to do with bees. My doctor questioned me as to there being anything likely to cause irritation, such as the use of disinfecting powder, &c., in my dog-kennels; but it never occurred to either of us that it could have anything to do with the bees. I shall be glad to be satisfied on the subject one way or other, and possibly others besides myself may be interested in hearing more of the 'bee disease.' - A Bee-keeper.

[Mr. Heddon says that about ten years ago he began to notice an itching sensation in the ears. This would appear only occasionally at first, but it gradually extended to the mouth, and near the root of the tongue. Later the sensation was very severe in the root of the mouth, just round and in front of the palate. The eyelids also swelled after first itching and burning. It

was about three years after the first appearance of the irritating symptoms that he in any way connected them with bee-poison. He found that to open a hive and breathe the odour of the bees brought on the irritation at once. He, however, persevered in working among the bees, until the irritation and tingling sensation crept down the bronchial tubes all round about the lungs, until one night, after a day's work among the bees, he woke up with asthma. To make sure that bee-poison was the cause of these symptoms, he made several tests. He kept away from his bees for a fortnight, and get rid of all the symptoms except an occasional tingling in the ears. No sooner was he amongst his bees again than the former symptoms reappeared in a more aggravated form. Finding that on every occasion when he went near his bees he was similarly affected, he made up his mind to have hired assistance in his apiary, and since he has done so he has been free from the disease. But if at any time he comes in contact with the poison, the symptoms at once reappear. He says, on one occasion when he was quite well, not having been near the bees for some weeks, a bee flew past his face, and within a few inches of it, discharging poison as she passed. Half an hour afterwards he was seized with one of the most severe paroxysms he has experienced. For more than eight hours he could not speak aloud. All, however, passed off, and by keeping away from the poison he keeps perfectly well. When we knew and saw how Mr. Heddon suffered, we felt flattered that he should have personally conducted us over his apiaries, and deeply regretted that our presence and his courtesy should have been the cause of his suffering so much during the rest of the evening. We have heard of similar cases of poisoning, but, fortunately, they are very rare, and the remedy is obvious.—Ed.

HALF A DAY WITH MR. HEDDON,

A TALK ABOUT HEDDON THUMBSCREWS, FRAMES,
AND TIN RESTS.

[1367.] Being in Chicago recently on the cheap tendays' excursion, I took the opportunity of running out to Dowagiac for a brief visit. I found Mr. Heddon all tired out with his labours as a leading official of the county fair, which embraces two other counties besides Cass, and is rather a 'big thing' in that part of Michigan. llowever, I accomplished my main object, which was to get some difficulties removed that had cropped up in the practical working of the new hive. They were briefly these: I. Failure of the thumbscrews, which, in my experience, are apt to shrink and swell, if screwed tight, in a dry hot time; they swell when moist, cool weather comes, and have to be started with a wrench. In some cases the thread gives way. 2. The tightening up of both frames and sections, so that everything becomes practically immovable—'fixed fast as fate.' bending of the tin rests, as the result of which frames are thrown out of the level.

Mr. Heddon proved to me that none of these difficulties exist in his apiary, and I am inclined to think that with me they are partly climatic, partly the result of the screws and frames being made to fit too tightly in the first place; and partly for want of more skill and attention on my part. The climate of Guelph is subject to very great and sudden changes, and watch must be kept of these. It is not much trouble to go through an apiary and either tighten or slacken the thumbscrews, as may be needed. Mr. Heddon's frames and thumbscrews fit very loosely. As long as there is not a bee-space left anywhere there is no need of the frames being at all tight. As for the thumbscrews they are so loose that they wobble. Yet their holding power is so great that a case, dependent only on their grip, remained without the least of flinching when Mr. Heddon and I stood on a board resting simply on the eight frames. The tin strips

are made of heavy tin, and this, I think, is necessary in order that they may keep their places perfectly.

The one fault with the new Heddon hive-if fault it be—is that it requires the greatest accuracy in mechanical construction and very careful handling. A botch carpenter cannot make the hive, and a botch bee-keeper cannot manipulate it successfully. I am not sure that this is a fault. It is not desirable that bee-keeping should tolerate slovenly and careless ways. Both as a science and an art we should go in for its being carried on with intelligence and skill. The best results are to be had by the dexterous use of the best appliances. A partial honey crop can be got by slip-shod bee-keepers who are content to go by the rule of thumb, but it is to be hoped that this class will always be in the minority, and will become 'small by degrees and beautifully less.'

I am well pleased with my trial of the new hive for two seasons, notwithstanding the difficulties I have mentioned. I do not care to invert the brood-nest more than once, and that only when the comb is not built evenly and fully at the bottom of the frame. Apart from that I see no use in inverting. The interchangeable feature of the hive is a grand one and wonderfully simplifies manipulation. For making artificial swarms it is unrivalled. It is especially adapted for producing comb honey, the only kind I raise. I used the extractor one season and abandoned it, I think for the term of my natural life. I am old fogyish enough to wish it had never been invented. Adulteration, over-production, low prices, and evils resulting from interference with the internal economy of the hive, have grown out of its use. Raising only comb honey, and wishing to handle my bees as little as possible, the new Heddon hive suits me better than any other that I have tried, and I am simply anxious to give it the most skilful management of which its peculiar construction and functions admit.

Mr. Hedden's explanations convinced me that before putting bees into the new hive it is necessary to see that the frames and thumbserews are in good and free working order. Anyone who proposes to adopt this hive to any extent should have a bit for making the thread holes for the thumbscrews, and personally attend to their proper adjustment. This done, if the screws have been, as they should be, boiled in tallow, they ought to work all right, no matter what the weather may be. A large number of bee-keepers, I was informed, have invested in the hive and only two or three have found any difficulty in the practical working of it. As yet, it has been but a comparatively short time before the public.

I was at first surprised at not finding more of the new hives in use in Mr. Heddon's apiary. There are only about fifty of them all told. But when I learned what an immense lot of old, bright, valuable frames of comb Mr. 11. had on hand, I could readily understand that its substitution for the former hive, a most excellent one of its kind, must be a work of time. - W. F. Clark, Guelph (Canadian Bee Journal.)

LA CIRE DES APEILLES ET SON UTILISATION. Par J. Dennler, traduction français par J. B. Leriche of La Motte-en-Santerre (Somme). This is a translation into French of Mr. Dennler's pamphlet on Das Bienenwachs und seine Verwertung, which we reviewed on page III of the Bee Journal for this year. This pamphlet will be useful to French bee-keepers, but we regret that Mr. Dennler, who is a perfect master of the French language did not translate it himself, and thus avoid some of the errors and omissions which naturally occur when the translator has not a perfect knowledge of the language he is translating from. The work has certainly lost by the translation, as the history connected with the subject has disappeared, and thus one of the most interesting portions of the original is gone. A translation of the original has appeared in the columns of the Journal so that our readers can of themselves form an opinion of the usefulness of the pamphlet.

We have received from M. Luigi Sartori of Milan two sheets of diagrams which he has had prepared for illustrating the natural history of bees and bee-keeping, and which are entitled Apiculture. Plate I contains the scientific part, and on this we find no less than seventythree carefully executed illustrations connected with the natural history of the bee. The illustrations are nicely lithographed in the natural colours of the objects represented. Amongst the best is fig. 22, a longitudinal section of the queeu-bee. There are also good sections of the worker bee at figs. 38 and 39. Plate 2 represents the practical part, and illustrates hives and appliances in general use. There are 69 illustrations which are also described. Each plate is accompanied by a description of the figures, and we are glad to find that the descriptions are correctly made in the various languages,—a very rare occurrence. The plates are on stout paper, and measure 3 feet 6 inches by 2 feet 6 inches each. They will be very useful for lectures as they can be had with the descriptions printed in Italian, French, German, or English.

Echoes from the Pives.

East Limerick, November 9th.—The last was a very good season in this district, the best for the last four years. I averaged 75 lbs. each from nine hives (including 104 sections and I6 lbs. extracted honey from one hive), and leaving twelve stocks for winter each provided with 20 to 25 lbs. of store—no sugar used. The average would have been much larger but for two swarms escaping.—East Limeuick.

NOTICES TO CORRESPONDENTS & INQUIRERS:

Letters or queries asking for addresses of manufacturers or correspondents, or where appliances can be purchased, or replies giving such information, can only be inserted as advertisements. The space devoted to letters, queries, and replies, is meant for the general good of bee-keepers, and not for advertisements. We wish our Correspondents to bear in mind that, as it is necessary for us to go to press in advance of the date of issue, queries cannot always be replied to in the issue immediately following the receipt of their communication.

All queries forwarded will be attended to, and those only of personal interest will be answered in this column.

interest will be answered in this column.

Major-General G.—Fumigation required.—The eggs are not those of the wax-moth, but we would recommend that yon fumigate all your spare combs with rather strong sulphur fumes. If the combs are badly infested it might be well worth your while to melt down your combs. Particular care should be exercised in thoroughly cleansing out your hives in the coming spring.

G. King, Jun.—Ivy Honey.—The two pieces of comb contain ivy honey. This honey has a cheese-like appearance. It solidities very quickly after it is stored. Ivy is the last good supply of food the bees have before going into winter quarters; it follows the heather-honey. The peculiar property of these two honeys is that they toughen almost as soon as stored; and it shows the perfect fitness of things, for a late large supply of almost any other kind would require evaporating, and there would be danger of its causing dysentery in the hive. Ivy honey does not possess any attractive taste, but it has been found suitable for winter and spring feeding.

J. Wilton.—The loss of time entailed on a stock after swarming, while waiting for their new queen to lay, may vary from eight days at the least, to perhaps twenty days. The old queen with the swarm lays as soon as cells are ready, which is sometimes the case in twenty-four hours.

CORRECTION.—Page 505, line 8 from top, for Apifuge and Fumigators read Apifuge and Slotted Dividers.

Editorial, Aotices, &c.

'FEED YOUR STOCKS.'

Every successful bee-keeper knows, that if at any time a stock is allowed to be short of food material damage arises, and that such damage increases in geometrical ratio the longer the scarcity prevails. Further; feeding must be done at the right time to attain the best results, and nothing short of the best results should ever satisfy any bee-keeper. We have reason to believe that a large number who really consider themselves advanced bee-keepers are often behindhand in those various attentions to their bees which are so essential to success, and that this negligence arises, in many cases, through the owner not making such full use of the beeliterature of the period as he might reasonably be

expected to do.

We are at all times auxious to afford any, and every, assistance to bee-keepers who may require it, and our columns are always open for any question to be put and discussed. In fact, the free discussion of moot points has helped on bee-keeping, perhaps, more than anything else. Many questions that are sent to us tend to show that the sender has either neglected to study the published experience of others, or, having scanned it, has not thought out the hints and information stored therein sufficiently well to obtain the full benefit of the advice given. Some of our readers may say, 'If bee-keeping entail such an amount of study, then I shall give it up.' Not so; it is not beekeeping, but successful beekeeping that requires our very best energies to be unsparingly applied to it. The bee-keeper who is contented to have a hive or two in his garden merely because they look appropriate to the surroundings, and not because he feels any real interest in them, or wishes to bestow any particular care upon them, must be likewise contented with probably no surplus honey, or, at the most, but a very small quantity. As an illustration of this let-alone policy, we may mention that we once visited a lady who had a hive of bees which she requested us to examine; for, as she pathetically put it, 'I cannot think what is wrong with them, they have been in the garden for four years, and I have had no honey.' We opened the hive, removed about 15 lbs. of honey, and offered

suggestions as to future management. The poor bees had been totally neglected the whole of the time, as the hive had never been opened since its arrival; their owner had never read anything as to their management. To those who can afford but little time for reading, the Journal may be useful as giving hints in season, but we would earnestly recommend the studied perusal of every work on bees that our reader can either buy or obtain the loan of. May we suggest that those who are the fortunate possessors of such books will kindly let their neighbours have them to read, and so obtain mutual advantage by educating and enabling them to take an intelligent part in any discussion that may arise, besides training them to become critical observers, from whom hints may hereafter be

Reading is, and ever will be, the best food, but practical lectures should by no means be overlooked. We would, however, point out that for a technical subject like bee-keeping it is important to make methodical notes of what we read, if the full benefit of such reading is to be enjoyed. Let the notes be classified as well as indexed, and it would then become a very simple matter to turn up all accumulated information on any given subject by consulting that portion of the book devoted to it. In cases where the source of information is a book, or periodical, belonging to the compiler, it would be sufficient to note somewhat

in this manner-

While in the case of hints noted from borrowed books, or gleaned from personal correspondence, a short, clear extract should be made, quoting the source whence derived. Such note-books would imperceptibly grow into most useful mines of information, not only for 'the chiel amang us takin' notes,' but for his friends. Foolscap size would obviate them becoming bulky so soon, and would therefore enable them to be the more easily circulated for mutual information, with permission to copy, or, being produced at our ideal friendly conversazione, would form a most interesting basis for comment and comparison. Different systems could then be brought side by side, and results noted which, by comparison with other note-books, would go far to show which particular system, or arrange-

ment, suited any particular district best. As beekeepers, we know full well that it is by hearty cooperation alone that our bees are enabled to carry out their manifold duties. Let us, therefore, adopt similar tactics; by so doing many mishaps will be avoided, and in case disease attack our bees we shall, in virtue of our increased knowledge, be able to detect it in such an early stage as to reduce the risk to a minimum; or, in the event of an accident, be fitted to deal promptly with it, without waiting for the arrival of a more experienced friend, or the next issue of the *Journal* to help us out of our dilemma.

THE STRUCTURE OF FLOWERS WITH REFERENCE TO INSECT AID IN THEIR FERTILISATION.

(Continued from page 501.)

The last but not the least remarkable example of the adaptation of flowers to the visits of insects for the purpose of fertilisation to which I will allude is that of the Orchidaceous family of plants. The flower of the orchis is very abnormal. Its genera vary amazingly in the structure of the anther, the column, the lip. and indeed of all parts, but in the consolidation of the style and stamen they are all agreed. 'The flowers,' to quote the words of an eminent modern botanist, Otto W. Thomé, ' are rarely solitary, usually in spikes, racemes, or panicles, and the superior perianth consists of two whorls, each of three leaves. Of these the inner whorl is always irregular and often has a spurred lip or labellum, the remaining five leaves of the perianth forming together the galea or helmet. The stamens are united with the style into a fleshly column or gynostemium, upon which the anthers are so placed as to stand above the stigma, which is but little developed and consists usually of a large viscid surface. Of the six stamens which are probably originally present only one, less often two, attain perfect development. When only one is thus developed it is always opposite the labellum, but when two, then one is on each side of the gynostemium. Only a few orchids have the pollen-grains perfectly distinct; usually they are united together in fours, and these again into granular masses, or the grains are combined by a viscid fluid into a club-shaped mass or pollinium within each anther lobe. The two pollinia terminate at their lower end in a pedicel consisting of the dried-up viscid substance, connected together by a viscid gland or rostellum, as in the bee orchis, or distinct as in Orchis morio.'

If we dissect a flower of the early purple orchis we shall find that the stigma is bilobed and consists of two almost confluent stigmas. It lies under the pouchformed rostellum. The anther consists of two rather widely separated cells, which are longitudinally open in front; each cell includes a pollen mass or pollinium. The pollinium consists of a number of wedge-shaped packets of pollen grains united together by exceedingly elastic thin threads. Below the pollen mass is the elastic candicle. The end of the caudicle is firmly attached to a viscid button-shaped disc. Each pollinium has its separate disc, which has a ball of viscid matter at its under side. The rostellum lies immediately below, and the balls of viscid matter lie concealed within it. Let me now try to explain how this mechanism acts. Suppose an insect, say a bee in search of honey, to alight on the labellum, which forms a good landing stage, and to push its head into the chamber, at the back of which lies the stigma, in order to reach with its probescis the end of the nectary, or what does quite as well to show the action, push a sharply pointed lead pencil into the nectary. Owing to the projection of the pouch-formed rostellum it is almost impossible to push an object into

the gangway of the nectary without touching the rostellum. When this is effected one or both of the viscid balls will almost invariably touch the intruding body. These balls are so viscid that they stick firmly to whatever they touch, and the viscid matter sets hard and dry like cement within a minute or so. As the anther cells are now open in front when the insect withdraws its head, or when the pencil is withdrawn, one or both pollinia will be withdrawn firmly attached to the object, sticking up like horns. The firmness of the cement is necessary, for if the pollinia were to fall sideways or backwards they would never fertilise the flower. Now let us suppose the insect to fly to another flower, or insert the pencil with the pollinium attached into another nectary. If this be done at once it is evident that the pollinium will be pushed into or against its old place, the anther cell. How then can the flower be fertilised. This is effected by a very beautiful contrivance. Within a minute the pollinia, by the contractivance. tion of the minute disc to which they are attached, move downwards to an angle of about forty-five degrees from the first upright position. When the insect sucks the next flower the pollen masses come in direct contact with the stigmatic surface. The stigma is so very viscid that it is certain to pull off some of these pollen packets and rupture the threads. The whole pollinium is scarcely ever retained by the stigma, so that one pollinium serves to fertilise several flowers. So economical is Nature in her workings that even a few pollen masses are not unworthy of her sedulous care.

Of all the pollen-carriers, and consequently flowerfertilisers, bees are the most assiduous. Attracted by the gay colours of the corolla, sweet scent, or the prospect of honey, they visit most flowers that are incapable of self-fertilisation. That bees can distinguish between one colour and another, and that they exhibit a preference for certain colours, has been clearly proved by Sir John Lubbock and others. The bodies of some bees and the legs of others are so admirably adapted for the collection and carriage of pollen that it is almost impossible for them to visit any flower in pursuit of honey without bearing away a large quantity of pollen grains. The body of the humble bee (Bombus terrestris) is the best adapted for pollen carrying. Lepidoptera stand next in order of importance to bees as pollen-carriers. long proboscides enable them to drain nectaries which less favoured insects cannot reach. The despised wasp is not without its use as a fertilising agent: for, according to Mr. Darwin, 'if wasps were to become extinct in

any district so would Epipactis latifolia. Honey, I need scarcely say, is the principal object of attraction to bees, butterflies, moths, and many other insects which assist in the work of fertilisation. It is secreted by specialised organs known as nectar glands. 'In the flower, according to Dr. Goodale, an eminent American botanist, 'these glands consist usually of specialised parenchyma, not unlike the secreting surface of the stigma.' 'Nectar glands,' continues the author, 'may occur in any part of the flower, upon its bracts or upon some part of the flower-stalk near it. From the nectar glands of proper floral organs the secretion of nectar is generally copious, and is prope to collect in minute cavities such as shallow pits, or in conspicuous special receptacles, the so-called nectaries. The period of most copious secretion of nectar usually coincides with the maturity of the anthers or of the stigma. Here we perceive another of Nature's beautiful contrivances for carrying out her purposes. Just at the time when the pollen is ready to do its work of fertilisation, or the stigma to receive it, a copious supply of

honey both attracts and rewards the insect pollen-carriers.

The odours of flowers must be classed amongst the most potent attractions of insects. White flowers are more generally fragrant than those of any other colour. As examples of the accuracy of this proposition I would

refer to those delicately-scented flowers the lily of the valley, the jasmine, and the butterfly orchis. I cannot do better than quote the words of Mr. Darwin in explanation of this:—'The fact of a large proportion of white flowers smelling sweetly may depend in part on those which are fertilised by moths requiring the double aid of conspicuousness in the dark and of odour. So great is the economy of Nature that most flowers which are fertilised by crepuscular or nocturnal insects emit their odour chiefly or exclusively in the evening.'

I have ventured to call attention to a comparatively large number of important facts, and for the purpose of giving my authorities have quoted largely. If these quotations have the effect, as I trust they may, of directing attention to and inducing a perusal of the works referred to, this paper will not have been written in vain. It will naturally be asked, Why has Nature planned all these contrivances to bring about cross-fertilisation? Mr. Darwin has clearly proved that plants which are the product of cross-fertilisation are both stronger in constitution and more prolitic in seed-bearing than those resulting from close-fertilisation. Another and more important result may have been designed, namely, the origin of new varieties and new species. If we consider how much the skilled nursery-man has effected, within living memory, in the direction of producing new varieties in such well-known plants as roses, strawberries, pelargoniums, primulas, and a host of other flowering and fruit-bearing plants, we may readily understand how pollen-carrying insects may in the countless ages that have passed have been instrumental in effecting changes of a similar character in plant development. That pollen-bearing insects such as bees and moths have been largely engaged in helping to clothe this earth of ours with some of its most beautiful forms cannot, I think, in the present state of knowledge be doubted. Devout minds, like that of Christian Conrad Sprengel, will perceive the wisdom and goodness of the great Creator, operating by means of natural agencies, in producing beautiful forms of plant life to delight the senses and supply the wants of His creature man. Even the atheist, on thoughtful consideration, must admit that the vegetable world, and especially the flower-bearing portion of it, affords ample evidence of design.-W. G. Wheatcroft (The Journal of Microscopy).

MY BEES.

BY MRS. REGINALD BRAY,

Author of 'Family Feats,' 'Ten of Them,' 'We Four,' &c. (Continued from page 514.)

CHAPTER III.—UNITING.

The next morning I hastened out to my bees, and stood gazing at my three straw skeps in a very dissatisfied mood.

I felt that when there were such hives as bar-frames no real lover of bees would endure such old-fashioned things as straw skeps.

'It seems easy enough; does it not, Watson?' I said,

as the latter drew near.

'What? bee-driving? Yes, ma'am. I should like to

see all these old hives got rid of.

'I wish I had not bought that new straw skep,' I said somewhat mournfully, for I had given a guinea for it; and as I wanted to make my bees pay, I felt it would be very extravagant to begin my bee-keeping in this somewhat reckless manner. Happy thought, 'Of course they will change it'.

I rushed for Neighbour's catalogue, and was soon engrossed in making up my mind which one I would have. I finally decided on one to hold ten bar-frames, price 11. 12s. 3d. I did wish hines were not quite so expensive,

but all one had to do to reassure oneself was to say, 'At least, I ought to get fifty pounds of honey,' and then work out a rule-of-three sum, fifty pounds at 1s, 6d. equal 37, 15s. Why I shall pay it off in no time; of course there are cheaper hives, but the best are generally cheapest in the end.

I decided that Watson should go up to London with the straw skep, and change it for the new har-frame, which was to be sent down. I felt it a trial that he could not bring it back with him, but as it would be decidedly cumbersome, and entail having a cab to the station, I controlled my impatience and managed to wait until it arrived the next day. How beautiful it looked. I brought it into the drawing-room and played with it as if it were a new toy. I pictured the frames filled with honey, and thick with clustering bees. I lost myself in a happy dream of delight, and was of no particular use or pleasure to my family for the rest of the evening.

The morning broke with a sunny, cloudless sky. It was impossible to have chosen a better day. Breakfast was a meal scarcely to be thought of, the household affairs were left to take eare of themselves. Orders were given that if even the Queen arrived, I was not to be interrupted; and, armed with smoker, scisors, and tape,

Watson and I were soon ready for our work.

One little boy of four years old, whom I may here say promises to be the only worthy son of his mother, entreated to watch. I was somewhat doubtful, for I did not wish him to run the chance of being stung.

'I don't eare, he replied; 'I don't care; no -not if I am

stung on the nose.'

I could not resist this, and accordingly stationed him behind a low yew hedge on a bank where I thought he would be quite safe. Others of the family came to look on at a respectful distance, lessons went to the wall for some time, and the servants were invited to 'come and see,' but they seemed to have too great a respect for bees to care to avail themselves very much of the privilege.

Watson and I had put veils over our heads, and I had carefully tied my sleeves at the wrist, but we were determined to do our work without gloves. I am afraid we were a little over-confident, we had an idea that our own bees would not sting us. It is impossible to lavish a wealth of affection upon any object and not expect an adequate return. The table with the frames and tapes for the combs was placed about three yards in front of the hives, and I had a chair there so that I might sit down comfortably and tie them in.

We gave the bees a puff or two of smoke. Very little, because as I said, we had great confidence in those bees, and I must say the first hive fully responded to our

trust.

The anxious moment came when Watson turned the hive upside down. I longed to do it, but it was so heavy that I knew I could not lift it. He placed it upside down in the pail, I hastily put an empty skep on the top, and the driving began. Watson did most of the rapping for I can assure you it is pretty hard work on a hot summer day; but every now and then I took my turn at that delicious 'thump, thump,' all round on the lower part of the hive. Every now and then we peeped in, and saw the bees running up as merrily as possible. At last, we had evidently got them all in the skep, and then standing them down as we had seen Mr. Joy do, we commenced cutting up the old hive and transferring the comb into the frames.

Oh, why had no kind friend warned us (as, my bee friends, I am warning you) to do all this part in some shed at a distance, for though the bees we had driven were behaving angelically, we were irritating the other bees which were yet for to come past endurance! Of course we should have given them some good puffs of smoke, so that they might have been employing them-

selves with their honey, but - we did not.

Our comb was soon all tied in, the frames put in the hives, and then came the moment to shake the bees in. 'I must do that part,' I cried, and with great pride lifted the skep. A sharp shake, a few puffs of smoke, and the bees had run down among the combs as successfully as under Mr. Joy's experienced hands.

We felt very proud of ourselves as we covered the hive up with a quilt, and turned our thoughts to the second hive, which we were going to unite with the first. Above all, we had not received a single sting.

Watson, as he had done before, lifted up the second hive, and put it in the pail, and I placed the skep over. At this moment I felt a sharp prick upon my foot. Not being so hardened to stings as I am now, I retired for a minute into the greenhouse to extract it.

These bees seem very nasty, said Watson, as I re-

turned. 'They have stung me once or twice.'

Then all at once, I cannot tell you why or wherefore, but those bees arose, and in a moment were upon us. The air was filled with infuriated—shall I say demons? it is the only suitable word. There was nothing for it but an ignominious flight, and we simply turned and fled.

I shouted to the children to rush to the house, for I dared not go near them. Watson and I rushed frantically between the thick rows of peas, as we knew that bees are not fond of anything bushy. He fled into the applehouse, where they left him in the dark, but they watted outside the door for him till he came out. I ran to the house. I felt two or three bees inside my veil, which is a most unpleasant sensation. I had not been nearly careful enough in tucking it in at the beginning. I tore it off hat and all, and was really greatly relieved when I got indoors to find I had only had six stings.

After a while, when I had recovered from the shock, I went to see after Watson. Alas! he had fared very badly; far worse than I had. He had not tied his sleeves at the wrist, and the bees had got up them and stung him fearfully. He got tired of counting the stings, but there must certainly have been over a

hundred.

However, like an Englishman who never acknowledges himself beaten, he was quite ready to return to the fray; and I do think we deserve some credit, for we went back and we finished those bees, and united them safely with the others. I will say we gave them a thorough good smoking, and we carefully tucked in our reils, and put on thick gloves.

I was none the worse for my few stings, but Watson was quite ill for a day or two, which I think is not to be wordered at. The only wonder is that he was not

much worse.

I must not forget to mention that one bee singled out my small boy, and actually stung him on the nose. His face swelled until it was a sight to behold; his eyes vanished almost entirely, and looked like slits. This was slightly mortifying to me, as my mother, who had not seen the children for some time, was coming that day. Of course I wanted the family to look their best, and it was hard to have one of them bearing a strong resemblance to a fat little porker.

As for the boy himself, he stoutly maintained that he did not care a pin; and so far from being frightened, he still remains the one of the family who takes a keen

interest in bees.

Now I hope that what I have said will not discourage young bee-keepers. There is not the slightest reason why they should be served as we were. I have driven bees since, and assisted on many occasions without having even been stang. The reason I have given the history of our misfortunes is that I think there is much to be learned from the failures of others, and I shall be very plud to feel that the perusal of them may impress upon beginners the great care which is required.

Our bees went on most prosperously, though our pleasure in them was a little damped for the time. It

was too late to put on supers that year, but I looked anxiously forward to the next summer and a plentiful harvest.

The chief trial I had was in leaving my bees. Every August we left the suburbs and went into the country for three months. I cannot describe how hard it was to bid farewell to my bees and leave them, knowing that when I returned in November the bees would be all shut up in their winter quarters, and I should see them no more till the spring.

(To be continued.)

Selected Query.

[3.]—Is that known as 'Good' candy switable for winter feeding, or for spring feeding? and how is it made and in what way is it given to the bees?

'Good' candy is excellent food for the bees during winter or early spring, but it is much too expensive for general use if made properly. Where a colony has no honey or syrup whatever, it is far superior to dry sugar or caudy, as these alone cannot possibly support a colony through the spring without the addition of a solutive, which cannot be obtained in sufficient quantities by condensation. Where a colony is simply short of stores, I should not use 'Good' candy. The candy is made by mixing icing sugar-this sugar is far the best, but expensive—with liquid honey until it is stiff enough to be moulded into any form. It is best given on top of cluster, first laying a piece of thin wood - such as dividers are made of, having several holes cut in it of a size to allow a bee to pass through—on the top of the frames, and then placing a cake of the candy, not more than half-inch thick, on top, covering a sheet of paper or enamel quilt over all and the quilts on that. If it is a very dry season and the bees have no honey, water must be given in the hive.—W. B. WEBSTER.

I have never used 'Good' candy. To appearance, it is much the same as a well-made sample of candy cake. It is highly spoken of in America as a winter bee-food, or for sending bees and queen by rail or otherwise. It is made by mixing liquid honey and the finest icing sugar in proportions so as to form a stiff dough, then placed over the frames the same way as emdy is used in this country. I should say it would be more expensive than candy-cake, and would serve the purpose no better than the latter.—William McNally, Glenluce, Scotland.

As I so very strongly condemn winter feeding of bees in any form, except sealed food in the combs, so I never use any candy for winter feeding. If bees have been so shamefully neglected as to require winter feeding, I believe candy as made from Mr. Cowan's receipt will keep some of them alive.—WILLIAM CARR, Newton-Heath Apiany.

Good' candy will do, but is expensive for spring feeding. Any other article but sealed stores can be called a substitute only for winter use, and a poor substitute at the best. To make the above candy, add only sufficient liquid honey to finely powdered loaf-sugar to make the whole into a stiff paste, thoroughly incorporated. Let the mixture be too dry rather than too soft, and apply the same above the frames immediately over the cluster.—Samuel Simmins.

The candy known as 'Good' candy is more suitable for spring food, and is made of honey and sugar. But for winter food I like a soft candy made of all sugar, and as this soft candy wants very careful making it should only be undertaken by those who have a knowledge of sugarboiling.—G. J. Buller.

For winter food I should prefer candy to Good' food, but for spring food I should prefer the latter to any

other. In making, it is more safe if the honey be liquid; when so worked up there is least fear of the food becoming too soft from atmospheric action, as when granulated honey is used. Your honey being in any suitable vessel, add thereto, finely powdered, best lump sugar, well mixing the two until sufficient sugar is added, so that you may handle the food without searcely soiling the fingers—remembering it is better to mix a little too stiff than too soft. The food may be given in a dummy or frame-feeder.—J. 11. Howard, Holme, Peterborough.

I find Mr. Cowan's recipe for candy very good, viz., a pint of water, let it boil, then stir in 6 lbs. of lump sugar: spread a piece of paper in large saucer and pour your candy into it. There is certainly the trouble of making the caudy, but I feel sure that any bee-keeper who has tried the early versus Porto Rico dry-sugar feeding will adopt the candy.—W. WOODLEY.

Good's Candy — so named from the inventor—is more suitable for spring than for winter food—being more liable to deliquesce than ordinary candy, when laid upon the frames. It is made by mixing very finely powdered sugar with liquid honey, to the consistency of stiff paste or dough. It is generally laid upon the frames beneath the quilts, but a better plan is to place it near the brood-nest in a hollow dummy-frame similar to the dry-sugar feeder, with a sufficient number of openings to allow the bees to obtain free access to the candy.— GEORGE RAYNOR.

Correspondence.

PATENTS RELATING TO APICULTURE. (580.)

[I368.] In September of last year I supplied you with a list of the patents relating to apiculture applied for during the years 1884, I885, and 1886, which you inserted on page 433 of the Bee Journal. I then promised that I would from time to time supply you with further information on the subject of these and future applications for patents.

In fulfilment of that promise I now send you for publication a complete list, showing those patents which have since been completed and 'sealed,' those 'abandoned,' and those since applied for. This list has been abstracted

from the official books at the Patent Office.

It will be seen that only eight of the patents have been completed and sealed, out of the nineteen for which patents were applied during the above three years, and thirteen abandoned,

The desire to protect inventions from being adopted and copied by others appears to be on the increase. The number of applications for patents during the present year is seventeen as against nineteen for the three previous years. None of these have been completed and

The time for lodging complete specifications has in several of these cases expired, but until the official list is published at the end of the year there is no ready means of knowing which of these are completed and which abandoned.

It may be well to point out that no person is justified i

in advertising anything as 'Patent' until the patent has been completed and sealed. In the case of a provisional acceptance, all that may be said is. Patent applied for.

WINTER-PASSAGES, &c.

[1369.] As a few remarks have been made in your valuable Journal on the above subject, I would like to give my plan, which I have found very successful, both in wintering and in working. I use a crown-board, and in making the hive I leave about three-sixteenths of an inch space over top of frames; and as bees invariably cluster at the top of frames, they can move with ease to any place they like, in fact I have noticed that the top bar of frames are covered with bees. I give them no extra covering except the watertight roof: I consider it a much better plan than disfiguring the combs by making holes.

My crates are made with slats of wood at bottom, the breadth of sections used except bee-space, and glass on two sides so that the sections are kept clean from comb or propolis; they are slid on the hive without killing a single bee, and if too much space is not given there will be very little comb built between crate and frames.—George Turner, Nov. 21.

HOW TO DO IT.

[1370.] Appears from Mr. Saddler's letter to be so very plain and easy that every bee-keeper ought, if next season is anything like favourable, to be able to say that he has done it. I have done it for several seasons with some stocks, but my average has not reached the 100 pounds yet. During the past season I have taken from twenty-seven stocks just over a ton of honey, average eighty-three pounds per hive. I use same size top-bar as does Mr. Saddler. He says, Throw metal ends away, and he ought to have added— and broad-shoulders too, for it is impossible to have either on bars to manipulate them as he describes. Our respected Editor, Mr. Raitt, and a host of others, in fact, most of the large honey-producers of the country, use the 15½ inch top bar. Is it not time, therefore, that the B. B. K. A. altered the rule, so that the standard top-bar shall be at least 15½ inches long?

It seems a strange contradiction for nearly all the large producers to use this bar and to write in this Journal in favour of it, and then for a beginner to be advised by this same Journal to use the 17-inch top-bar simply because that is the 'standard size.—ROBIN

Hoob.

THE NEW SECTIONS.

asks the question, 'Have the four-way sections been better finished than the two-way ones this year?' Briefly let me give my opinion. The greater part of the sections I have used this year were those having four bee-ways, and so far am highly pleased with them. The bees work them out and fill them quicker than the two-way ones; but wherein they excel most is the way they are built up to and on the section edge, thus giving a greater appearance of cemb surface. Bee-keepers

should see that the sections have passage-ways at least three-sixteenths wide, viz., a two-inch wide section should be one five-eighths at narrow part. The less the sections touch each other at corners the better; one quarter of an inch is sufficient. Having an ordinary well-made crate with sides full depth, four bee-way sections, and slotted zinc separators, I think we have the most perfect super procurable. Speaking of separators, I would never think of dispensing with these, whether the sections were one and a half or two inches wide. I tried three crates of the narrow size this summer without separators, and am glad I did not experiment further in that direction. The narrow sections with separators were better filled over than the wide ones.—WILLIAM MCNALLY, Glenluce, Scotland.

SEPARATORS.—THE NEW SECTIONS.

[1372.] Mr. A. Fryer's letter (1365) raises a practical point of considerable importance to comb honey-producers.

All the sections I had in use last season were the ordinary one-piece two bee-ways, with the exception of forty-eight of Lee's new pattern having four bee-ways, and so arranged to give through slotted dividers a vertical bee-

way between the sections from end to end.

It is generally understood that to secure perfectly built sections a rapid honey flow is a sine quâ non. My apiary is situated in the midst of a district consisting of a sandy soil, which, combined with the drought, caused the honey flow to be extremely slow and very limited in quantity. Without exception the one-piece sections of comb honey had an unusual number of pop-holes, in many extending the whole length of the bottom. My experience of working the thinner sections without separators coincides with Mr. Fryer's, as they are all bulged more or less so as to necessitate in packing for market the same relative positions they bore to each other in being filled. This disadvantage is quite sufficient to condemn the system advocated by some of discarding the use of separators. I also say separators for me with any size section.

In giving these thinner sections a trial the question arose, Will the bees fill a crate containing twenty-eight of the thin sections as quickly as a crate of twenty-one I-lb.; and if so, after debiting the extra cost of foundation, number of sections, and separators, required with the thin sections, will it pay from the £ s. d. point of view? My experience

gives a decided negative.

I now come to Lee's sections, and the difference in the perfect way these were filled out even to the very corners in comparison to the others, taken with the undoubted fact of their being more rapidly filled, was to me remarkable. On a close examination to my mind the reason was apparent. Through the vertical passages between the ends of sections, extending through the slotted dividers, a continuous cluster of bees was seen from end to end, very evidently secreting the wax for comb-building.

These vertical passages, combined with the slotted dividers, the four bee-ways, and the facility with which full sheets of foundation can be securely and rapidly fixed, taken together, convince me of their superiority, and I

shall not in future use any others.

With an apiary varying from 60 to 100 stocks, situated on the borders of an immense area of heather, the strength (which the folding one-piece sections lack) of Lee's sections to bear the strain of extracting is another

point of considerable advantage.

Relative to sections without separators, it may be worth repeating that in the large Canadian Exhibit at the Colonial I took special notice that out of many thousand sections worked without separators not one in ten could be found but what the face of the comb would touch a plane surface and always be liable to get bruised.—W. Soar, The Apiary, Valley End, Chobham, Surrey.

AFRICAN BEES.

[1373.] The bees which are natives of Africa are but little known to most of the readers of the B. B. J.: they may have heard of them being carried in boats on the Nile, and there the information ceases. Nor are they described or ever mentioned in any of our 'bee-books, in fact, little attention has ever been paid to them, if indeed any of our bee-men have the knowledge. Now, having in the course of my reading met with some incidental descriptions of these African bees and their manners and customs, I have copied out the most interesting from two volumes that may possibly not have fallen in the way of all of the readers of the B. B. J., and give them below. Both are from trustworthy authorities—one being the Life of Bishop James Hannington, who was murdered in East Equatorial Africa in 1886; and the other, the Heart of Africa, by Dr. Georg Schweinfurth, the German imperial naturalist. From the extracts I append, it will be seen that the African bee resembles the Syrian in her appearance and ferocious temper. The quotations give graphic pictures of the enormous colonies that would seem to characterise the race, for I have never heard of any other honey-bees dwelling together in such prodigious numbers.

