[No. 237. Vol. XV.]

JANUARY 6, 1887.

[PUBLISHED WEEKLY.]

Editorial, Notices, &c.

A RETROSPECT.

We have passed the threshold of another year, but before we commence the activities and duties of that on which we have entered it is desirable to cast a retrospective glance on the progress of api-

culture during the year 1886.

In looking back, then, on the year that has just passed our mind is chiefly attracted to the numerous shows which have been held in various parts of the United Kingdom. We are pleased to be able to note these visible indications of the growing interest taken in apiculture by agricultural and horticultural societies and by the public generally. Wherever a meeting of a society for the promotion of agriculture, horticulture, or floriculture, is now held, the bee-keepers are invited to take their part in adding an attraction and in giving a zest to the show. The claim of Apiculture to be allied to Agriculture is now generally recognised. This has been notably the case during the past year. The bee department at the Royal Agricultural Show, held at Norwich, was no unimportant auxiliary to the attractions of that exhibition. The visit to the department by their Royal Highnesses the Prince and Princess of Wales, their daughters, and suite, will cause it to be borne in remembrance by bee-keepers. On that occasion the number of exhibitors was very large and the exhibits were of a very diversified character, and the most improved methods of bee-culture were brought before the notice of British agriculturists in a very practical form. Again, when the Royal Horticultural Society renewed its provincial shows by holding one at Liverpool, the Council of the British Bee-keepers' Association rendered material assistance towards the arrangement of a department for bees, hives, honey, &c. The Royal Counties Society, which had held its meeting in 1885 at Southampton, this year held it on Southsea Common, on which occasion it was accompanied by that enterprising Association the Hants and Isle of Wight B. K. A.; and as this was the first occasion when a bee show had been held in Southsea, this Association made the best of the opportunity thus presented. The meeting of the Lincolnshire Agricultural Society, held at Lincoln,

was also an opportunity which the Lincolnshire B. K. A. took advantage of, much to the promotion of bee-keeping in that district. But the great and outstanding event of the year has been the South Kensington Exhibition. Never before has there been made so effective and complete a display of the products and appliances connected with bee-To be fully realised, it was necessary that it should have been witnessed. It was held in one of the finest buildings in the United Kingdom, in the large and commodious Conservatory adjoining the Albert Hall. No less than 290 exhibitors sent contributions to the Exhibition, and the amount of honey was calculated to be nearly twenty tons. The honey was of a superior quality, and it was exhibited in a most attractive form. There was a great rivalry among the competing counties for precedence. The premier prize was awarded to the Lancashire and Cheshire B.K.A. Conferences were held on the occasion, when important papers were read by several leading bee-After an interval of five weeks the delegates from Canada exhibited their honey at the Exhibition. This exhibit consisted of about eighteen tons of honey; but the flavour of the honey was by the best judges considered to be not comparable to that of the United Kingdom. The opportunity of practising fraternal courtesies and amenities towards the Canadian bec-keepers was not neglected; and many pleasant and instructive meetings were arranged, in which the mutual methods of conducting bee-keeping in Canada and Great Britain were carnestly discussed. The banquet, which was held in South Kensington Exhibition, and the Conversational Meeting in the evening, are amongst the most pleasant reminiscences of our retrospect. The visit of the Canadians will be long held in remembrance as a chief feature of the year 1886.

There has been a considerable development of the work of the B. B. K. A. in the counties. Dr. Walker was specially deputed to visit South Wales with a bee tent. In Glamorganshire the cause was much advanced. Thence he proceeded to Cardiganshire and Montgomeryshire. A lecturing tour was also conducted by Mr. W. B. Webster, who delivered lectures in the principal cities and villages in North Wales. Considerable progress has been made in Northumberland; and as the Royal Agricultural Society will hold its next annual meeting, in July

at Newcastle, it is expected that the work already begun there will be then consolidated and completed. The Association representing the counties of Lancashire and Cheshire has made considerable progress this year. By the presence of its representatives at the Liverpool and South Kensington Exhibition and by their regular attendance at the quarterly meetings of the B. B. K. A., the northern counties have been brought well in touch with the central Society. Ireland, too, has progressed considerably during the year; although not largely represented at the South Kensington Exhibition, it held its own, and secured a large share of the honours bestowed in proportion to the number of exhibits sent in for competition. The future of bee-keeping in the United Kingdom materially depends on the loyalty of the affiliated Associations and the support they are prepared to render to the Central Society. There is yet much fallow ground to be broken up, and the work before the Parent Association is as arduous as it is important. May all bee-keepers give cheerful and ready assistance in promoting the progress of the work which yet remains to be done.

In literature we may point to the large circulation Modern Bee-keeping, issued under the auspices of the British Bee-keepers' Association, has attained. A new edition, bringing the work up to the present times, consisting of 10,000 copies, has been issued. We may say, without fear of contradiction, that the circulation of this work is unprecedented in the annals of bee-literature, being far in advance of any work of a similar kind. Mr. Cowan's Guide-Book has also met with much success during the year; it has now reached its eighth edition, and the number of copies issued has been 15,000. The work has already been translated into the Swedish and French languages; and arrangements are now being made for its being translated into Danish, Russian, and Spanish. Mr. Cowan has also sent forth a pamphlet on Doubling and Storifying, which will prove of great service to bee-keepers desirous of increasing their produce of honey. edition of the Rev. F. G. Jenyns' work on Beekeeping for the Young has been published. first volume of Mr. Cheshire's work is completed, and the second is being continued in monthly parts.

By the aid of the various shows, and the action of the Honey Companies, the sale of honey has been much popularised, and a great impulse has been given to its sale during the year. Already we hear that the wholesale buyers are unable to purchase sufficient sections to meet the demands made upon them. This is promising news for the cultivators of honey and emphasises the advice we have frequently given to bee-keepers, namely, not to place before the public immediately after the honey season the whole of the produce of their apiaries, but to keep it in reserve till they are warranted in asking and obtaining a higher price for their honey. We hope the attention of bee-keepers will, in the expectation of increasing amounts of honey being produced, direct their

attention to the discovery of further utilities of honey in the way of beverages, comestibles, &c.

During the year considerable attention has been paid to the introduction of new races of bees. From Cyprus, Carniola, the Holy Land, South Africa, America, &c., there have been considerable importations. These attempts to introduce bees of superior powers have found much encouragement amongst our leading bee-masters, but the English black bee still continues to hold its place in the estimation of the great body of bee-keepers.

The imports of honey for the year are not yet complete; we hope, however, in the course of the present month to have full statistics before us, when we propose to take the opportunity of dealing with both the honey imports for 1886 and the wax

imports and exports for 1885.

Notwithstanding the grand display of honey at the South Kensington Exhibition, the season of 1886 cannot be pronounced to have been a prosperous one. In some localities it has been favourable, but the yield in the United Kingdom generally has not reached the average of previous honey years. Hope, however, ever dwells in the hearts of bee-keepers; and we trust, with enlarged experience, and with improved appliances, their best and brightest hopes for 1887 may be fully realised.

G. H.

USEFUL HINTS.

To our readers, old and young, experienced and novices, a hearty greeting with the new year: may it prove to each and all a year of happiness and prosperity, and not less so to our great care, the bees. The old departs, the new enters—enters in a mantle of white, departs with storm and hurricane, fatal, alas, to many a poor mariner—enters with joyous forecast. the pleasures of hope, to all, save the aged, the worn, and weary. Days are creeping out, fog and cloud will soon give place to sunshine, and our little sun-worshippers will soon again be flitting from flower to flower, and carrying home to their callow brood the precious burdens of pollen and nectar. At present many of our hives are deep below the banks of snow, but we cannot help anticipating, in thought at least, the good time coming. The late storms, we fear, will have disarranged many apiaries. Fortunately, our own have stood firm—not a hive overturned, not a roof displaced.

The departed year will assuredly rank as an annus mirabilis in the records of apiculture. Progress has been its watchword, and long will it be remembered in connexion with the gracious patronage of Royalty and the visit of Colonial apiarists to our shores. And not less, perhaps, by the importance of the bibliological additions to scientific and practical apicultural literature which have issued from the press. New editions of those truly practical works—Cowan's British Bee-keepers' Guide, and Modern Bee-keeping, have been called for; and Mr. Jenyns' excellent little work, A Book about Bees, has been published in so cheap a form as to render its usefulness to the rising generation tenfold that of the previous issue. Professor Cook, treating of the new work of Mr. James Heddon, Success in Bee Culture, says:—

'It is wholly, from first to last, practical. Rarely does any work bring such a profusion of rich, practical hints as does this. On every page is some suggestion which commends itself to the wise apiarist. I would advise any bee-keeper who has not read Success in Bee Culture to procure a copy and study it thoroughly, since nothing will tend more to win success.'

We need scarcely remark that Professor Cook is strongly in favour of 'inversion,' and uses the Heddon hive, of which he speaks most highly. He also refers in flattering terms to Mr. Simmins' brochure, The Non-Swarming System, as a 'racy little work from England,' and says:—

'If unfinished combs next to the entrance of a hive are a sure security against swarming, it is surely an interesting fact which can be turned to good use. Mr. Simmins' idea of crowding bees into the sections reminds me of much that has been said by two of our distinguished bee-keepers, Messrs. Hedden and Hutehinson. Simmins' method of direct introduction of queens is not new in America. This work, I am sure, will interest and benefit the American bee-keepers who may read it.'

We think the Professor confuses Mr. Simmins' former and later systems of 'Queen Introduction,' since his former plan, of introducing a queen with brood and bees, has been long practised in America and elsewhere; but so far as we are aware, his later system, of introducing a queen sola, after dark, at the top of the hive, and after thirty minutes' fasting, has never before been set forth as a system, nor practised individually. We still, therefore, adhere to our motto of 'Suum cuique,' in this, as in other cases.

HIVES AND STANDARD FRAMES.—In our last 'Hints' we confessed to a longing for a larger frame, which might be worked in connexion with the present Standard, and expressed an opinion that such a frame might be successfully introduced by private enterprise. We are pleased to learn that Mr. Simmins is of the same opinion, and that for three years his brain has been at work on the subject, resulting in the production of a live for which he is now obtaining a patent. By the courtesy of the inventor we have been favoured with a sight of the drawings, and a full description of the hive. To this hive Mr. Simmins referred in his letter (No. 700), and stated that if there appeared a desire for a larger frame, he might at some future date describe the hive he used, in which could be worked advantageously a $14'' \times 14''$ frame together with the present Standard. Without going into a full description of the hive-which, we hope, together with the drawings, may shortly appear in the Journal—we may say the distinctive features of the hive consist of four novelties, which are more particularly to be protected by patent, viz.:—(1.) A key arrangement for holding shallow frames and skeleton section-holders in place, for inversion, when desired. (2.) Folding skeleton section-frames, which can be used either with or without a rack, in various parts of the hive. (3.) A pliable adapting-board, and (4) a weather rabbet for protecting the joints of the hive. Besides these, there are other features entirely new to us, such as metal rests let into saw-cuts on floor-board; a sunk floorboard forming a permanent feeder; as hive-entrances, small circular holes; the plan of suspending the 14-inch frames, which are partly close-ended; bee-space provided at top of frames instead of bottom; an ingenious and simple plan of enlarging or diminishing the bee-space; the shallow, or super-frames $(12'' \times 6'')$, standing on end close up to the larger ones, &c. The hive itself, when complete, with roof, forms a most_picturesque object, and its appearance is thoroughly English, sound, and substantial, and it is clearly impervious to weather.

Taken as a whole it is simplicity itself, notwithstanding its various parts—all of which can be worked on the invertible system—although Mr. Simmins is not an advocate of the plan—and we cannot but augur a successful future for a hive which unites in itself so many good points, and which can be worked with the greatest ease, both with the standard and larger frames.

Flowers for Bees.—We have received a beautifully illustrated annual from Messrs. Webb & Sons, which they style Webb's Spring Catalogue of Vegetable and Flower Seeds, and in which they give a short but useful

essay on 'Flowers for Bees.' We quote the following as of considerable importance and interest:—

Wherever fruit trees are grown in quantity, either out of doors or under glass, no better assistants in ensuring fertilisation can be obtained than the bees, and some of the most successful market fruit growers attribute the regularity of their crops to the industrious aid of these insects. Most of our hardy fruit trees, however, flower in early spring, and there is a long period during which the bees have to seek their honey and pollen supplies in other directions. To assist in this we have prepared the following list of plants that are most serviceable for the purpose, and which are most frequented by the bees. The object is to obtain as long a succession of bloom as possible, and this can be effected with most annuals, or biennials, by sowing batches of seed at different times, so that plants are had in all stages. Have a good quantity of whatever plants are employed, as patches are not of much use, and will be scarcely sufficient to keep the bees at home, and it should be remembered that if this can be accomplished much time will be saved in the filling of supers, a quick return in honey amply compensating for expenditure in the purchase of seeds. Four plants that should be grown extensively are Limnanthes Douglasi, mignonette, borage, and the eorn-flower (Centaurea eyanus). As much ground as possible should be devoted to these. Sweet scabious is a good plant for summer flowering, and does particularly well on banks or mounds. Sweet alyssum and the white arabis also merit a portion of the ground, and will well repay for the space occupied. Wallflowers are almost indispensable in early spring, and cannot be too freely employed. The phacelia is a capital plant for a later period, as also are candytuft, stocks, and sweet peas.

'Suitable additions to this list will be found in the following annuals:—Ambrosia Mexicana, Calliopsis bicolor, Cerinthe major, Clarkia pulchella, Colinsia bicolor, Collomia coccinea, Gillia tricolor, Leptosiphon densiflorus, Lupins, Nasturtium, Phlox Drummondi, and Whitlavia grandiflora. Shrubs like the berberis, lilac, and ribes, are useful, and among trees the lime and sycamore are perhaps the heet.

the best.

All the sunflower tribes are favourites with the bees, also thyme, and most herbs may be added with advantage."

It is a pleasing circumstance that one of our largest and most successful firms of seed-growers acknowledges the growing importance of apiculture, as Messrs. Webb do by stating that:—

'The number of amateur apiarians has increased greatly in the past few years, for, apart from the bountiful stores of honey so easily obtained under the modern system of management, it is now generally recognised that bees perform a most important work in the garden.'

We may here mention that Mr. Cowan informs us that he has grown *Echinops sphærocephalus* for eight or ten years, and classes it high as a bee-plant.

Many of our readers, no doubt, are well acquainted with *Echinops Ritro*, an ornamental perennial border-plant, which bears a blue flower, and of which bees are

very fond.

Cyprian bee, some praising it highly, others condemning it utterly. Our own view, after some years' experience, is that it is, when thoroughly acclimatised, the best honey-bee of all. We have no difficulty in handling them, although, as with other races, colonies vary in temperament. The capping of their sections is extremely light, consequently the honey is more apt to 'sweat. The breeding power of the queens is simply marvellous, and large hives, with ample ventilation, are required to prevent swarming. The cross between the Cyprian and Italian is one of the best, if not the best. Next we should place that between the Syrian and Italian, or between the Syrian and Black. All these hybrids are splendid workers, extremely prolific, and produce fine sections, though somewhat more lightly sealed than those worked by pure Blacks. The cross between the Carniolans and the Eastern races has not proved very

successful with us in a few cases we have tried, but we hope to experiment further in this direction.

Thus far our Carniolans have failed to give anything like the surplus obtained from Cyprians, Syrians, Italians, and Blacks, but they are, undoubtedly, most amiable in temper, so much so, indeed, that 'a little child may lead them.'

Entrances, Manipulation, Changing Quilts, &c. Frost-bound as the country is, and blocked with snow, it seems sadly out of place to discuss these matters, but when the thaw comes, and the sun shines, a change of quilts, from damp to dry, will be advantageons. Entrances are best kept at summer's width, and should occasionally be cleared from dead bees and other refuse.

When changing quilts the amount of scaled honey near the tops of the frames should be noted, and, if required, foed must be supplied in shape of candy, &c., beneath the renewed quilts, since strong colonies will be breeding now, and the consumption of stores will increase daily.

But examination must be made on fine warm days only, and our watchwords must still be rest and quiet

repose.

After long frost dysentery will appear in many colonies, which must be treated as previously advised. Nothing tends more to keep bees healthy than an occasional cleansing flight. On Christmas Day, which was bright and warm, all our strongest colonies were in full flight, and their cheering hum spoke pleasantly of summer days to come.

Assuredly a sheltered position, with sunny southern aspect, conduces towards the healthiness of an apiary. Beware of bluetits and mice, keep the hives snug and warm, with plenty of covering, disturb as little as possible, and make all necessary preparation for the busy time coming, and when at last the harvest arrives you will reap the due reward of foresight and industry.

THE DEPARTURE OF MR. D. A. JONES FOR CANADA.

The last of the Canadian delegates, Mr. D. A. Jones, of Becton, Ontario, has taken his departure from our shores. Mr. Jones's time at the last was (as usual with parties sailing for the West) fully taken up, but the Lancashire and Cheshire bee-keepers were fortunate to have him spend his last evening in England (Wednesday, the 28th December, 1886) with some of their members at the Bear's Paw Restaurant, Liverpool, when the few members, who at the short notice Mr. Jones had given them of the exact day of his departure had been gathered together, spent a very enjoyable evening, Mr. Carr entering into a very interesting discussion on the merits of the improvements in the Carr-Stewarton hive, and on the best means of putting honey up cheaply and attractively for sale.

Mr. Jones, to those who saw him off at the steamer, expressed himself very warmly at the kindly way he had been entertained during his visit to England.

DEATH OF MR. J. LOWE.

All who take interest in bee-literature and doings will receive with regret the sad tidings that Mr. John Lowe died on the 15th December at his residence, Slateford House, near Edinburgh. From time to time during the last twenty-five years he has enriched the pages of the Journal of Horticulture with interesting communications on beestablects. He also, for a period, contributed weekly articles on the same subjects to the Farmer.

Mr. Lowe was a skilled practical bee-master, and first set up an apiary, within Edinburgh, near the Dean Bridge, but the Egyptian race which he introduced proving offensive to the surrounding inhabitants com-

pelled him to remove it.

As an able controversialist and elegant writer he had few equals. He held his opinions with great tenacity, and to his skirmish with Mr. Woodbury in 1863 on the subject of foul brood, and his persistency in maintaining it was only an artificial disease created by experimentalists, we are indebted for the efforts that were subsequently made to discover its cause and cure. The controversy brought into the field the testimony and experience of the highest authorities of the day, such as the 'Renfrewshire Bee-keeper,' the 'Hampshire,' 'B. and W.,' &c., &c. The result of their evidence was to prove that 'foul brood' was a real and not an artificial disease.

As a man and member of society Mr. Lowe was genial, affable, and unwilling to offend, being animated by a true Christian spirit, and cherishing the kindliest feelings towards all. It was his lot to be bereaved of his wife and children, save one daughter who survives him, but with fertitude he bore the loss, and meekly bowed to the stroke. Many of his reflections having reference to time and mortality are embodied in beautiful pieces of poetry.

Mr. Lowe was much respected by the circle in which he moved, and to show their appreciation of his worth and service in the Clydesdale Bank, where he long held a responsible position, the Directors, on his heing attacked by paralysis three years ago, generously retired him on a life pension of 150*l*. per annum.

The death of such a man, followed as it was on the 18th by that of Dr. John Mackenzie, who in 1860 wrote a little hook on *The Management of Bees*, makes a great blank in the bee-world.

MR. CORNEIL'S SECTION-CRATE AND SECTIONS.—AN APOLOGY,

I received a letter this morning from Mr. W. Chitty, of Pewsey, in which he complains that in the B. B. Journal for November 18th I used words that go beyond friendly criticism. I very much wish he had called attention to them in the Journal the following week, as it would have given me an earlier opportunity of tendering him, which I do now, my humble apology if any of my words have caused him any annoyance.—AMATEUR EXPERT, January 1st, 1887.

FRANCE.

At the close of the recent meeting of the 'Société Centrale d'Apiculture et d'Insectologie' of Paris, a disenssion took place regarding the Bee Association, or 'Groupement Apicole,' so designated, to be formed for Seinc-et-Oise. The Chairman pointed out that it was for the promoters of the movement to explain to the members present the basis upon which this new organization was to be brought about. Whereupon Monsieur Asset urged that in the articles of constitution provision should be made for the establishment of a practical apiary, stating that, although the primary object of the proposed 'groupement' was that of opposing certain municipal regulations which were considered an encroachment upon the bee-keeping interests, the apiary he advocated would serve as a means of raising funds for the Association.—L'Apiculteur.

According to the *Apiculteur*, the duties payable upon bee-produce, when imported into France by sea, are as follows:—*Wax*—Brown, yellow, or white, in admitted bulk, I france per 100 kilos, except Algerian, which is duty free. When manufactured into candles, I0 francs per 100 kilos. Wax refuse in bulk is also free. *Honey*, when imported by sea, is subject to a duty of 10 francs per 100 kilos gross weight, which brings it up to about 14 francs per 100 kilos uet.

BERKS BEE-KEEPERS' ASSOCIATION.

Windsor Branch.

The above branch held its annual general meeting at the Albert Institute, Windsor, on Thursday, December 16th. The meeting began with the hon, secretary's report for the year ISS6, and then followed the election of officers for the ensuing year. The hon, secretary, the Rev. R. Errington, congratulated the society upon its satisfactory condition. In January, ISS6, it became affiliated with the county society. The number of members on the books last year was I7. During the last twelve months they had risen to 42. In August the branch hold a show in the grounds of Clewer Pork the branch held a show in the grounds of Clewer Park, in conjunction with the Clewer Horticultural Society. Prizes were given away to the amount of about 67. The manipulating tent, presided over by Mr. A. D. Woodley, the expert to the County Association, brought in between 21, and 31, to the receipts. There were some good samples of comb and run honey shown, and one cottager sent over 100 lbs. of filled sections. Considering the size of the branch the show may be looked upon as very successful. The receipts amounted to 11l.15s.0d., while the total expenditure was 9t. 1s. 11d., leaving a balance of 2t. 13s. 1d. The hon secretary was invited again to take office, and the former committee were unanimously re-elected.

After the business of the meeting was concluded a social gathering of friends of members was held. Admission was by ticket, each member receiving two for distribution. Several members of the committee gave short addresses on various subjects connected with bee-keeping, and a discussion followed. There was a small exhibition of appliances by Mr. Sevenoaks, and hency by the hon, secretary. Mr. John Minter, of Clewer Nurseries, brought a microscope, and exhibited some very interesting slides. A table, presided over by Miss Goring, a member of the branch, was set apart for light refreshments in the shape of tea, coffee, and biscuits, the arrangements having been carried out by Mr. G. Cartland. After a very pleasant evening the company dispersed about ten p.m., several persons having given in their names as members for 1887.

Correspondence.

The Editor does not hold himself responsible for the opinions expressed by his correspondents. No attention will be tuken of anonymous communications, and correspondents are requested to write or, one side of the paper only, and give their real names and addresses, not necessarily for publication, but as a guarantee of good faith. Illustrations should be drawn on separate pieces of paper.

Communications relating to the literary department, reports of Associations, Shows, Meetings, Echoes, Queries, Books for Review, &c., must be addressed only to 'The Editor of the 'British Bee Journal,' clo Messrs. Strangeways and Sons, Tower Street, Upper St. Martin's Lane, London, W.C.' All business communications relating to Advertisements, &c., must be addressed to Mr. J. Huckle, King's Langley, Herts (see 2nd page of Advertisements).

****In order to facilitate reference, Correspondents, when speaking of any letter or query previously inserted, will oblige by mentioning the number of the letter, as well as the page on which it appears.

ELECTION OF COMMITTEE-MEN.

[753.] As the time approaches when the members of the British Bee-keepers' Association will be called upon to elect the Committee for the ensuing year the thought occurs to me, as indeed it has on previous occasions, that some guidance from you would be of much value in regard to the choice of the candidates who may offer themselves for the coming year. In venturing to broach the subject, let it not be thought that any pretence is made by me to stand in any other position than that of an ordinary member of the Association, heartly desiring its welfare; nor more particularly let it be supposed that any observation of mine should imply other than the fullest appreciation of the invaluable services which the Committee has devoted in the past, and notably during the year new closing, to the interests of the Association; but my feeling is that gratitude for these services should, besides securing for them a stereotyped expression of thanks at the annual meeting of the members, show itself in endeavouring to make the Committee more perfect in its individual composition, so that the work performed may be the contributions of all its members. An examination of the reports of Committee meetings in the British Bee Journals shows that a cortain number of gentlemen devote a large amount of time and labour, not to mention expense, in promoting the interests of the Association; and it may be concluded that from this section of the Committee the numerous sub-committees are also drawn. Now as the interests of the Association are so faithfully guarded by these more diligent members, it seems to be incumbent upon the electing body that no imperfect workers, or drones, should find a place in the new Committee. It is presumed that the number forming the Committee is requisite to carry on the work of the Association; if, therefore, any gentleman now forming one of that number foresees the probability of his not being able to undertake his full share of the work, it becomes his duty to abstain from offering himself.

You, Mr. Editor, may materially assist and influence a good choice by placing before your readers a record of the attendances of the several members at ordinary and special Committees during the past year, and by bringing under notice other eligible persons whom it would be to the interests of the Association to have upon the Com-

And here the thought strikes me that desirable as it is that the Committee shall be within easy distance of the place of meeting, one exception might be made to secure if possible an eligible member residing in the district in which the Royal Agricultural Show is held, who would thus be able to render valuable assistance to the Committee in carrying out the important work of the bee department at such show. I merely put this forward as a suggestion, thinking that something practical might arise out of it.

In venturing to open the subject I have endeavoured to avoid giving offence to anybody, and I may have erred in judgment in busying myself upon it, but if my act results in bringing assistance to the harder-worked members of the Committee I shall be rewarded.

Wishing you a happy new year, and prosperity to the Bee Journal, as also to the cause it aims to premote, I am, &c.,-J. GARRATT, Hockenden, St. Mary Cray, Dec. 28.

[The record of attendances at Committee-meetings would only partially show the interest taken by the Committee in the work of the Association, as a large amount of work is done by those who are unable to attend through means of the post. If a less number of Committee-men were elected by the members, and the Committee were given power to elect the remainder, as proposed by Mr. Stewart at the last annual meeting, many eligible members might be drafted in, and the large amount of work would be more easily overtaken.—Ep.]

NOTES OF SEASON 1886.

[754.] When I examined my hives in April I found all very flourishing and happy, except my two stocks of Ligurianised fiends, who had some honey left but no brood. I had removed their queens in October, and substituted two British princesses in their room, but the demons had evidently objected to the prospect of a peaceful reign, and had repeated the crime of January 30. I placed in the midst of each hive a comb full of brood and having a queen-cell on it; one stock immediately left the hive in disgust and quartered themselves upon their next neighbours, leaving the brood to perish; the other reared the brood and then left the hive, compelling the third hive from their own to make room for them. They did all (and more) of the sentry work required in the two hives during the summer, and just because my gardener chose to work one day for an hour in front of them, they sallied forth and stung some men who were slating the roof of the honse, a hundred yards off. Several were still alive in October who must be more than a year old, showing that the common idea of the working bee living only six or seven weeks in the summer is incorrect. Should any be still surviving next season I will let you know. Virgil gives seven years as the limit of a bee's life. Doubtless their numerous enemies, birds, &c., shorten their average life immensely, but I am not inclined to think that such industrious creatures die of premature exhaustion.

Upon two of my hives I placed very large sections, $12 \times 5 \times 2$ inches, with wooden separators. A few of these were filled with lovely large combs, quite even, of about $4\frac{1}{2}$ lbs., but in most of them the bees had built from top to bottom four large lemon-shaped combs, attached merely by the button at each end; the spaces between these were filled up with flounce-shaped picces, broad and wide at the bottom and rising up to a point, built on to the dividers. It was a most beautiful specimen of constructive engineering, but not very con-

venient for unpacking.

Two swarms in succession absolutely refused to make themselves comfortable in one of the hives vacated by the queenless Ligurians, though it was full of clear last year's comb. In each case they descreted it the next day, I suppose they knew by justinct that the habitations of the wicked could never be blessed. So I had to melt all the combs down and purify the hive thoroughly before I could get desirable tenants to take to it.

On the whole, my yield of honey per hive this year was about half that of last year, which I think pretty good, considering that we had only twenty-one really fine days between May 15 and August 15.—C. C. James, Papworth St. Agnes Rectory, St. Ives, Hunts.

A BEE-MAN'S TRIP TO AMERICA,

And his Gleanings from some Transatlantic Bee-keepers.

[755.] Acting on your suggestion I purpose for the benefit of our fellow-apiarians to take notes of such points of American bee-keepers' practice as are most likely to cause discussion or experiment in new directions in the old country, omitting all mention of such plans as most resemble our own. My object in this journey being chiefly connected with the manufacture of appliances my visits will generally be to those who are well known in connexion with that industry.

Dr. Tinker, New Philadelphia, Onio.

A pleasant twelve days' sea voyage and a tedious twenty-four hours in 'the cars' brought me at 8 p.m. within a few minutes' walk of the doctor's fireside, where, though unexpected and unknown, a letter of introduction from my father and an explanation of the object of my visit immediately procured for me a hearty welcome. Being unable to inspect bees or works at that late hour we naturally fell to talking of ourselves. The doctor had been suffering for some years from a slight but incurable deafness, which he found to be such an impediment to his obtaining eminence as a physician that he resolved to abandon his practice in favour of his present occupation, which had always been in accordance with his natural tastes. In his new vocation he has been so far successful that though of comparatively a few years' standing he is already justly considered one of the best authorities on bee matters generally in the United States. He has chiefly devoted his attention to the perfection

of cellar-wintering, queen-raising, and the manufacture of dovetailed sections. He finds that if kept in the dark, bees go into the hibernating condition at a temperature of 50° Fahr., and that their slumber (?) becomes more intense and the consumption of food less as this is reduced, until 41° are reached, beyond which point activity increases and more food is consumed. In a cellar kept at 41° a stock remains quiet and without taking food for seven to eight days, when the bees wake one another up, have a concert and a feast, and again go to sleep for a like period, consuming only an average per stock of one pound of food per month, and when put out, after two and a half to three months' confinement, voiding very little fæces. Bees kept on their summer stands usually consume four or five times as much food, and are always much weaker in spring. He generally puts his hives into winter quarters about the middle of November, and on the first fine day in February he prefers to take out all stocks and give one flight, though he does not consider this necessary. They are then replaced in the cellar and the temperature increased to 48°, when breeding commences without feeding, and when spring weather becomes assured they are put on their summer stands. He is convinced that this method is a long way ahead of any other, and his opinion is supported by the fact that in the spring of 1884 he was the possessor of the only live bees in his county, all others having perished.

For queen-raising he much prefers the 'grafting process.' He removes the queen from any strong stock, and three days afterwards examines for queen-cells. All such which are deficient in royal jelly he destroys as worthless, while from such as are well supplied with their food he removes the larve only, replacing them with others from worker-cells of the stock he selects to breed from, and being careful not to introduce any larva of over 10 in diameter when curled up. For the removal of the larvæ he uses a thin basswood twig, with the bark whittled to a long quill-pen-like point, and finds that by selecting small subjects a failure very rarely

occurs.

He thinks that queens raised from more mature larvae are generally the largest, but is of opinion that those raised from smaller worms generally live longer and are more prolific.

An inspection of his apiary and machinery next morning proved most interesting. His establishment is not a large one, but by employing a special machine of his own invention, and by giving their manufacture his personal attention, he produces sections which for whiteness, smoothness, and accuracy, are admitted by his rivals to be unequalled. He uses only white poplar, which cannot be made into one-piece sections, but in spite of this drawback the beautiful appearance of his dovetailed boxes causes a demand which he finds it difficult to supply.

A brief inspection of his apiary brought a very pleasant visit to a close, and I started on my road to Medina with mixed feelings of regret at leaving one whom I already respected and of pleasure in the prospect of making the personal acquaintance of the well-known veteran, Mr. A. I. Root, of whose establishment I intend writing you in my next.—J. A. Adnort, Medina, Ohio,

U.S.A., Dec. 15.

BEE-KEEPING IN CANADA.

[756.] Mr. C. N. Abbott's interesting letter under this heading, in your last issue, will have done much to enlighten English bee-keepers on the way our children manage things apicultural in Canada; but it cannot be regarded as complete in itself. With characteristic modesty, Mr. Abbott' has contented himself with merely mentioning the qualifications of his correspondent as those of a purely negative kind, such as that he is 'a

young friend lately arrived at Ontarie, and 'a young man who is not, and never has been, a bee-keeper.' The letter you have already published, however, will satisfy bee-keepers that any short-comings or omissions on the part of the correspondent will be more than supplemented by the graphic and humorous pen of Mr. Abbott.

The hives and sections exhibited over here by our

Canadian friends attracted so much attention among practical bee-keepers that it will be a surprise to your readers to learn that they have not been adopted in the country of their birth, and that those levely sections we all so much admired at the Colinderies were produced in hives something like those of twenty years ago, and not such as Mr. Abbott has at Southall. Why is this? Mr. Abbott is manifestly prepared to discover a reason. I hope he will not disappoint us. Let him be careful, at the same time, to indulge in charitable criticism only of our late visitors, and not lay himself open to the charge of speaking unkindly of them as soon as their backs are turned, after they had received every kindness and hospitality during their visit, which, I trust, afforded them as much pleasure as it did ourselves. Apropos of such criticism, and in reference to Mr. Abbott's postscript, the Canadians regard their country as an integral portion of the British Empire, and you can hardly offend them more than by calling them 'Yankees.'—A BRITISH BEE-KEEPER.

BRITISH AND AMERICAN INVENTIONS.

[755.] Like 'Amateur Expert,' 'Renfrewshire Beckeeper,' and others, I must add my protest against the theory that 'nearly all of the appliances have been furnished us by the inventive genius of the Americans.' Take one-piece sections of the present day as an example, and undoubtedly one of the most important and useful inventions.

As I think probably very few bee-keepers are aware of the real origin of folding sections, a short history correcting the generally accepted opinion that they are an American invention, may not be out of place at the

present moment.

At one of the annual exhibitions held at South Kensington, that for 'Agriculture and machinery used in connexion therewith,' and, if I mistake not, held in the year 1872, Messrs. Colman, of Norwich, had on exhibition, and in work, a machine for making boxes for packing tins of mustard; these boxes had V grooves cut at the required distances, just in the same way as the present one-piece folding section. To make these boxes, boards, about 5 ft. long, 6 in. wide, and $\frac{1}{2}$ in. thick, were passed through the machine, and came out the other end ready for folding together, and as rapidly as the attendant there could take them ont of the way. I think all will agree that this was the first, and, perhaps, most important step in the direction of one-piece sections.

As sectional supers came more to the front in 1875 and following years, I, in the former year, having in my mind's eye the machine described above, could at once see its adaptability for turning out sections. Losing no time, I consulted an engineer in 1875, or the early part of the following year, and from other inquiries found it would be infringing the patent of Messrs. Colman, and

was advised to let the matter drop.

However, not to be outdone, I made folding sections as follows:—The two ends and the top were six or eight inches wide, in these longitudinal saw-grooves were made every two inches, cutting through the wood within one-thirtieth of an inch, and when filled could be rapidly and easily subdivided into single sections, by simply running a penknife through the saw-groove. The bottom part of the ends were grooved to receive bottom rails, and being accurately made to drive in tightly, kept the section in position. The top and the upper part of the two ends were cut through at an angle of 45°, and on

the outside, when lying out flat, end to end, a wide piece of tape was glued on, thus forming the joints corresponding to the thin part of wood left uncut in the V joints of sections as now made

V joints of sections as now made.

This, then, the first folding section ever made, was exhibited at the Kensington Show of the B.B.K.A. and was awarded first prize at least one season before the American one-piece section was heard of in this country; and I have no hesitation in adding that, could I legally have applied the above machine to section-making, they would have been perfected in this country without any assistance from our American friends. I think there can be no manner of doubt this was a step two in the same direction; and up to this time, as far as my knowledge goes, the Americans had done nothing whatever towards perfecting a felding section.

What has followed since the time my exhibit was awarded a first prize requires no explanation further than that the Americans have simply followed out the idea first invented by Messrs. Colman, adapted to section-making by me, and still further carried out and perfected by the Americans in one-piece sections of

to-day

In the face of these facts, I most emphatically contend that in no sense can the Americans claim to be the inventors of the sections in question. It must be highly gratifying to all English hive-makers, in the *Journal* of of the 9th December, to have such high authorities agreeing that our appliances are far more substantial and better made with us than they are in any part of America.

I note, and quite agree with your remark in the same issue, that the Americans have frequently taken ideas from us, which they do not credit us with, flagrant instances of which can be pointed out to this day.—James Lee, December 23rd.

NEW BEE-SUBJUGATORS.

[756.] In your report of the Irish Bee-keepers' Association, on page 583, you tell us that 'Mr. Sproule handed round a bottle containing a substance mentioned in Mr. Cheshire's new book for rubbing on the hands to prevent the bees stinging while manipulating.' This was called methyl salicylate, but in Dublin was only known and sold as 'oil of winter-green.'

I have not seen the second volume of Mr. Cheshire's new book, in which this substance is named, for with the second volume I am wise by experience, having with his first volume patiently waited, month after month, for the separate parts, only to find the whole of the first volume published, whilst the monthly subscribers had arrived but halfway through. It is only fair to say that the publishers allowed me the cost of my monthly parts on returning them and purchasing the volume. I wanted to do the same with the second volume, but they didn't see the affair in my light, so I am impatiently waiting for the second volume complete.

As one who has taken some little interest in the true use of the bee's sting, I may be pardoned for having endeavoured for some time, by experiments, to discover a preventive against bees stinging, and this I have been doing until winter suspended my experiments, yet not before I had achieved success satisfactory to myself. I have, however, the greatest pleasure in hailing Mr. Cheshire as the discoverer of, perhaps, the most useful article in the apiary, and I feel sure your readers will thank him for generously presenting yet another discovery to the public.

Will you allow me now to say how far on the road I had gone (a different road but with the same goal); afterwards to make some new remarks on the discovery which will facilitate the making or obtaining it, and

also to acquaint our fraternity with another substance

which I believe is equally efficacious?

On one occasion I had been attacked by bees on my hands, from which I could not remove the smell of petroleum, although it was not discernible to myself. I had tried two or three good washings with soap in vain, so determined, as they were so susceptible to its odour, to use vascline (the jelly of petroleum) as the vehicle or basis of my lubricant, anticipating that when the bee came to sample the surface of skin (preparing for business) with its too highly sensitive palpi or feelers, placed near the sting aperture, she would find the adhesive and sticky slight film of vaseline, with which I had rubbed my hands, an unsuitable medium, besides rendering difficult the pincer-like purchase she obtains with her claws, by which to insert the sting. Scenting this substance successively with vanilla, vervain, bergamot, lavender, thyme, lemon, &c., separately, and in various combinations or chords; rubbing my hands with various herbs the essential oils of which, residing in the hairs of the leaves, were seized by the vaseline with which my hands were very slightly smeared, I had various degrees of success. We must bear in mind, en passant, that perfumes when skilfully mixed are capable of producing effects totally different from those of their separate components, that they may be tuned, so to speak, into harmonious chords or blends, just as the notes of musical instruments, or the colours on an artist's canvas may be so arranged as to produce an agreeable sensation upon the eye, the car, or the nostrils.

This is an Art
Which does mend Nature: change it rather: but
The Art itself is Nature.
Shakespeare.

We must also not forget that the slightness or intensity alone of almost every odour renders it agreeable or disagreeable to us (then how much more to the bee whose olfactories are susceptible to an incomprehensible degree). The scent of a crushed bee's poison in a hive arouses their anger, but the same chemical substance when 'like linked sweetness long drawn out' may be as agreeable and charming to them as the aroma of queen or home to a lost bee.

To resume; I came to the conclusion that any very slight soupcon of myrtle, olive, savin, bilberry, barberry, or dark green smooth-leafed scented sap evergreens produced very marked effects upon bees, to us favourable and the reverse, but this latter caused by intensity of

the odour.

I might have wandered about long enough without 'striking ite,' but you will admit I was very warm, as we used to say at the game of 'hide-and-seek,' very near Gaultheria procumbens, partridge-berry, tea-berry, or winter-green, of New Jersey, from which is extracted Gaultheria oil, or oil of winter-green, and new elixir. Any way I had got into the family when I was amongst the Ericacere, and I make no doubt that the whole family may be used as 'apifuges' (may I coin a word '), provided only that their scent be used weak enough.

Speaking theoretically (until spring comes), I have no hesitation in saying that essence of spiraea (meadow-sweet) 'will charm the angry insects down 'equally with oil of winter-green. True oil of winter-green is very expensive, some 2s. per ounce, though, like charity, a little of it goes a long way. Being so expensive, however, it is well that readers of the B.B.J. should know that oil of winter-green and essence of spiraea may be produced artificially by chemistry. Many chemists even are not aware of this, and I am in communication with a manufacturing chemist respecting the cost of artificially manufacturing these two substances. I will let you know the result so as to facilitate the cheapening and

obtaining of them, at present difficult. Meantime the following may be of interest:—

 $Salicylie\ acid + Wood\ ether\ \Big\{ \begin{array}{l} = Essential\ oil\ of\ winter-green\\ or salicylate\ of\ oxide\ of\ methyle. \end{array}$

Salicine + Bichromite of potash + Sulphurie aeid | = Essence of spiræa, or Salicylie aeid, or Hyduret of salicyle.

Oil of winter-green gently heated with an excess of of potash, adding afterwards an acid, deposits salicylic acid.

Salicylate of oxide of ethyle $C_4H_5O+C_{14}H_5O_5$, when purified, has the same smell as the true oil of wintergreen, imitated by methyl salicylate $C_2H_3O+C_{14}H_5O_5$, or $CH_3C_7H_5O_3$.

Now comes the strangest part of the business:—If methyl alcohol, or wood spirit, or hydrated oxide of methyl, be oxidised by means of a platinum wire heated to redness, and suspended in the same, the product is formic acid and water, the active ingredients in the beepoison itself. Again, if salicyl aldehyde (syn. essence of spiræa or meadow-sweet) be oxidised, salicylic acid $C_7 \coprod_5 O_3$ is formed, our remedy for foul brood.

We have, therefore, salicylic acid administered at the head of the bees as part of its food, and we have, alas! formic acid at the tail of the bee in its poison. Intermediate we have two apifuges (bee-tamers, subjugators, or what not), oil of winter-green and essence of spiraea, strongly-scented compounds of these two acids. I throw out the idea that bees will be more irascible during feeding with salicylised syrup than usual. Can we not now account for the beautiful scent we observe on opening some hives (especially demons), and also can we not account for the varying aromas of bees, by which they recognise their queen and co-immates of the hive, and by which guide too they work peacefully in the dark?

In using any of these apifuges it will be well to remember that failure will show not that the remedy is wrong, but that we, the dispensers, have probably used

too much of it.

Finally, I wish to tell your readers that Mr. Cheshire has opened a door by concentrating our attention on Gaultheria, and I shall be much mistaken if before long we find not only spirea equally effective as a protectant against stings, but nearly, if not all, the carbo-hydrates, the volatile odoriferous essences of plants, such as bergamot, carraway, cassia, cloves, lavender, mint, rose, peppermint, thyme, lemon-grass, and even turpentine. I think we shall find the very slight rubbing of hands with any pure oil or vaseline, using not more than a pin's head size, afterwards brushing the hands carelessly through a lavender bush or scented herb bed, rubbing the hands together afterwards, will prove effective.—R. A. II. Grimshaw, Cray Hill, Horsforth. near Leeds.

PHYSIOLOGICAL QUERIES.—INVERTIBLE HIVES.

[756.] On the larva assuming the pupa form, has it ever been noticed its relative position in the cells when the comb is in its normal position as built by the bees? Will inversion be in any way detrimental to the brood? These questions seem to arise in connexion with the untried invertible hives, which I have no recollection of ever having seen alluded to, but which may, perhaps, be more curious than useful, and yet it is a point worthy of notice. Some of our leading apiarists, from constant study of the internal economy of the hive, may, perhaps, throw some light on the question, which I cannot help thinking will not only be interesting, but prove of some benefit also. I use the word 'untried' advisedly, and would add a caution to all but the skilled to take the advice of 'Amateur Expert'-to go slow; and, to emphasise the caution, would beg leave to refer to R. F. Holtermann's communication in the Journal of Dec. 9th

to a question at the late conference by Mr. D. A. Jones, one of the respected delegates of the Ontario Honey Exhibit; and to the writer of the very valuable series of 'Useful Hints,' from which it appears the Kansas and Western U.S.A. bee-keepers have, after a season's trial, thrown the system overboard. If the system of inverting is an aid to success, it will make headway; but to rush to such a conclusion before testing practically would be simple folly, and would lead many to give up bee-keeping in disgust.—James Lee, Dec. 29th.

AMONG THE CARNIOLAN BEE-KEEPERS. By Thomas B. Blow, F.L.S.

[758.] Whilst greatly obliged to Mr. Benton for the slight corrections he has made on my observations in Carniola, yet I take exception to some of his remarks, as all through the article I strove to state facts only as I found them, and about which I have no wish or intention to enter into controversy.

I stated no reason for the mixed colouring of the hees around Trieste, though I did form an opinion of the cause, which is not the same as Mr. Benton's opinion.

The block that Mr. Dokoupil uses I can assert, from my dealings with him, is a perfect success; so is the candy he makes and uses with it; and though I have only his word that he was successful in sending bees to America, yet I have no doubt whatever that he has done so, for all the bees I have ever had from him have arrived in splendid condition, so fresh that I should not have hesitated in sending them on to America. He has entirely discarded the use of comb-honey with his travelling-boxes, using nothing but candy, and I certainly am of opinion that he is the most advanced bee-keeper in his district.

I was quite aware that very large apiaries were to be found around Laibach, and I stated 'that the district around is a great one for bees.' I knew, too, of the large hive-factory referred to, and had the catalogue of its productions in my pocket all through my journey, but my object was bees rather than appliances, and I did not eare to waste time in visiting it. I saw a number of frame and other hives of various patterns, but for one frame-hive I saw at least one hundred of the boxes I

spoke of.

I am quite certain about the statement of Mr. Ambrozic. 11e said he had sent many queens to South America by the plan mentioned, and that the loss per cent of queens was not great. He mentioned that out of one lot of thirty queens, twenty-six arrived safely and in good condition, and the voyage was a long one, too. I am sure bee-keepers would be glad to hear of Mr. Benton's plan of sending forty queens a long journey safely in one stock. Is it a plan only, or has it been successfully practised? I must still stand firmly by my statement that Carniolan bees have not the restless tendency of other races when travelling, and this remark I apply to all other races. During my journey from Cyprus the bees I had with me never ceased to worry and gnaw at the wires that covered the openings in the boxes, and this caused great mortality. I shipped Eastern bees on to America from Cyprus for Mr. Benton, and these arrived here in just the same state, and more than half the bees were dead in each nucleus hive. The Italians have similar tendencies, though less decided than the Eastern races.

I have imported from Carniola during the past summer dozens of full stocks, and they have always arrived in the most tranquil condition and with hardly

a dead bee.

I have the right, I believe, to speak with some authority on the suitability of the Eastern races of bees for this climate, as I have handled and had in my apiary a far larger number of stocks of these bees than any other individual in England. I have raised various

crosses from them and studied them a great deal. It is hardly likely that I should quietly drop these bees if they had had any good qualities after the trouble and expense of taking a journey to Cyprus and Syria. I admit that the Cyprians are better than Syrians, but that is not saying much, and I now unhesitatingly condemn both for use here. They do not winter well, are very liable to dysentery, and to spring dwindling, and on an average season they will not produce as much honey as blacks. I do not make these assertions on the results of a single stock or season, but from many stocks extending over some years. Mr. Benton has had no experience whatever with these races in this country, and we must judge by results here. With regard to the question of their irritability and robbing tendencies, the less said the better. They have a reputation in this country that they will not readily lose.

As I stated before, I have no desire to enter into any controversy or to charge Mr. Benton with change of opinion (as I changed my opinion of Cyprians after a year or two experience with them), but if we read his early experiences with Syrians they were then far ahead of all others, and now are despised. I do trust that Mr. Benton will abandon his profitless yearly Eastern expedition, and settle in Carniola, where there is great need of a scientific queen-raiser such as he, and I can assure him that he will have an unlimited demand for all the queens he may raise there, as no better bees can be

had and none more suitable for our climate.

NOMENCLATURE.

[759.] I should think about the last thing you need have done in a recent number was to deprecate the giving up of the Journal by any one whom depressed apiculture did not prevent continuing it, or to offer any 'excuse' for writing discursively on topics of general interest. To myself they were all very interesting, and I was glad to meet with the derivation of 'topsy-turvy' in a paragraph relating to a matter on which I had intended to write to you. As we shall soon begin a new year let us by all means start, if possible, with correct nomenclature. This was advocated some months ago in the matter of crates and racks, dividers and dummies, &c. I quite agree with you about the use of the words 'reverse' and 'invert,' but I am not sure that I agree with any one as to the sense of practising the plan indicated. What do the bees think of it, I wonder? Has any one tried the effect of an entrance at top of front of hive, with suitable arrangements for movement inside? Would the bees put the whole arrangement 'top-sidet'other-way?'

But nomenclature. I don't know why we have no right to use apiarian as a substantive. Such a practice is common enough with moderns and the man who wrote 'Eheu,' &c. But as I was once denominated an aparian, or, if it must be written, apearian, why I go in for

apiarist.

But I have not got to my object yet. It does not much matter whether we call the article which holds the sections a crate or a rack, but I think a serious error is being made in the use of the word 'rabbet.' We could not on any ground call a bottle a cork, but something similar to this is being done. You have copied it from Neighbour's advertisement of the Sandringham hive in which we read of shifting rabbets, and see that they are oblong pieces of wood which slip up and down in grooves. Now, surely it is the groove which may be called the rabbet, and not that which slides in it. One dictionary tells me that a rabbet is 'a joint in carpentery, a groove; while the Glossary of Architecture informs me that it is 'a rectangular recess or groove cut in a piece of timber to receive the edge of a plank.' Here at the edge it is no doubt most correctly spoken of, but I do not object to the use of the word by accommodation

elsewhere, only we ought certainly to keep the term for the hollowed space, and not for that which fills it. This is topsy-turvy work with a vengeance, and much of it would prevent our communicating intelligibly with one another. The fact is that 'rabbet' is a corruption of 'rebate,' something bated or beaten back, a term used in knitting, and a good example of a rabbet is the notch cut in a door-post to receive the door,—C. R. S., South Cornwall, December 20th, 1880,

SUNDRIES.

[760.] Our friend Simmins—and all bee-keepers ought to consider him as such—seems to have been somewhat 'riled' at 'A. H. B. K.'s remarks ament queen introduction, and well he might. But hard words, you know, take a long time to smooth down again, while nothing is gained by using them. 'A. H. B. K.'s 'law' is sound and practicable, but Simmins's is better, not in its efficiency, but in its simplicity. I have had considerable experience in both during the last season, and have been eminently successful with each. But who would go to the trouble, in the middle of the season, to deprive a stock of every means of raising a new mother, when by simply keeping your fresh queen in a receptacle by itself for half an hour the thing is done? Here you only handle one bee, but to deprive a populous colony of eggs and young brood at such a time, why, it will not bear comparison. Your to 'A. H. B. K.,' Simmins less than a quarter of the time. As to the success of each, they are about equal; neither Mr. Simmins's plan nor 'A. H. B. K.'s' are infallible, but both are near enough to infallibility to be considered a great success. Queen-cages must be at a discount; a very considerable one too. I would not give 'tuppence' for a bushel.

One colony of bees, occupying two skeps, standing side by side, as seen by 'Engine-driver,' was observed by

myself, and noticed some two years ago in B.B.J.
Our American friends are 'going in' for Mr. Cheshire's foul-brood cure, and according to their experience there is nothing to beat it. I daresay they would have discovered this before if it had been an American that had introduced it.

Professor A. J. Cook has discovered that coffee is aboat as pernicious to bacteria as water would be.

Fancy a County Association giving up the circulation of the *Bce Journal* in the place of the county expert! They say opinions differ. I should hardly think that the opinions of its members had been consulted at all.

What must we store our honey in? Mr. O. Hehner tells of elder-wine becoming poisonous by being stored in galvanised receptacles, and honey will be so affected. I know an instance of a family being poisoned by elderwine stored in red glazed crocks. Perhaps we had better not store honey in these likewise. We must stick to tin, it is far more preferable, if only for its cleanliness.

Honey at 1d. per pound net is the future price when 'S. L. B.'s 'Mexicans are introduced. Why, bee-keeping then will lose half its pleasures (?). No more gloves, no more veils, but what a glorious time for the bees that do sting! Mexicans will collect, Ligurians, Blacks, &c., will store, and we-well, it will be too common to eat honey then.—W. B. WEBSTER.

NOTICES TO CORRESPONDENTS & INQUIRERS.

- E. W. P.—Separating Pollen from Wax.—Melt the wax, and keep it just melted, but not boiling, for five or six hours, then let it cool, and the separation will then be found to have taken place.
- J. C. Merrick.—Packing Honey for Transport.—Please refer to page 303 of previous volume, where you will find full and clear directions for packing honey. The directions referred to were issued by the Irish and other beekeepers' Associations.

Business Directory.

For the use of Manufacturers and Purchasers of Bee-

keeping Appliances.

The Name and Address and Business of any Manufacturer will be inserted in this List, under one heading, for One Pound per annum. Additional headings, Five Shillings extra. Advertisers in 'The Bee Journal,' whose orders amount to Five Pounds per annum, will be inserted Free.

BEE-KEEPERS' GUIDE; or, MANUAL OF THE APIARY. By A. J. COOK. 14th Thousand. The whole work has been thoroughly revised, and contains the very latest in respect to Bee-keeping. Price 5s., postage 6d.

BEE JOURNAL OFFICE, KINGS LANGLEY.

NOW READY!

VOL. XIV. of

The British Bee Journal,

THOS. W. COWAN, F.G.S., F.R.M.S.,

Containing upwards of 600 pages, with numerous Illustrations, and Complete Index.

Bound in Cloth, price 10s. Cloth Cases for Binding, 1s. each; post free, 1s. 3d.

KENT & CO., 23 PATERNOSTER ROW, LONDON; J. HUCKLE, KINGS LANGLEY, HERTS.

Special Prepaid Advertisements.

No reduction made for continuous insertion.

Exchange Column.—Sales of Honey and Second-hand Goods.—Intended to aid Bee-keepers in the disposal of Bee-produce and Appliances for which they have no further use. Terms: Twelve words and under, Fourpence; for every additional Three words, One Penny extra.

1. CIMMINS' ORIGINAL NON-SWARMING SYSTEM includes also other subjects of the first importance to all who hope to compete successfully with present low prices. 2s. 6d., post free.

2. SIMMINS' METHODS OF DIRECT QUEEN INTRODUCTION, 6½d. Of the AUTHOR, Rottingdean, Brighton; Neighbour & Sons, 149 Regent Street, and 127 High Holborn; and J. Huckle, Kings Langley, Herts.

BEE-KEEPING, Plain and Practical: How to Make it Pay. By A. RUSBRIDGE, 1s. 6d., post free, 1s. 8d. Address J. Huckle, Kings Langley, Herts. 3932

THE MANAGEMENT OF STRAW SKEPS. Designed to teach the Cottager how to obtain the best results at the least possible cost. By attention to its teachings, Cottagers will be enabled to make their Bees a more profitable source of income than hitherto. Price One Penny. Six copies and upwards, post free. J. Huckle, Kings Langley.

WANTED.—Copies of British Bee Journal for January 7th, and October 14th, 1886. Full price given. Apply J. Huckle, Kings Langley, Herts.

RYTRACTED HONEY.—From the Right Hon. Lord Sndeley's Bee Farm (situate in the Fruit Plantations), mostly from unfinished Sections, in clear glass bottles, with special label, or in bulk. Prices on application to Estate Office, Toddington, Wineheombe. (156)

CANADIAN HONEY TINS.—The 60-lbs. empty Honey Tins, in which the Extracted Honey was brought from Canada, can be had at 1s. 2d. each, including the box. Also the 10-lbs. Tins, with self-fitting tops, at 3s. per dozen. Apply to J. HUCKLE, King's Langley, Herts.

A DVERTISEMENTS WANTED for Insertion in Report of Derlyshire Bee-keepers' Association, at 10s. Whole Page. Address W. T. Atkins, Secretary, North Street, Derly.

POR SALE.— Foundation Machine, Observatory and Frame Hives. Apply to C. C. Cust, Temple Terraee, Dorchester.

WANTED, by an educated young Man, a Situation in an Apiary as Clerk or otherwise. Good references. Country life main object. Address B., 28 Amhurst Park, London, N.

TOUR DOZEN 1-lb. Sections of Comb Honey for Sale. Good Colour. Apply to W. Hanson, Corringham, Gainsborough.

POR SALE, Half-Hundredweight of good Extracted Honey, at 6d. per lb. on Rail; buyer find receptacles. Also Single Comb Extractor, in good condition, 5s. Address A. Snook, S. Marston, Swindon, Wilts.

DO NOT LET YOUR BEES STARVE!

Boxes, ready for use. Thomas B. Blow, Welwyn, Herts.

Protect your BEES from the COLD!

POR SALE, 200 PIECES of CARPET, 1d. per Piece. 103 dozen various sizes, principally 9×18 ins. Address T. Burberry, Basingstoke.