Dr. Schweinfurth's experience was gained on the Nile about eleven hundred miles south from Alexandria, just outside the boundary of Egypt proper. It is evident that the Doctor's translator is not acquainted with the natural history of bees, or he would have avoided some curious renderings. He writes, vol. i., p. 73:—

'A place was soon reached where the stream takes a remarkable bend, and proceeds for eight miles in a northeasterly direction. This place has the singular name of Dyoorah-el-Esh, or the sack of corn. Now, as the northeast wind, of course, was adverse to any north-east progress, it was necessary that the boat should be towed by the crew. As the rope was being drawn along through the grass on the banks, it happened that it disturbed a swarm of bees. In a moment, like a great cloud, they burst upon the men who were dragging; every one of them threw himself headlong into the water, and hurried to regain the boat. The swarm followed at their heels, and in a few seconds filled every nook and cranny of the deck. What a seene of confusion ensued may readily be imagined.

'Without any foreboding of ill, I was arranging my plants in my cabin when I heard all around me a scampering, which I took at first to be merely the frolics of my people, as that was the order of the day. I called out to inquire the meaning of the noise, but only got excited gestures and reproachful looks in answer. The cry of gestures and reproachful looks in answer. The cry of "Bees! bees!" soon broke upon my ear, and I proceeded to light a pipe. My attempt was entirely in vain, in an instant bees in thousands are about me, and I am mercilessly stung all over my face and hands. To no purpose do I try to protect my face with a handkerchief, and the more violently I fling my hands about so much the more violent becomes the impetuosity of the irritated insects. The maddening pain is now in my cheek, now in my eye, now in my hair. The dogs from under my hed burst out frantically, overturning everything in their way. Losing well-nigh all control over myself, I fling myself in despair into the river; I dive down, but all in vain, for the stings rain down still upon my head. Not heeding the warnings of my people, I creep through the reedy grass to the swampy bank. The grass lacerates my hands, and I try to gain the mainland, hoping to find shelter in the woods. All at once four powerful arms seize me and drag me back with such force that I think I must be choked in the mud. I am compelled to go back on board, and flight is not to be thought of.

In the cooling moisture I had so far recovered my self-possession that it occurred to me to drag a sheet from my chest, and thus, at last, I found some protection; but I had first gradually to crush the bees which I had enclosed with me within this covering. Meantime, by great self-denial and courage on the part of my excellent people, my large dog was brought on board to me, and covered with cloths; the other, an animal from Khartoom, was unfortunately

lost. Cowering down convulsively, I lingered thus three full hours, whilst the buzzing continued uninterruptedly, and solitary stings penetrated periodically through the linen. Every one by degrees became equally passive as myself; at length a perfect silence reigned on board, the bees subsided into quietness. Meanwhile, some courageous men had crept stealthily to the bank, and had succeeded in setting fire to the reeds. The smoke rose to their assistance, and thus they contrived to scare away the bees from the boat, and setting it affoat they drove it to the other bank. Had the thought of the fire occurred at first our misfortune would have assumed a much milder character, but in the suddenness of the attack every one lost all presence of mind.

'Free from further apprehension we could now examine our injuries. With the help of a looking-glass and a pair of pincers I extracted all the stings from my face and hands, and inconvenience in these places soon passed away. But it was impossible to discover the stings in my hair; many of them had been broken off short in the midst of the fray, and remaining behind produced little ulcers, which for two days were acutely painful. Poor "Arslan" was terribly punished, especially about the head, but the stings had clung harmlessly in the long hair on his back. I was really sorry for the loss of my nice little dog, which was never recovered, and in all likelihood had been stung to death. These murderous bees belong to the striped variety

of our own honey-bee.

A mishap like ours has been seldom experienced in the waters of the White Nile. Consul Petherick, as his servant informed me, had once to undergo a similar misfortune. Our own grievance was not confined to ourselves: every boat of the sixteen which that day were sailing in our track was pestered by the same infliction. No imagination can adequately depict the confusion which must have spread in boats where were crowded together from sixty to eighty men. I felt ready in the evening for an encounter with half a secre of buffaloes or a brace of lions rather than have anything more to do with bees, and this was a sentiment in which all the ship's company heartily concurred. I took my quinine and awoke refreshed and cheerful, but several of the ill-used members of our party were suffering from violent fever. My own freedom from fever might perchance in a measure be attributed to my involuntary vapour bath. I had been sitting muffled up for some hours in my wet clothes through the heat of the day, and no vapour-bath more effectual could be contrived. Among the crews of the boats which followed us there were two deaths, which ensued as the result of the injuries which had been sustained.

Bishop Hannington's adventure occurred 700 miles farther south, between Zanzibar and Lake Nyanza, and not far from the latter. His biographer says:—

On Tuesday, September 8th, 1885, the long caravan was again in motion. The greatest care had now to be taken to guard against an attack from the rear. The path skirted the forest for a long distance, and every bush concealed a lurking foe. Mr. Thomson's caravan was here set upon and very roughly treated, while some of his cattle were killed. Mr. Jones writes: "As we were descending a steep track a rush was made upon the sick who were being carried in the rear by a host of Wa-Kikuyu. The men in charge of the sick fled, but they, strange to say, revived and flew for their lives, escaping with a few blows from clubs. When we heard the alarm the Bishop and some of our men ran back to the scene of action, and a volley put the enemy to flight. At the end of the plain there is a fine tree, towards which all our men at once made to rest beneath its shadow. They had scarcely sat down when they were attacked furiously by an enemy worse than the Wa-Kikuyu. A vast swarm of bees came down from the tree and settled upon the caravan in thousands. The men ran for their lives, many of them dropping their loads. The hecs covered the ground for some 200 yards in every direction from the tree. The Bishop bid the men who had dropped their loads return and fetch them, but though they tried they found it simply impossible to do so. Many of them actually cried like children, and called upon their mothers; every one was stung more or less. The Bishop made the attempt to reach the deserted loads himself, but was driven

back. He then draped himself in his mosquito-curtains and tried again, but before he got the loads he was stung most pitifully. My own eyes were so closed by the swelling from stings that I was almost totally blind for two days."

H. W. LETT, M.A.

PARALLEL VERSUS RIGHT-ANGLED FRAMES.

[1374.] This, at present, is one of those vexed questions we can all agree to differ upon, as it is almost entirely a matter of personal preference. We can, however, differ to agree that there is one plan of the two (having a balance of evidence in favour of it) which should be adopted or adhered to, and the other discarded.

In the first place, the support given to the right-angled theory is almost overwhelming by its influence. Mr. Cowan heads the list by arranging on this principle perhaps the most complete bee-hive extant—the Cowan—and, in his indispensable pamphlet on wintering bees, supports his preference by insisting on provision being made for sufficient and proper ventilation, without cold draughts, as a necessary condition for successful wintering. Next follows Mr. Cheshire, who arranged his hive on the same plan, but I perceive by the illustrations in his new work that he has changé tout cela, and adopted the parallel system. Then comes Langstroth, and lastly our own 'Useful Hints,' who, on p. 379 B. B. J., follows under the standard of thorough ventilation by the right-angled method.

Although the subject has been well discussed in past numbers, current inquirers will not be at the trouble of wading through ancient history; and even if they did, they would be scarcely able to come to a definite decision amongst such a mass of conflicting evidence from highly respectable authority on both sides. They would have to think it out for themselves even then. At any rate such was the case with myself, the result being that I decided to convert my hives from the mixed styles of arranging frames to broad shoulders placed parallel. This was done twelve months ago with the best results in wintering. I have not the presumption to place my opinion against those of the giants in beekeeping above named, but as the question was one upon which the doctors disagreed, I, a poor patient, went to Nature for her simples, and, finding them beneficial, adopted them in the meantime. I now give my ideas in favour of the parallel plan, seeing that it is truth alone we seek-the right successful way.

For some years I paid much attention to plants from various latitudes and altitudes, and I always found (as we can find in all cultivation under artificial conditions) that the more I imitated nature in the surrounding conditions of the plant, the greater was the success; and, conversely, the more nature was interfered with, the more numerous were the failures. I take it as a law in both animal and vegetable physiology, we may keep. Alpine plants in gardens, exotics in greenhouses, and bees in hives, but the closer we copy the fundamental conditions of their habitat the better they thrive.

Question is, How do bees build when left to themselves? They will build so as to hide the queen, keep the direct rays of light from striking the brood-combs, and conserve as much heat and freedom from draught as possible; they will also commence building as far away from the entrance as possible with these objects. These are theoretically their proceedings in a hollow tree or a cleft amongst tooks. Their conduct, practically, can well be ascertained in the case of swarms in skeps, about which, by the way, there is some difference of opinion. The most recent evidence is given by N. P. Lochill (p. 354), who says he has seen over a hundred skeps this season and not one had the combs rectangular. Mr. Webster (p. 432) went into his apiary and found a strong lot of evidence in favour of the parallel plan. In this month's *Record* Mr. R. R. Godfrey (no mean authority) states that only three out of seventy-eight skeps he has examined this season had their combs built straight to the entrance.

Next question is, D bees require a thorough ventilation, or is the bad air to escape by the doorway? Let us bore a hole anywhere in the hive and ask them; they answer by filling it up. This is simplicity itself, and one can successfully imitate them in their objections to erevices and openings by wintering down with American cloth quilts, shiny side down. We tuck our quilts in, use chaff-covers, dead-air spaces, and what not, to keep bees warm and dry in winter; why should we then permit unwarmed air (which must enter) to circulate through the very heart of the clusters, and when February and March come, through the very heart of the brood-nest also, and this when the temperature should be 20° to 30° higher inside than out. Thus do these disc-like currents reduce the temperature at the risk of chilling broad and killing bees. We are directed to examine in early spring as to condition of stores, and turn up the edges of quilts on right-angled frames, therefore, in a few seconds, the whole brood-nest is bathed in a current of external temperature. With parallel frames no such thing happens, for the current passes along the edges of the combs. Again, when snow lies on the ground and is struck by the rays of a winter's sun, the sloping alighting-board allows dazzling rays to be reflected up amongst every seam of bees, especially as entrances are to be left open full width. With weak stocks one is compelled either to use a dummy-board on each side of the right-angled frames, or cram them to one side, when bees can and do get by their thousands (on returning from cleansing flight) along the entrance into the space behind the dummy, to be starved to death. Another objection I have to right-angled frames is, that it is difficult to manipulate at the side of hives, especially if these be arranged on long stands, besides disturbing and attracting the notice of all leaving or returning bees when in full work by operating at the side, whereas by the parallel method we can quietly roll back the quilt, and insert or remove frames at pleasure, without the necessity of using smoke or any other frames than those exposed; we can even work slowly up to the last few frames with very little excitement, the quilt over the front frames remaining tight and propolised down. Another advantage of paralleled tersus right-angled frames is that we can have a super or two of sections on a hive, and if there be a likelihood of swarming give timely relief by adding a sheet or two of foundation at the back; these may be renewed at pleasure or used for extracting. By this means we accommodate the daily increasing population without disturbing either brood-nest or sections. Further, it is generally understood that bees will store surplus in the furthest obtainable space away from the entrance, so that filled parallel combs may be found in the rear, instead of half-filled right-angled combs. 1 also find my last sheet of brood facing doorwards with the opposite side of the comb well stored with honey, which may be extracted without injuring brood or contaminating honey. When working on the right-angled system I found brood and honey stored in anything but an orderly

The question of encouraging the spread of foul broad by practising the parallel plan is a very broad one and separate from the present. I know there is much to be said on the other side, but I will conclude with the quotation given by 'Useful Hints':—' Let each man be fully persuaded in his own mind. Prove all things. Hold fast that which is good.'—R. A. H. Grimshaw, Horsforth, near Leeds.

BEE-KEEPING IN SOUTH AUSTRALIA.

[1375.] Your correspondent Mr. Campbell in his letter (1241, page 494) casts some considerable doubt on the accuracy of the reported yield of Messrs. Coleman & May's apiary at Mount Barker. I find on page 439 of the Canadian Bee Journal for 1885 a long account of this same apiary, cut from the Adelaide Observer, which states that twenty-seven hives produced six tons of honey in 1884; the best hive giving 414 lbs. of extracted honey, with an average of 11½ lbs. a day for four days in the height of the season, and for some time maintained a record of 60 lbs. a week. Another collected 112 lbs, in three weeks. By natural swarming the twenty-seven hives increased to 100 between 1st October and 31st January. The above gives an average of about 498 lbs, per hive spring count. Evidently the Colonials do resemble the Americans in having a good honey country. I certainly see no reason to think they are trying to 'chaff' the Britisher. - W. M. GRAHAM, Edmonton.

[The above figures will also be found in the *Journal*, Vol. XIII., p. 352.—ED.]

BEE DISEASE.

[1376.] A bee-keeper's letter (1366) in last week's Journal reminds me of the singular effects of a sting that I received last summer. It was just beneath the eyebrow, where it joins the nose, and the pain was very acute, as in the case of other stings about the eyes. As the first pain subsided I was seized with a violent paroxysm of sneezing—sneezing about a dozen times right off. I then tried to go on with the manipulation upon which I had been engaged, but I had to give it up, as I kept on sneezing so constantly. I covered up the bees as well as I could (between the sneezes) and retired to the solitude of my dressing-room with all the symptoms of a violent cold in the head, and my face swelling freely. Alkaline drinks, inhaling ammonia, and other remedial measures, had no apparent effect; I could only sit in my chair, and sneeze and blow my nose alternately. Not only that, but I gasped for breath. The inside of the throat seemed to swell up, and the blood also rushed into my head. The cold in the head lasted over the next day, and then subsided.-T. F. L.

DISTRICT WORK IN GLOUCESTERSHIRE.

[1377.] I think it will soon he forr years ago that the Gloucestershire B.K.A. sent Mr. C. Browne to lecture here; that lecture did a vast amount of good, in showing what can be done with bees under the improved method of bee-keeping. After the lecture a local Society was started, the numbers increasing every year, till now we have twenty-nine members. I hope it will not be out of place to add, that until this year the parent Society took no notice whatever of us except receiving our subscriptions. I am pleased to state that this year we have been more leniently dealt with, in that the parent Society have placed at our service an extractor (Meadows' guinea patent), which, by the way, does its work exceedingly well. We also get two Bee Journals for distribution, which are much appreciated.

Now, a few words on our doings. We have meetings every fortnight during the summer; these meetings are held at one or other of the members' apiaries, when there is generally some practical work to be done. In the winter we have monthly meetings, when papers are read and discussions follow on the different subjects. We also during the winter get our orders together, and co-operate in sending them to the best and cheapest manufacturer; in doing this, we obtain our goods much cheaper than by sending orders individually.

On September 27th we held our second annual supper, which was served up in one of the case-making rooms of Messrs. Penley & Son, pyrotechnists. The chair was

taken by Mr. Penley, jun. After supper, Mr. Slade, Hon. Sec. to the Association, gave a very able address on 'How to Increase the Usefulness of a Local Society.'

This year three members have gone in for honours, obtaining two first prizes and three second prizes, and one third-class certificate.—A. J. Brown, Local Secretary, Bradley, Wotton-under-Edge, Gloucestershire.

Der Praktische Imker, Lehrbuch der rationellen Bienenzucht auf beweglichen und unbeweglichen Waben, von C. J. H. Gravenharst. Vierte, vermehrte und ver-besserte Auflage, mit III. Abbildungen in Holzschnitt und einem Titelbilde. (Braunschweig, 1887: C. A. Schwetsche und Sohn.) This, the fourth edition of the Practical Bee-keeping, has been entirely revised and rewritten by our old friend Mr. C. J. H. Gravenhorst. The author is the editor of the Deutsch Illustriertes Bienenzeitung, one of the leading German bee papers, and being a practical bee-keeper he knows what he is writing about. In these days when every one who begins beekeeping thinks he ought to write a book, bee literature such as it is, is plentiful enough, and the difficulty, for those who are not experienced, is to discern the evil from the good. Here is a work proceeding from a writer who is thoroughly acquainted with the subject, and who has consciously neglected no part of the literature connected with it. It can safely be placed in the hands of every one, for although Mr. Gravenhorst uses the Bogenstulper, a hive in the use of which he has become an adept, he is impartial, and his views are broad enough to cause him to describe the practical working of other hives and systems. As a specimen of fairness where we might expect bias, we may point out that besides the 'Bogenstulper' no less than fourteen other hives have been described and many illustrated, such, for instance, as the Langstroth, Heddon, and others. Beekeeping has made great strides during the last few years, so that what was recommended in I883 has had to give way to more modern ideas. The author seems equally well versed in our English, as well as American methods, which he clearly describes, without bias or prejudice, so that the work will be found useful to every bee-keeper. He describes the Luneberg straw hive used by the Heath bee-keepers, and gradually works up to the moveable comb hive, showing the great advantage of this over the old system, and demonstrates that, not withstanding their great skill, the hands of the Heath bee-keepers are tied by their adhering so tenaciously to their old straw hives, and that the time must come when only moveable hives will be used. The number of pages has increased from 252 in the third edition to 280 in this, and the engravings from 52 to III. Although, as the title implies, the book is a practical one, the author recognises the fact that the bee-keeper can only arrive at the best results when his practice is based upon a knowledge of the natural history of the bee. Bearing this in mind he treats of the theory in simple language and just sufficiently to assist the bee-keeper without wearying him, as so many books do. What we know of the author and his writings is sufficient guarantee that the information he gives can be relied upon. We are glad to see that he describes and illustrates, on page 115, the stomach mouth of the honey bee and that he agrees with Schönfeldt as to its uses and functions. On page 11% a correct illustration is given of a comb. In this there are cells of almost every shape, and they correspond to many of those we have cut from combs in England, on the Continent of Europe, and even during our rambles in North America this year, some of which we were able to show at our last Conversazione. Not the least interesting feature of the work is the introduction of the portraits of some of the great bee-keepers. Amongst these are Dzierzon, Kanitz, Weygandt, Butleroff, Berlepsch, Schönfeldt, Langstroth, and others. In the sixth chapter, amongst other things, the various diseases of bees are described.

Hilbert's remedies for foul brood, as well as the carbolic acid treatment described in the former edition, as practised in Germany, are also given. The work is well printed, and the engravings are equal to the justly celebrated ones of the Illustriertes Birnenzeitung, and show extreme care in their production. We congratulate the author on having the assistance of so excellent an artist. We think it highly flattering, and a sufficient recommendation of the work, that it has reached its fourth edition in a country where more books and bee-papers on bees are published annually than in any other country in the world. Our German reading friends will find in Der praktische Inker a work which will well repay their study, being that of a man who stands in the highest rank as a bee-keeper in Germany, and which has now become a standard of reference on all matters connected with bee-keeping. We hope the present edition may meet with the same favourable reception as that accorded to the former ones, and that it will tend to promote the more advanced methods of bee-keeping.

CEYLON FOLK LORE.

THE HONEY-DROP RIOT.

' How great events from little causes spring.'

A Mussulman went to a shop To buy a pot of honey:

This Mussulman he spilt a drop

When counting out the money.

Upon this drop did light a fly, And as she sucked the nectar,

A lizard that watched hard by

Came out and straight attacked her.

The shopman's cut was prowling round, And quick the lizard sighting,

She sprang upon it with one bound,

Through lungs and liver biting.

The Mussulman's lean, hungry dog Beside the door was lying;

But up he sprang, and all agog

(The wretched cat espying), He seized her with his great long teeth,

And heedless of her squealing,

He shook her till she ceased to breathe, And was devoid of feeling.

The shopman to the rescue flew,

And taking up a cleaver,

He chopped the poor dog clean in two. And forced him thus to leave her.

The Mussulman his 'tulwar' drew-Than he no man was bolder-

He cut the shopman's head right through,

And clove him to the shoulder. A little girl was passing by.

Who saw the horrid murder;

She ran, and as she ran did cry Till all the city heard her.

They rushed from east, they rushed from west,

With spears, or swords, or daggers: Each arms himself as he can best,

And down the street he swaggers.

The Magistrate doth hither ride,

With 'posse comitatus,' And in the ranks on either side

He finds a vast ' hiatus.

A hundred here, a hundred there,

Upon the ground are lying, And mothers weep and tear their hair,

And frantic wives are crying.

And all because a Mussuhaan Once hought a pot of honey,

And spilt a little from his can

When counting out the money.

R. T. Andrews,

Echoes from the Hives.

Honey Cott, Weston, Leamington, November 28th,—During the month now drawing to a close we have had some rough, stormy weather, which has given me a severe cold, and confined me to the house, so that I have had to content myself with looking at the hives from the window. There have been some sharp frests for several days, but this last week it has changed again, and bees are to-day, and have been for three or four days, very much on the wing, thus giving them a chance to better stand a long spell of stormy or frosty weather, which in all probability will soon be here. Naughty tomtits here again.—John Walton.

NOTICES TO CORRESPONDENTS & INQUIRERS.

A. Dee.—Entrances.—You should have your entrances open to 6 in. as soon as there is no longer any danger of robbers. Give up the zig-zag slides, as they are the cause of your losses. We have since 1884 always placed our frames 13 in. from centre to centre for the winter, and we believe that our uniform success in wintering is due in a great measure to this. There is nothing better than chaff for placing between hives and outer casing. When our bottomless box is placed on the top of the frames, chaff is poured into it, and is allowed to run over and fill the space. No patting is required.

A DISHEARTENED ONE.—Hives broken into.—In the evening push some crushed camphor through the entrance of each hive. The next evening carefully carry each hive into a warm and well-lighted room. Avoid any shaking, Let them stand half an hour to quieten, shading the entrances. Open up No. 1, shift the combs about 4 in. apart. Use no smoke if you can help it. Ascertain the queen is there, using a feather dipped in a very weak solution of Calvert's No. 5 carbolic acid. Repeat this process with No. 2, but remove the queen; then place the frames having bees on into No. 1 alternately with its own, making room for those which will now be removed from No. 3 in the same manner after its queen has been removed. Let the light well in between the frames before introducing the strange ones. Replace on stand; put a board before the entrance for the bees to mark when next they fly.

Expectancy.—Honey.—We consider the sample of honey to be pure and of good quality, and it is our opinion that it has been gathered from clover and wild flowers,

Replies to 'Useful Hints' Tomtits Problem have been received from Eric Lewis; Samuel Peter Kirkby; Darcy Grimshaw; T. A. Mackereth, jun.; G. W. Wells. These have been forwarded to the compiler of the 'Hints' for him to deal with.

Received from Messrs. Abbott Brothers several samples of honey jars. These are well designed, ornamental, and attractive to the eye. They will be found very serviceable for table honey.

COWAN'S GUIDE BOOK.

NEW EDITION of this Work will shortly be published. Intending Advertisers must forward Copies of their Advertisements during the present week.

ANOTHER HONEY COMPANY.

Most of the readers of the *Bee Journal* are familiar with the work that has been achieved by Mr. Simmins, by his hand and by his pen, for the advancement of apiculture generally, but chiefly in his apiaries in Sussex. He has had the foresight to perceive the growing capabilities of the beckeeping industry, and he has had the energy to assist in its development, and so to make it subservient as a means of livelihood. It has given us much pleasure to note the gradual extension of his business from his small apiary at Crawley to what are called the Great Sussex Apiaries; and now it would appear that the time has arrived when it is considered advisable that there should be a further development, and that it should enter upon a newphase.

We see, from our advertising columns, that the Great Sussex Apiaries, the sphere of Mr. Simmins' labours, will soon be converted into a Limited Liability Company, for the purpose more especially of extending the honey industry. The other ramifications of the business conducted by Mr. Simmins, namely, the trade in queens and the Factory at Brighton, will also be taken over by the Company. We gather that these will continue to be conducted under the supervision of Mr. Simmins; and we cannot entertain a doubt but that, if the same energy and business tact that have up to the present time been noticeable in the conduct of Mr. Simmins be continued when employed in a larger and wider sphere, the operations of the Company must be attended with a great measure of success.

The present appears to be a favourable opportunity for the extension of the honey industry. The value of pure honey, both as food and medicine, is now more generally recognised. Pure British honey has proved itself equal in quality to that of any other country on the face of the earth. The amount of honey imported into this country, when taken in connexion with that exported to other countries, is not (as we hope to demonstrate in an early issue) so large or formidable that it may not be easily overtaken by bee-keepers in this country when larger tracts of land are devoted to the production of honey-producing plants, and when, at the same time, those engaged in the work make a

fuller use of all the experience that has been gained and take advantage of the better appliances that have been manufactured of late years.

We deeply regret the continued depression of the agricultural industry. It is distressing in the extreme to see extensive farms lying waste without occupants. But the farmers' extremity may be the bee-keepers' opportunity. These unoccupied farms in many cases may be had at very low rentals, and it is a question which exercises many minds, to what extent these and may prove available for the extension of the production of honey. We are of opinion that at the present time Companies, with capital and with experienced persons at the helm, have before them an opportunity for progress in apiculture which should not be permitted to pass by.

We tender to Mr. Simmins and his fellow-workers our best wishes for the success of their new undertaking.

'BLEEDING' SECTIONS.

'Bleeding' sections are the bee-keepers' bane in winter. In summer his troubles are more numerous; they follow one another in more rapid succession: he is busy in head, heart, and limb. Always on the alert, with his faculties more or less at a tension, his cares are varied-'hee' cares I mean, of course—so that one more or less makes comparatively little difference. First, there is the weather; next, there is the honey flow; then comes a real, solid grievance in the shape of a swarm led off by his best queen, and just as they have nicely taken to the sections! Perhaps, to further aggravate the case, the whole lot has absconded, whither it is impossible to follow. Then the dealer has neglected to send off by first train the new hive you wired for yesterday, and a further supply of sections and foundation with it. Some of your stocks want another tier of sections on or they will make up their minds to swarm, and the season will be gone, and with it your only prospects of profit. Bother that dealer! I shall have to give my orders elsewhere next year. But who is that that has stopped at the garden-gate? It is the railway delivery van. Good! But as usual the hive is smashed, and the dealer is out of thin foundation; will forward it to-morrow! Was there ever anything so tiresome! And so you fume and frown, and get hot, and want a febrifuge, and the dog has to get out of the path pretty sharp, and then you are called to tea, and go with bad grace and

worse appetite, because you are anxious to get back to the 'blessed bees.' Bother making toast! I cannot stay for that. Give me some bread and butter; I want to go! And the patient wife looks up to see what is the matter.

But it is winter and the days of fogs and damp. The joys of harvest and the pleasures born of counting up a goodly array of well-filled sections have nearly obliterated the remembrance of the small troubles incidental to the honey-glut, and the troubles and anxieties of 'spring dwindling' were yet unborn; when, lo! on examining my sections that I had held over for a better price, I find they are all spoilt by 'bleeding.' 'Why is it, and what can I do with them?' This is the wail of woe that eomes to me from amongst a shoal of smaller troubles and difficulties. What help or consolation can I render? Sections will sometimes 'bleed' when filled with thin, watery honey; privet, for example, but it is highly improbable that any such has been gathered this dry season, when honey is unusually dense and ripe. Then, again, the thinner the sealing the greater the liability to 'bleed 'at all times. Happily the eraze for very thinly sealed comb-honey has subsided considerably during the past five years. Sections should never be removed until fully sealed; but 1 presume most of my readers are aware that if allowed to remain on too long the bees not only darken the surfaces of the comb by the heat from the hive and their traffic over it, but that they thicken the eappings of the eells also, by adding a second coating to give additional strength to the sealing, and very frequently by drawing long streaks of propolis across the surface of the sections as well. Consequently, for appearance, sections require to be taken as soon as practical, but for utility they require to be left on the hives as long as you possibly dare without endangering the pearly whiteness of the sealing.

The most fruitful source of 'bleeding' is damp—cold, damp air. We may learn a lesson from the bees. They make their larder on the top and outsides of the eluster, consequently in the coldest and dampest parts of the hive; to prevent 'bleeding' they strengthen and thicken the sealing of their stores in autumn. We, anxious to secure our share of their labours, take the sections as soon as practicable; consequently they are liable to damage by damp, as we discover to our grief. The remedy is to keep them dry, not necessarily warm, but dry; and exclude the air and the rapid changes of temperature in this elimate from them as much as possible. My method of storing mine may assist some of you. house is small, and the store-room accommodation in it is limited; consequently when I removed into it, I proeured some boxes from the groeer's, each will hold about 130 sections. I cover the bottom of each box annually with a clean sheet of paper. On this 1 lay strips of wood, $\frac{1}{2}$ in. \times 1 in. On these a layer of sections, having cleaned them all free from propolis; on the layer of sections another sheet of paper, a set of strips and another layer of sections, and so on to a third layer, and a sheet of paper to finish, and a close-fitting lid with plinths all round, each box holds three layers, and are fairly secure from noxious taints and flavours. But perhaps you will be inclined to think the last remark unnecessary. Very well, stand a section by the side of some rancid butter or game that is getting 'high,' or any food with a strong flavour-eheese for example —and note the results. As a further precaution, I stack my boxes in a dry place; the only available one is in a recess beside the fireplace in a bedroom. The room seldom or never has a fire in it, but the room underneath has one every day during winter, so that I am secure from damp.

Who of us has not noticed the shop-windows in towns 'steamy' with condensed vapour in winter? We must remember the glass is ir this state because it does not absorb moisture; all the other articles in the

window, even the woodwork, if unpainted, is absorbing moisture, and thus have a drier surface, while the glass is in a state of saturation. Few things absorb more readily than honey. Having absorbed to its utmost capacity, and, as I have explained, the sealing being thin, it gives way under the strain put upon it, commences to 'bleed,' and for sale purposes is spoilt as comb honey. Sections so exposed should always be hermetieally sealed, to merely enclose them in eardboard boxes is not sufficient. Woodley's eases are far preferable, or each should be glazed and enclosed in stout 'glazed' paper, as I have described in previous Journals. If so protected they keep well for an ordinary period, suffieient to dispose of them; and persons with slow sale should be careful not to expose too many at one time, but keep their reserve stored in boxes. Some of our brethren with brains fertile in inventive genius have been giving their thoughts in the direction of eases for hermetically sealing sections, with results which we shall see presently. So far as to prevention. Now as to cure. Alas! I know no remedy; to advise you to 'brush them over with a coat of melted wax' would be to tempt you to a trial of your patience that I should not eare to be responsible for the results. Were I the unhappy possessor of a quantity that were so spoilt in appearance as to be unsafeable for sections, I should try uncapping and extracting, and save the combs in the sections to be refilled next season. If that is not practicable, I would melt them down at a very low temperature, allow the wax to cool, and skim it off the top and sell as extracted. Our Canadian friends had to treat many so last year at the Colonial.

As to cure, I fear the ease is hopeless; because if I knew how properly to seal sections that have badly 'bled,' so that the sealing could not be detected by the minitiated from 'bees' work,' I would eross the Pond at onee, start a honey-factory without the aid of bees, win friend Root's 1000 dollars, and cease to be—

AMATEUR EXPERT.

USEFUL HINTS.

Weather.—Oceasional showers, a good deal of fog, frosty nights, and sunless days, are about what Englishmen expect to find in the weather reports for the month of November—the wretehed, miserable month, the month of suicides, of depression mental and physical—is once more inscribed on the 'hoary register of Time.' Launched well into December, with Christmas and New Year's Day close upon us—the cheery times of 'eards,' of good wishes for a happy future for our friends—let us rejoice in the hope, which ever springs eternal in the breast of man, that better times are in store for all, yea, even for the sorely depressed and suffering agricultural community, in the midst of which our pursuit as bee-keepers has chiefly east our lot. Even honest Hodge, with his half-dozen hives, cow, couple of pigs, few head of fowls, and two acres of land in prospect, and in which we hope soon to see him in possession, may cheerfully look to the future. Would that he could 'read, mark, learn and inwardly digest' a most excellent article on this and kindred subjects in the November number of the National Review, entitled 'The Decay of British Agriculture,' by W. J. Harris,—an article which we strongly recommend

to the careful study and deep thought of all our readers.
WINTER FLIGHTS of our bees on bright days should be encouraged by every means in our power, as nothing conduces more to the health of colonies than a good cleansing flight. And what are these means? Removal of hive-eovers to allow the sun's rays to fall directly upon the quilts during hours of sunshine; substitution of dry and warm quilts for damp cold ones; a southern aspect for the hives; and, lastly, pace our old friend Mr. Grimshaw (vide his letter 1374), hive frames ranged on the right-angled cold system, admitting 'the

direct rays of light'-and sunshine-' to strike the brood combs,' and by increased temperature to entice the bees We deprecate very warm interiors with very cold exteriors, which must create evils patent to all. In regard to currents of air chilling broad and bees the latter will provide against this by arranging the cluster according to circumstances. This by the way, as we have no intention of rearguing the vexata quæstio of parallel v. right-angled frames. In addition to the authorities quoted by our friend we should be greatly edified by the views on this subject of such veterans in the science as Messrs. Neighbour, Carr, W. B. Carr, Hooker, Scott, Raitt, and others who have a life-long experience, if only they would give it in the columns of our *Journal* for the benefit of all. On *our* side we claim all the foremost of our transatlantic brethren-all the most prominent of our European fraternity—and, above all, we claim the results of our system in the hands of such men as 'our' Mr. Cowan, Mr. W. B. Carr, and American apiarists, in the enormous yields of honey after safe wintering produced thereby. As regards the skep argument, we attach to it but little weight, but our own experience is, that as a rule the combs are built from back to front whenever the skep-base is placed perfeetly horizontal by spirit-level; and afterwards, if the back is raised one inch, the combs are always so built, cateris paribus, for bees as well as other creatures whilst dwellers on this sublunary sphere must build as gravitation compels. Now the skep in these enlightened days is par excellence the hive of the cottager—the uneducated—and how many of those skeps upon which Mr. Godfrey and others report were horizontally placed when the swarms were installed in them? Certainly we should imagine not one in a hundred! If one side of a hive is slightly raised, however slightly, gravitation compels the bees to build their combs cross-wise. Hence we cannot assign much importance to the skep argument. But we have digressed too far, and we trust that some of those able friends to whom we have already referred will give us the beuefit of their experience on this important subject.

QUEENS BY POST.—The 'dull season' of the year

offers a favourable opportunity of discussing subjects, oners a ravourable opportunity of an experience, no time for which, although of interest and importance, no time can be spared in the 'lively season.' One of these, we think is the transmission of queens by post. Mr. think, is the transmission of queens by post. Mr. Simmins, in his new book entitled A Modern Bee-Farm —which is just out of the publisher's hands and which appears a thoroughly practical and most useful addition to our bee lore—has a few remarks on this subject. On page 144, under the heading of 'Packing Queens,' he says: 'Queens may now be sent by post just as safely as an ordinary letter, and Benton's cage has rendered the system absolutely perfect, though as yet through some short-sightedness or prejudice on the part of the postal authorities many foreign queens have been returned to the senders. Mr. Benton then overcame that difficulty by registering the packages, but now again some one at the General Post Office, more officious thau wise, has seen fit to send back registered packages forwarded to myself. They now, therefore, are sent over by parcel post, but by what process of reasoning they are allowed to pass in that manner and not by letter post it is difficult to understand.' Now amongst the 'forbidden articles' for transmission by parcel post are 'live animals,' under which head bees are undoubtedly included, and we ourselves have met with refusal when endeavouring to pass them. This regulation applies to the 'Inland Parcel Post,' but we have no doubt that it is applicable also, in even a stronger sense, to the 'Foreign and Colonial Parcel Post. If, therefore, post-office officials act up to their rules, queen-bees and their necessary attendants are altogether excluded from transmission. There are so many bee-keepers who would benefit by the removal of this restriction that we think the committee of our Association should make a strenuous effort to get it cancelled. We find from a paragraph in the American Bee-Journal (vol. xxiii., p. 403), that 'At the National Beekeepers' Convention, held at Chicago in October 1879, Professor Cook was appointed to wait on the Postmaster-General and endeavour to get the ruling reversed which had excluded queen-bees from the mails. He went to Washington and having obtained the aid of the Hon. Edwin Willits, M.C., in presenting the matter to the Post Office Department, the bees were ordered to be admitted to the mails with "double-wire screens," &c. For the past six years, therefore, the United States mails have been freely used for the transmission of "queen-bees and their necessary attendants." privilege has been alike valuable to the breeders and purchasers of "queen-bees for the improvement of stock."' In Canada also the same permission is granted. In a communication to the postal authorities of the United States Mr. Cuthbertson, of the Toronto Post Office, writes: I have to inform you that this Department does not object to the bringing of queen-bees into Cauada by mail, provided they are put up in such a way as to guard against their causing any inconvenience or damage in the handling of the mail.' So important an industry is apiculture now in the United Kingdom that the queen traffic if stimulated by permission to pass through the letter post would soon assume much larger proportions than it at present enjoys and producers and purchasers would be greatly benefited thereby. If our influence were used with the postal authorities and the Postmaster-General were induced to receive an influential deputation on the subject, we can hardly suppose that a denial would be given, unless, indeed, our rulers are contented that the stigma should remain of Great Britain and Ireland remaining so far behind her colonies and other progressive nations. Now that we are patronised by royalty surely this is not asking a boon which cannot be granted! Let us then put our shoulders to the wheel and endeavour to obtain the removal of the reproach from the bee-keeping fraternity of these realms.

WORK IN APIARY for this month, and indeed for all the winter months, amongst the bees should be nil. Perfect rest, absolute abstention from interference, even so much as a jar or a shake, should be our rule. If necessary to change damp quilts or to place candy upon the frames it must be done absolutely, as far as practicable, without disturbance. Every jar or shake, even a rough or careless removal of the hive-roof or cover, raises the temperature of the hive by irritating and arousing the half-sleeping bees and causing them to foul their hives, while at the same time the internal moisture caused by such disturbance condenses and renders the whole interior of the hive damp and unhealthy. Therefore we say 'Leave the bees severely alone.' The only interference admissible is clearing the entrances of dead bees, débris and snow, and carefully and gently brushing off snow from the hives and their surroundings. But every active apiarist will find plenty of other work ready to his hand in preparing for the next campaign—work which has often been specified before and which we need not recapitulate-and, shall we add, in sharing and enjoying his Christmas rest (when it comes) together with his bees.

Solutions of Tomtits' Problem.—While thanking our Editor for his courtesy in admitting our junior readers to compete for prizes by solving our problem we must ask permission to trespass a little further on his space in order to give a list of competitors who were successful with their poetical solutions. The prizes—for we now propose to give three—have been adjudicated as follows:—

Eric Lewis, S. P. Kirkby, Deeston, Notts, Darcy Grimshaw, Horsforth, Leeds (third in merit), a modern feeder.

Although Mr. Lewis is beyond the age specified we have

great pleasure in offering him a hive, if he will do us the honour to accept it for his most excellent solution. Will he oblige us by forwarding his address? We shall also be glad to learn what 'feeder' Mr. Darcy Grimshaw prefers. Correct answers have also been received from Ellen Cobb, A. Harington, Frank Olyott, G. W. Wells. The prize poems are as follows:—

A practical answer our Editor seeks
To a problem on tomtits and bees in last week's:—
The idea of 'a modern frame-hive' makes me keen
To write for the prize—though no longer sixteen;
And if only I offer the proper solution,
Perhaps you may judge this a fair contribution.

Now if six little rascally tomtits assail
Six poor little bees on the head and the tail,
And peck them so fiercely—and that on the sly—
That, with none of their mates to defend them close by,
They are all little corpses in six minutes short,
Being swallowed, no doubt, to wind up the sport;
Then five score of avengers arrive on the scene
To punish all foes of their hive and their queen,
How many tomtits would be needed to slay
In but fifty minutes this later array?