PRITISH BEE-KEEPERS' PRACTICAL NOTE BOOK. By THOMAS W. COWAN, F.G.S., F.R.M.S., &c. Crown 8vo, boards, 1s.; postage 1d. Indispensable for every Bee-keeper. Published by J. Huckle, Kings Langley; may also be obtained of all Hive-dealers.

Send Post Card for CATALOGUE of

KITCHEN GARDEN and FLOWER SEEDS,

Herbaceous, Alpine, Aquatic, Spring-flowering Plants.

BEE PASTURAGE:

Dealing with the Propagation and Successful Cultivation of Honey and Pollen-producing Trees, Shrubs, and Plants.

Price One Shilling, post free.

Editorial, Hotices, &c.

HOW TO MAKE AN EXTRACTOR.

We have been frequently asked to give instructions for making an extractor. Although we do not think that it will generally pay an amateur to make one for himself, yet there are those who like to make all their own appliances, and for these we intend to comply with the request, and to give such details as may enable any one who understands working in tin to accomplish his object.

For this purpose we will select the simplest form of cylinder extractor, that known as 'Cowan's Amateur,' which has been the type for most of the extractors made since its introduction in 1875.

In our experiments on extractors, commencing in 1873, we made no less than thirteen different patterns, and by constant trial and alterations were able to decide on the best forms. Extractors were tried with four and six frames, but we found these as unsatisfactory as Mr. Root, who says in his A B C of Bee-culture:-'Experiments have been made almost without number, and the general decision now seems to be in favour of a machine made entirely of metal, with everything stationary about it except what must be revolved. The momentum of heavy metal revolving cans, or of honey after it has left the comb, defeats the very object we have in view; and nothing will so effectually convince one of the difference as an actual trial of the two machines side by side. With the light all metal machines the comb is revolved at the speed required almost instantly, and as soon as the honey is all out of the comb the operator is aware of it, by the decrease in the weight as he holds the crank in his hand; but with the heavy, unwieldy machines the stopping and starting take more time than doing the work. The same objections apply to making machines for emptying four combs at once. They require to be made much larger, and are correspondingly heavy and unwieldy.'

After trying extractors with revolving cans we found them so unsatisfactory that they were also given up. Experiment also enabled us to decide the distance the combs should be from the spindles; and this is of great importance, because if the combs are too near, as in some extractors we have seen, all the honey is not extracted; and although it may be convenient to have a can as small as possible in diameter, yet there is a limit to the minimum size for securing efficiency. In experimenting many hundred combs were extracted and carefully weighed, the bees allowed to clean them, after which

they were again weighted. The difference in the weights enabled us to determine the amount of loss in honey, and by this means we were enabled to arrive at the most suitable measurements.

Before proceeding we must here remark that no zinc or galvanised iron should on any account be used for extractors, or for any utensils for the reception of honey. The acid in the honey acts upon the zinc, and the oxide of zinc quickly poisons the honey. The same applies to galvanised iron, as the galvanising, as it is called, is only a coating of zinc. Nothing but tin or tinned iron should be used, and all iron parts coming in contact with honey should be tinned. We have always strongly insisted upon this, and have several times given our reasons for it in the Bee Journal.

The illustrations, will, we hope, assist in better understanding the construction of one of these extractors.

As we have a standard frame we will give dimensions suitable for this frame, and anyone having another size will have to alter the proportions to suit it.

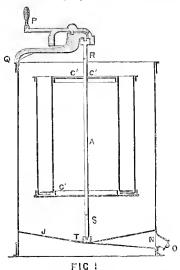

Fig. 1 gives a vertical section of the extractor, and fig. 2 is a horizontal section through the comb baskets.

We will commence by making the spindle and frame. The spindle A is made by rolling up a piece of tin, and making a tube \(\frac{5}{5}\) of an inch in diameter. It will next be necessary to make the grooves for the cages to slide in, and these will also form the uprights at the angles B. Cut four pieces of tin 15\(\frac{1}{2}\) inches long and 3\(\frac{1}{4}\) inches long and one inch wide, fold a seam along the two edges \(\frac{1}{4}\) of an inch wide, then turn these up at right angles \(\frac{1}{4}\) of an inch, and we shall get a trough in section like this \(\frac{1}{4}\). At one end cut the corner, and turn up the edge \(\frac{1}{2}\) an inch thus \(\frac{1}{4}\), as this will have to be placed to

the bottom, and form the ledge for the comb baskets to rest upon.

The frame for keeping these together, C C C' C', fig. 2,

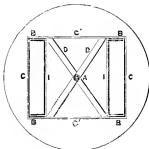

FIG 2

being 12×10 inches, we shall want strips of tin $1\frac{3}{4}$ inches wide with a seam folded on one edge $\frac{1}{4}$ of an inch wide and an $\frac{1}{8}$ of an inch wire folded in the other edge. These strips must be bent at right angles, so that when they are soldered together they may form two

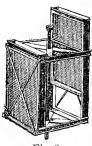

Fig. 3.

square bands 12×10 inches. Fig. 3 will show the arrangement of these at the top and bottom of the framework. The four uprights can now be soldered on to these bands. Place one of these with the wired edge down, and with a little solder tack the uprights in their proper position. It will be noticed, by referring to fig. 2, that they have to be fixed to the long sides, C C, taking care that the piece turned up at the end of the slides is at the bottom. Now tack on the top band to the npper ends of these slides, with the wired

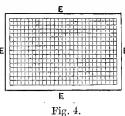

edge uppermost. Be careful before finally soldering that everything is perfectly square, or the cages will not slide in properly. When it is found correct the whole framework can be laid down in a position most On the two suitable for finally soldering all together. narrow sides solder two brace wires diagonally from the opposite corners, as shown in fig. 3. One will lay flat against the wire cage when it is in position, and the other to complete the X will have to be bent where the two wires intersect, so as to make it also lay flat. If these wires be $\frac{1}{8}$ of an inch thick and are well soldered at the ends and at the place of intersection they will be amply strong enough to prevent any bulging, even with the heaviest combs in the baskets. For fixing the spindle to this frame we must make two pieces, D D, in the form of an X. These can be made of strips of tin 15 inches wide, with wire folded in the edges for strength, or, if the wire is not used, the tin should be a little wider and folded three times. They should be when finished not less than $1\frac{1}{8}$ inches wide. Fix them as shown in fig. 2, and solder them where they cross. Then bore a inch hole in the centre of each, and push through the spindle, which must be firmly soldered in its place.

We will now make the comb baskets or cages. are in two halves, and are made two inches wide inside, so as to take combs of any thickness and sections, if it

be desired to extract the honey from them. The wire cloth used for the purpose, fig. 4, is made of stiff tinned wire four to five meshes to the inch. Two pieces are required $15 \times 9\frac{1}{3}$ inches and two pieces $15 \times 9\frac{1}{4}$ inches. Get a strip of tin long enough to go right round the edges E E $\frac{3}{4}$ of an inch wide and turn it up at right angles, thus L _ _ now place the wire cloth inside this and solder it in, being very careful to solder each wire. Next hammer down the turned-up edges flat on to the wire and again solder each wire to these. They will then present the appearance of fig. 4. We now

have to make frames for them. The frames, however, have only two sides and a bottom. Tin $2\frac{1}{8}$ inches wide will

do and turn up one edge at right angles for ‡ of an inch. Then bend them thus the long ends F F, fig. 5, being when finished I5 inches E and the short one G 95 inches for two of them, and the other two must be a little smaller so as to fit into these. We say when finished because we intend

to turn in a bead with a wire to strengthen the top and give something to take hold of. The wire-cloth frame, fig. 4, can now be soldered into these frames, and we shall have half a cage as seen in fig. 5, which shows a

frame of comb in position. We then put a wire along the top HH, turning the tin over it and soldering c the wire to the top end of the tin surrounding the wire cloth. The inner basket which has to fit into the outer one need only have the wire fixed along the top on that side where

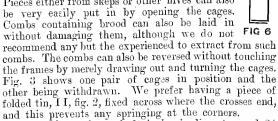

Fig. 5.

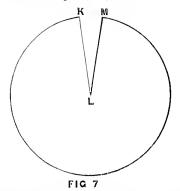

is placed the wire cloth, as it would be obviously in the way if it were also at the ends. The baskets when put together are seen in fig. 6. Should the frames have projecting shoulders, or long ends, holes must be cut

in the bottom of the cages or in the wire cloth to accommodate them.

The advantage of these baskets is that any thickness of comb can be put in for extraction. Pieces either from skeps or other hives can also

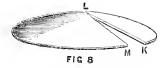

The can has to be made 18 inches in diameter and 24 inches high. The top and bottom must have a wired bead and against it a strong hoop at least one inch wide and of $\frac{3}{15}$ inch wrought-iron. This may be wide and of $\frac{3}{16}$ inch wrought-iron. This may be riveted on to the can. There is no difficulty in making any part of the can except the conical bottom, J, fig. 1. For this cut a circular piece, as in fig. 7. It must be 19

inches in diameter and a piece K L M must be cut out of it as shown, $2\frac{1}{4}$ inches wide at K M. Turn up the edges K L, M L half an inch in width and draw the opening together. It will then present the form of fig. 8. Tack on

temporarily a piece of tin across the opening to keep it the right distance apart. Then turn down the edge all

round the circumference, and try this bottom in the can, and if it is too tight or too loose untack the strip of tin across the opening and fix it in the right place. The bottom can now be laid down and a trough-shaped piece, fig. 9, soldered over the opening on the turned up edges K L, M L. This must be cut a little larger than the wedged-shaped piece art out of the bettern.

shaped piece cut out of the bottom, and will form the channel leading towards the honey valve. The bottom can then be soldered from the inside into position as shown in fig. 1. Then punch a hole at N and solder in the honey valve O. Before proceeding any further test the

Before proceeding any further test the can by pouring water into it, and if it leaks remedy the defects.

The tin work is now ready, and we have only to put the machine together and put on the gearing. The amateur had better purchase the gearing P and honey valve O, as it will be cheaper for him to do so than to make them. The bracket Q has to be screwed on to the can and the small gear wheel, which has a short length of iron rod R attached to it, is soldered into the top end of the hollow tin shaft into which it fits. A plain piece, S, carefully tinned, is soldered on the bottom, and this must work in a bearing T fixed to the bottom of the can, as shown in fig. 1.

Should the bee-keeper prefer it, he can substitute for the gearing a cranked handle at the top end of the shaft, this being kept in its place by a wrought-iron bar placed across the can and screwed to it, but he must not expect the same speed with this as with the multiplying gear, nor does it work so smoothly or evenly. These extractors are also made with an extra can below them: and in this case they have no conical bottom, but instead there is a bar of flat iron for the bottom of the spindle to work upon. The bottom of the extractor is made to fit in the top of the can and a wire gauze screen is used through which the honey is strained. Of course if such a can is used to hold about 50 lbs., both the conical bottom and the honey valve must be fitted into it instead of into the body of the extractor.

We hope that the description as well as the illustrations will be sufficiently clear to enable the amateur to make his own extractor.

BRITISH BEE-KEEPERS' ASSOCIATION.

The next Quarterly Conversazione will be held at 105 Jermyn Street, London, S.W., on Wednesday, January 19th, eommencing at six o'cloek. Mr. R. A. Grimshaw, of Horsforth, near Leeds, has kindly promised to read a short paper on 'The Vocal Organs of Bees.' The Secretary will be glad to receive notice of additional subjects for discussion from other members.

The annual general meeting of the members will be held at 105 Jermyn Street, S.W., on Wednesday, February 16th, at 3.30 p.m. The chair will be taken by the Baroness Burdett-Coutts, President of the Association. Notices of motion for this meeting should reach the Secretary not later than Monday, January 31st.

Foreign.

CANADA.

Our bees are once more in their winter quarters, and bee-keepers have a season of comparative leisure before them.

Our methods of wintering in Canada are various. A few, but I think none, of our most advanced bee-keepers winter their colonies upon their summer stands without any further protection than the summer hive. It appears in the past, when the old box-hive was still the prevailing, if not altogether the hive in use, colonies were always wintered in this manner, and our fathers state winter losses were rarely heard of. It may be that the shelter at that time afforded by our forests aided them, and the increased manipulation of the bees, close extracting, &e., interfere with successful wintering now. Certain it is that forty years ago great winter losses amongst bees in Canada were rare.

Two great methods of wintering bees are resorted to by Canadian bee-keepers, they are wintering in repositories and outdoor wintering in clamps or their equivalent. Repositories are either specially made for the purpose, or consist of cellars under dwelling-houses, which have originally been built for household purposes and are often used by the bee-keeper for both. Repositories specially constructed, are either houses double-walled and packed with sawdust between, making them frostproof cellars, generally with a workshop above; these repositories are ventilated in various ways, the houses generally have sub-earth ventilation by means of a tile pipe, running a sufficient length and depth under the soil, to enable the atmosphere passing into it from the end remote from the bee-house to be of an equal temperature by the time it enters the bee-house at the other end, and this irrespective of the rise and fall of the temperature outside. A pipe, often a wooden box, generally forms the other and upwards ventilator, and this ventilator can be opened or contracted to further regulate the temperature of the repository.

The colonies are placed at least twelve inches above the floor, and piled one above another with the lids off, and the propolised cloths on; sometimes the latter are replaced by clean cotton and a light chaff-cushion. Opinions vary as to the temperature of the repository; all agree it should never fall below 35° or even 40°. The tendency has been for the last year or two to raise the temperature in wintering, and in consequence many favour a temperature not lower than 50° to 55°.

Bees are generally placed in these quarters the latter part of November, and remain there until the bees can gather pollen and natural stores. Some will carry their bees out during early spring for a cleansing flight, and return them to the repository; such a method is very generally condemned. Towards spring the temperature is raised, and the bees commence brood-rearing, and all conditions being favourable when placed upon their summer stands are almost quite as strong, or even stronger than when placed indoors.

When wintering outside in clamps, the hives have an outer case, allowing sufficient packing of chaff or sawdust to keep out the frost, the lid is removed, passages bored through the upper half of the combs so as to permit the bees to pass from comb to comb without going around them (this prevents much loss), on the top bars of frames are placed strips to raise the cloth sufficiently to permit the bees to pass from comb to comb over the frames. The entrance is left open to allow the bees a flight when desired. We have a number of reports where hives were left covered entirely with snow for some time, and wintered well. We have also reports of colonies, which, buried in a dry soil over winter, and eoming out in fine condition; but such practices are

exceptional as yet, however satisfactory the results may prove to be. It is generally admitted that bees wintered on their summer stands and packed about with chaff and sawdust during the cold winter and spring, are less liable to spring-dwindling, and build up in good condition for the early honey flow.—R. F. HOLTERMANN, Brantford, Canada.

SWITZERLAND,

In passing a retrospective glance upon the main features of the year which has just closed from a bee-keeper's point of view, the Bulletin d'Apiculture de la Suisse Normande arrives at the conclusion that in Europe it has proved exceptionally unfavourable to apiculture.

In the course of its twelve months, adds the same Journal, the losses of prominent members of our community have been very severe. Switzerland deplores, among others, the removal by death, of M. Mona; Italy, Mr. C. Famagalli, the author of a hive largely in use among Italians; France, M. Jules Madaré, President of the Société de la Somme, and M. Maurice Girard, a distinguished entomologist and author of a valuable book on bees; Scotland has lost her James Anderson, a veteran of Scotch apiculture, who in his day was remarkably successful with the Stewarton hive; and, lastly, Russia has seen the passing away of Dr. A. Butlerow, Professor of Chemistry and of Medicine at the St. Petersburg University. Dr. Butlerow was the promoter of modern bee-keeping in Russia, and his works are considerable, among which is a Russian translation of Berlepsch's book. The deceased doctor was also founder of a school of apiculture.

Correspondence.

The Editor does not hold himself responsible for the opinions expressed by his correspondents. No attention will be taken of anonymous communications, and correspondents are requested to write or one side of the paper only, and give their real names and addresses, not necessarily for publication, but as a guarantee of good faith. Illustrations should be drawn on separate pieces of paper.

Communications relating to the literary department, reports of Associations, Shows, Meetings, Echoes, Queries, Books for Review, Ke., must be addressed only to "The Editor of the "British Bee Journal," clo Messrs. Strangeways and Sons, Tower Street, Upper St. Martin's Lane, London, W.C. All business communications relating to Advertisements, &c., must be addressed to Mr. J. Huckle, King's Langley, Herts (see 2nd page of Advertisements).

*In order to facilitate reference, Correspondents, when speaking of any letter or query previously inserted, will oblige by mentioning the number of the letter, as well as the page on which it appears.

SIMPLICITY IN FEEDING.

[761.] At one time I looked upon the work of feeding in large apiaries as one of the greatest annoyances, and the necessary preparation a waste of valuable time. Syrup had to be made over a stove before it was thought possible that it could be appropriated by the bees. I was satisfied that all this labour could be avoided, and before establishing out-apiaries I determined, if possible, that it should be done. The result of careful experiments was the present system known as 'dry-sugar feeding,' by means of dummies filled and arranged at the side of the brood-nest. Though the term applied to the new process was not exactly correct, as the sugar used (Porto Rico) is moist and soft, it is thus distinguished from syrup feeding, and appears appropriate.

Though invaluable for stimulative purposes, and in some cases to complete storage, at times it was still necessary to give syrup, when desirable, to feed rapidly, but this difficulty has been overcome by my self-acting syrup feeders. There was still, however, one other point

Many stocks are either neglected by their owner, or happen to run short of food before it is possible to feed in the ordinary way. Hence the use of 'candy' during winter, than which there is no more troublesome nor expensive food to make; expensive because of the great waste of time taken in its manufacture when one might | be profitably employed at something far more remunera-

It is pretty well understood by practical bee-keepers that the only suitable candy is that which always presents a moist surface to the bees, without wasting too freely, great care being required to get it just right, as, if too dry, the bees will not make much use of it until they can obtain water, while if too soft the whole will run away in waste, making everything sticky, the poor bees included, and thus doing more harm than good.

When I say that I have struck the 'happy medium,' and no more cooking is required, even for winter-feeding, or for supplementing the stores of those running short before spring opens, the importance of the following plan of giving uncooked sugar without the expense of a feeder will be acknowledged. Porto Rico sugar is of exactly the right condition to take the place of candy, if only properly applied. There is only one way that I have found it can be done without waste where the bees are admitted to the sugar from the bottom of the lump, and that is, when placed on the frames just over the

cluster, and pressed down tightly.

First lay a sheet of newspaper over the frames, on this place several pounds of the above-mentioned sugar and press it down well all round. It then forms into a cake with a crust that I have known to support the weight of clustering bees and newly-built combs, after the bulk had been used in spring, just as if it had been an inverted dish. No grains are wasted; first, because of the pressure, and then the moisture of the hive causing all to adhere closely together. No liquid appears, and yet the sugar is always in the best possible condition for use. The body of sugar adds an additional protection to the bees, and, unlike sticks of candy, the crust is left till last, forming a complete air-chamber immediately above the cluster.

A strong colony will soon open a way through the paper where it bulges down between the frames. For a weak lot a slight tear should be made to give them a start. Instead of paper a piece of cheese-cloth can be placed first on the frame, and would be preferable if

applied in mid-winter.

It is hardly necessary to say that this sugar can be moulded to any shape to suit the formation of roof or quilting, which latter should be very warm. For slow feeding, where it is known the bees have some stores on hand, or for brood stimulation later, porous cloth only need be applied; but where the case is urgent, or more rapid feeding is necessary, place a piece of oiled cloth next above the sugar, with smooth side to the same.

In cases of emergency, where bees have been bought in spring short of food, and being in odd hives, I have placed the usual dry-feeding dummy close on top of the frames, with the slot next to but standing across them. The hives being smaller than the 'standard,' no other feeders were at hand suitable. When covered up warm the sugar soon disappeared, and though side feeding is at times more convenient to the bee-keeper, without a doubt in cool weather, there is no place so suitable for the bees wherefrom to take their food as that immediately above the cluster.

I do not suppose every one will discontinue the preparation of bee-food by cooking, but at my own apiaries, of several hundred colonies, no time is now wasted in that manner, and I have no doubt this last application of 'dry-sugar feeding' will be welcomed by many who are now getting anxious about the condition of their stocks.—S. SIMMINS.

CAMPHOR AS A CURE OF FOUL BROOD.

[762.] I think we may safely come to the conclusion that camphor is useless as a cure of foul brood, as no one in reply to my Query 674 writes in its favour, and two write against it. I certainly expected to see some

one write in its favour, after its being recommended in the Journal by you, Mr. Editor, although you did not write from your own experience: and if report is correct our County Expert carried a stock of camphor with him on his tour, so as to supply any one with it where they had got foul brood. But in one apiary where he recommended its use, it did about as much good as it did in mine.

In reply to Mr. Ward, How are we to know when the disease has attacked the queen so as to displace her? If I was not certain about the queen I mentioned in my previous letter, I certainly should not have any faith in any other, as I had the pleasure of driving the bees this autumn at the same apiary she came from, and there is no trace of foul brood there at that time, and I don't believe there is within three miles of them.

He also says if the queen is healthy, the so-called Cheshire care will care a hive; my experience says it won't. When I first found out that I had got foul brood, I at once sent to one of his recognised agents for some, so as to have the right article, and I carried out his instructions as near to the letter as I possibly could upon the two hives that were affected, but to no purpose. I reduced it to about four times the strength he recommends, and then they would not take it. then tried spraying the combs with it, but they gradually got worse, and at last I turned them out and put them into a clean hive, and before I would go through that process of spraying, &c., again, I should give up beekeeping. I certainly mean trying one of his recommendations in the spring as regards putting some medicated syrup out for them to steal, and if it answers I will publish it in our Journal. Of one thing I feel certain, that there is no occasion to destroy your hives; that they can be disinfected. Three years ago I sold six hives for a gentleman who makes his own hives, and who was adopting the standard frame, these not being standard size. Knowing that he had got foul brood, I did not like to have any dealings with him (and if I had known as much about foul brood then as I do now I certainly should not), but he assured me that they had heen disinfected, and that there was nothing infectious about them; they had all had bees in them and died

I did not feel very easy about their coming upon my premises, so that I moved them as near direct as possible. Three went to one place, and the other three went to separate places, and they are not near one another by at least two miles. I examined the whole of these hives last autumn, and there is not a trace of foul brood in either of them; so that the gentleman was candid in saying they had been thoroughly disinfected. Further, I don't think it is communicated in wax-foundation, as I have supplied these four parties with foundation bought through the Journal, and they have now amongst them more than a score of bar-frame hives all clean.

I think Mr. Saddler has done us a good turn in publishing his experience of foul brood. I quite agree with him that the simplest way of dealing with foul brood is to destroy the affected combs. I tried putting clean combs into the centre of the brood-nest whilst feeding with salicylic acid, but after about the ninth day they took the disease as bad as the others. He quite bears ont my opinion that you may have the disease very bad in a hive, and yet the queen is not affected. Mr. Ward will say how do I know that. Just one instance. Two years ago a stock of Ligurians belonging to the gentleman I have previously mentioned, had got it very bad; he shook them off the bars into a straw skep, intending to keep them there for a couple of days, before putting them into another frame-hive, but not agreeing with the change they took flight, and went straight into the weather tileing of a gentleman's stable about half a mile off. As they had become such an intolerable

nuisance there, I was asked to come and take them out, which I did in September last, and there was not the least sign of foul brood anywhere; and there was no mistaking the Ligurian bees and the old queen; they had one unbroken piece of comb over five feet long.

I should like to see 'Knownothing' give us his recipe for using Calvert's No. 4, as I consider Is. 6d. per bottle for such a small bottle as Mr. Cheshire's agents send out is far too dear, and then carbolic can be bought

almost anywhere.

I am sorry that I cannot endorse your opinion of Mr. King's article on Foul Brood. It appears to me to be a rare piece of Yankeeism. He puts one small measure of the dissolved phenol crystals into a pail, and measures with the same measure 499 parts of what I may call syrup, and then makes a mark upon the pail, so as to have a correct measure. I should call that anything but a correct measure. Only fancy filling this small measure 499 times, and I cannot make anything else of it! The odds are if he tried it over half-a-dozen times, he would not make his measurements agree within half a pint on either occasion of trying. If he had quoted ounces or pints, I think any one could have understood it. And then when heated up to 150° Fahr, the bees would eat it with avidity. Let him try drinking his coffee heated up to that heat, and see how fast he could get on. And I have yet to learn that bees can take anything hotter than we bipeds can.

And then he wants us to believe upon hearsay evidence that he has cured his large apiary of foul brood in less than twelve months by using phenol, according to

his formula, not Mr. Cheshire's.

I should imagine that the manager of an apiary of 400 hives would be able to carry out Mr. Cheshire's instructions fairly well. And yet Mr. King says that in the experiments made with phenol previous to his taking them in hand, the solution had been used too strong, too sparingly, not half sweet enough, nor yet warm enough. And then to finish up, asks all that are interested to carry out Mr. Cheshire's formula literally and accurately. That last sentence has put me into a fog altogether.

It seems to be admitted by all your correspondents that the Cheshire formula is too strong, and that bees won't take enough of it to do them any good until it is reduced. 'Knownothing' says I am quite right in supposing that the disease is not propagated readily in a neighbourhood. I don't know when I said so: at least, my opinion is quite the reverse, but there is something peculiar about straw skeps and foul brood, of which more

anon.--Man of Kent.

P.S.—Will 'Platelayer' give us his experience of the last season, and whether his bottle of phenol is still on the shelf?

[We do not think we can yet come to the conclusion that camphor is useless as a cure for foul brood unless we disbelieve the statements that are constantly made by competent bee-keepers of complete cures by its means. We know it has not been successful in some cases, but we have no personal experience, having fortunately succeeded perfectly well with salicylic acid when foul brood was raging fearfully in our own apiary. However, we see frequent reports of cures effected by means of camphor in the leading Continental bee-papers. We attended a large meeting of the Société Romande d'Apiculture last October, and there met a gentleman who had successfully cured his hives with nothing but camphor. We have also heard of others who had succeeded with phenol, and even with common carbolic acid, as recommended in some German bee-books. In 1885 we attended a meeting of the Italian bee-keepers, when this question of phenol treatment was discussed. It was not favourably entertained; M. Tartuferi, one of the largest bee-keepers in Italy, and owner of a thousand hives, stating that he did

not want anything better or simpler than salicylic acid, having had no difficulty in enring his hives with it. Both salicylic and phenol have now been in use for upwards of ten years, and both have their advocates. We must, however, admit that although we have seen large apiaries that had been completely cured with the former, Mr. King's is the only wholesale treatment with phenol we have heard of, and hope it may be as successful as he states. It is true we have never detected any of the germs of foul brood in honey under the microscope, even with the highest powers; but it has not, we think, been conclusively proved that the virus of the disease may not be conveyed in it, and your experience, borne out by that of others, is strong evidence in favour of the theory that honey may be the medium through which foul brood may be promulgated. Pure phenol in crystals can be purchased at 3s. a pound. There is no difficulty in making the solutions, see page 153, Bee-keeper's Guide Book, where the proportions are given.—Ed.

MR. CORNEIL'S SECTION CRATE AND SECTIONS.—AN APOLOGY.

[763.] Having noticed 'Amateur Expert's' apology to Mr. W. Chitty in your last issue, I felt interested to examine both the original paper in the Bazaar and also the criticism. Referring to these, may I venture to say, in the first place, that while it is always pleasing to see a writer willing to apologise for any offence, real or imagined, that he may have caused, I quite fail in this case to see how any reasonable person could have taken offence? In the first paragraph relating to Mr. Chitty's paper, 'Amateur Expert' points out, but certainly not in an offensive manner, an error, which if uncorrected might have led many hee-keepers to spoil all their sections next year. Had I made such a mistake I should have felt grateful to anyone who set me right.

The next paragraph appears to call for no comment; and the same applies to the first part of the third: but if Mr. Chitty chooses to 'fit on the cap' as to misleading instruction in gardening and other journals—in which undoubtedly from time to time much that is misleading has appeared—I do not see that he need complain of unfriendly criticism. Had he complained that 'Amateur Expert' wrote under cover of a nom de plume instead of boldly signing his own name, I should fully sympathise with him.—J. LINGEN SEAGER.

SUNDRIES.

[764.] Having made a few new hives this winter, and being rather fond of having names for some of them, I should like to have one named Mel sapit Omnia, but as I fear being a cause of offeuce to 'Amateur Expert,' I should like to get his permission to have it done, as in the Journal for Sept. 2nd, page 408, he threatens pains and penalties to anyone infringing his trade-mark. By the bye, I was wondering what had become of him, thinking perhaps he was hybernating, like the bees; but it appears in our last, a fitful gleam of sunshine fetched him out, but only to reply to Mr. Chitty, and apologise,—for what?—what I think was a justifiable action in pointing out some discrepancies in his (Mr. Chitty's) description of Mr. Corneil's super? I hope we shall soon hear from him again, as we cannot afford to lose his remarks and experiences have been very instructive. I hope he will not forget to give us his experience with bees that are bred from that Cyprian or Holy Land queen which he introduced last autumn.

1 should like to say a few words about the Standard frame. 1 think it is a pity after all the trouble and bother of settling on a certain size, that a few are thinking and advocating changing, what to me appears a very

suitable size. If any alteration is deemed advisable, I should think shallow frames would be the most suitable, like those advocated in the *Record* by Mr. Carr, as at the late South Kensington show we had a specimen of what could be done with such a hive in a moderate season.—John Walton.

A ROMAN RELIC.

[765.] In I868, a gentleman of Colchester (Mr. Joslin) found in his grounds a monument to a Roman soldier (centurion). An interesting description of it was written by the Rev. B. Lodge. A doubt arose as to the name, &c., of a small sword or hanger at the right side of the figure. And in a note we read that Forcellini, quoting Antonius Augustinus, says that the weapon was without a point, to intimate that the superior officer, like the queen-bee, should direct, but have no sting.

Can any of your classical readers tell us anything about Autonius Augustinus, date, &c.?—J. LAWSON

Sisson.

[In 1587, Antonius Augustinus (or Antonio Agustin), archhishop of Tarragona, published a work, entitled, 'Dialogos de Medallas, Inscriciones, y otras Antiguedades, Ex Bibliotheca A. A. Plates, 4to. Tarragona, 1587.' There was another edition in 4to., Madrid, 1744. Of the above work there were two Italian versions. Also a Latin translation by And. Schott, Fol. Antverpiæ, 1617, and Antv. 1653–54, 3 parts, 68 plates.—Ep.]

INVERTIBLE HIVES.

[766.] May I be allowed to endorse Mr. James Lee's sound advice to bee-keepers, namely, to test new ideas practically before rushing to conclusions, and his further caution for all but the skilled 'to go slow'? A great deal of harm has, I believe, been done by those fertile workers, who have put forward crude, unfertilised notions in the guise of proved facts, and no doubt numbers of beginners have thrown up bee-keeping in disgust because they have failed to secure the impossible results these others professed to have obtained and promised them. It is an act of generosity, more or less, for a man to publish his ideas to the world; but what I complain about is that, in the bee-world especially, many writers forget to mention that their ideas are nothing more than ideas, and that they have never really been put to a practical test.

On the other hand, it is unfair to condemn a system without trial merely because it is new, or, perhaps, because in a single instance, and under unknown conditions, it has not proved successful. My own experience of the system of inversion, which Mr. Lee is entirely wrong in speaking of as untried, bears out this

view.

In 1885 I got some reversible frames from Messrs, Neighbour and others, but reversing them seemed to make no difference in results, as far as I could see; later on, however, happening to read Mr. Garratt's very interesting article on reversing skeps, I determined to give the plan a trial. The skep on which I experimented was in no way a specially selected one, but one of average strength. The result surprised me. It gave the earliest sections in the apiary, and a number far in excess of the average per stock. A single trial cannot be conclusive, but this one, I need hardly say, has very much modified the opinion formed previously; and I am very sanguine that, though reversing frames with its attendant disturbance of the brood-nest may do more harm than good, the Heddon system, so well spoken of by the majority of those who in America have tried it, may be a very long step in advance.

it, may be a very long step in advance.

Bee-keeping on modern principles is in its infancy, it is hardly out of the experimental stage, and I trust English authorities on bee matters will, while cautioning

novices not to go too fast, give every encouragement to progress and experiment, and condemn nothing merely on the ground that it has not been tried, or that it is of foreign invention.—D. A. Thomas,

POLLEN GRAINS IN HONEY. (741.)

[767.] In answer to your correspondent in *The British Bee Journal*, 16th December, 1886 (741), page 500, I drew attention to the beautiful object found in the honey-comb, 'pollen.' A paper of mine was read in reference to this object at the Royal Microscopical Society meeting in 1865—see Quarterly Journal of Microscopical Science, 1865, page 163. With regard to the various pollens which the bee collects they are far too numerous to name. They are often spores of different plants, as well as pollen, thus collected. The bee in collecting them makes up, or builds, the honey-comb, mixed together with the wax. If they are found in honey, it is by accident, or by pressure of the honeycomb, which is gently heated by the trade to extract the honey. Thus the pollen is often found in the honey of the shops, but the best way to get a great variety is to soften by gentle heat part of the honey-comb on a slide for the microscope; your correspondent will find then numerous pollens and spores of plants. A better way still to exhibit the pollen is to gather them from various flowers, and immerse them in olive oil on a slide for the microscope. I have mounted many very successfully, having made it a study for some years. There is a difference of opinion in respect to the food of the larvæ of bees. My belief is that honey forms the chief, and that pollen is not used as food.—Edmund Gill, Linn Villa, Sutton Hill, Surrey.

NOMENCLATURE.

[768.] I notice in your last issue that 'C. R. S., of South Cornwall,' calls attention to the word 'rabbet' being improperly used in your columns. Johnson's Dictionary informs me that a 'rabbet' is a joint made by paring two pieces of wood so that they wrap over one another.' Now the shifting slide mentioned in describing Neighbour's Sandringham hive is itself comprised of several 'rabbets,' so that it really may be called a rabbeted slide. Would this term suit 'C. R. S.' better? It seems to me a not very important matter to call attention to.—Alfred Neighbour.

NOMENCLATURE.

[769.] Mr. Editor, permit me to draw your attention to letter 759, page 9 ('Nomenclature'). I am much obliged to 'C. R. S.' for opening up this subject. By looking over the dictionary you will see that a 'rabbet' cannot be any way but on the edge, or at an outside. Such a rabbet as used in Neighbour's advertisement no one can understand. The English language is not so scarce of words as to necessitate the use of one word being used for two such different operations as the two mentioned. A rabbet has only two sides, that is, a bottom and one side. Now this one in Neighbour's advertisement has three sides, a bottom, and two sides. Our trade name for the latter is a rangele, although I do not find the word in the Dictionary.

While I am at it I might make a remark about bunping. You might try how 'jerk' would do instead of that very objectionable word 'bump. It was no wonder that Mr. Johns had some difficulty about what was meant. We can understand the crate, but the rack we must try and keep from our bees.—N. P.

COMMITTEE-MEN.

[770.] Though a new member of the B.B.K.A., I would respectfully make a suggestion on the above subject which has occurred to me through reading Mr. J. Garratt's letter (753) with the Editor's foot-note, in the B.B.J. of the 6th January, 1887. The committee should doubtless be chosen from members who live at a convenient distance to attend the committee and subcommittee meetings, but why not allow county representatives, who are qualified members of the B.B.K.A., to be ex-officio committee-men, so that the county representatives might render assistance to the committee where the large amount of work arises, viz., when they are undertaking important work in his county?—Nota.

THE SALTAIRE EXHIBITION.

[771.] While the question is at the front as to the Yorkshire B.K.A., &c., I would just like to ask you, sir, if a bee show could not be held in Saltaire during the great exhibition to be held there. The Prince of Wales is, I believe, going to be there, so if our friend Mr. Grimshaw with his active pen could only stir up some of the bee-keepers in the neighbourhood, something might be done as regards getting an assistant-secretary, seeing the whole county is too large for one, or, if it could be done, to be divided into parliamentary divisions, which is very feasible. Hoping something will be done, as to the show to be opened, I believe, in May next.—Samuel Watson, Brighouse.

[The Secretary of the B.B.K.A. informs us that he has had some correspondence with the secretary of the exhibition alluded to by our correspondent. The B.B.K.A. anticipate no difficulty in securing such an exhibit, providing the executive of the Saltaire Exhibition will provide the necessary attendance during the time.—Ed.]

BEE-CONCILIATORS.

[772.] I think most people agree that prevention is better than cure, and if Mr. Cheshire has discovered a means of preventing stings while manipulating, he has given a boon to the majority of bee-keepers by making it known in the generous manner he has done.

In the past and at the present time bees are looked apon as so many incorrigible 'demons,' or 'fiends' (see Journals), and we have therefore employed none but drastic measures, believing that anything of a mild character would be incapable of coping with their terrible diabolical natures. We have not studied their requirements, their rights, their claims, their feelings, but have driven, coerced, and even slaughtered them. Patrotism with bees is a crime. To defend home and stores a greater crime still. They must be subjugated. And how? Why, like unarmed rebels before soldiers, bayonets, sent head over heels, followed by volumes of burning smoke, or Mr. Webster's pleasant carbolic fumes. But with all our subjugating apparatus we get stung. What we want is peace and no coercion, and I hope Mr. Cheshire has found the remedy.

I consider Mr. Grimshaw's new coined word anything but appropriate for the 'family' he got into. 'Apifuges' would imply something to drive bees headlong in terror and confusion, and I feel sure that is not what Mr. Grimshaw wanted to discover when he commenced experiments last summer.

Now, sir, 'bee subjugators' have been used for many years, and have not proved absolutely infallible; and now we are going to try another 'law' I would suggest that it be called 'the bee conciliator.' Let us take advantage of the high development and fine, extreme sensitiveness of their olfactories, and present something of a pleasing, enchanting nature; something to move into activity

those gentle, amiable, social properties they possess, and at the same time subduing all pugnacious propensities. I feel certain such a remedy will be found, if it is not already.—A. GREEN, Selston, Alfreton.

THE BEES OF PALESTINE.

(Extract from Natural History of the Bible. By H. B. Tristram, M.A., LL.D., F.R.S.)

The honey-bee and honey are frequently mentioned in Scripture, and bees were, from a very early epoch, reclaimed and kept in hives, as well as sought for among the rocks. The hive-bee of Palestine much resembles our own Apis mellifica, and still more closely the hivebee of Italy and Southern Europe (Apis ligustica), but is decidedly smaller, and of a much lighter colour. The swarms, or colonies, are also generally more numerous, and the cells of the combs are of course a little smaller, while the combs themselves are frequently of great size and weight. It is the Apis fasciata of Latreille; and now, as of old, is quite as abundant in a wild state as reclaimed. Indeed, the wild bees, of precisely the same species, are far more numerous than their hived relatives, and the greater quantity of the honey sold in the south of Palestine is obtained from wild swarms.

Most of the allusions to bees in Scripture refer to these unreclaimed stocks, which when robbed attack their plunderers with great fury. In some parts of India so enormous are the swarms of wild bees, that there are ravines which it is impossible to traverse, owing to the fury of their attacks. The Amorites, which dwelt in that mountain, came out against you, and chased you, as bees do' (Deut. i. 44). 'They compassed me about like bees' (Ps. cxviii. 12). 'The Lord shall hiss for the fly that is in the attermost part of the rivers of Egypt, and for the bee that is in the land of Assyria' (Isa. vii. 18). In this passage allusion appears to be made to the wellknown custom of arresting bees by loud sounds, a custom which has come down from the earliest times, and is practised among ourselves in the tinkling and jingling of iron utensils to induce a swarm to settle when it has left the hive. The word 'hiss' alludes to the call to attention universally used in Eastern countries, which, instead of 'hallo,' or 'hey,' is always 'hist' or 'hiss.'

The abundance of bees of old is attested by the frequent mention of the Land of Promise as 'a land flowing with milk and honey' (Deut. viii. 8). Few countries are more admirably adapted for bees than this, with its dry climate and its stunted but varied flora, consisting, in large proportion, of aromatic thymes, mints, and other labiate plants, as well as of crocuses in spring; while the dry recesses of limestone rocks everywhere afford shelter and protection for the combs. Thus, the rocks are generally spoken of as the treasure-houses of the bees: 'With honey out of the rock should I have satisfied thee' (Ps. lxxxi. 16). Wild honey is also found in trees. Thus, 'All they of the land came to a wood; and there was honey upon the ground. And when the people were come into the wood, behold, the honey dropped' (I Sam. xiv. 25, 26).

In Judges, xiv. 8, we read of a swarm of bees taking up their abode in the carcass of the lion which Sauson had slain, upon which he propounded his riddle: 'Ont of the eater cometh forth meat, and out of the strong cometh forth sweetness.' We must not suppose that the carcass was a putrid and corrupt mass, for in the dry season the heat will speedily render a carcass in that climate a mere mummy without any offensive smell until it is moistened, and the ants speedily clear away all the softer parts of the body, if any are left by the vultures, so that merely the skeleton and hide would remain. Even in this country, wrens and sparrows have been known to make their nest in the body of an exposed crow or hawk.

In the wilderness of Judaca, bees are far more numerous

than in any other part of Palestine, and thus honey was part of the homely diet of the Baptist in the desert, as it is to this day among the Bedouins, who squeeze it from the comb and store it in skins. Such stores the meu possessed who petitioned Ishmael for their lives on that account: 'Slay us not, for we have treasures in the field of honey' (Jer. xli. 8).

Honey was from the earliest times an article of commerce from Palestine. It was among the delicacies sent down by Jacob with his sons to the governor of Egypt (Gen. xhii. 2), and is mentioned by Ezekiel among the commodities exported to Tyre: 'Judah, and the land of Israel, they were thy merchants: they traded in thy market . . . honey' (ch. xxvii. 17). It is probable that in several passages honey (Heb. debash) stands for the Arabic 'dibs,' the sweet syrup made by boiling down the juice of the grape to the consistency of treacle; but in most instances bees' honey is undoubtedly intended. Wax was also employed for various purposes, but not, so far as we know, for candles. It was an ingredient in various ointments and perfumes.

The method of keeping domesticated bees has probably not varied from the earliest times, and they are reared, especially in Galilee, in great numbers. The hives are very simple, consisting of large tubes of sun-dried mud, about eight inches in diameter and four feet long, closed with mud at each end, having only an aperture in the centre large enough for two or three bees to pass at a time. The insects appear to frequent both doors equally. These tubes are laid in rows horizontally and piled in a pyramid. I counted one of these colonies consisting of seventy-eight tubes, each a distinct hive. Coolness being the great object, the whole is thickly plastered over with mud and covered with boughs, while a branch is stuck in the ground at each end to assist the bees in alighting. At first we took these singular structures for orans or hen-houses. The barbarous practice of destroying the swarms for their honey is unknown. the hives are full the clay is removed from the ends of the pipes, and the honey extracted with an iron hook; those pieces of comb which contain young bees are carefully replaced, and the hives then closed up again. Honey, wild or from hives, is always to be purchased, and it is used for many culinary purposes, and especially for the preparation of sweet cakes. It has the delicate aromatic flavour of the thyme-scented honey of Hybla or Hymettus.

But, however extensive are the bee-colonies of the villages, the number of wild bees of the same species is far greater. The innumerable fissures and clefts of the limestone rocks, which everywhere flank the valleys, afford in their recesses secure shelter for any number of swarms; and many of the Bedouins, particularly in the wilderness of Judea, obtain their subsistence by beehunting, bringing into Jernsalem skins and jars of that wild honey on which John the Baptist fed in the wilderness, and which Jonathan had long before unwittingly tasted when the comb had dropped on the ground from the hollow tree in which it was suspended. When we see the busy multitude of bees about the cliffs, we call to mind the promise: With honey out of the stony rock would I have satisfied thee.' Amidst all its desolation the Land of Promise is, even to the present day, 'a land flowing with honey.'

The Orientals have a sweet tooth, and are in the habit of eating honey to a degree that would nauseate a Western stomach.

The Word of God is frequently compared in Scripture to honey for its sweetness (Ps. xix. 10, &c.) Deborah (bee) was a favourite and appropriate female name (Gen. xxxv.)

The number of species of humble bee in Palestine is very great, and mason bees are especially numerous, but their stores of honey are too inconsiderable to have been an object of search.

Queries.

Queries and Answers are inserted free of charge to Correspondents When more than one query is sent, each should be on a separate piece

of paper.
Our readers will greatly oblige us by answering, as far as their knowtage and because one greatey owage as og answering, as far is their know-ledge and observations permet, the Correspondents who seek assistance. Answers should always bear the number and title placed against the query replied to. Any queries unanswered in this way will be answered by the Editor and others.

[773.] Managing Stock on an Allotment Garden, -As sometime I may want to take some bees down into an allotment garden, I should be glad of the opinions of others as to the best way of managing a few stocks so as to run the least risk of losing swarms. I should not be able to go to look after them in the daytime, and only occasionally in the evening, as most of my spare time will be taken up among my bees at home. I do not particularly mind whether I work them for comb or extracted honey?-John Walton.

[774.] Separation of Wax from Pollen, &c.—Can any reader of the British Bee Journal inform me how I can separate the wax from old combs, pollen, &c.? Is there no cheap waxextractor to be got that would be useful to a cottager? or can I have one made, and what about the price? I have tried the boiling process mentioned in your last number, and find it a very tedious job. It is a great waste to throw all old combs away, and I am not able to purchase an extractor at prices advertised.—A. S.

NOTICES TO CORRESPONDENTS & INQUIRERS.

All queries forwarded will be attended to, and those only of personal interest will be answered in this column.

- J. B.—Treatment.—In the first place we think you erred in putting sections on your swarm, as the honey flow must have been nearly over at the time of putting them on. Secondly, when putting into winter quarters each comb should have been examined, and the bees confined by division hoards to as many combs only as they could cover, and, not having sufficient stores for winter, should have been fed. We advise you to leave them entirely alone, i.e., not to disturb, or even touch the hive, until a fine warm day enables you to raise the quilt, and, if food is required, place flat cakes of soft candy on the top of the frames, and cover up with dry and warm quilts. We think you will find the bees alive, but probably requiring food. The few dead, of which you speak, may be accounted for by the normal winter mortality. With the above exceptions your treatment was correct.
- S. L. B.—Carniolans.—You can prevent these from swarming by giving them plenty of room, and carrying out the instructions given in the pamphlet. If you refer to the article you allude to, you will see that we stated that, ' by giving plenty of room we were able to control them,' and that we did not given them up solely on account of their swarming propensities, but because we found other bees superior to them.
- W. (Salisbury).—1. Distance of Frames. We place our frames wider apart for winter, so as to get a larger number of bees to cluster compactly between each comb. It does not matter how thick the store combs are. Ours are usually $1\frac{1}{4}$ to $1\frac{\pi}{2}$ inches thick. 2. Doubling.—When doubling, as soon as the two lower hives are filled with bees, and before they become too crowded, add a third or a fourth if necessary. 3. Stands.—The hives are on low stands, and are, when piled up, much too heavy to be turned over by the wind. 4. Empty Combs.—If you have empty combs, you should use these in preference, to brush the bees back upon. Failing combs, you can use foundation. You must make sure of brushing the queen into the bive. 5. Position of Apiary .- Our neighbourhood is a good one, but we attribute our uniform harvests to the use of young queens only, which we breed by selecting only the best, and destroying all those not up to our standard. We should not expect black bees to give us quite as much, but even these can be improved by selection in breeding.

Business Directory.

For the use of Manufacturers and Purchasers of Bec-

keeping Appliances.

The Name and Address and Business of any Manufacturer will be inserted in this List, under one heading, for One Pound per annum. Additional headings, Five Shillings extra. Advertisers in 'The Bee Journal,' whose orders amount to Five Pounds per annum, will be inserted Free.

The British Bee Journal,

EDITED BY

THOS. W. COWAN, F.G.S., F.R.M.S.,

Containing upwards of 600 pages, with numerous Illustrations, and Complete Index.

Bound in Cloth, price 10s. Cloth Cases for Binding, 1s. each; post free, 1s. 3d.

KENT & CO., 23 PATERNOSTER ROW, LONDON; J. HUCKLE, KINGS LANGLEY, HERTS.

> HIVES AND SECTIONS. <

EFORE ordering their season's requirements, Bee-keepers will do well to notice prices of Hives, Sections, Foundation, &c. &c., supplied by THE BRITISH BEE-KEEPERS' STORES, 23 Cornhill, London, E.C. This Central Depôt (opposite the Royal Exchange) will, it is hoped, prove a convenience to Bee-keepers who may be in the City for a time, or in business.

Arrangements have been concluded with Mr. D. A. Jones, of Canada, for the supply of the celebrated 'JONES-HEDDON' HIVE,—the Hive of the Future,—and the various improved Half-pound and Pound SECTIONS, as exhibited by him at the Indian and Colonial Exhibition. The construction of these sections is such as to enable the bees to pass freely from one section to an adjoining one, and experience has shown that they are filled more rapidly and completely than the old sort in common use in Great Britain. The sizes of the sections kept in stock will be— $4\frac{1}{4} \times 4\frac{1}{4} \times 2$, $4\frac{1}{4} \times 4\frac{1}{4} \times 1\frac{1}{2}$, $4\frac{1}{4} \times 3\frac{1}{2} \times 1\frac{1}{2}$. The old kind, with closed sides, will also be kept in stock and sold at the same prices as the other kinds, but the kind advocated by our Canadian friend are strongly recommended by us to purchasers. Those who intend exhibiting should not fail to use the new kind. These Sections are made of the best basswood, and will be found superior to, and of better finish than, those of American manufacture.

The 'JONES-HEDDON' HIVE

Including bottom-board; queen-excluding division board, made of wood and perforated metal; cover; two six-inch brood-chambers, each containing eight frames; two surplus arrangements filled with sections, both with wide frames. Made of good sound Canadian Pine. Price, painted and complete, 17s. 6d.

The brood-chamber is in two sections; also the surplus arrangement, which may be interchanged or inverted at will. The cover, bottom-board, and top and bottom of each sectional case has one half of a regular bee-space, so that the surplus cases, with the sections, may be placed between the two brood chambers, or the latter part may be transposed or inverted—in fact, all parts of the hive are perfectly interchangeable.

THE 'JUBILEE' HIVE,

Double-walled, of good Canadian Pine, planed and with frames; to meet the requirements of Cottagers and others. Price, 5s.

Surplus arrangement for same, combining lift and super for sections. Price, 1s. 6d.

The 'IMPERIAL' HIVE, for Doubling.

This hive has been so arranged that the inner walls on which the frames in the upper tier rest, can be taken out and the hive used for sections, if required. For wintering, the upper storey is inverted and slides down over the body of the hive, thus forming a very compact, (practically) treble-walled hive. Price, 12s.

The 'Jubilee' and 'Imperial' Hives have been specially designed by Mr. D. A. JONES, the well-known Canadian Bee-keeper, in conjunction with leading British Apiarists. We hope this fact in itself will be a sufficient recommendation of the goods and a guarantee of their quality.

SAMPLE SHIPMENTS EXPECTED ABOUT THE MIDDLE OF FEBRUARY.

The CANADIAN Improved One-pound and Half-pound One-piece V-cut SECTIONS

Of best basswood, in original Cases of 500 Sections, at 11s. 3d. per Case.

SPECIAL—In order to facilitate our arrangements for supply of large consignments, and thereby reduce the cost of transport, we will allow a DISCOUNT OF FIVE PER CENT on all Orders for HIVES and SECTIONS received before 25th March. Orders will be executed in rotation, so please order early. No deposit required with order, but payment to be made before delivery, when purchaser receives notice of the goods being ready for despatch.

The British Bee-keepers' Stores, 23 Cornhill, London, E.C.

Editorial, Notices, &c.

BRAZILIAN BEES.

The last volume of the Journal contained various inquiries respecting the bees to be found in Brazil, which were not, however, satisfactorily answered. Some light has been thrown on this subject in a work recently published in two volumes entitled, Three Thousand Miles through Brazil, by J. W. Wells (Sampson Low). Mr. Wells was a civil engineer engaged in extensive surveys in the vast country of Brazil, and these volumes record the story of seventeen years of his life passed in the exercise of a profession which carried him over a very considerable portion of the country, and brought him into intimate relations with all the phases of Brazilian life. These years were passed in farms, in huts, under canvas, or with only the starlit skies for a canopy; riding, tramping, boating, canoeing, or rafting on many streams and rivers. Great varieties of climate were met with in these peregrinations.

The volumes do not record a specialist's researches and discoveries, but merely an engineer's matterof-fact experiences. In his life in the woods, the campos, and the marshes, he several times came in contact with the bees of that country. are generally the stingless bees (sp. Melipona), which are so frequently met with in Mexico and other parts of the American continent, but he also describes some singular bee-nests, the homes of

bees which are 'terrible stingers.'

When surveying his first section, in the Rio Paraopera, he came across some bees which are called Mandrasia bees. He says :-

'There are many varieties of small black bees, not larger than a common house-fly—good charitable bees that make excellent honey and do not sting; rarely a day passed but we found a nest of the mandrasia bee. really wonderful how the men found them out; I believe I might have spent a week in the woods without discovering a nest. It is only done by watching a bee when it hovers around a tree-trunk without apparently any ostensible purpose; suddenly it will disappear, and an accustomed eye may be able to distinguish a small hole in the trunk not larger than a pea, and on tapping the tree it will be found hollow in the vicinity of the hole; if the tree is felled and the hollow excavated with an axe, the cavity will be found to contain a mass of balls of thin brown wax, about the size of a large walnut,

and filled with deliciously fragrant honey far superior to that of the common English bee. The bees fly about in myriads, but inflict no inconvenience beyond their stickiness, for they are so sticky that they seem as though they have just emerged from a honey-pot.'

In passing from Masquita to Picada, while surveying his second section, he encounters others of the same species :-

'A small black bee, common to the grass districts, is very troublesome and annoying; it does not bite or sting; it worries one by its persistent creeping and crawling by dozens over hands, face, and neck, into eyes, ears, and gets tangled in the hair. Brush away a crowd, others instantly take their places. Open your mouth, a number are ready to explore it.'

In certain parts these bees are very trouble-

'Out in the open chapador there existed a considerable annovance in the form of bees. insect buzzes not, neither does it sting or bite, but it alights on one's flesh in myriads, and devotes all its energies to systematic tickling and minute exploration; it gets into one's ears, eyes, nose, down the back, into the hair, into the clothes; perpetual slapping availeth not, for if a dozen of the sticky things are smashed, a couple of dozen are hovering round for a place to prospect upon; the nuisance can be avoided to a certain extent by wrapping one's head in gauze. Fortunately the pest did not cover a considerable area.'

When passing up the Valley of the Sapão, the author finds bees in ant-hills, with 'tons of honey:'

'That day's march was up the valley; a notable feature of the day was the number of ant-hills four to six or seven feet high,-constructed of clay originally by a species of white ant, but then occupied -- certainly one out of every three-by "the bee of the white ants." bees had turned the ants out of their quarters and domiciled themselves in their place. Without exaggeration I believe many tons of honey could be collected from these mounds; in one hill alone we extracted sufficient to satisfy the appetites of every one—even the mules had their share. The honey is found in little compact balls of delicate black wax about one and a half inch in diameter; each ball is separate and distinct from its neighbour, and the honey is most excellent in flavour. The bees of course flew about us, but were perfectly harmless; they are small and black, not much bigger than a house-fly. The mystery is how they can conquer and drive off the white ants; perhaps many a battle was fought before they gave up possession; now the bees were evidently masters of the situation. Several dozens of the mounds were examined and more than a third were occupied by the bees, but only on two or three occasions was the same mound found occupied by the bees and ants.

On the Rio do Somno, a beautiful stream in a lovely country and climate, Mr. Wells saw some curious bee-nests, which are built by another species of bee, very different from the stingless Melipona:—

'The cliffs present bare smooth surfaces of variously coloured rocks, on which a very curious structure often attracted my attention; in a full view it resembles a dark bullock's hide stretched and nailed to the wall of rock, averaging eight by six feet in length and width; sideways it appears inflated and distended and culminates in a hanging point or apex, near its lower side. These curious formations are the nests of the shupé, a bee that produces great quantities of excellent honey, but are terrible stingers; and from the position the nests are in, half way up the smooth surface of the rocks, are difficult of access unless the gatherer is enveloped in leather and lowered down by ropes from above, which is sometimes done.'

'AMERICAN BEE-KEEPERS' MAGAZINE.

The price of the American Bee-keepers' Magazine has been reduced to 25 cents (one shilling) a-year, and it is now one of the cheapest bee journals in the world. This paper was started in 1873, and was for over two years edited by H. A. King, assisted by Mrs. E. S. Tupper, Professor A. Wood, and M. E. Williams, during part of the time. It subsequently passed into the hands of A. J. King & Co., and is now edited by Messrs. Aspinwall and Treadwell, who are both practical bee-keepers, as may be seen from their articles. The Journal has been very much improved since it was first started, and now contains practical articles by the leading American bee-keepers. We are able to judge of the improvements, as we have subscribed to it regularly since the first number was issued. Whilst wondering how they can print and circulate a journal forming a volume of over 400 pages at so low a price, we congratulate the proprietors on their enterprising policy, and wish them every success.

USEFUL HINTS.

WEATHER.—'First it hailed, then it blew, Then it friz, then it snew, Then there came a shower of rain, Then it friz and snew again:'—are lines which well describe English weather during the last five or six weeks; and although we have now a decided thaw, nevertheless it is a very cold one, and on the higher grounds, under hedges, and other places, the wreaths of snow still remain, 'waiting for more,' as our weather prophets say. We scarcely remember a winter more calculated to try the various systems of autumnal preparations for wintering; and where these have been faulty, or have not been made at all, especially where the supply of food has failed, the results will prove disastrous in the extreme.