In the first case 'tis plain that in twice minutes three Each tomtit has tackled his own little bee, And therefore if two could set upon one In half the time only the work would be done, And so, do you see, a little proportion Brings out the result—if stated with caution: For six bees in six minutes together conspire, After fighting their best, in one breath to expire; So one hundred in fifty is double the pace of the foul execution—needing, I guess, Jnst double the tits: so—in logic to delve—'Ceteris paribus' there will be twelve.

But before I conclude, I am not unaware,
That a pitfall may lurk 'neath the surface so fair:
For supposing that while all the others look on
One bee and one tomtit do battle alone,
And the tit by the dexterous use of his beak
In one minute lays low his antagonist weak,
And each couple in turn to th' arena descends
Till the sixth bee lies dead when the sixth minute ends;

Then, I reckon, one hundred in minutes the same Will take one hundred tomtits to finish the game; Again, if we double the pace as before 'Twill need of the tomtits just ten times a score;—(But methinks that the bees would scarcely endure To wait each for his turn in a tragedy sure.)

If my figures are wrong and my logic is vain,
Will 'Useful Hints' kindly reply in like strain,
And clear up all doubts for bee-keepers perplexed
By a Latin verse answer—he can!—in your next?

ERIC LEWIS.

As you have offered boys a bive, To get it, sir, I think I'll strive, And father's promised, if I win it, To put for me a swarm within it.

Six tomtits, then, sir, if you please, Will in six minutes kill six bees; It follows, then, clear as the sun, That in one minute they kill one.

In fifty minutes thus they will
Just manage fifty bees to kill;
And in this time, if I've not blundered,
Twelve tomtits, sir, would kill one hundred.

And now I've done my very best,
In faith I'll leave to you the rest.
My age is twelve, and, if I've won it,
Here's my address to put upon it.
BAMULL P. KIKKEY, Imperial Park, Beeston, Notts.

The little bees, within their hive,
All winter snug they lie,
Till Tom Tit comes, and with a tap,
He makes the bees reply.

And one by one snaps he them up, And, though he takes but few, He makes a hearty meal of them (Your answer is not 'two').

I thought it was, but oh, dear me!

How deep I've had to delve

Into my old arithmetic,

And find the answer's 'TWELVE.'

DARCY GRIMSHAW (age 14).

MY BEES.

BY MRS. REGINALD BRAY,

Author of 'Family Feats,' 'Ten of Them,' 'We Four,' &c.

(Continued from page 522.)
Chapter IV.—Supers and Supering.—Swarming.

Well, the winter came and passed away, and spring had come once more. We had fed up well in the autumn, and now commenced spring-feeding with great

diligence. We were amply rewarded by seeing the bees hurrying into the hives laden with pollen, a certain sign

that young brood had begun.

I could no longer resist putting on my supers. It was very foolish I know, for it was early in March, and you do no good by putting them on too early; you only make the hive cold and give the bees more space than they

But a few hot days had made the bees hang out in great numbers, and I was immediately seized with my old panic that they would swarm early. I did not wish for this, and still being slightly nervous at handling bees, I did not feel equal to looking for and cutting out the new queen-cells, if there should be any. So Watson and I got out our super-box, and feeling sure that there was no time to be lost, we put in a small piece of foundation-wax into each section to start them, and with great pride put the case on the hive. On the straw skep, of which we had one remaining, we placed a large glass super, and I watched anxiously day by day to see the bees come up. Of course, the bees did not go up for some weeks, and as the weather turned very cold at Easter, we should have done far better to continue feeding, and to have kept the bees warmly covered up.

Happily, however, summer came at last with a burst. The bees crowded up into the sections, and were a daily, I may say hourly, source of joy and delight to me. The work began merrily, and the combs seemed to grow before my eyes.

When, oh, horror! what were the bees about? I expected to see each of my 2-lb. sections filled with those fascinating little combs so beautifully fitted into their little boxes. My bees were running two lengths of comb at right angles to the sections, right through the whole length.

I looked, I shuddered, and I turned away once more rebuked for my folly. It was all my own fault, and it proved a case of 'more haste, less speed.' In the hurry of the evening when we had put the foundation into the sections, we had actually put the pieces across the section, instead of into the slits prepared for them; therefore, instead of training the bee into the way he should go, we had actually started him on the wrong track.

go, we had actually started him on the wrong track.

It was hard, but there was nothing to be done now, and we had to watch the bees continue building their long slips of combs the whole length of each row of sections. Still, honey the wrong way was better than no honey at all, and being of a sanguine temperament I soon persuaded myself that I rather liked it. It was

such a strange, original way of building the comb. After all, those little super boxes were very common. And all the time the bees grew stronger and stronger. They hung out in clusters outside the hive, and the number of drones convinced me there would soon be a swarm.

I watched eagerly, for I had read in the Bee Journal that to leave the hives even for a short time might be to lose a swarm, for the weather was so hot that the bees were simply boiled out of the hives. However, watch as closely as I might, I could not be always there; and it is my belief that those bees did swarm, and that they went away and I never saw or heard anything of them. Watson always maintains that they did not, but they suddenly grew much quieter; and the presence of a young queen leads me to believe that I was right, for it is always the old queen who goes forth with the swarm, she having, I suppose, more experience. The young queen remains in the parent hive.

By the end of July our sections were as full as they could be, and I wrote and asked Messrs. Neighbour to send a man down to take the super-box off for me, for the combs being made all the wrong way, I really did not know which way to set to work. Also, the box was so tightly fixed on to the hive by the propolis of the bees that I did not know how to take it off. None of the beebooks that I had gave any information as to this, and it was too large to slip a knife under.

This difficulty the man got over very cleverly. He took a thick piece of string, and drew it slowly right under the super-box, cutting through the propolis so that it could

be lifted off quite easily.

He smoked all the bees out of the super, making them run down into the body of the hive. The moment the box was lifted off, the hive was covered with the quilt and shut up, the unfortunate bees being left very angry and disappointed at being robbed of their honey.

The box of honey he carried into a shed at a distance, or we should have been beset by bees from all the hives, for they soon find out honey if it is anywhere within their reach. It was a difficult matter to take the combs out of the sections without breaking it, and most mortified I felt as I looked on, hearing him remark occasionally, 'What a pity such beautiful honey should

be spoilt!

However, it was all done at last, and when I saw nearly forty pounds of honey in large dishes, I cared no longer whether it had been made upside down or the wrong way. I had honey,—real, beautiful honey of my own, and with great pride I set 37. against my expenses of bee-keeping, for it is only fair to charge the house for it at the best price. I sometimes wished the household did not appreciate my honey quite so much; it would pay far better if they did not. For myself, I care very little about eating it; and as I said before, it is very hard to see the beautiful white comb eaten, and to hear the scrunch of the spoon as it cuts into it.

The bees in my straw skep never did much work in the glass super which we had put on, and as the autumn advanced they took what little honey they had put there down into the body of the hive. We wondered why they did not do so well, and eventually drove them and put them into a small bar-frame hive of Messrs. Neigh-We then found out the reason—the wax-moth had got into the hive. This is a troublesome little moth much to be dreaded in a weak stock, as it lays its eggs in cracks inside the hive, and sometimes on combs which are not covered by bees. When the caterpillar hatches out it eats its way through the wax, pollen, and brood, spinning a silky film as it goes, and spreading destruction. If stocks are strong you need have no fear, as the bees can guard against them. It will be found a very good plan to keep pieces of camphor in the hives, as they would be a great preventative both to the moth and foul brood, of which I shall have more to say later on. The bees have no dislike whatever to the camphor, and you

may push lumps of it between the bars without their being affected by it in the smallest degree.

A cousin of mine, finding one of her hives in a very weak state, suspected the presence of wax-moth, so, as the hive was a straw skep, she determined to drive the bees and burn the old hive, in order to get rid of it. She asked me to help her; and as this was the first time I had attempted driving since our scare, I determined to take all possible precautions. She, also, having been severely stung that summer, and her bees being of a very unamiable disposition, was equally careful.

We tucked our veils in with the greatest care, we put on two pairs of gloves each; and though we saw no bees coming out of the entrance, we gave them a thorough good dose of smoke. Having left them for some moments to regale themselves on honey, we turned the hive upside down. It was somewhat absurd, though very annoying, to find nothing in the hive but a few dead bees!

This same cousin had another hive, which she asked me to attend to and feed in the autumn during her absence from home. It was not a very strong stock, and the place was perfectly infested with wasps. I am sure they ate the honey as fast as the bees took it in; indeed, I used to feel quite nervous at going near the hive because

of the wasps.

One day when I went down I found the hive in a most disturbed state. The frames were all tumbled about and in the greatest disorder. I thought it looked very much as if 'Humpty-Dumpty had had a great fall.' I went to inquire of the servant left in charge: 'Did she know if anything had happened to the hive?' She thought for a moment, and then said, 'Well, she believed the boy had said something about the pony having got into the garden and knocked the hive over, but he had picked it up again all right.' 'Had he, indeed?' I only hoped that the boy and the pony had got thoroughly well stung. As this was not the only occasion when the pony got into the garden, that hive of bees did not prosper, and they all died off in the winter.

A sister of mine was much more fortunate. It is astonishing the luck that some people have. following letter, which I had from her, gives a most interesting account of the way in which she was, if I may say so, compelled to start bee-keeping. She had no particular wish to do so, because bee-stings took such an effect upon her that it was scarcely safe for her to keep

'DEAR E.—You will be surprised to hear that I am now in the possession of a magnificent hive of bees which

have not cost me a penny.

'As you know, I had no intention of keeping them, but yesterday morning a small swarm got under the tiles of the verandah. Duncan [her Scotch butler] and I went up on the roof to endeavour to entice them out. Fortunately I had a hive by me. We spread a sheet on the roof, and placed the hive in readiness, when a cloud appeared in the sky, and a huge swarm of bees, the largest I ever saw in my life, swirled round, frightening us horribly, and, attracted by the white sheet, dashed into the hive. The strange part was that the other swarm joined them, and I have got a hive as full of bees as you could wish.

'There is very little doubt where the swarms have come from. Mr. E.'s house is infested with bees. It is an old-fashioned farm-house, and the whole roof is full of them. There is no possible way of getting them out, and sometimes they cause great annoyance. Last summer his mother-in-law was staying with him, and greatly she enjoyed the beautiful scenery and summer

weather.

"If there is one thing I like," she said, "it is to be able to sleep with one's window wide open, and hear the sound of the birds.'

'Yes, that is very delightful! but early next morning she was awoke by another sound-a loud and alarming buzzing in the room. She opened her eyes, and oh horror, the room was full of bees! They had swarmed through the open window right into her room. To spring from her bed and rush out of the room was the work of a moment; and she took very good care never to sleep with her window open in that house again.'

I should much like to know whether any of my readers have ever known of such a remarkable instance of two swarms going into the same hive. Possibly the first swarm may have gone off without a queen, as this is sometimes the case. Swarming is, I think, one of the most interesting features of keeping bees.

When the hive has become overcrowded, the bees make preparations for swarming by commencing queencells. Sometimes they will start as many as seven or eight. They will have already produced a great number of drones, and when you see many of the latter about you may be quite certain that swarming is not far off.

A good deal depends upon the weather. Sometimes, just as bees are on the point of swarming, the weather becomes cold or wet, in which case the bees will destroy the queen-cells, and often delay the swarming for some weeks. When the swarming fever is on, the bees rush in and out of the hive in an excited state. The whole air seems full of bees. Sometimes they will rise up and go straight away, and you may lose your swarm; but usually they will settle on some bush or tree near. The old queen always goes out with the swarm, and she leaves before one of the new queens has emerged. If the bees are not inclined to cluster, it is a very good thing to squirt water over them with a garden syringe so as to resemble rain.

A bee-keeper should always have hives ready to receive he swarms, but do not sprinkle the hive with sugar, beer, or treacle, as is sometimes recommended; it is a great mistake. When bees swarm they are usually extremely good-tempered, as they have filled themselves with honey before leaving the hive.

If the bees have swarmed on the branch of a tree, lay a cloth or sheet underneath it, hold a straw skep underneath bottom upwards, and give a sharp shake to the branch. The bees, who are all clinging to each other, will fall in a mass into the skep. The queen is usually in the centre, but you should always get as many bees as possible, so as to be sure you have her.

After you have hived them, you should stand your skep on the cloth with the edge slightly raised, and the rest of the bees will soon find their way in if the queen is there. If she is not, the whole swarm will soon return to the parent hive.

If you desire to put the bees into a bar-frame hive, you can either shake them in at the top, having first removed two or three of the centre frames which you replace afterwards, or you may lay a board as level as possible from the ground on to the alighting-board (if the hive is a high one on legs), place the other end of the board on a box, flowerpots, or something. Lay a sheet over the board, covering the edge of the board where it rests on the alighting-board. Shake the bees on to the sheet and they will soon run into the hive. If you happen to have any frames of comb, or, better still, brood-comb which you can put into the hive, so much the better, as the bees will cluster on it at once, and attend to the young brood. If you have no comb you will aid the bees very much by filling the frames with foundation comb, which is made from the pure bees-wax, and can be purchased at any dealer in hives. It also acts as a guide to the bees, and the combs are better built than if the bees are left to go their own way.

The parent hive is now left queenless with thousands of young bees taking care of the brood, for all the old bees have left the hive. It is an interesting fact that a young bee when it first emerges is so young and tender that it is not trusted to leave the hive, but it remains as nurse to cherish and feed the young grubs for some days until it is strong enough to fly.

The old queen, as I have stated, has gone off with the swarm, leaving the queen-cells sealed over. After some days, sometimes as many as eight, one of these queen-cells hatches out. Then a very curious thing takes place, the queen rushes upon the other cells and proceeds to tear them to pieces and destroy the other queens. The worker-bees assist her in this murderous wish, unless they are still very much crowded and have determined to send off a second swarm, or, as it is usually called, 'a cast.' In this case they protect the cells and will not allow the queen to destroy them. In her endeavour to do this she sometimes ntters a shrill piping sound. Failing in this she evidently becomes too indignant to remain in the hive. She will not brook 'a rival near her throne,' and she rushes off with as many bees as will follow her.

These casts are not worth much, as they consist of few bees, the best plan is to take away the queen and return them to the hive. They can easily be prevented by cutting out all the queen-cells but one, after the swarm has left the hive.

Selected Query.

[4.]—What is the smallest amount of stores that it is safe to winter bees upon in a frame-hive, and what is the best way to feed in winter bees that are short of food?

A stock of bees cannot possibly live 'through' the winter, reckoning such winter to extend until the middle of March, having less than 20 lbs. of stores at the end of September, and pay the bee-keeper the next season. It would be quite possible for them to live on 13 lbs., but they would be of little use the following season. The regularity of the temperature in winter makes a vast difference as to the amount eaten. If we could obtain a regular temperature of from 40° to 45° Fahr, not more than 3 lbs. of stores would be consumed from November to February, but if the temperature is constantly varying 10 to 12 lbs. would be eaten in the same time, therefore it is not safe to trust them with less than 20 lbs. Either candy or Porto Rico sugar on top of the frames. In placing Porto Rico sugar on frames, holes must be made through the sheet of paper on which it lays and an enamel quilt used next over the sugar. - W. B. $\mathbf{W}_{\mathbf{ERSTER}}$.

The smallest amount of stores I ever wintered a stock upon was 10 lbs. It is not safe to winter on less than 20 lbs. of honey. The best way to feed in winter bees short of food is by candy cake placed on top of frames, made from recipe given in Cowan's Guide Book, care being taken not to make it too hard. In the case of large apiaries, there should always be a lot of spare combs of honey on hand to give to any stock that is likely to run short of food.—William McNally, Glenluce, Scotland.

From the accurate weighing of a large number of stocks, for a long series of years, I find the average consumption of food per stock from September 30th to April 30th is nine-tenths of an ounce per day, or about 12 lbs. But some weak stocks caused me nearly half as much again to keep up the necessary heat of the hive, so I always make my stocks up to contain about 16 lbs. of food at the end of September. If the bees have been so disgracefully neglected as to require feeding in winter, the best way is to give them cakes of candy placed on the top of the bars. — WILLIAM CARR, Newton Heath Apiary.

From 12 to 15 lbs. of sealed stores, in a box, placed over feed-hole; or, if you have any sections, they may be placed over feed-hole in same manner.—G. J. BULLER.

(1.) It is not advisable to winter an average colony upon less than 20 lbs. nett weight. (2.) By preference, combs of sealed stores laid close on frames—if none on hand then good candy.—Samuel Simmins.

From the Ist of October to end of January a colony kept quiet needs about 8 lbs. of food. From that time, until the early honey-flow, week by week, the consumption of stores increases, and the more young and vigorous your queen the greater a colony's need. Hence no good colony should be put up for winter, feeling a certainty for its future, with less than 30 lbs., or stores at command. Such a colony will go far ahead of one which is wintered upon a bare sufficiency, and that has to be upset ever and anon in giving further supplies during the early spring. We now have driven bees upon frame-feeders (if successful, to be illustrated and described later on) without any other stores than candy and one frame of empty comb in the centre; but as this is experiment up to date, we advise candy, in shallow I-lb. boxes, to be laid over hole in calico-sheet on top of frames, in number two, four, or six, as required. These covered very snugly above. — J. H. Howard, Model Apiary, Holme, Peterborough.

Twenty lbs. of honey for an average colony is the smallest quantity of stores it is safe to depend on to carry them through to end of February or March, then if short I would give candy containing a small proportion of pea-flour. If bees run short of food during the winter I should give candy over cluster of bees.—W. WOODLEY.

(I.) For a colony covering well eight standard frames 20 lbs. of sealed stores will suffice for four months' consumption—say from October to February. (2.) Place outside the brood-nest, close beside the cluster of bees, a comb of sealed honey; or lay upon the frames, around the cluster and under the quilts, candy, Good's candy, or barley sugar.—George Raynor.

In an ordinary winter, 20 lbs. of good sealed honey, with winter passage through each comb. Feed with best sugar candy under the quilt. This can be obtained at $3\frac{2}{3}d$. per lb. if 28 lbs. are bought at a time.—John M. Hooker.

ASSOCIATIONS.

ESSEX BEE-KEEPERS' ASSOCIATION.

The autumn county show held annually by this Association in the Corn Exchange, Chelmsford, in connexion with the Chrysanthemum Show of the Chelmsford Horticultural Society, brought together the largest number of exhibits yet staged in the county. There were in all twenty-three exhibitors, from various parts of the county, and fifty-eight entries staged, the honey shown weighing about four hundredweight. The quality on the whole may be pronounced as very good, sufficiently so, at any rate, to justify the Rev. G. Raynor, of Hazeleigh, Essex, who kindly acted as judge with his usual ability, in awarding the silver medal and certificate of the B.B.K.A. The former went to Mr. J. Debnam, expert of the Association, for the best lot of comb honey shown, and the latter to J. Runcieman, Widford, a cottager (who took the silver medal last year), for the best twelve jars of run honey in the show. The Association's bronze medal was awarded to Mr. Debnam for run honey at the summer show, held June 7, 8, in connexion with the Essex Agricultural Society's Exhibition. The hearthurning occasioned in many counties by the expert sweeping off all the prizes, or being excluded from showing—either course equally unjust—has been entirely averted in Essex by having separate classes for dealers in honey and amateurs, no one who purchases honey for resale being allowed to compete in the latter. The result is a keen competition among members. At this show seven amateurs entered twelve 1-lb. sections and eleven twelve 1-lb. jars. Another advantage of this arrangement is that when cottagers become skilled bee-keepers, as some few do, the higher prizes offered in the amateurs' classes induce them to enter in these,

rather than among the cottagers, thus leaving the average cottager a better chance in the cottagers' classes.

The class open to all members for the best single section is made a speciality in Essex, and that not at the county shows only. It was started last year with the object of encouraging the production of perfect sections, even among the smallest bee-keepers, and now a certificate and 2s, 6d, are offered to the promoters of any local horticultural or village show who will enter the prize on their schedule. There were thirteen entries in this class, and the winning section went near to taking the silver medal. Big supers, though they ought not to be encouraged, as unsaleable, will always, we suppose, take take prizes if well filled, as was that shown by Mr. Debnam, which contained about 29 lbs. of honey. A smaller one of Mr. French's, which took second prize, was as pretty a bit of work as one could wish to see in a bell glass. Seven showed beeswax, two more who had entered carrying off their exhibits when they saw what was staged against them. If many acted on this principle it would soon lead to exhibitors who bring their own things being allowed no further than the door.

The class for hive made by a cottager brought a barframe of excellent build and design, good enough for anybody's use; better, in fact, than the dealers can afford to sell. The maker is a retired coachman, who turned his hand to this sort of work for the first time last autumn, and has kept his eyes open ever since. In this class it is a good plan to invite suggestions from the judge, and write them on the hives. It interests the public, and is a material help to an exhibitor desirous

of improving.

The following is the prize list:—

Dealers.—Class 1, twelve 1-lb. sections: 1 and B.B.K.A. silver medal, W. Debnam, Chelmsford; 2, Ed. Durrant, Chelmsford. Class 2, twelve 1-lb. jars: 1, W. Debnam; 2, W. J. Braddy, Kelvedon.

AMATEURS.—Class 3, twelve 1-lb. sections: 1, P. Hills, Great Baddow; 2, Miss Chalk, Springfield Lyons; 3, Mrs. Cobb, Great Waltham; h.e., J. Runcieman, Widford; C. N. Brooks, Mistley. Class 4, twelve 1-lb. jars: 1 and B.B.K.A. eertificate, J. Runcieman; 2, W. Dance, Gosfield; 3, P. Hills; e., P. French, Boreham; Mrs. Cobb; R. R. Royds, Kelvedon Hatch.

OPEN TO ALL MEMBERS.—Class 5, single section: 1 and E.B.K.A. certificate: P. Hills; equal 2, J. Winter, Kelvedon Hatch, J. Runeieman; h.c., W. Debnam, S. J. Braddy. Class 6, super: 1, W. Debnam; 2, P. French; 3, Mrs. Cobb. Class 7, Beeswax: 1, D. Dudley, Great Totham; 2, W. Debnam; 3, Mrs. Thomas Jackson, Tillingham.

COTTAGERS, OPEN.—Class 8, single section: 1 and E.B.K.A. certificate, J. Winter; h.c., A. Mayell, Bradwell. Class 9, twelve 1-lb. sections: 1, J. Jillings, Broomfield; 2, J. Winter. Class 10, twelve 1-lb. jars: 1, J. Winter; 2, A. Mayell. Class 11, super: 1, J. Newnan, Little Baddow; 2, A. Mayell. Class 12, amateur-made hive: 1, W. Barltropp, Woodham Mortimer.

HORSFORTH DISTRICT B.K.A.

The members of the above Association met together on the 26th ult. at the residence of the hon. sec., N. F. Burniston, Esq., Throstle Nest, Horsforth. After an excellent dinner, the balance-sheet was read by the treasurer, and the usual business was proceeded with. The same officers were re-elected, new members were enrolled, and the Association looks forward hopefully to a period of great mutual usefulness in the coming year. A vote of thanks to Mrs. Burniston for her very practical assistance was proposed by Mr. R. A. H. Grimshaw, after which the meeting literally 'Closed in barmony.'

THE LINCOLNSHIRE HONEY FAIR.

This fair was held at Grantham on Saturday, December 3rd, being opened by the Mayor (Mr. Alderman Bell).

Compared with last year the total amount of honey was not so large, but the quality was excellent. same time a greater number of smaller producers were represented, instead of, as hitherto, the bulk of the honey being brought by one or two persons. ruled as follows:-Honey, 8d. to 10d. per lb.; and wax, of which there was a short supply, 1s. 8d. to 2s. per lb. The majority of the honey exhibited was the produce of clover and beans, but a choice lot from the Duke of Rutland's seat at Belvoir was evidently the product of a variety of flowers. There was a demand for extracted honey, section or comb honey being in little request.

Correspondence.

The Editor does not hold himself responsible for the opinions expressed by his correspondents. No attention will be taken of anonymous communications, and correspondents are requested to write on one side of the paper only, and give their real names and addresses, not necessarily for publication, but as a guarantee of good faith. Illustrations should be drawn on separate pieces of paper.

Communications relating to the literary department, reports of Associations, Shows, Meetings, Echoes, Queries, Books for Review, Ec., must be addressed only to 'The Editors of the 'British Bee Journal,' c/o Messrs. Strangeways and Sons, Tower Street, Cambridge Circus, W.C.' All business communications relating to Advertisements, &c., must be addressed to Mr. J. Huckle, Kings Langley, Herts (see 2nd page of Advertisements).

**In order to facilitate reference, Correspondents, when speaking of any letter or query previously inserted, will oblige by mentioning the number of the letter, as well as the page on which it appears.

MEMS, BY 'WOODLEIGH.'

[1378.] I was pleased to see Mr. Simmins' letter (1361) in a recent issue, re the 'price of honey,' and trust other large producers will be induced to give us their ideas on the rapid decline—or, ought I to say, the down-grade —tendency of the market-price of combhoney. No doubt, as Mr. S. avers, the production has exceeded the demand in many parts of the country, and consequently the price has ruled low, and I opine the average price for the year will be between Mr. Godfrey's Ωd , and Mr. Simmins $7\frac{1}{2}d$.

Mr. 5, pertinently observes that one cause of the low price can be traced to the usual custom of bee-keepers disposing of all their stock as soon as the honey season is over, and consequently the market is glutted, prices go down with a rush, and it is a long time before there is a turn in the price or dealers are disposed to give more

money than for previous parcels.

Others east the blame on the Honey Company, but I do not consider it fair to do so. If the H. C. gives 6s. or 6s. 6d. per dozen for sections, they take all risk of those sections becoming erystallised, and consequently unsaleable, fit only for mead or 'mella; 'also the expense of glazing or putting in cardboard boxes, or the new faney tin-cases, thus enhancing the price of the 6s. 6d. sections to 8s., and with a small commission and the subsequent carriage to the retailer the sections cannot cost him less than 9s. per dozen. Now if those beekeepers who grumble about the price given by the Honey Company, or other large dealers who supply the retailers, will set about finding a market for their honey, put it up in a saleable form, and it is of good colour and flavour, I have no doubt he, or they, will obtain the coveted price of 9s. per dozen wholesale, and, of course, 11s. or 12s. a dozen retail, for their sections.

I should be pleased to see quotations given, say once a-month, in B. B. J. as to the market price of both comb and extracted honey, it would be very nseful to beekeepers having a stock on hand, and it would come in very opportunely with Mr. Bellairs' extract from Board of Trade Returns of Foreign Honey he so kindly procures

and inserts periodically.

No doubt with the prevalent low prices of comb or section - honey that extracted pays the producer best, and probably many bee-keepers will go in for extracted honey in succeeding seasons. There are some rather heavy items of expense connected with the production of comb-honey in comparison with extracted; take, for instance, the following for, say, 1000 sections:-first, cost home will be 23s., and if full sheets of foundation are used for the sections of eight sheets to the pound you will want $10\frac{1}{2}$ lbs. at, say, 2s, 9d. per lb., costing, with carriage home, at least 30s. Here we have an expense of 53s, on every thousand sections that are produced. But the producer of extracted honey is spared that expense, as his combs serve over and over again, and the cappings he takes off nearly pay the expense of the time while extracting; and when we consider that the produce of extracted honey must be greater than comb by at least one third, we see that 1000 lbs. of extracted at 6d. per lb. is 25l., and with the one-third added 33l. 5s.; while the 1000 lbs. of comb in 1000 sections at $7\frac{1}{2}d$. (a fair price unglazed) would amount to 317.5s., deduct the above items of expense for sections and foundation, viz., 2l. 13s., and we have only 28l. 12s., or a balance in favour of the extracted of 4l. 13s, on every 1000 lbs. produced in an apiary. Then another great consideration in favour of extracted is that it is proof against the 'jars' of the railway porter while in transit.

In conclusion, may I ask a question?—' Do bees that are fed with phenolated syrup know strange bees from other hives that are being fed with the same kind of food?' as I have never had occasion to use phenol in food --in fact, not at all, except in a crude state, as I have stated before, for taking off sections. I have not been

able to verify above query.—Woodleight.

Considerable attention has been given to the subject of quotations of honey and wax. It formed a topic for discussion at the last quarterly meeting of county representatives. The difficulties arise through the many grades of honey which are produced from the flora of this country. A general quotation would in many instances be misleading. Has any bee-keeper the necessary experience to reply to our correspondent's last query. ---ED.]

DISHONOURABLE EXPERTS AND OTHER OFFICIALS.

[1379.] Although agreeing in the main with your remarks respecting experts and local secretaries as to the disposal of honey for others, I yet feel very strongly that when these officials and certified experts undertake the sale for or buy honey from us, we ought to consider them as 'hononrable men,' and that there is no risk of being treated as though some of the Long Firm' had us in their clutches. I hope it will be considered a duty by the parent or any local Association to dismiss at once and cancel the certificates of those who are proved wanting in integrity.

As an illustration I may state that one of these gentlemen called on me some three months ago, received payment of me for some of his 'goods,' looked at some surplus sections, and agreed to take about 50 lbs. at 7d. per lb., and send a cheque in payment. These were packed in a great hurry for his convenience and taken away. The packing-eases were returned, but no cheque, and in reply to three applications no answer whatever or notice of any kind has been returned.

Another time I was informed that prices were from 5d. to 9d. according to quality, and on sending over 50 lbs. was told that 4d, per lb. only could be given for the perfect sections, and, as was said, some fourteen or fifteen were smashed, only about Is. or 1s. 6d. could be given for them, so I had to accept about 14s. for the

Yet another leading 'expert' will never be engaged by a Committee here on account of alleged 'hocussing I can add to this list from unimpeachable by him. testimony.

These cases should warn the unwary, and I hope the

537

parent Society will soon cleanse the Augean stable, or we shall hegin to look upon our organizations as existing only for practice in manipulation for the purpose of extracting our honey indeed, and leaving our purses as empty as the honeyless cells.—A SHORN LAMB.

A TRIP TO THE HEATHER WITH THE BEES.

[1380.] 'Are you going to take your bees to the moors next week? Have you got any one to go with you?' are the questions asked by several of my acquaintances when the first of August comes round; but I have to reply I am going to take two friends that arranged to go with me months ago, and three on the bee-waggon are as many as can be conveniently seated. Every night for a week I have been busy fitting the hives up for the journey. Straw hives are secured on to the bottom boards by strong wire, and three screws are put through the cane hoop at the bottom and screwed into the wood. The crates for the frame-hives have all been examined, several sections are well advanced with comb since the honey harvest here last month, and a few are full: these I take out and put empty ones in their place. The hives are all screwed on to the bottom hoards, each hive is numbered, and particulars of each entered into a book.

The day of removal arrives, and the weather as propitious as ever. Nothing to do to-day but see that one of the colliery horses is secured and kept in the stable with plenty to eat. Seven p.m. and we commence to close the bees in with wire gauze, and take off ventilating covers, and commence loading the bee-waggon,—a waggon made for the purpose with two decks. Frame-hives are put below and straw hives above, all other requisite appliances put into the box, which is also the seat of the waggon. Then after partaking of a good supper we get our horse yoked and start our journey twenty miles west. The night is

very misty.

After getting a short distance out of the village we find a friend waiting for us with his hive at a lane end. We soon secure the hive into the waggon, and, knowing his ardent desire to go with us, I plan a seat for him; and then we get under way again. We soon come to a heavy bank, and we all get off. The horse rushes up, for he has no patience. We have several times to dismount, for it is a climb upward for twelve miles. Nothing eventful happens during the darkness. We occasionally meet companies of miners going to work, and in passing through colliery E-S-my friends are surprised to see in so many of the miners' cottages the people are all astir, and it is now one o'clock in the morning; but such is the miner's calling: he is wanted at all times of the night. At two o'clock it is very dark and the mist is very dense. The road being black I have to hold the lantern as far down as I can, and can just discern the roadside, and the road here is very uneven. We all sit close together with all our wraps on wishing for daybreak.

On arrival at H— H— there are signs of daybreak, and we put the lantern out, and by the time we arrive at B- we can hail with joy 'the smiling morn.' We have now reached the highest point of our journey, 868 feet above the sea level. The place we come from is ten miles inland, and only 108 feet above the sea level. Our progress has been slow—it is now 3.30 a.m.—but it has been all up-hill. We are now nearing the Derwent Valley. We pass down a steep hill shaded by trees, and then we strike the valley. The magnificent view that presents itself on this beautiful morning can never be eradicated from my memory. When we got a little further on, clear of the embankment on the right, I was transfixed for awhile in mute amazement. While I beheld the sublime scenery of that deep, wide valley, to the southward the mist had lifted and had the appearance of a long white cloud as white as snow; west and north-west was one vast, glorious panorama beyond my

pen to describe.

We now come to the brow of B— H—, a hill nearly a mile long; we adjust the shoe on to one of the hindwheels and walk down. A short distance in front is a flat cart making slow progress, for the men cannot 'break' the wheels; we overtake them and find they are bee-men from U—F—. There are nearly twenty hives on the cart, small in size, not more than twelve inches diameter and nine inches high inside. This size of hive has been used in their neighbourhood for generations; they looked in the cart really splendid. These men make their own skeps of rye-straw, and every lap of cane seemed to be at a measured distance. Arriving at the bottom of the valley, we halt close to the bridge crossing the river. In the first place we put the poke of corn to the horse's head, for there are still six miles to go, and some hard hills to climb. We all now seem ready for some refreshment, and as each of us opens our bundles we find there is no lack of choice. We have not halted long until other two waggons of bees draw up, and then begins a general inspection.

The scenery from the bridge and the music of the waters make my friends loth to obey the order to move on; but the horse has finished feeding and we are behind time, so there is no alternative but to move on. Before leaving, a note is put under a hotel door, informing them that we shall need a good dinner on returning. It is now a continual climb for three miles, but the scenery is charming. On our right the hills are clad to their crest with stately fir-trees, and in the open spaces we see the rabbits very numerous, taking their morning gambols. We soon come to a forest, where we descend a deep ravine, which almost shuts out the light of day. We find it easier getting down than getting out, for the We allow our horse time to recover hill is very steep. from the effects of the hill, and then we soon arrive at a farmhouse and a church which has two-thirds of its wall covered with ivy, and there is not another house to be seen neither right or left; but we find on inquiry that there is a scattered village over the brow of the hill on the right. Another half-hour brings us to the summit of our climb, and we have the river in view again, with the blue hills of heather right before us.

The view before us now is quite a change, more of a wild character, and although not so sublime, yet it gives to us a feeling of freedom; and, together with the light refreshing breeze from the hills, we are in the best of spirits. Another three-quarters of an hour bring us to our destination, a farmhouse by the roadside. enter a grass field, and drive across to where we have our stands. We first take our horse out and stable him, and then all hands are busy unloading and adjusting the hives on the stands as fast as we can. The sun is making us feel warm, and the bees are telling us it is high time they had their liberty. In half-an-hour we have them ready for removing the gauzes. I put on the bee-dress, and my friends step back a few paces; but they are not very cross when they are let out, except one that is not on a wire-bottom board. This one I let out last, and as soon as the gauze is off they come out like a shot from a gun, and make all fly. A dog standing watching us is sent howling up the field, and some sheep over the wall are also stung.

The bees are soon out in a cluster, and all is quiet. We are now glad to get to the farmhouse and find the good lady has our breakfast waiting for us, consisting of tea, bread, boiled eggs, and a large jug of milk. After breakfast I take the opportunity of having a short nap, but my friends are determined not to waste time with sleep. The sky is clear, and the sun is shining in his strength. The sportsmen are also cracking away at the grouse, for it is the 12th of August.

After my nap is over I get up to finish what we left undone in our haste to the hives, and I see my friends returning. They quite astonish me when they tell me the distance they have been. We soon have all put right with the hives, and then make down to the burn, and the day being so warm we strip and enjoy a refreshing bathe. We stroll back again, and have a look at the stands of bees that are planted at various distances along the wall in line with ours, and also up the south side of the field. The most of them are straw hives and a few wood boxes.

I am sure, Mr. Editor, the sight would interest you. On one of the stands the skeps are fixed on wood boxes four or five inches deep, and the entrance changed to the bottom of the box. They nearly all have a large sod on the top as a protection from the rain, which does not look at all respectable. There are well-nigh a hundred in this field. Some of the owners have gone in for cheapness with a vengeance; the bottom boards especially are very unsound. These cheap Jacks got a caution a few years ago. One of them in loading his cart to take his tees home broke one of the bottom boards, and the bees got out, stung the horse, and sent him galloping away up the bank; and on nearing a house with the door open it made a sharp turn to get in, and upset the cart, and all the hives went rolling down the hill. It finished all the hives, and many of the natives got a taste of honey.

After decorating our waggon with blooming heather we start for home. Arriving at the hotel at the bridge we leave our horse to the ostler; all our belongings are put into the box and locked in out of sight. We find the landlady has got the note ordering the dinner, which is nearly ready. There is just time for a walk around the garden, and then we sit down to a substantial dinner, which does us all a deal of good. After dinner I am inclined to rest at ease, but my friends want to see S-Spa Pleasure Grounds, and, being in no hurry to get home, we set off. A short walk brings us to the Grounds; a flat opening at the bottom of the valley, surrounded with trees in all directions. We stroll about through the wood, and along by the river side, until we are satisfied. After merely feeling the taste of the spa water-for we don't think we are in need of such medicine-we return and commence our journey home, feeling rather disappointed in having to leave this pleasant valley.

On reaching L- we fall in with some friends who have been on the same errand as ourselves. They are going to make a halt and feed their horse, and, for the sake of their company, and to hear how their bees have done at home, we halt as well, and rest for three-quarters of an hour, and then move on homewards. The scenery for the rest of our journey does not interest us much. There are so many collieries and coke-ovens that we see every day, but on arriving at K— we resolve to rest again and have some tea. We have felt the day to be such a happy release from the monotony of business life that we are in no hurry to be home. However, this has to be our last stop, and then we jog on home again. On nearing home I am startled by a movement behind me, and, turning round, am just in time to steady one of my friends from falling off the waggon. despised the demands of sleep, but now he is compelled to put himself into a secure position, and give way to sleep for ten minutes. We arrive at home at seven p.m. A friend is on the look-out for us, and takes charge of the conveyance. I leave all to him, and make no delay in getting off to bed, and have eleven hours of unconsciousness.—W. J.

THE NEW SECTIONS.

[1380.] In answer to Mr. Fryer (1365) as a beekeeper of seventeen years my experience of working sections without separators has taught me to avoid their omission, as in every case they have been omitted more or less bulged combs have been the result. I consider the small additional cost of separators well repaid with either $1\frac{1}{2}$ -inch or 2-inch sections. My experience is limited to two crates of Lee's new sections, consisting of 2-inch and $1\frac{1}{2}$ -inch; these have four bee-ways. Although the season's honey-flow was very slow, these sections were filled more perfectly than any I remember having since sections came into the market. The $1\frac{1}{2}$ -inch were the most beautiful I have ever seen, filled out perfectly level, without a single indentation. I much question, however, whether the latter will pay so well as the 2-inch when filled, as I do not think their market value will compensate for the additional outlay.—Frank Palmer, Sunning Hill, Berks.

SELECTED QUERY, No 2.

[1381.] The replies to this query if nothing else is amusing reading. Did it occur to any of the eight gentlemen who replied to this query that for all practical purposes a sheet of foundation is superior to a comb? Well, it is a fact. With one exception, and that is, for driven bees, and then stored combs are best.

This spare comb business I regard as the curse of the bar-frame system, as it is one of the surest ways of spreading fonl brood. There is nothing like foundation and the wax-kettle for keeping an apiary in health and vigour.

Those who recommend starters should study the subject properly before they turn teachers. This wireing business I regard as one of the modern humbugs and one of the aids to adulteration, as with good foundation it is not needed and is waste.—James Saddler, 35 East High Street, Forfar.

FOUL BROOD ONCE AGAIN.

[1382.] I suppose Mr. Ward has given me up as incurable, as he says it is useless to argue with a man who disbelieves everything, except that the disease is caused by the use of the bar-frame hive, and that it can be cured by simply taking away the combs.

To a certain extent, I say it is caused by the use of the bar-frame hive, for before you embark into the use of the bar-frame hive you have either seen some one manipulate one, or you have had a copy of some modern bee book lent you, or perhaps the Bee Journal; and you soon find out that there are some wonderful foreign bees, and if you are an enthusiast, you must try one, like your humble servant. I will leave you to read what the 'Platelayer' says in a previous number as to what follows. But if you are living in a district in which follows. But if you are living in a district in which follows to your black bees, then the bar-frame hive will never give you foul brood. There is not the least doubt in my mind, but that these pretty foreigners or their belongings brought the dire pest into this neighbourhood.

I am very sorry that I cannot enlighten the 'York-shireman' as to the why and wherefore of straw skeps missing the disease and frame-hives having it, but it is a fact here. I drove some bees out of straw skeps for a cottager, living a short distance from me, last August. One of the hives was so old and rotten, and the combs were so black when I came to turn it up that I made sure of finding the disease there; but when I came to pull the combs asunder I found there was no trace of disease.

I, like the 'Rector of Ore,' have been the means of several old bee-keepers adopting the frame-hive, and discarding the straw skep, with the result that they have had but very little honey, but plenty of foul brood, which is very annoying, particularly when their neighbour, who sticks to his straw skeps, gets his swarms and casts, and an occasional cap, from some stocks, and then to linish up, puts them over the brimstone tnb. (I don't admire the last proceeding.) It makes an old cottager think

there is something wrong with the new-fangled system. In reply to 'Yorkshireman' about selling bees having foul brood, I said to the bee-keeper in question, ' You will never attempt to sell your bees, knowing that you have got foul brood; but he says, 'If they don't ask me I shall not tell them,' so that I would advise every one buying bees to ask the question, llave you got foul brood?

I am like Mr. Ward, I say facts are stronger than opinions, and when he quotes me correctly and sticks to

facts, I will attempt to answer him farther.

'Useful Hints' thinks the fell disease is more likely to travel in the wake of the modern expert and the straw skep than the bar-frame hive. I think in justice to our county expert I ought to say that he is no way responsible for it in this neighbourhood, as I don't think he has examined

a single hive within two miles of me.

I was very much pleased to see the 'Platelayer's' letter, as I was afraid the fell disease had reached him from his silence, and having heard that it was getting very close to him. As the old saying is, prevention is better than cure, I would advise the 'Platelayer' to speculate in a bottle of Calvert's No. 5 carbolic acid, and use it amongst his hives, if he has not already done so.

A most interesting letter to me is that of Mr. W. G. Campbell (1341) from South Australia, from which it appears that they have got foul brood very bad out there, and that the Hon. Sec. S. A. B. K. A., Mr. Joyner, and a Mr. Bonny, have not succeeded with the Cheshire cure any better than I did; but when adopting the very same plan, that I have been doing, they have succeeded in driving the pest out: I live in hopes of doing the same

It must be a wonderful honey country out there, from their return of a member starting the season with three hives, and at the end of the season having twenty-two hives, and taking 3510 pounds of honey. I endorse our editor's remarks hoping he will send us some more reports of what they are doing out there at the anti-

podes.—MAN OF KENT.

'HOW TO DO IT' AND 'THE PRICE OF HONEY.

[1383.] I have been very unwell, or I would have written before to express my thanks to Mr. Saddler (1352, page 504) for his very lucid and instructive communication; it scatters a great deal of the fog which had hitherto surrounded this subject. The great object of my life has been to live and learn, for which I again tender to Mr. Saddler my best and warmest thanks, and only wish that the long distance could be overcome, so

as to procure a private tête-à-tête.
'The Price of Honey' (1359). Mr. C. Howes appears to come down sharp on poor unfortunate bee-keepers like myself, who cannot readily get a market for their honey. I have no doubt that Mr. Howes has a great deal of pluck and business go in him, therefore can feel no sympathy for those with less tact and business capacity, regarding such to be 'human drones.' Well, Mr. Editor, I think there are a great many species of drones, beside those we find in a bee-hive, whose value at present, I believe, is not fully known. There are different kinds of 'drones' to be found in the human hive, beside those who live on the industry of others; 1 mean a kind of mole drone, who move only in their immediate surroundings, believing the whole world to

possess their own happy privileges and surroundings.
'I guess and calculate,' Mr. Editor, there are more stocking machines in Leicester and neighbourhood than bee-keepers, and consequently a greater number of mouths to eat honey, having a much more thickly-populated county than Dorset. Take, for instance, my own district, within a radius of, say, only four miles, I can count about forty hee-keepers, who keep from ten to thirty hives each, more or less, and not what is worthy

the name of a town within twenty or thirty miles, Salisbury being about the nearest and largest; but in the neighbourhood of Salisbury at the present time there is any amount of honey to be bought for 4d.—such as it is. But to return to my own district, What is the result of so many keeping bees, mostly on the old system. Why, just this, some of them read the B.J., and at the close of the honey-harvest, see the advertisements for honey at 6d, or $6\frac{1}{2}d$, per lb.; they at once have recourse to the 'snlphur pit, unless some one more humane comes to the rescue, when you may have any amount of bees for the taking away. The honey is at once hawked about from door to door by the cottagers' wives at 6d. per lb., every village, or what some may call town, is besieged with honey-sellers at 6d., or some more lucky ones may get 61d. Now then, Mr. Howes, I would like to know how you would succeed in cramming honey down people's throats at Is. per lb., or getting a wholesale depot at 9d. per lb. You might as well undertake a journey to the moon, I think; while we poor unfortunates are daubed drones and grumblers because we ask the co-operation of our County Associations, and 'it serves us right if we have no buyers in our district.' Well, well, and what next must we read?

Just one word more, Mr. Editor. I see in the last

issue, which I call the leading article, page 500, on Keeping our Colonies Strong, which I always read with interest, believing it to be from your valuable pen, where in the third paragraph you touch on the same question of the sale of honey by County Associations or Secretaries, evidently the outcome of (what Mr. Holmes calls) my 'grumbling;' the light in which you put it, the thing, as you say, would be very untenable; but that is not what I proposed, to send honey to County Secretaries would be simply madness. What I suggested was just this: Members of County Associations should communicate their wants to their Secretary, who would be supplied with the names of County Secretaries by a properly-arranged system of co-operation; should be in communication with the wholesale and retail market in their several districts; could easily get a supply sent direct to the consumer or retailer from some of the members who have put themselves forward, and, doubtless, would be only too glad to allow a good commission on such sales. So effected in this way, there would be no double freight to pay or risk to run by the County Secretary. This would not prevent Mr. Holmes, or any one else, from paddling his own canoe if he prefer, but it would be a great boon to those living in districts like mine. Of course, there are other details to be worked out, but I submit they are not of a very gigantic or difficult character.-Sherborne, Dorset, November 28th.

EJECTION OF CHYLE FROM THE CHYLE STOMACH OF THE BEE.

By Pastor Schöfeld of Tentschel, Near Wahlstadt.

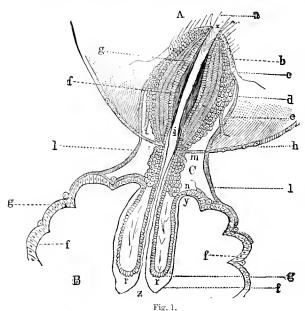

The opponents of my theory, which assumes the food for nourishing the brood to be prepared in the chyle stomach of the bee, and ejected from it into the cell, support their view, according to which chyle is a product of the salivary glands of the bee, by the mere assertion that the contents of the chyle stomach cannot be ejected externally. The part of the neck of the organ called by me the mouth of the stomach, projecting into the chyle stomach, is taken by them to be a valve, which, as it consists of only two very delicate membranes, the intima and the cellular layer, they think would close, or rather turn over, immediately on the contents of the stomach being pressed forward, thus making ejection quite impossible. This opinion, however, is based on a complete misconception of the structure of this organ.

I have fully described its real importance in the

Nordlingen Bienenzeitung, and have shown that there cannot be any question here of a valve arrangement.

For our present purpose I have only to explain that the peculiar prolongation of the neck of the mouth of stomach with the chyle stomach presents no hindrance to the ejection of the chyle.

As shown in sketch 1, which represents a longitudinal

- a. Feelers at the tip of the lips.

- y-z. Prolongation of the neck.

section through the middle of the honey stomach A, the mouth of the stomach, and its neck c, and the chyle stomach B, the real neck of the stomach mouth (m-n), which unites the honey stomach and the chyle stomach, consists of three membranous layers, being the intima, or innermost membrane, the cell layer, and the membrane of the annular muscle. The latter membrane disappears where the neck enters the chyle stomach at n, and then the prolongation inside the chyle stomach consists only of the intima and the cell layer. But these two membranes form a turning-in or duplicator. intima having become separated from the cellular layer iuside the honey stomach at i, it passes as through a round aperture of the chyle stomach into the latter for a distance of one millimetre; then again it takes an upward direction, and enters the intima of the chyle stomach, while the cellular layer follows, but before the turning point upward of the intima is reached, it retreats and passes into the cellular layer of the chyle stomach. By this simple but wonderful formation of a duplicator, the honey stomach has become moveable, which is of great importance to the bee, for when the honey stomach during the act of ejecting honey is contracted by its muscles and pulled forward, the contraction of course always commencing from behind, the prolongation turns over. But this lengthens the neck, which now no longer runs any risk of tearing, however delicate the membrane of which it is composed. The mouth of the stomach is now likewise enabled to rise, and so is the lower part of the honey stomach when the bee wants to obtain a But in supply of pollen from its honey stomach. order that the turning outwards may not be carried

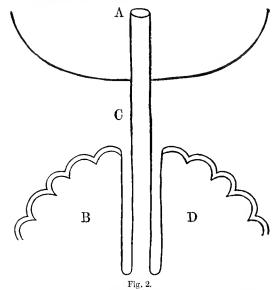

further than necessary, the mouth of the stomach is united to the chyle stomach by a number of muscular bands, which I have called safety muscles in the sketch They are not generally in a contracted state, but more in the shape of a semicircle; when, however, the turning outwards takes place they contract, and thus prevent an excessive extension. The presence of the safety muscles proves that the duplicator exists for the purpose of being turned outwards when necessary.

From this it is evident that because a turning outwards must take place during the act of ejecting honey, owing to the forward movement of the honey stomach, which necessarily follows, there is a possibility of such tilting to happen when ejection from the chyle stomach takes place, that therefore the prolongation

forms no hindrance to the act of ejection.

The mechanism of the ejection of the chyle is not more complicated than that of the ejection of honey. If the bee, in order to eject chyle, contracts the walls of the chyle stomach so that the contents of the stomach are lengthened out in front by pressure, and if, while this is taking place, the bee also contracts its honey stomach for a short moment afterwards, whereby the latter, as we have seen, is forced forward, then the intima or innermost membrane, which from i to the tip of the lips is firmly united to the mouth of the stomach, cannot help following the forward movement. It rises, therefore, from i to z, and when arrived at r, the cell layer rises simultaneously, rolling up from rtowards i, i.e. the whole prolongation is tilted outwards.

Representing the duplicator by single lines as in Fig. 2,

where A shows the honey stomach, B the chyle stomach, c the neck, and D the end of the duplicator, it will at once be understood that the duplicator must be tilted outwards when the honey stomach, with the walls of which the mouth of the stomach is firmly grown together, moves forward in consequence of the contraction of the muscle. But if the tilting takes place but a fraction of a millimetre, the chyle, in moving forward, following the pressure of the muscles, must necessarily also enter the tilted prolongation, and pass through the mouth of the stomach into the honey stomach, by the renewed contraction of which it is then ejected into the cell.

But the principal thing is this: the bee itself shows us that it is able to eject the contents of its chyle stomach. It is an old and well-known saying that worker-brood and drone-brood are supplied at first exclusively with completely digested chyle, which can at once pass into the blood; and that finally honey and pollen are administered shortly before the cell is sealed. The pollen is even visible to the naked eye through the skin of mature larvæ, and as the larvæ cannot live upon pollen alone, it was simply taken for granted they receive honey in addition. But as a sudden unprepared-for change in the food from pure chyle to honey and pollen, which the larvæ would have to digest, would have appeared too striking, Von Berlepsch was one of the first to assume (see The Bee and its Culture, 1869, § 50) that a gradual change takes place from the one kind of food to the other. He was mistaken, however, in supposing that the larvæ received as intermediate food partly chyle from the chyle stomach and partly undigested pollen from the honey stomach. Exact and careful microscopic examination of the food in the cells rather goes to prove that as long as the larva in its curved state at the bottom of cell does not quite fill up the cell—which is not the case till the fourth day—it only receives pure chyle, but as soon as the larva completely fills up the base of its cell, commencing from the evening of the fourth day, the larva, which now requires a large quantity of food, receives only chyme from the chyme stomach of the bee, instead of being supplied with chyle. This chyme is not yet completely digested, consequently it still contains the husks of the pollen-grains. At first there are exceptionally few husks (cuticula) in the food, but their number increases from hour to hour, until finally before the cell is sealed the larva is literally stuffed with chyme full of the husks of pollen-grains. As the latter, from the fourth day, can with certainty be made out in the food which still remains deposited in the cell, this is a sure proof that the pollen has been ejected from their chyle stomach by the workers attending to the feeding of the broad, because it is impossible for any digestion of pollen grains ever to take place in the honey stomach of the bee. I took the precaution to examine the contents of the honey stomach of more than 100 bees, and always found entire pollen grains only, but never any cuticula. Only very young bees which only quite recently left the cell are found to have pollen husks in their honey stomach, because they were fed with chyme by the old workers. — Deutsche illustrierte Bienenzeitung,

SWITZERLAND.

The half annual general meeting of the members of the Société Romande d'Apiculture was held lately at Neuchâtel. When nine o'clock a.m., arrived, the time appointed for the opening of the meeting, the members were so much interested in the examination of the bee show which was being held at the time in the same building, that it was not without difficulty that they could be drawn into the meeting-room. At first it was proposed that it should be held in the Salle du Tribunal, but it was afterwards decided in favour of one of the rooms of the new Academy building. It is understood that the bee section of the exhibition was a great success, and a number of visitors expressed their surprise at what they saw in it.

At the opening of the proceedings the Board of Management was represented by three of its members, but M. de Ribeaucourt arriving a short time afterwards M. Bonjour was voted to the chair, who mentioned with regret the unavoidable absence of M. Fusay, the President, and M. Bertrand. The minutes of the previous meeting held in the spring were read

and adopted without discussion.

M. Woiblet explained the position of the accounts up to the 31st of August. His statement showed that the receipts had been 2296 francs 50 cents, and the expenditure 1382 francs 85 cents; balance on hand, 913 francs 65 cents. It was stated that the Society consisted of 311 members. The retiring members of the Board were Messrs. de Dardel, Fusay, and de Ribeau-

court, but were re-elected by acclamation.

M. Vielle, who had been specially charged to report to the meeting his opinion on the exhibition, expressed his regret at being unable to do so fully, as it had not been possible for him to follow regularly the jury, but, generally speaking it was agreed that it excelled all former ones, and was even an improvement upon that held at Zurich in 1883. The foreign bees were all pure; they constituted a good collection, and prizes had been awarded to all of them. The show of hives and stocks took the form of a small village, and represented the systems most used in the country, such as Burki-Jeker, Dadant, and Layens. Their good quality and construction were much admired. Very few straw skeps on the fixed system were to be seen, but these few were good specimens of workmanship. The show of honey was both large and interesting; it was a great attraction inside the Hall. There was also a good display of combfoundation and wax in cakes. Several makers exhibited a number of new and modified bee implements, and the number of extractors on view was twenty-seven, besides those exhibited by the Society itself.

M. P. von Siebenthal having stated that at Bex there was an opinion among the bee-keepers that the Layens frames should be made two inches shorter, M. Borel-Petitpierre gave it as his opinion that Carniolan bees are an exception, and can be worked with hives of

an exceptionally large size.

M. de Ribeaucourt stated that he had kept Carniolans for the last eight years. His experience was that they had somewhat altered their ways in the course of years; they were now less inclined to swarm, and were very profitable. Truly, in the course of time they became crossed. They were rather late in developing their increasing propensities, but this, for bee-keepers in mountainous districts, was an advantage.

M. Langel remarked, however, that he had some stocks of crossed Carniolans. His were passionately fond of swarming, and became strong too soon in the spring It appeared to him, therefore, that his study of the Carniolan bees could be carried a little further.

M. J. Bonjour had every reason to be satisfied with his Carniolan bees. His experience was that they became strong early, and as a cross they were all that could be desired.

After a few remarks made by M. Nouguier upon the same subject, M. Langel would like to know if there were no means of establishing a honey market in order to assist exhibitors to dispose of their honey? A day for such a market might be fixed, as is done at Schaffhouse with advantage.

M. Lienhard seconded.

M. de Ribeaucourt replied to the effect that the question of a honey market had been mooted a year ago. The establishing of such a market would entirely agree with the objects of the Society, which were intended to promote the production and sale of bee products. He was in favour of an annual sale.

M. Vielle stated that almost all the exhibitors had put a selling price on their exhibits; in fact, he knew

some of them who were anxious to sell.

The conversation became very general upon this subject, and in the end it was decided that an advertisement should be issued, informing the public that a honey fair would be held in the pavilion on the following Wednesday.

Before closing, M. Archinard suggested that this question of a honey market should be further considered and reported upon at the meeting to be held next spring. M. Archinard's suggestion was adopted.

This done, M. Marc Boand read a paper upon propolis

and the various ways in which it can be used.

Mr. Boand concluded by suggesting that a tasteful certificate, suitable for framing, should be issued to all the members of the Society, as is done by the Horticultural Society, his opinion being that such a certificate might act as an inducement to join the Society .- Revue Internationale d'Apiculture,

NOTICES TO CORRESPONDENTS & INQUIRERS.

Letters or queries asking for addresses of manufacturers or correspondents, or where appliances can be purchased, or replies giving such information, can only be inserted as advertisements. The space devoted to letters, queries, and replies, is meant for the general good of bee-keepers, and not for advertisements. We wish our Correspondents to bear in mind that, as it is necessary for us to go to press in advance of the date of issue, queries cannot always be replied to in the issue immediately following the receipt of their communication.

All queries forwarded with be attended to, and those only of personal interest will be answered in this column.

- W. H. A.—1. Temperature for Store-room for Honey.—Sixty to seventy degrees. 2. Honey left in Outhouse.—Will be granulated.
- J. Kennedy, Coleraine.—Weeping Sections.—Is the dampness complained of only condensed moisture? If it is sticky probably the sections were removed from the hive before the bees had fully thickened the cappings. See reply to 'W. H. A.' Could you not manage to extract them without removing the comb from the boxes? Partly extract one side, then reverse and do about half that side again, reverse and finish. You would find built-out sections valuable for the first honey-flow. If granulated, you have no choice except to break them up. Let them be in a warm room for a few days before attempting to extract. It is advisable to keep sectioncases that may be on the hives rather late in the season carefully and rather warmly covered up, in order to encourage the bees to thicken the cappings sufficiently. Refer to 'Bleeding Sections,' p. 529.
- J. P. O .- 1. Bee Farm .- You will find in Mr. Simmins's new book, A Modern Bee Farm, some practical advice and some matter-of-fact figures as to the cost and conduct of a bee-farm. 2. Bullfinches.—If disinclined to shoot them, use a decoy cage.
- H. P. O.-Honey .- The honey is, no doubt, pure, but has a peculiar flavour, as if the source from which it had been partially gathered had imparted a slightly rank odour; and, like some of the Jamaica honey, the grain is rough.
- Ernest.—Sections still on.—It is very undesirable that bees should in any way be disturbed at this season of the year. If the supers are well and warmly wrapped up and kept dry it would be prident to leave them where they are till a more convenient season.
- J. H.—Gravenhorst's Der Praktische Imker has not been translated into the English language.
- J. H.—Honey Dew.—This may be distinguished from honey by colour, taste, and smell. The colour, more especially of that gathered from the sycamore and oak, is of a sooty blackness; the taste is sickly and is perceptibly different from that of honey; the odour is unpleasant.

COWAN'S GUIDE BOOK.

NEW EDITION of this Work will shortly be published. Intending Advertisers must forward Copies of their Advertisements during the present week.

HONEY IMPORTS AND EXPORTS.

It is with no slight feeling of satisfaction that we have written the above words, -- 'and exports.' They indicate that patience has met with its reward, and that a triumph has been achieved. There is a little history connected with this which should be narrated here.

In former times 'Honey' had its place in the annual returns of the imports and exports of the United Kingdom, but in the year 1871 it was struck out by the powers that be 'as being insignificant and of no interest to the community.' Since that time the honey industry has vastly increased, chiefly through the institution of the British Beekeepers' Association and its affiliated societies and the dissemination of bee-literature; and a very natural desire arose that honey should be restored to its former place in the annual published returns. In February 1885 we suggested that a representation should be made by the Committee of the B.B.K.A. to the Board of Trade of the great interest now taken by the bee-keepers throughout the kingdom in having reliable information respecting the imports and exports of honey. This suggestion was adopted, and in due time we were informed, through a communication from Mr. S. Seldon, of the Statistical Office, H. M. Customs, to E. H. Bellairs, Esq., dated 6th January, 1886, that 'on a representation of the Board of Customs to the Lords of the Treasury, the suggestion contained in your letter, dated February 16th, that honey should become a recognised article in the lists of imports, has been approved by their Lordships, and that from the 1st inst. the particulars of honey will be duly registered in the books of this office.

Since the beginning of 1883, through the kindness of Mr. Bellairs, bee-keepers have been put in possession of the value of honey imported into the United Kingdom month by month. But this information was incomplete and insufficient, and to some degree fallacious. We desired to know the quantity of honey represented by the annual value, the price it fetched in respective countries, the countries from which the honey was exported, the amount re-exported to foreign parts and that retained for home consumption; and without these

data we were without a full knowledge of the facts.

The Annual Statement of the Trade of the United Kingdom with Foreign Countries and British Possessions for the year 1886 has just been published, and from it we are able to extract the information of which we have been so long in search.

The amount of honey, its value, and the countries from which it has been imported into Great Britain,

are as follow:-

	Cwts.	£
From France	994	2,479
" Portugal	560	735
" United States of America	4,569	5,830
" Spanish West India Islands	5,272	4,618
" Chile	7,352	7,505
", Other Foreign Countries	694	1,160
Total from Foreign Countries	19,441	22,327
From Australasia	332	578
" British North America	426	618
" British West India Islands	1,354	2,087
Total from British Possessions	2,112	3,283
Total	21,553	25,610

From the above we gather that 2,413,936 pounds of honey have been brought into this country, the mean value whereof is a slight fraction less than 3d. per pound. French honey obtains the highest price, being close on $5\frac{1}{2}d$. per pound, while that from the Spanish West India Islands is the lowest, being rather less than 2d. per pound. The largest quantity comes from Chile. We have heard little of Chilian bees, or of the management of bees in that country. The southern and central portions of Chile, especially the broad valley of Aconcagna, are, we are aware, very fertile; and we presume that the honey is largely produced in those parts. The northern portion of Chile is for hundreds of miles a sterile waste, where vegetation is unknown and where rain is not seen once in a decade; yet in 1883 Chile exported 1,310,256 kilogrammes of honey; in 1884, 1,864,761; in 1885, 1,055,177; the kilogramme being rather more than two pounds. Now, while we are familiar with Californian, West Indian, French, and other honeys, we do not remember having ever seen Chilian honey exposed for sale; and we have often been exercised in our minds as to the ultimate disposal of the amount exported, We think that the statement of the exports of honey may possibly shed some light upon this. John Ruskin says that 'there are two sides to all things, and God means us to look on both.' We may apply this remark to foreign honey. We have hitherto been cognisant only of the value of honey imported; we now have before us both sides, the obverse and the reverse.

The amount of honey exported from Great Britain to other countries, with its value, is as follows:—

To Germany, Holland	Cwts. 8,526 6,821 4,181	£ 7,536 5,766 3,870
Total to Foreign Countries	19,528	17,172
To British Possessions	270	396
Total	19,798	17,568

Deducting the exports from the imports, the result is that only 1755 cwts., or 196,560 lbs., were retained for home consumption in the year 1886; and to that extent the bee-keepers of this country are not equal to supply the home demand. In previous years in making our comments on the 'Honey Imports,' though we guarded ourselves by the reservation, 'Provided no honey was re-exported,' we calculated that the amount of foreign honey imported to supply our wants amounted to a very considerable amount beyond the reality; and we feel assured that all bee-keepers, now that the true facts are apparent, will feel a sense of relief, and a weight of many thousands of hundredweights will be removed from their breasts. The rationale of the matter appears to be—Great Britain is a great carrying nation; the honey is shipped from many foreign ports, and London and Liverpool are the convenient entrepôts from which it is transhipped to foreign countries. In this way it is possible that the whole of the imported Chilian honey may be taken en bloc to other ports.

There is naught in the previous statement that should cause bee-keepers to relax their efforts or to rest upon their oars. It is clear that we are not equal, or rather that we have failed, to supply the home demand. This can, and ought to be accomplished. And besides that, it behoves us so to popularise the use of honey that it should not be, as it has too long been, an article of luxury for the higher and the middle classes, but should be looked upon as a necessity for the poorest of our people.

MY BEES

By Mrs. Reginald Bray. (Continued from page 534.)

Chapter V. -Condemned Bees.

August—cruel August came round all too soon for me and my bees. How I longed as I looked at the hives to be able to take them all with me. I was going to take eighteen canary birds, a bullfinch, two ponies, and eight children; but still a large portion of my heart was left behind. True, we were going to one of the loveliest parts of

Surrey, about six miles from Guildford, where the wild heather and great woods of Scotch firs almost made one believe that it was in Scotland; but as I have heard prettily expressed by the poet, 'Home is where thy affections rest,' and the Bee Journal had brought out a most aggravating little poem, which would run in my head, 'Hum, sweet hum! there's no sound on earth like hum, sweet hum.' Well, why should I not have 'Hum, sweet hum,' at Shere as well as near London? Besides, there I should have a chance of heather honey, and delude myself as much as I would, I never could allow that the flavour of my honey was equal to that of the Scotch.

The worst was that I had already spent a good deal of money upon my bees, what with new hives and skilled labour from Messrs. Neighbour, and one thing and another; I had to undergo a good deal of chaff and sarcastic queries as to 'when my bees were going to pay?'

I always, with great presence of mind, immediately alluded delicately to that 'forty pounds' which they were devouring so ruthlessly. This always checked unseemly remarks, but I own I did not like to talk of buying a new stock and hive in the country. It was too late in the year for a swarm, and to buy an entirely new hive with strong stock would be a very expensive affair.

Suddenly a brilliant idea shot through my mind—'Condemned bees.' I was in the very land for them. The cottagers all round kept bees on the old-fashioned principle, and destroyed all their best stocks every autumn for the sake of the honey. Now, perhaps, some of my readers may not know what 'condemned bees' are, so, for their sakes, I will give a description, for there is no cheaper way of starting bee-keeping, if you do not mind the trouble, besides the great satisfaction of having saved the lives of a reigning monarch and all her subjects.

Condemned bees are the bees which are going to be destroyed when the honey is taken. A hole is made in the ground in which sulphin is put and set alight. The hive is stood over it, and in a short time all those happy, merry little lives have succumbed, and the hive is a mass of dead and suffocated bees. I never saw the sight, and I would not do so for anything that could be offered. When one values the life of every bee one has, when one laments being stung because it costs a bee's life, why the idea of killing bees seems nothing else but wholesale mirder. Oh, when will cottagers learn the folly and the madness of destroying their bees?

Happily, in many parts of England straw skeps have quite gone out, but in our part of the world they are still extensively used; and it is quite extraordinary how difficult it is to make them see the wisdom from even a business point of view alone of saving their bees. They will, I suppose, never be convinced until they find that their honey no longer meets with a sale. When one compares the beautiful virgin honey in the section boxes with the nasty mess they bring one, full of bee-bread, dead grubs, and old black combs, one feels inclined to have nothing to do with it. The worst is that I feel compelled to buy a good deal of it every autumn. The cottagers have been accustomed to come round for years and years, one has not the heart to refuse to buy, so I always do so, and not only that, but they always ask the best price of good super honey. I do not like to be mean, so I always pay it.

This may not be business, but I am afraid I am not very business-like. The only thing I take care to do is, only to buy from my old established customers, and as these die out I shall certainly refuse to buy any honey except that which is worked on modern principles.

Now to return to my condemned bees. I had often read that the cottagers are thankful to let you drive the bees which they are going to destroy. You give them one shilling for the bees, and they have the advantage of having their honey all free from the crowds of bees

which they have suffocated. However, it is not so easy as you may think to get them to see their advantages. As you know there is an immense deal of superstition about bees. Many of them considered it 'unlucky,' and would prefer to kill their bees as their ancestors had done before them.

It was some time before I could hear of any that I could have; and it was now nearly the end of August. My hive, one of Messrs. Neighbour's fifteen-shilling ones with straw sides, was all ready, and I began to feel anxious. I kept reading in the Bee Journal that you ought to have two strong stocks and unite them together. That if you had only one they would probably all die off in the spring from the extra work they would be obliged to do in the autumn.

This was obvious, for just as the unfortunate bees have filled and sealed over their honey for the winter you turn them all out, put them in a new hive, and expect them to do the greater part of their summer work over again. A worker-bee's life is a hard one, so hard that during the working season a bee only lives about six weeks. If it were not for the extraordinary fertility of the queen the bees would soon dwindle away; but as she lays between two and three thousand eggs a-day, the

supply is constantly kept up.

Therefore, with driven bees in the autumn, it is necessary to supply them with as much syrup as they can possibly take, as they can fill their cells with this far more rapidly than gathering the honey from flowers, and at far less fatigue. Besides in the autumn there is very little honey to be gathered as most of the honey-producing

flowers are over.

Feeding also stimulates the queen to go on laying, and the greater number of young bees you can obtain the more chance for your success with your bees next spring.

One evening the keeper asked to speak to me, and told me that he had a hive which he was 'just going to take,' and if I liked I was welcome to the bees. That night I

could scarcely sleep for thinking of it.

There were many difficulties before me, for the keeper's cottage was at the top of a high hill on the Downs, and it would be quite impossible to carry the bees from there, so I thought the best plan would be to drive round and up by the road taking my new bar-frame with me. I did not know then that it is best to drive bees in the evening. They go more quietly into their new hive, and also you get all the bees, as in the middle of the day there are so many out at work. But this is not a rule by any means, you may drive at any time of the day you like. I only mention it, so that, if equally convenient, you can drive your bees late, you will also find them much quieter. Of course I do not mean in the dark, only just when the day is beginning to close in and few bees out at work.

No! if you want to be stung try doing anything with

your bees at night.

My eldest daughter, who in those days showed a greater turn for bees than she has developed since, went with me. The hive was placed in the cart. The smoker, brown paper, and matches (pray do not forget them, as it is so easy to do), veils, gloves, tapes for trying the brood comb in, and scissors, were all put in a basket, and we set off.

The keeper's cottage was situated in a lovely spot on the top of the Downs with a view stretching far away to Leith Hill, Ewhurst, Charterhouse, Hind Head, and Black Downs; but we had no eyes or thoughts for any-

thing but bees.

The keeper and his family came out with great interest to watch the proceedings, as they had not the

slightest idea of what we were going to do.

I gave N. charge of the smoker, and with great difficulty, for the hive was a heavy one, succeeded in turning it upside down in a pail. The skep was put on, and the driving began. The bees did not run very quickly, it was a dull, showery day, and the driving took a long time, over half-an-hour. N. helped me a good deal, but I know I was pretty well tired by the time I had got

all the bees into the skep.

I arranged with the keeper to take the brood-comb and some of the honey so as to start the bees, and transferred it, as has been previously described, and tied it into the frames with tapes. Then I took the skep to shake them in. As I had done on other occasions I gave a sharp shake and the bees fell with a thump into the

When, oh, horror! they all came up again. Up, up, they rose in myriads, the air was peopled with bees, one looked up and it had the effect of a brown snowstorm. I could have burst into tears! Happily I had stood an empty skep on their old stand to collect any wanderers, and thither they hurried back as fast as possible. They were perfectly good-tempered, or else too utterly frightened to think of us, for I only got one sting the whole time.

Said N., 'Let us look into the hive and see if the queen

is there.

I felt no hope, but sadly turned back the quilt and looked in. Oh, joy! yes, there was her majesty on the

brood comb with about fifty bees.

'Hope springs eternal in the human heart,' and I sat down to wait whilst my bees collected themselves in clusters on the skep in the old place. I had to drive them in with smoke; but at last they were all collected once more. Then I again cautiously approached the hive, shook them in and covered them up instantly, and with a long-drawn breath felt that they were safe at last. The entrance I had already closed, as we had to take the hive away, so I felt that now I had really got them quite successfully. The hive we carefully tied up with cords, for fear the lid should slip; and with what joyful hearts I can hardly describe we drove down the hill.

It was long past lunch-time, but I could not rest until the hive was placed on the stand prepared for it at the bottom on a little copse facing the south and completely sheltered from the north and east. I did not open the entrance thinking I had better leave them to quiet down for one hour or two before I set them free.

Later in the afternoon I went down and opened the entrance. The bees came out as quietly and happily as possible. It was almost impossible to believe that they had gone through all the commotion of the morning. Here they were working as busily as if they had never been disturbed in their lives.

I do not think any bees ever gave me quite the delight of those,—I had actually saved their lives. As each one hummed happily by, I said, 'But for me you would now be dead.' They did not evince any particular sign of gratitude, but in this life one ceases to look for much

except when it is a sense of favours to come.

I fed those bees continually. I never saw bees take down so much, a pint was gone in no time. It was such a continual trouble going down rather a steep hill to fill the bottle that I set myself to work to make a feeder which would hold a quart at a time. I thought if it were home-made it would cost me nothing, and I was determined not to spend another unnecessary penny. Accordingly I got a biscuit-tin, and with a chisel and mallet I cut the top of the lid out, leaving about half-an-inch all

Happily some one broke a window just at this time, and out of the broken pieces I got the glazier to cut me a piece of glass which I put into the lid myself with putty. So far my feeder had cost nothing except a penny for putty, and I began to feel rather triumphant. Then came a little difficulty, I wanted a hole cut in the bottom of the box, and a little funnel soldered in through which the bees were to come up, and another at the side through which I could pour the syrup. For this I was obliged to go to the blacksmith. Then I wanted a small board with a number of holes in it which was to fit the tin exactly, with a hole in the middle through which the funnel would pass; the syrup would be poured through the funnel at the side, the board would float upon it, and the bees would take the syrup through the holes. I cannot say that I had shown any great inventive genius in this, as there are many kinds of float-feeders. The only difference was that mine was home-made out of a biscuit-tim. The little wooden float I had to get from a carpenter; and I believe when complete it cost me rather more than it I had bought a new one; but there would not have been the same satisfaction about it.

It did not answer very well, for the tin bent so easily, and then the thoat did not rise and fall on the syrup as was intended; but as I looked at it several times a-day I kept it in order. I would not recommend any one

to try and make one like it.

One thing I have never confessed to any one before, but in a book of this sort no disaster must be left out. When I had timished feeding in the autumn and took my feeder off, I found such a number of drowned bees at the bottom under the float, that N. and I opened, emptied them sadly away, and kept the matter to ourselves, for I had boasted a good deal of that same feeder.

One thing I have forgotten to say, do not be deluded by being told that at the end of three or four days the bees will have mended up the combs tied into the frames, so that you may cut the tapes and draw them out.

Knowing that bees have a great dislike to the tapes, I went at the end of a week to take them away. I had given more than the time specified, so I thought I should be quite safe. I opened the hive, turned back the quilt, and cutting the tapes carefully drew them out. To my great dismay down fell the comb, as the bees had not made it nearly fast.

I did not much like the idea of putting my hand right into the middle of the hive to fish it up again. But there was nothing else to be done, and I had to get it up as best I might, tie it once more into the frame and put it back. After that I left the bees to gnaw the tapes and

get them out by themselves.

If they did not choose to get their work done in proper time they could scareely expect me to help them. The only thing I did was when I saw them struggling with a long piece of mangled tapo at the entrance, was to eatch it with a bit of stick and pull it out for them. In this way the tapes were all got out. It was rather a slovenly way I acknowledge, but wait till you have put your hand into a bee-hive and then you will not blame me.

When it was the end of October, and the time had nearly come for leaving Shere, even the thoughts of returning to my other hives could searcely reconcile me to leave these special bees who seemed to belong to me

more than any others.

I had fed them with syrup until every comb was full of honey, but still haunted by the idea that one set of condemned bees would not be able to take care of themselves and would die off in the spring, I determined to make every possible arrangement for their comfort.

That week I read a letter from a correspondent in the Bee Journal describing how he had fed his bees entirely on moist sugar, and how splendidly they had done. He described how he had filled the space on each side of the hives between the dummy boards and the sides with moist sugar, and how this had saved all the trouble of syrup feeding and the stock so fed had done as well as any of the others.

I sent to London to Messrs. Neighbour for the best West India sugar, as this has a great deal of moisture,

and is recommended as the best to use.

N. and I crammed it into the hive by handfuls. We pressed and we squeezed it in until we had got twelve pounds stowed safely away as a winter resort for the bees.

Then we covered them up for the last time that year and left them, enveloped in a most pigturesque straw

hackle which one of the Shere men had made for me in the most artistic manner. We left them feeling that whatever happened at least they would not starve.

The next time I saw those bees was on Christmas-day. It happened to be a lovely, sunny day, and the bees, tempted by the warmth and sunshine, came out to greet me in the most considerate way, thus adding not a little

to the happiness of the season.

Before I go further I must advise my readers never to be tempted as I was to fill their hives with sugar. The following spring, as I was not at Shere at the right time for inspecting my hives, I asked the afore-mentioned cousin to get an expert who lived near to overhaul my bees, and see whether they had finished all their honey and sugar and required feeding.

Oh, the state of that hive when he opened it! It was simply a sticky and unpleasant mess. The moisture condensed in the hive had partly melted the sugar, and the state of it was past describing. The bees themselves were in the most flourishing condition, and had not eaten

half their supply of honey.

The whole hive had to be cleaned out. He got an empty bar-frame and moved all the frames in, then he thoroughly cleaned it out, and replaced the frames. I have never tried feeding my bees with moist sugar again.

(To be continued.)

Foreign.

NORWAY.