Examining Hives.—No doubt we shall all be anxious to ascertain the condition of our colonies at the earliest possible suitable moment, but we must put in our caveat here, and deprecate any interference whatever with hives or colonies until that moment arrives. There is, perhaps, no kind of interference more injurious to bees than too early examinations after long and severe frost, when the abdomen is distended with fæcal matter, and when the slightest excitement will assuredly cause an outbreak of dysentery, which if the bees had been left to themselves might never have occurred at all.

What to no.—Until mild settled weather arrives—weather in which bees can the freely—let us content ourselves by keeping entrances clear, supplying soft

candy, where required, under quilts, by changing quickly damp quilts for dry ones, and by carefully looking to roofs and covers, and guarding against leakage, or snow penetration; all of which operations may, with care, be performed without the least jarring or disturbance. Where moveable floor-boards project beyond the hives, the projections forming a lodgment for snow and rain, and causing internal dampness, we advise a change for

Ventilation and Dampness.—As regards ventilation and dampness, however, as in most other matters, opinions vary. Professor Cook tells us that he sealed a large colony of bees with ice, frozen solid, at the entrance of the hive, that the colony remained thus, and also entombed in a snow-bank, for more than three months, and wintered exceptionally well. As the hive was glued, or propolised, at the top, he remarks that the ventilation must have been slight indeed, and hence he draws the inference that, under the best conditions, little heed need be given to ventilation. He tells us also that even during terribly disastrous winters bees have wintered in many cases remarkably well in very damp cellars.

From Mr. Heddon, too, we have the statement, 'In all my varied experience and observation I have been unable to discover any ill effects from dampness, of itself. We ourselves are wintering all our colonies under enamel-cloth, which allows of little or no upward ventilation, and we all know that bees, in a state of nature, so propolise the interior of their domicile as to render it impervious to air or moisture.'

Crown-boards v. Quilts. — Dr. Southward, who possesses a large apiary in Michigan, U.S., and has been very successful in out-door wintering, uses the old-fashioned wooden crown-board, which the bees propolise and glue down tightly. Over this he places chaff packing; and in the very severe winter of 1884-5 he carried

through his large apiary with almost no loss.

May it not be said to those, therefore, who adopt the practice of placing absorbents in the shape of pervious coverings over their bees—Aquilam volure docetis, which naughty boys translate as having reference to grand-mothers and eggs? We have repeatedly noticed that colonies left unmanipulated in the autumn, with quilts or crown-boards well propolised, have wintered perfectly and have been amongst the foremost hives at spring.

'Packing.'—Those who are in favour of the pervious quilt will no doubt be able to bring forward advantages possessed by it, but wherever it is used successfully we think it will be found that a good deal of outer packing —of sawdust, claff, cork-dust, or even boards—has been called into requisition.

FEEDING SKEPS.—In feeding colonies in skeps a large feed-hole—say of four inches diameter—is an advantage, since over this a large cake of warm soft candy may be placed, and will be taken with avidity by the bees.

The quantity of food contained in a skep may generally be pretty accurately determined by its weight, when halanced in the hands of one who knows its age and history, without breaking it off from the floor-board, which should never be done during the winter, as skeps are propolised more firmly to the floor-board than are frame or box-hives of any description; and it is best that they should remain so, having the entrance sufficiently large to admit of free ventilation, and to be kept clear of refuse.

Crossing the Various Races.—Since our remarks on this subject appeared in last 'Hints,' we have received the January number of the American Apiculturist, in which are some very able and suggestive papers by well-known apiarists on the methods of breeding bees in order to perpetuate desirable qualities.

BREEDING FOR QUALITIES.—Naturally the chief points to be considered in the solution of such a problem as breeding for qualities, are the prepotency of the queen

or the drone as regards certain points or characteristics, such as working qualities, temper, adherence to combs when under manipulation, comb-building, fecundity, &c. Dr. Tinker, who has given much attention to breeding, gives it as his opinion that 'the drone is prepotent in transmitting working qualities, disposition, and the form and size of the male progeny; while the queen is prepotent in transmitting fecundity; comb-building faculty; peculiar maternal instinct; and the form and size of the female progeny.'

HEREDITY.—He is careful to state that no rule in the heredity of bees is invariable, but exceptions, which establish rules, occur in the heredity of all the animal creation; these exceptions are, however, so few that the rules can be depended upon in developing a superior strain of bees. He also goes so far as to assert that 'the coming bee will be a cross-bred bee, developed from Syrian or Cyprian mother stock: the cross will be with Italian drones.' Mr. Demaree, writing on the same subject, says, 'I look to my breeding queens for the peculiar type of workers I want, and to the drones for

temperament.

When in last 'Hints' we stated that the cross between Cyprians and Italians was one of the best, if not the best, we omitted to say that the cross alluded to was from a Cyprian mother and an Italian drone. Our Syrio-Italian crosses have also been from Syrian queens mated with Italian drones, both crosses having proved excellent workers and of gentle disposition. Under manipulation they are very quiet, closely adhere to the combs, and rarely show any disposition to attack. The cross between the Syrian queen and the black drone is also a good bee, but more uncertain in temper than the two former crosses. The above remarks refer only to the first crosses, but we have no doubt that their good qualities may be transmitted to their progeny by careful breeding and selection.

We should like to see our queen-breeders advertising queens thus mated, being well assured that no better bees, or bees better adapted to the English climate, than the progeny of such queens exist. It must be generally conceded, particularly in times of depression and severe competition like the present, that attention should be given to producing a superior race of bees as well as to improvements in appliances. In this matter there can be no doubt that other nations — e.g., Germany and America—are far in advance of us. Is it not a fact that there is not a single isolated apiary in this country where any particular race of bees can be bred in its purity? We are aware of the various means by which, without complete isolation, queens may generally be caused to mate with selected drones, but there is always a doubt, hence the prevalence of the importation of queens into the country, many of which are of inferior quality. We do not even avail ourselves so far as we know of the best appliances for procuring pure fertilisation, such, for instance, as 'Alley's drone and queen trap,' which ought to be in use in every apiary professing to breed queens of specified races, even if possessed of an isolation of a two or three miles radius. Hence the constantly recurring complaints of hybridised queens being sent out as pure. Certainly there is room for improvement here, especially in the 'selection of the fittest' both as regards queens and drones. These remarks apply not only to one race, but to all, since our native black bees, or German brown, ought always to be bred by selection.

DRY HIVES.—Our previous remarks on dampness must not be misunderstood, or misconstrued into an approval of keeping hives in a state of perpetual dampness. We have quoted authorities to show that, under certain conditions, it is not injurious for a time at least, and this we did with a view to discourage too early, frequent, undesirable spring manipulations. But where dysentery exists, or hives have become saturated with moisture, or

combs mouldy, nothing more conduces to the recevery of the bees than a change to a clean, dry, warm hive, with an application of warm porous quilts as soon as weather will permit; and in extreme cases, weather failing, manipulation should be performed in a warm room, the hives being returned to their stands in the evening, when it is too late for the bees to fly. This is much better than allowing the bees to perish in foul, dysenteric, damp hives. In such cases we always operate indoors by lamplight, and at night, when scarcely a single bee leaves the combs or becomes excited.

Syrup-Feeding.—A Warning.—Let us warn our readers against syrup-feeding for some time to come. The only admissible food, before the end of February or middle of March—according to the weather—is sealed comb-honey, candy, or dry sugar. Several cases of destruction of colonies by syrup-feeding have already come under our notice. The bees become excited, and with distended abdomens, perish, or, attempting to fly, never return to the lives. If the food is consumed in cold weather, befouling and besmearing the combs and interior of the hive with swollen bodies, they fall, and decomposition increases the evil. Frames of scaled honey should be slightly warmed before being placed at the side of the cluster, a centre hole being cut in the

comb as passage-way for the bees.

PREPARATIONS.—Again, we advise all, especially those possessed of the larger apiaries, to make preparation for the approaching campaign-hives, sections and cases, foundation, and fixing the same in frames and section boxes-may well and profitably occupy spare time in the evening or otherwise. Hives which have been previously in use should be scraped thoroughly clean, disinfected, and repainted. Spare quilts and floorboards should be kept dry and ready for use. Removal of hives to new positions may be made, and apiaries set in order, and kept neat, no accumulation of 'odds and ends' being allowed, nor refuse of any kind. Where not objected to, sawdust spread around the hive is beneficial, absorbing moisture and preventing the chilling of bees which settle upon it. Many other little matters, toe numerous to mention, will occur to those who give thought and time to their bees.

'AMATEUR EXPERT' WAKES UP AND 'JOTS.' 'Mel sapit Omnia.'

Hybernating! 'A. E.' hybernating! No, no, friend J. Walton. It is with me, as it was with that immertal son of Vulcan,—

'Toiling, rejoicing, sorrowing, Onward through life he goes; Each morning sees some task begun, Each evening sees its close; Something attempted, something done, Has earned a night's repose.'

And then, besides that, 'Mel sapit Omnia' with me. And so you wish to savour your new hive with 'mel.' I thank you for the compliment; put the words on, by all means.

Since I 'jotted' last I spent a most enjoyable day with Mr. and Mrs. Jones and Mr. Corneil, who came dewn to my 'hive.' I showed them some of my local 'lions,' which included a real primitive English apiary, a herd of shorthorn cattle, a nobleman's park and grounds, as well as a portion of the inside of the mansion, one of the finest private collections of old paintings in the kingdom, a real live Earl, and—would you believe it?—an oak with the largest girth round the butt they had ever seen. Chalk that, please; that is one point for the old country.

As the pheasants flew up he would call out for his shooting-iron, for, be it known, a mighty hunter is D. A. Jones. Our evergreens, most of which were new

to them, gave them unbounded delight; and to get clear of the fogs of London, and see the clear vault above them once more, gave them a far better character of an English winter than they had begun to entertain. I packed them up some few samples of seeds of things they saw, also sprays of various evergreens-holly, ivy, and mistletoe. Even the old people over yonder will feel young at the sight. One who left here when twenty years of age begged that a spray of holly with berries might be brought back to her. How one's heart goes out to them at the thought! The Atlantic now rolls between us, but space can never divide hearts that are knit to-But the leave-taking came at last—a true gether. Canadian one—and now they are at home once more, amongst kindred and friends.

I have heard from Mr. McKnight, who is full of 'recollections of the enjoyable time they spent in dear old England.' May none of us say a word that shall mar the pleasure of those recollections.

Now I predicted that we should all want to rush off and change our hives and appliances that we have proved for those that we have not, and this seems very near being realised. Let us, by all means, 'prove all things,' but, at the same time, take especial care to 'cleave to that which is good.' I know of a ploughman that complained of his plough, and the farmer sent for the maker, who could not only make a plough, but guide it as well as a few men. Having gone a few furrows with it himself he told the farmer-a modern one, seated on his hunter—the plough had a serious fault, but it was all behind the handles. Well, it is much like that with our hives. Capable of improvement they are, but the chief fault, speaking metaphorically, is 'behind the handles.'

I am highly delighted to see our esteemed friend, Mr J. Lee, keeps his pen from getting rusty.

You will not give me much more room, but I am inclined to think if I wanted to work an 'off' apiary as Mr. J. Walton suggests, I should 'clip the queen's wings,' put the hives on very low stands, and have alightingboards right down on to the ground.

As to that Holyland queen, thereby hangs a tale. I am not quite sure, but when I closed up in October there seemed every probability of my having a case for Mr. Cheshire, probably of arrenotokia. (What words these men of science find for us!) I have not yet quite shaped all my 'burning deeds and thoughts,' but must bring these discursive 'Jottings' to a close by wishing you all 'A very happy new year.'—AMATEUR EXPERT.

SPAIN.

In a letter addressed to the Bulletin d'Apiculture de la Suisse Romande, Mr. Fr. Andreu, of Mahon, Minorea, writes as follows:—'The bee flora of this island is rich in honey and in variety. The only enemy which bees have to contend with are the northerly winds, which are terrible. There are plenty of old-fashioned apiaries ranging from forty and a hundred hives each, but only a very small profit is derived thereform, the hives being very much neglected and the cottagers ignorant of the art. The introduction of the new hives will revolutionise Spanish apiaries, particularly in these parts of the country. Then will the good quality of our honeys be appreciated abroad, which deserve to be better known than they are at present. When we first imported new hives from England, a few years ago, they proved to be a new article to everybedy; but the earliest results obtained with them were so good that they soon became a subject of general conversation and of articles in the press. Several bee-keepers adopted our hives as soon as they had seen the advantages they offered and the results we obtained from them.

'We have every reason for being satisfied with the results obtained last season, one hive having brought in 125 francs, or say an average of 90 francs per hive, although a great many of them had only been stocked of late. At present, however, they are all well provisioned with plenty of brood, so that better things are to be expected from them next season.
Our hives are mostly square in shape and on the

supering system.

Generally speaking, everything new here in Spain is criticised, particularly anything relating to agriculture, but thanks to the good results we are obtaining and our offers to assist in anything we can, bee-keeping is attracting more attention than heretofore. There are already a number of small apiaries in this island, where the new system of hives predominates, and many are projected on the mainland.

DEVON AND EXETER BEE-KEEPERS' ASSOCIATION.

TORQUAY BRANCH.

The annual meeting of the above took place on Thursday evening, January 13th, in Wood's Rooms, Torquay. The report and statement of accounts were read and adopted, the accounts showing a balance in hand of nearly 4l. Mr. Masters proposed and Mr. Vallance seconded that the following should form the Committee for this year: Messrs. R. Kitson (chairman), II. Bradshaw, W. Winget, Rev. W. B. Davis, Messrs. G. Pullen, J. Coombes, J. French, and G. Vail, Hon. Sec. It was resolved that the meetings be held quarterly. Mr. Winget proposed a vote of thanks to Mr. Kitson for all his work during the past year, which was seconded by Mr. French.

Correspondence.

The Editor does not hold himself responsible for the opinions expressed by his correspondents. No attention will be taken of anonymous communications, and correspondents are requested to write or one side of the paper only, and give their real names and addresses, not necessarily for publication, but as a guarantee of good faith. Hustrations should be drawn on separate pieces of paper.

Communications relating to the literary department, reports of Associations, Shows, Meetings, Echoes, Queries, Books for Review, &c., must be addressed only to "The Editor of the "British Bee Journal," c/o Messrs. Strangeways and Sons, Tower Street, Upper St. Martin's Lane, London, W.C.' All business communications relating to Advertisements, &c., must be addressed to Mr. J. Huckle, King's Langley, Herts (see 2nd page of Advertisements).

****In order to facilitate reference, Correspondents, when speaking of any letter or query previously inserted, will oblige by mentioning the number of the letter, as well as the page on which it appears.

BEE-KEEPING IN SPAIN.

[775.] Bee-keeping is still carried on in the old-fashioned style in Spain, and amongst the bee-keepers there are very few indeed who use modern hives. The hives in general use are most varied in form and in the materials from which they are constructed. Some are round, others square or long and are made of cork, basket-work covered with mud, straw and wood, and even hollowed trunks of trees are commonly used.

In all Spain there are only three or four provinces where bee-keeping is carried on largely as a business, more especially in the Alcarria, where almost every village of any importance possesses from ten to twelve colmenares, each of these containing from thirty to forty hives (colmenas). A colmenar [what we should understand as a bee-house.—Ep.] is a small structure of brick. Up the centre of this building is a passage into which open the doors on either side of it of the fifteen or twenty compartments which contain as many hives. Outside are generally placed two or three common hives to receive any of the swarms that may leave the hives in the colmenar.

In the Alcarria the laws for the protection of hives

are very stringent. The bees are also frequently moved from one locality to another to lengthen the honey harvest. In the other provinces landed proprietors and farmers generally keep from two to six hives, but this is principally either for their own use or for amusement.

Bee-keeping is still in a primitive condition, and not much attention is given to the bees. They are selected and purchased and their surroundings are kept clean, but they are then left entirely to themselves. They are in no way assisted, and are allowed to work in their hives just as they like without any interference on the part of the bee-keeper.

Lately a few Spanish gentlemen have purchased from abroad modern hives made on the improved systems; but this has been more for curiosity and for their own amusement than with the object of their general application.

Like most of our large landowners, Mr. M—— and his brother Count de B—— are amateur bee-keepers; but as a member of several agricultural societies Mr. M—— takes a very great interest in such matters, and having read the French translation of your excellent work (the British Bee-keeper's Guide-book) thought it might be very beneficial to propagate the new methods and sound teaching it contains amongst our agriculturists.—C. Wellen-Kamp, Chaftan Mallorga.

[The Spanish translation is already in the press, and will be ready in time for the work of the spring season.

—Ed.]

WAX-MELTING.

[776.] A lady correspondent is in trouble about melting her old combs, and no one of our many gentlemen bee-keepers seems to have sufficient chivalry to help her. I have not time just now to write much, but will tell her what I can in a few words.

If you are fastidious don't take the job in hand, it is 'messy' from beginning to end; but if you do not mind a little mess you will like the wax when you have clarified it. Get a large saucepan and boil all your old combs in it, until all the wax has left the pollen and other débris. Next get a piece of cheese-cloth, or other strainer that you do not much value, tie it rather baggy' over a pan, and pour the contents of the saucepan on to it; you will then get the water and wax in the pan and the debris on the top of the strainer. If the bees are not flying, burn the latter out of the way or bury it, which you prefer; when the contents of the pan are cold the wax will be on the top, and you can remove it from the liquor, and of course throw the latter away. I have a tin baking-dish that holds about a quart, into this I put some water and also the wax, first removing any impurities that might have settled on the underneath side of it. I now place this vessel inside a saucepan with some water in the latter, but not sufficient to make the tin containing the wax to float about. Now make the saucepan hot, but not boiling, and keep it hot as long as you can, but do not let it boil, and the longer you keep it hot, and the slower you allow it to cool, the clearer your wax will get. You may stand the tin dish and its contents in the oven if you have a kitchener; but it is risky: you must watch the heat, and be sure to keep it covered or you will spoil the colour by making it dark. The impurities will again have settled, which you must remove. I wanted to say something about foundation making and spoiling, but have not time, and perhaps some would vote me a nuisance and meddler; but if this is any help to 'A. S.', or any in trouble like her, it will have answered the purpose of—AMATEUR EXPERT.

SUSSEX AND YORKSHIRE,

[777.] It is very probable that in the course of a few weeks I shall, for business reasons, be obliged to remove my place of abode from this my native county (Yorkshire), to the southern one, Sussex, and shall feel obliged

if any reader of this Journal, who is acquainted with the neighbourhood of Petworth in that county, would give me some information under the following heads:—
(a) Nature of bee flora in the district. (b) Time of honey harvest in an average scason. (c) Prevailing winds. (d) Is there any heather near and at what distance? Any other remarks likely to be useful would be gladly welcomed.

Now a few words as to Yorkshire. I regard it, Mr. Editor, as a blot upon the reputation of this county of broad acres that its Association should be so inactive, to put it mildly. I have heard of the County Secretary once, and then it was only casually through a friend who had heard of a visit he paid to an apiary or apiaries in Ryedale. The district round here is a very good one for bees, and bee-keepers are multiplying yearly, until sections, which before the Royal Show of 1883 were an unknown commodity here, are now getting difficult to sell.

When I first heard of County Associations some three years since, I naturally expected that Yorkshire would possess a good one, but was disappointed to find, after some inquiry, that it existed 'somewhere in the West Riding.' Its existence must be infinitesimally microscopical, seeing that our energetic friend, Mr. Grimshaw, cannot 'spot' it. I hope he may be successful in galvanising it into life, and may he be elected district adviser.—Old Ebor.

INVERTIBLE HIVES. (766.)

[778.] I quite endorse that portion of Mr. Thomas's remarks when he says that 'many writers forget to mention that their ideas are nothing more than ideas, and that they have never really been put to the practical test.' As 'it is unfair to condemn a system without trial merely because it is new, or, perhaps, because in a single instance, and under unknown conditions, it has not proved successful,' so also is it unfair, and even wicked, to advocate the use of a certain hive for the purpose of selling it, or a certain system of management, with the experience of a single season, and with one or two lives only.

I am sure that the readers of the *Journal* as well as myself will be much obliged to Mr. Thomas if he will give us his 'own experience of the system of inversion' in detail, and will also give the names of 'the majority of those who in America have tried it,' and have 'so well spoken' of 'the Heddon system,' and in what periodicals

they have written, and when.

Å friendly discussion on the advantages or disadvantages of this hive and system in the Journal will be at any rate as useful as the long discussions as to the latest fashion of introducing a queen, and may be the means of obtaining information useful to those who think with Mr. Lee and others that it is 'best to go slow' in adopting radical changes in bee-keeping, especially for beginners, and that 'the old, experienced bee-keepers should thoroughly test these novelties first,' is the sound advice of Mr. H. R. Boordman, an experienced American bee-keeper.

Although I quite agree with Mr. Thomas that 'beekeeping on modern principles is in its infancy,' I also think that if a profit or income is desired from the pursuit, that simple, inexpensive hives, with standard frames and walls at least \(\frac{3}{4}\) inch thick, are all that are necessary to obtain success, providing always that the seasons are favourable and that the bee-keeper has fairly mastered the rudiments of the subject, and does not overmanipulate his bees, as in my opinion is generally done.

There are not a few of us bee-keepers who cannot look back with regret at useless bee furniture, &c., that we in

our novitiate have spent our money on.

I cannot, as an old bee-keeper, close these few remarks without a word of caution as to the purchase of the

Jones-Heddon hive of the substance exhibited. I will not at present say anything as to the system, as I do not feel that sufficient time has elapsed since it was introduced to enable English bee-keepers to form a sound opinion. It also appears, from the statement of Mr. Holterman, of Brantford, in Canada (in the Journal, 724), who says, 'to the best of my knowledge, and I am pretty well posted as to apiculture in Canada, that there was not one colony in the Heddon hive last winter,' that the Canadians have not any more experience in these particular 'invertible' hives than we have in England; and I venture to say that not one pound of the Canadian honey at the Exhibition was obtained from bees in a Jones-Heddon hive.

There is one thing that I, as a practical bee-keeper of thirty-live years experience, feel bound to say, that \(\frac{a}{2} \) of an inch in thickness, as in the Jenes-Heddon hive exhibited at the Conversazione at South Kensington, is not sufficient for the external walls of hives that are wintered out-of-doors in this country.

In Mr. Heddon's book, Success in Bee-keeping, he describes the thickness of his hives thus:— The end pieces being $\frac{\tau}{8}$, and the side pieces of $\frac{3}{4}$ inch lumber after being dressed on both sides, the long pieces being nailed

into the short ones.'

I would suggest to those English manufacturers who propose making hives on this plan that they should not use less than, at the least, \(\frac{2}{3}\)-inch stuff for the outside of these single-walled hives. This will be just double the thickness of the hive exhibited by Mr. Jones, one of which I hope to try next season with an outer case.—

John M. Hooker.

FOUL BROOD.

[779.] The 'Man of Kent' is amusing in his way of slashing about a scientific subject, and in the second and third paragraphs of his last letter he jumbles up my name with that of Mr. Cheshire in a very funny manner. I beg to inform him I have no agents recognised or otherwise.

As regards his replies to my question which he puts into paragraphs two and five, I do not consider either attempt any reply at all. If the 'so-called Cheshire cure' failed him because the bees would not take it 'four times stronger' than recommended by Mr. Cheshire, nobody will blame the bees or Mr. Cheshire either, but when he says in his last paragraph that all admit the Cheshire formula is too strong, I find myself in 'a fog' as he is.

No wonder his experience differs from mine and others, and that he can agree with Mr. Saddler that it is simpler to destroy the combs—and I should add the bees too—but even that he has tried without success, and the net result of his experience really is that when the bees themselves take the matter in hand and fly away to a gentleman's stable the disease is cured—

probably by ammonia.

If the 'Man of Kent' will kindly inform me how to distinguish a diseased queen from a healthy one without reference to her brood, I shall be ever grateful to him.—
Thomas F. Ward, Church House, Highgate, Middlesex, January 14, 1887.

DRY SUGAR FEEDING.

[780.] For the satisfaction of others I can endorse Mr. Simmins' plan of dry sugar feeding for or in winter, so far as regards skeps. It is not my own experience, but that of a life-long bee-keeper in Seascale. If he fears the bees are likely to run short of stores in midwinter or early spring. His plan was to fill a hand basin with raw sugar, tightly pressed down; damp the face of sugar, then reverse the basin and place the same over the crown of hive, first removing the cork or plug in the eed-hole, covering all well up afterwards,

and on next inspection always found the sugar taken clean up. I had this some four years ago, but never tested it. These skeps were within a quarter mile of the sca-shore, and exposed to storms from the west.— W. G., Rastrick.

A SMALL VOICE FROM YORKSHIRE,

[781.] Having seen it stated in the British Bee Journal that we bee-keepers in Yorkshire keep very quiet about our doings, perhaps you will give me space in the Journal to make a few remarks as to my doings in the bee line during the last nine years, as I have been a bee-keeper for a little over that time, and perhaps keep bees on a different system to most of your correspondents, I may first of all state that I have tried most plans of keeping bees, and am, I may say, a good amateur carpenter, so that I can go into the profit part of the business as a guide, at all events, to the Yorkshire working man.

I find that a hive with ten Woodbury frames is the largest that should be used for this county, and I also think that if any one has used Abbott's wide-shouldered frames they have no wish to try any others. I made a hive on Mr. Simmins' plan last year, but find the frames simply detestable, and I am sorry to have to say that, as I so heartily agree with, I may say, everything else that Mr. Simmins states. During all these years I have wintered a few single-walled hives, and find them just as good as those with double walls if the outside frames (two on one side and one on the others) are removed and dummies put in their place. This makes the hive double-walled on two sides, and I find seven frames the bees number to winter the bees on, as when confined to that space you require no chaff-cushions, slips at the ends of the frames, or winter-passages.

My first swarm last year was from a single-walled hive, although I had four skeps and seven double-walled hives. I have never found the slightest difference between the single and double, if only the bees are confined on seven combs. I use the ordinary summer

quilt.

On looking at my accounts I find that at the end of 1879 I was 40l, 17s, 4d. on the wrong side, but I then kept a good many bees and had a large stock (for me) of hives and appliances. At the end of last season I was 30l, 7s, 7d, to the good for the nine years. I have, of course, put down all the honey as having been sold, although I have given a good deal away, &c., but I am putting myself in the place of a working man, in which case, perhaps, nearly all would have been sold. A working man, however, would not have got his account so much on the wrong side to start with, as I have always tried anything new that came out that I thought worth trying.

One year I had more than twenty hives and did not get a single pound of honey, and had to spend 71. on sugar in the autumn to keep them alive. I never knew such a season, and hope I never shall again. There was not a single bee alive, the following spring, in the whole

district, except my own.

My plan of keeping bees is as follows:

Supposing I winter eight hives, and they each swarm twice, I put two swarms together, in every instance, on seven or eight frames only (according to size of swarms), and put a super on at once. This is supposing I have been able to give them old combs. If they have foundation, I put them on ten frames, feed for a few days, and then remove two or three frames and super them. This I have done for many years, and I can quite endorse what Mr. Simmins says about it at once crowding the bees into the supers.

In 1884 I wintered 8 hives, and took 550 lbs. of honey.

1885 , 7 , 600 lbs. ,

1886 , 15 ,, 350 lbs. ,

Last season was only a moderate one all over England.

The stocks, after they have swarmed, I always extract from, and I do not see that it does much harm disturbing

the brood-nest.

I have an idea that the swarms, being young bees, take better to supers. In the autumn I bring them up into pairs and join them, so that I always keep my bees strong in both summer and winter, and am never bothered with having worn-out queens. Yorkshire is not a very first-rate county for bee-keeping, so that we do not look for very great results, although 1 have taken more than 80 lbs. in sections off one hive.

Last year I tried Mr. Blow's 8\frac{1}{2} \times 1\frac{1}{4} \text{ sections, which}

work with a row of $4\frac{1}{4} \times 4\frac{1}{4}$ sections.

In every case the bees started first with the large sections, and a most beautiful shape they are. I should like them better if they were two inches wide, as I never am able to get sections built out the right weight with dividers unless they are two inches wide, which is the only width I shall ever use, and I shall certainly always use dividers.

As one of your correspondents remarked, 'We never hear anything of the Yorkshire Bee-keepers' Associa-I am not a member of it myself and do not think I should ever become one. I have often induced cottagers to start bees in frame-hives, but have always found them go back to the old skep; and with prices as low as they have become I do not think the average working man would make anything out of bees, and

certainly not unless he was a good carpenter.

If I ever joined an Association it would be for the pleasure I should have in talking over matters with brother bee-keepers, and not from any advantage I should expect to get from it. What greater pleasure can one have than talking with Mr. Abbott, say, for a couple of hours, over a good cigar?—as I have had the pleasure of doing. I fear this letter has grown longer than it ought to have done, but as I am letting off nine years' ideas in it, it seems to me miserably short, as I could go on indefinitely on such an interesting subject; but perhaps at some future time you will allow me a little more space, Mr. Editor. May 1 recommend beekeepers, during this stormy weather when the snow is on the ground, not only to shade the entrances, but to spread some loose hay, or straw, or leaves, all about the front of their hives. This will save hundreds of bees which would otherwise, if the sun came out, perish in the snow.

I fear some may think that 1 am rather dogmatic in my views and have written as if I was able and wishful to lay down the law to others; but such is not the least my desire, and my excuse must be that it is most difficult to condense a great deal into a small space without appearing to dictate. I do not altogether think it undesirable for a cottager to keep bees in frame-hives, but with present prices very few would make it pay, and

they must be pretty good carpenters.

I forgot to say that I only keep black bees. Are they hardier than other breeds, or would, say, Italians winter as well on my plan without chaff-cushions, &c.? Perhaps some one of more experience can tell me. How is it that people will go in for extractors with gearing? Mine is one of Abbott's without gearing, and if I so desired I could throw out all the brood with it. Very few turns, and the honey is out. Why get up unnecessary speed?—Arthur J. H. Wood, Bellwood, Ripon.

P.S.—I ought to state that in 1886 I bought some skeps cheap in the spring (about March), so that I did not actually winter fifteen hives. If I did not explain this it would look as if I had not followed my plan of always doubling in the autumn.

In 1885 I also had a skep in addition to the seven frame-hives, but as I sold the swarm from it, I did not count it in stating the amount of honey I took.

---A. W.

TOADS EATING BEES.—SURFACE FOR HIVES.—MISTAKE OF A BEE.

[782.] I am sorry that truth compels me to confirm the statement of Mr. Walton, that toads are very destructive to bees. The hive of a very strong stock of blacks had a small alighting-board, so that during the late honey season incoming bees collided against those that were leaving the hive and frequently both fell to the ground. To overcome this fault I placed a board sloping up from the ground to the edge of the alighting board, the hive being on nine inch legs. One night in June on visiting this hive with a lantern 1 found a toad seated close to the edge of the alightingboard. He apparently attracted the best in some way (I heard no noise), remaining quite still until the bees were within his reach, when he pounced upon them and bottled one after the other most rapidly, taking several while I watched him. I removed the toad to a distant part of the garden, and altered the board so that it no longer touched the ground. On several other occasions I have found toads near the hives at night and have observed them pick up the bees that have been recently killed (such as robbers) and devour them. I have never observed them stand on their hind-legs to reach the bees.

I find that a very good surface for hives to stand upon can be made by first spreading a layer of brick rubbish or stones, then a layer of fine cinder siftings mixed with a small quantity of gas tar, and then again a layer of This after wetting forms a solid smooth surface in which no weeds will grow and in which nothing will burrow. If four square tiles or bricks are let into the surface (taking care they are level) the legs of hives resting upon them are preserved from decay, and there is no harbour for insects such as ants or earwigs.

Curious Mistake of a Bec.—A lady was sitting at needlework in June, 1886, near an open window, upon the sill of which she placed her reel of cotton, the end of the reel that was uppermost (it was standing on end) had no label upon it. The reel had not been in this position many minutes before a bee with its legs laden with pollen alighted upon it and deposited its load of pollen in the hollow of the reel. After a few minutes it again returned with a second load and so continued for about two hours, during which time it had made a number of journeys, always returning loaded with pollen which it deposited as at first. Unfortunately the reel was removed and its contents thrown away without the result of the numerous journeys being observed. I should be glad to know if any of your numerous readers have observed similar behaviour in a bee.—HAROLD Address, Middleton, Northampton.

NOMENCLATURE.

[783.] There must always be different opinions as to the amount of accuracy desirable in treating of any given object. I am not too particular, I think, but sometimes I find it difficult to follow, as I strive to do, the descriptions of designs figured in your useful paper. Even if we accept Johnson's definition a 'rabbet' as a 'joint made,' &c., I do not think Mr. Neighbour is in a better position. He says 'the shifting slide is itself comprised of several rabbets. What! a block of wood comprised of joints? Impossible. Fitted to others in its place by joints, but surely it cannot be made up of them, any more than the well-known 'trimmings' in Pickwick could have been the leg of mutton. Strictly, I take a rabbet, or a scarf, &c., to be no thing at all, but only a form; but waiving this I do not object to the groove in which the piece of timber slides being called a rabbet, though it is not strictly so, or, what is more like it, the piece taken out of the top of these moveable ends (of top hive), but if I understand aright that E E are the blocks of wood then I do think

the right use of terms forbids to call them rabbets. I quite see Mr. Neighbour's position, and I assure him that I have no desire to act the part of the captious critic. He wants a handy word to designate his ingenious device, but he must not use one which is already applied to a form of juncture of two pieces of wood, and it is not for me to suggest one, which, in truth, I find not easy, for 'ends' and 'carriers' and 'blocks' are already appropriated.—C. R. S.

A DISCLAIMER.

[784.] A reference is made in the last issue of the Journal by 'Man of Kent' to my 'Agents' calling attention to the price charged for phenol as excessive. Since I have no agents, and stated so in the Journal now quite two years since, I ask who are representing themselves so to be? When my experiments and discoveries were first promulgated, I agreed to guarantee phenol and give directions through Messrs. Holland and Lyon, receiving a royalty of 4d. per bottle which royalty was to supply a sum to be devoted to further experiments. As a result, I have not received, as I before stated, sufficient to pay the postage of the letters I have been called upon to write in connexion with this subject. It is simply preposterous that I, who have not been excelled by any living bee-keeper in the amount of time and energy I have devoted without any thought of reward beyond that of following research and aiding my fellows, should be not once or twice, but frequently in your Journal, addressed as though guilty of extortion. I have sought no man's silver or gold, but, on the contrary, have expended and am expending my own freely, in my devotion to scientific apiculture. I trust that care will be in future exercised that such statements as those made by 'Man of Kent' may not appear, and that you will in justice publish this disclaimer.— F. CHESHIRE, Avenue House, Acton, W.

[It seems to us just possible that the phenol might have been purchased by 'Man of Kent' while the agencies were still in force.]

GLEANINGS.

In the Bienenzeitung, Major V. Mann gives his experience with regard to drones having white eyes. He refers to what Baron V. Berlepsch says respecting them in the Bienenzeitung in 1885, p. 169: 'I possess a Cyprian colony, in which there are several hundred such drones; only one single drone has eyes of the usual colour.' Major V. Mann says that in all his experience he never saw a drone with white eyes return to a hive when once it left it. He has seen them in numbers in front of his bee-house crawling about in the grass, and saw them rise fifty or sixty cm., but always to drop down again. He also saw them come out of the entrance and crawl about on the alighting-board. Some were put into a box, taken into a room, and placed on a table, with the lid slightly opened. The drones did not leave quickly as other bees do, but came out languidly, crawled on the table, and dropped on the floor. None flew towards the window. He concluded that these abnormal drones are blind. They, however, have a keen sense of smell. He placed half a ripe pear on the window-sill, and they crawled out of the box towards it, and remained upon it, but none of them attempted to go towards the light of the window. During the slaughter of the drones he observed those with white eves were driven out much sooner than the normal drones. Six days after these albinos were driven out he examined the hive, and could not discover one, although there were plenty of others. When he took hold of them a yellowish liquid faces was ejected, which does not occur if an ordinary drone is grasped. He is of opinion that these albino drones are diseased.

In a note F. M. Vogel, who has examined them microscopically, says the eyes are quite transparent, the pigment being absent, and the hairs at the corners of the facets are also colourless. The simple eyes were also white. The lower of these simple eyes projected, and shone like a fine crystal. He agrees with Major V. Mann in considering them blind.

In the Chemical News A. B. Griffiths, who has been studying the action of salicylic acid on ferments, states that a solution containing 0.2 grains of salicylic acid per 1000 c. cm. of water quickly destroys some microorganisms, such as Mycoderma aceti, Bacterium lactis, and other. It seems to act upon and to dissolve the cellwalls of these organisms. Although living torulæ are not destroyed, their activity is impeded by the solution of salicylic acid. Saliva does not exert its fermentative faculties in the presence of this acid.

Replies to Queries.

*** In their answers, Correspondents are respectfully requested to mention in each instance the number and the title of the query asked.

(773.) Managing Stock on Allotment Garden. —I have for several years managed stocks on allotment gardens half a mile away, and have had excellent results from the following plan. I use a hive containing twelve standard frames, having another the same size full of empty combs, which I place on the top when the first is full of brood, and when doing so (about the end of June) I take one comb of brood from the bottom hive, placing in the top one among the empty combs, and place an empty frame with narrow strips of guide, not in the place of the brood extracted, but immediately over the entrance and in front. This frame will not be filled with comb before the harvest closes, and the top hive will contain 80 lbs. of honey in a good season, and swarming is prevented. I have taken in this way over 100 lbs. from one stock.—T. F. Ward.

[773.] Managing Stock on an Allotment Garden.—I should go to work on the non-swarming system, as bees always work better for sending off a swarm. Make it as soon as there are any drones in the hive. It is very easy to prevent after-swarming by giving them room to work in. Place two empty frames with eomb starters in the front part of the hive next the door. As soon as they are drawn out replace them by others. Cut those drawn out to fill the sections. The best way to cut the combs is to have a box just to hold the comb with saw-cuts $\frac{1}{4} \times \frac{1}{4}$, or the size of the inside of section, and with the comb so cut fill the sections.—R. L. Richardson, Gresham House, Corbridge.

Queries.

Queries and Answers are inserted free of charge to Correspondents When more than one query is sent, each should be on a separate piece at name.

of paper.

Our readers will greatly oblige us by answering, as far as their knowledge and observations permit, the Correspondents who seek assistance. Answers should always bear the number and title placed against the query replied to. Any queries unanswered in this way will be answered by the Editor and others.

[785.] Clover for front of Hives.—A lady has a plot of ground in front of her half-dozen bee-hives which is generally full of weeds all summer, owing to her gardener being shy of the bees. Can any one advise her what mixture of white clover and other seeds to sow it with so that it will grass itself over?—Mrs. Summer.

[786.] Specimens of Honey.—I have been hunting up for some time now all the specimens of honey I can get hold of, and am anxious to make it as comprehensive as possible; and I noticed at a recent meeting held in London that the following exhibited samples of honey which I would like to have the address of, viz., Messrs. Haw, Gardner, & Co., Liverpool (Chilian, Cuban, &e., honey), Mr. Liddell, Laneaster (English heather), and Mr. Carr, Higher Bebington (white clover). If any bee-keeper can give me

the addresses of any others who could possibly assist me in this matter I would deem it a great favour.—Aros.

[787.] Would any of your readers give instructions for making an unicomb observatory hive?—Castle Douglas.

[788.] Would some experienced bee-keepers kindly give treatment for bees badly troubled with dysentery? Also, the most suitable coverings for hives 'kept in a bee-house,' for spring, when breeding is at the height; for summer, during the honey-glut; and also for winter? Is the American-cloth so often mentioned in the B. B. Journal the same material as is often called oil-cloth?—FAR NORTH.

Echoes from the Hives.

Port Mahon, Minorca, Dec. 27 .- On Nov. 1st we looked over the eleven hives in our apiary. My best hive had ten combs full of brood, and the rest four or five each. (I had stimulated them just a little after the summer heats.) On the 15th of this month, profiting by a very fine day or two, we looked them over again. Best hive had brood in only six combs, the rest in two to four. Shall not handle them again till the middle of February, when I intend to begin stimulating. We calculated they had 2 cwt. of honey for winter, which, though not sufficient in a cold climate, I consider all that is necessary in a country where they can pasture all the winter long when the weather permits it. One of my transferred hives occupied five storeys last summer, though it was transferred so late that only a fortnight's honey-flow fell to its lot (from May 1 to 15), and only 50 lbs. of honey were got out of it. By November we had reduced it to two storeys. On examining it this month we found the lower storey empty of broad and honey, and, as the combs were new, I thought constant passage through them to the upper storey would soil them, and reversed the order of things, putting the lower and empty storey on top. Now what I wish to inquire, Mr. Editor, is whether I did right in so changing the two storeys? for evidently the bees had not intended to winter in the lower I preferred to leave the empty combs on to taking them off, thinking the bees would at times occupy them and thus keep them clear of moths, &c. Our climate being comparatively mild (thermometer generally ranges about 55° to 65° Fahrenheit, and never goes below 40°) I do not anticipate any bad results, but may be mistaken for all that. Two or three months ago I wrote a couple of articles on modern bee-keeping for one of the most influential of Spanish journals published in Barcelona, the Diario, which caused quite a sensation, and overwhelmed me with letters of inquiry from all parts of Spain. I have hopes that next spring will witness many attempts at hee-keeping in framehives on the part of amateurs. Whether success will attend their efforts is at best problematical, though under proper teaching much might be done in this beautiful climate. I am sorry I have succeeded in obtaining but a few subscribers to the British Bee Journal, as the generality do not understand the English language. French is more generally spoken, and I have therefore given course to many copies of Cowan's Guide in that language, also to the Swiss Bulletin d'Apiculture of Mr. Cowan's friend, Mons. Bertrand.—F. C. Andreu.

[We should not have changed the hives in the way you have done, but would have preferred to have left only the one containing stores. The stores should he at the top of the hive where the heat is greatest.—Ed.]

Honey Cott, Weston, Leamingion, January 10th, 1887.—Since my last echo, written at the beginning of December, the weather has not been suitable for bees getting out in any considerable numbers, but as we have had a fall of snow, I have found a few brought out by the reflection. On Saturday last snow fell to the depth of nearly a foot, and so made plenty of work in clearing the roofs of the hives, and putting blocks and boards to shade the entrances to prevent the bees being enticed out—to their deaths; for I find, as a rule, when once they are on the wing they mever get back to their hives when snow is on the ground.—John Walton,

NOTICES TO CORRESPONDENTS & INQUIRERS.

All queries forwarded will be attended to, and those only of personal nterest will be answered in this column.

W. C. C. -1. Wax. -In No. 186, Vol. XIV., we gave statistics of the amount of wax imported and exported during the year 1884, from which it appeared that we imported in that year 28,258 cwts., value 105,813l., and re-exported 10,378 cwts., value 36,467l.; in 1885 we imported 38,295 cwts., value 140,253l., and re-exported 10,328 cwts., value 26,7061. The value of the honey imported in 1885 was 61,344., but we are not in a position to say the amount or the value of the honey re-exported.—
2. Uses of Honey.—The Rev. V. H. Moyle, who has devoted much time and attention to this subject, has published a leaflet showing the chief manufactures in which honey is an ingredient, which would render you much assistance. 2. Uses of Wax.—Wax is valuable for many purposes in this country, but it is of still more importance in parts of Europe and America. It forms a considerable branch of trade and manufacture as an article of extensive use in the religious ceremonies of the inhabitants. Humboldt informs us that wax to the value of upwards of 83,000l. was at one time annually exported from Cuba to New Spain, where the quantities used in the festivals of the Church are very great, even in the smallest villages. The value of that exported from Cuba in 1803 was upwards of 130,0001. At the Zurich Exhibition, in the year 1883, there were no less than twenty-two distinct uses of wax exhibited, among which were, --painting in wax colours, wax modelling, wax salve, wax plaster, wax tapers, moulds of teeth, anatomical preparations in wax, meerschaum tubes, wax matches, comb foundation, candles, medals, photographs, &c. Wax is applied extensively in the arts and manufactures.

T. P.—Transferring Combs from large frames to Standard.— Do not attempt it until the weather is warm, or you will so check the prosperity of your stock as to render it useless for the season. You need not fear loss of brood; even if you have to cut off some parts of the comb containing it you can give the cuttings for the bees to hatch out, the only loss being the few cells actually divided by the knife. In a strong colony this will soon he repaired.

O. T.—1. Combs Built Irregularly.—From your letter you do not appear to have been sufficiently careful in spacing your frames, and probably your hives did not stand level. Hence your difficulty. In your new hives keep your frame 1.25 inches from centre to centre, preferaby by metal ends.—2. Supers not accepted.—There are so many reasons for this that without fuller particulars we cannot name the special one. The colony which deserted the lower hive for the super, and made that its home, did so from the absence of queen-excluder, allowing the queen to ascend and make her brood-nest there. A conversation with some experienced bee-keeper would do more good than much reading. We hope you will suceed in future as well as you appear to have done in your first season.

D. Shaw.—Langstroth Hive.—You cannot do better than use the Langstroth hive as you have done, but we should prefer having an outer casing, and the space between the two filled with chaff, for winter. When using the Carr-Stewarton we did not get more honey than we have done with the ordinary frame-hive, in which the bees developed much faster. Shallow hives were tried long before the moveable frame-hive was invented, and are still used in some places, but they have not been found profitable. We should advise you only to try one or two, and compare results before you go in largely for the Heddon hive. In this live, the frames are always kept at a certain distance apart, by wide ends, and are kept in their places by means of screws; but, having tried such frames, we should not care to use them again. We hope to be able to give a description and illustration of Shuck's invertible hive shortly.

M. H.—Dysentery in an Observatory Hive.—We advise you to procure a small box, sufficiently large to receive the two frames—side by side—from the observatory hive, and to transfer frames and bees to this box. The frames should be transferred in the room in which the observatory stands, and the sides, bottom and top bars of

the frames (while the bees are npon them) should be scraped, or sponged, clean and a little salicylic acid solution, or Condy's fluid, applied, so as to wet the frames as little as possible. A cake of soft candy— (finely powdered loaf sugar mixed with liquid honey to the consistency of putty) - should be laid upon the tops of the frames in the box, covered with thin paper and pressed closely down upon the frames. Cover over with several thicknesses of flannel or woollen cloth of loose texture, and over all a board to keep the material close to the frames. Place the box in the position which the observatory hive occupied, providing an exit for the bees to fly outside. It was an error to feed with syrup, and this has probably caused the mischief, but it is very difficult to winter bees in an observatory hive, especially small colonies, and it is doubtful whether yours will recover. Failing the box recommended, it will be best thoroughly to disinfect and clean the observatory hive and to return the bees to it. When transferring disturb the bees as little as possible. An expert would perform the operation in five minutes.

-Soft|Candy. —We can recommend Good's candy, a kind of food much used in America, which is made by mixing together liquid honey and very finely powdered loaf-sugar until the consistency of dough, or stiff putty, is attained. The paste is then laid on the frames over the cluster in the form of a cake, and covered with the quilt.

A Hawes Bee-keeper.—We have forwarded a sample of your honey to Mr. O. Helmer, and trust to be able to insert his report thereon in our next issue.

DRY SUGAR FEEDING.—Referring to Mr. Simmins's letter on dry-sugar feeding, in last Journal, will be kindly state. Will the usual-size hole for syrup feeding cut in quilts, say, $1\frac{1}{2} \times \frac{1}{2}$, be sufficient to pile the sigar over, or must there be a larger hole made? I mean to have ticking next frames, the sugar placed on that, and then the thick quilts over the sugar, or American-cloth next the sugar if preferred, and, Will the sugar so placed do for stimulating feeding in the spring?—F. J.

Croaring.—May I say that on several occasions I have heard such a sound coming from the hives as a correspondent called 'croaking?' I could hardly believe it came from a hive at first, but I have no doubt now. -Br. W.

Hedges .- I also saw in the Journal a correspondent making inquiries about a hedge for the protection of hives. I would say that a willow hedge answers the purpose admirably. I planted such a hedge three years ago, by putting in willow sticks about four feet long, crosswise, and the first year it certainly protected the hives. Now it is seven feet high, and, although my apiary is in a very exposed situation, during the recent gales my hives and covers were not displaced in the least. It seems the hest time to plant is early spring, and it requires constant clipping to keep it within bounds, but repays the lahour by making a thick, bushy hedge. My hedge is made up of several varieties of willow—I think six or seven—the bloom of which in spring is very pretty, besides supplying the bees with pollen. -BR. W.

ERRATUM.-Page 16, colmun 1, line 16, for promulgated read propagated.

Show Announcements.

Giving Name and Address of Secretary, Date and Place of Show, Date of Closing Entries. Terms: Three Insertions and under, Two Skillings and Sixpence; additional insertions, Sixpence each. No charge made to those Associations whose Shows are announced in our general Advertising

July 11-15.—Royal Agricultural Show at Newcastle-on-Tyne. Entries close May 12. Sec. J. Huckle, Kings Langley.

August 3-5.—Yorkshire Agricultural Society at York, Secretary, H. L. Rickards, Poole, near Leeds.

HOW TO MAKE A BELLOWS SMOKER.

A good smoker is an indispensable implement in the apiary. One of the best is the Bingham, and although

there are many sold as Bingham smokers, some of these are only very inferior imitations of it. There is nothing more trying to the patience than to find, during an operation, that the smoker one is using will not work and will not send forth the needed smoke; and yet it has been our lot, not unfrequently, to come across such a smoker when assisting a brother bee-keeper in his manipulations. We have seen some made in this country that worked quite as well as the originals, but the majority are made with a view to cheap-Bingham Smoker.

ness, and not efficiency, and quite regardless of the principles upon which a smoker should be constructed.

The usual defects consist in using unsuitable springs, and leather for bellows, and in not making the entrance in the barrel above the blast-pipe in the shape of a funnel. This defect, if the pipe and the hole above it are not exactly in a line, causes a great deal of air which ought to be

driven into the smoker to pass on one side, and the full power of the bellows is not utilised. The spring being of steel

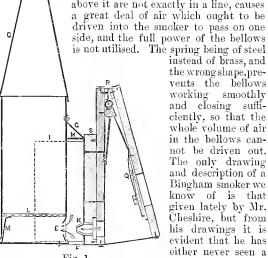

Fig. 1. genuine one, or else he has never dissected one to ascertain its mechanism, and has not understood the principles upon which it is constructed. We need hardly say that if any one made a smoker from the drawing given by him, it would only resemble the Bingham in outward appearance, and would be no better than many of the imitations at present in the market. The illustration he

gives on page 13 of the practical part of Bees and Beekeeping, and which appears to be an exact facsimile of the illustration given in the first and second editions of our Guide-book (see illustration in previous column), with the smoke added, is that of an old pattern discarded in 1883; but even in this the interior is similar to the one we are about to describe, and which has been the only pattern

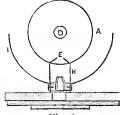

Fig. 2.

sent out by Mr. Bingham since 1883.

The illustrations we give are drawn one quarter of full size, or a scale of 3 inches to a foot, except Fig. 9, which is 2 inches to the foot.

Fig. 1 is a vertical, and Fig. 2 a horizontal section, through the blast pipe and top board of the bellows. Fig 3 is a section of the bottom board through the valve.

We will first make the tin work of the smoker. The barrel, A, is $2\frac{1}{2}$ inches in diameter and $6\frac{1}{4}$ inches

long. No solder should be used, as the heat would soon melt it and the smoker would come to pieces; therefore all the joints in the tin work must be made without it. The lower edge of the barrel is turned outwards, and the bottom has its edge turned over this, as shown at B. The nozzle, C, is $5\frac{1}{2}$ inches long, and fits over the top end of the barrel, tapering to the top, at which the opening, D, is half an inch in diameter.

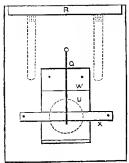

Three quarters of an inch

Fig. 4.

from the bottom of the barrel bore a half-inch hole, E. Then get a piece of wood an inch in diameter, and cut one end to the shape of a cone. Place the pointed end in the hole and drive in the tin until you have a funnel as seen in the illustration. This funnel, although apparently of trifling importance, and is omitted in nine out of ten smokers as well as in the illustration above alluded to, adds greatly to their efficiency. If the blast-pipe does not correspond exactly with the hole in the barrel, without the funnel, part of the air is blown on to the round surface and is lost, whereas when it impinges on the inner sides of the funne, it is propelled forward, in the direction of the arrows,

through the opening, E, and not a particle of air is wasted.

We have next to make the snpport, F.G., which carries the barrel and the hand-guard. This should be a piece of tin $7\frac{1}{2}$ inches long and $1\frac{5}{8}$ inches wide. At $1\frac{3}{4}$ inches from

one end cut in \(\frac{3}{5}\) of an ineh with a pair of shears, on each side, and turn these edges over and hammer them down flat. Do the same thing at the other end and turn down the edges of the centre part at at right angles, thus: Turn up the end, F, at right angles, and the end, G, at an angle of forty-five degrees, as seen in Fig. 1. The distance between F and G should be $4\frac{1}{2}$ inches from angle to angle.

For the hand-guard, cut a Fig. 5.

piece of tin $6\frac{1}{2}$ inches by 4 inches and bend it, as shown at I, Fig. 2. Then get a short piece, II, and turn up the end at right angles, thus: L. The top end must be shaped as shown at H,

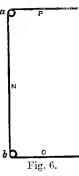

Fig. 2, as it is intended to support the barrel. This piece as well as the hand-guard can now be riveted to the support, F G. At $\frac{3}{4}$ of an inch from the end corresponding to the hole in the barrel, punch a $\frac{5}{8}$ -inch hole to allow the blast-pipe to pass through. The support is now ready to be fixed to the barrel by means of two rivets, seen in Fig. 1. The grating, L, is of sheet-iron, with 1-inch holes punched closely all over it. Two strips of sheet-iron, $\frac{3}{16}$ of an inch wide, are riveted on in the shape of a cross and turned down right at angles to form legs, M, which must be $1\frac{1}{5}$ of an

inch long. Before putting in the grating, spring the legs ont a little, so that when pushed down the barrel it will be kept in position.

We will next make the springs. There is nothing better for this purpose than No. 16 brass spring wire; and this, together with the shape, is what makes the

Bingham bellows work so smoothly and plea-

Fig. 7. santly, without fatiguing the hand of the operator. The best way to make them is to drive into the edge of a piece of inch board two iron pins $\frac{1}{10}$ of an inch in diameter, and projecting about $\frac{3}{4}$ of an inch. Cut your wire 14 inches long and lay it on the board against the iron pins, so that both ends project the same length beyond them. By referring to Fig. 6 it will be seen that the end, P, is turned to

the right over pin a, and the end O to the left over pin b. Each end must have two complete turns and part of a third turn until the ends P and O stand at right angles, in

the position shown in Fig. 6. The wire is then taken off the pins and bent at N, until the two spirals meet and the wires P and O are brought in contact with each other, as shown in Fig. 7. Close to the coils give the wires a slight bend, seen in Fig. 8, which shows the spring when it is slightly pressed down, as it would be when between the two boards of the bellows. The springs, however, are stronger if left at right angles. The only metal work remaining to be made is the spring Q, of which a side view is seen in Fig. 1, and a plan in Fig. 5. This consists of a piece of No. 22 brass spring wire 3 inches long bent into the shape shown in Fig. 1, so as to allow the valve sufficient play, and an eye is turned at the end through which it is fastened by means of a tack to the bottom board of the bellows.

We will next proceed to make the bellows. For the wood-work we can have nothing better than wellseasoned yellow pine free from knots, as lime-wood, which is usually used, is not so common with us as it is in

The pieces of wood necessary will be:

Two pieces $5\frac{1}{2} \times 5 \times \frac{3}{8}$ inches, planed on both sides. Two pieces $4\frac{3}{4} \times \frac{1}{2} \times \frac{3}{16}$ inches at one edge, and $\frac{1}{5}$ inch

at the other, as shown at R, Figs. 1, 4, and 5. One piece S, Fig. 1, $4\frac{3}{4} \times \frac{7}{8} \times \frac{1}{2}$ inch, with a groove $\frac{1}{10}$ inch wide, sawn half way through $\frac{1}{4}$ inch from the ends. These are to allow the wire to pass through which is used for fastening the support of the barrel F G to the woodwork.

One piece T, $2\frac{1}{2} \times \frac{3}{8} \times \frac{3}{8}$ inch. One piece U, $2 \times 2 \times \frac{1}{4}$ inch for valve.

In the board, Fig. 4, taking as a centre \(\frac{3}{4}\) inch from the edge cut out with a centrebit a 5 inch In board, Fig. 5, two inches from the edge, cut out a hole 11 inches in dia-

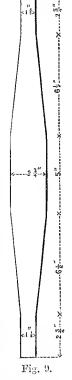

In piece S, at $\frac{3}{4}$ inch from one end, bore a 7 inch hole, and drive into it tightly a piece of brass tube, the mouth of which is contracted to $\frac{3}{8}$ inch as seen at K. This contraction is easily made by driving the tube into a conical hole drilled in a piece of iron. Just below the blast-pipe chisel out a piece 1 inch deep to admit a strip of wire gauze which is to be placed there to prevent the possibility of any dirt or ash from the smoker getting accidentally into the bellows.

The piece S can now be glued on the board, Fig. 4, in the position shown by the dotted lines, it being on the underside in the illustration. To prevent its being broken off, drive two wire nails through, and clinch them as shown in Fig. 1. Glue the strips R on each of the boards, with the thickest edges towards the hinge, and the piece T $\frac{3}{8}$ of an inch away from R, Fig. 4. Secure all these pieces with a couple of nails each, but do not allow the points of the nails to go through the boards, and thus disfigure them. The piece of wood V, Fig. 4, is $3\frac{1}{2}$ inches long by $\frac{3}{16}$ th inch square. The two ends are rounded, so as to allow them to fit tightly into the holes of the spirals in the spring. A piece of No. 22 wire is inserted through the holes, and lays along the side of the wood, and when the springs are in the

position seen in Fig. 4 the ends of the wire are turned up, and prevent the springs from slipping off.

The boards are now ready to put together, and to have the hinge put on. This is a strip of leather 5 inches long and 11 inches wide.

Lay the two boards, Figs. 4 and 5, so that the strips R face each other. Then glue the ends, and put on the leather. The valve U can then be fixed. It has a groove sawn out through half its length to allow the spring Q to work in it and keep it in its place, and this side is rounded off as shown in Fig. 3. The valve can be fixed to a piece of leather W, $3\frac{1}{4} \times 2$ inches, by means of a short tack driven through the centre, the point being riveted on the other side. The wood of the valve should not be glued to the leather. Two tacks at one end, Fig. 5, will keep the leather in its place, and allow it to move freely up and down at the other end. Now nail the spring Q in its place, and put the loose end into the groove of the valve. Nail a strip of leather about

 $4\frac{1}{2}$ inches long by $\frac{3}{8}$ inch wide loosely over the valve, so that when this is open, the opening does not exceed $\frac{1}{4}$ of an inch.

The leather used for the bellows should be Persian, or a similar strong and not too pliable leather, and must be cut to the size and shape shown in Fig. 9. The widest part of the leather is $2\frac{3}{4}$ inches, and the narrow ends $1\frac{1}{5}$ inches. If many pieces are to be cut it is better to have the pattern made of sheet zinc to cut the leather

out by.

The spring being in its place and at right angles, we shall want something to neep the distance apart while we are fixing on the leather. This distance apart while we are fixing on the leather. This shall want something to keep the boards the exact can be a stout wire cramp, bent thus $\begin{bmatrix} 1 \\ 4 \end{bmatrix}$, the distance between the points being just $2\frac{a}{4}$ inches, or a piece of wood may be used with a notch the same size cut out of it. Carefully glue the edges of the boards, commencing from the narrowest part, and lay on the leather, starting from where the tapered part begins; and before removing the cramp, drive in a tack close to the end in each board. The ends and other sides can then be glued, and the leather secured in its place. The two end pieces which have to go over the hinge are better fastened with paste. Where the ends overlap, the edges should be thinned down by paring with a sharp knife. All round the edge we can nail strips of leather ¹/₄ inch wide by means of tacks, of which there should be six on the longest side and five on the shortest. These strips of leather need not be glued.

It now remains only to put the bellows and barrel

together to complete the smoker.

The support of the barrel is slipped on to the piece of wood S and a couple of tacks, as seen in Fig. 2, are driven into the wood on each side through the tin sides of the support F, G, which we previously turned down at right angles. As an additional precaution against accident and breakage we can tie the support to the wood by means of annealed iron wire, which is passed through the saw grooves in piece S and over the angles of support F, G. Bring the ends together and two or three twists

with a pair of pliers will make all firm.

If our instructions are carefully carried out we shall have a real Bingham that will send a greater volume of smoke, and that to a greater distance, than any other smoker we know. We have had such a smoker in use since 1878, and although we have been obliged to renew the barrel which became worn through from constant use, nothing has been done to the hellows, which is just as good as it was on the first day we had it. A smoker like this will burn almost any sort of fuel that will produce smoke when smouldering. We use old rags, brown paper or sacking, but peat, decayed wood, or even ordinary fire wood will do, when it is well kindled.

In using old rags we tear them into strips about four or five inches wide, and roll them up loosely until they nearly fill the barrel, they are then tied to prevent them from unwinding when stored away, for we always get a lot ready at one time. One end of the roll for about $\frac{1}{4}$ of an inch is dipped into a weak solution of saltpetre and when dry this end will light easily with a match. Brown paper is rolled up in the same way, but we generally lay in a few straws, cut to the same length, between the layers. One end of these brown paper rolls is also soaked in the solution of saltpetre.

When we use sacking it is generally from an artificial manure bag, as these cost us nothing. The edges of these rolls are also soaked in saltpetre solution to make them light more readily. Firewood is cut four inches long and split into pieces $\frac{1}{1}$ to $\frac{1}{2}$ an inch square, and must be perfectly dry. To light it put a few live coals or lighted shavings into the barrel and fill up with the sticks. Put in the lighted end of either fuel used towards the grating.

When the smoker is stood on end, as in Fig. I, the upward draught causes the fuel to burn freely. When

we wish to extinguish it the smoker is laid down on the bellows bottom and the nozzle plugged. A smoker properly charged will burn for five or six hours without any replenishing. A roll of rag five inches long and $2\frac{1}{2}$ inches in diameter has lasted us during a whole days operations. If the grating gets stopped up it can be cleaned with a wire, and the nozzle should always be kept clear.

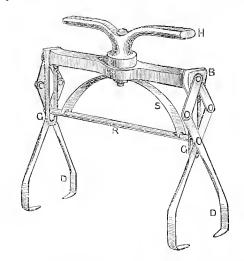

We hope these details will enable those who have

We hope these details will enable those who have asked us to give them to make an efficient smoker and will explain the reasons for the complaints we get from time to time about smokers not working properly.

WEBSTERS SWIVEL FRAME-LIFTER,

This appliance, which was shown at the Conversazione of the British Bee-keepers' Association, held on the 19th inst, and evidently met the approval of all present, is the invention of Mr. W. B. Webster, and will no doubt supply a want long felt.

As the illustration denotes, it consists of a handle II revolving on a swivel, a bar B, which carries two dogs or clutches D, one on each end; these being opened by raising the rod R, but automatically closing by the pressure of the spring S on each end of same rod,

two guides G G carry this rod and keep the whole firm, preventing any swaying of the clutches. Such is a description of this ingenious appliance; its manner of

use will present itself to our readers.

As is well known, in removing a frame from a hive, both hands have to be employed; with this instrument, only one—the left hand—is needed, leaving the right hand free to do anything that is required, such as catching the queen, on taking one off the comb the frame can be replaced in the hive, still only using the left hand to do so. If both sides of the frame have to be examined, it can be turned round in its natural position by means of the swivel handle; this will be found of great importance, as in the ordinary method the frames have to be turned upside down in order to examine the opposite side; the bees being thus 'inverted,' commence righting themselves, throwing all into confusion, in which the queen joins, and so frequently escaping observation. By the peculiar arrangement of the clutches, the heavier a frame is the tighter the grip, there being, therefore, no chances whatever of its falling.

In the Heddon hive this will no doubt be found a very necessary appliance, there being no 'ears' to the frames to hold by, when any necessity arises for removing

one.

BRITISH BEE-KEEPERS' ASSOCIATION.

Committee meeting held at 105 Jermyn Street, on Wednesday, January 19th. Present the Hon. and Rev. II. Bligh (in the Chair), Rev. Dr. Bartrum, Rev. F. G. Jenvns, Rev. F. S. Sclater, Captain Bush, Captain Campbell, J. M. Hooker, H. Jonas, and the Secretary. The minutes of the last meeting having been read and confirmed, Dr. Bartrum moved, and the Chairman seconded, That this Association desires to express the deep sense of the loss the Royal Agricultural Society and the British Bee-keepers' Association have experienced in the death of Mr. H. M. Jenkins, late Secretary of the Royal Agricultural Society. Mr. Jenkins was always most willing and anxions to assist in the advancement of British bee-keeping as an industry closely connected with the progress of agriculture; and this Association desires to express its deep and sincere sympathy with Mrs. Jenkins in the affliction that has befallen her, and begs to assure her that the memory of Mr. Jenkins will be long and gratefully cherished by this Association.'

On the motion of Mr. Jonas, and seconded by Captain Bush, it was resolved to arrange for an expert's or lecturing tour in the Northern counties preparatory to

the Newcastle Show.

The statement of accounts for the past year, as audited and duly signed by the Auditor, Treasurer, and Secretary, was presented, and, after some discussion, was passed, and ordered to be printed in the Report.

The Finance Committee presented a lengthy report of the financial condition of the Association, accompanied by statistics and recommendations in regard to the expenditure during the ensuing year.

Captain Bush moved, and Captain Campbell seconded, a vote of thanks to the Finance Committee, for their full

and complete report.

Prior to the Conversazione, which commenced at six o'clock, a meeting of County Representatives was held. There were present, W. Horton Ellis, Devon; Mr. A. B. Lipscombe, Herts; Rev. W. E. Burkitt, Wilts; J. Garratt, Kent; T. J. Witt, Surrey; W. L. McClure,

Lancashire and Cheshire.

The minutes of the last Quarterly Conference having been read, Mr. McClure called attention to the rules laid down for the management of the County Competition at South Kensington, and on behalf of the Lancashire and Cheshire Association he was requested to state that it was considered advisable that in any such future competition the regulation as to corking of the bottles of honey should be dispensed with, and that the mode of fastening the mouths of the bottles should be left entirely to the discretion of the exhibitor, and that in the event of any method being adopted which in the opinion of the judges was not secure the same should be disqualified. In regard to sections, Mr. McClure further recommended that no limit should be made in regard to size or weight, and that the mode of protecting them from bees or other injury should be left entirely open, in order that scope might be given for new inventions in this direction.

The matter having been discussed, the Chairman

The matter having been discussed, the Chairman pointed out that the regulations had been made upon the recommendations and suggestions of the County Representatives themselves at a fully attended meeting; and although some members of the Committee were in accord with Mr. McClure's views, the majority were of opinion that for exhibition purposes it was necessary to have the regulations defined. In the event of any such competitions being arranged in the future, full consideration would be given to the views of the Lancashire

and Cheshire Association.

The meeting then resolved itself into the Conversazione, when among the audience assembled were the Rev. F. G. Jenyns, the Hon. and Rev. Henry Bligh, the Rev. Dr. Bartrum, Mr. Jonas, Captain Campbell, Mr. Meggy, Mr. Grimshaw, Mr. T. B. Blow, Mr. Hen-

derson, Mr. Garratt, Mr. Sambels, Mr. Baldwin, Mr. Haviland, the Rev. W. E. Burkitt, Mr. J. Lee, and

other gentlemen, and two ladies.

The Rev. F. G. Jenyns (Chairman), in opening the proceedings, said the Committee felt great satisfaction at seeing so many friends of their cause gathered together for the purpose of hearing the paper which Mr. Grimshaw had kindly promised to read, entitled 'The Vocal Organs of Bees.' It had been said—and he thought with truth—that there was nothing too minute in nature to justify the closest and most careful observation; there was no doubt that wonderful discoveries had, in many instances, been led up to from insignificant beginnings. At first sight it seemed to be unimportant what cause gave rise to the buzzing or humming, but at all events the subject was interesting to bee-lovers, as, indeed, was everything connected with the organization of the bee. He hoped and believed he would learn something that evening, which possibly some day or other might be turned to practical use. He knew very little respecting the organs of sound in the bee, and what little knowledge he had was gained from Mr. Cheshire. That gentleman, if he could have been present, would have no doubt contributed some valuable information to the discussion-valuable, because given by a very close observer who had a thorough acquaintance with the subject.

Mr. Grimshaw, in the course of a few prefatory remarks, said he felt considerable diffidence in speaking on a high scientific subject before the select audience present that evening, and for the purpose of showing how the paper he was about to read had originated he wished to carry their minds back twelve months to the quarterly meeting held in January, 1886, when he had the honour of communicating to them by means of a paper his opinions regarding the bee-sting. On that occasion the discussion which followed trenched upon the subject of the vocal and auditory organs of bees, and his views thereon were asked. At that time he had almost completed a paper on the question, and he undertook with their consent to read it on the earliest opportunity. He had now much pleasure in

doing so, as follows:-

THE VOCAL ORGANS OF BEES.

It may be thought that the subject I have chosen to say a few words on is more fitted for discussion amongst physiologists than bee-keepers. Perhaps so; yet the interesting conversation at the quarterly meeting just a year ago leads me to suppose that the more the beekeeper studies the construction and habits of his favourites, the more successful will he become as a honey-farmer, exactly as the most economical and trustworthy engineer is he who best has studied the scientific 'why and wherefore' of the intricate machinery under his charge. If bees can hear, we may reasonably conclude they have a voice. If bees have a voice, there is at once a strong presumption that they can hear, and that these two faculties are given them for the purpose of communicating with each other. I know of nothing in nature having the one organ without the other.

It is on record that during swarming bees have been dispersed by the noise of a band of music, re-assembling in the intervals of silence. The whole of an apiary has been suddenly aroused by the noise emitted by an injured queen, the bees stinging every living thing within reach. A sound uttered by the Death's-head moth (Acherontia atropos) is said to paralyse them. The queen and imprisoned young queens evidently hear and reply to each other before the issue of a swarm. Kirby tells us (The Honey Bee, Nat. Lib., p. 54) that the antennae, 'by a peculiar structure may collect notices from the atmosphere, receive pulses or vibrations, and communicate them to the sensorium, which communications, though not precisely to be called hearing, may answer

the same purpose. I wonder why this is not precisely to be called hearing! Then, again, they are provided with depressions on the antennæ which Mr. Cheshire reasonably suggests are 'auditory hollows,' connected as these depressions are with the end of a nerve, precisely as the auditory hollow on the transmitter of a telephone is connected with the telegraphic nerve-wire. Such an extremely sensitive diaphragm may easily be susceptible to myriads of impressions from members of their own kind, although not responding by visible signs to unintelligible tones made by methods used upon them in vain by modern scientists.

It is well said* that we ourselves are not visibly affected by the sound of booming cannon, the roar of thunder, or the surging of the waves on a rock-bound coast; yet let a child's tiny shriek fall on one's ear in our crowded streets and all is alarm and agitation. To deny the power of hearing to bees because they don't respond to our sound productions, is equal to doubting the efficacy of the telephone or microphone when their transmitting accuracy is disturbed by violent usage.

Much could be advanced, and innumerable instances quoted, in favour of the theory that our favourite insects can hear, much also that they cannot: amongst the ancient unbelievers being Linnæus and Bonnet: Aristotle and Iluber remain doubtful, yet the latter somewhan inconsistently gives instances of sounds uttered by them with the effects produced upon the hearers. Then comes the question, Can they speak? I mean by speaking the utterance of sounds intelligible to themselves.

Dr. Wollaston (Ins. Misc., p. 104) says, 'Since there is nothing in the constitution of the atmosphere to prevent vibrations much more frequent than any of which we are conscious, we may imagine that animals, like the crickets (Grylli), whose powers appear to commence nearly where ours terminate, may have the faculty of hearing still sharper sounds which, at present, we do not know to exist; and that there may be other insects (this is what I wish you to specially notice), having nothing in common with us, but endowed with a power of exciting, and a sense that perceives, vibrations indeed of the same nature as those which constitute our ordinary sounds, but so remote that the animals who perceive them may be said to possess another sense, agreeing with our own solely in the medium by which it is excited, and possibly wholly unaffected by the slower vibrations of which we are sensible. This is what I call a fair description of intensely sensitive auditory organs. Flies on the diaphragm of a microphone have been heard to utter trumpet tones otherwise inaudible to us.

If I can show that bees utter sounds certainly understood by us, how many more must there be which we, with our comparatively coarse appreciation and imperfect comprehension, are unacquainted with? We all know the lazy contented boom of the drone, as contrasted with the irritated whizz and whirr of the disturbed honeygatherer. We recognise the contented hum of the quiet prosperous hive in opposition to the sharp 'poop, poop' of the lost queenless bee. The sounds of swarming are as distinct to us as are our own distinctive notes. Many of these regular tones, 'familiar to us as household words,' are doubtless of no special moment to the bee, yet they show to their community that 'all goes well,' everything is as it should be outside the hive; these involuntary notes are a sort of perpetual assurance that the outside world is going on much as it should.

Our vocal organs, as we know, consist, firstly, of a reservoir of air in the lungs, which can be compressed by means of the diaphragm and the rib-muscles, and expressed either gently or with considerable force; and, secondly, of an air-tube (the throat), at the opening of which is the glottis. It is the striking of air upon the lips of the glottis which, with muscular contraction and

expansion tightening or slackening them, causes the varying sounds of the human voice. Let them be so tightened that they touch each other, and their vibrations become so rapid that a high note in the scale results; slacken them, and the notes fall in exact ratio. From the human voice let us go to the sound produced in some musical instruments—the oboë, the bassoon, and various others. Here two pieces of reed are scraped down until they are exceedingly thin; they are fastened together and placed within the lips, when, after a little practice, we are able to produce the peculiar buzzing notes which give to reed instruments their characteristic charm.

So, I contend, is it with the vocal organs of bees; they have their air reservoirs (I do not allude to the trachea in the abdomen) which serve for them the same purposes as our own, namely, for oxygenizing the life finid, and for uttering these signals to others of their

kind which we term language.

Behind each of the bee's four-wings, two on either side, are spiracles or air-throats, and these are so placed with regard to the wing, that upon air being expelled from the reservoirs, it impinges upon the edge of the wing exactly as the air from the lungs of the musician strikes upon the edges of the reeds, or upon the lips of the glottis in the case of vocalists, causing such vibrations as produce notes. Add to this, muscular tightening or slackening of the film, and its height or depth is varied. This, I imagine, will produce the voice-tones which may be a perfectly comprehensible language to bees, although unheard by us, in the same sense as a whispered conversation at the other end of the room would be here inaudible. In passing:-A young son of mine has informed me that last season he repeatedly observed his pet humble bees vibrate their wings when not extended so as to join the two side wings together by the bent plate and hooks, and that the sound produced with the wings, so to speak, loose, were quite distinct in tone and character from the usual bee-notes,

I do not suppose this theory will ever be more than a hypothesis until we introduce the receiver of the microphone into the observatory-hive-not a difficult thing for scientists. As for the well-known notes we actually hear, it is no new theory that they are produced as Swammerdam says: - 'By the motion of the wings, which is increased by the internal air propelled out of their bodies through the air-tubes at the same time; for some of these pipes open with wide apertures under the wings. Certain cavities, also, fit for receiving and vibrating the air, and formed under and behind the wings. contribute to this. Nor must the shoulder-blades be excluded from their share in this music, since they are placed just above the wings, joined to the chest, and having under their breadth the openings of several air pipes. It is thus the motion of the wings, with the assistance of all these parts, and by force of the propelled air, makes the humming noise peculiar to that insect. Reaumur attributes the sounds of bees to the wings beating more or less rapidly against the air, according also, it may be, to the different angles at which it is struck; † and he expressly says, that a bee whose wings are eradicated is perfectly mute. Hunter, on the the other hand, affirms that, though the wings be: off, and the legs held fast, they can still emit a shrill peevish sound, as they can also do when their wings are smeared with honey, and even when they are held under water, which he observed to vibrate at the point of contact with the air-holes at the root of the wings.

Since writing the above, the sixth part of Mr. Cheshire's admirable work on bees has appeared, and he, as ever, goes most exhaustively into the question. He quotes Landois, who noticed three tones in the flight sound:—(1), the wing beats, (2), vibrations in the

^{*} Biblia Naturæ, i. p. 168. † Mémoires, p. 617. ‡ Phil. Trans. 1792.

abdominal rings, (3), notes from the true vocal apparatus placed in the stigmatic orifices (he stopped these with wax and brought the humming to a close at once). Mr. Cheshire tells us that the wings undoubtedly do the buzzing, but the lumming is as clearly the outcome of an apparatus within the spiracles of the bee. He goes on to describe this anatomically, and concludes by attributing the voice of the bee to sounds emitted by plaited and fringed curtains lying behind the edges of the spiracle, these curtains being played upon by air puffed in and out at the will of the bee. Whether by this means, or by the air being forced against the wing edges, by vibration of the wings, or by all of these methods, I hope I have shown you that there is a strong weight of evidence, containing facts which if not already known to us may be easily verified, in support of the assertion that bees, in common with many other insects can hear, by organs not dissimilar to ours, that they can also utter varying voice tones by a method also much resembling that producing the voice-tones of man and the greater part of animated nature which intercommunicates impressions and desires, and that these two faculties, hearing and speaking, are possessed by bees, not without an object, as we can perceive always in the works of nature if we examine them closely, but with the distinct object of being used as we use language, and as every other animal uses language which possesses the apparatus suitable for vocal signalling.

Granting this much may we not, without disagreeing on points of anatomical structure, conclude that the voice of bees is duplex, first vibratory by the wings as exemplified by the hummer wood, continuous during flight, and conveying only a general assurance of contentment or alarm; secondly, truly vocal by means of the air-sac (the lungs), the spiracle (the throat), and one or more vibrating lips against which the air strikes in respiration, producing notes some of which even we can hear and understand? The vibratory method I will illustrate by the hummer and the truly vocal by the

oboë reed. The discussion on preceding paper, with the remainder of the matters discussed at the Conversazione, will be given in our next issue.—Ed.]

Correspondence.

The Editor does not hold himself responsible for the opinions expressed by his correspondents. No attention will be taken of anonymous communications, and correspondents are requested to write or one side of the paper only, and give their real names and addresses, not necessarily for publication, but as a guarantee of good faith. Illustrations should be drawn on separate pieces of paper.

Communications relating to the literary department, reports of Associations, Shows, Meetings, Echoes, Queries, Books for Review, &c., must be addressed only to "The Editors of the "British Bee Journal," c/o Messrs. Strangeways and Sons, Tower Street, Upper St. Martin's Lane, London, W.C.' All business communications relating to Advertisements, &c., must be addressed to Mr. J. Huckle, King's Langley, Herts (see 2nd page of Advertisements).

**In order to facilitate reference, Correspondents, when speaking of any letter or query previously inserted, will oblige by mentioning the number of the letter, as well as the page on which it appears.

TWO VISITS TO AN APIARY IN WALES.

[789.] Glanrafon, the residence of Nicholas Bennett, Esq., J.P. for Moutgomeryshire, is situated in the lovely valley of Llawry Clyn, through which the noted trout stream, the Trannou, flows. Although Glanrafon is only a few miles from the summit of Plynlimmon, contrary to what might be expected, it is admirably situated for beeculture, being sheltered by lofty hills covered with rich, honey-yielding plants flowering at various periods of the year. In the spring immense quantities of plants of the orders Salicaceæ and Corylaceæ shed their pollen; the latter, however, has little attraction for bees, being windfertilised; but, later on, in addition to other honey-

yielding plants, scores of acres of white clover are cultivated—thence an immense quantity of honey of the richest aroma might be collected; but,

'Alas! full many a flower is born to blush unseen, And waste its sweetness on the desert air.

Some of the hills appear to be gilded when they are covered at a period of the year with the blossoms of Lotus corniculatus (a plant much visited by bees). At the same period one hill is a mass of thousands of 'white butterflies, the flowers of the sweetest of plants, Orchis bifolia. There are also miles of plants of the order Ericaceæ which tinge the mountains with the purple heather.

Mr. Bennett may truly be said to be a disciple of Dr. Bevan, having enjoyed the friendship and acquaintance of the 'bee-doctor' in his early days for a considerable time, and from him learning a great deal of bee-keeping,

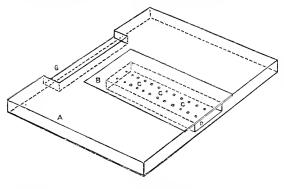

Mr. Bennett is now advanced in years, and vast improvements have been made in apiculture since Bevan's time, but still with very great regard for his first beemaster he shows his visitors a very rare work upon bees by his friend Dr. Bevan. Mr. Bennett has all his life studied bees with his favourite hives, facsimile Bevan's, from which he has taken immense quantities of the richest and most beautiful honey. January, 1886, found the apiary consisting of a large number of Bevan's hives, and, alas! the poor bees gone to their final rest, excepting one solitary colony in a very weak condition. It might be mentioned that the much-respected mother of this gentleman, Mrs. Bennett, when only fourteen years old, found a stray swarm on the Plynlimmon Hills, and successfully hived it berself in a milk stean (a small milk pail), without help, from which the whole of the neighbourhood has been supplied with stocks through her kindness. Mrs. Bennett had great delight and success with her bees, but she has gone to her rest many years ago, and the stocks of bees in the apiary dwindled down to almost extinction. The surviving queen was found in possession of a space between the ceiling and floor of a large room of the hall—the bees of which plundering all hives in the vicinity. As it has been impossible to disturb 'the Gipsies,' as Mr. Bennett has named them (and it might be added Mr. Bennett has the greatest regard for Gipsies of another kind, and is a true and good friend to them), they must have an immense quantity of honey, having never swarmed and being each year exceedingly strong in bees.

Mr. Bennett has taken immense quantities of honey of delicious aroma and other good qualities, but at the time of the visit he was sorely distressed about his stock in Bevan's hive-'his sole remaining joy,' or 'last of his flock.' He consented with great reluctance to have the hive opened or examined!—knowing nothing of the modern methods of bee-keeping, having not even so much as heard of the existence of the British Bee Journal. No John Peels about, and work of County Associations complete, &c. However, one of Bevan's hives was prepared for the reception of moveable frames -frames prepared and all got ready for transferring the stock to the new hive—but, upon turning it out, behold! the honey had been extracted by the six-legged bees to their dwelling already mentioned, and only about half a pound of bees left, but queen extra muros! A few days after a frame with adhering bees was lifted out of the now modern hive, a fertile queen was placed right in their midst, which was joyfully received, and which eventually built the colony into a very successful and prosperous one. Mr. Bennett was amazed at these proceedings, telling a friend some time after that he thought he was fifty years in advance of any bee-keeper in his neighbourhood with his Bevan's hives, but now he found he was fifty years back!

1887, January. During the year such progress has been made, such knowledge gained, that Mr. Bennett

expressed to me that he could hardly have believed it could have been possible to have made such alterations and improvements in his apiary. There is now a goodsized bee-house filled with hives, of course with moveable frames and all latest improvements; a large row of hives containing Standard sized frames, suitable for the production of comb or extracted honey, and all capable of working on the very latest systems of honey production. The hives are arranged most artistically amongst the shrubs of his pretty and picturesque garden. The manipulating house is fitted up with improved Raynor extractors, wax extractors, honey ripeners, &c.; arrangements and apparatus for queen-raising; compartments for sections and feeders, &c.; in fact, a complete arrangement of modern bee-keeping apparatus. Then there is the workshop fitted with a beautiful lathe, built by the late R. Roberts of Manchester, connected with which is a circular saw, drilling machine, fret-saw, &c.; and an adjoining room fitted up as a complete smithy. It should, however, be mentioned that Mr. Bennett has all this for his private amusement and pleasure, and in no way with a view to pecuniary interest. He is a most ingenious gentleman, and has devised some very useful plans for feeding bees, preventing bees from robbing, and others connected with managing and arranging hives.

Perhaps the fellowing illustration of the eleverness of Mr. Bennett may be useful to some of your readers. Fitting up a hive with moveable combs he fixed it in such a manner that the 'Gipsies' were forced to travel through it—this was easily done by making a hole at the back of the hive and fixing it on the outside of the entrance of the wall through which the bees made their way to and from their inaccessible stores; but, for a long time, no notice was taken of their furnished apartments, until Mr. Bennett hit upon the plan of placing a comb containing eggs and brood into this hive; the bees, as

- A Floor-board. Sheet of Tin perforated.
- c Holes in perforation, 3/1 diam. p Entrance for Feeder.
- E Feeder. F Uncovered Spout to place in D. G Bee Entrance.

Feeder.

he calculated, immediately took possession, filled eight standard frames with honey in a week, wax foundations took their place, and a very large quan-

tity of honey thus secured at various intervals during the season. Mr. Bennett has also invented a floor-board and a modification of Messrs. Neighbour's feeder, by means of which condemned bees may be fed. This parish contains an

enormous amount of sickening superstitions con-

nected with bee-keeping and bees, an account of which I am afraid would make these notes too long; but, with your permission, I shall be pleased to communicate at some future time.—T. Bonner-Chambers, F.L.S., London.

YORKSHIRE COUNTY ASSOCIATION.

'Another race the spring and fall supplies; They droop successive, and successive rise.'

[790,] I fear your readers are getting 'Yorkshire relish ad nauseam, but I intend to pursue the subject relentlessly until one of four things happens: (1.) Until you, père Editor, are siek of the question, and your gorge rises proportionately with my choler. (2,) Until we are convinced, by a communication from the 11on. Sec. that the Association is so working as to justify its fitness to survive, that it has a raison d'être. (3.) Until it explodes with pop-gun report, and melts into thin air, leaving us unfettered to form new Associations in districts where we will not 'give to airy nothings a local habitation and a name;' or finally (4.), Until the B.B.K.A. emancipate us by expunging the Association from their books.

With all respect to the Hon. Sec. (who, I hear, is an estimable gentleman) may I ask one pertinent question? Does he read his B.B.J.? and, if so, why does he leave us so totally in the dark by not responding to our inquiries either in love or anger? Neither contemptuous silence nor sulks befit the occasion, for if my comments call forth no reply, surely those of your other correspondents should command some sort of courteous consideration. Even the gods of wood and stone had their prophets who spoke, but now, alas! the invocation to Baal brings not the fire to our sacrifice.

· For ever close the impenetrable door; It naught avails that in its torpid veins Year after year life's tottering spark remains.'

Instead of 'Up mounts the chief' to tell us of the Association and its work, so that helpers might join in it, we have only the gloom and silence of space. Poor Milton's lines steal into the mind:

'The sun to me is dark and silent as the moon When she deserts the night, hid in her vacant interlunar cave.'

I want to make a dreary, dry, and weary subject arouse the interest of my brother bee-keepers of the county, hine illæ lachrymæ. Are we to conclude that our Hon. Sec. scorns to speak, or dreads to speak, under some such idea as, 'Sh, sir, if I utter but a single tone the whole thing will collapse.' Would we could cremate it, and preserve 'the sacred ashes in a little urn,' perchance to be mistaken for Prince's mixture by some snuff-taking New Zealander var. Macaulay!

I saw in an index the other day 'Bees and rheumatism,' I should have liked to read something about 'Bees and bile, for my bile was very active on the 6th inst. when I received the following, the signature, &c., of which I will suppress :-

'Dear Sir,-Excuse me for being so bold as to write to you, but as I have seen your name in the B.B.J., and as I am a Yorkshire bee-keeper, I should be glad to join any Society that would be a help to us in bee-keeping. I did join the Yorkshire Society, and I wrote twice for information about my bees, and I got no reply until the contributions became due, but declined to pay. I have fourteen frame-hives. There are only two more in our village, and they are all for the brimstone pit here. I shall be glad, if you ever come my way, to give me a call, as I take a great interest in bees.

Such a letter ought to do more either to awaken the Association into new life, or to give it the coup de grace, and cause it to be put decently away than any amount of appeals or diatribes from—R. A. II. GRIMSHAW.

TOMTITS AGAIN.

[791.] I wish to say a few words on the black-headed tit. I have four good stocks of bees in bar-frame hives. On the 12th of January I noticed something or other had visited two of my hives by the zigzag blocks under the porch having been removed, as they did not fit very

tight; and about fifty wings and legs of bees were lying about near to the hives. I kept watch for about half an hour, and I saw, to my surprise, that it was a blackheaded tit, and then it was at the entrance tapping, when out came a bee to see what was the matter. No sooner had it appeared than Master Tit caught it and flew away with it. He came back in five minutes and fetched another, and I got my gun and shot it; then I set a trap at the entrance and caught two others. I can prove that they were not dead bees before they were caught by them, for they disturbed the bees so as to cause several to fly about.—B. W.

APIFUGES.

[792.] Mr. A. Green (page 17) considers the word inappropriate. I certainly paused before I dared take the extreme liberty of coining a word; but as far as I can see it must hold the field until a better is given; one not twice its length and having an absence of euphony.

If the Latin dictionary be referred to, the verb fugio will be found to bear the construction, to run away, to be off, to vanish, avoid, forbear; and it was in any, or all, of these senses I used it (there is semi-conciliation here), not in the sense of a helter-skelter, terrified stampedo down amongst the frames. If we use bee-conciliators we shall in all probability find our hands covered with bees during manipulation, a consummation not devoutly to be wished.—It. A. II. G., Horsforth, near Leeds.

PHYSIOLOGICAL QUERIES.—INVERTIBLE HIVES. [756.]

[793.] I see James Lee, in B. B. J. of January 6, very properly calls attention to the state of the larvæ in the cells when the comb is in its normal position as built by the hees. J. Lee asks if inversion is detrimental to the brood, and he seems very strongly to object to invertible hives, which, he says, have not been tried. I beg to say I have tried them with several hives this season, and all gave me nearly double the amount of scations.

gave me nearly double the amount of sections.

I see D. A. Thomas gives a good account of inversion with one hive, I having tried several, claim a right to say it is a good plan, and it seems not to hinder the bees in their work, as breeding goes on the same; and my hives went into winter stronger than any other hives that were not inverted. I do not like the reversible frames, as they disturb the brood-nest too much, so I think the Heddon hive just what is wanted, and mean to try a few this next season, as I did so well with my upside-down ones last; and as the Jones-Heddon hive is so cheap I advise the cottager bee-keeper to try it.

Bee-keeping is now taking a step in the right way, I think. With the valuable B. B. J. first (not the expert), and the British Bee-keepers' Stores with its cheap appliances, keeping down the price of hives of fancy dealers, and the British Honey Company last, but not least, to buy our honey for cash and to sell it cheap, so all can have a taste; with the New Year and the Jubilee Year too, I trust the cottager is going to have his chance to gather honey to help in these bad times. It was out of his reach when hives were such a price and no market for his honey.—Devonshire Dumpling.

SALTAIRE EXHIBITION.

[794.] I notice on page 17 an appeal from Mr. Samuel Watson for something to be done towards getting together a bee show at the above exhibition about seven miles from here; and it is suggested that I should 'stir up' some of the bee-keepers in the neighbourhood. Now, Mr. Watson, don't you think I've done a fair share of stirring up lately? You see our live-barred-gate of an

Association prevents any action beyond 'stirring up;' anything more would be audacious presumption so long as it hangs with the proverbial tenacity of a creaking gate.

I can assure the Secretary of the B. B. K. A. that the attendance at Saltaire will be enormous, and it would be a fitting opportunity for the County Association to rise to the occasion and distinguish itself; but let us have no fiasco. If we have anything let them give us such manipulation as will tend to promote scientific beekeeping in the district.—R. A. H. G., Horsforth, near Leeds.

CLEAR AWAY THE SNOW.

[795.]In most towns there is a law requiring every householder to clear away the snow without delay from the front of his own house. As our bees are not able to do this for themselves their masters should make it a point of conscience to do it for them, and thereby save thousands of precious lives. Snow has been lying in front of my apiary for twenty-four days, and this morning, feeling sure that the brilliant sun and milder weather would have wakened up my pets, I went to enjoy the sight of their pleasure. The whole scene was alive with them, as on a fine day in April; but alas! the snow was plentifully sprinkled with dead and dying, those who had alighted and fallen upon it becoming quickly numbed and stiff. My wife, ever fertile in resource, suggested covering the snow with ashes, so I shovelled it away as fast as I could, clearing about two yards in front of the hives and sprinkling ashes plentifully over the remaining patches of ice. Straw or hay would probably have done as well; but I shall always in future make it a rule to clear away the snow immediately after a fall, and thus guard as well as I can against their first flight being fatal. I did not observe a single bee that had settled on the snow recover itself.

While watching one of my hives I was greatly surprised to see an unmistakable drone make its appearance. Can any one tell me what has been observed of drones surviving the winter? I thought they were never allowed to try the experiment. I doubt if this one will be allowed to re-enter. I also noticed one bee dragging out a team of three dead ones fastened together lengthwise by the feet. I thought it did both his brains and his heart great credit.—C. C. James, Papworth St. Agnes St. Ives, Hunts, January 19th.

RAISING THE TEMPERATURE.—A CHEAP FEEDER.—WAX EXTRACTOR.

[796.] In examining my stocks during the cold weather last spring, I used an indiarubber hot-water bottle placed over the frames to prevent loss of heat. After removing the box of cork-dust on top of the quilt, I placed the bottle on the calico quilt, leaving the two back frames clear which may then be examined, and so on; before closing up I put a loose quilt over the bottle for a minute or so, so as to confine the heat; it may then be removed, and the corkdust-box replaced, the bees will not only have suffered no loss of heat, but will probably have gained some by the transaction. I did not find it excited them if not kept on too long; but on one occasion when I raised the temperature too high in a stock suffering from dysentery, it made them leave the hive in large numbers, they voided their freces very freely, and I noticed a marked improvement in their eondition afterwards, and dysentery soon left them; I infer, therefore, that when bees are lethargic from being in this state, raising the temperature on a suitable day may be of great advantage to them.

Those who continue to use syrup for spring feeding instead of following the very excellent plan Mr. Simmins has given us for feeding with dry sugar, can make

very cheap feeders by taking a piece of wood six inches square, cutting a two-inch square hole in the middle, and covering this with a piece of tin four inches square, tacked on at one corner, having previously bored about a dozen or so holes in it, corresponding with the hole in the wood; this forms the stage over the feed-hole. Invert over this with a small tin shovel the ordinary glass jam or marmalade jar, of which there are usually quantities about. This feeder can be made by anyone for a few pence except the shovel, which should cost 6d. I have used nothing but this the last two years for autumn feeding.

WAX EXTRACTOR.—For this purpose I bought last year a tin saucepan and steamer, 7 in. in diameter, at a cost of Is. Id. In the steamer I had a tin dish made I in. deep, raised by strips of tin \(\frac{1}{4}\) in. off the bottom, and the same distance clear from the sides all round, with a small spout from it, coming through the steamer, extending about 3 in. beyond and downwards at an angle of about 45°, for the melted wax to run through. In this saucer I have a perforated zinc cylinder, with bottom of same material, \(\frac{1}{4}\) in. less in diameter than the rim of the dish, raised \(\frac{1}{4}\) in. from the bottom by cross strips of tin, and coming up to the top of the steamer to hold the wax to be melted. These additions cost me Is., so that I have a very serviceable wax extractor for 2s. Id. I may say I followed as well as I could the plan in Cowan's Guide-Book. Would this suit your correspondent 'A.S.' (774)?—W. II. Jenkins.

AN EXPERIENCE IN MOVING BEES.

[797.] A recent experience of mine may possibly be useful as a warning to other bee-keepers. Last Monday I moved a skep to a stand some ten yards distant, in a diagonal line, from its former position. For three or four weeks before the snow had been lying all about and the bees had not left their hive for a longer time than that. I thought it was quite safe to move them, and was so advised by a friend more competent than myself. The next day was warm and bright, and the bees came out in numbers. I was away from home all the middle of the day and did not see them flying; but the next time I looked at my hives, on Thursday morning, I found more than fifty bees lying dead on the alighting board of an empty wooden hive I had placed on the old stand, and several more bodies scattered about the neighbourhood. The only way I see of accounting for this is the following. I had placed a plank leaning against the front of the skep during the snow to shade the entrance. It did not prevent ingress or egress, but I suppose it so disguised the front of the skep as to make it unrecognisable to the bees who returned, and that they accordingly flew off to the old position and then perished. Had I known the thaw was coming so rapidly, I should have, of course, removed the plank; but on Tuesday morning the snow was still so deep and so glaring in the sun, that I thought it better to leave it. I am afraid the loss of life will be serious at this time of the year; it is sad to see the beautiful yellow Italians lying crowded on the alighting board of the empty hive.—F. C. Hodgson.

GLEANINGS,

Our attention has been called to our translation and summary of Dr. de Planta's researches on the nectar of plants to the last but one paragraph, on page 543 of previous volume. Dr. de Planta has explained to us more clearly the ideas he meant to convey with regard to canc-sugar in honey. The paragraph should therefore read thus:—'Whilst cane sugar is present in a great number of nectars, and often in considerable quantities, it is, on the contrary, generally rare in honeys, and is frequently entirely absent. It is found only in the honeys of the Alps in relatively larger quantities.'

In the Bulletin d'Apieulture de la Suisse Romande, G. de Layens says that when a queen is removed from a colony with a view, for example, of making an artificial swarm, the bees build drone-comb, and from this beekeepers have generally concluded that they continue to do this until the queen becomes fecundated. By his experiments and observations, he concludes this is a mistake, and that from the moment the young queen leaves the cell to the time she is fecundated the bees build worker-comb, and not drone-comb, as many beekeepers think.

In the American Bee Journal, T. J. Burrill says:—The flowers of the honey locust (we presume he means effectischia triacanthus) are what botanists call polygamous, that is, they are sometimes perfect, having both stamens and pistils, and sometimes these organs are in separate flowers. In this case they are evidently upon different trees, and the case is not a very uncommon one. Probably these trees will continue year after year to do just the same thing; still it would not be surprising upon close looking if some of both kinds of flowers

should be found on the same tree.

In Hive-Bees indigenous to India, J. C. Douglas says Apis dorsata builds under boughs, normally a single comb, but under favourable conditions, as in caves, it duplicates its comb. Cells, four and a half to the inch, no drone-comb differing from worker found in any comb examined. In a comb from S. Coimbatore the actual measurements were—three cells = 645", i.e. 215" each, or 465 cells per inch; other three were 225", 218", 230"; average, 4425 per inch. The Sikkim variety is larger than that found in the plains, and the hill varieties generally appear darker and larger than those of the plains: specimens from Jubbulpore are very light-coloured. A comb of the Sikkim variety would be interesting, to ascertain if it differed from the comb of the plains, and if it has drone-cells. In many parts it migrates at certain seasons, and it leaves its comb readily on failure of pasturage. It is reputed vicious, but this is not confirmed by experts; nor is its sting exceptionally severe. This hee is confined to the plains, or does not extend beyond about 3000 feet of altitude. It builds no special drone-comb, all its cells are the same size, and its drone is not differentiated from the worker, as is that of other species, but is of the same size and shape as the worker, excepting that it has the eyes meeting as in the drone of A. mellifica.

In the Bienenwirtschaftliges Centralblatt M. Ilgen describes his experiment with regard to the requirements of water by bees. He says at certain seasons bees require water more than at others. They cannot raise brood without it, and he finds in the spring they need more than at any other time. Owing to inclement weather in the spring they are frequently unable to get any, and many perish in the endeavour to find it. He has tried various ways of supplying it in the hives and finds the best is by filling combs with water, and placing them in the hives near the outside, putting a comb of honey on the outside next to them. He found weak colonies did not take the water, and the quantity consumed by the various stocks was in proportion to their strength. When bees are supplied with water in this way they do not fly out to get it, consequently the mortality is much smaller.

In the Bee-keepers' Guide J. E. Pond, junr., says, 'Every bee-keeper of experience knows that bees don't like to store honey in shallow cells, and that they won't rear brood in cells more than regulation depth. My thoughts on this just gave me a clue to the whole business. My top bars are z-inch wide. In early spring I shave the combs in brood-chamber to just the width of the bar, and replace them in the hive just bee-space apart. When the honey season begins I put on sections and the bees at once occupy them, for they find the room they want for storage, and they at once use it; the brood-chamber being used only for its legitimate purpose, viz.,

that of rearing brood. Of course the size of the chamber must be preportioned to the size of the colony to produce the best results; but no matter how much room is given honey will not be stored in shallow cells so long as space can be found in which to work up deep ones. This with myself is not a matter of theory; it is one of experimental knowledge. I have practised the above method for four seasons and find the results the same. [This entirely agrees with our experience, and with what we have for many years taught, and for this reason we use no projections or distance-guides to our frames.—Ep.]

In the Bulletin d'Apiculture de la Suisse Romande, E. Bertrand says one colony headed by a Cyprian queen, raised at Nyon in 1885, a daughter of one received direct from Mr. F. Benton a few years ago, has shown qualities worthy of being recorded. It gathered this season about 40 kilos (about 88 lbs.) which is the maximum quantity of honey collected by any colony during this bad season. After the honey harvest, i.e. from 8th to 24th June, it gave six natural swarms of which four weighed from 2,900 kilos (6 lbs.), to 2,200 kilos (nearly 5 lbs.), and two smaller ones and the stock still remained strong. The colony rapidly developed in the spring, and wishing to raise queens under the best possible conditions they were kept a little cramped for room, notwithstanding that they were supplied with two supers which increased the size of the hive to 100 litres (about 6100 cubic inches). Notwithstanding this room the bees crowded outside; 80 queen-cells were constructed. The mother of this colony was crossed probably with an Italian or a cross breed drone, the workers being well marked. The workers produced are very active and tolerably quiet, which he particularly mentions as a contrast to the character and the want of activity of the imported queen. He says home-bred Cyprians the same as Italians produce superior bees to those imported. The cross breeding seems to produce excellent results, and the introduction of Cyprians into an apiary ought to give bees with good qualities. The future will be able to settle this point.

In the same journal we find M. Du Pasquier stating that he employs quicklime as a remedy for bee-stings.

It neutralises the poison which is an acid.

In the Canadian Bee Journal G. M. Doolittle says he uses side storing only in commexion with top storing and never recommends exclusive side storing. Bees, he says, prefer to build combs at the sides of the hives, and store honey on the top, therefore he gets sections filled with comb at the sides and when they are raised to the top they are at once filled with honey. He uses wide frames which are interchangeable, so that the process causes but little labour, and after years of trial of all kinds of systems he says he knows no other system which will give

as good results.

In the American Bee Journal, H. B. Hill, referring to a visit he paid to Mr. J. B. Hall's apiary in Canada, says, one of the things he saw there that interested him was the Caucasian bee. These are smaller than the common bee, and very dark, with a distinct silvery band bordering the back segment of the abdomen, and in mass present a bluish appearance. He says they do not seem to know how to gather honey. One of the assistants thought 'They went to the field to get what they wanted to eat in the honey season, and came home without any.' Although they are accused of being unprolific, he thinks they can raise more queens and drones to the square inch than any other race of bees in America. The Cancasian bees are very gentle in their disposition, and Mr. Hall says 'they were the quietest bees he had ever handled.' It is impossible to handle them so roughly as to make them sting the operator, although if squeezed they will sting. They appear to be very hardy winterers. When crossed with Mr. Hall's 'comb honey' bee, they are very prolific as comb-honey producers, and are beautiful as well as gentle.

In the Bec-keeper's Magazine we find II. F. Shannon

giving the Carniolan bees a very good character. He says they are very hardy, and the best comb-builders he ever had, and that they make the nicest section honey. They protect their hives as well as Italians, as far as he is able to judge. He has some Carniolan swarms that built more comb in August and September than the best Italian stands did in the honey season. They also work on red clover as well, if not better than Italians; but they swarm more, and some queens raise very poorlymarked bees.

In the American Bee Journal we find that at the Marshall County Convention the Mayor of Marshallstown stated he successfully prevented swarms from settling in high trees by using what is called a 'Yankee Queen-stick.' It is made by taking a stick two inches square, the top end dressed down to \(\frac{1}{5} \) square for about a foot. On this are nailed laths, six or eight inches long, to form a network. When a swarm is about to settle, this queen-stick is held among them, and he found that

they would settle on it.

In the Official Report of the United States Entomologist, N. W. McLain, on 'The Production of Wax,' says he observed that if pieces of new comb were exposed on a warm day the bees would tear off pieces of the wax and carry them to their hives for use in comb-building. He therefore put pieces of new comb in a shallow, square tin pan having a close fitting cover, and having holes in the bottom. This pan was placed on the cloth covering the frames, and holes made through this to correspond with holes in tin pan, so as to admit the bees. The heat avising from the bees produced a high temperature, which kept the wax plastic and easily worked. When this assistance was given comb-foundation was worked out with great rapidity, principally by the young bees, aided by the field bees at night, as the comb-building progressed more rapidly at night than by day. There being no necessity for wax producing, the working force laboured without hindrance during the day in the fields, and with equal energy by night in the hive.

In the Canadian Bee Journal, S. Corneil says he finds it most desirable to raise queens during swarming time. Cells nearly ripe are placed in cages on the frames over a cluster. When a hive swarms, one of the unfertilised queens is at once run in at the entrance of the old hive, and in twenty-nine out of thirty cases last season they were accepted. This is a sure plan to prevent second swarms, and at the same time can ten or twelve days.

swarms, and at the same time gain ten or twelve days.

In the Journal of the Royal Microscopical Society we find that Herr K. Müllenhoff, continuing his studies of bees, has investigated the behaviour of the insect in gathering and storing the honey. He discusses the damping and the compression of the pollen, the marvellous advoitness of the bee in forcing its way into flowers, the careful avoidance of mixing the kind of pollen during one gathering, the renewed salivating and compression which the pollen receives from the younger indoor workers before it is stored in the cells, which are always the cells of workers and not of drones. The pollen is frequently deposited in layers, and frequently hermetically sealed with honey, over which a thin pellicle, like a layer of cream on milk, is formed, and this can be pushed aside for the deposition of more honey or walked over without causing overflow. The bees which are going up and down over the full cells often exhibit protruded stings, and that in normal circumstances. Drops of poison from the end of the sting are seen to be deposited on the honey, and the presence of formic acid, absent in pure nectar, is thus explained. The acid doubtless exerts an antiseptic influence on the honey; and the author has beautifully shown that in uncovered honey-cells none is present, and that fermentation soon sets in, which could however be prevented by the addition of 10 per cent formic acid. Herr Müllenhoff suggests the possible expediency of removing the honey from the uncovered cells, and thus

economising the time and energy of the bees, while the honey could be readily and cheaply preserved by the addition of $\frac{1}{10}$ per cent formic acid from a pipette.

In the Canadian Bee Journal, in an editorial it is stated that those who have not used full sheets of section foundation in their sections should try and observe the difference in quantity of honey secured. Our experiments have fully convinced us that sections should contain full sheets, and with the beautiful light section foundation we are now making there is no danger of any backbone in the comb honey. In a letter from Mr. Corneil lately he says:— Dr. Tinker wrote me to try a quarter-inch starter in the bottom of the section as well as the usual starter at the top. I did so, and as my section cases reverse just as readily as not, I reversed the cases, when the two starters were joined, or nearly so, and the result is that the sections are filled, without so much as a hole for the passage of a single bee.

BEES, AND THEIR MANAGEMENT. - On Tuesday evening, January 18th, the attention of the Uttoxeter Mutual Improvement Society was directed to the above subject, Mr. Thomas Harper reading a paper upon Bees, and this was followed by a descriptive lecture by Mr. F. Harper. Mr. J. Spencer presided, and in his opening remarks said he had known Mcssrs. Harper as practical bee-keepers for some time, and as they were well acquainted with the subject they were to speak upon he had no doubt but that their remarks would be interesting and profitable. The paper was then read, in which the writer briefly traced the history of the honey-bee, mentioning several varieties now kept in this country. The physiology of the bee was described, showing how these insects are fitted by nature for the objects of their existence-to gather honey, and to assist in the fertilisation of flowers which afterwards produce fruits or seeds. value of honey as a heat and force-producing food was spoken of, and some of the uses to which it may be put were mentioned. Mr. F. Harper followed with some remarks upon the best methods of managing bees, he also exhibited hives and various appliances, and explained their use and advantages. The methods of supering and doubling were shown, also driving condemned bees, and making artificial swarms from either straw or bar-frame hives. At the close, pieces of comb and comb-foundation, dead bees (including queens, drones, and workers) were passed round, as well as sections of comb-honey. The meeting was well attended, and included a good number of young men, who were very much interested in the subject. At the close a vote of thanks was given to Messrs. Harper for the trouble they had taken.

Echoes from the Pives.

Mayfield, Sussex.—One of my stocks of bees got blown over by the severe storm at Christmas time, and as I was away and the men rather afraid of bees it was put back on its stand almost anyhow. On my going down to the country about a fortnight after I found that the hive was raised from the floor-board on two sides about two inches, allowing the cold wind and air to pass through. I took the hive indoors, rearranged the frames, which had got rather mixed up, and found the bees none the worse. This seems to show that cold does not necessarily injure bees, the weather having been of the coldest and most wintry description.—J. B. S.

Replies to Queries.

*** In their answers, Correspondents are respectfully requested to mention in each instance the number and the title of the query asked.

[773.] Managing Stock on Allotment Garden. (J. Walton.)—If for comb-honey, use ten frames in brood-nest, and 'tier up' your racks by placing empty one under partially filled one. If for extracted, use empty combs in supers, and extract freely or 'tier up' with another set of combs as with racks. Clip the queen's wings, have the hive almost on the ground with alighting-board touching the

same, all grass and weeds clear around the live; the bees will swarm even then sometimes.—W. B. Webster.

[774.] Separating Wax from Pollen.—Tie your combs up tight in a piece of strainer cloth along with a stone or stones of sufficient weight to sink this bundle to the bottom of your boiler, light the fire and let it boil a short time, then allow it to get cold. Your wax will be in a sheet at top; press the bundle a little with a stick while boiling. You must remelt this sheet of wax by water heat, and allow it to cool gradually in tall vessels.—W. B. Webster.

[785.] Clover in Front of Hive.—Why not sow Limnanthes? This does not grow very high, and looks nice; it sows itself after the first year, and provides plenty of honey. If you particularly desire clover and grass, purchase some lawn grass seed already mixed of a good firm.—W. B. Webster.

[786.] Specimens of Honey. (Aros.)—Mr. Carr, of Higher Bebington, Cheshire, can give you the addresses of the parties mentioned.—W. B. Webster.

[787.] (Castle Douglas.)—An Unicomb observatory hive is an oblong case having the two longest sides fitted, preferably, with double glass $\frac{3}{4}$ inch apart, of sufficient inside capacity to take your frame with $\frac{1}{4}$ inch bee space all round, a removable cover fitting on top with a ventilating hole covered with perforated zinc, a chamber called a flight-chamber at bottom and underneath, communicating with oblong case, having perforated zinc on one side for the purpose of ventilation. An observatory (full) hive is differently constructed, and would require illustrations.—W. B. Wedster.

[788.] Dysentery. (Far North.)—If hive is damp, remove frames—indoors—en bloc into a fresh dry hive. Provide clean dry quilts, place some nice warm cakes of candy under quilt, enamel cloth on top of frames, then felt and chaff cushions on top make good coverings for hives during winter and spring; for summer remove chaff cushions. Enamel cloth is American cloth of a description that has little or no smell.—W. B. Webster.

NOTICES TO CORRESPONDENTS & INQUIRERS.

All queries forwarded will be attended to, and those only of personnl atcrest will be answered in this column.

- H. T.—Uniting queenless stock to another in different-shaped hire.—There is no doubt that your stock is queenless. You can now only prepare for uniting by approaching the hives to one another a yard a-day, reckoning only those days on which the bees are flying freely. When the weather is suitable for uniting (which will not be until April) get some standard frames, cut out the combs from the odd-sized frames, and splice them into the standards; you can then easily unite the two lots by opening out the frames of the receiving stock with as little disturbance as possible, and gently placing the others between them alternately.
- W. G.—Queen jound on alighting-board.—It is not likely that there were two queens present, and therefore your stock is queenless. You can do nothing at present, but when the weather is warmer you must unite with another stock. In the meantime, approach the hives to one another by a yard a-day, reckoning only the days when the bees are flying freely.
- A Cottager.—Making Foundation, &c.—We do not think the apparatus you describe well adapted for making foundation, and do not advise you to persevere with it. In dipping, so much depends on the temperature of the wax that it is doubtful if you ever succeed in making the plain wax-sheets. It is much better to continue the small strips of well-made foundation, which many skilled bee-keepers give to swarms in preference to whole sheets. Queen-raising by nuclei is described in most of our bee-books, and articles have appeared in the Journal. The queen in a swarm may be found by shaking out the bees, and as they run back into the skep guided by feather she may be easily picked up. Evening is the best time to do this.
- J. B. S.—1. Bees on Roof of House.—Bees twenty feet from the ground should do as well as if nearer to the ground, considering that in a natural state they live in hollow trees. 2. Ligarianizing Six Stocks from Two.—Stimulate

your two stocks, and devote them to providing drones and queens as you propose. It does not follow that your neighbours will not have black drones flying as soon as you have Ligurians, still if your queens should be mated with blacks your hybrids will do you good service.

E. F. S.—1. Bees in Roof of House.—As you say you do not understand bees, you had better let some more experienced bee-keeper undertake the job of removal; which is one which often taxes the skill and patience of good bee-men. 2. Hive Making.—Refer to pp. 59 and 69, Vol. XIV., by following the directions there given you cannot fail to make a good serviceable hive. 3. Becoming a Bee-keeper. - Get Modern Bee-keeping and Cowan's Guide, read them, and also get acquainted with an experienced bee-keeper—your county swarms with them—discuss what you read with him, and with a little practice you will soon get on.

Surrey.—Transferring Carniolans.—The operation must not be performed before April, and then only in fine, warm weather. A Carniolan queen may be introduced at any time during the summer, but if done during the honey harvest the income will be checked. We advise you to leave the introduction till near the close of the season, unless you intend to increase by swarming, when the queen might be given advantageously to the old stock after the departure of the swarm. From experience we say that Ligurians are better honey-gatherers than Carniolans, and about as gentle when properly handled. We should doubt whether the cross between Carniolans and blacks are superior to either race pure.