BEE-KEEPING IN NORWAY,

We had a very pleasant and instructive conversation with Mr. Young, and, of course, made all possible inquiries about the state of bee-keeping in Norway.

Bees can be kept very well as far north as Drontheim. In Norway, as here in Canada, there is no method by which the number of colonies can be ascertained, but the number of colonies kept are estimated at about 40,000; of these about 2000 are kept in the moveable-frame hive, the balance in straw skeps.

The Government of Norway realise the importance of apiculture as an industry, and have sent Mr. Young, at their expense, to Canada and the United States, to pro-

mote the interests of bee-keepers.

Wintering is done very successfully in some of the old straw-skep hives. Many think the bees in the moveable-frame hive do not winter as well, but such is not the ease; on the contrary, the honey taken by means of the moveable-frame hive is mostly extracted. On account of so few frame-hives, and but little comb-foundation being used, the average yield per colony for the country is not great, but he thinks if properly conducted it would be 70 pounds to 100 pounds per colony.

The chief sources of honey are clover, basswood, and heather. The clover is mostly alsike: there is but little

white.

The Norwegian Bee-keepers' Association has some 1500 members, has been in existence three years, the Bee Journal two and a half years. Every member gets this Journal free, and the Journal is the property of the Association, and under their control; and one having goods to advertise ean do so in the advertising columns. Fifty eents entitle a bee-keeper to membership and the paper, which is monthly. Any one not in the country pays \$1: this extra charge being made to cover the extra postage.

Mr. Young also very kindly presented us with a copy of his book on bee-keeping. He may justly be called 'the father of advanced bee-keeping in Norway.'—Canadian

Honey Producer,

FRANCE.

FRENCH BEE-KEEPERS AND PROTECTION.

At the Congress of bee-keepers held at the Orangeries des Tuileries of Paris on the 23rd of September last, the

following resolutions were proposed:—

First.—In view of the fact that bee-keeping is being affected by the cheapness of sugar and the competition of foreign agricultural products sold at low prices, the Congress calls upon the Government to put an import duty of ten francs per 100 kilos upon foreign honey and wax imported into France.

The Congress further records that railway carriage should also be reduced in proportion to the reduction which has taken place of late, and which, compared with the prices ruling twenty years ago, may be com-

puted at twenty per cent.

Second.—Considering how seriously cérésine (ozokerite) is competing and ruining the price of beeswax, and particularly in view of the fact that this cérésine is often mixed with genuine beeswax, and palmed off to the public as such, the Congress is of opinion that a heavy import duty of, say, 100 francs per 100 kilos should be imposed against this foreign mineral, to the end the interests of apiculture may be protected as they deserve to be.

Third,—Whereas the municipal regulations issued by certain mayors regarding the distance at which apiaries should be kept from public thoroughfares are often dictated by mere personal enunity, the Congress is of opinion that the General Council should be consulted

before the new rural code is drawn up.

The Congress is, however, of opinion that all such regulations are an obstruction against the progress of apiculture, and would prefer, therefore, that the principle of liberty secured by the Bill of 28th September, 1871, and provided that 'the keeping of bees as well as that of domestic animals should not be placed under any restrictions' should remain unaltered.

Fourth.—That whereas tuition is the best means by which rational principles can be rendered popular, the Congress puts on record the hope that a bee station or school be established on one of the State properties out-

side Paris, viz., at Meudon or at St. Cloud.

The Congress would further suggest that the beesection of agricultural shows got up by the Government be judged by a competent jury composed of bee-keepers.

It also suggests that when agricultural shows are held in districts where bee-keeping might be carried on with advantage, a bee-section should be added thereto.

The above resolutions are to be forwarded to the French Ministry for Agriculture.

ASSOCIATIONS.

IRISH BEE-KEEPERS' ASSOCIATION.

The Committee met on the 6th inst. Present: Rev. P. Kavanagh (in the chair), Dr. Knight, Mr. Read, Mr. Milner, and the Ilon. Secretary. Sample hives made by Messrs. Abbott and Edmondson, after the Association's pattern, were inspected carefully and approved, subject to slight alterations being made in them.

LEICESTERSHIRE BEE-KEEPERS' ASSOCIATION.

The Committee met on Saturday, December 10th, to receive the Report and Balance-sheet. On the Report touching on the weak financial condition of the Association, each member of the Committee present 'came down with some chink,' and expressed a hope that others would follow the example, and that Messrs. Bickley's and De-la-Bere's offers would not fall to the ground. The former, as previously mentioned in this

Journal, offers to pay 1l, to relieve the debt if nine others will do the same; the latter offers to double his subscription if fifteen others will do the same.—E. B.

Review.

A MODERN BEE FARM AND ITS ECONOMIC MANAGE-MENT. By S. Simmins, published by T. Pettitt & Co., London.—This is a useful book for those intending to cultivate bees, more particularly for such as intend to make it a business, as the author gives instructions deduced from his own experience of over twenty years, and says, 'The reader will, therefore, have the benefit of a lengthened and varied experience, and by following one recognised system, there will be little possibility of one being confused by the usual multiplicity of ideas upon any one subject. Mr. Simmins has endeavoured to place the management of bees before those who wish to become bee-keepers in as clear a manner as possible, and with few exceptions describes only such hives and appliances as he makes and uses. With regard to the value of honey as an inducement to make bee-keeping a business, the author says, 'While an increased production has lowered the value, there is at the same time a larger and increasing demand for the bee-keeper's commodity; and as he now has the benefit of improved appliances there is no difficulty in competing with present rates. In fact, it appears likely that very soon it will not pay foreign countries to send their honey here, as continued improvements are reducing the cost of production at home.

After honey was superseded by sngar, bee-keeping seems to have fallen into the background, but light began to dawn, and it was some thirty years since that, by using hives wherein all the combs could be removed separately at will, a great stimulus was given to both practical and scientific bee-keeping, consequently the ranks began to swell, as it became known that much larger harvests could be secured than by the old fixed-comb methods, and in every way the bees could be brought

more under control.

But more light was yet needed, and *Bee Journals* were established, but it was not until the year 1873 that this country could boast of one, and that was founded by Mr. C. N. Abbott, of Southall, who ably conducted it for about ten years, when it passed into the hands of the Rev. H. R. Peel.

Soon after this paper was established we find Mr. Abbott inaugurating the British Bee-keepers' Association, his object being the diffusion of the knowledge of bee-keeping, especially among the poorer classes, as a means

of bettering their condition.

The work consists of 195 pages, and is divided into twenty-five chapters. In Chapter V. the author gives his experience with different sorts of bees, much of which agrees with ours, but when he says that 'There is no doubt that the leather-coloured Ligurians, mentioned by the Americans as being superior to any, are nothing more nor less than hybrids,' we must most emphatically disagree with him. We have never considered the colour of bees in breeding, and have always insisted that other points were of greater importance. Our best Italians have been dark, or what might be called 'leather-coloured,' but they were none the less pure for all that.

We have had the opportunity of studying the bees in their native country, and have repeatedly stated that we have seen dark bees in Italy in parts where not a single bee of the black race exists. The Italian beekeepers themselves do not put any value on the colouring. Colour has always been considered a point of beauty in other countries; and as there has been a demand for such, the Italian breeders have endeavoured to meet it, but not without very much injuring the race. We

know for a fact that many breeders breed solely for colour in order to supply the English and American trade: this is why such an immense number of imported We obtained our strain of queens are worthless. energetic workers, without any admixture of common blood, but then only by getting direct from Italy such queens as we desired regardless of colour. We therefore believe that there may be 'leather-coloured' Ligurians. and that they need not uccessarily be hybrids. Although usually Italians have three bands,—and this is a good sign of their purity,—yet we have seen the pure races producing bees with one, two, and three bands, and that in Northern Italy where a black bee does not exist. We are pleased to find the author in agreement with us on so many points which we have repeatedly insisted upon, with regard to the queen never being too prolific, having only young queens in the apiary, requeening every year, and on breeding to improve the strain. In Chapter X. 'the Economic' hive and other appliances used and made by the author are described and illustrated.

There are also interesting chapters on How to stock a frame-hive, Wintering, the Production of Honey, &c., then there are also the Simmins' non-swarming system. and his method of queen-introduction, as well as a chapter on the production of wax. His own apiaries are described and illustrated on page 148, and much useful information may be picked up by those going in for bee-keeping on a large scale. The estimates given of probable expenditure and income are useful and interesting: and we commend them to the consideration of our renders as coming from a practical bee-keeper; but they should be received cum grano salis, more especially as Mr. Simmins himself says, 'I do not by any means wish or intend that the estimated returns are to be taken as implying certainty.' We would suggest that in making the estimate the bee-keeper should put down interest on capital employed, and make a deduction for annual depreciation of plant, &c. Besides a certain allowance must be made for appliances becoming obsolete. This is a heavy item, and at Captain Hetherington's we saw an enormous building, formerly a chapel, completely filled with such disused things.

We have in mind several good bee-keepers who have failed when working on a large scale; and where one would have the energy and perseverance of Mr. Simmins, who has succeeded and made it pay, there are a great many who would find it a serious loss,—at any rate in our climate.

The author recommends planting for bees, and considers twenty-five acres a suitable space to provide pasturage for I00 colonies. We have practised planting for bees, and have no doubt it has increased our harvests considerably; and those who are already farmers and cannot easily get out of their farms would do well to try planting in moderation; but in these times of agricultural depression, when, as is well known, that except in a few favoured localities farming does not pay, we should hesitate to recommend any one to burden himself with land for such a purpose.

We have for many years had a farm on our hands, and although highly cultivated we have no hesitation in saying it has been carried on at a great loss to ourselves. Where any one had to make a living such a loss would be a serious drawback, and would considerably reduce the profits derived from bees. Very much rather would we recommend the bee-keeper to induce his neighbours to plant crops that would provide the pasturage, even if he had to supply the seed for nothing. His advice to intending appliance-makers is good, and we commend it to their serious consideration, as it is impossible for beginners without machinery or capital to compete with long-established firms.

In the practical part the book contains many hints, and it is also suitably illustrated. In addition the

neatly-bound copy contains a photograph of the author and his family, one of a frame with queen and workers, and two of his home and covered apiaries. written by a practical man, bee-keepers will find in it much that is useful.

Correspondence.

The Editor does not hold himself responsible for the opinions expressed by his correspondents. No attention will be taken of anonymous communications, and correspondents are requested to write on one side of the paper only, and give their real names and addresses, not necessarily for publication, but as a guarantee of good faith. Illustrations should be drawn on separate pieces of paper.

Communications relating to the literary department, reports of Associations, Shores, Meetings, Echoes, Queries, Books for Review, f.c., must be addressed only to 'The Editor of the "British Bee Journal," c/o Messrs. Strangeways and Sons, Tower Street, Cambridge Circus, W.C.' All business communications relating to Advertisements, &c., must be addressed to Mr. J. Huckler, Kings Langley, Herts (see 2nd page of Advertisements).

**In order to facilitate reference, Correspondents, when speaking of any letter or query previously inserted, will oblige by mentioning the number of the letter, as well as the page on which it appears.

OUR HONEY IMPORTS,

The value of honey imported into the United Kingdom during the month of November, 1887, amounted to 10671. From a return furnished by the Statistical Department of Her Majesty's Customs, to E. H. Bellairs, Wingfield, Christehurch.

'A, E,' WANTS A DIPLOMA.

' Seeking the bubble reputation even at the cannon's mouth.'

[1384.] I want a diploma, and with it the right to write two or more Roman capital letters after my name. It must be something novel and puzzling, B.A., M.A., LL.D., D.D., or even Ph.D., are all too commonplace to satisfy my ambition. In my youthful folly I used to scorn such things, but as one grows grey (or bald) the memories of

the follies of youth are not always pleasant companions. I have gone in for scientific (?) lecturing, and the unpleasant discovery has been forced upon me that, though I may possess the ripe and mellow wisdom of a sage and 'hold not the parchment,' I am as a sounding brass or a tinkling cymbal; but with the parchment, though I may be a numskall no man dare question my ability or qualifications. Would the tale of how I made this discovery amuse you? Draw up your chairs while the wind roars outside and I will tell you. In a quiet old town named Dulborough, so near to S. Kensington that at night you can see the glare of London lights, and almost hear the roar of its traffic, I have a friend. He is large-limbed, large-hearted, and large-brained. He is a schoolmaster; until recently he worked under 'management, which simply meant the Rector, for, as usual, none of the other managers ever cared a brass farthing about how the school went on. So my friend, as many others of like courage have done before him, simply rebelled and tendered his resignation. Thinking there was an opening he started a middle-class school, and met with success far beyond his hopes or expectations. He is a hee-keeper, and being burly as well, that is a sufficient guarantee that he is a jovial fellow. The worst thing about him is his name. His surname, which is neither pleasant nor poetical, like the rest of us he could avoid; but how he must bless his father and his god-parents when he has to write his Christian (?) unmes thus:-Jacob Banoni Zachariah Bangs! Wonder if his old man believed in the British nation being the lost ten tribes? Now my friend not only taught small boys by day, but he also filled a much-felt want by opening a series of evening classes under the Science and Art Department, South Kensington.

Dulberough being an agricultural centre he chose Agriculture as one of his subjects, Animal Physiology being another. Although this ancient town boasts of a

mayor and corporation and a history far beyond Julius Cæsar, yet I venture to say that a sleepier place is not to be found in the kingdom. My friend not being a 'native' thought he would help to enliven it a little during the long winter evenings, so he organized open nights' in connexion with his classes. On one occasion he got the music class to sing some carols, on another he got a local physician and a Cambridge B.A. to bring his skeleton and lecture in connexion with the class on Animal Physiology; and finding these 'open nights' were appreciated, he asked me to give him a turn on Bees in relation to Agriculture. I agreed and went. I alighted at the station-one of three I remember and 'All change here.' There were seven flys and cabs to take us into the town (which Kelly's Directory credits with 7000 inhabitants), and about three times that number of urchins to earry our parcels. In the town itself the stillness was painful, and my footfall on the pavement awakened echoes that made me feel the whole troop of urchins I saw at the station were in pursuit. But presently my eye caught something that attracted my attention, it was a handbill announcing myself to lecture on 'Bees in connexion with Agriculture,' at 7 p.m., and also that A. P. E. Slaughter, Esq., M.R.C.V.S., would 'dissect an eye, in connexion with Animal Physiology,' at 8 p.m. that evening. I found the school, my friend, and his class. I set up my Cheshire diagrams and the few things I had brought, including a few flowers, and waited for the clock to point to the honr; and while doing so my friend, with very great regard for my feelings, went on to explain, that however able I may be to deal with the subject, the Science and Art Department would not recognise that hour as a lesson unless he took some part, as I was not a 'certified' teacher. Would I mind him taking the first five minutes, and I following on as his assistant? Of course I did not mind, so he went on to speak of the relative value of certain cereals as food, and introduced myself as about to speak of the value of 'Bees as fertilisers.' My friend was a model chairman, no flattery, no taffy, so, having a fair start, I was soon in full swing, and was alarmed to find it only wanted five minutes to eight, and I only just 'warm' to my subject. I apologised, got a few minutes grace, and went on, till, at ten minutes past eight, I resumed my seat.

When I commenced I began to wonder what had become of my coadjutor with the five Roman capitals dnly 'certified,' but at a few minutes to the hour I was no longer left in doubt, a head was thrust in at the door, and speedily withdrawn; this was repeated at intervals of a few minutes, until as I sat down in walked a swell as stiff as buckram, carrying a dish covered with a napkin. He sported an 'Imperial,' with the ends well waxed, a masher collar, rings, jewellery profuse, and, in fact, had all the airs of a 'big pot!' I removed my gear speedily, and withdrew into an obscure corner to ruminate, until all being to his satisfaction he commenced by turning to a large diagram on animal physiology, and attempted to explain the various parts of the eye. But I soon found he had made an error, and so did he, as he referred to a long sheet of notes which he had prepared. Correcting himself he essayed to proceed by commencing afresh at the beginning; arriving at the old spot he repeated his former mistake, and went back with flushed face to commence again. This time he did not get so far as on the two previous 'tries' before he said something outrageous, and was gently put right by my friend. This instead of helping him only increased his confusion; until laying down a small cane that he had been using as a pointer, he looked across to a lady sitting there and said: 'I told you so. I have not felt well all day, and several professional engagements during the past fortnight have prevented my reading up the subject. I cannot possibly go on; I will (Alas that the wife of a man's come next week.'

bosom should be the unwilling spectator of her lord's discomfiture!) At this a young male student who had been taking copions notes after me, and helping a young lady student to copy off some of them during the interval, gave a loud 'guffaw,' which upset the poor fellow entirely. But my friend was equal to the occasion. He took the diagram, and talked on in his own lucid style, and at the proper moment the 'duly certified' M.R.C.V.S. took up his lance and dissected the eye. How his hand trembled! All ended well at last, as the tales do.

My friend 'J. B. Z. Bangs' wrote me early in June: 'All his students had passed, some with honours. Two in the Agriculture class were disqualified from taking Queen's prizes, because they had not sat a previous year in the elementary class.' Poor return this,' remarked he, for doing two years' work in one year!'

I left that meeting with such an impression of the value of a 'diploma' as I never dreamt of before. Will the B.B.K.A. get chartered as a 'learned' society with the power to grant them? I have found the letters; see how grand they look.—AMATEUR EXPERT, A.U.G.

QUERY.-What do those three letters stand for?

PRICE OF HONEY.

[1385.] I notice that 'Woodleigh' [1378] appears to consider I have said the supply of comb-honey has exceeded the demand. Nothing could be more contrary to my own experience, and if he will again refer to my article [1361] he will find no such statement.

What he will find is I have there endeavoured to show that a false impression is always produced early in the season; and a superficial observer is led to believe there is an over-production, when in reality the entire produce of the country is thrown upon the market to be disposed of in three months, leaving the remainder of the year honey-less.

I have yet to see the supply in excess of the demand, neither do I expect such to be case for many years to come. Long before Christmas dealers find the supply slackens, and the price of comb-honey rises considerably, while in many cases it is retailed at something like the old figures. It is just because this article is so abundant at one time, and then so scarce at another period of the same year, that we find such fluctuations in its marketable value.

It would be found were three times the weight of comb-honey placed upon the market between this and next June that has already been produced this year, the whole would be disposed of at higher rates than have ruled during the earlier part of the past season, provided it could be distributed evenly throughout the other eight or nine months. As it is the supply drops off, and the article is lost sight of, until once again it is suddenly brought before the public in large quantities; but by the time it is getting to be appreciated the season's produce is exhausted. All the time this 'gap' is to be found year after year, it is self-evident that the supply is far short of the demand—a demand which is ready to grow with a constant and increasing supply.

Generally speaking, prices of comb have come down considerably, partly because of the 'rush' at the commencement of each season, but principally for the reason that the old rates were quite prohibitory, and such as could not be adopted by any company or individual dealer who had the slightest knowledge of the laws that govern 'snpply and demand.' And though the demand is yet in advance of the irregular snpply, that is no reason why high prices will ever rule again; but it does show that there is no need to sacrifice good comb-honey at the price of extracted, as many have done as soon as their crop is off the hive.—S. SIMMINS.

RIGHT-ANGLED VERSUS PARALLEL FRAMES.

[1886.] Prove all things, hold fast that which is good. Had Mr. R. A. H. Grimshaw done this I am 'fully persuaded' that he would have written different from what he has done. His admission that he has adopted the broad-shoulder frame proves that he is behind the times. No bee-keeper who wishes to take the most out of his bees could tolerate a hive with a frame at a fixed distance. When I commenced to make frame-hives, Abbott was praising up the broad shoulder, and I adopted it, but after using it for about two months I took a chisel and punched them all off; and would advise Mr. Grimshaw to do the same, unless he is one of those that have more love for drones than honey.

He says 'he went to Nature for her samples.' The rose, the pansy, or the chrysanthemum of the present day—the product of Nature—has not science turned the mens of these flowers into petals? It is the same

mens of these flowers into petals? It is the same with a frame-hive. Nature has nothing to do with it, man has brought his superior knowledge to bear on the question, and he sees that by setting the frames a certain way at a certain distance apart he can make his bees do better than they would do if left to themselves.

Again, the question of draught. Before there can be a draught there must be two openings, and it applies as equally to parallel as right-angled frames. The difficulty in manipulating right-angled frames exists only in Mr. Grimshaw's imagination; it is practice that makes the difference.

I deny that giving sheets of foundation at the back is an advantage, as it can be done equally as well at the side of a right-angled hive as at the back of a parallel one.

The modern cure for swarming is room above and air below.

Bees do not store their surplus at the furthest obtainable space away from the entrance, but above and around the brood-nest. In hundreds of cases I have seen honey sealed down to the very door in right-angled hives, and more of it than ever we could see in a parallel one.—Jas. Saddler, Forfar.

FOUL BROOD.

[1387.] Having read a good deal on the above subject. and seeing there are a great many who have not much faith in the Cheshire cure, I think it nothing but fairness to give an account of how I cured a very badly diseased stock which had dwindled down to such an extent that they did not cover two standard size frames. disease appeared in a straw skep belonging to a labourer close by, and having heard they were doomed to the sulphur-pit, I asked if he would permit me to drive them, which he did, when I found that they were as above described. To be certain that such was the case, I sent a piece of the comb with broad to Mr. Cheshire, who was good enough to inform me that it was a very bad case, and advised me to consult your valuable Journal as to the best means of cure; which I did, with the result that I got a bottle of phenol as prescribed by Mr. Cheshire, and, after putting them in a new bar-frame hive, with three frames having full sheets of foundation, I fed them with syrup mixed with phenol as per instructions, which the bees took eagerly, and which induced the queen to recommence laying (being then the second week in September); so, after making them up to five frames, I packed up for winter, but not before seeing that brood was being hatched out. Well, letting well alone until early spring, when, on a warm day, I examined them to see how they had fared, during what we all know to be a very severe winter, and to my delight I found three out of the five frames with brood in all stages, and

plenty of food. Later on I put more frames and stimulated with a little warm syrup (with no phenol or chemicals whatever mixed with it), which encouraged breeding so fast that I found by the end of May they were preparing for swarming, which I prevented by the usual way, viz., cutting out queen-cells and giving plenty of room. I took 22 lbs. of sectional honey from them, leaving ten frames of food for their own consumption, which about a fortnight since I reduced to seven, and thoroughly examined them, and I found no foul brood or any disease whatsoever, and this stock is quite as strong as any I have. I merely write this letter to give heart to those who may have the ill-luck of having this, I may say the worst of all diseases, amongst their busy pets. It is such a simple remedy that any inexperienced person could use it; and I may say that I have not had much experience myself, having only commenced bee-keeping in June, 1885, so it clearly shows that all praise is due to the Cheshire cure for curing this stock so badly diseased.—E. H. PIKE, Arthur Cottage, Park Street, Slough, December 6th.

DRONE-COMB.

[1388.] If it is not too late I want to suggest a point that you might mention in connexion with the little discussion in British Bee Journal concerning the design of bees in building drone or worker-comb. It is this: In the early part of the season when bees build comb without foundation a fair proportion is sure to be drone, especially if the queen's supersedure is near at hand when drones may be needed, whereas in the fall if a colony is fed and obliged to build combs in which to store the food, the combs, on the testimony of a number who have tried the experiment, will all be worker, no drones being desired. Does not this point pretty strongly to the conclusion that drone-comb is built because the bees desire drone-brood?—Extract from a letter received from Dr. C. C. Miller, Marengo, November 25.

ECONOMICAL CUSHION AND FEEDER.

[1389.] This cushion and feeder has many advantages over anything of the kind that I have yet heard of. No quilts are required, there is no trouble in removing in spring to put the feeding-stage on, as it is always there ready at hand. This has ever been a trouble, having to provide so many quilts for winter use; and again in spring they are sometimes troublesome when putting the feeding-stages on, as one hole is here and the other there. If a cushion had only the advantage of dispensing with these nuisances they would be worth the extra trouble in making them; they are quickly put on and much pleasanter to work with, besides their value as a winter covering. These are simple matters worth thinking about in favour of the cushion. Any ordinary cushion will answer the above purpose, but the cushion I am writing about has several other and very important advantages. It is so arranged that all kinds of feeding can be made use of at any time when on the hive, and one can be done equally as well as another. To do this various feeders, or means of feeding, have to be made use of, but in the economical cushion feeder all is combined in one. Dry sugar, candy, or liquid, can be used with very little alteration in the feeder, and in supplying the bees with liquid food it can be given either fast or slow in the centre of the cushion. It is so contrived that those various means of feeding can be made use of, and close to the ordinary feeding-stage there is another smaller one to supply the bees with water, sweetened, in early spring, when it is too cold for the bees to leave their hives and seek it elsewhere. This water-stage is a hollow tube, 11 in. inside, with a piece of perforated zinc at the bottom of it for the in-

verted bottle to stand on. Besides the above properties that this cushion and feeder contains, there is yet another of very great importance. We are told to cut holes through the combs to give the bees passage-way from one comb to another. This may be very good advice, but I, like many more, do not like the idea of damaging the combs. For this purpose some will recommend passages over the tops of the frames. If this will answer the purpose, there will be no need to damage the combs. Where this cushion is used, there is a passage-way provided along the centre of the under side of the cushion over the tops of the frames, $2\frac{1}{2}$ in. broad by $\frac{3}{5}$ in., which gives the bees passage-way to any part of the hive, and to their food and water. What I have stated is merely to show the various purposes that are here combined in one simple arrangement, and the value of it as a good winter covering. I think there is nothing that will answer so well when packed with chaff. I have said nothing how this cushion is made, but should any one wish to know more about it, and how it is made, I should be glad to explain this in a future number of the B. B. J.—R. Philipson, Keswick, Cumberland.

FOUNDATION versus WORKED COMBS.

[1390.] Mr. Saddler's strictures on the replies to Selected Query No. 2 are nothing if not satirical. These may safely be left for the parties interested to answer. 'For all Two points, however, are worth notice. practical purposes a sheet of foundation is superior to a comb' is Mr. Saddler's opinion. To refute this is easy. Given a stock in April in need of extension of broodnest, it is incredible that a sheet of foundation can be so soon filled with eggs and brood, and with no more wear and tear of bee-life than a clean worker-comb; the facility of giving sealed or partially uncapped stores should also be taken into consideration. Later in the year, when the honey-flow is expected, the advantages of combs may not be so great, but are still considerably over plain foundation. Has Mr. Saddler ever tried doubling or tiering hives filled with clean comb for the production of extracted honey? If not, let him do so next season, and I venture to predict the result. It is important that the combs given for the latter purpose be clean. No old stores should be allowed; these given when honey is to be gathered frequently cause the stock to 'loaf' and do little when others fill freely; those with deep cells, i.e., farther from centre to centre, are most most valuable, as they save handling.

To store combs, when preparing for winter, those that can be spared which contain much food are valuable for stimulation and building up colonies in spring, and should be put away securely in comb-boxes, or other receptacles mice-proof. Combs containing little had better be uncapped and given to the bees to clear, not too late in season, and may then be closely packed in hives that will tier; if the latter are dressed with carbolic acid and water it will tend to keep them in good

condition.

Mr. Saddler, in his last paragraph, writes strongly, somewhat ignoring the hints lately given in the Bee Journal on courtesy in refnting what we consider errors in others; in turn I will ask if he has studied this wiring business,' to what extent, and with what result, more particularly in regard to the clause at the end of his article, p. 538? If he will do this, I will endeavour to show later on how there need be no danger apprehended from spare combs spreading foul broad, nor 'waste' in wiring frames of foundation.-John Edex, St. Neots.

QUERY.

[1391.] I should like to have the opinion of some of our leading bee-keepers on the following questions:— I. What number of frames are generally thought sufficient to prevent swarming, as I find that a double hive with twenty frames is not sufficient to keep them at home? This number of frames and a crate of 2-lb. sections did not give them sufficient room. I am now making a third tier to some of my hives. 2. What number of bees are there generally supposed to be in a three-storey hive, with thirty frames and well crowded with bees. 3. Would it not be better to make frames I-in. broad, or a little over, for filling with dronefoundation to be filled with drone-comb for extracting purposes? As with the ordinary frame, when filled with drone-comb, it projects so far on each side of the frame; it is more liable to be damaged when in the extractor. A broader frame would protect it. Is there any objection to these broad frames?—R. P., Keswick.

BEES IN THE ARGENTINE REPUBLIC.

The bee abounds, and eight distinct species are recognised: The tiosimi, yana, mosa mosa, mestiso quilaya, cani, quella, and alpamisqui. These Índian names are significant of the characteristics of these industrious and useful insects. The people of the country revel in the rich supplies they afford of a delicious and invigorating food. Tate of several of these varieties of honey, and preferred above all others that of the toisimi bee, known as the cardon honey; for it is only found in the trunk of that cactus. Expressed from the comb, it becomes after a few months perfectly white and granulated; and when eaten with hread or parched corn is considered delicious and sustaining. The Santiaganians prefer the cardon, but they also highly prize the lechignaña, the product of a bee which makes its hive in trees, and feeds upon the first spring flowers; for the flavour of the houey depends upon the food of the insect. The comb looks as if formed of the finest tissue paper, and has no admixture of wax. Myriads of bees exist in the Chaco, bordering the Salado; and large parties, provided with sacks and a provision of parched corn, cross over in the month of December to collect the produce of the wild hives. They take very good care, however, not to venture beyond the woods and plain immediately adjucent to the river; for with the Indians also honey is a staple article of food, and they prefer above all other varieties one that is found in that region—the eyrobaña, which is the deposit of a bee that feeds upon the fragrant ybirapaye. Forlorn, emaciated invalids join these parties, and, after an absence of a few weeks, return fat, well, and so changed that it is like the working of a miracle. This is ascribed to the properties of the wild honey, which, with parched corn, is for the time the only food of those engaged in these expeditions. A considerable quantity of wax is still sold to the village merchants, and finds its way to the neighbouring provinces; but the trade in this article must have diminished, for, according to Azara, ten thousand pounds were collected annually in Santiago before the Revolution. The process of pre-paring it for sale is simple enough. The comb is boiled in water, which is frequently stirred, and as the wax rises to the surface, a bunch of twigs is immersed, to which it adheres; it is then bleached by a daily exposure to the action of the sun for some weeks.—T. PAGE, U.S.N., Voyage in the 'Waterwitch.'

TOMTITS.—At the Astwood Bank Mutual Improvement Society's meeting last week, J. Hiam gave his annual chat on Natural History. Last year it was on Modern Bee-keeping. This year he took the subject of English birds found in the locality, and amongst curiosities for illustrations was a tomtit roosting in an old boot which has been used every winter for the last seven years. Query:—If tomtits kill bees, what is the best way to deal with them? Is Parus major the tomtit always referred to? At Redditch it is known as the 'Tom Collier.

NOTICES TO CORRESPONDENTS & INQUIRERS.

Letters or queries asking for addresses of manufacturers or correspondents, or where appliances can be purchased, or replies giving such information, can only be inserted as advertisements. The space devoted to letters, queries, and replies, is meant for the general good of beekeepers, and not for advertisements. We wish our Correspondents to bear in mind that, as it is necessary for us to go to press in advance of the date of issue, queries cannot always be replied to in the issue immediately following the receipt of their communication.

All queries forwarded will be attended to, and those only of personal interest will be answered in this column.

- F.I Pearson.—Sour or rancid honey is dangerous honey for bees, and, being foreign, is probably adulterated. We should reserve it until spring, and, after boiling and skimming, try the effect upon a single colony, when the bees are working vigorously, before venturing to use it in quantity as bee-food. We cannot suggest any other use for it.
- Sweet-Tooth.—Toffy or Barley-Sugar.—Refuse honey is not suitable for making toffy or barley-sugar; these should be made from the best houey and refined sugar, the proportion of honey to the sugar being very small. Great care is to be taken with the manipulation, or the flavour of the honey will be altogether lost. If too much honey is used the candy will become sticky, and the result unsatisfactory.
- W. G. Preece, Jun.—Sartori's Diagrams.—The diagrams are published by L. Sartori, No. 6, Via Confalonieri, Milan, Italy. We do not know the price, but we pre-sented a set to the British Bee-keepers' Association, which, when mounted, will be available for use.
- An Inquirer.—Zig-zag Entrances.—Experience has shown that they do not allow of sufficient ventilation, and become choked with dead bees, and we have found that more bees are lost with their use than in those hives without them. Our advice is to open the entrances to six inches and either use plain slides or triangular
- F. Jellico.—Propolis.—For removing propolis from glass, alcohol or benzine may be used. Root advises that glass, &c., can be cleaned most expeditiously by boiling it in a kettle of water with wood ashes.
- R. R. Godfrey.—Thanks for the Grantham paper, but the report of the Grantham Honey Fair was inserted in previous week's issue.
- G. Murrall.—Hawthorn.—The hawthorn, or may, is much frequented by bees both for honey and pollen. A buffcoloured pollen is obtained from it.
- Maugerron.—Lee's Frames and Sections. The principal improvement in these frames consists of a continuous dovetailed groove, and does away with nailing. In these the foundation is fixed at the time of putting the frame together. The top-rail of the frame is in two parts, with the dovetailed grooves on the under-side, which receive the ends of the bars tongued to fit these grooves. The lower ends of the bars have similar grooves and receive the bottom rail, which is also in two parts. For putting the frames together, a frame-block is required. The sections are on the same principle; full sheets of thin foundation are used, and are secured by pressing the half-rails together.

COWAN'S GUIDE BOOK.

NEW EDITION of this Work will shortly be published. Intending Advertisers must forward Copies of their Advertisements during the present week.

[PUBLISHED WEEKLY.]

Editorial, Hotices, &c.

CHRISTMAS GREETING.

The Editor joins with the compiler of 'Useful Hints' in a Christmas greeting to all subscribers and friends, and trusts that the festive season may prove a happy one to all of them.

OUR WAX IMPORTS AND EXPORTS.

In our last issue we presented our readers with the statistics of the imports and exports of honey, as given in the Annual Statement of the trade of the United Kingdom for the year 1886. We now proceed to extract from the same publication the amount and value of wax for the same year. The following tabular account specifies the countries from which wax is imported and the amount and value of the same:—

,	01 010 500		
		ewts.	£
From	Germany	5,937	$14,\!527$
,,	France	919	4,831
1,	Portugal	1,270	6,872

There is considerable difficulty in affirming the quality of wax brought to this country. It requires great experience in detecting adulterated waxes; even among analysts there are fine gradations and nice distinctions between absolutely pure and commercially pure wax. Then there are many kinds of wax, vegetable, mineral, and insect, but

we may generally deduce the quality of the wax from the value given. The mean of the value imported is 4l. 2s. per cwt. The wax from Chile fetches the highest price, 7l. per cwt., while that from Germany is only about 2l. 8s.

The following amounts are re-exported:

To Russia, Germany, Holland, France, Other Foreign Countries	2,577 994 1,840	£ 8,660 8,337 4,964 7,950 9,280
Total to Foreign Countries	10,480	39,199
To British Possessions	238	532
Total	10,718	39,731

This will leave for home consumption 20,108 ewts.; value 86,646l.

The total quantities of wax, with their value for the years 1884, 1885, and 1886, are,—

1884. 1885. 1886. 10,378 cwts. 10,328 cwts. 10,718 cwts. 36,467*l*. 36,706*l*. 39,731*l*.

The amount re-exported for the same years, and the value thereof, are,—

1884. 1885. 1886. 28,258 ewts. 38,295 ewts. 30,826 ewts. 105,813*l*. 149,253*l*. 126,377*l*.

There appears from the above to be a wide field for the production of wax. This article enters into the manufacture of numerous articles; at the Zurich exhibition there were shown twenty-two different articles in which wax was a constituent. There would therefore appear to be abundance of scope for energetic and enterprising private beekeepers and Honey Companies to endeavour to overtake the importations of wax into this country.

FIXING FOUNDATION IN LEE'S FRAMES.

It is well known that foundation for broad frames, if used in full sheets, should be wired, otherwise it is liable to buckle. This we have long found to be the case, but it was not of very great importance until we, some years ago, introduced the plan of placing the frames $1\frac{1}{4}$ inches from centre to centre to prevent the production of drone broad. The combs would become wavy, so that in some places the cells were a little more and in

others a little less than the right depth. avoid this unevenness wired foundation was used with success. There are many bee-keepers, however, who do not use wired foundation, and for these Mr. W. B. Carr has devised a simple method of fixing foundation in Lee's frames so that they may obtain perfectly level combs. The suggestion communicated to us by Mr. Carr consists of a slight horizontal centre bar across the frame. This, like the top and bottom bars of Lee's frames, is in two halves, and slides in a continuous devetail groove like the others. The top, middle, and bottom bars are all made to grip the foundation, so that it is rigid instead of hanging loose as usually used. Mr. Carr has found by experience, when using a shallow frame of Lee's pattern, no appreciable harm came from allowing the bottom bar to grip the foundation. With the standard frame, a specimen of which Mr. Carr was good enough to send us, the depth of each division of foundation is only about 31 inches, so that he does not fear any bulging. He does not anticipate any difficulty with the centre bar passing through where brood is thickest, because he has found that shallow frames in the upper of the two body boxes generally have the foundation of a row of cells along each face of bottom bar.

The specimen sent has the comb completely built out to the very bottom as well as the sides. With the centre bar slighter and projecting only inch from midrib, Mr. Carr feels certain the bees will embed the bar in the comb, so that there would be no interruption of cells so far as the surface went. The queen would pass the bar, and there would be only a row of broodless cells along the face of the bar. This way of fixing foundation would secure,-1, perfect immunity from breakdown when using full sheets for swarms; 2, combs as true as if built between dividers; 3, economy by using thinner foundation (say eight or nine sheets to the pound instead of six); 4, combs which will not break in extracting; 5, hives may safely be sent by rail fitted with full sheets of foundation; 6, those favouring winter passages may make popholes in foundation where they please.

We are pleased with the suggestion, and have no doubt but that Mr. Lee will have no difficulty in making frames with centre bars for trial. If successful, and we do not see why it should not be so, it would be a much more expeditions way of fixing foundation than wiring.

USEFUL HINTS.

A Christmas greeting to all our friends and readers. May the festive season prove to them the happiest on record—a season of family union, recording, indeed, the flight of time and the changes to which life here must ever be subject, but not on that account less happy, if only we have a good and sure hope of the great hereafter, when 'Time shall be no more.' At present the 'seasonable weather' of which we hear so much, when long hard frost and snow prevail, is conspicuous by its absence; but, seeing that old 'Father Christmas' often dons his hoary locks and icy beard, together with his brilliant crown-wreath of hollyberries, a few days before his actual advent, we elders

may yet have, to our sorrow, a taste of his quality, and youth may rejoice in skimming over the frozen lakes and rolling in the fleecy snow-bank. On Christmas-day, a few years ago, we noticed a wasp enter one of our hives, and bees were flying freely, even carrying home

occasional loads of pollen.

Weather.—Frequent storms of rain have prevailed of late, a low temperature, and nightly frosts. In our neighbourhood, the rainfall for November was 3:52 in., against 2:25 in. for the corresponding month of last year; the total rainfall, thus far, for the present year being 17:21 in., which is very far short of our annual average. During the last fortnight no opportunity of flight for our bees has occurred, and quiet and rest beneath warm quilts prevail, but soon, we trust, Sol's rays may exert their influence, and, the shortest day being already past, we shall soon be looking forward to

spring flights.