- T. M. G .- Foundation .- You will find it difficult to get foundation drawn out in time to use on the doubling system during the present year, and if successful the new combs, being tender, would not be well adapted for Having twenty colonies, and not wishing for increase, we advise you to take away, say, the two outside frames from each colony, and supply their places with whole sheets of foundation, the bees being confined by division-boards. Cover up warmly and feed with syrup at the feed-hole. As the colonies increase in population give more foundation, and spread brood judiciously until your hives are well filled with bees and brood, which they ought to be by the time the honey-flow arrives, when you may proceed to doubling, using the forty frames of old comb previously abstracted in the npper hives. To these latter any combs which can be spared from the lower hives may be added and foundation again given below. Do not remove combs in the first instance until the bees are crowded—about the end of April or early in May. Much depends upon the season.
- T. Hill.—Canon Tristram's Natural History of the Bible is published by the S.P.C.K., Northumberland Avenue, price 7s. 6d.

TRADE CATALOGUES.—We have received from Messrs. Abbott, Brothers, Southall, London and Paris, their catalogue of bee-hives and appliances. This valuable catalogue has been considerably enlarged, and contains many improvements in appliances and reductions in prices. Also from Mr. Redshaw, The Apiary, South Wigton, near Lyster, his catalogue of hives and bee-keeping appliances. On the outside page of the wrapper will be found four very complete collections of bee-keeping appliances suitable to a beginner, with the prices attached.

In answer to several inquiries we beg to say that the 'British Bee-keepers' Stores,' 23 Cornhill, E.C., are in no way connected with the British Bee-keepers' Association or with the British Honey Company.

Wax Smelting.—F. H. Lemare of 1 Sydney Terrace, Guildford, writes:—If the lady, said by "Amateur Expert" to be in trouble as to "Wax Smelting" would think it worth while to send her combs, there is a man here who would melt them for her and return the wax. His calculation is, that 4 lbs. of comb produce 1 lb. of wax, and his charge is at the rate of 6d. for the I lb, of wax. Of course only I lb. of wax would not pay. The melted wax is free from 'pollen and other débris.' In looking over the catalogue of Mr. Redshaw, South Wigton, near Leicester, we note his wax extractor, which he styles 'The Poor Man's Friend,' which would be found of great service for small lots of wax and for slender purses.

Dead Queen—Dead Bees have been forwarded to Mr. Cheshire, and we await his report.

Show Announcements.

Giving Name and Address of Secretary, Date and Place of Show, Date of Closing Entries. Terms: Three Insertions and under, Two Shillings and Sixpence; additional insertions, Sixpence each. No charge made to those Associations whose Shows are announced in our general Advertising

July I1-15.-Royal Agricultural Show at Newcastle-on-Tyne. Entries close May 12. Sec. J. Huckle, Kings Langley.

August 3-5.—Yorkshire Agricultural Society at York, Secretary, H. L. Rickards, Poole, near Leeds.

Editorial. Notices. &c.

OUTLINES OF BEE-KEEPING FOR BEGINNERS,

I.—Where bees may be kept, and who is suited TO KEEPING THEM.

1. Bees can be kept in any place where there is a small piece of garden, and fields, meadows, or heath, within easy reach, more especially near orchards and fruit gardens, or where clover, sainfoin, mustard, rape, and buckwheat, are cultivated.

2. The best spot to select for placing the hives is in a garden not far from the house, where they will be sheltered from wind and be free from disturbance by strangers, and out of the way of domestic animals. It is very important if such a sheltered place cannot be found to plant a hedge or other wind guard on the northern side of the hives; and if there are a few fruit trees about so as to shelter the bees from the fierce rays of a

summer sun it would be an advantage.

3. Most persons can keep bees if they have sufficient time to spare during summer, when most of the work has to be done. Even the cottager who is at work from morning till night will be able to devote a little of his leisure time to this pursuit, which will add to his income in an agreeable manner. Any one who is sufficiently vigorous and strong, and can still lift from fifty to sixty pounds in weight, can walk without assistance, and has good eyes sharp enough to distinguish a bee's egg at the bottom of a cell, is able to keep bees.

4. The object of keeping bees is generally either pleasure or profit. If they are kept for pleasure it is better to have only two or three hives; but if profit be the object the bee-keeper should possess at least ten or a dozen hives. In either case not more hives should be kept than can be properly attended to, for one hive well looked after will make a better return than a dozen that

are neglected.

5. There are some districts where bee-pasturage is so scarce that the bees even in the best seasons cannot procure the necessary stores to keep them through the winter. These are not suitable districts for keeping bees.

6. Places exposed to the wind, or on the borders of wide rivers and lakes, where there are many manufactories, such as breweries and sugar refineries, which affure the bees, who there meet with certain death, are also not suitable.

7. Those who suffer so severely from a sting as to be obliged to call in a doctor, or take to their beds, or who have not sufficient courage to bear calmly an occasional sting, or who will not attend to their bees themselves, and are not able to make their hives, or have not got the means to procure them, or will not when needed feed their bees if they are in want, had better not undertake beekeeping. (To be continued.)

TEACHERS AND BEE-KEEPING.

Three or four months ago we drew attention to a suggestion thrown out at the Annual Meeting of the British Bee-Keepers' Association held at South Kensington. It was to the effect that a great impetus would be given to bee-keeping if the attention of masters and mistresses of schools of various grades throughout the country were called to the subject. From altogether another quarter the idea is again brought to our notice, as will be seen from a letter in this week's issue of the Journal. (P. 49). A further proposal of a practical kind in connexion with the point is that 'The Teachers' Union' could be turned to good account for the purpose advocated. We entirely approve of the suggestion. Such an existing organization, if interested in the matter, would not only save much trouble and expense to those anxious to make a move in the direction indicated, but would furnish excellent opportunities for securing intelligent audiences to lecturers on apiculture.

Now in order to give new energy to the suggestion of our correspondent we would point out two or three simple matters which should at once engage the attention of the Committee of the B.B.K.A. In the first place, means should be taken to ascertain the names of schoolmasters and schoolmistresses who already possess stocked hives or are interested in the pursuit of bee-keeping. To all such an appeal might be made to do what is in their power to promote the spread of information about apiculture. Next, from among these names a selection should be made of those known to belong to 'The Teachers' Union.' These friends should be requested to try and secure the interest of the officials of the Union in their own neighbourhood.

When once the sympathies of such leading members were aroused there would be no difficulty in making arrangements for lectures, and possibly for the display of hives and honey. This last point would be certain to exert a powerful attractive influence. A third matter would be the securing of efficient lecturers or exponents of the elements of beekeeping. This might be accomplished either by the Committee of the B.B.K:A. taking the subject in hand, or by individual and qualified members of the Association offering their services to the branch of 'The Teachers' Union' nearest their own abodes.

We have before pointed out the immediate advantages which would be gained by teachers who might be induced to interest themselves in api-culture. The importance of this point will justify a repeated reference to it. In the first place, then, bee-keeping supplies a hobby admirably adapted to those whose profession makes a severe call on physical energy, and especially on brain power. certain amount of bodily exercise is required in attending to hives, while no exhausting toil is needed. The mental faculties are quietly and healthfully called out in devising various little expedients for making improvements, meeting difficulties, or securing the best results in honey and strength of stocks. These considerations tell with great force in the case of female teachers, and we are thoroughly convinced that an immense development of bee-keeping is yet to take place through our gentler sex. A second benefit would be the certainty that pupils of these teachers would be aroused to take interest primarily in our pet insects, and later on in natural history generally. We need not point out to our readers the humanising and elevating consequences of such results. Thirdly, a fresh link would be forged in the happy bonds existing between many teachers and their pupils; and so an indirect stimulus would be applied to those feelings of mutual regard, which go so far in lending a zest to efforts to impart knowledge on the one hand, and to imbibe it on the other. Fourthly, the giving away of sections or other small quantities of honey would often afford pleasure to the givers and receivers, and would certainly call further attention to the industrious producers of the delicious article of food. We say nothing of the profits to be derived from a few well-managed hives, though this money-consideration would be, in many instances, by no means an unworthy or futile motive for keeping bees. We repeat our conviction that the enlistment of schoolmasters and schoolmistresses in the army of apiculturists would prove an immense addition to our power. No such recruiting officers could be elsewhere secured. Each one is the centre of a company of possible additions to our rank and file. Each one possesses more than average ability and intelligence, which, if brought to bear on bee-keeping, would assuredly aid in its development. We invite them to help in an endeavour to gain our school-teachers to the interests of the good cause.

In a future number we will comment on the second suggestion contained in our correspondent's letter—the subdivision of County Associations.

NOVELTIES.

WALTON'S HONEY BOTTLE.

On page 542 of our last volume we described a wicker-work covering for honey jars which was introduced by Mr. E. C. Walton, Muskham, Newark, at the Norwich Show; and we are now able to give an illustration of it which the inventor has been good enough to send us. The cover is made to suit any sized jar, and it will be seen that by slipping up the ring the jar can be easily removed for cleaning purposes.

USEFUL HINTS.

The departure of frost, with a return of mild weather, and an occasional bright day, have afforded our bees an opportunity of flight after a long confinement, and at present all colonies appear healthy and strong.

Pollen and Syrur.—Soon will the crocuses and snowdrops tempt the bees to pollen-gathering, and stimulate the queens to breeding in earnest. Then the time will have arrived for supplying artificial pollen, and for gentle feeding to stimulate to further efforts. Pea, rye, or wheat meal may be sprinkled upon the crocus blooms, and will be duly appreciated by the bees. It may also be placed in skeps or boxes, amongst shavings, and placed in a warm, sunny spot near the hives; a piece of honey-comb laid upon the shavings will soon guide the bees to the spot. A graduated feeder, in which one, two, or three holes can be used at pleasure, is best for this early season by those who follow up this practice of stimulating. For ourselves we prefer to uncap a few cells near the brood-nest, which arouses the bees sufficiently.

Taking a Peep.—To ascertain the condition of the bees, and the amount of food, gently turn aside the quilt—on a fine day only—and notice the number of bees crowding to the top of the hive, on the admission of light; also the quantity of sealed honey at the top of the frames.

If there are no winter passages in the combs, although the outside frames contain honey, bees will often starve from inability to reach it. In such a case feed with soft, warm candy over the cluster. A flat cake of two or three pounds, rolled in thin muslin, and pressed down upon the frames, the quilts and chafficushion laid upon it, and over all a board, or flat straw cover, will enable the bees to feed in comfort, until warmer weather encourages them to extend their circle to the outside combs. At present this is the only examination admissible, except in extreme cases, when indoor manipulation must be resorted to.

SMALL Colonies.—Small or weak colonies should be closely confined by division-boards, and fed as recommended above, with a view to union with stronger ones later on, or the preservation of their queens, which will often be found of great use when the general overhauling takes place.

Foon.—For various kinds of food refer back to former 'Hints' under 'Heddon's Syrup,' 'Good's Food,' 'Frames of Honey,' &c., of which, we consider the latter, as general food, the best. It should never, however, be given when granulated, a cold slab of granulated honeycomb being about as useful as a slab of ice at this time of year. All such combs should be removed from the hives, the division-boards moved up to the cluster, and

Good's (soft) candy placed on the frames above the

CLEANING FLOOR-BOARDS.—As spring advances, and the bees begin to work, a change of floor-boards is advantageons. Let the hive be gently raised from the board by pushing wedges beneath, allowing it to remain in the raised position for a few minutes until the bees are quiet, when it may be placed on a clean, dry board on its former stand. When board and stand are inseparable, the hive should be removed while the board is scraped and thoroughly cleaned. If boards are separate from the hive—as we much prefer them—it is a very easy matter to slip under the hive a dry, clean board in place of the foul one.

DEFUNCT COLONIES.—When bees are flying freely it is well to watch the hives carefully and to note any showing no signs of energy or life; or when clearing entrances, if dead bees are found in numbers; in either case an examination should be made at once to fully ascertain the state of such colonies, which often will be found to have perished. These hives should be removed

since they afford incentives to robbing.

Water.—Strong colonies when breeding largely during the spring months require a constant supply of water, which is best given in shallow tronghs near the apiary, stones being placed in the water to prevent drowning. These should be filled up, as required, with clean water, in which a handful of salt has been mixed. Some advise a comb filled with water to be placed inside the hive, but in a large apiary the plan involves too much labour and disturbance of hives. The bees prefer to carry in water, and if it be found near home much bee-life will be saved, since many bees perish while searching for water in ditches and ponds during the prevalence of cold winds. Let the water troughs be placed in a sheltered spot with the sun full upon them. Italian bees are far more eager in the pursuit of water than are the black races, which may probably, be accounted for by the extraordinary fecundity of their queens.

SPRING DWINDLING.—This searching for water is often a prolific source of spring dwindling: also too early and too frequent manipulation, and stimulation by driblets of syrup, may be placed in the same category. However prolific a queen may be, when in the early part of the spring—the breeding season—her subjects are reduced in numbers until they cover two or three frames only, it is best to unite such small colonies, for, although with care and constant attention they may be built up to strong ones by the time the autumn arrives, yet no surplus must be expected from them. The union, how-ever, should not be made sooner than the month of April, or early May, when, by judicious feeding and the addittion of a frame or two of brood from the the arrival of the principal honey-harvest. There is no better rule in apiculture than that which demands that 'All colonies must be kept strong.' Weak colonies never give satisfaction, but bring endless disappointments, causing many beginners to give up bee-keeping in disgust. Let it be remembered that in our changeable climate, even in the finest summers, and in districts where nectar-yielding plants abound, the harvest is short, and only strong colonies can yield a satisfactory return. This, of course, is taking a honey-view, but where the sale of bees, or queens, or general increase of colonies, is the object, a different method must be pursued-a subject which concerns the expert more than the general apiarist, and into which we shall not, therefore, enter. Strong colonies, young and prolific queens, plentiful store, a southern aspect with shelter from the north, and as little disturbance as possible, are golden

FOUNDATION.—For some years we have used in our own apiary the light, flat-bottomed wire foundation for brood combs with the best results, and on our recom-

mendation large quantities have been sold, affording to the purchasers general satisfaction. The article is of American manufacture, and, being desirous of encouraging our own trade, we intend in future to wire the frames, and to use English foundation of a light description, since, with the heavier foundations, we have found the bees, especially in the 'honey-flow,' to leave a solid septum, indeed, scarcely to draw out the foundation at all. The small instrument introduced by Mr. Cowan at the Conversazione held at the Colinderies we find very useful in imbedding the wire in the foundation, but we are not aware who the manufacturer is, or where the article can be obtained. Perhaps the inventor will kindly say.

HIVES.—Whether invertible hives will ever come into general use remains to be proved. Catering for those who believe in, or feel inclined to try, the plan, Mr. Neighbour has introduced an extremely well-made substantial hive, of four invertible and interchangeable boxes, which may be used for obtaining either extracted or comb honey, and which appears to us to avoid the objectionable points in the American Heddon hive, the walls being much thicker, and the close-ended frames being dispensed with. Perfect simplicity and a moderate

price are also great recommendations.

PREPARATIONS.—Again let us advise all apiarists to have an eye to preparation for the fast approaching season.

'All things decent and in order' is the best of mottoes.

In Memoriam.

It is with feelings of the deepest regret that we are called upon to chronicle the early and sudden death of our friend and fellow-worker, Mr. Charles James Fox Kenworthy, Hon. Sec. of the Middlesex Bee-keepers' Association. He died of diphtheria, after a few days' illness, on the 26th ult., at Kerrison Lodge, The Park, Ealing, in the thirty-fourth year of his age. Mr. Kenworthy was the eldest son of Mr. James Lees Kenworthy, F.R.A.S., an old and respected resident in Ealing, and was related to Mr. C. N. Abbott, of Southall, and to Mr. Charles Atlee, a gentleman who took a deep interest in the formation of the British Bee-keepers' Association. Mr. Kenworthy's father kept several hives of bees, and from his earliest years his son imbibed a love for bees and bee-keeping. As he grew in years this love strengthened with his strength, and he became in time a very expert manipulator; and it was ever his delight to assist young bee-keepers and to impart whatever knowledge he possessed to others.

Mr. Kenworthy was intimately connected with the history of the British Bee-keepers' Association. When Mr. Hunter, who was the first Secretary of this Association, resigned his office in September 1875, he was succeeded by Mr. Cleaver, who officiated from September 1875 to June 1876, when, in consequence of his numerous other engagements, he was compelled to resign. The position of the Association was at this time very uncertain, and its finances at a low ebb. The committee of that day were highly pleased to accept the willing services of Mr. Kenworthy as Secretary, as he was known to many of them as an enthusiast in bee-keeping and well versed in keeping accounts. Mr. Kenworthy began his duties on the 15th of June, 1876, being then in his twenty-second year. During his Secretaryship the B.B.K.A. (in September 1876) held a three-days show in Alexandra Palace, in which Mr. Kenworthy had a favourable opportunity of exercising his special powers of organisation. In a great measure the success of that exhibition was due to him, and it was said on the occasion that his exertions on behalf of the Association were beyond all praise.' In the early part of 1878 Mr. Kenworthy, in consequence of the

pressure of other duties, family afflictions, and the unhappy divisions then existing in the Association, resigned the office of Secretary. On the 25th March, 1878, the Secretaryship was accepted by the Rev. II. R. Peel, who, by his experience, energy, and decision, placed the Association on that firm and solid basis which from

that time it has occupied.

In April 1884, it was intimated to Mr. Kenworthy that the Middlesex Bee-keepers' Association, which had been recently established, required the services of a Secretary. He at once expressed his readiness to act in that capacity. The work connected with a county like Middlesex is most arduous and difficult, but Mr. Kenworthy has been unwearying in his endeavours to bring it abreast with the other successful Associations in the land. For some time he has been associated in his office with the Hon, and Rev. H. Bligh. Within the last few weeks he has introduced some new ideas into the management of the Association, and he has been working out the details of this scheme in a most masterly manner. Mr. Bligh, in a letter now before us, says, 'that ever since we struck out the idea of my being associated with him he has seemed to work energetically and to have developed great power of administration. He will be much missed in the Association, and it will be difficult to find any equal to him at the level to which he had raised himself.

At the establishment of the Bee and Fruit Farming Company he was appointed Secretary; and at the last annual meeting of the British Honey Company he was elected its auditor.

Mr. Kenworthy's work, however, was principally among the young. He was always a boy amidst boys, participating in their joys and pleasures, and sympathising with all their cares and sorrows. He was a staunch advocate of total abstinence during his whole life, and he was never weary of inculcating temperance principles among the youth by whom he was surrounded, and in promoting their moral and social welfare. He took a prominent part in all schemes which would beneficially employ the leisure time of his young friends; and so we find him the Secretary of Bands of Hope, the Beaver Swimming Club, the 'Crusaders' Cricket Club, and so forth. By his soft, winning, and attractive manners, he won all hearts, both young and old. His character was most estimable; he was amiable, genial, kind-hearted, and generous, and ever willing to assist in any work which had for its object the advancement of his fellow-creatures.

He was buried in Ealing Cemetery on Saturday, the 29th ult., a large concourse of friends and neighbours testifying, by their attendance, their high esteem for him and his life-work, and their sympathy with his bereaved relatives. We were pleased to see, among others, as representing bee-keepers, the Hon. and Rev. 11. Bligh, Mr. J. Garratt, and Mr. G. Henderson.

[The writer of the above is reminded that it has been his melancholy duty, within the space of a very few years, to pen obituary notices of three Secretaries of

the British Bee-keepers' Association.]

JOTTINGS BY AMATEUR EXPERT. 'Mel sapit Omnia.'

Mr. Grimshaw is at 'York' again; he means to succeed if it is to be done by wearying all parties interested by his importunity. I have a suggestion to make to him, which I hope he will be able to accept and act upon. What Swanmore is to Hants, and Hertford is to Herts, Leeds may become, in his able hands, to York, if he can only be induced to go to work. Let him ask all the clergy, &c., if they will allow him to lecture on bees in their village schools and talk to the people in simple language, taking a few simple appliances with him; and having shown them some inducements for keeping bees, give them five minutes of the wonders of the busy insects themselves, and ask them all to join a 'bee-club,' and show them

what he can give them for their one shilling per annum. Mr. Huckle will give him some leaflets and back numbers of the B. B. J. for distribution. I am quite sure Mr. Grimshaw will gain more profit from this than he ever can by throwing stones into a pond that does not even contain a frog to croak.

Talking about croaking reminds me. I hope all those who own 'croaking' bees are satisfied with Mr. Grimshaw's excellent paper on the 'Vocal Organs of the Bee,' and that they will endeavour to notice the different 'croaks' in future, and moreover that none of them will ever 'croak' themselves.

There is one line in 'Devonshire Dumpling's' letter that will make the 'fancy dealers' close their teeth tight, I guess. It is about 'cheap appliances and low prices.' The worst thing they will wish him is that he were a manufacturer, and had to live on some of the 'fancy' profits gained from some of their wares.

The Rev. C. C. James is going to shut his stable-door now he has lost his horse. He says, 'Snow has been laying in front of my apiary for twenty-four days.' I did not allow the snow to lay in front of mine for forty-eight hours, as I went and shovelled it away, consequently I enjoyed the sight of a flight of my pets, and I don't think I lost a dozen through the snow. They brought out their dead, and I judge the llight did them no end of good altogether. Keep the ground in front of your hives rolled hard so that you can shovel the snow away when it comes, and as they say across the Atlantic, Don't you forget it!

Mr. F. C. Hodgson should have removed all traces of his old stand as far as possible and not have placed an empty wooded hive there, as he confesses he did; the board in front did not do so much harm as the 'decoy' hive, as the board probably helped them to mark their new site, but seeing a hive on their old site they attempted to enter that, and so perished.

My voting list for the Committee of the B.B.K.A. reveals the fact that we have lost the future services of Mr. D. Stewart. In losing him we lose an old and useful member whose place it will be difficult to fill. Living in town as he does he was always at hand when important work wanted doing. He worked hard at the Healtheries, and much of the success of the reception we were able to give to the Canadians, I believe, was due to his efforts. Last year he advocated reform, but now we lose him altogether. I for one am deeply sorry.

The Ontario B. K. A. had a 'rousing' meeting on January 6th to welcome home their delegates. Mr. Jones had not arrived in time; the other three, viz., Messrs. Pettit, Corneil, and McKnight, were all present, they were highly flattered by our treatment of them. They were gracious enough not to insist that their honey was better-flavoured than British, and they have great hopes, which I have no doubt they will realise, of finding a good market in England for the future. Mr. Corneil said British bee-keepers were a class of men that knew their business, and there was nothing equal to a trip to London to take the conceit out of a man—even a bee-keeper. They managed to hand over 930% for their I6-91 tons of honey, that they sent, after all their expenses were paid. The expenses were heavy of course, although they had a heavy subsidy from the Government, and the price realised is a fair one considering the price of honey in Canada.

Here is a wrinkle that may be of use to some one. A Michigan man found a bees' nest in the arm of a tree six inches in diameter and sixty feet from the ground; he wanted the honey, so he shot the bough off with his rifle, taking sixty-four bullets to complete the job. I confess it would have cost me a night's sleep scheming how to do it before I should have hit on that plan.— AMATEUR EXPERT.

CANADA.

Seventh annual meeting of the Ontario Bee-keepers' Association, 1.30 p.m., January 5th, 1887, in the City

Chambers, Toronto.

The President, Mr. S. T. Pettit, of Belmont, occupied the chair, and in his opening remarks stated that no doubt the production of honey would require to be very much increased to permit Canadian honey to remain constantly upon the British market, for should this constant supply fail they must expect to lose very much of the vantage-ground they would previously have secured. He would emphasise the necessity of sending only the very best honey as to colour, texture, and flavour. For extracted honey only such as had been capped by the bees previous to extracting should be produced, and for this purpose recommended the tiering-up system as allowing ample room for storing and at the same time ripening of honey. No one contended that artificially ripened honey was better than naturally ripened honey, whilst many claimed that the artificially ripened was very much inferior. The question of legislation re foul brood was before the Association, a committee to see railway directors about reducing freight on honey, and also to see about arranging to send honey to the British

Mr. J. A. Abbott, of London, England, was introduced. He was warmly greeted, and expressed his acknowledgment of his warm reception. Mr. Abbott was elected an

honorary member of the Association.

Mr. J. B. Hall then stated he was one of a committee from the Oxford Bee-keepers' Association to ask the O.B.A. to seek for legislation for foul brood. At a later stage of the Convention a committee was appointed to ask the Legislature to pass an Act to that effect.

Mr. S. Corneil, of Lindsay, then brought up the proposition of asking the Government to grant a sum of money to pay the expenses of a scientific lecturer to

deliver a course of lectures in Canada.

The impression was that after the late grant beekeepers should not ask for such an outlay, and for the present the matter was dropped.

The evening session now opened. This session had been set apart in honour of the returned delegates.

Mr. S. T. Pettit addressed the meeting. He mentioned how Doctor Thom, of Streetsville, had, in his retiring address as President of the Association, pointed out the advisability of the display at Kensington, and, step by step, the work had been executed until, at the close of the Exhibition, they felt their most sanguine expecta-tions had been realised, and Ontario bee-keepers had every reason to congratulate themselves on their success. The different characteristics of honey from other colonies were given, and in his opinion none could compete in any quantity with Ontario honey. He emphasised the necessity of sending only the clearest and best honey, and by so doing they would have a trade-mark which could not be imitated to any extent.

Mr. S. Corneil then spoke. He mentioned the mistake made by sending too large packages of extracted honey, also crates of comb honey, both for selling and exhibition purposes. They had used a very small package of tin, also in glass, besides distributing free to visitors a large quantity in 'tastes' of honey. He was satisfied with proper management Britain could consume more honey than Ontario could produce. The honey must, how-

ever, not go through too many hands.
Mr. R. McKnight then related, in his well-known pleasing strain, many amusing incidents of their journey and work. He thought much credit was due to those who had brought out their honey, not knowing what their returns would be; also to the Ontario Government for their grant, and the Dominion Government for their ever-ready and courteous assistance, also the transport lines. Mr. McKnight had a large number of letters speaking in the highest terms of Ontario honey.

A unanimous vote of thanks was then passed to the British bee-keepers for their very kind reception of the Ontario delegates, and all the attention which had been shown them.

Mr. Abbott thanked the Association on behalf of the British bee-keepers.

9 a.m., January 6.

President in the chair. A discussion upon the hive question then took place. There was a very great diversity of opinion as to the best hive. Mr. Pettit thought a frame not less than 8 inches, or more than 9 inches, would be the best, and he recommended the tiering-up system. There were some who thought a hive with comb less than 8 inches advisable, and one or two did not object to a frame a little deeper than 9 inches. The tiering-up system was recommended to enable honey to be ripened, and at the same time allow bees ample storage room.

Mr. J. B. Hall then spoke of what had been done during the presidency of Mr. Pettit, and largely through his instrumentality they had secured incorporation, a grant of \$1000 to defray expenses at the Colonial, an annual grant of \$500, the grand display of honey in England, and he would, therefore, ask the Association

to re-elect Mr. Pettit.

Rev. W. F. Clarke objected to presidencies for more

than one year

The Rev. W. F. Clarke and Mr. J. B. Hall were also nominated, the latter, however, asked to withdraw, and when his request was not granted he asked all who wished him well to support Mr. Pettit.

Mr. Pettit was elected President, and Mr. J. B. Hall

Vice-President.

The Directors were then elected, who, during a meeting after the close of the Convention, elected Mr. W. Couse of Meadowvale, Ontario, Secretary.

The utility of perforated metal was next discussed. All who had used it and knew what it was to be with and without it testified that it was a great acquisition

to the apiary.

Mr. Abbott related the first experiments with it, how it had been in favour, but was now but little used; the variation in the honey flow might, however, make the

The afternoon session consisted chiefly of business, and at 3.30 p.m. the Convention adjourned to meet in Woodstock the second week in January, 1838.—R. F. Holtermann, Brantford, Canada.

ASSOCIATIONS.

CORNWALL BEE-KEEPERS' ASSOCIATION.

The annual meeting of the Cornwall Bee-keepers' Association was held on Wednesday, January 26, at the Town Hall, Truro, under the presidency of the Rev. C. R. Sowell. There were also present the Rev. A. R. Tomlinson, Mrs. Tomlinson, Mrs. Polwhele, Mrs. Hockin, Messrs. T. R. Polwhele, T. Cragoe, T. Treleaven, G. E. George, G. Gradidge, and C. Kent (hon. secretary).

On the motion of Mr. Cragoe, seconded by Mr. Gradidge, the following report of the committee was

adopted:-

The committee have to congratulate the Association upon an increase in the number of members and upon having passed a fairly successful year. Our members now number 179 as compared with 160 last year, but the total subscriptions promised and received are slightly less, being 42l, 18s, 6d, as compared with 46l, 3s, last year, The amount not paid is 111. 10s. 6d., but the committee have every reason to believe that the greater part of this will be collected during the coming year. The visits to the apiaries of members in 1885 were so greatly appre-

ciated that the committee decided to adopt a similar course in the past year. This useful work was carried out by the Rev. C. R. Sowell, Rev. J. A. Kempe, Mr. T. Treleaven, and the Secretary. It would be a great advantage if a few of our members could gain experts' certificates to enable the committee to divide the county into districts, and so carry out a systematic visitation to all members, at least once a-year, at slight cost. The annual show of appliances was again held in connexion with the Royal Cornwall Agricultural Association's exhibition, and the St. Austell local committee made a grant of 15l. towards the expenses. Mr. S. J. Baldwin was engaged as expert, and the show was a most attractive and successful one, though owing to its being held so early in the season the competition in the honey classes was limited. Shows were also held at St. Germans, Wadebridge, and Fowey, but in neither case did the takings meet the expenses. At these shows the manipulation tent was under the charge of the Rev. J. A. Kempe, Rev. C. R. Sowell, Mr. T. Treleaven, and Mr. E. Gradidge, to whom the thanks of the committee are due for their kind exertions to promote the interests of the

The statement of accounts showed that the assets

exceeded the liabilities by 21. 8s. 1d.

The Earl of Mount Edgeumbe was re-elected president. The vice-presidents were re-appointed as follows:—Hon and Rev. J. Townshend Boscawen, Mrs. Digby Collins, Mr. T. Martin (Plymouth), Lord Robartes, Sir John St. Aubyn, Bart., M.P., and the Earl of St. Germans. Mr. A. P. Nix was re-elected treasurer, and Mr. C. Kent secretary. The following were elected as the committee:—Mr. A. Bailey, Liskeard; Mr. W. K. Baker, Towednack; Mr. J. Branwell, jun., Penzance; Mr. G. H. Chilcott, Truro; Mr. T. Cragoe, Sunset, Truro; Mr. G. Dixon, Truro; Mr. G. Gradidge, Truro; Mr. G. E. George, Probus; Mr. J. W. Harrison, Tregony; Mrs. Hockin, Flushing; Mr. J. Lander, Laveddon, Bodmin; Mr. H. B. Neame, Portreath; Mr. W. Nickell, Helland; Mr. W. Prockter, Launceston; Mr. T. R. Polwhele, Polwhele, Truro; Mrs. Polwhele, Polwhele, Truro; Mrs. Polwhele, Polwhele, Truro; Mrs. Tom, Rosedale, Truro; Rev. A. R. Tomlinson, St. Michael Penkivel; Mrs. T. Treleaven, Creed; Mr. J. Williams, Scorrier House, Scorrier.

Williams, Scorrier House, Scorrier.

Votes of thanks to the Chairman for presiding and the Mayor for the use of the room terminated the pro-

ceedings.

BERKS BEE-KEEPERS' ASSOCIATION.

We give below an abstract of the Annual Report of the above Association, which was held at Reading on Saturday last. In our issue of January 6th, we had the pleasure to notice a pleasant social gathering of the members and friends in the Windsor district. We understand that arrangements have been made to hold one of a similar nature at Reading, on February 24th; and it is hoped to extend these gatherings to all the eleven districts into which the county has been divided, thereby enabling its members to talk over bee matters, and take counsel with each other for the coming season. Arrangements have been made by the Berks B. K. A., in connexion with the Hants and Isle of Wight B. K. A., to take charge of the bee department of the Royal Counties Agricultural Societies Show to be held at Reading in June next. A show will also be held at Windsor in connexion with Prince Consort's Association, in which Her Majesty takes so great an interest, besides shows in other parts of the county.

The Committee beg to present their Seventh Annual Report to the Members, and to congratulate them on the strength of the Association—there being now 266 members on the list, conclusively proving that its ad-

vantages and privileges are being appreciated, and that the Association has been enabled to spread and encourage modern bee-keeping among a larger circle and over a wider area. This increase has been largely due to the adoption of the District or Branch system, which has been very successfully at work during the past year. The thanks of the members are due to those gentlemen who have so kindly undertaken the duties of District Honorary Secretaries, for their earnest efforts on behalf of the Association. There are still wanting Hon. Secretaries for the Abingdon, Bradfield, and Maidenhead Districts.

Among the chief features of a very active year's work was the Great Exhibition of Honey, &c.. held by the British Bee-keepers' Association at South Kensington, from July 30th to August 5th, and it may safely be said that on no previous occasion has there been brought together such a magnificent display, notwithstanding the fact that the honey season had been but an indifferent one. On the invitation of the British Bee-keepers' Association, your Committee decided to take part in the County Competition, and sent out a circular asking members to contribute to the display, which was responded to by the following:—Messrs. Bowly, Bunce, Champion, Clegg, Coombes, E. Cooper, G. M. May, Miller, Rayer, Reeley, Whittle, Wright, W. Woodley, and Woodley Bros. The Committee were enabled to stage upwards of half a ton of honey and wax on the Berkshire stand, proving that the County can hold her own in the bee-keeping world.

The Annual Show was held at Reading, on August 26th, when the Corporation kindly granted your Committee the free use of the Abbey Ruins, and the Reading Horticultural Society allowed their large tent to be used on the occasion. This was one of the most successful shows ever held by a County Association, and almost the first that has been held independently. The classes for honey, wax, hives, &c., were well filled. Class 14, for recent inventions of service to bee-keeping, and Classes 15 to 20, for honey in its applied form, were particularly noteworthy. The prizes were kindly distributed by Mrs. Murdoch. The Silver Medal of the British Bee-keepers' Association was won by the Rev. R. Errington; the Bronze by W. Woodley; and the Certificate by Woodley Bros. The judging, which was a very arduous task, was ably carried out by the Hon. and Rev. II. Bligh, Rev. J. L. Seager, and Otto Hebner, Esq., F.C.S., F.I.C. The bee tent was a source of much interest, and the driving competition by amateurs was well contested. The show was visited during the day by upwards of 3000 people.

Very successful shows have been held under the auspices of the Windsor Branch, at Clewer, on August 2nd, in conjunction with the Clewer Horticultural Society; and by the Faringdon District, in conjunction

with the Faringdon Horticultural Society.

The *Ree Journal* has been circulated among most of the members, and under the now system adopted this year, considerable improvement has been apparent, but with the more rapid issue difficulties continue to arise by members detaining it more than the allotted time.

Most of the members' apiaries were visited by the expert at the commencement of the season. He reports that, owing to the late spring, bees were in a very backward condition, and, in consequence, the honey yield must

be considered below the average.

The bee tent has been of much use at the various local shows, viz., Henley-on-Thames (in conjunction with the Oxfordshire Bee-keepers' Association), Reading (twice), Whitchurch, Steventon, Shiplake, Windsor, Easthampstead, Bradfield, Winkfield, Abingdon, Faringdon, Maidenhead, Remenham, Wokingham, and Waltham-St.-Lawrance, when lectures have been given on practical bee-keeping, by Messrs. A. D. Woodley, Fewtrell, Webster, and Cobb.

In June of this year the Royal Counties' Agricultural Society will hold their Annual Show at Reading, when your Committee propose to unite with the Hants and Isle of Wight Bee-keepers' Association in a joint Show. To make the Bee Department a success, members are asked to kindly be prepared to exhibit and otherwise

support the Committee.

With great regret the Committee have to announce the resignation of the Hon. Secretary, Mr. Bowly, who has ceased to reside in the county, and is at too great a distance to give the necessary personal attention to the duties. The thanks of the members are due to him for the vast amount of time and labour he has devoted to the interest and welfare of the Association; his duties have been ably carried on by Mr. A. D. Woodley. The Association have also lost the services of Mrs. Curry, and Mr. W B. Kingswood from the Committee.

The Committee regret to have to present you with a Balance-sheet showing a deficit, but this is more than met by arrears of subscriptions and out-

standing accounts.

HUNTS BEE-KEEPERS ASSOCIATION.

The annual meeting of the Huntingdonshire Beekeepers' Association was beld in the 'Fountain' hotel at Huntingdon, on Saturday, January 15th. The President, the Earl of Sandwich, was in the chair, and the members present included Col. Marshall, Rev. H. S. Budge, Rev. C. C. James, Mr. T. Coote, jun., and Messrs. C. N. White, J. H. Howard, A. Childs, E. Allen, Z. Hobbs, &c., &c.

The first business was to present the balance-sheet for the past year. This showed a deficit of 5l. 3s. $4\frac{1}{2}d$., the receipts being ISl. 16s. 6d. and the expenditure 23l. 19s. $10\frac{1}{2}d$. The Secretary (Mr. C. N. White) then read the annual report. Lectures had been given at Hemingford Abbots and at Offord Cluney, and from both of these places new members bad been promised for the ensuing year. The bee-tent was erected at the annual show, and addresses were then given to large audiences by Mr. J. II. Howard and the Secretary (Mr. C. N. White). At the annual show held at St. Ives on August 5th, the B.B.K.A. silver medal was awarded to Mr. T. Cook of Yaxley, the bronze medal to Mr. J. II. Howard, jun., of Holme, and the certificate of the Association to Mr. J. H. King of Holme. The report and balance-sheet were adopted upon the motion of Col. Marshall and the Rev. II. S. Budge.

Lord Sandwich accepted again the office of president. Captain Fellows, M.P., Mr. F. R. Beart, Captain Duneombe, Lord Esme Gordon, Lord Douglas Gordon, and Messrs. H. Goodman, A. W. Marshall, A. Sperling, C. P. Tebbutt, A. J. Thornhill, W. Wells, T. Coote, jun., and Mrs. Puckle, were elected vice-presidents; Rev. C. G. Hill, Mr. J. H. Howard, Rev. J. Jickling, Mr. J. Linton, Rev. N. Royds, Mr. G. J. Rust, Rev. C. C. James, and Messrs. F. B. Thackray, A. Sharp, B. Bull, Z. Hobbs, A. Childs, and E. Allen, were elected Committee; Col. A. W. Marshall treasurer; and C. N. White secretary. Mr. J. Linton and Mr. J. II. Howard were appointed to represent the Society at the quarterly

meetings of the British Bee-keepers' Association.

The Earl of Sandwich moved that in future the members of the Society should be divided into two classes-cottagers and amateurs; and that, in order to prevent the bulk of the prizes falling into the hands of two or three individuals, no member should be permitted to take more than one first and one second prize at any competition. This was seconded by the Rev. H. S.

Budge, and unanimously adopted. The meeting concluded with a vote of thanks to the Earl of Sandwich for his services as chairman.

HANTS & ISLE OF WIGHT BEE-KEEPERS ASSOCIATION.

SWANMORE BRANCH.

 Λ committee meeting of the above Society was held on Tuesday evening, January 25th, 1887, at Swammore Vicarage; when there were present the Rev. W. E. Medlicott (in the chair). Miss Medlicott, Miss Myers, and Messrs C. Martin, E. Ainsley, G. Horner, and H. W. West (Hon. Secretary).

The hon, secretary said that he had called the meeting to consider the advisability of holding a series of lectures in the villages comprising the district; he stated that he was himself most strongly in favour of the scheme, as from his experience of last year, not only were the lectures then given well attended, but that many people who then knew nothing whatever of beekeeping, were now, through hearing those lectures, bee-keepers. The hon sec. also said that the number of new members gained at those lectures more than paid

the expense of them.

A discussion then ensued, the Rev. W. E. Medlicott, Miss Myers, Mr. C. Martin, &c., taking part in it. The Rev. W. E. Medlicott expressed himself most strongly in favour of the lectures being held, and also kindly offered to give two of the series. Mr. C. Martin followed, to the effect that he was sure the lectures were a means of doing good work amongst the poorer class, and rightly mentioned that that was the class which they wanted to reach; in concluding, he also said that he would be happy to help the hon, sec. by taking one or two of the lectures. The hon, see, thanked both these gentlemen for their kind offers, and the meeting closed with a vote of thanks to the chairman.

Correspondence.

The Editor does not hold himself responsible for the opinions expressed

The Editor does not hold himself responsible for the opinions expressed by his correspondents. No attention will be taken of anonymous communications, and correspondents are requested to write on one side of the paper only, and give their real names and addresses, not necessarily for publication, but as a guarantee of good faith. Plustrations should be drawn on separate pieces of paper.

Communications relating to the literary department, reports of Associations, Shows, Meetings, Echoes, Queries, Books for Review, &c., must be addressed only to 'The Editor of the 'British Bee Journal,' clo Messrs. Strangeways and Sons, Tover Street, Upper St. Martin's Lane, London, W.C. All business communications relating to Advertisements, &c., must be addressed to Mr. J. Huckle, King's Langley, Herts (see 2nd page of Advertisements).

**** ** In order to facilitate reference, Correspondents, when speaking of any letter or query previously inserted, will oblige by mentioning the number of the letter, as well as the page on which it appears.

TWO SUGGESTIONS.

[798.] With your permission I should like to offer two suggestions for the consideration of your readers in general, and of the Committee of the B.B.K.A. in particular. I have been examining the Rev. F. G. Jenyns' Book about Bees—a most interesting book—and I have been thinking two things which I hope every teacher in the country will do. I can conceive no hobby which a teacher can follow which is at once so pleasurable and profitable as bee-keeping. Even our lady teachers might take it up. All would find in it wholesome relaxation for both mind and body, and any one fond of using tools could, perhaps, make a hive or two.

Many teachers keep bees, but many do not. How shall we induce them to do so? Well, the Teachers' Union includes more than 300 local associations, whose meetings are held in some school, monthly, bi-monthly, or quarterly. Could not some of our experts be sent to address each of the County Associations upon the subject of bee-keeping once during the coming season? The dates of meetings could be obtained from the local secretaries, whose addresses would be found in the Annual Report of the Union. I think many would be glad to hear about the subject. Last year I addressed the members of one Association upon bee-keeping, and by the time this appears in print shall, I hope, have brought the *Book about Bees* under the notice of the members. I made, at least, one convert. I forgot to mention that meetings are held generally on Saturday afternoons, and that the Union numbers about 13,000 members.

My second suggestion is this. Our County Associations are not able to do so much as I think they might, because they embrace too large an area. Why not follow the example of the Teachers' Union, and have district associations, each with its honorary officers? The meetings might be held in some school, the use of which most school managers would readily grant for so useful an object. The teachers would, if bee-keepers, be pleased to act as local secretaries, at any rate, for their own parish, and the Association would be more in touch with its members. The cottagers would, perhaps, he more easily reached by this means.

If you, Mr. Editor, will kindly allow these suggestions to be discussed—if they are deemed of sufficient general interest to be discussed—in the columns of the B.B.J., perhaps some practical result may follow? Such, at any

rate, is the hope of-A WORKER.

JUDGING APPLIANCES AT SHOWS.

[799.] Most of us will remember that when the great annual bee-shows were being held in various parts of the kingdom during the past summer, the decisions of the judges called forth rather severe comments from several, both exhibitors and non-exhibitors. It is not my desire to rekindle a phase of the subject which is happily now laying dormant, but to suggest what I hope will prevent a repetition of some of the anomalies then complained of. Undoubtedly the judges have far too much to do in a given time. The amount of work involved in doing justice to our large classes of appliances is equal to the work expected of the agricultural-implement judges at the Royal Agricultural Society, and similar shows; and yet we expect two, or three men at most, to do the work of ten or a dozen. Consequently many of the newest appliances do not get sufficient attention, exhibitors especially stay away, at least until they have forgotten the disgust with which they left the last show at which they exhibited, and bee-keepers generally do not attach as much value to the awards as they would if those awards gave more satisfaction when made. To increase the number of judges is not practical on the score of costs: moreover, outsiders would be rather amused at the sight, so that all thoughts of reform in that quarter had better be abandoned at the outset. Possibly it would be wise to select the judges from a wider area; but this by the way.

The next best remedy I have to suggest is on the lines of what was commenced at the spring quarterly conversazione of the British Bee-keepers' Association last year. Appliances were brought to that meeting and discussed, and a vote taken as to their utility. At the last Conversazione, held on January 19th, of this year, the vote was dispensed with, and I think wisely, because that vote was not binding on the Committee of the B. B. K. A. to grant a certificate of utility, consequently it might lead to disappointment and unpleasant-But I think those who bring out new appliances from time to time might well be encouraged to bring or send them to the Conversaziones and get the members there assembled to discuss them, and the new points in the various appliances should be recorded to the credit of those who first exhibited them, subject of course to the protest of any who may be able to prove priority. This will probably prove the most fruitful source of any trouble there may be in my scheme, but something of this kind may well be recognised amongst us, as we do not as a rule go to the Patent Office; and I much doubt

if anything appertaining to bee-hives could ever be granted a patent 'that would hold water,' but the fact of our avoiding the Patent Office need not prevent us from doing justice to any one who had applied a new idea to bee-appliances, by withholding the credit of the same from any exhibitor who may have pirated another's ideas.

The next requirement is a Standing Committee of members of the B. B. K. A. for appliances only. Its members need not be chosen exclusively from those fifteen overworked gentlemen that compose the General Committee of the B. B. K. A., although those who usually act as judges at our great shows should of necessity be on it. The duties of this, which we will name 'Appliance Committee, should be to thoroughly overhaul the new appliances that may be submitted from time to time, and award certificates to those of sufficient merit. Then when these various articles already certified as containing merit are brought together at the great shows, the duty of the judges would be to define the degrees of merit in each case and make their awards accordingly. A silver medal, awarded after such an ordeal, would be far more valuable in the eyes of manufacturers and bee-keepers generally, and we should get the award of one set of judges at one show reversed by another set at another show less seldom than at present; competition in ideas and workmanship would be more spirited, and judging would be done with greater care.

What I should wish for, above all things, is to see this well discussed by those most interested; as a rule we are far too apathetic in everything except grumbling. Some of my remarks may seem like reflecting on those gentlemen who undertake the duties of judges from time to time, I need scarcely assure them I give them every credit for doing their best; what I desire is, that their best efforts may for the future give satisfaction. — AMATEUR

Expert.

YORKSHIRE ASSOCIATION.

[800.] I see by your show announcements that the Yorkshire show is announced to be held at York in August. Now, I hope that the show, and especially the bee-department, may be a success, and I trust that the bee-keepers of Yorkshire will do all they can to make it so. I also notice that the Ilon. Secretary resides at Poole, which is only a few miles from Horsforth, so that I was rather surprised that Mr. Grimshaw was not acquainted with him. Now, I think that if Mr. Grimshaw and the Secretary would co-operate, and use their best endeavours, they would greatly improve the exhibition, and also the Yorkshire B.K.A., which, there can be no doubt, requires improvement. We should be pleased to see Yorkshire enter the county competition at the B.B.K.A.'s annual show, as I feel confident that there are many practical bee-keepers in Yorkshire, and I think Yorkshiremen would prove bad to beat.

Mr. Editor, I must not trespass too much upon your space, but I cannot close this without another word to the Yorkshire Association, which has been somewhat like the fat boy in Pickwick, doing its work and going about half asleep; but let it wake up with the present year, as there is a great deal of work to be done, and let it be done in a manner worthy of our grand old county, and then it will be a pleasure to belong to the Yorkshire

B.K.A.—A. WOODIEAD, Goole.

THE HEDDON HIVE.

[801.] I have just seen your issue for January 6th, and am very pleased to find our old friend James Lee coming to the fore again. I am also glad to be able to confirm all his statements with reference to one-piece sections, &c. As I was one of the few bee-keepers who took special notice of the machine referred to, I can

perhaps throw some light on the reversable hive and its application to practical bec-keeping. In nearly all my conversations with bee-keepers on this side the question of the Heddon hive has turned up, and, excepting in the case of those most interested in its sale, the verdict has been invariably against it. At the Ontario Convention the opinion of the meeting as to the best hive was asked; and though many practical honey-raisers spoke on the subject, no one mentioned the Heddon, or owned to using a reversing hive of any kind; and on the matter being put to the vote, the meeting was almost unanimously in favour of the Langstroth. I am further able, through the courtesy of Mr. Aspinal, editor of the Bee-keepers' Mayazine, to give an extract from a letter which will appear in the February number of that journal, from the pen of the Rev. W. F. Clarke, the chief, if not the only disinterested advocate of the Heddon hive in this country. He says, in reply to another correspondent, and referring to the half bee-space, 'I visited Mr. Heddon on my way to the North American Bec-keepers' annual meeting in October, and he distinctly told me that he never claimed to have that feature patented. Moreover, he thought so little of it that he meant to cease using it. And further, 'It is a mistake to suppose that ease of inverting is the main feature of this hive; it is not. I see no need of inverting the brood frames more than once, the object being to get the comb built out evenly and fully. With such shallow frames even once inverting is not always necessary. I judge from my own experience, and from conversations with Mr. Heddon and his assistants, that the inversion of the section rack is unnecessary, and often inadvisable.

Mr. Clarke mentions the many advantages possessed by this hive, but he does not give one which was not also common to the old Carr-Stewarton, and almost equally so to the Woodbury, or any other frame-hive. I have it also on good authority that Mr. Heddon gave it as his opinion that the mere making of hives 5 inches deep would not be any infringement of his patent. Where then is the valuable part of his 'invention?' He disclaims and abandons the half bee-space, does not think much of the reversing, and claims nothing for the shallow boxes. I hope some one will enlighten us upon this. I shall look with interest at the future numbers of

the Bee-keeper's Magazine.

By the way, many of ns might take that little monthly with advantage. It is 'well gotten up,' and costs only twenty-five cents per aunum—1s. 1d.—which low price is making it popular. Its circulation is about 9000.—J. A. Abbott, New York, January 18th, 1887.

SIMPLICITY IN FEEDING.

[802.] In addition to the method lately explained, there are others which suggest themselves in cases of emergency for early spring feeding. Where a colony has been found short soon after mid-winter, I have given lumps of granulated honey placed upon the bare frames, and so kept them along until syrup could be fed with safety.

At other times, rather than break open the cluster, a frame of sealed stores has been laid on the top-bars and all covered up warm. Certainly the comb is cut about more than when inserted below, but then in cases of this kind we are fortunate in being able to save the stock, and there is a great advantage in thus placing the comb of honey, as it is within easy reach of every seam of hees.

A note of warning here may not be out of place. If colonies have died from any cause, and stores are carelessly left in the hive, the other bees will find it out as soon as a few warm days come; and in carrying that little honey home to their own hive much needless loss of life will occur, just at the time when every bee should be restrained from flying as far as possible.

In like manner out-door feeding is very injurious, unless in skilful hands, and even after the hives are well populated with young bees, the practice is liable to lead to serious loss of strength.

Several correspondents wish to know if the Porto Rico sugar may be placed over the feed-hole in first thicknesss of material laid on the frames. Using it in that manner has proved quite satisfactory to myself; but the hole must be immediately above the cluster, and to prevent the closing of so small a space by pressure from above, a piece of wood 6 inches long by $1\frac{1}{2}$ inches deep should be placed close to the opening before arranging the sugar.—S. SIMMINS.

INVERTIBLE 1HVES (793).

[803.] In my remarks (778) I ventured to state it as my opinion that 'a friendly discussion on the advantages or disadvantages of this hive and system in the Journal' would be the means of obtaining information useful to those who wish to be careful how they discard their present hives and appliances before rushing into the trouble and expense of purchasing others, however much they may have been cracked up by those who, themselves, have had to admit that they are, at present, for all practical purposes untried, either for wintering or honey-getting. I had hoped that this suggestion would have elicited the attention of some of our many practical and experienced bee-keepers, whose names alone would have been a guarantee for the soundness of their opinions and advice, whether for or against this or any other particular system or theory in connexion with bee-

keeping.

'Devonshire Dumpling,' who may for aught I know be one of these, prefers to give his ideas under an assumed name, which many will think somewhat detracts from their value, writes: 'I beg to say I have tried them with several hives this season, and all gave me nearly double the amount of sections,'—I presume he means double the amount of sections that other hives gave that were not

inverted

It is no uncommon thing in some seasons for different colonies in an apiary, in similar hives, and under precisely the same conditions, so far as we know, to give us double the amount of honey that others do, whether we are working for comb or for extracted honey: therefore, as 'Devonshire Dumpling' says, 'I having tried several' (hives) 'claim a right to say it is a good plan.' I think we may fairly ask him to give in the Journal more detailed particulars of his experience, the conditions under which the comparison as to the yield of honey was made, the total number of colonies in the apiary, the number of those inverted, the ages (approximate) of the queens, description of the hives that each was in, the number of swarms from each inverted or other hive, and the number of sections or pounds of extracted honey, and other information he may be able to give, will, I am sure, be most interesting to your readers.

It would almost appear unnecessary for 'D. D.' to try the Jones-Heddon hive, as the invertible hive he has used gives 'nearly double the amount of sections' of his ordinary hives. Surely he cannot hope to do more than nearly double his *crop* by the use of a particular

'cheap' hive.

However cheap invertible hives can be obtained, you, Mr. Editor, will, I think, agree with me the time is not yet come for 'the cottager bee-keeper to try it.' What is required for the cottager, and what can now be obtained from most or all British manufacturers of hives, is simply a hive with standard frames and walls at least \$\frac{3}{4}\$ inches (not \$\frac{9}{4}\$ inches) thick, enough to stand exposure in our damp and variable climate, having a proper projecting roof or cover.

Competition has brought the price of hives down, and

it is only by the use of machinery and the quantity sold that there can be any profit; and I am convinced that the British hive-maker can hold his own against all the world if sound workmanship and finish are taken into consideration.

To be cheap a thing must be what it professes, well made, suitable to the conditions and purposes for which it is intended, otherwise it is 'dear at any price,' however

small.—John M. Hooker.

INVERTIBLE THVES (793.)

[804.] The 'Devonshire Dumpling' has entirely misapprehended my views as to invertible hives. I simply advised that caution should be used, and I still think it will be wise for bee-keepers to pause before going largely into inversion of hives. Nothing I have written justifies the assertion that 'I seem very strongly to object to invertible hives.' So far from my condemning invertible hives, I have designed a hive and frames complete, which I think will favourably compare with the cheap hives of which 'Devonshire Dumpling' speaks. These hives can be used as invertible hives, or not, at the pleasure of their owners. The improvements in construction embrace every requisite of a modern hive, and I am bold enough to say that the method adopted is a step forward in several details that have hitherto been done in a crude and makeshift manner at the best. I am patenting this hive, and I hope shortly to have the unbiassed opinions of reliable apiarists on its merits.

I read with astonishment 'Devonshire Dumpling's' advice to cottagers, to try the Jones-Heddon hive. Surely it requires no argument to prove its utter unsuitability to the cottage bee-keeper, seeing more skill and judgment is required to manipulate this hive successfully

than any other in use at the present day.

With regard to 'Devonshire Dumpling's' experience in inverting, I would remark that facts stated under a nom de plume lose half their value. I, for one, am anxious for information, and ask 'Devonshire Dumpling' to give us further particulars of his management. The expression used of having 'tried the inversion of several hives this season' is a loose way of putting it, and what would be preferred, I apprehend, is something more than such an unknown quantity.—James Lee, January 22nd.

INVERTIBLE HIVES.

[805.] Whilst all our inventors are busying themselves over new designs for invertible hives I take this opportunity to warn them off my latest invention—the grandest and most decided advance in bee-culture of modern times. Even if scouted by an unsympathetic public I look to a grateful posterity to creet a statue (wax) in my honour. It is such a great and well-known advantage to be able to reverse the hive at any and every time and renders the bees so comfortable and contented that I propose at once making a hive to have every facility in that direction. It will be constructed with circular frames fixed to an axle passing through the centres, the body of hive to be cylindrical and to be half inch wider in inside diameter than the outside of frames. a portion of the top staves being removed to allow of a section crate above, the said section crate to be either fixed or revolve separately. The brood combs when finished will resemble cart-wheels revolving in a barrel with a hole up top for the bees to get into the sections, the centres of frames being connected to a handle outside. It will be among other advantages: 1st, A great novelty (this is enough alone to command an enormous sale). 2nd, The immense saving of labour to the bees in having the honey just collected and stored at bottom of frames carried upstairs by revolving the handle, and a fresh set of cells brought down handy for the field bees; I do not think it necessary to be constantly inverting itperhaps for a man with but little spare time once every ten minutes would be often enough. 3rd, A great inducement for the queen to lay eggs when she comes unexpectedly upon empty cells which she distinctly remembers filling a few minutes before and thus be stimulated to renewed efforts. To enumerate all the advantages would, I fear, cause our conviteous Editor to hint about advertisement columns, so I must conclude with an appeal to the honour of brother bee-keepers not to appropriate my idea, as the doctors—I mean circumstances over which I have no control—prevent me from taking out a patent in—Colney Hatch.

FOUL BROOD.

[806.] Just a few lines in reply to Mr. Ward. He says he has no agents recognised or otherwise. I don't know where I said that he had, in fact, I don't know what he sells.

Mr. Cheshire's cure did not fail with me because I gave it to them four times stronger than recommended, as it was quite the reverse of that. That sentence should have been 'reduced four times below the strength recommended,' but by some means the word 'below' was omitted. I don't know whether the mistake was mine or the printer's, but even then I don't see how he manages to make it stronger by reduction; but I suppose in these days of inverted hives, he thought he would invert me. Perhaps I went too far in saying that all agree that the Cheshire formula is too strong, but even Mr. Ward recommends giving it to the bees in small doses.

Inverted again, killed the bees, and then could not cure foul brood, but now we have it ammonia's the thing; take out a patent, Mr. Ward, as there is plenty of that about, but not where that lot of bees went to. I am sorry that I cannot tell him how to distinguish a diseased queen from a healthy one, but if he wants to requeen any of his hives I should advise him to get his queens from an apiary that he knows to be clear of

foul brood.

Thanks, Mr. Editor, for your footnote to your last letter, I am in hopes that the correspondence will do some of us afflicted ones good.—Man of Kent.

HIVES PATENTED IN THE UNITED STATES.

[807.] Your readers may not be aware that the specifications of patents taken out in all countries where there is a patent law are filed and can be inspected in the library at the Patent Office, Chancery Lane, without payment of any fee, simply by signing your name and address in a book as you enter. There is also a

library of the scientific books of all countries.

After the little business I had at the Patent Office this week was done I amused myself looking at the places and specifications of some of the American bee-hives. Seeing from the general indexes the great number of hives that had been patented in the United States I thought it might be of interest to your readers to know the number of patents taken out under the heading 'bee-hives,' not including extractors, feeders and smokers, &c., and I counted up the numbers, which are as follows:—From the commencement up to the end of the year 1873, 591; 1874, 22; 1875, 17; 1876, 22; 1877, 33; 1878, 33; 1879, 18; 1880, 12; 1881, 10; 1882, 8; 1883, 16; 1884, 8; 1885, 20; part of 1886, 6: total, 816.

You will see that the year 1886 is not yet completed, but up to the latest returns the enormous number of 816 patents have been taken out for 'bee-hives.' I examined about thirty of the most recent ones, and I should much like those gentlemen who consider that we get all our best ideas from America to spend a day there in search of ideas worthy of imitation, and I feel convinced that whatever their opinion of the superiority of American

appliances had previously been he will go away surprised to find that any one would ever patent the rubbish he sees illustrated and described there. Upon inquiry of a patent agent, I find a patent costs more there than here, since the alteration of our patent law.—John M. Hooker.

Echoes from the Hives.

Honey Cott, Weston, Leamington, January 19th.—After such a long spell of cold weather we have had a grand change, and such a time for the bees to fly; there was no mistake about their enjoying it, after being cooped up so long. As there was such a lot of snow lying about among my hives, I had to put straw down to save the bees from settling on it to their destruction. January 20th.-On looking over some hives to-day, at dinner-time, with the sun shining bright and warm, the pleasant hum of the bees was very enjoyable after such severe weather; bees on the whole look bright and healthy. January 25th.-Another nice mild day, bees flying in great numbers. January 26th. -Such a lovely day! I took advantage of it, and had the afternoon to look over my stocks, and found four lots that had lost a good number of bees (bad management); but I excuse myself on the plea that I had not time or a chance to see to them; a couple of stocks had dysentery very bad; found all other stocks in fair order; had quite a job in drying quilts, &c. January 27th.—Sun shining very warm again, birds and bees singing away, hope we shall not have a pinch for it. January 31st .- A very nice day again, bees fetching water, showing they are making a move for breeding, &c.—John Walton.

Tref Eglwys.—Bees here had first flight on 20th January. They were unable to fly from 12th November to 20th January. To-day, 29th January, first pollen gathered. Leg of one pollen-gatherer sent to editor with this note.—T. Bonner Chambers, F.L.S.

South Cornwall, January 25th.—It is long since I sent forth a sound from these parts (in this column at least). Like many others, I suppose, there has been little or nothing to report. The weather has not been so severe as in some parts of England, but we have had an unsettled and uncomfortable winter. Yet bees have flown at intervals. Many are out to-day, and I have had the opportunity of taking a peep at some of them. I perceive that five stocks are well supplied with sealed stores till breeding sets in at any rate, and I expect that nine others are equally well off. I am sorry to say that I know of two small stocks starved to death for want of judgment. But 'live and learn,' only in the process the bees do not do the former. In your last number you mentioned the use of crown-boards. I have used them (in five slips) for years a-top of some of Lee's hives, which stand well. They have their uses. They make a snug cover for winter, and enable you to close a portion of the top of the hive when repairing, say, towards the close of the season, with a single Benthall crate. But the disadvantage for winter work is this, that if they lie next the hive you cannot well inspect at this season without a jar, therefore put down a cloth first, and, if you like, your slips on top of this. So I see the top-ventilation theory is being given up. I don't wonder at it. I remember years ago mentioning to Mr. Abbott how inconsistent it seemed to me with the determined practice of the bees to propolise every crevice.—C. R. S.

Loughbriekland, Co. Down.—This parish lies high, from 400 to 500 feet above the sea. The few bee-keepers in it find it well suited for producing honey. All stocks that were properly prepared have wintered so far well, and are fairly strong. Since the snow melted the bees have had several cleansing flights.—H. W. Lett, M.A.

Replies to Queries.

. In their answers, Correspondents are respectfully requested to mention in each instance the number and the title of the query asked.

[774.] Separation of Wax from Pollen, &c.—Like your correspondent 'A. S.', I have been perplexed in the separation of wax from all refuse, but now I find it is easily

separated by a wax-extractor that is within the reach of every cottager, invented and made by myself, and the price would be complete, 3s. 6d., or a cheaper one still without a receptacle for the wax for 2s.; but a basin will answer this purpose. I have lent mine to several bee-keepers in my district, and they say it is a great boon, as there is no mess and no time wasted and extracts every particle of wax from any old combs, cannot get out of repair, and will last a lifetime.—WM. KILLICK, Sandhurst.

NOTICES TO CORRESPONDENTS & INQUIRERS.

All queries forwarded will be attended to, and those only of personal interest will be answered in this column.

- W. G.—Uniting Queenless Stock when Frames are not interchangeable.—See reply to H. T., page 41 current volume.
- INQUIRER.—The American Bee-keepers' Magazine may be procured through Mr. Huckle, Kings Langley, Herts.
- John Richardson. Non-swarming. Consult Simmins's Non-swarming System as applied to Hives in Present use.
- BEESWING.—Distance of Combs.—The distance, by actual measurement, from centre to centre of naturally-built combs is $1\frac{\eta}{20}$ inch, and that is the distance preserved by properly constructed metal ends. If you wish to reduce the space it can be done by putting ends on alternate frames only.
- J. P.—The comb forwarded is not affected with foul brood. The brood has been chilled and dried up. It is difficult to say what has been the cause of the decay of the hive. Probably the queen has died, the bees have been unable to raise another in her stead, and they have gradually dwindled away.
- GEN. B.—1. Utilising Sections for Feeding.—If you have a stock in a frame-hive short of food you can hang the sections in a frame, tying a string round them if they do not fit well. Uncap them, warm them, and place them within the divider, crowding the bees by removing outside combs. You can give sections to bees in skeps by placing them over the feed-hole and covering up, but at this season candy or dry sugar is better; in either case remove the sections when the honey is cleared out and give others.

 2. Sugar for Dry Feeding.—Porto-Rico.
- Constant Reader.—1. Uniting.—Wait for a few weeks until the weather is warmer and the bees more active. Meanwhile, get the two stocks together by moving one, or both, not more than a-yard a-day, only counting such days as the bees are flying freely. If they are short of food you can give some combs from the stocks you found dead with plenty of food—provided, of course, they did not die of disease. To unite, if in frame-hives, open out the frames of one and place the others between them alternately; if in skeps drive both, mix, and return to the combs. 2. Robbing.—You had better remove the honey from the dead stocks—robbing, when once set up, is difficult to stop.
- S. G. F., Hornsey.—I. Size of Floor-board.—The position of the floor-board is quite correctly shown. It is the size of the outer casing, and answers as a support both to it and the hive which is placed inside. 2. Spring Feeding. It is impossible to say how long you must feed the bees when you first have them, but you must occasionally examine the hives, and if the bees are not bringing in sufficient to supply their requirements they must be fed nntil they do. 3. Number of Frames.—Twelve frames would not be too many in an Abbott hive, but they must only be given to the bees gradually as they need them; there should never be more frames in the stock hive than can be covered by the bees. 4. Distance of Baskets from Spindle in Extractor.—We think four inches too close, and have found five inches the nearest that the cages can be brought to the central spindle without considerably diminishing the extractive power.

PUTTING SWARMS TOGETHER.—Will Mr. A. J. H. Wood tell me how to put two swarms together if they don't swarm on the same day? When I attempt this they fight dreadfully with great loss of bees.—Beeswing.

Size of Extractor.—Will any reader of the Journal inform me what extractor will suit best for a small apiary? I have five hives, and some of the frames are larger than others. The largest size is 13½ inches long by 10½ inches deep, the top bar being 17 inches long.—W. M.

We much regret that, through want of space, we have been obliged to postpone the appearance of the Discussion on Mr. Grimshaw's paper,

Show Announcements.

Giving Name and Address of Secretary, Date and Place of Show, Date of Closing Entries. Terms: Three Insertions and under, Two Shillings and Sixpence; additional insertions, Sixpence each. No charge made to those Associations whose Shows are announced in our general Advertising Columns.

July 11-15.—Royal Agricultural Show at Newcastle-on-Tyne. Entries close May 12. J. Huckle, Kings Langley.

August 3-5.—Yorkshire Agricultural Society at York, Secretary, H. L. Rickards, Poole, near Leeds.

Business Birectory.

The Name and Address and Business of any Manufacturer will be inserted in this List, under one heading, for One Pound per annum. Additional headings, Five Shillings Advertisers in 'The Bee Journal,' whose orders amount to Five Pounds per annum, will be inserted Free.

HIVES AND OTHER APPLIANCES.

ABBOTT BROS., Southall, London. Appleton, H. M., 256a Hetwell Road, Bristol. Baldwin, S. J., Bromley, Kent. Baldwin, S. J., Bromley, Rent.
Blow, T. B., Welwyn, Herts.

WMY BUY A HIVE?

WHEN you can get one by looking in the Dictionary Greatest number of words from OBSERVATORY. Entrance Fee, 1s. Prize:—An OBSERVATORY HIVE, If entries insufficient, half money returned. Enclose a Post-card for successful onc. Entries close February 21, Results week after. Address-

Mr. CHITTY, Apiarist, PEWSEY.

BE GIVEN AWAY!

ONE AND A HALF DOZEN

Clark's Patent Climax Hives.

IN order that these Hives may be more generally known, the Licensee has determined to give away among Purchasers of undermentioned Goods during this February, One Dozen No. 2, and Half-dozen No. 1 HIVES (full particulars given in last year's Advertisement), at the rate of one among every thirty Purchasers, to be distributed by a lottery, to conduct which he will endeavour to obtain the assistance of persons of known integrity. Purchasers of any two articles above 1s. to have one chance, and each 2s. 6d. one chance; every further 2s. 6d. an additional chance.

N.B.—In order to have a chance of securing one of these Hives gratis, Orders must be sent in during February, as the lottery will take place early in March and Hives at once forwarded to respective Winners.

PRICES.

Finest quality White Basswood A SECTIONS, $4\frac{1}{4} \times 4\frac{1}{4} \times 2$, per 100, 3s.; 500, 11s.; 1000, 21s. $5\frac{1}{4} \times 6\frac{1}{4}$, per 100, 3s. 6d.; 500, 13s.; 1000, 25s. PURE FOUNDATION, BROOD, per lb. 2s.; 5 lbs., 1s. 10d.; 5 lbs. to 25 lbs., 1s. 9\frac{1}{2}d.; SUPER ditto, per lb. 2s. 9d. SMOKER (Bingham), 2s. 9d. REGULATING FEEDERS, 1s. 6d. LITTLE WONDER. EXTRACTOR, 10s. VEILS, 1s. 3d. PINE'S METAL ENDS, per gross, 7s.

TOOLS FOR HIVE MAKING.

Set of 36 best Cast Steel Black Bits and Iron Brace, 15s. 6d Beech Brace, Lignum head, 26 Bits ditto, 18s. 6d. Set of 12 Cast Steel Chisels, from 1 in. down, 5s. 6d. Handles, 2d. each. Tenon Saw File, 3½d.; Hand Saw, 4d. Marking Guages, 9d. Mortice ditto, from 2s. 6d. to 3s. 6d. Best Twist Gimlets, assorted, three, $10\frac{1}{2}d$. Small Hammer, 1s.; larger, 1s. 6d. Name Stamps, Steel, 4d. per letter. Oil Stones from 1s. to 3s. Best Smoothing Planes, 2 in. 3s. 6d, 2½ 4s., 2½ 4s. 3d. Best Jack Plane, 4s. 9d. Best Try Plane, 6s. 6d. Best Cast Steel Hand Saw, 22 ins., 4s.; 24 ins., 4s. 6d. Tenon Saw, 14 ins., Iron Back, 3s. 9d.; Brass ditto, 5s. 6d. Dove-tail Saw, 3s. 2 ft. Rules, 2 fold, 1s. and 1s. 6d.; 4 fold, 1s. 3d. to 2s. 3d. Spokeshave, 1s. 1d. Squares, 6 in., 1s. 8d.; 9 in., 2s. 3d.; 12 in., 3s.

Kindly oblige by adding sufficient postage for small packages of goods.

[PUBLISHED WEEKLY.]

Editorial, Notices, &c.

DISTRICT ASSOCIATIONS.

In our last issue we noticed one or two suggestions made in a letter from a correspondent (); and we promised to say something this week about the second of his proposals. This related to the formation of branches or district Associations of the County Associations. It is somewhat remarkable that a practical emphasis to this idea was given by the report of one of our most flourishing Associations, which appeared in our columns last week.

Now, we who are bee-keepers, and who wish to make our own views widely prevail, may learn a lesson from political workers. Their watchword is, 'Organize, organize, organize.' The loss of most elections on one side or the other is put down to the want of organization; and most victories are hailed as evidence of what can be done by organization. So far as truth lies in these assertions, all that it amounts to is that to push a cause you must have plenty of people interested in the cause—interested so as to work for it—working for it systematically. Let us, then, see how far these requisites will be secured by the formation of a number of District Associations of bee-keepers.

Our first point is to secure numbers to show an interest in the subject of apiculture. There are, happily, now thousands throughout the country who keep bees, and who manage them in an intelligent manner. Many of these also, we are glad to know, are members of our various County Associations. Still there are very large numbers who do not think it worth while to join these bodies, because they feel it doubtful how far they will derive advantage from membership. Distance from headquarters, inconveniences of getting to the meetings, the uninteresting nature of much of the necessary routine business, all combine to prevent people from joining the larger Associations. But if only four or five neighbouring bee-keepers will but combine to talk with each other about their methods, their difficulties, and their successes, a great stimulus will be given both to the pursuit of bee-keeping and to united efforts to improve the art. Then, if such a small Society be affiliated to the central County Association, new strength will be added to the parent body, while each of the remoter and district members will feel possessed of a share in the larger Society and its doings. One very important matter in each case will be the securing of an energetic man as the honorary secretary for each small branch. Still further stimulus may be given by holding shows—on however diminutive a scale—once a-year. Then, the best exhibits in each of these should, as a rule, be reserved for the county show. Prizes and commendations thus gained will promote a healthy emulation, and the successful competitors will learn to believe in their own powers, and will be led on to renewed effort for improved methods and more careful attention to details.

A last essential—but by no means the least—will be encouragement from the more influential bodies. We, therefore, would very earnestly commend this matter, in the first place, to the notice of the Committee of the B.B.K.A. We venture to suggest the collection of information from those Associations where the plan of branches is in full operation. From the knowledge thus gained, it would be no difficult matter to select such salient points as might be embodied in a leaflet for circulation wherever the possibility of establishing District Associations seemed advisable or possible.

Associations seemed advisable or possible.

There are many counties which have cultivated District Associations with success, for example, the Herts, the Hants, the Bucks, the Staffordshire, &c.

At the beginning of this article we referred to the report of the Berks County Association. On turning to it, in our last week's issue, it will be seen that there are affiliated branches to the number of eleven. The vigour these have imparted to the central body is manifest from the shows held in various neighbourhoods. We had the pleasure of acting as judge at one of these, and were distinctly impressed with the excellence of the exhibits, the best of which subsequently took the first prize at the County Show at Reading. We know also the excellent spirit prevailing among the members of this District Association, and we have reason to believe a similar good feeling exists in all the affiliated branches. In advocating the adoption of our correspondent's suggestions, we are, therefore, speaking from known facts of the advantages that would certainly come from its adoption. But, while earnestly directing the attention of the Committee of the B.B.K.A. to this matter, we would, with equal fervour, urge all central Committees to promote in every possible way the establishment of branches

in all towns and villages in which the existence of even three or four bee-keepers is known. As the rain-drops make the runnels, and the runnels the streamlets; the streamlets, again, form the rivers; and the rivers replenish the ocean itself; so we may expect wonderful results from the union of individuals into small societies; of these into t'ounty Associations, and of the County Associations with the great central body—the B. B. K. A.

SCIENTIFIC SUBJECTS AT CONVERSAZIONES.

There is an idea that scientific subjects should not be brought forward at meetings of bee-keepers, but that only those of a practical character should be discussed. We have always considered this a mistake, and we are glad to find gentlemen willing to bring forward scientific papers for discussion, anticipating that something, however little, may be added to our previous stock of knowledge. There are plenty of persons who do not know what has been discovered in any particular branch of study, or where to refer to for the information, that it must always be of some use to have papers similar to the one read by Mr. Grimshaw at the last Conversazione of the B. B. K. A., and more especially when the subject is handled in so pleasant and able a style. That beekeepers do take an interest in such subjects was evinced by the discussion which followed.

It is difficult for bee-keepers generally, to get information on scientific subjects, as our knowledge in these is constantly increasing, and the discoveries are published in pamphlets and proceedings of scientific societies not accessible to every one. There is no book to guide the scientific student and to point out what has been done in any particular direction, and by whom, or where the information is to be found. For instance, how many beckeepers are there who know that Leuckart discovered and propounded that the larvæ of worker bees were weaned, whilst those of queens were not, but were fed with the same food during the whole of their larval existence; or that this discovery was published in 1855 at p. 209 of the Bienenzeitung, and that it is referred to in several books? Or how many know what has been done with regard to arriving at some knowledge of the difference of the food of larvæ and that of the queen and drone, or of the discoveries of Schönfeld, Holz, Schiemenz, and others, in connexion with this? Or that Schiemenz, after elaborate researches and a minute description of the five gland systems in the bee, arrived at the conclusion that the food given to the queen 'consists of secretion from system 1, although the others cannot be excluded from its composition? There is, as we have said, absolutely no work in the English language that gives us this and similar information, or a correct history of the more recent discoveries in connexion with the life-history of bees, which are found scattered in different publications. The French bee-keepers are more fortunate, as they have their Maurice Girard, who, in 1878, published an excellent compilation, a new edition of which was not long since published, with references, of all that was known up to that time. We have no similar book of recent date, and until this want is supplied the student will have to wade through volumes of Bee Journals and other books to find what he wants. These Conversaziones assist greatly in spreading such a knowledge, and frequently

add something new to that previously known.

The subject chosen by Mr. Grimshaw was not a new one, and, as he observed, had been studied by Swammerdam and others in the last century. Many doubtful points were cleared up later by Dr. II. Landois, who, in 1867, published Die Ton- und Stimmapparate der Insecten, which treats the subject in a most exhaustive

M. Girard, in the book above alluded to, manner. entitled Les Abeilles, in describing the various sounds produced by the bee, makes constant reference to Landois. Mr. Grimshaw refers to Mr. Cheshire; but in justice to those who have written before him, we must point out that he has added nothing to what was already known, and appears to have taken his information from Girard, even to the 'plaited and fringed curtains lying behind the edges of the spiracle' (see pp. 55-60 of the work above mentioned). He does not appear to have paid much attention to Landois's work, or he would not have made the ludicrous mistake he has in the title, which he gives. To eall a 'Stimmapparate' (voice apparatus) a 'Stummaparate' (dull apparatus), to say the least is droll. In 1868 Marey registered, by the 'graphic method,' the number of vibrations of the wings, and the tone produced in consequence; but Girard points out that these experiments are very uncertain, owing to the difficulty of performing them. The chairman pointed out this difficulty; and it is also shown by the fact that Landois gives the notes formed by the wing-beats of the hee as representing 440 vibrations, whereas the graphic method only gives 190, but he also observes that when the bee is tired the vibrations decrease to 330. Girard says the humming sound is not produced by the wings only; and an example he gives is that of a humble bee (Bombus terrestris, hortorum, or lapidarius), which, if shut up in a box, and the wings are only producing a slight tremulous motion, a loud humming noise will be heard—a sign of anger or fear. If the spiracles, he says, be stopped with wax, the humming will cease. Chabrier and Burmeister, as well as Landois, have recognised three different tones: 1st, produced by the wingbeats; 2nd, by the vibration of the abdominal rings; and, 3rd, the most acute and intense, from the action of a true vocal apparatus placed in the stigmatic orifices. We were pleased to find a reference made by Mr. Meggy to an article which appeared a couple of years ago in a German magazine on the subject.

That bees possess a voice nas been long admitted; and Baron von Berlepsch, Oettl, Dr. Pollmann, and many others, have described the various sounds. Stahala has given to the sounds different meanings, whether correct or not we cannot say; at any rate it is generally supposed that they are understood by the bees. For instance, he says, if in winter one taps the hive and a loud 'Huumm' is heard, it is a sign that the bees have their queen and sufficient food. The loud 'Dzi-dzi' is heard when both stores and bees are dwindling. The loud 'Dziiiii' will be heard when they are too cold. 'Huuunuu' is produced by queenless stocks both in summer and winter. A loud 'Wuh-wuh-wuh' is only heard when breeding is going on, but never when the hive is queenless or has an unfertilised queen. Besides these there are some dozen other sounds given, such as those produced by the young queens and hees in

anger or otherwise.

When, however, we come to the question of hearing, we encounter a very much greater difficulty. The depressions on the antennæ have long been observed, and in 1838 A. Lefebvre published his Note sur le sentiment olfactif des Insectes, in which he describes these as organs of smell; and in 1847 Erichson held the same views in his De fabrica et usu Antennarum in Insectis, In 1850 Ed. Perris continued Erichson's observations, and published (arriving at the same results) his Mémoire sur le siège de l'Odorat dans les Articulés; and more recently, in 1881, G. Hauser published an elaborate treatise, in which he went most exhaustively into the question, entitled Physiologische und histologische Untersuchungen über das Geruchsorgan der Insecteu, which is by far the most important work we have on the subject, and he also arrives at the same conclusion, and is followed by Schiemenz in 1883, who holds the same opinions. On the other hand, we find Dr. Braxton Hicks, in

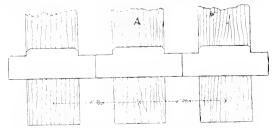

1860, in his paper, On certain Sensory Organs in Insects hitherto undescribed, states 'that there is every reason to think that the antennal organs are those of hearing? This view he also expresses in The Honey Bee, published by him in conjunction with J. Samuelson. Again, in 1878, we find V. Graber writing and holding a similar view in Uber neue, of ocystenartige Sinnesorgane der Insecten; and also Paolo Mayer, Sopra certi organi di senso nelle Antenne dei Ditteri in 1878.

That they are organs of hearing is by no means proved, and Mr. Cheshire's is only an opinion which adds nothing to what is already known. It would be interesting if Mr. Grimshaw would try his experiments with a microphone on bees, for Sir John Lubbock, who had an extremely sensitive microphone sent him by Professor Bell and attached it to the under side of one of his ants' nests, could distinguish nothing but the ants walking about. But he says, 'It is, however, far from improbable that auts may produce sounds entirely beyond our range of hearing. Indeed, it is not impossible that insects may possess senses or sensations of which we can no more form an idea than we should have been able to conceive red or green if the human race had been blind. The human ear is sensitive to vibrations reaching at the outside to 38,000 in a second. The sensation of red is produced when 470 millions of millions of vibrations enter the eye in a similar time; but between these two numbers vibrations produce on us only the sensation of heat; we have no special organs of sense adapted to them. There is, however, no reason in the nature of things why this should be the case with animals, and the problematical organs possessed by many of the lower forms may have relation to sensations which we do not perceive. He further describes structures which he only says' may very probably be auditory organs' That bees should hear seems reasonable; but it has not yet been satisfactorily proved where the auditory organs are situated, and certainly the weight of evidence so far is in favour of these depressions on the antennæ being considered olfactory.

Another question of interest and importance brought before the meeting by Mr. Grimshaw, was that of using an essential oil to prevent bee-stings. The idea of using something as a preservative is also not a new one, and carbolic acid, oil of tar, a solution of clay, and other things have, from time to time, been recommended; but none of these would be very pleasant on the face. Some years ago we came across a receipt which was said to be a sure preservative against stings of every sort, including those of the bee and mosquito:- $\frac{1}{2}$ oz. oil of peppermint, $\frac{1}{2}$ oz. oil of winter-green, $\frac{1}{2}$ oz. spirits of camphor, and \(\frac{1}{2} \) oz. of glycerine: the mixture to be well shaken before use, and to be rubbed on sparingly over the exposed parts of the body. We have never tried it, as we do not fear a sting or two, and can manage very well with smoke or carbolic acid; but there may be those who would like to do so, and report their experience. In a list we have before us of Messrs. Burgoyne, Burbidges, Cyriax & Farries, the price quoted for oil of winter-green is 1s. 9d. an ounce, and as there is no difficulty in cultivating Gaultheria procumbens, we do not see why, if there were a demand for it, the plant could not be grown. It is very common in America, grows freely in this country in a peat border, and is easily increased by division. If, however, it can be made artificially, and is equally as good, there would be no necessity at all for cultivating the plant. Bee-keepers will owe Mr. Grimshaw a debt of gratitude for bringing this matter before the meeting, and also in his able article on bee-subjugators, on p. 7 of this year's Journal, in which he goes into the question very thoroughly. We hope his endeavours to get essence of spirea manufactured cheaply will succeed, and that he will be rewarded by finding it as efficacious as he anticipates.

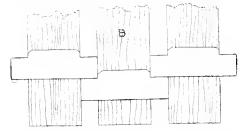

A NEW METAL END.

We have received from Mr. W. Boughton Carr a specimen of his new 'metal end' for frames, and by his kindness, are enabled to give our readers illustrations of

A, Top view of frames, with 'metal ends,' showing frames spaced at usual distance of $1\frac{9}{20}$ from centre to centre.

the manner in which it is used. This metal end is different to any of those in common use, and, in our opinion, removes many of the objections raised against

B, The same, with frames spaced to allow a quarter inch between the face of combs.

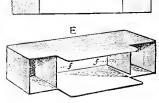

them. Since Mr. Abbott first introduced broad shoulders in England, in 1873, this manner of keeping the frames at the proper distance apart has been extensively

C, View of under side of frames, showing the 'metal end' of centre frame drawn back for closing up to the quarter inch distance without altering the level of either upper or lower side of frames. D, Sectional view of 'metal end' from the outside. E, Perspective view of ditto from the inside. (D and E are full size.)

adopted. Lately, however, metal ends in one form or another have come into use, but their shape is such that a frame furnished with them could not be conveniently used in a hive where there are no such ends used. The

ordinary cast-metal end is so thick on the under side of the top bar, that the rabbet on which it slides has to be cut deeper to accommodate it: and if a frame without these ends be used, it necessarily stands below the level of the top of the hive at least an 4th of an inch, and is

D

brought so much closer to the bottom board. Another objection to them is that the distance between the frames is fixed, and they could not be brought closer together. The new metal end which we have before us gets over these

difficulties and can be used in any hive where they have not been previously used, and in other hives a very trifling alteration would make them equally serviceable. Mr. Carr's end (figs D and E) is made of tin, stamped out of one piece and being made by machinery, the greatest accuracy is secured. It fits on the frame end like a collar, and can be slipped on and off very easily, the mouth of the collar having the sides (ff, fig. E) unsoldered, there is sufficient spring in them to grip hold of the wood and to retain the end at any part it may be placed. Fig. A shows the ends pushed up against the side bar of the frame, and in this way provides the usual distance of $I\frac{9}{20}$ from centre to centre. If, however, we wish to bring the frames closer together so as to allow only $\frac{1}{1}$ of an inch between the face of the combs, we have merely to slip back the ends on every alternate frame as in Fig. B, and our object will be accomplished.

It will be noticed that if such ends are used when they are pushed back, the wood of the frame comes in contact with the top of the runner, but as the tin of the metal end is so thin, the level of the frames is not perceptibly altered. The possibility of moving the frame laterally we consider an important improvement, and one that will be appreciated by those who, like ourselves, have ob-

jected to any projection on the frame-ends.

For many years we have advocated bringing the frames to 1½ inches from centre to centre for the purpose of preventing the production of useless drone brood. This was impossible with the ordinary ends; but with these even those who have not acquired the skill or patience to adjust their frames, are enabled within certain limits, to do so mechanically, without the danger of bringing them too close together and thus injuring the brood. Those who have used ends of the old pattern and wish to adopt these, would have to raise the metal runners an eighth of an inch, and if these are not used, an eighth inch strip of wood must be nailed on to the rabbet.

The following are some of the advantages claimed by the inventor for this new metal end over the ordinary one now in use:—

- 1. The triangular \(\frac{1}{4}\)-inch projection for gauging the distance between the frame and side of the hive is done away with as of no real use whatever, the distance being accurately kept by the end of top bar working against the outer wall of the hive.
- 2. Being made of tin, instead of east metal, the $\frac{1}{3}$ -inch bearing on which the top bar rests in the old style of 'end' is replaced by a collar of tin passing all round the bar, and this collar being no thicker than paper, neither stands up above tops of frames, nor raises the frame up perceptibly on the under side, from the bevelled runner on which it works.
- 3. They give the long-desired lateral movement which enables the bee-keeper to alter the spacing of frames at eertain times, for certain purposes. This alteration can be effected very rapidly without removing a frame, and almost without disturbing the bees.
- 4. No alteration is made in the distance between bottom bar and floor-board, nor does it interfere with the level of tops of frames if the 'ends' are removed altogether.
- 5. They are put on and taken off more easily, and when on are far more secure.
- 6. They cannot drop off through shrinkage of top bar, and may be tightened up in a moment if they should become loose.
- 7. They combine extreme lightness with strength, and, while as cheap, are less liable to breakage than 'ends' made of type metal.
- 8. The 'end' makes a perfect gauge for enabling manufacturers to produce top bars of uniform width and thickness. (The want of uniformity in this respect has long been felt.)
- 9. There is no need to remove the 'end' when extracting honey. The reduced size of projecting shoulder allowing it to pass through the ordinary mesh of wire used for eages.

ASSOCIATIONS.

BRITISH BEE-KEEPERS' ASSOCIATION.

Mr. Grimshaw's Paper on the Vocal Organs of Bees,

Discussion.

Mr. Meggy thanked Mr. Grimshaw for the interesting facts he had laid before them, and would be glad to know whether he had seen an article which appeared about a couple of years ago in a German magazine in reference to the sounds made by bees. The writer stated that he had observed forty different sounds made by bees, from which he inferred that the latter must have means of communication by sound. These particulars were made known before Mr. Cheshire brought out his work, and before special attention had been called to the question.

Mr. Grimshaw was sorry that he had not read the article referred to. He had had various theories on the subject, and had been obliged to dismiss them almost as soon as formed. He was in hopes about twelve months ago that some interesting discoveries would be made by a gentleman, whose research was, however, unfortunately stopped by death. He had proposed at swarming time time to introduce the receiver of a microphone in the hive, and at the following season turn the microphone on to the bees at the mouth of the hive, so as to see whether he could produce the same state of contentment. He had heard of cases where one lot of bees in quite a distant part of the manipulating tent have ascended up their wall or post upon hearing the agreeable noise made by the driving in a skep going on in another part of the tent.

The Chairman thought that Mr. Cheshire drew a distinction between buzzing and humaning, the buzzing being connected with the wings, and the humming with the spiracles. He (the Chairman) had gathered from Mr. Grimshaw's paper that it was through the spiracles the varying sounds were emitted, whilst the noise made by the wings did not vary at all. It would be interesting to know whether the peculiar sound they were all acquainted with was affected in pitch according to the speed of the wings' vibrations or the way in which the air escaped through the spiracles. One would imagine that it was far more difficult to make a distinction of sounds by wings than by spiracles.

Mr. Webster said the difference of sound in the wingvibrations was easily explained. In the case of a tuningfork with extra long prongs the vibrations would he less frequent than with shorter prongs, and the sound produced consequently deeper than that which resulted from quicker vibrations; and there was no doubt that the high or low notes were governed by the pace of the wing vibrations.

Mr. Grimshaw indorsed Mr. Webster's opinion. The notes varied in the musical scale *pro rata* with the number of wing-beats. The drone sounds were low tones compared to the sharp, shrill sounds of the busy workers, whose wings were quickly beating. If one placed his ear immediately outside a frame-hive, tones of all kinds could be heard.

The Chairman remarked that when hanging in a cluster they could not vibrate their wings.

Mr. Grimshaw had no doubt in his own mind that, independently of the wing-sounds, the noises heard in the hive were produced by the bees conversing together — perhaps arranging to kill the queen or drones. (Laughter.) He fully believed that they did converse as intelligently as other members of the animal kingdom. Their brain weight in comparison with the weight of their body ranked very high indeed, much higher than the ant, so much praised by Sir John Lubbock.

In reply to the Chairman, who asked whether Mr. Grimshaw believed that the chief means of communica-

tion possessed by bees was through the voice, and not by touch, the latter gentleman said that he was not prepared to speculate so much as that. It was well known that the olfactory organs of bees were singularly acute, and in a high state of development. They could trace flowers at great distances by smell. He could not hazard a conjecture as to the principal means of their intercommunication, but he thought that the vocal organs could claim their due share. were not given without an object. It was necessary for bees to intercommunicate, and it was fair to assume that the vocal organs took part in such intercourse.

The Chairman said that some of Huber's experiments went to show that if the queen were separated from the rest of the hive the bees could not be assured of the safety of the queen unless they could touch her. They were quite near enough to talk, but could not tell one

another that the queen was safe.

Mr. Grimshaw thought that if the organs of touch were the only means of communication the news passed

with extraordinary rapidity.

Mr. Meggy thought Hnber's experiments threw some doubt on the question of intercommunication by hearing, and he suggested that Mr. Grimshaw should, during the following summer, undertake to repeat Huber's ex-

Mr. Baldwin said that he had tried to make the bees raise queens while the queen was present. He had divided a hive and placed two pieces of perforated zinc with a space of more than half an inch between the halves. The bees, however, did not attempt to raise queens; but after he removed the queen they started doing so on both sides of the division. In the first instance they could not touch the queen, but evidently knew that she was there.

Mr. Grimshaw said he founded his views on the law of nature. Every organ had its use, and he contended that as the bees were provided with vocal and auditory organs they must use them. These organs were not

rudimentary, but perfect.

Mr. Meggy said he was satisfied that Huber was wrong, and he hoped that Mr. Grimshaw would not hesitate to repeat the experiments of that naturalist

because he was a man of great fame.

Captain Campbell explained some experiments he and his son had adopted in reference to the vocal and

auditory organs of bees.

Mr. Haviland would like to know, in reference to Mr. Baldwin's experiments, whether the entrances of the divided hive were close together, and whether the bees had access to each part by running in and out; because if the entrances were so close together that the bees of one division could return to the other, they would be able, of course, to communicate with one another. Huber particularly requested that other people would test his observations. There was no doubt that several of the conclusions be came to were not perfectly accurate, and it would be a good thing if they could be tested again. He had often wondered why Mr. Cheshire or others had not done so. If Mr. Cheshire would say what sort of experiments would be the most advantageous to try, a great deal of evidence would soon Le accumulated. He (the speaker) would like to know which sound Mr. Cheshire attributed to the air coming out of the spiracles against the wings. The ordinary sounds made by the bees when flying were caused by the beating of the wings against the air. The wings did not come near the spiracles in the act of flight. The only other noise made by the wings he thought was similar to the piping of queens, that was the rubbing of the wings together the same as grasshoppers did. He put three young queens recently hatched in an observatory hive, after having cut off their wings. The bees killed two of those queens, and were very angry with the other queen for twenty-four hours. She ran

about to escape them; wherever she stopped she piped, although there was no other queen in the hive.

Mr. Grimshaw said he drew a distinction between buzzing or humming, and the vocal sounds. In his opinion the noises heard when the bees were comparatively at rest were the vocal sounds, and were caused by the blowing of air in and out on the plaiting or curtain which was within the spiracle, and also on the edges of the wings. He contended that if they could hear (and they were furnished with auditory hollows)

they could speak.

Mr. Baldwin said the hive he referred to was known as a twin hive with entrances at opposite ends. It had one entrance at the south and the other at the north. He divided it and put in the division a piece of perforated zinc, and turned the hive round to east and west. He left the bees with the perforated zinc division about five days, and there was no attempt to raise queens. He then divided the brood, giving eggs to both parts of the hive, and put in the double division with about 5 inch between, and then the bees did not attempt to raise queens. The queen in the one part was continually As they refused to raise queens with egg-raising. the double division, he took away the queen, when they started raising queens.

The Chairman considered Mr. Baldwin's experiment went far towards disproving the accuracy of Huber's observations, but the result of Mr. Baldwin's research seemed to him unanswerable, except on the theory that bees could speak and hear. Still, whatever might be the purpose for which their auditory and vocal powers were given them, he thought it was going too far with the present knowledge at command to suppose that these powers were capable of being employed in the same way by the bees amongst themselves as those of human beings. On behalf of the company present, he heartily thanked

Mr. Grimshaw for his interesting paper.
Mr. Sambels then exhibited a new and improved section crate.

Fig. 1.

Mr. Sambels explained that his super crate was the same as he had shown at the last quarterly Conference of the Hertford branch of the Herts B.K.A. But a description of it was not given at the time in the B. B. Journal for want of space, consequently he had brought it to this meeting that those present might have an opportunity of criticising it. He was not a manufacturer of bee-keepers'

Fig. 2.

appliances, but had designed it for his own use, because he thought it combined all the good points that he had seen in others, as well as a few that he had seen nowhere else. Proceeding to take it to pieces, he said the crate was made of four pieces of board $4\frac{1}{4}$ inches deep, which was exactly the depth of the sections he intended to use. The bee-space was a separate frame of four pieces of wood, as seen at B, Fig. 1, and in section at B, Fig. 2, it was rabbeted out to give greater strength for removing, when stuck down with propolis. On the insides of the two sides of the crate were tacked two fillets 16 of an inch square to form a bee-space round the end of each row of sections. In the front end of the crate were fitted two iron thumb-screws, T, Fig. I, with brass thumb-pieces and nuts, which, when screwed tightly against a sliding board, pressed the latter tightly against the sections and dividers, and so held all in position by pressure. The beespace was made separate from the crate to allow of the crate being inverted without removing the bee-space. He did not believe any amount of inverting would increase the amount of honey stored in any one hive if the bees were kept from idleness by other methods, but he believed inverting supers at the proper time would decrease the number of 'pop-holes' in the sections. The dividers (D, Fig. 2) were perforated with slots, to allow the bees free access from one row of sections to another; they were also cut sufficiently short at the ends for a similar purpose. He had two sections fitted with foundation on Mr. Corneil's plan, which was done for the especial benefit of his Hertford friends, but he would like to point out a plan of fixing foundation they had been using in Herts for the

past two years: it was recently explained by some contributor, whose name he did not remember, in the Journal. consisted of simply running a saw-kerf the length of the end quarter of each section, and having folded the section as seen in fig. 3, the foundation was then placed in position, and the second flap of the section closed on it, holding it

secure. He need scarce point out that was not practical for the narrow strip at the bottom, unless you used fourpiece sections, but was a great saving of time and trouble. He would also call attention to the fact that his sections had 'ways' on all four sides.

(Mr. Sambels requests us to state that having had several inquiries already since the Hertford Conference, to save the time of his friends and himself, he has placed the original super-crate in the hands of Mr. Blow, who will be happy to supply purchasers in the usual way.)

The Chairman expressed the indebtedness of the meeting to Mr. Sambels for his kindness in laying

before them his new contrivance.

Mr. Webster then exhibited his frame swivel (see p. 33, January 27), which was invented for the purpose of doing away with the necessity of using both hands to lift a frame out of the hive. By means of the swivel one hand only was employed for lifting the frame, whilst the other was free for manipulations. The swivel was also contrived to permit of the frame being turned round while held up. He also exhibited another invention of a similar character which needed a pin to be put through every

The Chairman considered it a very ingenious idea, and complimented Mr. Webster, at the same time suggesting that the grippers should be made wider and stronger, so that a frame, when filled, might be held securely. He thought it would most probably come into general use.

Mr. Webster then exhibited his fumigator, which was intended to be used with carbolic acid, and was constructed to prevent any of the acid being blown on to the hands of the manipulator. He had not used smoke for two years, and had found that carbolic answered every purpose of smoke.

Captain Campbell said when the bees were really savage a few drops of ammonia must be put in.

Mr. Webster said when the bees were very savage he preferred covering them up and leaving them alone for an hour or two, until a more favourable opportunity.

Mr. Baldwin wished to know whether there was any special objection to smoke. He found it answer very well.

The Chairman thought carbolic of more effect than smoke. Having failed with smoke on one occasion, he saturated his pocket-handkerchief with a very weak solution of carbolic, and after wringing it out he stripped off the quilt and laid it on, when the bees became perfectly quiet in a minute or two, and he took out the frames without any further difficulty

Mr. Baldwin related his experiences at Lichfield, where he attempted to handle a hive of Cyprian bees after using smoke, and had cause to regret his mistake. He knew nothing about these particular bees when asked to handle them, and never expected to find Cyprians at Lichfield. As soon as he saw their breed, of course he altered his tactics, and proceeded with more care and ultimate success. The whole affair was a source of amusement to the owner, who told his friend of the joke he had played. There was no doubt that the remedy to be used must vary according to the breed of the bees.

Mr. Blow said he had almost abandoned Cyprians altogether, and he thought all wise bee-keepers would do the same. Their advantages were counterbalanced by disadvantages. Smoke must not be used in handling. He kept one stock just for experiments. If great care and gentleness were employed, and a long time allowed for manipulations, the operator could avoid being stung, but otherwise they were uncontrollable. Carbolic acid was no better than smoke for Cyprians. That breed of bees was not suited to the English climate, but if they were kept they must be handled upon Mr. Raynor's system, that was, with the utmost care and gentleness.

Mr. Baldwin said it would be difficult to follow Mr. Webster's advice in the bee tent by putting off manipulations when the bees were angry, which would cause great dissatisfaction to an audience.

Mr. Webster admitted this, and said he had no objection to smoke, but the fumigator was far more convenient, involving much less trouble.

Mr. Grimshaw laid before the meeting a sample of his 'apifuge,' which he believed to be a genuine sting-pre-

At this juncture Mr. Garratt took the chair on the retirement of the Rev. F. G. Jenyns, who was compelled to leave the meeting.

Mr. Stanford said, in reference to the oil of wintergreen, that Mr. R. Sproule, of the Irish Association, obtained some early in the season, and certainly its effects were magical.

Mr. Webster remembered that Mr. Hart brought a bottle of the oil to the Reading Show, which was described as containing a preventive of bee-stings. Mr. Cheshire took the bottle home with him.

Mr. Sambels asked whether the plant referred to was not similar to meadow-sweet, of which there was plenty to be obtained.

Mr. Grimshaw replied that an immense quantity of that plant would be required to obtain a few drops of essential oil by distillation.

Mr. Haviland said that the danger during manipulations was not confined to the operator. He always had fears for the safety of persons looking on, or moving about near at hand.

The Chairman commented on the interesting discussion which had taken place, and said he was sure all bee-keepers would be pleased to know that something had been discovered which would assist them greatly in controlling their bees. He thought the meeting would desire to express its best thanks to those gentlemen who had so kindly introduced subjects for consideration. By their aid the Conversazione had been most pleasing and profitable. The company were specially indebted to Mr. Grimshaw for his very able contribution.

Mr. Grimshaw thanked the Chairman for his kind remarks. Without presuming to claim credit for anything original in discovery, invention, or research, it always afforded him immense gratification if he could be the means of starting an interesting discussion. He concluded by expressing his acknowledgments for the patience with which they had listened to him.

The proceedings then terminated.

YORKSHIRE BEE-KEEPER'S ASSOCIATION.

A meeting of this Society was held on the 29th ult. at the Church Institute, Leeds, Thomas Clark, Esq., Burley-

in-Wharfedale, in the chair.

After the conclusion of official business, the hon. sec. (G. H. L. Rickards, Esq.) made a proposal, seconded by Mr. Daniel, of Horsforth, and carried unanimously, That a paragraph report of the meeting be drawn up and disseminated amongst the newspapers in suitable parts of the county, embodying Mr. Grimshaw's suggestion that off-shoots, or district societies, are the best means by which County Association work can be efficiently carried on in a county so vast in extent as our own; that a single body of workers, however diligent, cannot do justice to subscribing members so far away from the central body: and that subscribers cannot be expected to go to the expense and trouble of attending meetings, &c., so far away from their own district as the official body necessarily is; and that bee-keepers in various parts of Yorkshire are hereby carnestly desired to assist in systematising the work of the county by uniting together in forming district associations, appointing their own district secretary, having perfect self-government, fixing their own terms of subscription, &c. Also, that by a subscription to the parent society of 5s. per annum per branch society, the district secretary and another member of such district society thus become members of committee of the Yorkshire County Association. They would besides have the advantage of the bee-tent for shows, of purchasing requirements in large co-operative quantities at reduced rates, and of participating in competition for prizes, and exhibiting honey for sale, &c., at honey fairs, &c.

It was also decided that the hon, sec, be instructed to subscribe for a copy of the British Bee Journal.

A proposal by Mr. Rickards, seconded by Mr. Dodgson, of Skipton, to the effect that Mr. R. A. H. Grimshaw, of Horsforth, be appointed joint hon, sec. with himself, was

carried unanimously.

The question of the Saltaire Exhibition was then brought forward by Mr. Rickards, who said he had offered (to the Exhibition Committee) to have exhibitions of bee-manipulations every Wednesday afternoon provided the expenses were paid, but he could not lay before the meeting any definite decision as yet.

Respecting the recent strictures on the Association in the B.B.J. the hon. sec. gave a satisfactory explanation

as to why they had not been replied to by him.

The annual meeting of the members of the Worcestershire B. K. A. will be held at the Guild Hall, Worcester, on Saturday, February 19, at 3 p.m. In the unavoidable absence of the President, Earl Beauchamp, the chair will be taken by Walter Holland, Esq., Mayor of Worcester, one of the Vice-Presidents of the Association.

The members of the Middlesex B. K. A. are reminded that their Annual Meeting will be held on Thursday, the 10th inst., at 105 Jermyn Street, at 5.30 p.m.

Correspondence.

The Editor does not hold himself responsible for the opinions expressed by his correspondents. No attention will be taken of anonymous communications, and correspondents are requested to write on one side of the paper only, and give their real names and addresses, not necessarily for publication, but as a guarantee of good faith. Illustrations should be drawn on separate pieces of paper.

Communications relating to the literary department, reports of Associations, Shows, Meetings, Echoes, Queries, Books for Review, bec., must be addressed only to 'The Editor of the 'British Bee Journal,' clo Messes. Strongeways and Sens. Tower Street, Upper St. Martin's Lane, London, W.C. Alb business communications relating to Advertisements, etc., must be addressed to Mr. J. Huckle, King's Langley, Herts (see 2nd page of Advertisements).

***In order to facilitate reference, Correspondents, when speaking of any letter or query previously inserted, will oblige by mentioning the number of the letter, as well as the page on which it appears.

YORKSHIRE COUNTY ASSOCIATION.

[808.] Those of your readers who have followed this subject through your columns during the last few months will be considerably diverted to know that I might have 'saved my wind to blow my porridge with 'until the last letter from me appeared. The hon sec does not take nor read the British Bee Journal, so that all our appeals and complaints did not reach him. Now, however, he is posted up somewhat, through the kindness of a friend in sending him a few copies of the B. B. J. This resulted in a courteous invitation being sent me by Mr. Rickards to attend a meeting of the Y. C. A., with results which will be found in another column of the Journal.

To prevent a recurrence of our worthy hon, sec, not being kept an courant with 'what is going on,' my first proposal (carried unanimously) as a member of the \dot{Y} .C.A. was that the Association do henceforth subscribe for one

copy of the B. E. J., to be filed by the hon. sec.
A satirical friend has suggested that 1 bave been dexterously translated into the 'upper house,' bien! nous verrons. I don't care what house it may be called if it only give birth to measures beneficial to the bee-keeping fraternity, viz., active district associations. ---R. A. II. G.

VILLAGE CLUBS.

[809.] With reference to your article and 'A Worker's letter in your issue of the B,B,J for this week I should like, with your permission, to make one or two remarks on the subdivision of County Associations. I feel the more prompted to do this from having read Mr. Grimshaw's different letters in relation to the York Association, and also 'Amateur Expert's' most (in my opinion) valuable suggestion, in the current number of the B. B. J., in reply

to that gentleman.

With regard to the subdivisions of County Associations it may, perhaps, be of some slight service if you would kindly make known the terms, &c., upon which the Hants and Isle of Wight Bee-keepers' Association proceeded to carry out this very idea,—'the subdivision of the county,'—now more than twelve months ago. Some two years ago a Village Bee Club was started here in Swanmore, and in the course of a year its numbers had so increased that it was deemed advisable to hold a meeting of its members and to elect regular officers and committee. This was done, and the neighbouring villages hearing of our doings came in to join us, until our Village Club had swollen to the extent of fifteen villages and some eighty members. I was a member of the Hants County Association and also was chosen Secretary of the Village Club, and as such began to feel that if we went on as we were going, we must eventually come into antagonism with the County Association itself. In this difficulty I wrote to our Hon. County Secretary, explaining the whole thing to him; he, I must say, met me in the most handsome and gentlemanly manner, and the result of our correspondence was that a special general meeting of our Village

Club was called, and I moved a resolution that we should be affiliated to the Hants County Association. This, to my pleasant surprise, after some argument was carried manimously. We thus became part and parcel of the Hants Association, no longer in antagonism to, but working in all good fellowship and harmony with it.

The terms of our amalgamation were as follows:-First of all we were to have our own officers, and to govern ourselves by our own Committee, &c.; also to have our own rules. On our subscriptions, as an affiliation fee, we pay to the County Association the amount of 25 per cent, we retaining the 75 per cent for our own purposes, such as prizes at shows, expenses of lectures, printing, &c. For the said affiliation fee of 25 per cent the County Association agree to consider all our members full members of their body and entitled to all their benefits.

I do not know, Mr. Editor, if I have already trespassed too much on your space, but I should like to be allowed to say that the above scheme has now worked thoroughly well with us here for more than twelve months, and I think that after that amount of trial I may fairly

recommend it.

A word also, if I may, as to holding simple lectures on bee-keeping. Last year we held a series in different villages, and the amount of astonishment expressed at the different views, by people who had hardly any idea what bee-keeping is, was very great. New members at once flocked in, and already this year I have several members joining who were convinced by the last year's lectures; so much good did I consider they did, that another series begins on Monday next, February

I shall be most happy more fully to explain anything should any reader of the B. B. J., or member of a County Association, wishing to help his over-worked (and at the best of times they have a lot to do) County Secretary,

care for any further details.

In conclusion, I enclose you a copy of our rules and officers, and also our last year's report.—H. W. West, Hon. Sec., Hants and Isle of Wight Bec-keepers' Association, Swanmore Branch, Feb. 5.

PREVENTING SWARMS SETTLING ON HIGH TREES.

[810.] In the *Journal* for January 27th, under the heading 'Gleanings,' there is a paragraph relating how an American gentleman succeeded in preventing swarms settling in high trees by using what is called a 'Yankee queen-stick.' I have attained the same end by placing a round felt hat on end of a long pole, and holding it up among the bees. It does not seem to be of much use raising the hat among the swarming bees till once they are on the point of settling, then place the hat as close as possible to the spot where they are preparing to cluster. This seems, in my experience, to be a condition of success. It is simply a modification of Langstroth's bee-bob.

Early last summer I told a neighbouring bee-keeper of the plan, and when his bees swarmed, and were beginning to cluster in a low bush, he stuck an empty hive in centre, and the bees at once took possession.

I would recommend bee-keepers whose hives may stand near trees, or high thorn hedges, to try the method, being careful to attend to what appears to me to be the condition of success-placing the hat as near as possible to the spot where the swarm is preparing to cluster. This seems to be the experience of our American friends as well.—John Peters, Gourock, Scotland, 5th February.

LEAF-CUTTING BEES.

[811.] In reference to your correspondent wishing to know if others have noticed similar behaviour in a bee, which he mentions under the title of Curious mistake | This crack we could readily explore. The arm was

of a bee,' I would say, last August I was on a vist to a friend near London, and being in his green-house I noticed a small bee, about half the size of our common hive bee, busy at a reel on a shelf. I found he visited this reel and had nearly filled the hollow with small pieces of the vine leaf, cut beautifully round, and wedged into the hole. After replacing the reel I watched the little fellow over and over again go to the vine, cut a leaf and then fix it into the hole with some glutinous matter. I do not know what became of it. I have also often noticed the same kind of bee visit holes in posts in our garden here, and deposit an extraordinary quantity of leaf-cuttings.

I do not think there was any mistake on the part of

the bee.—Br. W., Cowley, St. John.

CURIOUS MISTAKE OF A BEE. (782.)

[812.] I am reluctant to believe that one of our beloved and dear little friends made the mistake mentioned in the above paragraph. The reel of cotton is so very unlike the cell of a bee. It is much more probable that it was the work of the rose leaf cutter. This 'little busy bee' builds its nest in the crevice of a wall or in chinks in timber-work, and in using the reel of cotton it was carrying out its usual instinctive propensities. only mistake made was in taking the reel for a permanent abode. The rose-leaf cutter is smaller than our black bee, but might easily have been mistaken for one by a easual observer. It is a great pest to florists, as it disfigures the roses by cutting hundreds of small circular pieces out of the leaves. It commences its nest by putting at the far end a plug of these pieces; then comes a supply of pollen, next an egg, then more pollen, then another layer of leaves, and so on until it has filled up its apartment. Probably in another hour it would have filled up the hole in the reel. It is a pity that this was not preserved.

I wonder if it would interest the readers of the Journal if I now go on to tell of a great puzzle I got into last summer in respect to the proceedings of a rose-leaf cutter? If I do 1 fear I shall be too diffuse and wearisome, but that I can't help. I must begin by writing about a garden-seat I made. Its manufacture may give a useful hint to some of our amateurs. The basis or stand was the frame of an old sofa. On this I nailed two boards of inch stuff, each a foot wide; next a reclining back of the same stuff, then end-boards for arms, cut in curves as tastefully as lack of artistic skill and bad chisels would permit. Oh, but you can't think how grand it looked when finished and painted! placed it on a small lawn on the southern side of a high grassy bank, which the inhabitants of this countrycertainly 'a peculiar people,' but possibly not very 'zealous of good works'—perversely call a ditch. Thus sheltered it made a very pleasant lounge on a summer's Yes, don't be impatient, I am coming to my subject now. I was sitting on this soat one day in June or July, when I saw a bee come out of a crack between the two boards forming the seat, close to the end-board or arm. I was wondering for a minute or two where it came from, when it came back, bearing in its mandible a circular bit of leaf. Another minute of wondering, and out it came once more. I suppose it made a dozen or more journeys while I waited and watched. Well enough I might be puzzled, for the crack seemed to lead to nowhere! In my extremity I called in a friend who is well known hereabouts for his scientific attainments, and who is indeed of world-wide fame by his publications and work in connexion with ocean telegraphy. He came, and after a minute examination of the premises taken possession of by the bee, he was quite as much bewildered as I had been. There seemed to be no place beyond the crack to which the bee could get access.

nailed flush on to the seat, and over the end was placed a piece of wood covering the joint. My friend measured and tapped and stood, watch in hand, timing the bee, which made an entrance and exit once in about three minutes. Nowhere to go! Then what became of the multitudinous loads it carried into the crack? learned and the unlearned might have been seen on their knees—nay, prone upon the grass—looking earnestly, prying in all directions, but they failed to solve the mystery. The next day I took off the strip of wood nailed between the arm and soat, to see if, by any chance, a hollow place had inadvertently been left. But no, all was solid. There was no visible interstice but the open crack.

In my despair, I then most reluctantly resolved to take off the end, or arm, which, as I have said, was made of inch stuff. With some difficulty I accomplished this, for, with the usual result of amateur carpentry, I had succeeded in nailing it on so very tight that for a long time it refused to come asunder. At length the mystery was revealed. The arm had formed part of a large American box, the boards of which were joined by what, I believe, is called the 'groove-and-tongue' method. I had quite forgotten that the edge of the arm I had nailed to the seat contained the groove. So here was a narrow channel running the whole length of the arm, about twenty inches long, and crossing the crack. Into this channel, right and left of the crack, the bee had been working, and had nearly filled it up with rose-leaves, pollen, and eggs. In due time, but for my interference, the progeny would have come forth to add to the troubles of rose cultivators.

This is my diffuse and prolix story. I could scarcely expect the Editor to find it of sufficient interest for publication but for the fact that at this season there iu less than usual to be said about bees.—C. C. P., Valentia,

County Kerry, January 22, 1887.