KEEPING COMB-HONEY.—Those who have kept carefully a few of their best sections, free from granulation or 'bleeding,' will be able to find a good market for such in London and our larger towns at the joyful Christmastide. What more beautiful or more suggestive of summer days than bright, transparent sections, artistically adorned with the crimson-berried holly, on the Christmas breakfast-table? We thank Mr. Simmins for his excellent letter (1385) on the price of honey being dependent, in a great measure, on the ability to keep it in a saleable condition, and so to place it upon the market when demand calls, instead of forcing a sale immediately on removal from the hives. These are views we have repeatedly expressed, both in 'Hints' and elsewhere, and we see no reason for qualifying them at present. With the exception of a few sections presented to friends, and those consumed in our own household, we have still on hand the whole of our last summer's sections, to which we have just given a careful inspection, without finding a single one granulated or bleeding, and this has been accomplished by keeping them dark in a dry, warm atmosphere, and free from

WHITE CANDY is made by boiling gently 10 lbs. of granulated cane sugar in three pints of water for about ten minutes, well stirring meanwhile. The pan is then placed in snow or iced water, and the thickened syrup stirred until it becomes a consolidated white mass, when it is rolled and patted into cakes. Given to bees above the frames, it is more easily consumed than ordinary candy, since it contains more water, but not

enough to cause deliquescence.

Sholtz Candy, or Good's?—In The Hive and Honey Bee Mr. Langstroth gives the following recipe of the Rev. M. Sholtz, of Silesia (Europe), who recommends the candy so prepared as a substitute for sugarcandy in feeding bees:—'Take one pint of honey and 4 lbs. of very finely powdered lump-sugar; heat the honey, without adding water, and mix it with the sugar, working them together to a stiff, doughy mass. When thus thoroughly incorporated, cut it into slices or form it into cakes or lumps, and wrap them in a piece of coarse linen and place them in the frames. Thin slices enclosed in linen may be pushed down between the combs. The plasticity of this mass enables the apiarist to apply the food in any manner he may desire.' Surely this is none other than the well-known 'Good's Candy.'

Either of the above candies may be laid over the cluster or packed in wired frames and placed beside it.

HIVE-BUILDING in this country, as a science, has certainly arrived at a pitch of excellence never reached before, thunks to the B. B. K. A. for all its fostering cure. Cheap hives (many, alas! too cheap) are now considered a sine qual non: but we more than doubt whether a low-priced hive is really the cheapest in the end. We should like to see all hives double-walled, with spaces filled with a good non-conductive material in this

uncertain, changeable climate of ours. There is a very mistaken idea abroad that the spaces between the walls, when filled with air alone, form sufficient protection for the bees, and such spaces have been erroneously termed 'dead-air spaces,' the word 'dead' implying-if it has any meaning at all-that the air in these spaces has no communication with the external atmosphere, and is as good a non-conductor of heat as cork-dust, sawdust, or chaff. This we consider a great mistake. Even if these hollow walls were perfectly air-tight or hermetically sealed, owing to the great mobility of the confined air the heat would be carried quickly from one side of the cavities to the other, and so become dissipated. But in our experience the spaces never are air-tight, and therefore these so-called double-walled hives are in reality little, if any, better than those with good and substantial single walls. But when the spaces are filled with a light, porous material such as cork-dust, which is an excellent non-conductor, we obtain a hive which maintains a more equable temperature, both in summer and winter, than any other of which we have experience. We have had in use in our own apiary for some ten years hives of this description, and in them the bees always do well; indeed, we do not remember losing a single colony in any of these hives. The cork-dust, being well packed, prevents the circulation of air in the spaces, and affords perfect immunity from external changes of temperature.

INTRODUCING QUEENS is an old and well-worn subject, but we cannot refrain from quoting a remark by the editor of the American Apiculturist, Mr. Alley, who for some thirty years has bred and introduced more queens, probably, than any man living. In an editorial note in the issue for this month he remarks: 'Bees that have been queenless a long time do not care for a queen, and will not readily accept one.' This dictum tallies so exactly with our own experience and with the well-known fact that young bees receive a queen more willingly than old ones, that a reference, we think, may well be made to it, without any desire to resuscitate the embittered controversy which raged in our columns on this subject some time ago.

KEEP GEESE, KEEP BEES.—A curious fact is related in the Moray Express to the effect that 'a Morayshire farmer went to Forres and sold a goose for 7s. 6d. He then and there bought two calves for 6s., returning home with Is. 6d. in favour of the goose? Hence, the remedy for agricultural depression is said to lie 'evidently in breeding geese!' To this Dr. Wingate Saul replies: 'At a weekly stock sale in Lancaster a good healthy calf was recently sold for the tenth part of the value of the goose—viz., 9d.; and why? Because such is the present deplorable condition of agriculture, at least as far as stock-raising goes, that if you let a farm rent-free, and supplied the occupier with calves at nine farthings a-piece, he could not rear them without losing money. Alas! poor farmers, between calves and geese, to what straits are ye come? We bee-keepers do not confess to being either 'Essex calves' or 'geese,' and we unhesitatingly invite you to migrate into Essex, and to take up some of the uncultivated farms, rent-free, and there to set up your hives. Read Mr. Simmins' Modern Bee Farm where you will find it stated that 'the beekeeper who is also a farmer has every advantage, and can make profits both ways.' Mr. Simmins well advises amhitious, unfledged hive-makers to pause before investing largely in advertising their wares, or otherwise their efforts may 'end in smoke.' This advice reminds us of an aged Australian friend—a cleric, but a 'Johnian punster'-who, when asked by some colonists whether he thought tobacco cultivation in that fine climate would prove remunerative, gave a doubtful answer, but added that 'of one thing he felt quite certain, viz., that, whether successful or not, it would assuredly "end in smoke." But we do think that bee-farms established on our uncultivated lands, and conducted on enlightened modern principles, would offer more prospects of a dividend than either calves or geese: therefore, we say to farmers, as the good old hishop said to his poverty-stricken clergy, 'Keep bees! keep bees!' We have heard the objection raised to Mr. Gladstone's advice to distressed farmers 'to grow strawberries,' that if all farmers were to follow it, the country-and, indeed, the world—would soon be 'over-strawberried.' And objections will no doubt be made, that if all farmers take to producing honey the world will soon be over-honeyed. But that time has not come yet, and when it does the great millennium of peace and plenty will have arrived also, and, in a world so full of sweetness, that glorious prophecy will have been fulfilled, that 'the wolf shall dwell with the lamb, and the leopard shall lie down with the kid; and the calf and the young lion and the fatling together, and a little child shall lead them.' Then, indeed, we shall no longer learn war, 'neither shall nation lift up the sword against nation, but they shall beat their swords into ploughshares and their spears into pruning-hooks.

OUR PROBLEM AND ITS SOLUTIONS.—Judging from the several solutions received, our problem appears to to have puzzled 'seniors' almost more than 'juniors.' To the names of those given in our last, as sending correct answers, we have to add—R. Ballantine, T. Rawson, and A. Wilson, all of whom were too late for competition. We give the solution of the former, as well worthy of a place in our columns:—

If six tomtits six minutes take
To tear six bees asunder,
Each bird must then six minutes work
To gain his share of plunder;
Then why should not twelve fierce tomtits
One hundred bees devour
In fifty minutes all complete?
Thus, ten would take an hour.
R. Ballantine, age fourteen.

We also take the liberty of publishing one of the 'rejected addresses,' that of a senior, marked, 'Not for competition:'—

My wife and I, with our four little T's, In minutes six kill half-a-dozen bees; One bee apiece per minute is the pace; At which we thin the honey-making race; We two alone then, schoolmasters say, In fifty minutes should a hundred slay.

Senior

Unfortunately, 'one bee apiece per minute' is not the pace. Does not our correspondent see that if it were the six tits would kill thirty-six bees in six minutes? The 'rule of common sense' would teach us that, by the terms of the question, six tits kill one bee per minute. But it is required that two bees be killed per minute (the given rate being one hundred bees in fifty minutes). Therefore, the pace being doubled, the number of tits must also be doubled, and,—

'By very simple logic, and not far to delve, We quickly discover the correct number Twelve.'

Altogether we have received twenty answers to our question, of which ten are right and ten wrong. The greater part of our junior competitors have given neat solutions by the rules of compound proportion, stating the 'antecedents' and 'consequents' in proper order, and bringing out the answer correctly. We thank all for their efforts, and trusting that the unsuccessful will keep up their courage, and 'Try, try again' on the next occasion, when, doubtless, their perseverance will be rewarded.

We have given orders for the respective prizes to be forwarded to their destination as early as possible.

MY BEES

By Mrs. Reginald Bray, Author of 'Family Feats,' 'Ten of Them,' 'We Four,' &c.

(Continued from page 546.)

CHAPTER VI.—FOUL BROOD.

When I returned to Heathhourne, my hives were all shut up up for the winter. It was an inexpressible comfort to feel that Watson would have looked after their welfare as carefully as I had done. My great anxiety over my Shere hive always was that there was no one who took a special interest and delight in it.

When March came round I was very careful not to put my supers on too soon. The spring as it always has been ever since I began to keep bees, was very late. Not until the end of May did I put them on, and the bees did not show the slightest signs of going up into them.

In the middle of June we had some bitterly cold weather. We were quite thankful indoors to sit over fires, and the bees did little or no work outside. I read that bee-keepers were removing their supers, and had commenced feeding again.

I wished to do so, but I had not recovered my nerve entirely, and I had been stung several times in putting it on. One little girl had also been severely stung. Thinking that it would be quite safe to look over the wall where the bees were she mounted her stilts which made her over eight foot high, and gracefully leaning on the top of the wall she watched my operations.

Alas! the bees flew straight up, and she had to beat an ignominious retreat, stilts and all, having been stung six times. However, she has plenty of pluck, and in regard for my anxious feelings she assured me that she did not mind. I hope she spoke the truth.

I did not feel as happy about my bees as usual, on the hive which had supers, and which I shall call number I, the bees as I said, would not go up in them. In number 2 the bees did not seem at all strong, indeed they behaved in a very strange manner. They dawdled listlessly in and out of the entrance, stopped to gossip with each other as though they had no particular object or aim in life.

I was very unhappy, my merry, buzzing bees, these wretched, dejected-looking creatures. My heart misgave me that the queen was dead! I opened the hive and examined it. No trace, alas! of a queen, only a queen-cell in process of making, but not yet sealed over, so it would be some time before her majesty would come, and in the meantime my bees were dwindling away. I wrung my hands in despair, sat for a short time in silent agony, then rushed to my writing-table and wrote a telegram to Messys. Neighbour for a new queen

to Messrs. Neighbour for a new queen.

The next day she arrived, ignominiously for her majesty, in the pockets of one of their men who was going to introduce her for me to her new subjects. This is not such a very easy matter. Though the bees are utterly lost without a queen, they are by no means ready to welcome a new one.

If a strange queen were to be suddenly introduced into a queenless hive, the bees would at once attack and destroy her. The easiest way is to put the queen in a small wired cage which is made for the purpose. This is fixed into the combs, and the bees thus get accustomed to her and feed her through the wires, after which she may be released. This the expert proceeded to do.

Having put the queen into the eage with a card placed beneath it he selected the centre comb with brood, and placing the cage on it pressed it down, and then closed up the hive. He told us that in about twenty-four hours we might remove the cage, and watch and see if the bees received the queen kindly; if they should attack her and seize her by the legs or wings I must cage her again and release her the next day. He cut out the

queen-cell which they had commenced, as if the bees have no chance of raising another, they are more likely to take to the new queen.

to take to the new queen.

Oh dear! how I hoped that the bees would receive the queen well when I released her! I attended carefully to my instructions, and said 'Yes, yes!' as if it were the simplest thing in the world to me to catch the queen and recage her. Inwardly I intended to leave her some hours longer than he said to make sure that she would be welcomed before I let her go. I have heard since that the longer the bees have been without a queen the longer it is necessary to keen the queen caged.

longer it is necessary to keep the queen caged.

The next day all my plans were changed. That afternoon a swarm of bees was seen flying through the air at their own sweet will; nobody knew whence they came or whom they belonged to. Now, whether it were that same swarm or not I cannot say, but Watson was out that afternoon and he found a man in great distress with a swarm of bees in his garden. He did not dare to touch them and he did not know how to get rid of them. As a last resource he offered them to Watson for five shillings. This was a chance, indeed, for my weak hive; a whole swarm and queen to add to it, instead of my poor solitary caged queen. Watson hurried home and told me. I closed at once with the bargain, and he went off with a straw skep to hive them. We did not unite them to our stock that night, as I should like to have done, because of the imprisoned queen. I wrote by post to ask Messrs. Neighbour to take back the queen, and explained the circumstances. This they did very civilly, and the following evening the queen was taken out and the swarm put into the hive

After this I hoped that all would go on well, and for a time things looked better and the bees worked well. Hive No. 2 was fairly flourishing, though no chance of any super honey. In No. I the bees still obstinately refused to go up into the supers, and, what was worse, they seemed dwindling. Sometimes I thought I perceived a peculiar odour when I was close to the hives. I asked N. anxiously, but she said that she noticed nothing. Watson also did not think there was any, so I earnestly trusted that my nose deceived me, though horrid thoughts would come into my mind of that gruesome enemy to bees 'foul brood.' The worst was that all my neighbours' bees had died off and they had not a single bee remaining. The hives were empty, desolate places.

Surely such a terrible misfortune as 'foul brood' was not going to overtake me! I continually read about it in the *Bee Journal*. Some correspondents wrote such ghastly accounts: how it was ntterly incurable, that there was nothing to be done but to destroy your bees, hives, and all, and to commence bee-keeping afresh. I would not believe in the possibility of such evil. I did not know of any in the neighbourhood. The season had been so late; the weather had been so cold. It was no wonder that the bees were not very flourishing. Why should I have such conceit as to think that my noso was any better than that of other people?

was any better than that of other people?

It was now nearly the end of July, and I had given up hopes of any honey this season. It was rather hard, but I consoled myself by thinking that I could not expect to have forty pounds of honey off one hive every summer, and I had little doubt that the immense quantities of honey which I read of being taken off hives in a good season were very much exaggerated. Anyhow, this summer was pronounced by the *Bec Journal* to be one of the worst that had been known for forty years. One morning Watson told methat he had heard of a lot of bees that were to be had very cheap at an estate that was going to be sold in the neighbourhood. I could not resist the chance of a bargain, and sent him over to examine the hives. He came back and reported that they looked very strong indeed. The hives felt very heavy; there seemed to be lots of bees, and on some of

them there were supers with honey. They consisted of four straw skeps, two old-fashioned bar-frames, and one very remarkable one that had something the appearance of a Chinese Pagoda. That the hives were old-fashioned I did not mind, because if I liked we could unite them with my bees, who were getting 'small by degrees and beautifully less.' I went in to ask Mrs. Graham whether she would not like to join in this chance of getting bees at a bargain, and she agreed to take three straw hives.

After some days of anxious waiting and a little bargaining had been gone through all was settled. The money, which averaged about 10s. a hive, was paid. The hives were mine and there was nothing now to be done but to fetch them. The evenings were now so long that it was of very little use thinking of moving them till about nine o'clock, as the hees would not have

all gone home.

The place was about two miles or so off, and about 8.30 Watson started off with the coachman to drive the cart and the boy Tom to help to tie up and move the bives. He also took some pieces of stuff to stop up the entrances so as to prevent the bees coming out. I knew he could not be back before ten o'clock, as it would take a long time to tie up all the hives. Accordingly I waited fairly patiently until that hour, then I went out and walked anxiously up and down the lane.

I waited and waited, but it was nearly half past ten before he arrived, and I had begun to feel anxious lest any misfortune had occurred, when I heard the joyful sound of the footsteps of the horse in the silence of the summer night. Presently the cart loomed in the distance, the hives in their white sheets looking like so many ghosts. 'Oh, you have got them,' I exclaimed eagerly

as he drew up at the stable entrance.

'Yes, ma'am, but a rare job we had. There was actually a man coming to take off the supers. We were only just in time. He arrived a few minutes after we did, and I just told him the hives were ours and he had nothing to do with them.'

'What a shame!' I exclaimed, thinking of the risk we had run of losing what would probably be the only honey

I should have this season.

'Well,' said Watson, 'it seems the owner has never cared about the bees, and this man has been in the habit of taking it every summer. He was civil enough when I explained how it was, but the worst is that he had been in the morning and loosened all the supers, so we had a great piece of work to tie them fast, and I am afraid as it is a good many bees have got out in the sheets. The bar-frames are all right, as the supers are under the covers, but it is the straw skeps that I am afraid of, as they have only a box of sections over the hole at the top. I drew near to the cart, and I heard a sound of the most infuriated buzzing that ever met my ears. The bees had indeed got out of the hole at the top, and the sheets round were simply bulged out with bees who had crowded out, and could not find their way back into the hive. I cautiously placed my hand on the sheet but as hastily withdrew it, for the buzzing, wriggling mass had a most uncomfortable feel, besides which there was a good chance of a sting through the sheet.'

Well, it is quite plain that we cannot take the sheets off these to-night, I said. 'We must leave them as they are until the morning, and perhaps the bees will find their way back into the hive when they are left quiet.'

So we merely placed the hives on their stands for the night. Three of the straw skeps were put in Mrs. Graham's hee-house, and the rest in our kitchen garden by the side of the others. We undid the sheets of all that we could, but left the entrances closed up till the morning.

My thoughts were full of bees that night. Whenever I closed my eyes I seemed to see myriads of bees, whilst the buzzing still sounded in my ears.

The mornings were very, very light now, and at about

5.30 I crept out of bed, put on a few clothes, and my dressing-gown, and covering all deficiencies with a fur cloak and a hat, cautiously unfastened the drawing-room window, which opened on the lawn, and hurried off to my hives.

There is no such beauty as the beauty of an early morning; the heavy dew still upon the grass, and the

shimmer of the sun upon the dew-drops.

When I turned the corner by the wall there was Watson equally anxious as myself. He could not rest, and was even there before me. He had taken the stoppings out of the hives from which the sheets had been taken, and the bees were working busily and quietly

as though they had never been disturbed.

Then we turned to those other awful hives in Mrs. Graham's bee-house. There they stood, a ghastly row, enveloped in their white drapery, still bulging out with bees, which seemed more furious than ever. Of course they had not been able to get back into the hive as I had hoped, for the entrance had been stopped up before

the sheets were tied on.

We stood and gazed in silent dismay. I simply dared not undo those sheets. Neither Watson nor I are very deficient in courage, but it required the courage of a volunteer of the 'Forlorn Hope' to unfasten and turn back the sheets of those three hives, and let loose a multitude of angry demons upon us. It would really be at the risk of our lives. Besides, then we should have to take the stopping out of the entrances before the bees could get back into the hives.

I should like to know what some of the experts would have done when face to face with such an emergency. For my part I would as soon face a mad bull. At least there would be only one enemy to cope with, and here we had hundreds and thousands, for the hives were very

strong.

Necessity is a mother of invention. I looked at those sheets, they were only twill calico, my very commonest. Something must be sacrificed, so I gave a little gasp, and said, 'I shall cut a hole in the sheets for the bees to come out.'

Watson agreed that it was the only thing to be done, so I returned to the house to complete my toilette, and to don veil and gloves, for I had no intention of being

stung if I could help it.

Whilst I was gone Watson prepared the smoker, and being anxious to quiet them as much as possible, we put a little of the tobacco-paper which is used for fumigating greenhouses in the smoker. Then I took the scissors, and with as much care as I could take to avoid snipping bees in half, I cut two slips at right angles to each other in the sheet just opposite the entrance.

The bees then began to hurry out, but our work was not yet done, for we had to work about with a bit of stick to pull out the bits of stuff with which the entrances were stopped up. This was no easy matter, for it had

to be done by feeling.

Then, when we had cleared the entrances, we had to arrange little slips of wood as bridges from the hole in the sheets to the entrances of the hives, otherwise the bees would not have been able to find their way back. It was done at last, and actually without a sting. Our plan was quite successful, and it was an immense relief to see the bees hurrying out of the sheets and then quietly returning to enter the hives in the proper manner.

It was now breakfast time, and I was obliged to tear myself away, feeling I had done a very hard morning's

work

It took a long time for the bees to liberate themselves, but at last the bees of two hives were all released. We were able to unite and turn back the sheets, though we did not remove them for a day, as we did not want to have to lift up the hives.

The third hive was not in a satisfactory state, the bees

did not seem able to get back into the hive, and they flew about in an aimless and unhappy manner. At last I could bear it no longer, so I cautiously unfastened the sheet, and gently laid it down. Alas! the bees were quiet enough now. I ventured to take up the hive and look in at the bottom. Oh, sad and piteous sight! the combs had all fallen down in the move, and there was a mass of dead and crushed bees that would have made a heart of stone ache!

We sadly took away that hive, picked out the few survivors, and united them with one of the other hives.

It was a crushing lesson to us never again to undertake a move without carefully attending to the rules for

moving laid down in Mr. Cowan's book.

After a few days had gone by I began to think whether it would not be as well to ask Messrs. Neighbour to send down an expert to overhaul my hives, and if he thought well to nuite some of them with my two original hives, which daily grew weaker and weaker. Accordingly I arranged with them that Mr. Marshall, of whose manipulation I cannot speak too highly, was to come down and examine my hives.

I hastily sent a telegram to a bee friend living in London to come down and witness the operations. This friend had kept bees for some time very successfully on a balcony in Kensington. They were a great interest and amusement, though occasionally they gave her an alarm lest they should swarm into any of her neighbours' houses, and more than once she had to send hastily to Messrs. Neighbour to come and prevent such

a dire catastrophe.

She arrived soon after lunch, bringing a butterfly-net to act as a veil. It was not a very suitable article, and I had to tie it round to prevent the bees crawling up underneath. We waited for some little time, and then we saw Mr. Marshall coming across the lawn.

I led the way somewhat triumphantly to the corner where the six hives stood,—an imposing sight. My two I knew were weak, but the new ones were undoubtedly

as strong as strong could be.

We turned the corner, and Mr. Marshall gave a curious glance at those hives which, as I have before said, were of a somewhat remarkable make, especially the Chinese

Something in that look made my heart stand still, and an ominous foreboding crept over me. I do not know whether the sun went in, and the sky became overclouded, but I almost think it did.

'I know those hives,' was his somewhat laconic

remark.

'Really!' I said, in a cheerful tone, though feeling

iuwardly that something dreadful was coming.

'Why, I went down to look at them to see if they would suit us, but we would not have had them at a gift.' Yes, there was no doubt the whole brightness of the

day was gone!

What—what?' I managed to gasp, feeling like the lady of the nursery rhyme, 'Speak, speak, or my heart will break.'

FOUL BROOD!' said he.

Then there was a dead silence. For a moment I could not speak, but determined that no one should guess my feelings, led him as cheerfully as I could to my hives No. I and No. 2. I almost hoped now that the enemy was there also, because it would be almost too dreadful to think that I should have introduced that dire disease into a healthy stock.

He took off the lids one by one, he looked in, he took a sniff at each, whilst 'I stood silent, dumb, with anguish like the wretchedest of (wo)men.' Then he replaced them, and the answer I anticipated came, 'Reeking with

foul brood.

'I suppose I had better destroy the whole lot,' said I, every dismal story rushing through my brain. 'There is no cure: is there?'

'No cure!' exclaimed Mr. Marshall. 'Destroy all these hives! Not a bit of it; we'll have them all cured by next spring.

If ever I blessed any one in the course of my life, I blessed Mr. Marshall for those words. My spirits, which had gone below zero, rushed up with a bound, and I was able to stand and endure it whilst he gave us a lecture upon 'foul brood,' and showed me how I ought to have known it.

Very useful and very instructive that lecture was, but it would have been a thousand times more interesting if my own beloved bees had not formed the subject

Foul brood is a disease which affects the brood. It is caused by a bacillus. You can easily tell it, for the caps of the sealed brood are indented, and tiny holes seen in them. If you open the cells, you find the young brood dead, and in a sticky, discoloured mass, truly a sickening sight, whilst the odour which I had perceived is very unpleasant. Of course the brood all dying off, the bees in the hive dwindle away, and the mature bees are themselves infected by it. It is terribly infectious, and as an infected hive becomes very weak it is often robbed by stranger bees, who may thus carry the disease into the whole neighbourhood.

All honour be due to Mr. Cheshire, who has invented

But for the present I am not going to give the account of that, as I only used it later, and I will at present continue the history of my experiences exactly as they

'Lumps of camphor,' continued Mr. Marshall, 'will effect a cure. It disinfects the hive, prevents the foul brood spreading, the putrid grubs gradually dry up, and

then the bees can clean out the cells.'

My two hives were decidedly weak, but the others were so very strong that their chance of recovery was great. We hastily sent to the chemist for some lump camphor, and he placed good-sized bits of it between all the combs, and told us that when this had dissolved, as camphor will do exposed to the air, to put in some more, and to keep on doing this till the hives were shut up for the winter.

My two hives required feeding at once, but the new hives were all so filled with honey that they did not require any feeding at all, nor did the two which were in Mrs. Graham's bee-house, which were also infected in the same way, but which fortunately were extremely

strong stocks.

He then took off the honey in the supers. This also was rather a disappointment, as in several of the supers there was only a little work done, and altogether I only got about 10 lbs.

I did not care much about doing that little sum: 31. 10s. for eight hives of diseased bees, and 10 lbs. of

honey. Bee-keepers, pity me!

(To be continued.)

Foreign.

FRANCE.

The general Congress will be held at the Palais de l'Industrie of Paris, between the 23rd January and the 8th of February next.

The programme relating to the honey and wax sections is very similar to the one issued last year. Honey will be divided into four groups, as follows:--Honey in the comb, run honey from the heather districts, run honey from artificial prairies, and run honey from mountainous districts.

No provision has been made for honoy from the plains

of Brittany.

Exhibitors will be expected to declare the number of their hives and the amount of their harvest.

No lots under 4 kilos weight will be entitled to

In the honey group, one gold, four silver, and six bronze medals will be placed at the disposal of the

Wax will be divided into two sections, viz., one for lots not under 4 kilos and not exceeding 25 kilos, and the other for larger quantities; but no exhibitor will be allowed to compete in both sections. The Jury will make their awards on the 26th January, and those allotted to the wax sections will probably consist of one gold, two silver, and five bronze medals. The whole of these prizes will only be awarded in the event of the Jury considering that they are justified by the merit of

Application for admission must be made before the 1st of January next. Printed forms may be had from the Ministry of Agriculture.

Notice is also given that bee-keepers intending to contribute to the great Exhibition of 1889, must send in their application before February next.

The Apiculteur of Paris has new completed its thirty-

first year of existence.

CANADA.

The report of the quarterly meeting of the British Bee-keepers' Association, October 19th, at which Mr. Cowan gave a description of his trip amongst beekeepers of America, is no doubt read with interest by all, by those even in America, for few of us have made, even in our own country, so extensive a tour, and one which would be so entertaining, and even instructive. We all have a desire, however, to visit other beekeepers, and spend a few pleasant hours, or even days, in conversing with them upon the points which we know they have made a special study of; next to having been there ourselves is to hear from those who have been.

There are few, if any, Canadian bee-keepers who have visited the apiary of Captain Hetherington; and how well such a visit would repay an apiarist who depends

upon the production of honey for a living.

I see the question of yield in an apiary was brought We do not think that England or Britain can take the palm from Canada or America, especially the northern part of America, upon that score. This year, bad as the season has been, I secured 270lbs. of extracted honey from one colony, with sufficient honey to winter on, and no increase. Another year I secured an average of 225lbs., increase from three colonies to ten. Last year a young man who purchased a colony from me took 230lbs. of honey, and increased to three, with enough to winter on. I hear a lady at St. Mary's, in an apiary of over fifty colonies, secured an average yield of 225lbs.

Volume i. page 6, American Apiculturist, L. C. Root writes: In 1870 he took 361 lbs. from a single colony; since that he has taken 484 lbs. from one stock. In 1881 be took from an apiary of forty colonies 9727 lbs., a little over 243 lbs. to the hive on an average. have heard of yields from a single colony as high as 900 lbs., but the reports came from sources less satisfactory to myself, and then we place less value upon the yield from a single colony; with us it is an established saying, -one, too, which appears to be borne out in practical experience, that one or a few colonies will give more

honey per colony than a larger apiary.

Canada is the land of my adoption. This and justice will not permit me to pass unchallenged the expression or thought that we do not take—equal to England—advantage of 'Nature's gifts.' I am pleased Mr. Cowan did not see any skeps in America. We have the box hives, which are about the same as your straw skeps. In Ontario they are becoming rare; in the province of Quebec, I regret to say, they are rather plentiful, decidedly in the majority; but it would scarcely be just to say we had not reached that stage of advancement to know of the superiority of the moveable frame-hive. I think Mr. Baldwin is correct in the statement that England has nothing to fear from American com-

559

The question is before us in America, 'Can the specialist produce the cheapest honey, or one who com-bines bee-keeping with other pursuits?' I am satisfied that hee-keeping can be combined with many pursuits to advantage. This can be done in such a way that the wages for a year's work, which the specialist has to add to his cost of honey, does not require to be added by those bee-keepers, and if either has to go to the wall the specialist in America will have to do so. They cannot afford to undersell you after freight and other expenses are taken into consideration; nor do Canadians consider it policy to attempt to undersell British boney. We rather take this view of it. The proper introduction of our honey will increase the demand for heney, and then let the difference in the honey of each country, push in selling, diversity of tastes, and any other differences, give each their market.—R. F. HOLTERMANN, Brantford, Ont.

Reviews.

ILLUSTRIERTES LEHRBUCH DER BIENENZUCHT, by J. G. Bessler. Published by W. Kohlhammer, Stuttgard. This is an instructive book for beginners, and is not intended to come in competition with more expensive, advanced, or complete works on the subject of bees and bee-keeping. The author has gleaned the best of both theory and practice, and to avoid verbosity has illustrated it with 137 engravings. He commences by giving a brief history of bee-keeping from the earliest times, and introduces some very amusing pictures showing how bees were in those days kept in the trunks of trees, and the manner of taking the honey. The armour the ancients wore to protect themselves against the stings of bees contrasts strangely with the simple veil of to-day. Just sufficient of the natural history of the bee is touched upon to give an idea of its structure without wearying the bee-keeper with the science. Bee-life within the hive is next entered into, and in chapter 6 the enemies of bees are illustrated and described. The description and treatment of disease are not omitted, and in the practical part, to which the largest portion of the volume is devoted, numerous hives and appliances used both in Germany and in other countries are described and figured. One of the most interesting chapters is that devoted to bee-flora, and the author has adopted the system advocated and carried out by M. Kramer of Zurich in giving the values to the different flowers as honey, pollen, and propelis producers. The list contains 278 different varieties, many of which do not and would not find places in our lists. We are pleased to find that many of the plants yield as well with us as they do in Germany, and some have no values placed against them, as the author does not consider them of sufficient importance as bee flowers. There are others from which the bees only get honey after piercing the corollas, such as, for instance, Lonicera caprifolium, but here we find the author gives this plant a much higher honey value than we do. The table also gives the times of flowering of these plants. This volume is written in simple language, and will be found useful, more especially, as the author says in the preface, that it is published at a low price to bring it within the reach of all. M. Bessler is already known as the author of Geschichte der Bienenzucht, which we reviewed on page 180 of the British Bee Journal for 1886.

We have also received from M. Bessler a photograph, 16 in. by I2 in. sontaining the portraits of nearly 250

of the leading bec-keepers. These are all medallion portraits neatly arranged within an oval frame, tastefully and artistically decorated at the corners. Among the portraits we easily recognise, notwithstanding their small size, the likenesses of many of those who have done so much for the science of bee-keeping, and who have been the means of raising it to its present position as an industry.

Correspondence.

The Editor does not hold himself responsible for the opinions expressed by his correspondents. No attention will be taken of anonymous communications, and correspondents are requested to write on one side of the paper only, and give their real names and addresses, not necessarily for publication, but as a guarantre of good faith. Illustrations should be dearn on separate pieces of paper.

Communications relating to the literary department, reports of Associations, Shows, Meetings, Echoes, Queries, Books for Review, &c., must be addressed only to 'The Editor of the 'British Bee Journal,' c/o Messes, Strangerays and Sons, Tower Street, Cambridge Circus, W.C.' All business communications relating to Advertisements, &c., must be addressed to Mr. J. Hucker, Kings Langley, Herts (see 2nd page of Advertisements).

**In order to facilitate reference, Correspondents, when speaking of any letter or query previously inserted, will oblige by mentioning the number of the letter, as well as the page on which it appears.

COMB IN SECTIONS: WHOLE SHEETS OF FOUNDATION AND STARTERS.

1392.] All advanced bee-keepers are fully cognisant of the utility of having a good supply of sections, filled or partially filled with comb, ready for the coming season. These sections are, as a rule, the residue of the previous year's harvest. When the racks are removed from off the hives, preparatory to putting the bees into winter quarters, quite a number of the sections will be found to be partially filled, mostly, though not always, with honey of poor quality. This is extracted, the sections returned to the hives for the bees to clear out. They are then carefully packed away, and brought out again when the time has arrived for the racks to be placed upon the hives. The plan of 'tiering up,' which is quite a modern —even in the bee world where everything is modern system of obtaining honey, gives a much larger number of these unfinished sections than the plan before adopted of using but one rack, removing the full sections and replacing with empties; hence at the commencement of the following season, when the first rack is placed on the bive, the bee-keeper will most likely fill this with these partially filled sections, with the result of having a very irregular lot for his first crop instead of being the best. The plan of putting some partially built combs in the first rack placed on a hive at the commencement of the harvest is greatly to be commended, its advantages being very evident, but only inasmuch as it acts as an inducement for the bees to 'go up' in the supers-nothing more. This inducement can be easily proved by filling some sections with comb and others with foundation, and giving them to the bees; those filled with comb will be rapidly occupied, while for some time little attention is paid to the foundation. We find that when the bees once take possession of the racks they will never leavo them again during the honey flow, providing no swarming takes place or disease thins their numbers. If the racks are occupied, honey only, as a rule, will be stored in them, as a consequence more room is given the queen for her to fill with eggs. This gives a great impetus to the colony, and, unless more space is given, swarming will take place. This large increase is just what is wanted. The hive is enlarged by giving an empty rack of sections, swarming is retarded, and we then obtain a greater amount of honey in the supers. It is my purpose to call particular attention not to supering and its various methods, but more particularly to the fact of sections being badly finished where partially filled ones from the previous year are used, and the means by which this can be avoided. This only applies to those sections which have been about three-quarters to wholly

filled with comb, not to those which have the foundation (starter) just started, as little or no difference will be perceived in the finish of these. We shall find that the side cells of the offending sections are scarcely touched, which gives the finished section quite a convex surface. There is little doubt but that this arises from ripe honey being taken from the combs below, and stored direct into the sections. Being ripe this is sealed over as soon as the cell is full, the bees not elongating the same as they do in newly built combs, and a little later on in the season when unripe honey is being stored. In these cases the comb-builders keep adding to the depth of the cells iustead of sealing them over, the honey not then being in a fit condition. If we can once start them on to honey-comb building they will continue to add to the depth of cells until the opposing comb or separator prevents any further addition. then—the honey being ripe—sealed over. Where a comb is provided with cells much below the usual depth of honey-comb, and there being no opposing comb or separator, the bees will at once add to it; and as they have once commenced in earnest so will they continue. All things being in a normal condition, therefore our plan is evident. All sections which are full of irregularly (convex) formed combs should be reduced until the cells are less than half an inch in depth, by simply shaving them with a sharp, warm knife. If this is done the bees will finish them off equally as well as with foundation. It is a deal the best plan to place but two or three of such sections in a rack, the rest to be made up of those having only foundation.

The superior finish of sections where whole sheets of foundation are used is very marked. Especially is this so where the foundation fits the section exactly except at bottom, the bottom being fitted with an upright very narrow strip (1/4 in.) almost meeting the larger upper piece, a plan first introduced by Mr. Corneil, of Canada, but in this case—in fact, as in all—the hive must be perfectly level, so that the upper portion of foundation hangs perfectly true to the lower.

I have experienced during the past season a great difficulty in securing whole sheets of foundation perfectly true in the section, there being more or less 'buckling just where the sheets touch the sides, which to obtain tinely finished sections must not occur. I have overcome this failing by using a machine which by the almost momentary pressure of a lever affixes the foundation with molten wax firmly and truly in position, a description of which I will give in a future letter. By fixing the foundation with molten wax quite a quantity of it is saved in comparison to other methods, such as 'mashing' about a quarter of an inch of the edge into the wood, or fixing it in a slit of the top bar.

Many prefer starters only in the sections; I do when I have to eat them myself, in fact, when running a few hives just for home consumption, I recommend as little foundation to be used in the supers as possible; just a start that the combs may not get into a muddle. the machine before alluded to this start can be placed in the section without the use of any foundation whatever. What is nicer than eating a section where the necessity of disengaging a sticky lump of wax is avoided? and this most assuredly will be the case in most instances where whole sheets are used, no matter what make or thickness of the foundation. The plan of using white bees-(?) wax, so much in vogue now, does not alter this condition of things, as natural coloured bees-wax is made as thin, and even thinner, although, on account of its colour, it does not appear to be so.

There is no doubt that the public taste (optical) for a finely finished section will gain the ascendancy, and whole sheets of foundation will have to be used where a market is to be made, but this will not prevent the home consumer from indulging in an article that can be eaten without the above disadvantage, - W.B. WEBSTER,

IN THE HUT.

· At every trifle, scorn to take offence; That shows great pride and little sense: Good nature and good sense will always join; To err is human, to forgive Divine!

[1393.] The prime minister recently put the cloture on the McN—s, 'Amateur Expert,' and 'X-Tractor,' High time too (perhaps a shade tardy), but I should have first liked the opportunity—I now take it—of expressing my regret, now the affair is over. if anything has been said in the 'hut' which has caused pain or anger to anyone; acerbity and ill-natured rancour is no part of the huttites' creed. Good temper and mutual edification are our cardinal principles. I may say, however, that for the future such criticisms as 'the hut' comes in for, and is allowed to appear in these columns, will pass unheeded and unanswered: so any oue can have a shot at it and its inmates who likes. If no reply be returned, perhaps they may rest assured it is not for want of ammunition.

We should like you to give us your idea on the stridulation theory of Cheshire. He dispenses entirely with the trachea and spiracles as accounting for the piping of queens. If he be right, the croaking of drones will be accounted for by the same means. I have not a queen accessible at the moment. The quotation is:—'No other part of the body, so far as I have been able to discover, suggests, by its conformation, that it could be employed in stridulating, save the joint of the collar (the junction of the pro and mesathorax), and here eight or nine delicate line indentations occur; and possibly the tremor of the abdomen may be accompanied by a rasping of these loosely-articulated parts, so as to increase the sound.'—(p. 158.) Still, it seems there are parts we have missed; at least, I have with my paltry quarterinch, and if too minute for that stridulant tones would not be very loud, I think. I will have a search on a dried queen, I cannot form an opinion in 'the hut,' yet methinks we should hear her majesty's tones oftener than on the eve of casts issuing, and also that the chitine of the rings on the reflying princess's thorax would be scarcely hard and rasp enough to be audible.