INSECTS AT FAULT.

[813.] The incident related by Harold Adcock in your issue of the 20th instant, reminded me of a similar occurrence I witnessed last autumn. When a wasp flew in at the open dining-room window, and after careering rapidly round the room above the heads of the family, who were seated at the table, suddenly darted into one of a series of deep circular holes, each about the size of a honeycomb cell, which embellished the edge of the oak mantelshelf. After remaining a few seconds he emerged, and flying straight to the open window disappeared.
On searching the hole we found he had deposited a

small live green caterpillar, many insect remains were entombed also in the same repository, so doubtless he had been in the habit of utilising the ornamental aperture

as a store-room.

Subsequent cold winds necessitated the closing of the windows, no further opportunity was therefore afforded of watching the interesting movements of this erratic specimen of 'Vespa vulgaris.'— EMILY CULVERHOUSE, The Hundred Acres, Sutton, Surrey, Jan. 30.

THE HEDDON HIVE.

[814.] We need scarcely wait for the appearance of the February number of the Bee-keeper's Magazine, as advised by Mr. Jas. A. Abbott in the Journal last week (801), to see Mr. Heddon's own disclaimer of the advantages (?) of the half bee-space, or the good points that he now claims for his new hive, as he has given them to the world on page 789 of the Canadian Bee Journal for Dec. 29th, 1886, and also in his circular for I887 to his customers and friends. His own words

'The combined experience of my foreman, students, and myself, during the past season, brings us unanimously to a conclusion somewhat at variance with those with which we entered the season of 1886.

'After the first inversion of the brood-combs which seeures the complete filling of the frames, we never care to invert them again. When the brood-chamber is large and deep, by virtue of its being composed of two broad-sections, the interchanging of them accomplishes all, and better, than can be accomplished by inverting. When the brood-chamber is contracted to one case, it is then so small and shallow that all the favourable conditions that could result from inverting are always present. In regard to reversing surplus sections, we find the following serious objections to

inverting them by whole cases.

' If the combs are not sufficiently developed to be properly attached to the sides of the sections, they will fall over, making a bad mess. On the other hand, if they are pretty nearly all capped over and then reversed, they will either be finished without being attached at the top at all, or else, what is oftener the case, be ridged and made to look bungled as they are attached to the bottom-piece, now at the top of the case. They are also not so white and beautiful as those not so reversed. There is, however, a short period in the development of these little surplus combs in which inverting results in all the advantages ever claimed for it; but as it is a fact that the combs of a whole case are rarely all at this stage of development at one time, we are unanimously in favour of inverting them by wide frames

'In the light of the foregoing we unanimously advise making the new hive with full, rather than half bee-spaces, as was adopted when considering both systems three years ago. This will also save much complication when using the new hive in the same apiary with other style of hives with full bee-spaces. The grand functions of the hive consist first, in the arrangement by which the combs can be divested of queens or workers, and their conditions instantly determined without the labour of removing or exposing them to robber bees. Second, a brood chamber divided in horizontal sections. Third, the break-joint honey-board as used with the new hive. Fourth, the set screws for tightly compressing the frames to avoid propolis, and to support them when we may desire to invert them.'

My quotation is rather long-winded, but from it I conclude: (a) 'Spreading brood,' as we practise it, is equally as good as Mr. Heddon's 'inverting,' or, as he now recommends, 'interchanging.' (b) If the season is bad no amount of inverting section cases will get the sections finished off, quickly, white and clean, and with few 'pop-holes,' while in a good honey flow most of us have not much to complain of on that score, if our stocks are strong. The removal of the centre rows of sections and placing the half-finished outside ones in their places, we scarcely need Mr. Heddon to tell us, is advisable sometimes. (c) How Mr. Heddon can clear his frames from queen and workers more quickly and easily than we can from our ordinary standard frame hives I shall be happy to learn, at present I don't see it. (d) The 'break-joint honey-board' is with us an 'improvement' that we have relegated to the limbo of antiquity. (e) The set screws for sections may be useful, but for brood frames we shall at present decline their use with thanks. (f) The distance the Americans are ahead of us, and the amount they can learn us, if this is their 'latest and best,' is very infinitesimal indeed.—AMATEUR EXPERT.

NOTICES TO CORRESPONDENTS & INQUIRERS.

All queries forwarded will be attended to, and those only of personal interest will be answered in this column.

Castle Douglas .- 1. Ends of Sheet Metal. -- Your end is ingeniously formed, bur we do not consider it as good as the cast metal ends at present in use, and the important space of 1 inch between frame and hive side is not kept. There would be also a vast amount of propolization.

2. Fixing Foundation.—Your plan of only partly dividing the top bar by a saw-cut on the under side, so that it might be sprung open to receive the sheet, would not be so convenient as having the cut through it. The small grip upon the sheet would not in all cases be sufficient to

prevent falling, and the nails would not bring the top bar down flat, but would allow it to remain concave on the upper surface.

W. Wilson.—1. Skep Overthrown.—By the syrup running cut, the combs are certainly broken down. When righting it you should have removed the floor-board and replaced the combs, keeping them as nearly as possible in place by putting two or three sticks through them. They will now be fixed together in a mass, giving you more trouble to separate; still, you had better do so the first warm day before brood is in progress. If you have some bar-frame bives and some stored combs, it would be as well to make up a set of four or five, drive the bees and hive them on them, giving them the broken combs to clear out when weather permits. 2. Bees in Skep Dead.—Your neighbour must have made a mistake as to the age of the hive. A swarm of 1885 could not have existed until now without broad combs. From the combs being so small, and no brood having been raised in them, it must have been a late cast or virgin swarm of 1886 which lost the queen, and consequently died out. 3. Inversion.—Had you placed a sheet of excluder between the skeps when inverting, the combs would have been built downwards in the top one instead of continued upwards, as was the case. Your plan of inverting frames by a piece of hoop-iron pivoted to the end bar is similar to Neighbour's plan. Your experience of the combs being less liable to damage in extracting after inversion, owing to their being built and fixed to all sides of the frames, is in accordance with others'.

O. W.—If the honey in the outside frames is not granulated the bees will reach it through the winter passages, and use it when the temperature is sufficiently warm. Meanwhile warm candy—made, as you propose, of fine sugar and syrup—placed over the cluster will be advisable, until you can examine the hive.

M. Humfrey.—Observatory hive, Dysentery, Quilts, &c.—
The hive may be cleaned a second time, but the bees are not in sufficient numbers to draw out foundation. Continue te feed with candy. Toward April you may give syrup. If the bees survive they will require to be reinforced with young bees at spring. You may change the damp floor-boards; you will then discover which hives are attacked by mice, and by reducing the size of entrance may keep them out in future. You are quite right in changing damp quilts for dry ones.

F. W. C.—Removing.—Spring Flowers.—Separating Doubled Hives.—If the removal had been made a month earlier there would have been less chance of bees returning. During the winter months we constantly move colonies short distances, and never lose bees to any extent worth naming. If fine days occur soon after removal, a few bees will fly around the old spot, but eventually return to their hive. Possibly a sudden change of temperature chilled the bees. You will find the colonies none the worse in the end. Your spring flowers are much earlier than ours. We have no bloom at present, neither furze, crocus, nor snowdrop. Our experience, too, differs respecting condemned bees, of which we have about twenty lots, and have often had more during many past years, but have no robbing; indeed, when possessed of plentiful stores, they are far less given to robbing than the Eastern races of bees. To separate your double hives, at any time during mild weather inject smoke into the lower hive, so driving the bees into the upper one, which remove at once from the lower, placing it on a fresh floor-board, and setting it on the old stand. Then examine the lower hive, and transfer any trames containing broad to the centre of the other, making room for them by abstracting sealed or empty combs. Any adhering bees may be shaken on a board in front of the populated hive, or on the top of the frames. A careful look-out must be kept for the queen when manipulating the lower hive. Another plan is to separate the two hives, placing each on separate floor-boards, and manipulating each hive singly, transferring queen, bees, brood, and sufficient store of sealed honey, to one, and reserving the remaining combs for future use. The operation is very simple and should be quickly performed. Separate the hives with a chisel, blow in a little smoke, and operate

towards evening to avoid robbing. We advise you to break up the combs of heather honey; it would be bad policy to give them to a swarm. Messrs. Turner, Radeliffe-on-Trent, Notts, advertise in our columns a very useful 'Squeezer' for heather honey, which is of more value than other kinds of honey, and, from its greater density, of less value to the bees. It is very likely that you may find the bees domiciled in the upper hives, in which case you have simply to remove the lower. In that case the first plan suggested is the best.

AMATEUR.—Queenless Stock.—In all probability your bees became queenless and deserted, to join some other colony, on one of the fine mild days on which the bees were flying freely, since the departure of the late severe weather; or they might have dwindled and been driven out by robbers. This might have occurred immediately after packing for winter from injury to or loss of queen.

R. Chapman.—1. Tar.—Yes. Stockholm and gas tar should be heated nearly to boiling point, and well mixed, being allowed to cool before the spirit of turpentine is added. The more turpentine used the quicker the mixture dries. A pint of turpentine to ten pints of tar will do, or two of turps to ten of tar, if you wish it to dry quickly. We do not paint over the tar, but if any other colour is desired it may be done. 2. Deep Frame.—There has been no authorised decision in regard to a deeper frame than the Standard. From 10 in. to 12 in. deep by 12 or 14 in. long is a good size. Your experience with the deeper frame is the same as our own. Abbott's frame increased in depth to 14 in. would be rather too deep. We should prefer 12 in, depth. 3. Bee Farm.—Judging from your description of the four-acre piece of land, with its surroundings of woods, limes, hawthorn, &c., we should think it a good speculation at a moderate rent. 4. Pheasants.—Pheasants do not devour bees, neither do fowls, but we have seen them occasionally pick up a drone. 5. $Becoming\ Experts$.—We can hardly advise you as to your sons becoming experts. If handy, industrious, honest, and anxious to learn, young men of from seventeen to nineteen years of age would find no difficulty, we should think, in making arrangements with some of our larger apiarists on the terms you suggest. Mr. Simmins, we believe, trains young men; probably others also who are possessed of large and well-managed apiaries.

W. C. T.—There should be no difficulty in your obtaining information respecting the examination for a third-class certificate. Mr. Kent, hon. sec. of the Cornwall B. K. A., Truro, would be pleased to give you the desired information.

FAR NORTH.—The samples of enamel cloth forwarded are suitable for placing on tops of frames. Nos. 1 and 2 are the best for the purpose.

R. E. LLOYD.—Both samples of Porto Rico are good; but No. 2 brown is the more suitable for feeding bees on Mr. Simmins' plan.

C. C. M.—There is no occasion for suspecting foul brood in the hive from which the frame forwarded came. The comb is healthy and the honey in good condition. The comb was slightly mouldy, and the hive must have been damp. We consider the measures taken were the hest that could have been adopted for the preservation of the remaining bees.

H. L.—The foundation remaining from last year may be advantageously utilised this season. You can remove the brittleness, and render it fit for use by hot water. Let it be hot to the hand; about one pint of boiling to two of cold will be right. Just hold the sheet in the water for half a minute.

J. H.—Your letter respecting the Yorkshire Bee-keepers' Association has been received with thanks; but we consider, now that Mr. Grimshaw has consented to be consecretary with Mr. Rickards, and new hopes are entertained for the future success of the Association, that it would be more discreet not to publish it.

Received from Mr. John Smith, the Royal Nursery, Clewer, Windsor, a packet of seeds, sought after by bees, containing twelve assorted varieties, with full directions for cultivation,

Received from Mr. Henry Dobbie, Cringlefold, Norwich, Descriptive Catalogue of Vegetable and other Sceds, Herbs, &c.

Correction.—Useful Hints, p. 45, 7 lines from end, for and the close-ended frames being dispensed with, read but the close-ended frames have not been dispensed with.

We have reports of several County Associations in type, to which we hope to give insertion in our next issue.

Show Announcements.

Giving Name and Address of Secretary, Date and Place of Show, Date of Closing Entries. Terms: Three Insertions and under, Two Shillings and Sixpence; additional insertions, Siapence each. No charge made to those Associations whose Shows are announced in our general Advertising

July 11-15.—Royal Agricultural Show at Newcastle-on-Tyne. Entries close May 12. J. Huckle, Kings Langley.

August 3-5.—Yorkshire Agricultural Society at York, Secretary, H. L. Rickards, Poole, near Leeds.

Business Directory.

The Name and Address and Business of any Manufacturer will be inserted in this List, under one heading, for One Pound per annum. Additional headings, Five Shillings extra. Advertisers in 'The Bee Journal,' whose orders amount to Five Pounds per annum, will be inserted Free.

CHAPMAN HONEY PLANT.

WILL send to any address 26 varieties of BEE-FLOWER SEEDS, including the Noted CHAPMAN HONEY PLANT, for 2s. post paid. GARDEN SEEDS.

I will send 21 packets of Garden Seeds to any address for 2s. 6d. post paid. BAR-FRAME HIVES with Straw bodies, the hive least affected by heat or cold. My Hives and Appliances are all forwarded carriage paid, and returnable if not approved on arrival. Please send your address on post-card, and I will send Descriptive and Priced Catalogue post free. Address John Moore, Seed Merchant, Market Place, and Prospect Farm, Warwick.

ARE BARGAINS.—Owing to change of Pattern, I have bought Mr. Blow's OLD PATTERN HIVES, 'Standard' size. 10/6 for 7/6, 15/0 for 12/0, 21/0 for 18/0. Two Cork Hives, 35/0 for 25/0; Cowan, 27/6 for 24/0, all new. DARK FOUNDATION, 1/5 per lb. MELILOTUS LEUCANTHA, 2/6 per 100. Address E. Jackson, Welwyn, Herts.

CREW CAP JARS.— Fifty 2-gross Cases of new Straight Shape 1-lb. JARS to be Sold at a great reduction, together or separately. Address Fredk. Pearson, Stockton Heath, Warrington.

RARLY BEE FLOWERS.—Plant now.—
per 100, free. Address S. S. Goldsmith, Boxworth, St. Ives, Hunts.

TOR SALE.—OBSERVATORY and FRAME HIVES, STOCK FOUNDATION and FOUNDATION MACHINE, with SECTION CRATES and FRAMES, to be sold cheap. Apply to C. Cust, 3 Temple Terrace, Dorchester.

TANDARD BROAD-SHOULDER FRAMES, 1s. 8d, per doz. STANDARD FRAMES, with Metal Ends complete, 1s. 6d. per doz. All made of best Pine, with saw-eut for Foundation. Sample, 3 Stamps, free. Terms for quantities. Address

A. GREEN, Selston, Alfreton. A 2350

TO BE GIVEN AWAY!

ONE AND A HALF DOZEN

Clark's Patent Climax Hives.

In order that these Hives may be more generally known, the Licensee has determined to give away among Purchasers of undermentioned Goods during this February, One Dozen No. 2, and Half-dozen No. 1 HIVES (full particulars given in last year's Advertisement), at the rate of one among every thirty Purchasers, to be distributed by a lottery, to conduct which he will endeavour to obtain the assistance of persons of known integrity. Purchasers of any two articles above Is. to have one chance, and each 2s. 6d. one chance; every further 2s. 6d. an additional chance.

N.B.—In order to have a chance of securing one of these Hives gratis, Orders must be sent in during February, as the lottery will take place early in March and Hives at once forwarded to respective Winners.

PRICES.

Finest quality White Basswood A SECTIONS, $4\frac{1}{4} \times 4\frac{1}{4} \times 2$, per 100, 3s.; 500, 11s.; 1000, 21s. $5\frac{1}{4} \times 6\frac{1}{4}$, per 100, 3s. 6d.; 500, 13s.; 1000, 25s. PURE FOUNDATION, BROOD, per lb. 2s.; 5 lbs., 1s. 10d.; 5 lbs. to 25 lbs., 1s. $9\frac{1}{2}d.$; SUPER ditto, per lb. 2s. 9d. SMOKER (Bingham), 2s. 9d. REGULATING FEEDERS, 1s. 6d. 'LITTLE WONDER' EXTRACTOR, 10s. 'VEILS, 1s. 3d. PINE'S METAL ENDS, per gross, 7s.

TOOLS FOR HIVE MAKING.

Set of 36 best Cast Steel Black Bits and Iron Brace, 15s. 6d. Beech Brace, Lignum head, 26 Bits ditto, 18s. 6d. Set of 12 Cast Steel Chisels, from I in. down, 5s. 6d. Handles, 2d. each. Tenon Saw File, 3½d.; Hand Saw, 4d. Marking Gnages, 9d. Mortice ditto, from 2s. 6d. to 3s. 6d. Best Twist Gimlets, assorted, three, 10½d. Small Hammer, 1s.; larger, 1s. 6d. Name Stamps, Steel, 4d. per letter. Oil Stames from 1s. to 3s. Best Smoothing Planes, 2 in. 3s. 6d, 2½ 4s., 2½ 4s. 3d. Best Jack Plane, 4s. 9d. Best Try Plane, 6s. 6d. Best Cast Steel Hand Saw, 22 ins., 4s.; 24 ins., 4s. 6d. Tenon Saw, 14 ins., Iron Back, 3s. 9d.; Brass ditto, 5s. 6d. Dove-tail Saw, 3s. 2 ft. Rules, 2 fold, 1s. and 1s. 6d.; 4 fold, 1s. 3d. to 2s. 3d. Spokeshave, 1s. 1d. Squares, 6 in., 1s. 8d.; 9 in., 2s. 3d.; 12 in., 3s.

Kindly oblige by adding sufficient postage for small packages of goods.

All Orders to be addressed to W. J. GREEN, Hive Works, Friar Street, Sudbury, Suffolk.

OUTLINES OF BEE-KEEPING FOR BEGINNERS.

(Continued from page 43.)

II.—How to commence Bee-keeping.

1. The beginner should never make a start on a large scale. He had better commence with one or two hives, and increase as he gets experience, not forgetting that there is a great deal to learn—although not more than any one of ordinary intelligence can manage—before he can expect to be a successful bee-keeper.

2. The best time to commence is in the spring, and it can be either by the purchase of a swarm, or a stock of bees, in a skep or a wooden hive. If the bee-keeper decide on the purchase of a hive, he should secure this from the nearest bee-keeper of his neighbourhood in the beginning of April. If he is not able to afford the cost of such a hive, he will have to begin with a swarm, which he should secure in May or the beginning of June.

3. If he has had no previous experience in keeping bees, it would be better for him to consult, and get the help of, the county expert; or if he is not able to do this, to enlist the services of a practical bee-

keeper in his district.

4. Should he not be able to get any such help, he must try and get a swarm from a hive which was known to have swarmed the previous season, because the queen of such a swarm would be a young one and in her prime. The larger the swarm, the better. The bec-keeper can judge the strength of the swarm by its weight or measure. Three pounds of bees, or a little more than a gallon, would be a medium swarm; and five pounds, or about seven quarts, would be a good swarm.

5. Much greater care should be exercised in purchasing an old hive, and it should be well examined before it is taken. If in a skep, blow in a little smoke at the entrance, and after a few minutes turn it up. The hive should be full of bees, and these can be driven down with a few more puffs of smoke. (Instead of smoke carbolic acid can be used; but this will be explained in another chapter.) Examine the combs, and see that they are free from mould, and if, on pushing them apart, brood is found, it shows that the queen

is present. The combs should be straight and regular, coming down to the bottom of the hive. If the combs in such a hive are not too black or old, it can be purchased, especially if it had swarmed the previous season. This hive can be kept for supplying swarms, or the bees can be driven and the combs transferred to a frame-hive in the manner to be explained later.

6. If the purchase of a frame-hive has been decided upon, the same observations should be made while the bee-keeper is taking out the combs and examining the hive. If the operator is a skilful one, and his movements are carefully watched by the beginner, this will be as good as a lesson for him.

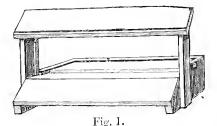

7. Make up your mind to be guided by the instructions given for at least two years, with what help can be obtained from the expert or a friend, and only after that try experiments.

BLOW'S BRITISH HEDDON INVERTIBLE HIVE.

We noted in our account of the meeting of Herts bee-keepers at Hertford that Mr. T. B. Blow, of Welwyn, exhibited a hive on the reversing principle, and at the time we had not space to describe it, but we promised to do so in some future number.

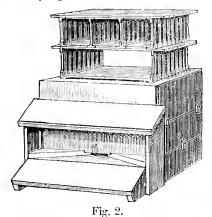

Mr. Blow has endeavoured to combine in this hive the use of the shallow bars suitable for extracting purposes or to hold sections, and the ordinary Standard bar-frames.

Fig. 1 shows the floor-board, which is so constructed as to have a full entrance the whole width of the hive

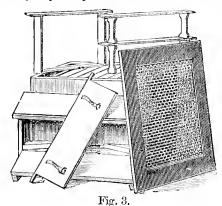

so that very ellicient ventilation is secured in the hottest weather, and the risk of swarming through overheating, &c., is avoided. A half bee-space is fitted round three sides of the floor-board, and to the front is fixed the porch. This is a feature not at all noticed in the foreign reversible hives, but is of great importance, not only as

a shelter from the sun's rays, but as a roof to prevent water getting on the alighting board and rendering the hees chilled when they are returning home during a sudden storm in the spring.

From the illustrations, 2 and 3, it will be seen that each body will hold ten bar frames and one dummy. To the dummy springs are attached, and the frames are held firmly in place by this means and each box can be

readily inverted without any danger of the bars falling out. It is claimed that spring dummies have an advantage over screws, as the pressure from the springs is always constant, whereas if any shrinkage takes place, the

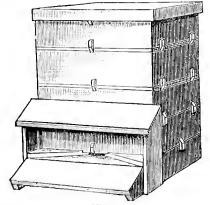

Fig. 4.

pressure from screws will cease, and, again, if screws are wood they swell when exposed to wet, or if iron they rust.

Each frame will contain three 1-lb. sections, thus a hive with two super boxes on will hold sixty pounds. Dividers can be very easily applied, and if used have four slots, enabling the bees to get very free access to

all parts of the combs.

Two of the bodies form a hive that will take standard bar frames, see fig. 3, so that the introduction of these shallow invertible boxes does mean that the appliances at present in use are to be thrown aside as useless. To keep the boxes in exact position, one upon another, it was originally intended to use buttons, as in the Stewarton hive, and as shown in the engravings, but loose tongues of wood have been found to answer better, more especially when two boxes are used with standard bars for wintering purposes. A queen-excluding dunmy with half beespace in each side is used between the body boxes and super boxes. Fig. 4 shows the hive complete with two body boxes and two supers.

At the meeting referred to, this hive was very favour-

ably received as a step in the right direction.

SIMMINS' SELF-ACTING SYRUP-CAN.

On page 115, Vol. XIII., was given a full description of several styles of feeders invented by Mr. Simminsviz., the Commercial, the Frame, and the Amateur Feeders. The principal feature in these feeders is that they dispense with cooking, and reduce sugar to syrup without stirring by the addition of water in certain proportions. The loaf-sugar and cold water should be put in the feeder in the proportion of 1 lb. of sugar to halfpint of water. Warm water should be used in cold weather, or, if preferred, at all times; though if cold be used the sugar will soon be reduced to syrup. The Selfacting Syrup-Can, recently brought out by Mr. Simmins, is fitted with a lining of perforated zinc, and the syrup is made on the principle of the above feeders; and as the trouble of cooking or mixing sugar and water is thus done away with, it will be found a great saving of time, and will prove a great accommodation in all apiaries where the practice of feeding with syrup is still adhered to.

USEFUL HINTS.

WEATHER.—A fortnight's fine weather, with several days of brilliant sunshine, and high temperature, have effectually aroused the bees and enticed them forth in search of pollen, of which at present they find but little. The nut-hushes, laden with catkins and shedding pollen abundantly, have been our chief source of supply, the crocus and snowdrops not yet having made their appearance.

SPRING FLOWERS.—Soon, however, we may hope to welcome these sweet harbingers of spring, together with mezereon, the bloom of the elms, poplars, furze, aconites, et hoc genus onne, gladdening our hearts, as well as the bees, after the long and trying winter, now, as we hope, drawing to its close, although, while writing, severe frost has again appeared, and the clouds are threatening

Manipulating.—The late fine weather may have tempted the inexperienced to manipulate too freely, the ill effects of which will soon become apparent from the dwindling of the population where the brood-nest has been broken or much disturbed. At this early period we cannot too strongly urge, upon all, the absolute necessity of abstaining from interference with colonies further than merely raising quilts, supplying food where it is required, and a change of floor-board, all of which operations should be performed with the minimum of disturbance.

FEEDING.—Consumption of stores by strong colonies,

during the late fine weather, will have become more rapid; and it behoves the careful apiarist to have an eye to this matter, and not to allow his forwardest and best stocks to perish from want of food. Often have we beheld this piteous sight—hives literally full of bees utterly prostrated by famine—the dead and dying bees blocking the entrances, covering the floor-boards, or languidly clustering between the combs emptied of their honey, but partly filled with starving brood. Prevent the occurrence of so painful a catastrophe by a timely supply of food. Soft warm candy, or sealed honey, should still be given.

Moderate Supply.—Soon, in finer, warmer weather, syrup will be admissible, precautions against robbing being taken, and care being exercised against too rapid feeding, for if colonies are overfed, mischief will result from filling up the brood-combs and thus giving a check to the production of brood. Food supplied in excess is almost as bad as starvation. This warning becomes more necessary where colonies are only moderate in strength and confined by division-boards to a few combs. In such case the brood-nest is quickly filled, breeding altogether ceases, and day by day the colony becomes smaller until the end comes.

SMALL COLONIES.—Hence building up small colonies is a work requiring much care and judgment, lacking which it is far better to unite.

Equalisation.—Here one of the great advantages of moveable combs is realised. Given a small colony with little food or brood, and a large one with abundance—or the converse—what more easy than to transpose brood or honey, and thus to equalise the two, always providing that frames are interchangeable? But whatever manipulation may be deemed necessary at this early season, 'when 'twere done 'twere well 'twere done quickly,' that no chance of robbing and consequent encasement of queens may be afforded.

Moto for 'Journal.'—Thinking of Shakespeare

reminds one that 'our Journal' is sadly in want of a motto. Why should we not have one, and what better one could we adopt-in these days of sedition, change, home rule, misrule, and what not-than 'Stick to your Journal.'—Cymbeline, Act iv. Scene 2. (Shakespeare.) Yes, we say emphatically, if you have the interests of bee-keepers — whether cottagers, amateurs, or professionals—at heart, 'Stick to your *Journal*.' Not that we apprehend sedition in our camp, but we would have all our fraternity loyal and true, and eager to extend its circulation to all classes of our fellow-countrymen by all means in their power, realising, as we do in our own person, how great would have been the advantage derived in our younger days from the perusal of such an organ. Post tenebras lux! and the deprivation of 'the Journal' now would assuredly cause the deprived justly to exclaim, 'Quanta sunt tenebra! va mihi! va mihi, væ!' ('How great the darkness to me! Woe to me, woe to me be!')

QUEENLESSNESS may generally be discovered when the bees begin their spring flights. Listlessness or inactivity, carrying in little or no pollen, sluggislness or want of alacrity in entering the live on returning from the fields, restlessness exhibited by going in and out of the hive in an inquiring manner, indisposition to defend the hive, are all more or less signs of the loss of queen. Colonies acting thus should be examined at the earliest opportunity, and will generally be found to possess neither eggs, brood, nor queen, in which case an early union should be made with some other colony.

Spring Management.—Next in importance after a good and safe system of wintering, we place spring management; and, with a view to honey production, the first requisite is to obtain large colonies by the time the honey harvest begins. It is of no use for hives to possess the maximum of population when the harvest is nearly over. It must be a very weak colony, or a very

poor queen, that cannot raise the population to 'boiling point during a plentiful harvest, but after this the bees are merely consumers instead of producers until another harvest arrives. Evident as the truth of this statement must appear to any one for a moment considering the matter, how many there are who keep bees on the plan of getting their colonies up to full strength just when the honey harvest ends! It may be from want of care, knowledge, or experience, or from not doing things at the proper time, or, indeed, from a variety of causes; but certain it is that with many bee-keepers this is the rule and not the exception. Again, therefore, we reiterate our former advice to keep no weak colonies, but to make it a rule to have all strong and full of bees by the end of May or the beginning of June, when the white clover commences to bloom. Sometimes and in a few districts surplus may be obtained from fruit-bloom, but in this climate, with its frequent cold and late springs, it is very rarely indeed that bees can do more than supply their own necessities of daily consumption before the time above mentioned, even in our southern counties. If we take the 7th of June as the general time at which colonies should be ready for the harvest, then six weeks previously—i.e., about the 25th of April -preparations should commence for raising the population of the hives by stimulating to brood-rearing, by judicious and careful brood-spreading, by the union of weak colonies, and, in all these operatious, by the least possible interference with or manipulation of the bees and their hives. By such means we venture to say that half-a-dozen strong colonies thus prepared will collect more honey than a score of others which have been left to their own devices or treated according to ordinary methods, whether the object be comb or extracted honey. Our ideas on stimulation and brood-spreading we hope to give in future 'Hints,' also advice as to the manner and time of the general spring overhauling or examination of colonies,—which is not yet.

PATENTS.—A more general inclination appears to be springing up amongst English inventors of apicultural

appliances to resort to the Patent Office for protecting their inventions. The recent reduction in fees for patenting, and the reasonable sum for which provisional protection for a period of nine months can be obtained, together with the unscrupulous manner in which any unpatented article or idea is seized upon by other interested persons, readily accounts for this development. Mr. Root, editor of American Gleanings, some time ago made the following statement in regard to the same subject from an American point of view: - 'I am very glad indeed to note the disposition among bee-keepers of forbearing to copy the works of each other, patent or no patent. The supply dealer who would unhesitatingly copy something well known to be the property of another, without getting the privilege of doing so, by purchase or otherwise, would very likely lose more than he made, so strong is the disposition of our people to give honour to whom honour is due.' He would be a very bold man who would endorse this statement if it were applied to Englishmen. And yet we have always believed that honour and honesty prevailed, to say the least, in as great a degree on this side of the Atlantic as on the other. The subject has of late been repeatedly brought under our notice by inventors submitting their novelties for inspection and advice, almost invariably with the proviso that the invention is to be protected, and must therefore be considered private and confidential. Amongst the last articles with which we have been favoured are a standard frame, and sections of various sizes and shapes, by our old friend, Mr. James Lee, which bid fair in our estimation to hold the field against all comers. So great is the ingenuity displayed, and yet so perfect the simplicity, that we shall be much deceived if the invention does not command a very

large sale both in England and America, in both of

which countries we understand that it is intended to take out patents. More at present we must not divulge, except that it is in contemplation to provide perfect machinery for turning out the articles in the large quantities likely to be demanded. The speaimens forwarded to us are of the most perfect and accurate construction, and when arrangements are completed, can be supplied at the present prices of good frames and sections both here and in America. We believe that hives on the same principle will be supplied also, but a specimen of these we have not yet seen. The reproach, if there be any truth in it, that for our best ideas in apicultural appliances we are indebted to Americans, is surely being wiped out, and now we are going to turn the tables upon our cousins. Can we fancy ourselves sending sections to America, and actually manufacturing them in that country, instead of receiving them from thence? 'So the world wags, so the world wags.'

PREPARING HIVES, SUPERS, &c.—We well remember the late Mr. Pettitt, of Dover, exclaiming loudly against painting hives, because, as he maintained, it prevented the escape of moisture from the interior, an idea contrary to the natural instinct of the bee, which leads it to cover the interior walls of its domicile with varnish, or propolis, to prevent the escape of heat or moisture. Hence we find experienced apiarists recommending a coating of varnish to be applied to the inner walls of modern frame-hives. A composition, formed of twothirds resin and one-third beeswax, should be melted, mixed well together, and applied warm with a brush, care being taken to brush it well into the corners and cracks, thus saving the bees much labour at a season when time and labour mean honey. Mr. Heddon recommends lubricating the hive bearings with tallow, and rubbing it well into the wood, when, he says, you will enjoy the luxury of removing covers, supers, honey cases, &c., in the twinkling of an eye, without a snap, jar, or bee protest.

ASSOCIATIONS.

BUCKS BEE-KEEPERS' ASSOCIATION.

The annual meeting of this Association was held on Thursday, February 3rd, at the George Hotel, Aylesbury, when there were present the Rev. J. Hill in the Chair, the Rev. E. K. Clay, the Rev. F. S. Sclater (Hon. Secretary), Mr. W. Sturdy, &c. The Secretary read

the annual report and balance-sheet.

The Committee congratulated the Association on the fine exhibit of honey which secured for Buckinghamshire the fourth prize in Class I. at the recent South Kensington Show, and which included honey collected from thirty-eight different bee-masters. Lectures have been given at Amersham and Wolverton, whilst the bee-tent has been usefully employed at Stoke Green, High Wycombe, Denham, Mentmore, and Oving. Experts' work has been chiefly done through the local advisers, to whom the thanks of the Association are due. honey census has been very partially collected this year, through the failure of members to make a return as requested. Returns were received from fifty-five members. Honey yield:—Extracted, 2018 lbs.; I-lb. sections, 2596; 2-lbs., 81; other supers, 193 lbs.; wax, 48 lbs. The Association was able to sell at a good price the whole of the honey taken to London. From the balancesheet it appeared that there was a deficit on the year of 12l. 1s. 2d.

Baron F. de Rothschild, M.P., was elected President for the ensuing year, and the other officers were reelected.

The annual drawing for three hives afterwards took place, the winners being, 1st, Mr. W. Garrett, Fenny Stratford; 2nd, Mr. J. Elliott, Wicken; 3rd, Mr. C. Middleton, Eton.

DERBYSHIRE BEE-KEEPERS' ASSOCIATION.

The fifth annual general meeting of the Derbyshire Bee-keepers' Association was held in the Guildhall on Friday, 21st January, 1887. Col. Sir H. Wilmot, Bart., V. C. C. B., presided, and amongst those present were the Rev. J. Wadham, and Messrs. W. Newton, W. Wilks, W. Handley, D. Cooper, A. Cooper, Holmes, Fearn, Johnson, Austin, Sims, Boden, Atkins, and Hodder. We extract the following from the Report for the past

'The Committee, in setting before you their fifth Report, are glad to be able to congratulate the members of the Association upon the sure and steady progress which has characterised their efforts for the past year, and upon the permanent position it has now attained in the county. The number of subscribing members is now 350, which, with twenty-three denors to the prize fund, makes a total of 373 as against 267 last year. After paying all expenses, we are able to carry forward a balance of 25l. 16s. $2\frac{1}{2}d$.; the sum being 7l. 8s. 4d. in 1885. The annual show for 1886 was, by permission of the Committee of the Derbyshire Agricultural Society, held in connexion with theirs, on September 8th and 9th, and was a great success. The number of exhibitors was about the same as last year, but the apparatus showed a marked improvement. The quantity of honey was much larger, and its quality pronounced by the judges to be of the first order. The Committee, in concluding their Report, desire to point out the good accruing to the Society from the various lectures held in different parts of the county, and trust that the members generally will do all in their power to advance the cause of the Association.'

The President (the Duke of Devonshire) and Vice-Presidents were re-elected. Mr. Copestake was reappointed Treasurer, and Mr. W. T. Adkins, Secretary. The Secretary then moved the re-election of the District Secretaries, which was carried. The draw for the two prize hives next took place, the successful members being Mr. G. Griffin, Clay Cross, and Mr. J. Dowens, FoxIow, Buxton. It was decided to allow the Secretary a sum of 10% per annum for his services, instead of 5% as hitherto accorded.

-

ESSEX BEE-KEEPERS ASSOCIATION.

The Annual Meeting of the Essex Bee-keepers' Association was held on Saturday evening at the Corn Exchange, Chelmsford, Mr. G. H. Anbrey presiding. There were also present Messrs. F. H. Meggy (hon. secretary), Reginald Christy, Leonard Brown, Edmund Durrant, F. Maryon, W. T. Braddy, W. Debnam, and others. The annual report and accounts were presented. The report recapitulated the work of the year, and recommended that from the 1st of January agricultural labourers should be admitted to the benefits of membership on ihe payment of a subscription of 1s. per annum. The financial statement showed that, notwithstanding the heavy expenditure during the past year entailed by the holding of county shows, and the large number of members visited by the expert and receiving copies of the Bee Journal, the income for the year balanced the expenditure and left a small surplus to carry forward. It was shown that there were about ninety new members, the total number of members and donors being over 300.

HEREFORDSHIRE BEE-KEEPERS' ASSOCIATION.

The annual meeting of the members of the above Association was held on Monday, January 31st, in the Woolhope Club Room, at the Free Library, when there was a good attendance. Dr. Chapman was voted to the Chair.

From the annual statement of accounts it appeared

that there was a balance in favour of the Association of 13l. 19s. 4d. The report stated that the season had been moderately favourable, and fair yields were reported from most districts, the honey not being contaminated with honey-dew so much as last year. Three private demonstrations had been given in the gardens of members with most satisfactory results, and the report dwelt upon the advantages of this plan to cottage bee-keepers who did not attend horticultural shows. Demonstrations were also held in connexion with the horticultural shows at Hereford (St. Peter's) and Ross. Honey fairs had been organized in different parts of the county with much success, and the Association had taken a part in the Exhibition at South Kensington.

On the election of officers Mr. Rankin was unanimously re-elected President. The Committee, with the exception of those members who had resigned, were relected, and the Rev. James Oakley, the Rev. — Herbert, Mr. Edgar Morris, and Mr. Spencer were added to it. Mr. Watkins was re-elected as Secretary, the work he had done for the Association having been warmly enlogised. Messrs. Hole and Meadham were elected experts, and Mr. F. James representative to the Bee-keepers'

Association.

GLAMORGANSHIRE BEE-KEEPERS' ASSOCIATION.

The annual meeting of the Glamorgan B. K. A. was held at Cardiff on Thursday, February 3rd, C. F. Gooch, Esq., in the chair. The Report and Balancesheet were passed. After the election of Committee and Chairman, the latter referred in very warm terms to the past services of the Hon. Sec., Mr. E. Thornton, and he was sure all the members would regret that he felt it necessary to resign. A cordial vote of thanks was given to Mr. Thornton for his past services. Mr. Clark, Penarth, was elected hon. sec., and Mr. W. Gay, 4 Flora Street, Cathays, Cardiff, was elected hon. asst. sec. and expert for the County. Messrs. D. A. Thomas, Ysgnboaven, and C. F. Gooch, Cardiff, were elected representatives for the County. Mr. W. Gay, certified expert of the B.B.K.A., and expert of the county, then read a paper on the profitable management of a hive, &c. A general discussion followed. A vote of thanks to the chairman concluded the proceedings.

LEICESTERSHIRE BEE-KEEPERS' ASSOCIATION.

The general annual meeting of this Association was held on Saturday, January 29th, at the Old Town Hall, Leicester. Mr. Carter, of Mill Hill House, Leicester,

was voted to the chair.

The Report and Balance Sheet were adopted. A discussion then followed on the ways and means of improving the position of the Association; and as the employment of an expert to visit the members was thought likely to be beneficial in this direction, it was proposed by Mr. Meadows, seconded by Mr. J. Cooper, and carried, that the prize-money usually offered for appliances be applied towards paying the expenses of an expert.

Proposed by Mr. Fosbrook, seconded by Mr. Foxon, and carried, That arrangements be made for an expert to visit the apiaries of such members as required his assistance.

After a short discussion on the difficulties members found in disposing of their honey, it was proposed by the Rev. M. A. Thomson, seconded by Mr. Meadows, and carried unanimously, That a honey fair be held in the current year in accordance with Rule.X.

The business of electing Committee and Officers was then proceeded with. The re-election of the Secretary was coupled with a gratuity of three guineas, and a hearty vote of thanks to him and his wife. A special vote of thanks to the Leicestershire Agricultural Asso-

ciation for their liberality was passed. The meeting closed with a vote of thanks to the Chairman.

Both before and after the meeting Mr. W. P. Meadows interested the bee-keepers present by exhibiting and explaining the working of the Jones-Heddon and the Bebington hives.

OXFORDSHIRE BEE-KEEPERS' ASSOCIATION.

The annual meeting was held at the Clarendon Hotel on Wednesday, January 26th, when there was a large number of members present. The Right Hon, the Earl

of Jersey (President) occupied the Chair.

The Secretary presented the balance-sheet, from which it appeared that the total receipts amounted to 33l. 7s. 3d., while the expenditure reached 35t. 2s., being a balance on the wrong side of 1t. 14s. 9d. The report stated that the number of those who have joined the Society during the year was no less than 61; thus, notwithstanding the loss of 25 members, there is a net increase of 36 members, bringing the total membership of the Society from 102 to 138. A spring tour had been undertaken by Messrs. Perry and Cobb, the former taking the northern, the latter the southern part of the The autumn tour was carried out by Mr. county. Cobb alone. Nearly every member was visited, and had his bees examined, and advice given to him. It was decided not to hold a show this year, partly on account of the expense incurred the previous year, and partly because it was hoped that an offer which was made to secretaries of flower shows would accomplish the same object as a honey show. The bee-tent again visited several places, viz., Henley (two days), when the Berks Association also sent a tent with exhibits of honey, bee-furniture, and appliances; Trinity College, on the occasion of the Royal Horticultural Show at Commemoration; Headington, Watlington, Woodstock, and Shipston. At the latter place the Rev. II. Barton acted as expert.

On the election of officers Earl Jersey was re-elected President; the Rev. F. C. Dillon, Secretary; the Vice-Presidents were re-elected, and the following were elected Local Secretaries:—The Rev. II. Sturges (Witney), the Rev. W. Neame (Isip), the Rev. D. Thomas (Cuddesdon), the Rev. C. Williams, of Benson (Watlington district), Mr. W. C. Hayes (Chipping Norton), Mr. Scrivener (Bicester), Mr. C. Harris (Oxford), and Mr. T. Hughes, of Combe (Woodstock district).

At the conclusion of the meeting the Earl of Jersey, with characteristic generosity, handed the Secretary an amount to cover the deficit on last year's account.

HORSFORTH DISTRICT BEE-KEEPERS' ASSOCIATION.

The bee-keepers of Horsforth have met, and come to the following conclusions:—I. The society shall be called the Horsforth District Bee-keepers' Association. 2. The annual subscription shall be 2s. 6d. 3. That monthly moveable meetings at convenient centres be summoned by the hon. secretary, for purposes of mutual improvement in bee-culture. 4. That 5s. be at once forwarded to the hon. secs. of the Yorkshire Bee-keepers' Association, thereby qualifying the Hon. Sec. and another member as County committee-men, in accordance with the recent resolution of the Y.B.K.A. 5. That bee-keepers within the district desirous of joining the Association be hereby invited to communicate at once with the district secretary. 6. That the district hon. sec. be N. F. G. Burniston, Esq., Throstle Nest Apiary, Horsforth, near Leeds. 7. That the treasurer and district adviser be A. W. Henderson, Esq., Bank Terrace, Horsforth.

The members at the close of the meeting congratulated themselves upon being the first to have the honour of taking this new departure in our county.

Correspondence.

The Editor does not hold himself responsible for the opinions expressed by his correspondents. No attention will be taken of anonymous communications, and correspondents are requested to write on one side of the paper only, and give their real names and addresses, not necessarily for publication, but as a guarantee of good faith. Illustrations should be drawn on separate pieces of paper.

Communications relating to the literary department, reports of Associations, Shows, Meetings, Echoes, Queries, Books for Review, &c., must be addressed only to "The Editor of the "British Bee Journal," clo Messrs. Strangeways and Sons, Tower Street, Upper St. Martin's Lane, London, W.C.' All business communications relating to Advertisements, &c., must be addressed to Mr. J. Huckler, King's Langley, Herts (see 2nd page of Advertisements).

***In order to facilitate reference, Correspondents, when speaking of any letter or query previously inserted, will oblige by mentioning the number of the letter, as well as the page on which it appears.

WINTER MANAGEMENT IN CANADA.

[815.] You did me the honour of asking me to occasionally pen a few lines for the Journal. Nothing would afford me greater pleasure than to do so if I were persuaded that anything I could write would be of interest or profit to your readers. I certainly owe you and your constituents a debt which cannot be paid by me in this way. I have no fait!: in my ability to teach the British bee-keeper the mysteries of his craft. I know them now too well to doubt their skill in these, or to esteem my own in any way superior to theirs. I am conscious enough of the fact, however, that I owe both them and you a heavy debt of gratitude, and would discharge it (in part) in this way. But how shall I place the first item to the credit side of my account with you? is the question that suggests itself to me. I repeat, Not by a lesson in beekeeping certainly. Let present circumstances then suggest my topic.

It is ten o'clock p.m. The family have retired, and I sit aloue at the table with a bright fire blazing in the grate. The temperature of the room is about 65°. The glass outside registers 3° below zero. What a difference in temperature between the within and the You say, How intensely cold it must be to without! cause the mercury to drop so low! Methinks your sympathies go out to the unfortunate men and women who are compelled to be out on such a night, and you bless your stars your home is in Old England and not in Canada. What are McKnight's feelings you, perchance, ask yourself? Well, they are those of the poet when he

wrote-

'Backward, turn backward, O Time, in your flight, And make me a boy again just for to-night!

for I hear the merry jingling of the sleigh-bells and the rollicking laughter of a happy sleighing party out for a pleasure drive. Wrapped in their warm robes they skim over the well-beaten snow road, the hoofs of the horses keeping time to the 'tinkling of the bells,' and the hilarity of the party raised to its highest pitch by the bracing air of a genuine typical Canadian winter night. The earth is blanketed with the 'beautiful snow,' a foot and a half thick; the air is as still as death, the moon looks down from a cloudless sky aud her rays are reflected back with such brilliancy that the very stars are chased out of the firmament. It is not a night for Canadian youth to huddle together by the 'ingleside,' but such an one as they love to meet with one another on the hillside and engage in the exciting sport of 'toboggen' sliding -strike across country on snow-shoes, or drive out in sleighing parties. It is, I repeat, just such a night as Canadian youth delight in, and will suffer nothing by comparison with one of sleet and wind or of heavy hanging clouds without either.

Pray don't pity us because of the severity of our climate. We don't need your commiseration on this score. But how, you ask, does it affect your beckeepers? Well, it necessitates a different mode of winter management from that practised by our British

brethren. It makes winter protection a necessary element on success. We winter in two ways-indoors and out. The indoors method I need not dwell upon, as you do net need to practise it. Every house has its cellar, and most people keep their bees where they keep their roots and perishable vegetables. A few have 'bee-houses' specially constructed for wintering their pets. Those who winter on the summer stands use double-walled hives, or something better than a simple outer case. These doublewalled hives, however, are the exception and not the general rule.

I shall attempt to briefly describe the method generally practised in outdoor wintering. It consists of an outer case with some kind of packing between and above. This outer case is constructed in the following way, with modifications here and there. First make a rough stand five or six inches wider every way than the bottom hoard of the hive. Now set your hive on this stand with the centre of the bottom board over the centre of the stand. The stand will then project five or six inches every way beyond the outer limits of the bottom board. Now make a case the outer limits of which will correspond with the outer limits of the stand. This case must be open at bottom and top; the top of this case should be six inches higher in front than back and about twice the height of the hive. When this case is placed over the hive it rests on the stand, which makes a nicely fitting bottom for it. The front of this case must have an opening below corresponding with the entrance to the hive. Now erect a nice little bridge between the hive and the outer case that will permit the bees free access to the outer world, and preventing the packing when put in from blocking up this passage. The hive is now surrounded by a case with an empty space between and around of some five inches or so. Before packing between and above the hive itself must be prepared. This is usually done by spreading a quilt over the top of the barframes. This quilt should be a little larger than the top of the hive. The empty super is now placed on the top of the hive and this keeps the quilt securely in its place. The case is now ready for the packing, and the best material for this purpose is cerk-dust, such as fresh grapes from the Mediterranean are usually put up in. The next best is dry saw-dust, such as may be procured in a factory where dry deals and hoards are repped in; saw-dust from green logs should never be used. straw, dry leaves or chaff will do, but not so well. Whatever material is used it should be well packed around and ever the hive right up to the roof of the case. The quilt over the bars precludes the possibility of the packing getting to the cluster. A roof or top, projecting a little over the frame, is now put on and the work is done. Some people place a device on top of the bars and under the quilt to allow the hees a passage over the top bars. I have put them away both with and without this device and found no difference in wintering. The front of the case being higher than the back causes the roof to shed the rain freely. I did up fourteen stocks in this way last year and the rain came through the winter finely. I have over forty put away at the present moment, and I have no fears for their safety.

Probably you prepare your own bees for winter in some such way. If so this paper will be neither interesting nor prefitable to your readers.—R. McKnight, Owen Sound, Ontario.

BEE-KEEPING IN CANADA.

[816.] A correspondent under the above heading, B.B.J. p. 605, writes in a tone which can scarcely be passed in silence with justice. I am in a position to speak with knowledge of the Caledonian Show; it is not far from the home of my parents, not far from my present place of residence, and I have been in the place many In the first place, the Caledonian Show is not what we know as a large show. The directors of such a show as the Caledonian generally know but little about beekeeping, and it is considered one of the most insignificant of the departments. The prizes only extend to the best 10 lbs. of extracted, or, in a mistake, they may even say strained honey, and the best 10 lbs. of comb honey.

Now, at just such a show I have seen a pan of broken comb take the first prize from beautifully filled sections, and the dark inferior grades of honey get the preference because the judges knew nothing about bee-keeping, and

they think such looks more natural.

We must remember that bee-keeping has made wonderful progress during the last few years, and the knowledge the bee-keepers possess has not yet been transmitted to the general public, or, at least, only in a small measure. So much so, that at our Provincial Exhibition last year, when showing goods to the judges, they glanced over the list, and then remarked, 'Wax and honey extractor, is that not all the same thing?' But is that an indication of the state of apiculture in our land? Far from it.

The hives spoken of at Caledonia were either framehives, or they were there as a joke, or a curiosity. I have no hesitancy in saying this as bee-keepers know better in that locality. No intelligent bee-keeper uses the box-hive. I have been amongst many bee-keepers during the last five or six years; and with the exception of the second year when I went to a box-hive locality, and purchased seventy-nine stocks in such hives and transferred them during fruit-bloom, I have rarely seen a box-hive.

There are, however, quite a few in exceptional localities in Ontario, although, I believe, more in the province of Quebec. Ontario is the honey-producing part of Canada, at present however. These remarks, coupled with my previons one on Canadian hives, will, I think, throw sufficient light upon the question. I regret that Mr. S. T. Pettit, the President of our O.B. K. A., should have found it necessary to leave England before the time when the British and Canadian bee-keepers met; there would have been another Canadian to assist in throwing additional light upon bee-keeping as conducted here. The conversational powers of a few (three) must have been, at times, taxed to the utmost.

I have had the pleasure of meeting with Mr. J. A. Abbott of Southall, London, England, and spent an afternoon partly journeying by rail with him. I learned very much of interest and solid profit from him, and had a very pleasant time. It is a bad season to judge of beekeeping in Canada, but I think Mr. Abbott will have gleaned sufficiently to be in a position to endorse the majority of the statements made, or the tenor of them.—

R. F. HOLTERMANN, Brantford, Canada.

DOUBLING.

[817.] Last season I followed the instruction in your admirable article on doubling, and as a consequence had large stocks and no swarms. I have six hives, and my average was sixty-one pounds per hive, section and extracted, taking the $4\frac{1}{4} \times 4\frac{1}{4}$ section at one pound. The previous season, commencing with three stocks and increasing by natural swarming to six, I had an average of eighty-three pounds per hive. The difference in the season would account for this increased result. There is, however, one drawback to this method of doubling; that is, brood in the upper boxes. One of my hives had four bodies, holding twelve frames in the lower hive, ten in the others, and had brood in the middle frame of all the upper boxes in September, which was a great inconvenience in extracting; and when I had worked the hive gradually down, I found the lowest compartment quite empty of brood or honey. In another hive what held twenty-two frames in the body and twenty in the upper, I had brood in both, and a quantity of drone-comb drawn

out between the two tiers of frames and well up into some of the upper ones. I therefore think that some kind of queen-excluder should be used above the frames in the lower body; not excluder-zine, which I consider an abomination, and would, in all probability, make the bees swarm; but either by strips of wood on the top of the frames leaving the required width between, or a properly made board to fit the hive, with long strips cut out of it, or the top bar made wide enough to prevent the queeu going up. I have no difficulty with queens in my sections, and the bees seem to find no hindrance to their working by having to pass through the narrow strips of the section. The hive that gave me the best result last year was one with twenty-five frames in the body and sections above. I had 108 lb. sections on at one time, and full of bees, but owing to the season had only sixtythree completed. Can you suggest any plan to overcome this difficulty?—W. H. Jenkins.

[You do not say so, but we presume you have your frames fixed by broad shoulders or some other means, to the regulation distance apart of about $1\frac{1}{2}$ in, from centre to centre. This, we think, is the main cause why you have brood right up into the top storey. We keep the two lower storeys for brood and bring the combs to $I_{\frac{1}{4}}$ in. from centre to centre, but when we add our third storey the frames in this are placed at 13 in. from centre to centre. The queen seldom rises into this storey as the combs are too thick for her to lay in, and they form a better barrier to the storey above than any queenexcluder. We tried boards with slits in them the same as Heddon now uses before we used excluder zinc more than twelve years ago, when we worked large supers, but as they were constantly shrinking and expanding they did not exclude the queen from the supers. We have placed a square of enamel cloth over the frames 15 in smaller all round than the top of the hive, and this prevents both queen and bees from passing up the centre, which is the most likely place for the queen to use in going up. It is carrying out the principle of the Stewarton hive, in which the openings into the supers are on either side of the broad nest. Another way is, when you put on a third storey to remove all combs containing honey in the lower hives, and to put them into the upper hive, placing them $1\frac{3}{4}$ in. from centre to centre, and giving the lower storeys empty combs for the queen to lay in. When combs are only used for extracting there is not such an objection to the queen going up as there is when sections are worked. Still an endeavour should be made to keep the queen to the two lower boxes and secure honey in the two upper ones.—Ed.]

HONEY IN ZINC VESSELS.

[818.] Having in November and December read the various opinions in the B. B. J. as to the danger of keeping honey in zinc vessels, and having myself in use a large galvanised iron reservoir obtained during the summer from Messrs. Abbott, I without delay bottled off its contents, which had been standing about ten weeks, into glass jars, and at the same time made a careful chemical examination. I may say that the vessel had been in use all through the summer and autumn, the quantity of honey it contained varying according as I drew off and sold, or added to the store. It had never been cleaned or emptied. As the result of analysis, I could find no trace of zinc in any of the clear honey bottled off. I found, however, on washing out the dregs with hot water, that the washings had a metallic taste, and contained a considerable quantity of ziuc salts in solution.

I draw the conclusion that the action on the hive is confined to the film of honey in immediate contact with it, which remains adherent and does not diffuse through the main mass unless it is rubbed off and stirred up. As there must always be risk of such disturbance, the use of

unprotected galvanized reservoirs cannot be considered

free from danger.

To arrive at something certain as to the energy of the chemical action, I, on the 30th of November, cleaned a piece of sheet zine six inches by two inches, having a surface of twenty-four square inches. And, after weighing it on a delicate chemical balance, I immersed it in half a pound of clear pure honey contained in a covered glass beaker which 1 kept on the chimney-shelf from day to day, occasionally warming on the hob and stirring with a glass rod. I took out the zinc a few times, washed it with distilled water, and re-weighed. The weights were as follows:—

				Grammes.
Nov. 30, 1886.	Original	weight	of clean	zine = 29.0250
Dec. 1 ,,	Weight	after im	mersion	=29.0134
,, 2 ,,	11	.,	11	=29.0075
., 14 ,,	11	,,	11	=28.99990
Jan. 29, 1887.	.,		• • •	=28.9910

Total loss of weight in two months=0.034 grammes or 0.52 grains of metallic zinc. The action is thus seen to be slow and of no great amount even with the assistance

of heat and stirring.

I intend to varnish the inside of my reservoir. Can any of your readers say whether the ordinary varnish sold as 'White Hard' spirit varnish, would answer the purpose of protection without giving a taste to the honey?—R. E. LLOYD.

DISTRICT ASSOCIATIONS.

[819.] I am delighted to see your leader on this subject, it gives all your readers the lines to work on, and I

need not say how my ideas exactly coincide.

'Amateur Expert,' who is always terse and business-like, even in his most playful vein, places me under obligations to him for his valuable hints. I shall make it a point to try and pierce the veil of his incognito, which he freely admitted nearly fell (or was torn) from

the statue at one of the Canadian gatherings.

These very hints of 'A. E.' (without any effort on my part) have brought me letters asking for advice as to the formation of District Associations, and my help in lecturing in various parts of our county: with each of these I have complied, and so will continue to the fullest extent of my leisure, but our county is so large and individual exertion so seemingly barren of results, that a score or two working enthusiasts might be imported from our champion counties with the greatest advantage to us. My time, however, is so fully occupied by business that I must often let the will go for the deed.

business that I must often let the will go for the deed.

There is a splendid harvest of young bee-keepers who are longing for the Society and mutual pleasure of association, but the workers (may I say the HIGH and DRY?)

are hard to move. They do not fear

Lest they by thousands tumble from their honey'd dome. Into a gulph of blue sulphurous flame.'