Some of us who are beginning to fail in our natural masticatory machinery well know the peculiar twinge given to the nerves at the basis of our teeth by the intense sweetness and coldness of certain kinds of honey. If a recent statement be true, a minute quantity of formic acid ejected into the honey would accentuate the pain. I do not, however, for one, believe in the idea that the bee pierces the cell cap and saws into it with its sting, and, inserting the latter, injects a small supply of poison into the honey.' I think the acid would prevent granulation, for is it not in order to convert our canesugar, in syrup-making, into grape-sugar that we put vinegar - acetic acid - in, and also produce grape-sugar by boiling any starchy and saccharine substance with

almost any other dilute acid?

What a nuisance is the midrib of sections, where full sheets are given! But still greater is this the case when one has a store of new frames filled with immaculately pure combs of heather honey. We will scrape this off the midrib, which, by the way, is found of nearly the same thickness as when it was inserted into the frame; the foundations of the worker-cells are still raised and distinct. These shall be returned to the hives in spring. The heather-honey shall be slightly warmed and stained, or used for making mead; and wherever possible dark brood-comb cut out, so that new comb may be built in its place — new either for stores or brood — brood of a fine and large development by reason of the large cells. This provision of annually new cells for brood-raising we consider a sine quâ non,

With regard to the tightening and loosening of the wooden screws of section-cases, hive-doors, and wherever wood comes in friction with wood, do not forget the ex-

cellency of black-lead as a lubricant.

In fixing foundation in frames, why may we not string silk threads from one side bar to the other, so that when it is drawn out and fixed to the sides the foundation or comb cannot, if it break, fall across? Where the string crosses cells, as they are drawn out, the bees will gnaw it away, leaving it attached and embedded in the wax at the edges.—X-TRACTOR.

[Careful microscopic scrutiny has enabled Landois to determine that certain ants do possess a true organ of sound, in the form of a triangular field on the upper surface of the fourth abdominal ring. This is ribbed, and when rubbed is capable of emitting a stridulating sound, Westwood (Modern Classification of Insects, vol. ii.) thinks this sound is produced by the action of the large collar against the front of the mesathorax. Whichever it may be with respect to ants, it has nothing to do Landois has shown that the piping of with bees. queens is produced by the spiracles and trachea, the tone being due to the large size of the spiracles. If Landois' experiments be repeated, and two queens placed in separate cages close to each other the piping sound will be produced. The contraction and expansion of the abdomen is for the purpose of forcing the air through the spiracles. If the spiracles are stopped with wax the piping will cease. This disposes of the stridulating theory. Die Ton- und Stimmapparate der Insecten, by Dr. II. Landois, will give you all the reliable information respecting sound produced by insects. Although with you we do not believe that the bee pierces the cell-cap for the purpose of injecting formic acid, as it has a simpler method of doing, we do not think there is any doubt about a small quantity of formic acid being in the honey; and if you will refer to the British Bee Journal for 1883, p. 267, you will see there that we stated that Dr. Planta had found formic acid, and that this he considered served as a preservative of the honey and prevented its fermentation. Dr. Müllenhoff's experiments also corroborated this. By using the thinnest flat-bottom foundation, we have found no nuisance in the midrib of sections worked with full sheets .- ED.]

AGRICULTURE AND APICULTURE.

[1394.] In these days of agricultural depression it is well to notice the rapid strides being made by one of its branches—that of bee-keeping. Indeed, it appears quite probable that so far from the farming industry embracing the other in its downfall, the present distress can be made vet another stepping-stone to add still greater prosperity to the profession of bee-culture; and the latter may even in a measure help to restore somewhat of the old position held by the lower agricultural classes.

A few years since people were ever ready to rent or purchase small farms at exorbitant prices, but to-day things are so radically changed that many farms want a tenant, while some are even let at a merely nominal rent just to keep the ground in order and clear the taxes, There are, of course, some who still make farming pay by improved methods and implements in connexion with large holdings, but the small farmers cannot hold out under old rents.

Without here going into the deeper causes we can see that the reaction has been severe and unparalleled, and now its benefit to bee-keepers comes in many of the landlords' restrictions as to working the land have to disappear, and the man who wants a moderate-sized holding for the main purpose of growing bee-forage can have land almost on his own conditions, and in many places at a price quite within the mark for farming to that end.

Working in this way the combined farming may be made to yield a double profit, if the work is only carried out in a systematic manner. Corn-growing must, of course, be the most insignificant object, even if it is followed at all, though of course there must be a change in the crops every two or three years, if only for the

sake of mending and cleaning the land.

Dairy farming is not yet played out, and would work well with bee-farming operations; but then of course the dairy must be under the skilled management of a good man and wife. Then 1 am aware that poultry on a small scale pays well with a good run, and this department could be under the management of the wife and family, with the master's eye to regulate matters. With the young chickens located near a few aeres of borage they will thrive amazingly and require little other food.

I have not much faith in growing fruit, except on a large scale as a speciality, though I have always had the impression that pear-trees would pay well, requiring little or no attention during the busy time. Many kinds can hang almost into winter and will keep long after other fruit is gone, and, what is of the most importance, a good price can be secured for genuine fruit. Of course one would grow a few of the earlier kinds, but these will seldom keep for any time, while some that ripen on the trees soon go 'sleepy.' Though some apples will keep till better prices can be secured, these, as well as nearly all smaller fruit, seem so plentiful as to be hardly worth the trouble of taking to market.

Tomatoes are still profitable, and with these and other fruits that can be grown out of season under glass the master may find profitable occupation while the bees are idle; but he must first make himself acquainted with the simple rules of culture, or he is liable to lose very much more than he will gain from any supplementary occupation he may undertake. And, moreover, if the bees are to be the primary object the master must give them his personal and undivided attention throughout the season. Every other interest engaged in should be such that can be managed at this time by some other suitable

person.—S. Simmins.

PRICE OF HONEY.

[1395.] Mr. Simmins (1385) says his experience is contrary to his admissions in his previous letter (1361), where he says the price of comb-honey has been lower than it should be; then farther on he says bee-keepers are to blame for placing their whole crop on the market at one time. Here he admits the market is glutted and the supply exceeds the demand, with the inevitable and invariable result of low prices, and if dealers once grasp the impression (it may be a false one) it takes a long time to disabuse their minds, in fact, the season for comb-honey will be practically gone past ere it can be done. Do I hear a chorus of retorts, The season for comb-honey is never past, but only requires judicious handling to eke it out from year to year?

Now if comb-boney was a commodity that would keep an unlimited time, no doubt the season could and would be extended somewhat, but bee-keepers on a large scale and retailers of honey will bear me out when I assert that a large percentage of sections deteriorate in appearance, and consequently in value, by age. The Secretary and working staff of the British Iloney Company know this by practical experience, and no doubt could throw much light on this subject, as they are dealing with honey of all sorts and conditions the year through, and keeping a constant supply in the retailers' hands all the year round; and as they receive honey from all parts of the country and from every kind of plant that blooms, they could for the benefit of beekeepers give the ordinary percentage of granulated sections, also of weeping sections, also the demand there is for section or comb-honey during the months of, say, January, February, March, and April.

Now, as regards extracted honey, the case may be different as to the demand, and it may probably be ready during a greater part of the year, and consequently not subject to any great fluctuations, for the simple reason that it is an article that will keep an in-

definite time without deteriorating in quality or appearance. We know that there is a larger part of the crop put on the market at close of honey harvest in consequence of many bee-keepers wishing to realise to meet the many demands sure to crop up at beginning of winter, but as to the rise in price of sections held over Christmas I am sorry to say I have not been able to make any more per gross than for those sold earlier, and in some instances have had to take less in previous years, say, in February and March; perhaps it may be that I do not possess that commercial acumen required to extract higher prices from dealers. I, in my countryfied simplicity, have believed them when they have told me the season for comb-honey has past and there is very little demand for it at this time of the year.

'Do not hold comb-honey into the new year' is my advice to those whom it may concern. Depend on it that strawberries and cream at Christmas would not be devoured with the gusto of midsummer; the reason is obvious why Mr. Simmins should think and contend that there would be a popular demand for sections of honey the year through; and if we can devise any plan to keep comb-honey in its pristine purity and beauty free from leakage and consequent messiness we should be able to induce a larger constituency of retailers to embark in the trade, and thus bring it to the notice of the millions in the large towns and centres of population, thus increasing the demand for a larger quantity; but I doubt if we shall by any device extend the honey season far into the winter months.—Woodleigh.

PARALLEL v. RIGHT-ANGLED FRAME.

[1396.] There is a rude, dictatorial tone about Mr. Saddler's communication which makes replying to him an exceedingly distasteful task. I do earnestly commend him to a perusal of the recent remarks by 'Useful Hints,' and your editorial on 'Parsons and Bees;' nevertheless be must be answered, there are many

unpleasant yet necessary tasks in the world.

He says my admission that I have adopted broadshoulder frames proves that I am behind the times. I answer this remark by stating that I had tried other plans, including metal ends, and discarded them in favour of the one adopted. This was a distinct decision come to by all my neighbours and myself, after frequent trial and approbation. Besides (to use a Hibernicism), if I am behind the times I am in the company of multitudes of advanced bee-keepers; some four thousand, I believe there are, of these misguided framists in the British Isles. Call us broad-shouldered, strong-framed, and, if you like, slightly waxy hee-keepers. 'Abbott,' vide Mr. Saddler's letter (after this, let us for ever forward forbear using titles of courtesy towards each other), 'Abbott' has more of his frames in use than probably any other frame-maker in the world, certainly several times the quantity of any single maker in the United Kingdom. I have made the inquiry, and am informed that four men are engaged winter and summer at the machines making nothing else. This is being behind the times, forsooth! Fancy any bee-keeper adopting any particular style of frame, using it for only two months, then discarding it, and laying down the law after the manner of one Dogberry of vore! Fancy, too, punching shoulders off with a chisel! As an inventive genius, and an alleged advanced bee-keeper (or hive-maker, I don't know which), why could be not, instead of doing so much punching, 'tax his learned faculties,' and cut out a notch from the back of the shoulder, which would have enabled him to distance his frames as he pleased?

As to the question of draught, if my remarks be referred to it will be found that the two openings required would be found in the bive door and the

turned-up edge of the quilt during the early spring Further on in your correspondent's manipulations. remarks I am told, with an effrontery which I take to be characteristic, that 'the difficulty in manipulating right-angled frames exists only in my imagination, that it is practice that makes the difference. Why cannot people who pose as quidnuncs at least read the articles they criticise? In my remarks I made special allusion to hives, several of which are placed on long stands—a common practice in exposed, windy districts—the difficulty of manipulating these being evident on the face of it.

Mr. Saddler misquotes me thus:—'He (myself) says he went to Nature for her samples.' I did not; I said 'simples.' He (Mr. S.) continues, 'The rose, the pansy (sic), or the chrysanthemum of the present day—the product of Nature—has not science turned the stamens of these flowers into petals? Nature has nothing to do with it.' (This is really reductio ad absurdum.) No, Sir, Science has not done this; get a specimen of Nymphæa alba, and then dogmatize. Let growers of orchids say whether they would not give the ears off their heads, so to speak, for an hour or two's chat with the collector of these exotics in the tropics and their varied homes, so as to get at the surrounding natural conditions of their habitat. Mr. S. alludes, I presume, to the double rose and the double chrysanthemum, which 'sport' with doubling tendency, this tendency being what is called 'fixed' by the gardener. Shakespeare tells us:-

'This is an Art which doth mend Nature; Change it rather, but the Art itself is Nature.'

I suppose the 'divine Williams' will now be taken to task, after the recent Baconian method!—R. A. H. GRIM-SHAW, Horsforth, near Leeds.

BEES IN NATAL: THEIR COMPANIONS AND PARASITES.

[1397.] I am posting to you to-day some specimens of an insect which is common in hives here, and of which I cannot ascertain the name, or whether it is hurtful to the bees. These insects are certainly more numerous in weak stocks than strong ones; bees seem to pay no attention to them, whether running on combs or frame, or holding on to a hind leg by their disproportionately long nippers. If bees are thrown from a frame on to the ground in any quantity, one or two of these insects will be seen hurrying to catch hold of the bees' hind-legs to be lifted into the hive again. They also are to be seen on swarms when knit on bushes, &c. So far as I can observe they do not penetrate deeply into the hive usually, but prefer being at the top, especially hiding under cover of the frames, between the cover and the frames the cocoon is most frequently to be found. The cocoon is white, circular, and a little more than one eighth of an inch across, nearly flat at the top, and when the insect within is nearly perfect it can be dimly seen through the covering.

Another insect I have seen on bees here is apparently a kind of tick, but I have no glass strong enough to let me see them well. They are grey in colour, about the size of a small pin's head, roundish, and look well filled

out. They soon dry up when removed from the bees.

Lately in a friend's hive I saw the largest 'death's head' moth I ever saw: it was a little way down the third frame from the end, and was entirely covered with bees, except just its head and shoulders and top of the back between the insertion of the wings. Both bees and moth were quite quiet. This upsets what I have always believed before, that bees avoid these moths in terror. When I stuck a penknife into the moth's back to remove it the loudness of its shrieks (I notice other moths shriek here) quite astonished me, but the bees took very little

notice, and apparently only got off its wings because they felt it was being moved off the comb.

Bees are said not to like bad smells, but I saw a huge swarm of bees which had taken possession of an unsavoury rabbit-hutch, much to the distress of the children who owned the rabbit. They were afraid to remove him for a long time, and watched him through the bars. From the time the bees began to enter till they were perfectly quiet and knitted into a mass the rabbit lay as still as if dead, with his ears tight to his back.

I send two or three of these insects which have been in spirits of wine, and two or three which have been in cotton-wool since I took them. I hope they will arrive

safely.

If I can I will put in a specimen or two of our bees, though I believe you have seen them. They are not so pretty as Ligurians though much like them. Amongst them are a few smaller bees, and without the band. These are much blacker than the ordinary ones. I do not see why this difference exists, but it is noticed by several bee-keepers. - J. R. WARD, St. Mary's Parsonage,

Richmond, Natal, Nov. 15, 1887.
[The insects sent are Chelifers* (claw-bearers). Chelifers constitute a group of animals allied to the Spiders and Mites. From their resemblance to scorpions without tails they are called Pseudo-scorpions, or False Scorpions. Their palpi are elongated and armed with pincers. The species live under the loose bark of trees, in chinks of old furniture, They are also to be found under the elytra of beetles, but their object in occupying this position is unknown. There is, however, little known respecting them, and any observations regarding their habits would he most useful. Kirby makes mention of the peculiar mode of progression of the book-crab (Chelifer cancroides). All must admire the peculiar instinct in the insects making the special use of their pincers, and thus getting into the hives. It appears to us that they enter hives for much the same purpose as earwigs in this country, which are not desirable companions to bees, but which do little harm—especially to strong stocks. 2. From the description we should say that the parasite on the bees is the Braula cæca, or some species of mite. 3. The Death's Head moth (Acherontia atropos) is remarkable also in this country for the shrieking or squeaking sound which it emits. This sound, together with its dark colour and its skull-like mark on its thorax, has led to its being regarded with superstitious dislike. How the noise it emits is produced is not satisfactorily known. for the authorities differ very widely as to its cause. Schroeter says that it utters the cry when it rubs its tongue against its head; Rösel, that it is produced by the friction of the thorax and abdomen; while Réanmur believes that the cry comes from the mouth, or rather from the tongue, and that it is produced by the friction of the palpi against that organ. Huber denies this; as also does Passerini, who says that the sound is due to the alternative inspiration and expiration of air from the central canal of the proboscis into a peculiar cavity of the head destined for giving it the required resonance. But a number of French savans who instituted a series of experiments to ascertain the actual cause of the noise, came to the conclusion that it was not attributable to any of those above given, but that it remains to be discovered.

We shall be pleased by your forwarding further communications.—Ed.]

BEES IN MINORCA.

[1398.] Having been brought up the best part of my life in the United States, I was greatly interested on reading the account in the British Bee Journal of the progress of modern bee-culture in that land of 'magnificent distances.' And as this progress has mainly taken

^{*} Χηλή, a claw, and φέρω, I bear.

place during my absence, I would thank you very much to answer a few questions, such, for instance, as the respective size and depth of American and Canadian hives and frames.

I take it for granted that you prefer the British standard, as your own Cowan hive is adjusted to it; this is the kind I have introduced with good results in Minorca. But some people object to the standard frame as not being deep enough and large enough, preferring the Langstroth or Dadant; and what has almost made me waver is the penchant of your friend, M. Bertrand, in his Revue Internationale, for the latter, and against smaller hives and combs. It is a mystery to me how Germany, the land where, I believe, a larger portion of bee-publications is published than in any other country, and where the subject is most scientifically treated, should insist in preferring its Normalmaas and Burki-Jekers, when the above Revue insists that its favourite Dadants produce double the quantity of honey. Could you give us any light on the subject?

The past summer was exceedingly hot and dry, and we were months without any rain. Consequently our honeycrop was shorter than we could have wished. Still, we managed to get some 800 lbs. out of sixteen hives, besides half-a-dozen good swarms. But the bee-most broubled us to an unusual extent, many moths being double the size of other years, and of a light lead colour. The larvæ were also disgustingly large, and of a similar

colour.

Besides our home-apiary, increased to some thirty lives, we have just been starting another in the interior, of about fifty more, which we intend to increase to a hundred the coming spring. This we accomplished by transferring some ninety old-fashioned cylinder hives into forty-five bar-frames. The honey in that district is very fine. This fall the weather has likewise been unfavourable, but our November is often warm enough for transferring, and the fields are always carpeted with flowers that yield much pollen, but little honey. (By the way, what shall I do with combs half full of

pollen?)

I must except our rosemary, Clematis cirrhosa, and a kind of heather (Erica), which yield honey in considerable quantities. A fortnight ago my bees were booming on Cirrhosa as in our April honey flow. In the interior they have acre upon acre of heather, which some years yields a second honey-flow so abundant that occasionally hives will throw off a swarm as in spring. This plant blooms till after Christmas, but heather honey is not liked here. The hives, however, keep very strong, and seldom need feeding. A friend of mine, for whom we set up a bar-frame hive in that locality, told me they were capping two racks of twenty-one sections in mid-November, the second storey beneath being a solid mass of honey. But the weather is now stormy and unfavourable for such operations. As to rosemary, it is an evergreen that flowers nearly every month of the year and its honey is very fine.

By the way, a certain Mr. Furness declares, in Gleanings for April, that the great majority of American apiarists 'are abandoning the large brood-chambers of ten and twenty years ago and using eight, and even less, L. (Langstroth) frames for both comb and extracted honey.' '1,' says he, 'left over fifty colonies on five L. frames the entire season, from April to October last year, and never had better or larger swarms, or got better results than I did from these contracted hives.' Does he contract with excluder zine? The Editor, Mr. Root, does not seem to disapprove of this; and even Dr. Miller, the able apiculturist, adds, 'I also had most of my colonies on no more than five L. frames from April to October, but for all that I want a hive capable of holding ten frames some parts of the year,' which would seem to indicate that Mr. Furness does not, You, Mr. Editor, who have so recently

returned from the States might probably explain to us the modus operandi of the five-frame system of contraction. I see that Mr. Simmins in his new book, A Modern Bee-Farm, also favours contraction during the honey-flow.

A few days ago we received a Carniolan queen from the latter gentleman, but imagine our surprise at finding both queen and bees as like ours as two peas! We have, however, introduced her majesty to a pretty strong

colony and await results.

I had been much puzzled by your former statement in the B. B. J. that in England Clematis vitalba did not furnish pollen to bees. At last a friend, who is also a botanist, has cast some light on the subject. It appears that what in our vernacular is wrongly called Vitalba here is another species, and the true name is Clematis cirrhosa, our bees gathering both honey and pollen from it.—F. C. Andreu, Port Mahon, Minorca, Dec. 1.

[We have become so used to working the British standard that we would not be able to get such good results with any other size. The standard size was adopted, after very careful consideration, as the best, for both extracted and comb honey, although at that time comb honey was most considered. Its advantage is that it is just large enough when working for comb honey, and small enough for storifying, without the necessity of using supers of a different size to the body-box when working for extracted honey. The large hives, such as the Dadant and Layens, are both excellent, but more suited for extracted than comb honey. By using two or more of our sized hives you can expand to any extent. The standard frame has an advantage in being neither too deep nor too shallow for general use, as the results obtained have shown. Putting a second box on the top when the stock-box is crowded and honey is coming in is not too much, but could not be conveniently done with a much larger trame. We do not know why the Germans retain small frames and hives, and we think M. Bertrand quite right in his criticisms, as there is no doubt but that, all things being equal, a larger hive, such as ours, or those used in Switzerland, will give double the quantity of honey. The Langstroth is but very little larger than our Standard, and this hive is in more general use in America than any other. The object of contraction is, when working for comb honey in sections, to force the bees up into the supers. Supposing a ten-frame hive is just full of bees when the honey-flow commences, it is evident that if a crate of sections were put on the top it would be no inducement to the bees to work in it until they found they were too crowded below. Thus much time would be wasted, and several days' honey-flow lost. By removing two of the frames (or more) and contracting the space to eight frames by means of division-boards, the bees are at once so crowded that they have no alternative but to go above or out at the entrance, and honey being plentiful they are generally contented to work in the supers. You will see in the Guide-Book that we endeavour to get our stocks strong and full of bees, so that they can take advantage of the honey-flow, and by giving space in advance of their requirements, we do not require to contract our hives, our frame not necessitating this; but we can do so if we like. You can keep your combs half full of pollen until the spring, but they should be subjected to the fumes of burning brimstone to destroy the waxmoth or larva. They will probably be useful in the spring, but, if you should not require them then, you can shake out the dried pollen, if it has contracted sufficiently, or you can cut down the cells to the minima You seem to have funny names for flowers in your part of the world. Rosemary with us would mean something quite different to Clematis cirrhosa. This has several English names, viz., Evergreen clematis, Spanish travellers'-joy, and Spanish wild cucumber. It does not in any way resemble Clematis vitalba, which is the common travellers'-joy found with us. We are glad you have been able to clear up the mystery respecting the pollen,--ED.]

BEE-KEEPING IN THE CRIMEA.

(Extract of a Letter from A. de Zoubareff, Moscow, December 10th,)

[1399.] I have also been travelling with my wife this autumn, and have spent the largest part of the time in Sebastopol. The climate of this city is superb. Its destruction, caused by the war, has contributed much towards its embellishment, so that if you have not seen it within the last five years, you would be astonished at the marvellous progress that has been made in buildings, pavements, and plantations, although these last are somewhat hindered in their growth by the southern sun. As regards apiculture in the Crimea, it amounts to next to nothing. The honey has a bad flavour, which I am inclined to attribute to the tobacco plantations. Some years ago I got some honey from the Valley of Roses (Kasanlik, Bulgaria), thinking to find the aroma of these flowers in the honey. Unfortunately the taste was very disagreeable, slightly bitter, resembling tobacco. Has any one ever observed the influence of tobacco on the quality of the honey?

Our peasants are beginning to take to bee-keeping, and I am doing my best to prevent the introduction of hives on wrong principles. Have you ever heard of an apiary being attacked and almost entirely destroyed by large numbers of dragon-flies? an event which actually occured this summer in Siberia. The baffled bee-keeper made use of his gun, and was successful in driving away the

villanous creatures.

STANDARD TOP BAR.

[1400.] In your issue of 1st December I notice your correspondent 'Robin Hood,' in his letter (1370) page 524, thinks that it is time the B.B.K.A. altered the rule relating to the size of standard frame top bar. I think that if they have a rule to that effect it should certainly be rescinded, and let bee-keepers use what size top bar they like best, though for my part I prefer a 17 in. bar, and it is certainly the best size for a beginner; but is not the frame of a Cowan hive and of Simmins' Economic hive acknowledged by the B.B.K.A. to be standard size, and they have both a $15\frac{1}{2}$ in. top bar?

I do not think that the size of top bar has anything to do with success or failure, although I cannot say the the same for metal ends and broad shoulders; but they have their advantages, also disadvantages, the latter

predominating.

In a former issue the question was asked: Have fourway sections been better finished than two-way sections? My experience is that they have. They have been filled more quickly, have fewer popholes, and are built up to the edge of section, as Mr. W. McNally has already informed you, but I have used no separators. Many sections weighed 20 ozs., and very few under 16 ozs. They were projecting too much to be glazed or to pack safely. I should advise slotted separators to be used.

I should like to see the experience of those bee-keepers who have tried the shallow invertible hives during the past season, as it had many champions during the last winter months, but perhaps they have had a check to their enthusiasm, also what results have been obtained with

Mr. Simmins' Union Hive with large frames.

Bee-keepers have several times been invited to form district societies, making their own rules, &c. Now in many districts where such a society might flourish there is, perhaps, not a single bee-keeper who has had any experience in working a society, and has no idea of the rules that should be drawn up, not having seen any belonging to bee associations; so after having read the invitation think no more about it, not that they are not interested in the movement, but they know not how to

go about the work of carrying on such a society. Now, if some experienced bee-keeper would write an article in your valuable Journal on How to work a District Association, it would instruct many who are at present ignorant in such work, and would be the means of creating a number of small societies, which would strengthen our Counties and B. B. K. A.'s considerably.—J. WOODHEAD,

TWENTY YEARS EXPERIENCE OF THE MOOR SEASONS.

[1401.] My last paper, ' Λ Trip to the Heather with the Bees, I wrote with the sole object of interesting the readers of the Bee Journal. What I stated was strictly true; in fact, the words used failed to fully express the pleasure I have often found in these journeys. My object now in the present communication is to give an experience that will in a measure help your readers to

decide as to the worth of the moor season.

My first season, 1867, was a remarkable one. It was the best I have had. We had had a very wet summer that year. It commenced to rain in July and rained almost incessantly up to the beginning of September. August was very wet. The bees did not get a start until September, and in that month we had a fortnight of very fine weather with heavy dews at night. It was most extraordinary what the bees accomplished that season: I well remember it. The friend I went with had a large stock of hives (all straw hives; we knew nothing about frame-hives at our place then). He put on his best hives two supers, one 12 in. dia. $\times 4\frac{1}{2}$ high, and on the top of this a super that would hold fully a stone of honey. Everything put on to the hive was full, except a third swarm that was a mere handful of bees when hived. On this he put a large super, more for the sake of having it at the moors to change any of the others with. Well, in the centre of this the bees put a comb the full size of the super, two inches thick and nearly all sealed. In one of my supers the bees had run the honey into a solid mass; there were only tunnels running through it here and there.

The next year, 1868, was the hot, dry summer. The take this year was rather above the average. 1869 was another hot, dry summer, but not near so dry as the previous year. The heather came into bloom earlier this year than ever it was known by the oldest inhabitants on Muggeswick Moor. It was a better season than the previous year, but the most of the bee-men were too late in getting their bees landed at the moor. One party I know who got warning about the forward state of the heather took his bees to the moor in July, and he had a large take of honey. I well remember this season. It was the 5th or 6th of August when I got mine landed, and I had them let out by six o'clock that morning, and after I got my breakfast, between seven and eight o'clock, I went to see them, and I was astonished at the sight I saw. Every bee I could see was working with a vengeance, none dulling about, but going in and out without halting a moment, and they had only been let out about an hour and a half. Some that read this will be slow to believe it, but it is quite true. I would not believe it myself if I had not seen it. The heather was at its best, and you could feel a sweet smell when you were standing near it. 1 am not quite certain whether it was the following year or 1871, but it was either one or the other that the season was remarkable. We had a cold and late spring-a long continuance of east winds —and the summer was cold and wet. The heather was late this season, but when the bees were there it came a fortnight very fine, and at the right time, calm weather with heavy dews at nights; indeed, I well remember this was the only period of fine weather we got that year, but notwithstanding the bees got very little, simply because there was nothing, or at least very little, in the plant. Now I have had several years like this,

but not so remarkable as this one; and the main object I have in writing is for the readers of the Bee Journal to understand that fine weather in August is not the only thing that is required to make a good moor season. If we have a wet spring and not so much of these cold east winds, and a hot summer, the heather will have plenty in it, and if fine in August a splendid season, but even if it is showery weather when the heather is in bloom the bees are not so much stopped in their work as you would naturally suppose, for I have been at the moor on a day when I have seen several showers, and the bees just flocked home when the shower was coming, and as soon as ever it ceased raining they were out again as if every hive was swarming. You see the trip the bees have to make to the stuff is so short; and more than that, heather is a very hardy plant; it will stand cold and wet better than any other honey-producing plant to my knowledge: but supposing there has been a week of fine weather when the heather is at its best and there comes down a very heavy thunder-shower, the season will be done. When the like of this happens I always go for my bees the next day, for no matter how fine the weather may come after the hives never get an ounce heavier, but soon get lighter.

I might here say in reference to those that have suffered by the honey-stealers, that it is nearly always those that let their hives stay after the season is done that get their hives and supers stolen. I have only suffered once: it was in 1885 when I got my best hive stolen and two supers of honey. In 1874 I would have been robbed, but as soon as the thieves had started their operations there were some geese the farmer had in an outhouse commenced to make a great noise through being disturbed that the farm people were roused and

the thieves had to decamp.

In my time there has only been one real famine at the moors; it was in 1876. It had been a wet summer, and it rained incessantly all the time they were at the moors, more than two-thirds of the hives died; all along the rows of hives they were lying on the grass like chaff. This famine made great havoc of the bees in our neighbourhood, and several I know gave up the business.

I would like to impress upon those that may intend trying the moor season the importance of providing sufficient ventilation. I know some will be ready to say, Remove the quilt of the section crate, and they will travel all right; but no, this I have learnt to my sorrow, will only do on a cool night. On a close, warm night more than this is needed, and in my hives I have at the back a hole eight inches long and $\frac{3}{4}$ inch in height opposite the entrance for ganze with a wood cover to fit in when the

hives are set up.

In conclusion, I would advise all those hat intend taking bees to the moors to make sure and get a quiet horse. The experience I had one dark night will show the importance of this. After getting a short distance from home I stopped just after crossing a bridge and left the horse to go and speak to a friend who was driving behind. My horse without a moment's warning bolted over the embankment on the left; fortunately the cart did not upset, and I ran and got the horse turned to the road, and he just could manage to struggle up the embankment on to the road again, but in doing so the hamestich broke; fortunately it broke at a joint that made it easy to tie with a piece of rope. After this he wheeled about at some dressed stones by the roadside. After this again he took fright at the noise of a steamengine and ran away, but was pulled up before damage was done, and when we got to the moor we missed the right track and ran right into a bog, and the horse sunk right up to his hoofs, but being a powerful horse he went right through the bog and up a steep hill and we got landed in safety. After this I would never take my bees to a place that in order to get to it we had to cross the moor. I would warn your readers that it is a very

dangerous thing when any of the moor has to be crossed. I have known several accidents happen from this cause. The friend that went with me in 1867 had a very bad accident from this. In walking over the moor you may think some tracks smooth enough to cross with a cart, but when you come to try it you find it to be a dangerous business.—W. J.

NOTICES TO CORRESPONDENTS & INQUIRERS.

Letters or queries asking for addresses of manufacturers or correspondents, or where appliances can be purchased, or replies giving such information, can only be inserted as advertisements. The space devoted to letters, queries, and replies, is meant for the general good of bee-keepers, and not for advertisements. We wish our Correspondents to bear in mind that, as it is necessary for us to go to press in advance of the date of issue, queries cannot always be replied to in the issue immediately following the receipt of their communication.

W. G. Preece, Jun.—Sartori's Diagrams.—The price of the Italian diagrams mentioned as having been prepared by

L. Sartori is five francs post free.

Rev. F. W. Pudsey.—Cowan Hire.—1. These can be used for transportation to the heather by having the racks Fig. 7, in Guide Book, placed on the top at the ends of the frames, and also by putting one at the bottom to steady them. Or fix the frames by putting in sticks as directed on pages 106 and 107. Were we sending our hives to the heather we should only send the body boxes with temporary floor-board screwed on, and leave the outer cases at home.—2. You will see that we reduce the length of our top-bar as we generally use metal corners as shown on page 33, which is a full-sized sketch. If you wish to retain the 17-inch bar you would have to add a rabbeted strip on the outside, cutting down the hive side to suit it. We thank you for your complimentary remarks.

Mornino Star.—1. 'The Woodbury Hive' is 14½ inches square and 9 inches deep, taking ten frames. The frame is 13 inches by 7½ inches, with a ½-inch projection (lug) at each end, for resting on the rabbets. These are inside dimensions, both as regards hive and frames.—2. Carbolic Acid Solution for Removing Sections.—To a quart of warm water add 1½ ounce each of Calvert's No. 5 carbolic acid, and of glycerine. Shake well before using. In this solution steep a piece of common strainer, or flannel, wring it dry, and spread it over the section case, when the bees will at once retreat if the sections are sealed. When sections are unfinished the bees will sometimes remain for a time to gorge themselves on the unsealed honey, but, as a rule, they are easily dislodged by the dreaded scent of the carbolic acid.

W. T. Cadness.—I. Middlesex B.K.A.—By an oversight the expert missed you in making his autumn tour. The Secretary of the M.B.K.A. for your locality is W. M. Graham, Latymer Lodge, Church Street, Lower Edmonton. Subscriptions for 1888 are due before January 31st next. No record of honey produced in Middlesex has yet been published, but the Annual Report of the M.B.K.A. for 1887, about to be issued, will contain some information on this point. 2. Trap for the Escape of Bees.—We have not seen an illustration of the trap referred to. 3. Funigating Combs.—Ordinary stick brimstone, placed in an old tin with a live coal, and the box containing the combs set over it, is the mode of funigating combs. A piece the size of a walnut would do a large box full. 4. The library is not open for reference; only members of B. B. K.A. can borrow books, which they may have at home.

Simmins' New Book.

' HAZELEIGH RECTORY, Dec. 3, 1887.

'The paper, letterpress and plates, are most excellent.... The treatise appears eminently a practical one, and such as can be "understanded by the people," which is more than can be said of many modern books on our pet subject. I trust you may have a large sale for it, which I do not doubt, as Mr.——told me he had numerous applications for your book. '(Rev.) GEORGE RAYNOR.

One gentleman writes: 'I lent your book to a friend; he read it twice over. He requested to have a prolongation of the loan of it to read it a third time.'

'Laidach, Carniola, Austria, Dec. 2, 1887.

'The new book came this morning. It is now midnight, and I have spent the whole day with it. You have indeed done well what few accomplish at all—made a book which is full of interest to every enthusiastic bee-master; yet for the beginner a simple, pointed guide to success. . . . Since Langstroth's book nothing, except Cheshire's magnificent work, compares in interest or value to this. It has given me already more in value than the price of the work.

'FRANK BENTON.'

One who has kept bees for a number of years says: 'I have just finished reading your book (Modern Bee Farm) for the third time, and beg to thank you for the great treat it has been. As I happen to have thousands of acres of heather within easy distance, I am specially pleased with the chapters treating on working for heather honey.'

BLUE OR AMBER

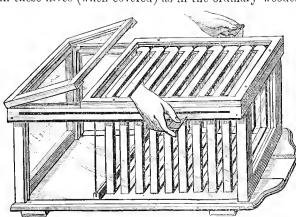

WE beg to submit a few of the advantages claimed for our New Observatory Hive, THE 'SPECIAL' It is inexpensive, and is made of clean, well-seasoned wood, and first quality 21-oz. glass.

There are no extras to the Hive proper, the Glass Dummy, the Nine Patent Frames, and the Handles or moving the Frames, are all included in the price quoted.

Although Combs are all visible on both sides, the natural Brood Nest is preserved, which enables the bees to do quite as well in these hives (when covered) as in the ordinary wooden ones.

Price, Complete,

15/-

Packed in strong
Wooden Case
(which is returnable) 2s. extra.

The entrance is cut in floorboard, so that by merely placing a piece of wood or glass across it a tunnel is formed. The front top frame can be easily removed, and a super put over the nine frames.

The bees can be fed from back of hive without disturbing the hive or frames in any way, the top frame behind the dummy is hinged (as shown) and works independently. The hive is made so simply that it can be put together or taken to piecos in three minutes, and when in pieces will fold into one-fourth its bulk.

It takes the ordinary Standard Frames.

ABBOTT BROS, are the true and first Inventors of this Hive, and they trust their efforts to supply a public want have not been in vain.

If fitted with 4 inch British Plate Glass, £1 0 0 [If made of Oak, Walnut, or Mahogany, £1 5 0 And if French Polished and Stopped, £1 10 0

NOTICE.

A large number of subscriptions expire with the present issue. This fact is indicated in the usual way by the *Journal* being enclosed in a coloured wrapper. A form for the renewal of the subscription will be found enclosed in the *Journal* itself. We trust our subscribers will favour us with their orders previous to the date of the next issue.

END OF VOLUME THE FIFTEENTH.

With this number we are brought to the close of another volume—the fifteenth of our series. The temporary stoppage at this station in the history of our Journal furnishes us with a favourable opportunity,—an opportunity of which we gladly avail ourselves,—of thanking, in all sincerity, the numerous friends who have rendered us assistance during the past year; and it also enables us to acknowledge the many testimonials we are constantly receiving of the appreciation of our labours, and of the approval of the mode of conduct of the Journal.

Our volume this year has extended to 580 pages, and the copious index testifies to the variety and extent of the subjects which have passed under our notice. Apiculture is developing itself in every direction; and in none is this development more visible than in the amount of literature that is devoted to its elucidation. In this country two periodicals are altogether given up to its treatment, and several others, of a cognate character, touch upon it incidentally. In Germany, and on the Continent generally, and in America, the number of apicultural periodicals is very great. Besides these, books,—scientific, physiological, and practical, are continually issuing from the press. The Voice from all these, to compilers of books and conductors of publications, is that of encouragement to advance in the further evolution of the subject they have undertaken; and we trust, with the continued assistance of those who have favoured us in the past, to obey that Voice, and ever to be in the vanguard of all that will lead to the greater development and the more enlarged knowledge of the economy and management of the Honey Bee.

During the past year there have been no shows similar to that held in South Kensington in the year 1886—though we fain would have wished that the Jubilee year had not passed by without its having been signalised by such an exhibition—yet the year has been one of steady and continued progress, and shows much promise for the future. The present year cannot be pronounced to have been marked by any remarkable degree of prosperity, yet we have had no reason as bee-keepers to complain, but, on the other hand, much cause to rejoice and to be thankful with the amount of success which has been vouchsafed to us.

Again thanking our friends for their kindness in the past, and hoping that there will be a continuance of their favours for the future, we trust that the Coming Year may be one of prosperity and happiness to all bee-keepers.

FACTS.

This Jubilee year will soon come to a close, and 1887 will have been inscribed on the pages of History as a season memorable for loyal rejoicings and for the accomplishment and inauguration of various praiseworthy and noble undertakings. Beekeeping has made wonderful strides in our Queen's reign, but such development we do not intend to trace on this occasion, but rather to dwell on facts springing from the result of such advance-The nineteenth century, undoubtedly the age of invention and the age of steam and electricity, may be looked upon as a wonderful period of the world's history. Men's minds have been fruitful in developing vast and wonderful undertakings, largely to the benefit of their fellowcreatures, but often, unhappily, in a contrary direction. Bees have had their share of both sides of the picture. We are all aware how great have been the improvements in our system of apiculture. Bec-keeping has not only become a fashionable pursuit, but now ranks as one of Great Britain's rising industries. Honey was once a luxury, but now forms one of our staple foods; where one pound was used years since the consumption may now be reckoned by the hundredweight. person who speaks of the present low price of honey overlooks the fact, that whereas he was able to obtain 1s. 6d. and 2s. per lb. for the product of his apiary ten years since, now with modern improve-

ments the quantity of honey from his apiary has largely increased, the quality likewise improved, and the facilities for selling it greater, so that, in spite of the apparently low price, the careful beekeeper, on balancing his accounts, finds that his profits have more than doubled themselves, and this with less labour and outlay than before. We have noticed the ever-increasing production of honey all over the world, but this is not the danger the apiculturist has to contend with. America and Canada may collect their tons of pure nectar, and yet there is room for more. By an increased sale of honey our British productions will come to the front; once let a man taste prime honey, and he will never go back to inferior. The danger we have to contend with is the unprincipled scientist, the man who uses his knowledge of bees for unlawful purposes; and further, the man who advances his nefarious scheme without the aid of bees at all. The history of the first of these individuals we have recently learnt from a clergyman who had been travelling in the Far West, and visited many of the adulterating bee farms. This apparent bee-keeper settles down to carry out his practices in a quiet place with a favourable climate; he has a large number of hives, but the pasturage of the district is quite immaterial to him, as his bees have to obtain their stores from large feeders placed all over the apiary. Containing what? Our informant was unable to find out, as although everything in the establishment was shown to him without reserve, yet he was not permitted to taste the contents of the vats or feeders from whence the bees were obtaining their supplies. The latter of these scientific beekeepers is best described in the following quotation from a magazine of this month:—'Artificial honey now made in New York is so much like the genuine article that only experts can detect the difference. It is in racks, the same as the natural product, and now and then the wings and legs of a lew dead bees are to be seen to further the deception. It can be sold at a profit of 5d. per pound.

We know too well the practice of mixing glucose with honey, and the methods of detecting it, and how a London firm has been manufacturing another substance, palming it off as honey. But we feel confident that the bee fraternity, located in whatever part of the world, will, as the Cornish motto has it, 'One and all' endeavour to stop such practices, prejudicial not only to the bee industry, but injurious to the health of the community at large.

WINTER PACKING.

The simplest way to pack bees snug and warm for winter is to fill up the space between the dummy and the hive-side with loose cork-dust, chaff, or sawdust, and cover the tops of the frames with several thicknesses of carpet. This simple method has the prime recommendation of answering the purpose of keeping the bees warm, as well as being so simple that no one can excuse themselves from so packing their bees on the score of trouble or expense. But I found, although this plan answered well, it had its drawbacks. My dummies do not fit down on the bottom board by a bee-space, this not only saves bee-life, but improves the circulation of the

hive: but in early spring it used to find my bees a job at which they used to work with energy, it was carrying out the winter packing. This led me to adopt the 'mattrass' shown at Fig. 1 instead of loose packing;

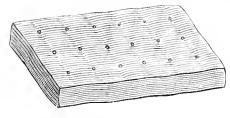

Fig. 1.

there are also other advantages which quite recompense me for the extra first cost and trouble entailed in their adoption.

After extracting is done, at the close of the honey season, I put the last of my frames back outside the dummies in the stock hive to get them well cleaned. As fast as they are cleaned I remove them, and if there are only a few bees clustering outside the dummies after all the frames are removed, I begin to wish to see that empty space filled with packing. We often get very cold nights, even early in October, before one has quite got all in 'ship-shape' for winter packing, so four years ago I abandoned the loose cork-dust for the 'mattresses' I now use.

They are made of 'tick,' the material used by upholsterers for the cases of feather beds. They require to be cut pretty accurate so as to fit snug all round, and care is required to make the corners square. Mine are two inches thick when stuffed. I use cork-dust for packing, and stitch them down upholsterer fashion with twine, using small 'tufts' of tick to prevent the twine from pulling through. I cannot tell you the exact cost of mine, but I know it was a trifling sum, the main item was the ticking. I got a sack full of cork-dust from the greengrocer's wife for a 'section.' If you want to ingratiate yourself into the good graces of the ladies, there is one of two ways that I never knew to fail; one is to take notice of the children, the other is 'mel.' As to making the mattresses, that found me amusement of an evening or two as a relaxation from harder toil, or 'slinging ink.' You will remember the fate of 'Miles Standish,' because he did not follow Cæsar's advice although he knew it well. So I cut out one mattrass myself, drew out the sewing-machine and rattled away, this only drew forth the mild request that I would not break it, 'I was not treading a turning-lathe, remember:' but, however, although it is a good thing to show you can help yourself; that first attempt was not a complete success, the corners were provokingly round and I wanted them bold, but I had learnt a wrinkle that I remedied in my next; the first was slightly too short also, I allowed too much for 'bulging' when filled, and was disappointed to find it did not 'bulge' but very little.

My piece cut a dozen, and I contrived so that I had scarce a scrap of waste. I could see there was an unusual large pile of needlework ready to be machined, so I got a school girl to make them for me, giving her her choice of 'pence' or 'honey.' The 'mel' won again; she was so enraptured with the idea that she got two of her mates to help, and the dozen were done in one evening. A slit about two inches long was left to lill them at, the filling I did myself, having shot the cork-dust into an oval foot-pan for the purpose. The tying down requires a little care, but with ordinary care and a little common sense you may so tie them, that, with the exception of the indentations made by the twine, they will be so level and the edges so square that they will stand against the dummy, if the ends touch the hive-sides, just as tight as they should do, in a Combination hive for example, even

if the dummy is several inches distant from the hive wall.

If your hives are packed with loose packing — and fle upon you if they are not packed at all — you all know how awkward it is to examine the frames in early spring, so here is a nice little job for you by the fireside this winter during the long evenings, so that in spring they will be ready for use; you can then empty out the loose packing and put the mattrasses in their place. I can answer that once having used them you will never resort to loose packing again; and when you remove a mattrass from a dummy, if you feel how warm it is, I am sure you will hesitate ever to remove them and disturb the bees in early spring unnecessarily.

For the top I use one cotton quilt and two carpet ditto; the cotton quilts are renewed each year, they get so coated with propolis. When I have new quilts I lay them on a board, place an empty food-bottle exactly on the centre of the quilt, and run the point of my penknife nearly around the bottle; this leaves a small piece to act as a hinge. The carpet quilts are all bound with braid, and last me some years, but they are all cut as described for the food-bottle, and by this method all the holes come 'plumb' one over the other in all my quilts. I have the character of 'making mattresses for my bees to lie on, and sheets and blankets to keep them warm, and that is why they bring me in so much profit.' In spring, if I wish to gently stimulate, I remove the two carpet quilts, lay the flap of the calico quilt back under the first carpet quilt, the flap of the first carpet quilt is laid back in its turn under the top one, and the feeder stage is placed on the flap of the top quilt, and so all is kept in position. Bulgy! No, it is not, if you lay them down neatly and turn your quilts around so that no two flaps come one under the other. This brings me to my 'trays.' In October, 1882, when the B. B. J. was in the hands of the veteran C. N. A., he told us to make trays by nailing four pieces of wood together for an outside frame,

and by fixing four more pieces in the middle of this frame in this fashion (Fig. 2). You thus have a centre hole in which you may place your feeding-stage. I thought 1 knew better, so I made them without the feeder hole. This I have remedied; they are now made like Fig. 3. The wood with

Fig. 2.

which the trays are made should not exceed three inches in depth, as too great a depth of packing is liable to

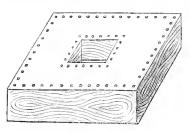

Fig. 3.

get mouldy. The trays described by Mr. Abbott were only covered with canvas at the bottoms, but mine are covered both top and bottom: this prevents the chaff with which they are filled from getting spilt. The bottom canvas should be fixed somewhat loose and 'baggy,' and the tray should not be filled very tight. The chaff I use is wheaten chaff from the winnowing machine (not chopped straw), and the centre hole is filled with odd pieces of flannel in winter, when the feeder is not in use.

All my hives are so packed this year, and I have a few mattresses to spare in case I am compelled to remove any

of the frames in early spring, which I scarce think will be necessary as they have all this season's queens and plenty of stores. I flatter myself that my winter packing will last me for years, and give me little further trouble; moreover, that it is easy of removal in spring, will not make a litter in the bee-garden as a lot of loose packing does, and can be kept on, if early summer should prove cold as the past did, right up to the time of supering or storifying.—Amateur Expert.

MY BEES

By Mrs. REGINALD BRAY,
Author of 'Family Feats,' 'Ten of Them,' 'We Four,' &c.
(Concluded from page 558.)

CHAPTER VII.—EXPERTS.

It was almost a relief to leave my hives that August, and I looked forward to my clean, healthy Shere hive with unmixed feelings of delight. I pictured the supers filled with honey; the box held eighteen pounds, so that if I got that full it would make up to me a little. I wrote to my cousin to ask her to open the hive and tell me if the super boxes were full. I felt as if I wanted some comfort.

Before I left Shere 1 had put the box all ready, placed a piece of foundation the *right way* in the sections, and had asked a neighbour to put the box on the right time.

My cousin wrote back to say that no super box was on. I could hardly believe the words, for though it was a bad season, I knew that Shere abounded in clover-fields, and my sister kept writing to me of the pounds and pounds of honey which she kept taking off her hives.

I think there must have been a fate against me that year, but until I got there and rushed to look for myself I could hardly believe that the supers were not on. I turned back the quilt and examined the hive. Oh dear, it was hard! The bees were as thick and as crowded as they could be, in splendid condition, actually wanting room. They had forced their way between the dummy board and the outside of the hive, and had built combs down between it and filled up all the space. I was obliged to remove all this, push the dummy board close up to the outside, and give them a new frame. I had rather a piece of work over it, for I had no one to help me; and it is a very great assistance both to nerve and body to have a companion who can do the smoking whilst you are at work. Then it was not an easy place to work in. The boughs of the tree above kept catching in my veil. I had no stand to rest the frames on, and I was obliged to take out one whilst I was clearing out the superfluous comb.

I leant the frame covered with bees up against the hive. In an evil moment it fell down and I had to pick it up again. This made the bees very cross, and the crosser they got the more nervous and hurried I became.

They stung me several times, but at last I got them all in order, and went away thankfully. One arm and hand were almost useless for two or three days, but to no one would I acknowledge that bee-stings were anything but a slight temporary inconvenience. Before I came away I put on the box of sections. I knew it could not really be of much good, but the weather was so lovely that I thought I might, perhaps, get so much as one little box filled, or they might at least fill some with comb, which would come in useful for the next season. It is hardly necessary to say that they did not do any work at all.

Autumn came all too fast, the super box had to be taken off, and the bees fed up before the winter. It unfortunately proved a very long, severe winter, and being away I could make no examination of those bees

until after Easter, when it was well on in April. I then got Mr. Osborne of Albury to examine them, and take them completely in charge. He said they were in splendid condition, but having just finished all their supply of honey it was now necessary to feed them up well. They had a nice supply of young brood, but the weather was very cold and scarcely any honey flowers out yet. If the bees did not have sufficient food they would draw their brood. In other words, pull them out of the cells and throw them out of the hive.

I returned to Heathbourne in better spirits, hoping to find that the foul brood was cured. I had only lost the bees of one hive, and that was quite late in the spring, and evidently from want of food. I had looked at it one day very early in the spring and found every drop of honey gone. Too impatient even to wait whilst the syrup was being made, I hastily fetched one of those precious combs of honey which Mr. Marshall had taken off the hives in August and put it into the hive. I suppose it is not the most economical way of feeding bees, but I dared not waste a moment. We fed up well, but a return of frost and snow in February was too much for a weak stock, and they died off. However, when I heard of bee-keepers losing stock after stock of their bees that winter—one in particular having lost seventeen hives-I think I was very fortunate; and it showed the good effect of Mr. Marshall's camphor, for if the disease had not been completely checked in the summer, I am sure we should have lost all our hives.

About this time I had the good fortune to hear of some clever experts in the neighbourhood. How it was that I had never before discovered Messrs. Bennett & Wood, Temperley Road, Balham, I cannot imagine. It was the thing I had longed for ever since I had first started bees. Often and often had I said, Oh, if there was only some one near whom I could consult!' Of course I could have Mr. Marshall when I liked, but as he had to come from a distance I had to pay accordingly, and I looked upon bim as a luxury to be only had on rare occasions.

Mr. Wood was a most enthusiastic bee-keeper, and in him I found a kindred spirit. He undertook the charge of Mrs. Graham's hives, which were getting rather weak for want of feeding. However, under his skilful management they soon began to improve.

In May he and Mr. Bennett drove the bees from the two straw skeps, and placed each stock in Mrs. Graham's bar-frames. A little later he added about five thousand bees to strengthen one hive which was weak. A curious incident happened in bringing these bees, and it only shows what creatures of resource bees are, and the rapid way in which they set to work.

Mr. Wood found it necessary to go to Kent to buy those bees, for had he brought them from anywhere near they would have returned to the hive from whence they had been taken.

The bees were brought up in a box on a frame of brood-comb. Of course they had no queen, as they were going to be united to a stock which was already provided with one.

They were necessarily in this box all night, and the next morning when Mr. Wood took them out to put in the hive, he found they had actually commenced starting eight queen-cells.

I now got Mr. Wood to drive my bees, as I was anxious to get rid of the old hives, and also I thought it would be as well to unite two stocks in each of my bar-frames.

The hive in which the bees had died had been all purified and repainted, and into this we put the bees of two of the hives, into the other the bees of the Chinese Pagoda and an old hive, whilst Watson got one of Mr. Bennett's bar-frame hives and his bees were put into it. In this way we got rid of all our old infected hives, which were immediately condemned to be burnt. The combs were well started with brood, but alas! there was the fatal foul brood still to be seen. Nothing like so bad as it had been in the autumn, which showed how effective Mr. Marshall's camphor had been. Indeed, I think it must have stopped it for the time, but, doubtless, the germs remained, so that when the breeding season came round it began to break forth again.

Mr. Wood was most encouraging. He had often coped with this grim enemy and destroyed it, and he gave us every hope that in a few weeks it would be entirely got rid of.

He had found Mr. Cheshire's cure an absolute success. Feed an infected colony with syrup in which phenol, as used by Mr. Cheshire, has been mixed. The following is the receipt:

Solution No. 8 Sugar syrup 1 pint.

Made in the usual way.

The bees must be well fed with this. The worst is that the bees are not at all partial to it. They will take it down on cold days and nights, when they cannot get much honey, but otherwise they prefer their food without any medicine. The only thing to be done then is to pour the syrup over the combs. The bees will clear it all up, and in this way they are compelled to take

Under this treatment there is no doubt that my bees improved, rapidly increasing in great numbers, and I had to cut out many queen-cells to prevent swarming, whilst the foul brood rapidly diminished. I eannot pronounce it entirely cured until next summer comes; if I then find any traces of it I shall try giving each hive a new queen, as recommended in the British Bee Journal. In the meantime, besides putting lumps of camphor as before, I have tied a bottle of carbolic acid into each hive, with a piece of wool put in for a stopper.

My Shere bees were working well under Mr. Osborne's care, though such was their desire to swarm that over thirty queen-cells were cut out by him in the course of the year.

From this hive I received some beautiful honey, several of the sections being sealed over and ready to take by the Jubilee. I need hardly say that this was the only thing necessary to make my summer a real Jubilee.

And now the summer, alas! has ended, and the bees are all safely shut up for the winter, and should I find my bees in a satisfactory condition next year I shall ask the Editor to allow me to say a few words later. I am tempted to give a description of a beautiful Observatory hive purchased from Messrs. Neighbour' but I am informed that my space is limited. I can only say that it has been of untold delight to me. It is one of those in which the bees are as safely housed as in the ordinary bar-frame hives, but with this advantage, that you can raise any frame into a glass case above the hive and watch all the movements of the bees in perfect safety. I have the hive in the house, and a passage is made through the window for the exit of the bees.

In a little book written by my sister, Lady Clay, called Failures and Fortunes in Farming,* she mentions once being tempted to exclaim, with Mallock, 'Is life worth living?

To that I reply, 'Yes,' if you keep bees, and above all have an Observatory hive and take in the British $Bee\ Journal.$

[The compiler of the above says, 'Whatever merit these chapters may possess I owe entirely to Mr. Cowan's book, British Bee-keepers' Guide Book, published by Messrs. Houlston & Sons, and to Modern Bee-keeping, published by Messrs. Longman & Co. I do not profess to give the whole of the practical management of bees. Those who require to go thoroughly into the subject I must refer to those two books and to the British Bee Journal.]

To be had from Lady Clay, Barrows Lea, Shere, Guildford,

Correspondence.

The Editor does not hold himself responsible for the opinions expressed by his correspondents. No attention will be taken of anonymous communications, and correspondents are requested to write on one side of the paper only, and give their real names and addresses, not necessarily for publication, but as a guarantee of good faith. Illustrations should be drawn on separate pieces of paper.

Communications relating to the literary department, reports of Associations, Shows, Meetings, Echoes, Queries, Books for Review, &c., must be addressed only to 'The Editors of the 'British Bee Journal,' c/o Messrs. Strangeways and Sons, Tower Street, Cambridge Circus, W.C.' All business communications relating to Advertisements, &c., must be addressed to Mr. J. Hucker, Kings Langley, Herts (see 2nd page of Advertisements).

***In order to facilitate reference, Correspondents, when speaking of any letter or query previously inserted, will oblige by mentioning the number of the letter, as well as the page on which it appears.

SCRIPTURE TEXTS WHEREIN THE WORD HONEY OR HONEY-COMB IS MENTIONED.

[1402.] Should it be within the line of admissible matter for insertion in the Journal kindly find a corner for the enclosed. It may possibly interest some of your readers to see a record of the numerous passages that appear in Holy Writ where the word 'honey' or 'honey-comb' is mentioned. It might also lead them to a search to supplement those I give, or, failing that, might notice the passages given, when they could but find a great deal for thought, if only the references made to honey. The light in which it is placed before us is evidence of its value in ancient times. I have not found a price quoted for honey in my readings, but that merchants traded in honey at fairs and markets is told us in Ezekiel, chap. xxvii. Perhaps some of your correspondents can enlighten us as to the earliest money value quotations for honey: it would be very interesting.

Here I would mention I have a pleasurable recollection of a visit to a village school, and offering three prizes, first, second, and third, to the boy or girl who should give me the largest number of texts from Scripture in which the word 'honey' or 'honey-comb' is found, each text to be written out in full, the schoolmaster very kindly undertaking to be the examiner. (The work was, of course, done out of school hours.) There were was, of course, done out of school hours.) twelve children who entered the field of search (ten girls and two boys); the highest number, 51, was given by a boy, three girls came close after him with 45, 45, 46, four with from 30 to 39, four with from 20 to 25. The work of two of the girls, aged ten, was of great merit. I have thought since how many of these children might probably as they grew up become bee-keepers, having had their thoughts thus directed in their child-hood. They were very enthusiastic at the time.

WORKING FOR HONEY.

(Extract of a letter to Mr. J. Walton, Weston, Leamington.)

[1403.] I will now give you my method of working for honey, both comb and extracted. I will first point out the disadvantages of the old system of working, i.e., supering old stocks for section honey—1st, the liability to swarm just as they have got to work nicely in supers, leaving a lot of half-filled sections; 2nd, the great amount of brood to take care of and feed, which at the time of our honey season is generally short and sharp; it keeps too many bees at home on household work. Every beekeeper knows (or should know) that when honey is coming in plentifully a swarm will do wonders in a short time. The reason is this, 'it's all hands to the No babies to feed, or next to none. Therefore all the bees can go foraging and collecting honey to bring home. All the bees in the swarm are capable of honeygathering, or what are termed field-bees; and the sharper the honey is gathered, the better and quicker the sections are filled and finished. Also, it is a well-known fact that when a swarm has got the 'go' in them, the more honey the more wax they make, which is the proper condition we want for sections. Now, my object is to point out how to make the bees do the most in the shortest time, or, in plain words, get all that is to be got (as the Quaker says, 'Get it honestly if you can, my boy, but get it'). I should give the preference to 6-in. frames, ten frames in a hive, two stock boxes to make brood nest; but it can be worked with the Standard or any other sized frame, or skeps in conjunction with frame-

Well, I shall suppose that the hives are all 6-in. frames, and the hives and section-case are all one pattern; also, that I had a piece of land suitable for arranging the apiary. I should place all the hives in

clumps of threes.

I have only given a small number of hives to show how to arrange them; there should be trees for protectionit might be fruit trees, or only shrubs, according to taste. I think they are necessary as shelter and land-marks for bees. We will suppose the bees have plenty of food, either natural or good syrup, to carry them on to the middle of April, which they ought to have (I don't believe in early stimulative feeding). Some time in March, when weather is suitable, run them over, and see how they stand as regards food, queens, brood, &c. Make food, that is, give food to those requiring it, in the shape of a full comb of honey from some other hive, or a comb filled with syrup, and placed as close to the brood-nest as possible, but don't break the cluster more than you can help. But if the stocks have been well looked after in the autumn they will not want any feeding until April. Join any colony that is queenless to the next, then about the first week in April, if the weather is fine, start feeding out of doors (if you are far enough away from other people's bees), it is the best feed, by a long way, for stimulating and keeping your bees at home, and for keeping them from robbing; in fact, it keeps them out of mischief. Place a pan (a large milk-pan is best), get a lot of old ginger-beer corks to make a float, fill almost full with warm water, then sprinkle a few pounds of sugar into the water, over corks, making only sweetened water, keep the feeder going until they get enough to do without it; that you will soon see, for they won't scarcely look at it if there is honey on the 'go.' About the first week in May, or before, if the weather has been good, overhaul them again, and if the top brood box has got a lot of stores,

top. That will make room for the queen, for the bees will soon shift the stores, and the shifting starts to rapid breeding. Well, we will presume that all the stocks are pretty near swarming point. When the honey begins to come in, go through the lot and see which are the forwardest lots. I will deal with three hives, a, b, c. That will show you how the whole apiary is to be worked. Well, see which of the three hives is strongest. If they have not started queen-cells, select the combs of hatching-brood and place them, ten in number, in one box. Brush all bees from the other combs on to the other combs first mentioned. This is to crowd them and make them get to swarming as quick as possible (the other combs of brood can be placed on one of the other stocks for them to look after). As soon as they have swarmed, hive them on their old stand on full sheets of foundation, if you have not got some good clean combs to spare: if so, use them. We want all the wax-building done in supers. Well, if placed on old combs, I should super at once; they will start straight away if honey is coming in fast, and neither of the other two hives have swarmed. Well, about ten o'clock a.m., when they are well in the field at work gathering honey (a, b, c) take a and c clean away to a new station, the farthest point from where they have been standing. All the field-bees coming home will go to their old station, and finding only one hive in the place of three they will all go into that. The swarm will welcome the strangers if filled with honey (and it should only be done when honey is coming in), then pile on section-cases as fast as you can. There will be at least twelve to fifteen lbs, of bees in the one lot, swarming impulse is satisfied, and they go to work with a will; it is a treat to see them at it, Keep them on one set of combs, that will send all the bees into the supers. This method is simply to wear out all the old bees in honey-gathering and waxbuilding. Keep putting on cases as fast as the bees fill them. When you have six cases of sections filled then you can start taking the bottom lots; keep working from the bottom, they fill and seal better than raising the supers. Always take off whole cases at the time. By using carbolic cloth (or house flannel is best) you can drive them out of sections as fast as you like; I like three pieces of flannel, and with a little smoke you can make sharp work of it.

I will now explain what to do with the brood and bees the swarm b came from. That being the best lot and earliest, that is what you want for queen-raising. By having a few hives made with three entrances, or better still, a floor-board with three entrances cut into it, you can divide the brood and bees, giving queen-cells to each nucleus lot. One hive, by using two light division-boards, makes three small lots to raise three young queens in. I should raise enough young queens so as to give each stock one, after the honey season is over, for they are the foundation of successful beekeeping.

Now, we will treat the other two lots, which have had all the field, or flying bees, taken away, as before explained. They are to be placed in a new station. In a few days there will have been enough young bees hatched out to make them up to honey-gathering strength. Now place sets of empty combs on top of the two sets of brood combs, using excluding honey boards (in both comb and extracted), place brood combs 1 5-16 from centre to centre, and the sets of empty combs 2 in. from centre to centre; the former keeps the brood chambers for brood and the honey chambers for honey. Thick combs are best to shave off for extracting. You will no doubt see by my method that I practise swarming without increase (unless increase is desired), then build up from nucleus lots by giving empty combs or foundation, but I am supposing I have stock enough, and don't want to increase. By placing one nucleus

against every clump of three hives they can be easily joined when the honey season is over, so as to get the young queens on good lay through August and September, which mean strong hives for winter and

success in bee-keeping.

P.S.—I should clip all queens after they have been fertilised to prevent swarms from straying away. You might try what course you like and they will swarm, if you super with sections and the queens are over a year old. I have only to refer you to the Stewarton method of joining swarms to prove to you what can be done by joining swarms together, only with my plan you only want one out of every three to swarm and the job is done. Of course, if two or more hives swarmed at the same time from the same clump, you have only to join swarms, giving the old queens to a and c, which you intend to run for extracting .- WALTER MARSHALL.

'A. E.' WANTS A DIPLŌMA.

[1404.] When I read letter I384 on p. 548, I confess to having experienced such a touch of sadness as seldom overtakes me. No wonder 'A. E.' finds the wool getting thin on the top of his head, where the wool ought to be. Although my wool is still thick (and for the matter of that, I am much afraid my head is also, for I, too, like 'A. E.,' despised 'bandles') I find my name would look much better with more or less of the alphabet as a conclusion to the whole matter. That is, of course, for gulling the public.

Now, it so happens, Mr. Editor, that I have taken my first-class certificate, and it has become a matter of surprise to me that 'A. E.' has never had one conferred on him honoris causa. This might be a step towards restoring the prestige of our disconsolate friend. Can we not get the prefix 'Royal' to our B.B.K.A.? Then, of course we should at once all become Fellows, and if an announcement that a lecture would be delivered by Antonio Demosthenes Blank, Esq., F.R.B.B.K.A., did

not draw the public nothing would.

By the bye, why, oh, why, does 'A. E.' never 'jot' now? He used to do it well and often. Is it the want of these same letters he longs for? Let him remember that in our B, B, J, he is among friends who admire him for his worth, and not for any title, and that we like him to sling ink, even if we do occasionally get a splash, -F, C, E, B, B, K, A,

FOUNDATION v. WORKED COMBS.

[1405,] Yes, Mr. John Edey, it is my opinion that for all practical purposes a sheet of foundation is superior to a comb, and it is not so easy to refute as may at first sight appear to you. And it seems to me incredible that a stock could be found in April in need of extension of brood-nests, as here, at least, our stocks do not reach the lowest point till the first week of May. And we consider them good if they can fill four frames of brood at that time, and before they can fill the seven or eight they have or should have been wintered on, it is at least the last week of May; and it is not advisable to extend the broad-nest until these are packed with broad, and bees lying behind the dummies. Now, Mr. Edey, when you have got a hive in this position, I will tell you how to use a sheet of foundation to make it superior to any comb. Place it in the centre, and the two combs next it close up to it for forty-eight hours; at the end of that time open out to a quarter of an inch, and you will find an egg in almost every cell. Giving scaled or partially uncapped stores is no facility with me, as I pour the syrup into the tops of combs, and save the bees the trouble.

Mr. Edey asks if ever 1 have tried tiering hives filled with clean comb. I ask, in reply, if he thought I was writing from theory, and would refer him to J. II. Howard's reply to query No. 2, and would add that common sense would say that he would do better with full sheets all over. Again, he says, 'It is important that the combs be clean;' and as those who reply to query No. 2 advise the combs to be wrought in the brood-nest I would ask how they are to be got clean and

free from pollen?

Mr. Edey, in his last paragraph, accuses me of writing strongly and somewhat uncourteously, but I am afraid business interest has somewhat sharpened his susceptibility. He asks if I have 'studied this wiring business.' I reply that I have to the extent of buying some wire and never using it, nor never shall while I can get foundation that does not need it, and can extract from it without breaking a single comb; and when a man spends his money for what is no advantage to him my term for it is waste. But as many will continue to use not only clean but old pollen-clogged combs, I believe it would be a blessing to them if Mr. Edey could show how there need be no danger from them spreading foul brood.—James Saddler, Forfar.

PRICE OF HONEY.

[1406.] I should not trespass on your space again with this subject but for the fact that 'Sherborne' has asked me two or three questions in his letter of the 8th inst. He asks what I would do if placed in circumstances similar to himself. If he will take the trouble to read carefully the recent Journals in which articles have appeared from the pens of 'Useful Hints,' Mr. R. R. Godfrey, and others, I think he will find a way out of the difficulty he mentions. In one place Mr. Godfrey says he has seen honey vendors standing side by side in the markets, and 'those who sold the most were those who charged the most,' simply because of the difference in the 'get-up' of their 'sales.' Mr. Useful Hints,' and also Mr. Simmins, say, 'It is a great mistake to rush honey on the market all at once.' Mr. Simmins further says, 'Our supply is not equal to our demand.'

Now, what are we to infer from these various 'hints?' Only that the price I quoted may be obtained if things are managed in the right way. I suppose every county has its quantity of cottagers who have honey for sale at low prices; but surely 'Sherborne' will not place honey from the sulphur-pit alongside pure honey from the extractor! With what little experience I have of beekeeping—and that is very limited—I have learnt that prices are on the down-grade. But why should it be so? When the comparison between honey and butter, both as to quality and expense, is properly considered, my opinion is that it is not so much that honey should 'go down' as that the education of the parents of families

should 'go up.'

Let the B.B.K.A. publish in leaflet form articles on 'Honey, and its qualities, dietary and medicinally.' Then have these scattered freely by bee-keepers all over the country, and I think we should have less complaining

about the difficulty of selling.

While on this subject kindly allow me to say that it appears to me a strange anomaly that many of our great masters are trying to increase bee-keepers in this country, and yet advocating the 'down-grade' in the price of honey. They may be able to profitably produce it at a low price, owing to long and varied experience, and knowing so well how toobtain the best possible results from each hive; but how about us who have not this experience? Are we to lose every year by it, simply because the larger producers can afford to sell against us? If beekeeping is to spread as it ought then we must hold ont all the inducement possible to our neighbours, and all charge a reasonable price for the produce. Besides, is it not possible, and also probable, that if prices go down then adulteration by too much feeding follows as a result?—Charles Howes.

Queries and Replies.

1. Robbers, how known.—Where bees are of the same race, how is it known when robbing is going on? If Ligurians are seen entering a black hive, or vice verså, it is plain they are entering other people's premises. But among, e.g. Ligurians, entering a Ligurian hive, how can we know that some of them belong to another hive of Ligurians?—[A. When the robbers are of the same race as the colony attacked, the fact that robbing is being carried on may be easily ascertained by the commotion at the entrance, where a series of single combats will be in progress. The attacking bees may be known by their actions -a suspicious, wary hovering in front of the hive, and a sudden dash at the entrance when a chance is given. Where the plundered hive is queenless, generally no resistance is offered, and often the queenless bees will join the plunderers in carrying off their own sweets, and, deserting their hive, will unite with the robbers.]

2. Renewal of Robbing in Spring.—If a particular

hive has been persistently robbed in the autumn, the robbing only ceasing on all the bees retiring to their winter quarters, is it certain, or likely, that some months after, when they all come again in spring, the robbing bees will have forgotten the assailed hive and leave it in peace? Or would it be wise during the winter to change its place, so as to throw them off the scent? And if this latter precaution were taken, the hive moved, say a perch or two, can we rely on these bees themselves, those moved having so far forgotten as not to be puzzled and lost by the change of place? This last query, indeed, is much more general, and one I have often wished to put: because, from various other causes, one often finds it expedient to change the place of a hive when it caunot well be done gradually—two feet at a time—in the orthodox way. Can it safely be done at a jump during the winter rest?—[A. It is not likely that bees which have attacked one particular hive in the autumn will renew the attack in spring. At this season you may safely remove the hive to the distance of a perch or two. if carefully done during cold weather, when the bees are not fiving.

3. Combs.—Is there any rule among experts as to the number of years combs may be used before they become too contracted for breeding, or otherwise unfit? Would four years be too much?—[A. We have used combs in the same hive for fifteen years, and bees have prospered upon them. The old useless pollen and cocoons were removed, as occasion required, broken cells were repaired, or rebuilt, and all other necessary operations were performed. This took place in a 'Grecian hive,' and was tried for the sake of experiment, a prolific queen being always kept at the head of the colony. As a general rule, however, it is better to remove combs five or six years old, especially when very dark, heavy, and clogged with pollon and to expert their places with foundation.

with pollen, and to supply their places with foundation.]

4. Two years ago I laid in a very large stock of foundation, both ordinary and 'super:' which is not nearly all used up yet. Can it still be made available by dipping in hot water? And if so, could you give any directions in detail; that is, as to the heat of the water or the length of time to leave the combs in it?—[A. Before inserting the foundation in the frames apply heat to the whole sheets—about 90° Fahr.—by placing it near a fire, on the plate-rack over a kitchen-range is a suitable place, for a short time, until it becomes sufficiently pliable to manipulate. Then cut into proper sizes for frames or sections, and insert them in the frames, in a warm room. This operation may be performed now, or at any time before the frames, &c., are required for use. Before placing frames of foundation, so filled, in the hives, or putting swarms upon them, plunge them into hot water, of no higher temperature than 100° Fahr., for a few seconds, and when sufficiently limp, they are fit

for immediate use, and will be drawn out as quickly and

as perfectly, by the bees, as new foundation.]

5. Drone Comb and Drone Foundation.—Mr. Cowan in speaking of rearing selected drones (p. 89) says, 'Introduce drone comb into the centre of the brood nest.' But is drone-comb manufactured, except thin, for supers? I have never met with it, nor seen it advertised.—[A. No, drone comb is not manufactured, but we believe drone foundation is. You confuse the terms, 'comb' and 'foundation.' Mr. Cowan's advice is to insert drone comb not foundation. Of the former he supposes all bee-keepers to have a stock in hand, kept

over from previous years.

6. Artificial Swarming.—Under 'Artificial Swarming' Mr. Cowan mentions a method recommended as very simple and easy; but which seems to be open to a fatal objection in practice. It is in making three colonies out of two. The brood without bees of hive A is put in a hive where B stood, while B itself is moved farther on. Thus, the old bees of B, returning to their original place, are supposed to nurse the broad of A and raise a queen. Now while the bees of B are gathering back from fields &c., to their old locality, many hours must elapse before they are collected in any numbers; and meantime the brood is left untended. Would it not most likely be chilled and perish?—[A. We certainly see no 'fatal objection in practice' to Mr. Cowan's directions for making three colonies from two, given under the heading 'Artificial Swarming.' He gives very particular directions that this method is only to be practised on a 'fine day when most of the bees are flying and when colonies are ready for swarming, which suppose warm, and at times sultry weather. At such times there is no fear of chilling brood; indeed the excitement of the returning bees, on finding their queen gone and their combs changed, will raise the hive to a higher temperature than the brood experienced before being transferred; and in two or three hours the bees will settle down quietly, and form queen-cells, unless a fertilised queen be caged on a brood comb, which is by far the better plan and in that case she will probably be well received after twelve hours confinement. We have pursued this plan in hundreds of instances and never knew it fail when properly carried out with strong colonies.

7. Releasing Queen at Sunset.—In a number of the B. E. J., and in many other places, I have seen it re-commended as one of the essential points in safe iutroducing, to release the queen very late, just when it is getting too dark to work with the bees. Now in the case of the pipe-cover cage, does not this do away with the very advantage supposed to be gained? For we are told often that the great point in this form is that you can see how the gueen is received; and if the bees attempt to ball her she can be rescued and caged for another day. Do the advocates of the very late releasing contemplate leaving her to take her chance?—[A. There can be no possible reason why a queen should not be released from a pipe-cover, or any other cage, late in the evening. Since no one can manipulate bees in the dark, there must be time for performing the operation by daylight. Five minutes, at most, are required. The essential points are to notice the animus of the bees towards the queen, both before and after releasing her. If they are encasingvulgarly called balling—the cage, showing every disposition to use their stings, and uttering a shrill, hissing sound, while clinging so closely to the cage that it is almost impossible to dislodge them, then we say, don't release her, either at night or morning, but close the hive and leave it for another twelve hours. If, on the other hand, the bees appear kindly disposed towards the queen, feeding her through the wires of the cage, and carrying on the work of the hive with that pleasing, well-known, contented hum; then, whether it be night or morning, release the queen, carefully noticing how the bees receive her. If she is allowed to perambulate the comb, accepting food when offered, and all goes on quietly and harmoniously, close the hive gently and carefully, and the introduction is safely accomplished. Forty-eight hours afterwards you may verify the insertion by 'interviewing' the queen, if there are no robber-bees about, but do not keep the hive open long, and be careful to close it quietly, after a careful, gentle manipulation. For our own part we introduce at all hours during daylight—and sometimes by lamplight—and we do not lose three queens out of a hundred. Indeed there is no reason why a single queen should ever be lost when using the pipe-cover cage. The great mistake made by beginners is that they release the queen before the bees have accepted her, when, on closing the hive, she is encased by the emaged and excited bees, and, in nine cases out of ten, is crushed to death, or maimed for life, in their crucl (?) or loving (?) embrace.]

8. Queen-cage.—A very distinguished foreign expert who, happening to be writing, recommended strongly this very late releasing, also described to me an improved pipe cover-cage, to be made with wire gauze. Not having much leisure for this kind of work I should like to have it carried out by 'skilled labour.' Could you tell me the address of any one who makes such cages, to whom I could apply? as the dealers I presume only sell them?—[.4. The wire gauze cage has no advantage over the finely-wrought cage of thin wire. Indeed the latter has an advantage from the freer communication afforded between the bees and the queen, both for feeding and

fraternising (sororising?)]

Ants and Bees in Jamaica.—The biting ants, which march in compact column a few inches wide and many yards long, do not do much injury, unless you deliberately stand in the middle of them and wait for them to crawl up. They marched through the house one night, and turned me out of bed at midnight. I was bitten, perhaps, in a dozen places, but the bites were very trifling. The bees are more troublesome. The natives hollow out logs for them, or utilise the empty packing-cases left by passing caravans, which they place in the upper branches of the taller trees. These you see perched up in the trees all about, each with its swarm of bees. When the honey season comes, the boxes are lowered at night into a fire of dry grass, the bees destroyed, and the honey taken. Occasionally the bees seem to get very angry, and huzz furiously around their houses, descending on any bird, animal, or man that happens to pass beneath at the time. Baxter keeps a swarm in the loft here. Once when they were angry they came down and killed a tame eagle which he kept; another time they killed a small monkey which I had bought as entomological attendant for my dogs. Rats are a nuisance; they swarm everywhere. They and the white ants between them give a housekeeper au anxious time of it. One day I went up to the store-room to get a pot of honey. Two rats had eaten through the cover, and then gone iu after the honey. They had got so sticky that they could not jump out, and there they had apparently remained for some days. I should think they must have been very thirsty.-The Church Missionary Gleaner.