Enthusiasm is wanting amongst those who have learnt their bee-keeping by practice and current literature without association, and they appear now desirons of sipping their nectar under their own hedges. To all such 'high and dry' I now appeal for the sake of those others who want light and leading. The Yorks B. K. A. have now (before 'A Worker's' suggestion in a recent issue was made) passed a resolution inviting the beekeepers of various parts of Yorkshire, without more ado, to form themselves into District Associations, no matter how small. These are to be entirely self-governed and self-officered; they are to have the fullest and freest liberty, and by payment of 5s. per annum per Association to 'the County,' can have the advantage of their secretary and another member being on the committee, with themselves having all the privileges of membership. So that now nothing remains but for our

brethren in various parts of Yorkshire to organize themselves, and this will be perhaps best done by one or two in each district calling, by cheap advertisement in daily paper, a meeting of bee-keepers to discuss and carry out the idea. I would suggest as a start that—

Bradford, Scarborough, Doncaster, Skipton, Walton, Brighouse, Harrogate, York, Wakefield, Thirsk, Hull, Goole, Middlesbrough, Barnsley, Harrogate,

be the first great districts (each of which is equal to some counties), to again subdivide some time in the dim and distant future by the natural process of development, i.e., by the simple one of

> 'When the church can raise a choir, Why then they'll raise a song,'

no matter how small the choir. So pull yourselves together, ye 'high and dry,' and let us have some public spirit for the sake of the bees who sacrifice so much for us and our service. Don't let us be saturated with the spirit of this ditty:

'We're honey-and-wax-young-men, We're wood-nails-and-tacks-young-men, Oh, isn't it funny, we're going to make honey Turn fast into money-young-men.'

It's all very nice to think of

'A golden hive, on a golden bank, Where golden bees by alchemical prank Gather gold instead of honey.'

> 'Ho, ho, to ye, Woe, woe, to ye'

if ye turn from the warning in the sulphur-pit couplet.— R. A. H. G., Horsforth, near Leeds.

SELECTED DRONES.

[820.] The question of the survival of the fittest amongst bees is a very important one, and no doubt ought to receive more attention than it does at present. We all know that some queens possess better qualities than others, and we ought to preserve those good qualities as far as we can; but how can this best be done? I know, sir, that your advice is very valuable on this subject, and ought to be acted upon; but without all act upon it, the few will not obtain the results expected.

I think it is quite as important that the drones should be selected as the queens, and here arises the difficulty. Supposing the strongest two hives in the apiary containing two of the best queens are chosen in the spring for breeding queens and drones, it is absolutely necessary that the drones be flying before any others within a radius of several miles, or the probability is that the young queens will not mate with the drones prepared for them, and as skeps generally produce drones early, there is but little time for getting a lot of selected queens impregnated by selected drones. Virgin queens (bees) are somewhat like the tender sex of another species, they prefer selecting their own husbands, and will not always accept what is offered them.

Early last June, a hive was found to be queenless and without brood. A frame of brood was at once given and a queen raised from that brood—or eggs, rather. Her majesty began to lay and, in due course, young bees appeared, two-thirds of which were, in appearance, beautiful Ligurians. They are hybrids, of course.

Now, sir, there was not a single Ligurian within a distance of three miles, and therefore this young queen must have been mated by a drone from that distance. There were plenty of English bees near and doubtless many drones at that time, but she rejected them.—A. Green, Selston, Alfreton.

RESUSCITATION OF BEES.

[821.] On Wednesday, the 19th ult., a thaw set in, and upon visiting my hives I found that, although shaded as they were, the bright half-hour's sunshine about noon had tempted the bees out, and about two hundred had paid the penalty, and were to be found upon the snow and ice, apparently dead. I picked up about a score, and while engaged in conversation with another person I suddenly became cognisant of a movement on the part of the bees in my hand. As it was evident the bees had been revived by the warmth, I heated a saucer in an oven, and gathered up sufficient (of the to all appearance dead bees) to fill the saucer, and after changing the saucer a time or two for one freshly heated, I had the pleasure of seeing nearly the whole of the bees revive, and return to their respective hives. It was the more remarkable as some were taken from pools of icy water, and others had small particles of snow and ice clingnig to their bodies.—G. N. RAILWAY.

MADAGASCAR BEES.

[822.] As communication between Madagascar and the rest of the world is very slow, I have only just heard of the question asked by 'Colenso' as regards the cubic contents of the hollow tree stated by me to contain about two hundred and eighty cubic feet. I must thank 'Colenso' for kindly pointing out a very stupid miscalculation, and apologise to your readers for the same. What I should have written was about sixty cubic feet, if in my mind's eye I had not seen a tree of twice the diameter.—C. P. C., Madagascar.

PHYSIOLOGICAL QUERIES, &c. (756).

[823.] No reply to the former query has yet appeared in the Journal, which I regret, as it is an interesting subject, and evidently has an important bearing on the new system of inversion advocated by a certain section of American apiarists, and more lately brought before the notice of bee-keepers in this country. The discussion raised relative to the latter question is instructive. I had several opportunities of closely examining the Jones-Heddon hive at the Colinderies, and from personal observation I can fully endorse the remark of J. M. Hooker (766) that hives of such thin material are not sufficient for use in this country, and I should never think of using them without an outer case, and the hive then becomes too expensive.

'Devonshire Dumpling's' advice to cottagers to try the Jones-Heddon appears to me too ridiculous to notice, and I can only account for such advice by supposing 'D. D.' is endeavouring to grind his axe at the expense of the poor cottager. I am one of those looking for information that can be relied on, and if 'D. D.' will give the particulars of his management, and if he would also add the district where his apiary is situated, it would give additional interest to the information. The one or two isolated cases given without any particulars furnish no data sufficiently reliable to be a guide, and my advice must also be to go slow with the new system.—W. Soar, 1 Sussey Villas, Kensington.

PHYSIOLOGICAL QUERIES: INVERTIBLE HIVE.

[824.] I beg J. Lee's pardon if I misapprehended his views as to invertible hives. I see it is the Jones-Heddon hive he objects to, and not so much the upsidedown plan: and I am glad to see J. Lee is making a hive like the Jones-Heddon, but one that is adapted to the British climate. So far, so good. I see he seems astonished at my advice to cottagers to try it. Now, Mr. James Lee, you say that your British Invertible hive requires no arguments to prove its utter unsuit-

ability to the cottager, as it required more skill and judgment to work it; I say 'work' it, as some of my cottage bec-keepers might not understand what 'manipulate' means. I did not think of advising a cottager that was not a bee-keeper, or a *Journal* reader, or one unskilled. Does 'J. L.' think, after the establishment of the Bee-keepers' Association for so long, and the *British* Bee Journal, with all its useful information, that cottagers have made no progress? Surely they are not all kidglove bee-keepers that subscribe to the *Journal*; and what does the *Journal* teach them? I venture to say that there are more skilled cottage bee-keepers on the weather side than on the lee of the ship, or the advice of the Journal cannot be much good; but yet it has come from a monthly one to a weekly one, and I fancy, Mr. Editor, it is going the right road to be twice aweek soon. I hope we shall get some skilled cottagers if we have none now equal to the gentlemen bee-keepers. And how much more skill does it require to work the Jones-Heddon hive? Are there British Invertible hives in this country? Ilas J. Lee had any experience with either? by his inquiry I should say not; and as my invertible hive is not very easy to work, I think the Heddon hive will be easier—more honey I do not expect.—Devonshire Dumpling,

INVERTIBLE HIVES. (793.)

[825.] I see J. M. Hooker (803) is coming down on poor 'Devonshire Dumpling' like a thousand of bricks. Poor 'Dumpling!' I hope he will escape in safety, as I have the pleasure of knowing him and am well acquainted with his mode of working. I tried inversion last season, although on a smaller scale than 'D. D.' 'J. M. H.' is not far from the mark in supposing 'D. D.' 'to be one of these.' I don't suppose 'D. D.' will mind me telling 'J. M. H.' that he had one swarm last summer from a right-side-up hive. I can assure 'A. E.' that a hot dumpling is a 'rum article' for 'fancy dealers' to close their teeth on. I think 'D. D.' knows a little about manufacturing hives, as well as how to use them and the profits to be derived from them. I have used cheeseboxes and they answered very well, and they are much thinner than the Jones - Heddon. Our friend Neighbour has got a 'nebby hive' which no doubt will suit I. M. Hooker, as it is $\frac{3}{4}$ inches thick and prettily decorated with thumb-screws. Hurrah for Mr. Simmins! I am sure we are all glad to see his notice in the valuable British Bee Journal—good luck to them all, dealers, fancy dealers, upside downers, and rightside uppers.—Apple Dumpling.

The Bee's Sting a Useful Tool.—From lengthened observations, Mr. W. F. Clarke, a Canadian, has come to the conclusion that the most important function of the bee's sting is not stinging, but its use by that wonderful creature as a tool. Mr. Clarke says he is convinced that the most important office of the bee's sting is that which is performed in doing the artistic cell work, capping the comb, and infusing the formic acid by means of which honey receives its keeping qualities. The sting is really a skilfully contrived little trowel, with which the bee finishes off and caps the cells when they are filled brimful of honey. This explains why honey extracted before it is capped over does not keep well. The formic acid has not been injected into it. This is done in the very act of putting the last touches on the cell work. As the little pliant trowel is worked to and fro with such dexterity, the darts, of which there are two, pierce the plastic cell surface, and leave the nectar beneath its tiny drops of the fluid which makes it keep well. This is the 'art preservative' of honey. Herein we see, says Mr. Clarke, that the sting and the poison-bag, with which so many of us would like to dispense, are essential to the storage of the luscious product, and that without them the beautiful comb-honey of commerce would be a thing unknown. This is certainly a most wonderful provision of nature.—Iron.

Replies to Queries.

. In their answers, Correspondents are respectfully requested to mention in each instance the number and the title of the query asked.

[774.] SEPARATION OF WAX FROM POLLEN.—I always found extracting wax was a messy job, as after boiling and straining through a cloth, as described by 'Amateur Expert,' I buried cloth, wax, and all, because it was so messy, and I made up my mind never so do any more; but speaking to neighbour Killick on the subject, he told me it was an nnnecessary trouble, and offered to lend me his extractor, which offer I soon accepted, as he said there was no mess; and having a few old combs that I had not disposed of, I followed his instructions, and, to my surprise, every morsel of wax was extracted, leaving all the pollen, &c., easily to be cleared away, and the wax wanted no more refining. It is the best and simplest one I ever saw, and every cottager should have one that has only got a few stalls of bees, as I think we ought to produce more wax, and get it made into foundation, instead of purchasing so much, now it can be done so easy with little experience, and the times won't allow us to be too extravagant .- T. B.

Queries.

Queries and Answers are inserted free of charge to Correspondents When more than one query is sent, each should be on a separate piece of name.

of paper.

Our readers will greatly oblige us by answering, as far as their knowledge and observations permit, the Correspondents who seek assistance.

Answers should always bear the number and title placed against the
query replied to. Any queries unanswered in this way will be answered
by the Editor and others.

[826.] Crates of Thirty-five Sections.— Have any of your readers tried crates of thirty-five sections instead of twenty-one? If so I should be glad to hear their experience thereon. Having a hive suitable for storifying, and wishing to work for sections, I thought of having two crates made to carry thirty-five sections to each. There are nine frames in the hive at present, well covered, and with plenty of scaled stores, but when full it takes fifteen frames.—West Somerset.

[827.] Moveable Frame-hive.—To whom is due the honour of the invention of the moveable frame-hive? Give the date or year.—Douglas.

[828.] Glass Hive.—Who was the first inventor of glass hives?—Douglas.

[829.] Poisonous Honey.—Is honey produced from the rose-laurel and the yellow azalea proved to be poisonous? If so, how does it not poison the bees when they gather it?—Douglas.

Echoes from the Pives.

Plymstocks, South Devon, Jan. 26th.—The sun coming out brightly, and the bees flying, I ventured to examine and see if there were sufficient stores. Found them rather short, so shall have to try Mr. Simmins' latest dodge. Received with what equanimity I could the first sting of the season. I have been wintering my three stocks under enamel cloth, and am amazed at the result. They were very short of stores when put into winter quarters, owing to an illness which prevented me feeding, and yet they are not entirely without now, and wonderfully strong. One lot was a single driven stock and they were fairly fed up before I got ill, they are now nearly as strong as the others. Your advice in the 'Correspondents' column, Mr. Editor, made me hesitate before trying this plan, but 'Useful Hints' decided me for it, and I'm glad he did.—Trevon Saynon.

Malvern, January 28th.—To-day being beautifully fine, and bees flying freely, I took the opportunity to examine my hives. I found all in good condition, scarcely any stores touched, and in one stock breeding had not only commenced but there was a quantity of scaled brood, and a good number of young bees flying out for the first time. This is the more remarkable considering the sharp frosts we have had.

Swanmore, Bishop Waltham, January 29th.—After a long spell of very bad weather we have at last a few mild days on which it has been possible for the bees to get out for a flight, and of which they have not failed to avail themselves. The general report of the district is that so far the bees seem to have wintered well. My own are all apparently strong and no signs of dysentery.—H. W. West.

North Leicestershire, January 31st.—From December 6th to 31st inst. (fifty-one days), the bulk of the bees kept to close quarters; a few ventured out on the 18th and 19th, but only to perish in the snow. Losses are almost nil, but some stocks are very short of food, apparently through late breeding in October and November. Since the 26th the bees have been in flight daily, and seem very much inclined to while away their time in robbing all round.—E. B.

Uttoxeter .- On February 2nd I was called upon by the coachman from Miss W---, with a request to go and see her bees. I said it was too early to examine bees yet. But, he said, Miss W—— is afraid they will be short of food. Impossible, I said, I attended to them myself in the antumn and they had abundance. Being urged I promised to go on the following Friday if it was a nice day. Friday, February 4th, was a fine day, so I set off to the place in question, a distance of about five miles. The coachman acting as my assistant, we commenced with No. I, a barframe hive. As soon as the roof was lifted off I said, Something has been the matter here, and was answered that the hive had been blown over late last autumn, and George (servant-lad) said he had put it all right again. Well, I said, if bees will winter this way, they will winter nearly any way. The bars were all out of place, nearly cornerways in the hive, the quilt laid on anyhow just over the cluster, there was an opening in the left front corner that I could get both my hands in right into the hive without touching quilt, hive, or bars. Well, I thought, this is enough to kill them all, such a winter as we have had. But the bees were healthy and well and numerous. Their loss had been very small. It was only the work of a minute or so to put all right, in doing so I saw a patch of brood in various stages on one bar about as big as a five-shilling piece. The straw hives (four or five in number) were then examined, and floor-boards cleaned; all were in good order. Lastly, another bar-frame hive was looked at, which was all right, only some of the quilting a little damp; this was changed, and all made snug and comfortable. I may say, in conclusion, that this lady has kept bees now for some years, devoting time, attention, &c., to them, and every penny profit realised is devoted to charitable purposes,—an example worthy of imitation. - F. Harpen, Uttoxeter, Staffordshire.

Fakenham, Norfolk, February 7th.—Not having opened one of my hives since August, and as I did not feed in the autumn (though I had taken 60 lbs. from it), I was anxious to know what state the bees were in. January 28th being a very fine and warm day I could not resist the temptation to look at them (against instructions). To my great surprise I found grubs and brood on two frames which appeared to be in a forward state; there was plenty of food, very few dead bees, and quilts perfectly dry. Is it not unusually early? I did not winter them in the usual way; instead of cutting holes through the combs, I left the empty crate on, so that the bees could run over the top of the frames. I put the wood dividers down to keep the bees from getting through, and then put the quilts in the crate. I also put a piece of glass across, so that I could see the bees, and left them on twelve frames. I peeped at them several times during the very cold weather, and always found them between the frames and crate, going from one end of the hive to the other, and appeared very healthy. I have now reduced the number of frames, which is usually done in the autumn. I generally winter in that way, and do not reduce the number of frames till early spring, and always find them in good condition.

Alton, Feb. 10.—Mice in Hives.—Thinking it would be of interest to the readers of your valuable Journal, I herewith give an account of my finding traces of mice in my hives. As soon as the snow was gone, and the weather warm, and the bees were out having a cleansing flight, I went round my apiary to open the roofs of hives to give them an airing; when, on opening one of the hives—the bees being placed at the back part of the hive—I saw a lot

of dead bees on the top of the covering, all wet, and shook them all off. I went again next day, when I saw a lot more all bitten to pieces. I went again the following day, when there was another lot, having a hole bitten between the wings, also a large plum-stone carried up with them. Being at once convinced that the bees did not carry the stone up, I put in a trap for mice. Next morning there was one mouse, second morning caught three, third morning two mice, making a total of six mice. The trap was placed on the floor-board inside of hive in front of the division-board. I have now twenty stocks of bees, which all appear very strong. I examined the one where the mice had been at play, and found no damage done by them, and, to my delight, found a large patch of brood, this being on Saturday the 5th, it being a very warm day; so, judging by the one, the bees are very forward in this district. I have not lost one stock this winter. - F. G. AYLING.

Lismore, Feb. 12.—The weather is very dry here, not a drop of rain these last eight days, some of which were sunny and fine, allowing bees to fly freely. Some days, however, there were frosts at night and light cold wind by day, so that the bees, on the whole, have not had as much benefit from the crocuses—which are now out in sheets—as might have been expected; still I have seen a good many little orange-coloured loads going into the hives. I think my bees have now given up going back to the old site. I stuck a big branch of laurel in front of the hives, and this seems to have at last attracted their attention to the change of locality. Besides crocuses and snowdrops and gorse, we have in the gardens here a good deal of a dwarf heath now in bloom, on which the bees work most energetically on tine days, seeming to prefer it to anything. A good deal of hazel is also out. I alluded some time ago to a plan I have adopted of feeding my hives in spring without removing roofs or disturbing the cushions, &c. I found last spring that some hives which I tilted up a tiny bit in front, and fed by pouring in a little syrup, got on just as well as the hives on which I had elaborate and scientific feeders; so, for convenience sake, I have adopted the plan to all my hives, only making an entrance at back of hives by means of a tin tube about 7 inch wide, with a little flat rim or eollar at one end by which to secure it after the wall of the hive has been bored to receive it. The pipe is made long enough to project 1 inch beyond the inner wall of the hive. When not open for syrup to he poured through, I keep it closed with a cork. By means of a funnel with bent pipe I pour into each hive at evening its allowance of syrup. In one or two hives I have a little trough beneath the pipe on the floor-hoard about 3 inch deep, with wooden sides and coarse perforated zinc cover, through which the bees can suck the syrup. The trough can hold about two wineglass-fuls of syrup. In this way any one can feed twenty or thirty hives in a few minutes, and there is no fear of disturbance of quilt or roofs and covers put on insecurely. Also where hives are exposed to wind, and have to be secured, they need not be disturbed. I bore the hole for the pipe at the centre of the back of the hive, about I inch above the floor-board. My frames are at right angles to the door. For ladies who do not like lifting off heavy hiveroofs this plan is very convenient.—F. W. C.

Navan, Ireland.—The past honey season has been a fairly good one in this district. I commenced the season with seventeen stocks of bees, thirteen in bar-frame hives and four in skeps. I obtained about 600 sections and nearly 200 lbs. of extracted honey. From three of the straw hives I got very little, as they swarmed and took to the sections badly. The other gave me over forty sections. My bar-frame hives seldom swarm. From my best hive I took eighty-three sections and 16 lbs. of extracted honey; another gave me 62 lbs. of extracted and twenty-one sections. I intended to have sent some honey to the Irish Association's Honey Market, but getting what I considered fair offers, I sold privately. I got from 9s. to 12s. per dozen.—M. D.

NOTICES TO CORRESPONDENTS & INQUIRERS.

All queries forwarded will be attended to, and those only of personal interest will be answered in this column.

J. DRINKALL,—Why Drones do not store Honey.—There are physiological reasons why drones are not able to store honey. The tongue is much shorter than that of the worker, and the body is much larger, so that the drone cannot put its head and thorax into worker-cells. The gland structures are also different, and those producing the ferments necessary to convert the cane sugar of nectar into the grape sugar of honey are so altered and diminished in size as to make them incapable of yielding this secretion. In bees there are four systems of glands which yield secreting fluids. In the drone, System I. is entirely wanting, but, according to Schiemenz (Ueber das herkommen des Futtersaftes und die Speicheldrüsen der Biene, 1883), this system exists in the worker for the purpose of supplying a secretion for brood-food, and also for feeding the queen, with probably additions from the other glands. System II. in the drone is different, the secreting cells of the worker being replaced by fat-cells. In System III, the glands, as well as the reservoirs attached to them, are much smaller in the drone; therefore secretion could not be produced in nearly the same quantities as in those of the worker. If these three systems are brought into action either together or separately in the conversion of nectar into honey it is evident that drones are not physiologically adapted for this purpose.

W. M.—Size of Extractor.—You have now evidently found out one of the disadvantages of not having all your frames Standard size. The Raynor extractor will take your largest size; the cages of this are 11¼ inches.

BEESWING.—Putting Swarms Together.—Throw both the swarms on to a board in front of the hive that they are to occupy, and let them run in. Secure the least valuable of the two queens if you happen to see her; do this just before dusk. Prop up the front of the hive at least an inch to give them a clear passage. You can sprinkle each lot with syrup scented with a few drops of essence of peppermint if you like, but there is no absolute necessity.

DE B.—Buttercups, gorse, and broom secrete honey, but not to a great extent; they are, however, prolific in the production of pollen, especially gorse and broom. The horse-chestnut produces both honey and pollen, the former rather copiously.

F. H., Kent.—Queen - excluding Zinc for Dividers between Sections.—There seems every reason to suppose that this, or zinc, or tin, having even larger holes, would be less obstruction to the work of the bees than close sheets of wood or tin, while preventing hulging of the combs. Try it by all means.

W. T. C.—No. Glass is quite unsuitable for putting on the top of frames at any time. You can exhibit honey at a show of the B. B. K. A. without being a member.

HONEY-DROP.—Stimulating.—It is best to commence by uncapping cells around the brood-nest, and when brood is in progress give thin syrup. Whether your stocks have sufficient stores depends upon the amount contained in the ten frames upon which they were wintered. If well filled there should be plenty.

R. G.—We hope to be able to give insertion to the engravings of your plan of reversing frames in our next issue.

J. A. B.—Poisonous British Honey.—We have had no experience of poisonous honey, and are doubtful if there is any dangerously poisonous nectar secreted in this country.

Hawes Bee-keeper.—A sample of your honey having been submitted for analysis to Mr. Hehner, he states that it is unadulterated.

Putting Swarms Together.—I may say I join swarms in the usual way. If they come off on the same day they join without any precautions. If some time has elapsed I smoke well the hive I am going to unite to and throw the other swarm on to board in front of hive, and sprinkle with thin syrup. If I see any signs of fighting I at once open out the hive and mix the bees with the last swarm, sprinkling all with syrup. Young bees do not often require you to use scented syrup. The mere fact of opening out the hive stops the fighting to a great extent by frightening the bees.—Arthur J. H. Wood.

A RECTIFICATION.—In my letter to the British Bee Journal

of January 20th, I said, in reference to a 2-lb. section sold by Mr. Blow of $8\frac{1}{2} \times 4\frac{1}{2}$ dimensions, 'I should like them better if they were 2 inches wide.' I find they are 2 inches and the mistake arose from my using very thin tin dividers with them and wooden dividers with the 1-lb. sections running parallel with them, so that the 2-lb. did not come nearly so far to the end of the crate as the 1-lb. At the same time I ought not to have made the mistake, as it is depreciating what I look upon as a most beautiful section, as in my opinion it is very necessary to keep down the height of sections if we wish them finished quickly and well. I only used these sections on three bives and they were well finished off in every case.—Arthur J. H. Wood, Ripon.

Show Announcements.

Giving Name and Address of Secretary, Date and Place of Show, Date of Closing Entries. Terms: Three Insertions and under, Two Shillings and Sixpence; additional insertions, Sixpence each. No charge made to those Associations whose Shows are announced in our general Advertising Columns.

July 11–15.—Royal Agricultural Show at Newcastle-on-Tyne. Entries close May 12. J. Huckle, Kings Langley.

August 3-5.—Yorkshire Agricultural Society at York, Secretary, H. L. Rickards, Poole, near Leeds.

THE MEXICAN BEE.

There is not so much known about the different bees in the American Continent as might be expected. In these days when there is a great tendency to obtain everything new and novel, and when there is such a great desire to introduce new races, it cannot be unprofitable to glean what information we can of the numerous varieties. By the Mexican bee many have thought that there is only one variety, 'the Stingless Bee;' but besides this we are assured there are many other kinds domesticated in that country. We doubt but that many of the species which are said to be without stings do in fact possess that organ, though often a feeble one, and are not readily provoked to use it. Great attention is paid to the Mexican bees by the natives, not so much on account of their honey, although remarkably rich and delicate, as for the sake of the wax. In Yucatan there are colonies of them domesticated consisting of five or six hundred hives.

Hernandez describes several kinds of the insect in Mexico,—one resembling the European, and which produces a honey like our own. It is domesticated by the Indians, who lodge the swarms, he says, in the hollows of trees. A second species is noticed by the same author as smaller than ours, so much smaller as to resemble 'winged ants,' and as without stings. They build their nests, which are composed of several layers, in the rocks, and also suspend them on trees. Their honey is dark-coloured and high-flavoured. The cells are of smaller dimensions than those of the domestic bee; and it is probable, though not so stated, contain only brood; the honey being found in small cups. The larvæ, it appears, are esteemed a delicacy, for the historian tells us that when roasted and seasoned with salt they have the taste and flavour of sweet almonds. This species collect their honey and live much in the same way with the honeybees of Europe. Other small stingless bees are mentioned, which establish themselves underground in nests of a globular shape, but of very coarse workmanship; their honey, too, is inferior, and is never used but in default of better. In domesticating their bees the Mexicans lodge them in hives formed of short logs of wood, from 2 to 3 feet long, hollowed out about 5 inches in diameter, having the ends filled with clay and a hole for entrance bored on one side, about half-way between the ends. They are suspended in a horizontal position from the branches of trees.

The interior of a hive presents, like that of a humble bee, a confused and irregular appearance. The combs, which have but one series of cells, are placed, some in a vertical position and others horizontal. They are grouped together in an oval mass, and occupy nearly half of the internal space, while the other half is stored with the honey cups. The honey as has been stated, is deposited in small globular bags, hung round the sides of the hives, or placed at the bottom; some of these receptacles are more than 1 inches in diameter; and in many instances are so connected together that, as in the case of cells of common honey-comb, one side serves for two cups, thus combining economy and strength. And these magazines of honey being altogether apart from the brood combs, and noways connected with them, great facility is afforded in depriving the bees of their The honey is thin in consistency, but of a very agreeable flavour, and gives out a rich aromatic perfume. The wax is coarse, and of a brownish yellow; propolis does not appear to be used. The Mexican bee is smaller by one-fifth than the European. Many of the species to which has been given the denomination of Melipona or Trigona are described as having no stings, or at least so feeble a weapon as to produce no sensible injury; and from this circumstance they are known in the Spanish colonies by the name of Angelitos, or little angels. The population of a hive is generally under a thousand.

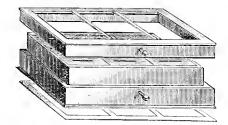

A glance at the habits of some of the many varieties cannot fail to be of great interest, although the introduction into our apiaries of the so-called 'stingless bee' might be the reverse of an improvement. We have noticed that the honey in Mexico obtained from these bees was thin in consistency, and this in a country where the bee flora is almost perfect; what could we expect on these shores? perhaps the honey would not keep and soon turn sour. The fact of the Mexican bee storing its honey in large cells, or cups, and always away from the brood; what a revolution in apiculture its introduction would cause!

NEIGHBOUR'S INVERTIBLE PRIZE SECTION RACK.

This improved rack was shown by Messrs, G. Neighbour & Sons at the great show at South Kensington last autumn, where it was awarded a silver medal.

The illustration shows so clearly the arrangement that only a few words will be needed in explanation. The outer easing of the rack is really in two halves, and each can be used separately if required. It will be seen that the rack consists of a tray composed of a frame with two bars across the bottom and four sides, which are half the height of the sections. The frame is just half a bee-space in thickness, so that to have the full bee-space an additional frame, also half bee-space thick, has to be placed between the tray and the tops of the hive-frames to secure the requisite bee-space. Three rows of seven sections are put in this tray, and they are wedged up by means of a screw working against a board at the ends of them. The top tray is the exact

counterpart of the lower one, and slips over the sections. These two form an outer casing, and by serewing up the sections the whole case can be inverted; or by merely

removing the upper half any of the sections can be

removed separately.

These eases are used in pairs for storifying, are made with either wood or metal cross bars, and by the above arrangement are perfectly interchangeable and invertible. Great care must be exercised in inverting just at the right time. The centre sections are always more advanced than those at the sides, and the inversion should only take place when the outer ones are in a sufficiently forward state.

BEE-KEEPING IN IRELAND—HONEY PRODUCE IN 1885.

In reference to the above the Registrar-General states: An effort was made to ascertain the extent to which bee-keeping is followed in Ireland, and the degree of success attained in this special branch of rural economy. The inquiry related to the season of I885. As this was the first occasion on which any inquiry in relation to this subject was made, it can be readily understood that the returns were in many instances defective; and that therefore the results obtained do not set forth the actual fact with that accuracy and completeness which may be hoped for in future, now that it is known that returns regarding this question will be collected each year with the agricultural statistics, and that the enumerators have, according to instructions, pointed out to all those bee-keepers who had not hitherto kept any records on the subject, the desirability of noting the particulars as to which information is required. From the tabulated returns it will be seen that there were 21,327 swarms at work in Ireland during the season of 1885, of which 6927 were located in the province of Leinster; 6554, in Munster; 6440, in Ulster; and 1406, in Connaught. Of the 21,327 swarms, 5283 were at work 'in hives having moveable frames,' and 16,044 'in other hives.' The quantity of honey produced, according to the returns, was 302,297 lbs. Of this 89,226 lbs, were produced in the province of Leinster; 103,528 lbs. in Munster; 83,348 lbs. in Ulster; and 26,195 lbs. in Connaught. Of the 302,297 lbs., 105,414 lbs. were produced 'in hives having moveable frames,' and 196,883lbs.'in other hives.' It was stated that 187,481 lbs. was 'run honey,' and 114,816 lbs. 'section honey.' The average number of pounds of honey to each hive having a moveable frame was—For the whole of Ireland 20 lbs.; in Leinster, 19 lbs.; in Munster, 20 lbs.; in Ulster, 20 lbs.; and in Connaught, 24 lbs. The average number of pounds to each of the other hives was-For Ireland, 12 lbs.; in Leinster, 11 lbs.; in Munster, 15 lbs.; in Ulster, 11 lbs.; and in Connaught, 16 lbs. The average quantity produced in all hives was: In the whole of Ireland, 14 lbs.; in Leinster it was 13 lbs.; in Munster, 16 lbs.; in Ulster, 13 lbs.; and in Connaught, 19 lbs. The number of stocks brought through the winter of 1885-6 amounted to 15,362, of which 4493 were in hives having moveable frames, and 10,869 in other hives. According to the returns collected there were 7165 lbs. of wax manufactured in 1885, of which 1573 lbs. were from hives having moveable frames, and 5592 lbs. from other hives.

JOTTINGS BY AMATEUR EXPERT.

'Mel sapit Omnia.'

We have got over the annual meeting and the election of the Committee of the B.B.K.A. Mr. D. Stewart's place is filled by the Rev. G. V. Oddie, a very good beekeeper, but a gentleman probably not known by a dozen members of the B.B.K.A. ontside his own county. This gives Herts four seats on the Committee of the B.B.K.A., and three of the four gentlemen live almost within sight of one another. Very handy this if they all happen to be on the same sub-committee.

The Rev. G. Raynor carried his 'reform bill,' lowering the qualification from 11. to 10s., although some of us 'Radicals' wanted 'universal suffrage; but if defeated

we still hope.

I was struck with the fact that each of the candidates got fewer votes this year than formerly, although the roll' of the B.B.K.A. is larger than it ever was. The reason, I learn, is, that members generally used greater discrimination than heretofore, and instead of giving all their votes, only voted in many cases for those they actually knew. This is a healthy sign. Many votes were also lost through the members failing to brass-

up' in time.

The meeting was not only a very full one, but was marked by the keen interest taken by all present in the proceedings. While this is so, we never need fear as to the future of the B.B.K.A. I was sorry Mr. Cowan was not present, but he is very hard at work to get his work well in hand before April, when he hopes to see the scenery between the 'Atlantic and the Pacific.' Imagine him toiling, as he often does, for the good of others, from 6 a.m. to 10.30 or 11 p.m., and all for the love of it, and yet we sing, 'Britons never shall be slaves!' It reminds me of an old girl who said, 'She not only liked work, but she actually loved it.

Our President was as gracious as she always is. Her Ladyship is a true 'Queen Bee' in her benevolence as well as her devotion. To her influence with H.R.H. we mainly owe our great show at the 'Colonial;' from her purse came a good slice of the prize money; nay, more, to her Ladyship we are mainly indebted for the privilege of getting the medals cast from the die of the Indian and Colonial Exhibition medals; and, to crown all, when there was no wherewithal to pay for the medals, from our President's purse at once the money

was forthcoming.

After this, some of the exhibitors who had almost despaired of ever getting their medals will understand why they have been so long in coming. Doubtless most or all will get them by the time this sees the light; and, for myself, I confess when I do get mine I shall value it more for the sake of the Baroness than for its other associations. While jotting about medals, may I say I think the new pattern B. B. K. A.'s medals are very pretty; the device of the 'queen-bee' has given place to a view of a modern apiary. Had I been in position to have given a suggestion at the time the thing was being considered, I should have gone in for a bust of her ladyship the President. What do the readers of the B.B.J. say to that?

I have run out my allotted space before I turn to 'jot' about passing matters. May I tell 'F. H., Kent,' if he uses queen-excluder zinc for dividers he will not get his sections finished smooth, but they will be undulated, like the waves of the sea on a small scale. What a rebuke from the bees themselves to those who advocate narrow sections for storing as being more 'natural!'

How homely friend McKnight makes us feel one can almost see him sitting by his 'ingleside' over yonder, burning his 'midnight oil' for us. The two 'Dumplings' are jovial fellows. Mr. Grimshaw, too, I imagine, is in the height of his element; from quoting poetry he turns poet (?) himself. Well, I hope he will get plenty of

work to do. There is nothing beats good 'chatty' meetings of district associations and lecturing in small villages for getting new members: and as to my incog. the must be joking, as I thought long ago he had seen through it, considering at Jermyn Street he has more than once been within nose-rubbing distance of—AMATEUR EXPERT.

BRITISH BEE-KEEPERS' ASSOCIATION.

The Annual General Meeting of the above Association was held on Wednesday, February 16th, 1887, at 3.30 p.m., at the offices of the Royal Society for the Prevention of Cruelty to Animals, 105 Jermyn Street, St. James's. The spacious Board Room was crowded by an audience of ladies and gentlemen, amongst whom were the Baroness Burdett-Coutts (President of the Association), the Hon. and Rev. Henry Bligh, the Rev. Association), the Holl and Rev. Helify Bligh, the Rev. Dr. Bartrum, the Rev. F. G. Jenyns, the Rev. J. L. Seager, the Rev. F. S. Sclater, the Rev. W. E. Burkitt, Mr. Hooker, Captain Bush, Mr. Zehetmayer, Mr. Otto Hehner, Mr. Sambels, Mr. Haviland, Mr. Blow, Mr. Lyon, Mr. Baldwin, Mr. Meggy, Mr. Horton Ellis, Dr. Wolken, Mr. Easter, Mr. Afgerse, Mr. Hordone, Mr. Wolken, Mr. Easter, Mr. Afgerse, Mr. Hordone, Mr. Walker, Mr. Eastty, Mr. Athawes, Mr. Henderson, Mr. Bunbury, Mr. Neighbour, Mr. Graham, and Mr. Willard.

Owing to the absence of the President at the commencement of the proceedings, her Ladyship having a prior engagement, the Hon. and Rev. Henry Bligh took

the chair temporarily.

The Secretary read the minutes of the last Annual

General Meeting, which were confirmed.

Mr. Horton Ellis moved a vote of thanks to the retiring officers and committee for their services during the past year. As one of the county representatives, he wished to say that bee-keepers all over the kingdom must feel indebted to those gentlemen whose zeal in their duties had done so much to benefit the cause.

The Rev. W. E. Burkitt seconded the motion, which

was carried unanimously.

At this juncture the Baroness Burdett-Coutts arrived, and presided till the conclusion of the proceedings.

Her ladyship moved that the report and balance-sheet issued for the year 1886 be received and adopted, with a vote of thanks to Mr. Kirchner, the auditor, which resolution was passed unanimously. The following is the report:-

The Committee have much pleasure in presenting to the members their report for the year 1886. In no previous year has the work of the Association been more successful; this success being mainly due to the support and patronage which has been given to the Association by their Royal Highnesses the Prince and Princess of Wales, and other members of the Royal Family, and to the loyal and pecuniary support given by the County Affiliated Branches.

Considerable progress has been made both in North and South Wales, associations having been formed in the counties of Glamorgan, Cardigan, and Montgomery. The Committee are much indebted to Dr. G. Walker and Mr. W. B. Webster for their lecturing tours in North and South Wales.

As indicated in the last report, the Committee have taken steps to provide a work on bee-keeping in the Welsh language. The 'Skep' pamphlet translated into Welsh was issued early in the year, and efforts are now being made (the Committee heing aided by some residents in Wales) to translate and circulate 'Modern Bee-Keeping' in Welsh also.

The Royal Agricultural Show of 1887 will be held at Newcastle-on-

in Welsh also.

The Royal Agricultural Show of 1887 will be held at Newcastle-on-Tyne. The Committee consider this an opportune time for the Association to endeavour to advance and consolidate their work in the North of England. With this view they have resolved to arrange for a lecturing or expert's tour during the ensuing spring months.

Considerable assistance is also needed towards the development of the work in many of the larger counties, such as Yorkshire, and others. The funds at the disposal of the Committee being very limited, they are reluctantly compelled to withhold assistance in some cases where it is urgently needed. It is therefore hoped that the aims and objects of the Association will be made more widely known by the members and others interested in the progress of our home industries. home industries.

home industries.

During the past year the work of the Committee has been more than usually arduons. In addition to the ordinary standing subcommittees, it was found necessary to appoint other special subcommittees for certain particular work.

Seventeen general committee meetings have been held during the year, in addition to a large number of sub-committee meetings.

The sixth edition of 'Modern Bee-Kceping,' consisting of 10,000

copies, has been issued during the year. A special sub-committee was appointed for the revision of the work, and a fair proportion of this edition has already been disposed of.

Four quarterly meetings have been held during the year for the discussion of various subjects connected with bec-keeping. As intimated in the last report, the usual papers have been dispensed with at these meetings, and in place thereof discussions have been introduced upon various subjects. Several new inventions have been submitted to these meetings for criticism.

A special social meeting to welcome the representatives of Canadian bec-keepers attending the Indian and Colonial Exhibition, consisting of Mr. Pettit, President of the Ontario Bec-Keepers' Association, and Messers, S. Corneil, D. A. Jones, and R. McKnight, was held at South Kensington on October 6th. Upwards of 100 sat down to lancheon. Dr. May, Educational Commissioner for Ontario, and Pasteur Descoulayes, Secretary of the Société Romande d'Apiculture, were also present. Subsequently a conference was held in the Conference Room attached to the Indian and Colonial Exhibition, at which nearly 250 members and friends attended.

Examinations for third-class certificates have been held in the counties of Buckinghamshire, Glamorganshire, Hampshire, Hertfordshire, Lancashire, Leicestershire, Middlesex, Somersetshire, Staffordshire, Lancashire, Leicestershire, Middlesex,

Three candidates have taken second-class certificates during the

The Committee are much indebted to the following gentlemen for

Three candidates have taken second-class certificates during the year.

The Committee are much indebted to the following gentlemen for acting as examiners or judges at county shows, viz., Rev. C. G. Anderson, Rev. Dr. Bartrun, E. H. Bellahrs, W. Bronghton Carr, R. R. Godfrey, W. N. Griffin, J. M. Hooker, the Rev. F. G. Jenyns, the Rev. F. S. Sclater, the Rev. J. Lingen Seager, and Dr. G. Walker.

The Committee much regret that they have not been able to provide for the exhibition of the historical collection of appliances, ancient and modern, presented to the Association by Mr. T. W. Cowan in 1885. The provision of a permanent museum for this and other objects of the Association only awaits the necessary funds.

Three exhibitions have been held during the year.

1. At Liverpool, in connexion with the show of the Royal Horticultural Society. In consequence of the early date at which this show was beld, it was found impracticable to arrange for a thoroughly representative display of honey, &c. The department allotted to bees and bee-keeping appliances, although small, proved one of the most attractive in the exhibition. The Committee were supported most efficiently by the executive of the Lancashire and Cheshire Association, 101. being contributed by this affiliated branch towards the expenses. The Rev. Dr. Bartrum, Mr. W. Broughton Carr, and Dr. Walker, officiated as judges, to whom thanks are due for their grantitions services.

2. At Norwich, in connexion with the Royal Agricultural Society's Annual Exhibition. This exhibition of honey and appliances was by far the best ever held in connexion with the Royal Agricultural Society. The entries were large and the exhibits numerons, and of good quality, occupying a space of 200 feet in length by 20 feet in width. The Bee Department was honoured by a special visit from their Royal Highnesses the Prince and Princess of Wales, the Royal Princesses, the Ladies in-Waiting, with other distinguished visitors from Sandringham. The Royal party made a thorough inspection of

3. At South Kensington, the Committee were enabled to arrange for what may be considered the grandest and most effective display of honey and bee-keeping appliances that has ever taken place in this country. Such an exhibition was rendered possible by the kind permission of H.R.H. the Prince of Wales, Excentive President of the Royal Commission of the Indian and Colonial Exhibition, and by the

Royal Commission of the Indian and Colonnal Exhibition, and by the support given by the President of the Association, and those who subscribed liberally to the Donation and Guarantee Funds.

The Committee were most loyally supported, both pecuniarily and otherwise, by a large number of the county associations. Reference to the balance-sheet will show that several of the county branches contributed largely to the fund raised for carrying out the exhibition, apart from the ordinary statement of income and expenditure. A separate balance-sheet relating to this show, together with a list of contributors to the donation and guarantee funds, is published at the class of this report.

separate balance-sheet relating to this show, together with a list of contributors to the donation and guarantee funds, is published at the close of this report.

The thanks of the Association are due to Sir Philip Cunliffe Owen, Secretary to the Royal Commission, who was most assiduous in his labours to promote the success of the exhibition, and also to the President and Council of the Royal Horticultural Society, who gave material assistance, Mossrs, T. W. Cowan, C. E. Fletcher, R. R. Godfrey, and W. Martin, also merit the thanks of the Association for performing the most difficult task of judging so large a quantity of exhibits. The Committee have much pleasure in announcing that His Royal Highness the President of the Royal Commission has been pleased to permit the exhibitors at this exhibition to receive medals struck from the dies as used by the Royal Commission.

The Committee feel sure that this act on the part of His Royal Highness, and the munificence of the generous donor who provided for the cost of these medals, will be highly appreciated, both by the exhibitors and the members of the Association generally.

The thanks of the Association are due to Mr. T. W. Cowan and Rev. F. G. Jenyns for donations of books to the Library.

The Committee consider that the Association has much reason to congratulate itself on the work of the past year. A great stimulus has been given to the industry of bee-keeping throughout the United Kingdom, and the demand for honey has considerably increased,

Great progress has been made by Honey Companies and other agencies in bringing the value of pure British honey under the notice of the residents of London and other large tevns.

The Finance Committee have again to report their satisfaction with the manner in which the accounts have been kept by Mr. Huckle. The receipts and expenditure have been exceptionally large in connexion with the several exhibitions held during the year, so that the work devolving on the Secretary has been very heavy. The assets of the Association having been carefully valued, they are glad to report that the accounts for the year show a balance on the right side.

The Lay G. Baynov said that the processive duty had

The Rev. G. Raynor said that the pleasing duty had fallen to his lot for several years past of proposing a vote of thanks to the Council of the Royal Society for the Prevention of Cruelty to Animals for the gratuitous use of their Board Room for committee and other meetings, and he had much gratification in asking the meeting to vote a similar resolution on that occasion. He need not enlarge on the benefit derived by the Association from the kindness of the R. S. P. C. A., and he thought the members present could hardly express their thanks in sufficiently warm language. From his own personal knowledge he felt sure that the goodness of the Royal Society was highly appreciated, because they of the B. B. K. A. would certainly be in a difficulty if deprived of the advantage of meeting in that beautiful room.

The Rev. F. T. Scott had much pleasure in seconding Mr. Rayner's proposition. The Society conferred an immense advantage on the B. B. K. A. by placing their Board Room at its disposal. It was a most comfortable room, and well snited to the requirements of the Association, which was thus saved considerable expense. Some charitable institutions proposed to commemorate the lubilee year by providing themselves with new offices, but he did not think the Association would be able to do that, nor was there any necessity while they had

such excellent accommodation.

The resolution was carried unanimously.

The President returned thanks on behalf of the Royal Society for the Prevention of Cruelty to Animals in her capacity as President of the Ladies Committee of that body. It was a source of great pleasure to the Society to know that their Board Room was occupied from time to time by an Association whose objects tended to the furtherance of those principles in which the Society was

deeply interested.

The Rev. Dr. Bartrum moved the re-election of the President, Vice-Presidents, Treasurer, Auditors, Analyst, Librarian, and Secretary for the year 1887. He considered it a great privilege to be allowed to propose, as he had done in previous years, the re-election of the noble lady in the chair that day, who stood at the head of their Association, and who was, in fact, their queenbee. She was an excellent example of the advantage to the community at large of ladies taking their proper place in the social scale. It was a great gain to the cause of bee-keeping that their Society was led by one who showed so much active sympathy with the work, and who was always ready to assist with her counsel and benevelence-indeed, the Association could scarcely go on were it not for the valuable aid given by the Baroness. The Vice-Presidents proposed to be elected were the heads of the various County Associations, among which were the Princess Christian, some Dukes and Earls, and, generally speaking, persons occupying leading posi-tions in society. He moved that Mr. W. O'B. Glennie tions in society. He moved be re-appointed Treasurer. That geutleman held an official position in the Bank of England, and had been a staunch friend of the cause and a member of the Committee many years. With regard to Mr. Otto Hehner, Mr. Henderson, and Mr. Huckle, they were well known to the members of the Association, and their claims on account of past valuable services were indisputable.

The Rev. F. G. Jenyns seconded the motion, which

was carried unanimously.

The President, in acknowledging the honour conferred upon her, said it was difficult to express how much she appreciated it. Every opportunity that she could find to promote so useful and important an industry as beekeeping would be utilised for that purpose. A great many public objects which had arisen, developed, or been created during the reign of Her Majesty the Queen, would during the present year, no doubt, be brought prominently under notice. It might be that so small an industry as the one in which they were engaged would not obtain a very large share of public attention; but she thought that if statistics were published of the agri-cultural and food developments during the last fifty years, the production of honey could not be left out of consideration, and their Society must take credit for having popularised an industry which had added greatly to the welfare and amusement of all classes. She was afraid that any advice of hers in regard to management would not be very valuable, but they would remember that the bees managed their own affairs extremely well, and in that respect did not give much trouble to their queens. (Laughter.) It was a great pleasure to be for another year associated with those officers of the Society who had always co-operated with her in the kindest way when she required any information. (Applause.)
The Secretary read the results of the election of Com-

mittee for the year 1887, the following members being successful:—T. W. Cowan, Hon. and Rev. II. Bligh, Revs. G. Raynor, F. S. Sclater, F. T. Scott, J. L. Seager, E. Bartrun, F. G. Jenyns, G. V. Oddie, Captains Bush, C. D. Campbell, Messrs. W. H. Dunman, J. M. Hooker, H. Long, C. W. Weller.

H. Jonas, G. Walker.

Captain Bush moved a hearty vote of thanks to the scrutineer of the voting-papers (Mr. Dunstan), for the satisfactory manner in which he had performed his troublesome and uninteresting task.

The Rev. F. S. Schater seconded the vote, which was

unanimously carried.

The Hon, and Rev. Henry Bligh said a sad task had now fallen to his lot, and that was to move a resolution with respect to their late friend, Mr. Fox Kenworthy, who within a few weeks had passed away, and left vacant an onerous post in the bee world. Perhaps there was no one better qualified to speak of that gentleman, and the good name he had left behind, than himself (Mr. Bligh), because he had acted with their lamented friend as co-secretary of the Middlesex Bee-keepers' Association for the last two or three years. He (the speaker) never met with any one more thoroughly devoted to his work, or one who was more ready to give his time and labour, at considerable self-sacrifice, to their cause. At the time he was taken from them his good work was beginning to develope itself and show the results of continuous efforts. Mr. Kenworthy was known to them not only as Secretary of the Middlesex Bee-keepers' Association, but he had also acted for a considerable time as Secretary of the parent body at a time of great difficulty. The resolution was:-

That the members of the B.B.K.A., assembled at the annual general meeting, have heard with the deepest regret of the early death of Mr. Fox Kenworthy, formerly Honorary Secretary of the Association, and wish to record their appreciation of the good work which, under difficult circumstances, he then did for it; and also wish to express their deep sympathy with Mrs. Kenworthy on the death of a son who was highly esteemed and respected by all.

Mr. Hooker seconded the motion, and said he heartily endorsed Mr. Bligh's eulogy of the late gentleman, whom he knew both in his private and public capacity.

The President thought there was no need to go through the formality of putting the resolution to the meeting, because the expression of regret and sympathy contained therein must commend it to every one.

The Rev. G. Rayner moved:

'(1) That in Rule 4 the words, "Subscribers of 11. per annum and life members alone shall be eligible for election as members of the Committee," be omitted, and in lieu thereof be added the words, "Subscribers of 10s, per annum, donors of prizes of 11, in the preceding year, and life members alone, be eligible for election as members of the

Committee," (2) That in Rule 5, the words "but not" be omitted, and in lien thereof be added the words "and also."

He entered into a retrospective view of the subject, and recounted the proceedings which took place at the previous annual general meeting in reference to the motion of Mr. Stewart, which was lost on being put to the vote. He opposed Mr. Stewart's proposition on that oceasion because it was introduced at the fag end of the meeting, when very few members remained to discuss the question. There was now a good opportunity of considering the matter, and he would like to know the sense of the meeting thereon. Mr. Cowan was fully in accord with the motion, but earnestly hoped the qualification would not be reduced below 10s.

The Rev. F. G. Jenyns seconded the resolution.

Captain Bush opposed the reduction of the qualifi-cation. He said that nearly all the members of the Committee lived some distance in the country, perhaps twenty to fifty miles; and surely, if they could afford to pay the expense of travelling to and from London to attend meetings, they could afford to pay 11. annually to the Association. The resolution was a mistake, because members desirous of being put on the Committee would be willing to raise their subscriptions to the required amount; and if they could not do so, probably they were not in a position to spare the requisite time to attend meetings. Besides, the Association would most likely suffer a pecuniary loss if the resolution were carried, and he did not think it would be better served.

Mr. J. Eastty supported the resolution, saying that there were bee-keepers in London who would probably be willing to serve on the Committee, but who could not afford to pay 11. annually. Bees were successfully kept in South Kensington, and he himself had raised 18 lbs.

of honey in Bermondsey.

Mr. Bunbury said the reasons which held good in reducing the qualification to 10s, were equally in favour of a reduction to 5s., and he moved as an amendment that a 5s. annual payment entitle the subscriber to serve on the Committee.

Mr. Meggy seconded the amendment, and said that he believed the success of the Association depended on the

width of its basis.

Mr. Sambels spoke in favour of the amendment, and pointed out that, under the present rules the Committee, by uniting amongst themselves, could return any member they chose, owing to the plurality of their votes.

Mr. Baldwin hoped that in no ease was the amount of subscription paid to the Association governed by a desire

for plurality of votes.

The Rev. F. G. Jenyns explained that the united strength of the Committee's polling power only amounted to sixty votes.

Mr. Athawes supported the amendment, and objected

to plurality of voting.

The Rev. G. Raynor disputed the eogency of Captain Bush's arguments. He thought, as a tentative measure, 10s. was low enough, because every person who had the well-being of the Association at heart would be prepared to pay that small amount, especially as it constituted the qualification necessary to serve on the Committee. was of opinion that it would be better to pass the resolution, and see how it worked for a year or two.

Mr. Horton Ellis having seconded the amendment, in the place of Mr. Meggy, who was ruled out of order, it was put to the vote, and negatived by 14 to 7. The original motion was then earried by a majority of 10;

15 for, and 5 against.

The Hon. and Rev. Henry Bligh moved:-

'That in Rule 8 the words "from the unsuccessful Candidates, according to the priority of votes obtained at the Election," be omitted, and in lien thereof be added the words, "by the Acting Committee."

The Rev. F. S. Sclater seconded the motion.

The Rev. G. Raynor suggested that the substituted

words should be, 'from those members who are eligible and willing to serve.'

A long discussion ensued in which the President, Mr. Sambels, Mr. Lyon, the Ilon. and Rev. Henry Bligh, the Rev. J. L. Seager, and Mr. Blow took part, the mover undertaking to withdraw his motion. This course being objected to, a division was taken, when a majority of 12 were in favour of the withdrawal-18 for, and 6

The Rev. Dr. Bartrum moved:

'That the following words be added to Rule 8: "Every member willing to serve on the Committee, and who has not served during the previous year, must be nominated by one or two members of the Association. The name or names of the person or persons so nominating, together with the name of the nominee, shall be stated on the voting paper. Every member desirous of nominating a member of the Committee shall have a paper sent him for that purpose, on applying to the Secretary for the same, the written consent of the nominee to be forwarded to the Secretary with the nomination paper."

He thought the present system of electing members of the Committee was unsatisfactory, and different to that carried out by other institutions. In the case of the British Dairy Farmers' Association, with which he was acquainted, the practice he had endeavoured to embody in the resolution was in force, and had acted very well. It seemed to him that old and tried friends of the causo like Mr. Cowan and Mr. Raynor ought not to be put to the trouble every year of finding a nominator. Those who had done good work in the past should be freed from such obligation. However, that was a question for the meeting to decide.

Mr. Baldwin suggested that the nomination form to

bound up with the rules.

Mr. Sambels seconded the resolution.

Mr. Haviland thought the old members of the Committee would find no trouble in obtaining nominations.

Mr. Athawes moved as an amendment that the words 'who has not served during the previous year' and 'one or,' be omitted.

Mr. Hooker seconded, and Mr. Blow supported the

amendment.

The Rev. Dr. Bartrum consented to the omission of the

words 'one or.

The Rev. G. Raynor and the Rev. F. G. Jenyns agreed with Dr. Bartrum in thinking that old members of the Committee ought to be exempted from the rule compelling annual nominations.

The amendment having been put to the meeting, was carried by a majority of 3-14 in favour and 11 against. It was then submitted as a substantive motion in the

following form, and carried unanimously :-

'That the following words be added to Rule 8: "Every member willing to serve on the Committee must be nominated by two members of the Association. The names of the persons so nominating, together with the name of the nominee, shall be stated on the voting paper. Every member desirons of nominating a member of the Committee, shall have a paper sent him for that purpose, on applying to the Secretary for the same, the written consent of the nominee to be forwarded to the Secretary with the nomination paper."

The Rev. W. E. Burkitt moved:-

'That in framing Schedules, special care should be used to make all Rules definite, and that they should be strictly enforced; also that it should be the duty of the Committee to make sure that the Judges shall make themselves acquainted with the Schedule before commencing their duties.

Mr. Walker seconded the motion.

The Rev. F. T. Scott objected to that part of the resolution which saddled the committee with the duty of making sure that the judges studied the Schedule before commencing their duties.

The Rev. G. Raynor thought that meeting was

scarcely the proper tribunal before which to bring any improper action of the judges, to whom a certain amount

of discretion must be allowed.

The Rev. Dr. Bartrum thought the motion implied a censure on those gentlemen who, at enormous trouble and personal inconvenience, had undertaken an onerous task. He hoped Mr. Burkitt would be satisfied with the protest he had made without pressing the motion to a division.

The Rev. J. L. Seager moved:-

'That the Committee be requested to draw up a form of Rules for exhibition, with a view to establishing uniformity at all shows throughout the Counties; a recommendation being added that the shows should be advertised as being held under the B.B.K.A. Rules.

He thought, possibly, that this would prove generally acceptable, as well as meet Mr. Burkitt's wishes.

The Rev. F. S. Sclater seconded, and Mr. Sambels supported the motion.

The Rev. W. E. Burkitt agreed to withdraw his

resolution, and support Mr. Seager's.

After a few words from the President, Mr. Seager's motion was carried unanimously.

The Hon. and Rev. Henry Bligh moved a hearty vote of thanks to the Baroness Burdett-Coutts, for her kindness in being present, and for the admirable way in which she had presided over the meeting that day. He also wished to draw their attention specially to the Baroness's goodness i relation to the medal. It had been debated by the Committee what form the medals commemorative of the South Kensington Exhibition should take, and ultimately application was made for leave to give the Colonial Exhibition Medal to all those who had exhibited at the Honey Show. This, however, it was found would involve a very large cost-quite beyond the means at the disposal of the Committee. At this juncture the President kindly came forward, and generously offered to defray the whole expense. He was quite sure they would all thoroughly appreciate such

kindness, and tender her their most heartfelt thanks. The resolution having been carried by acclamation, the President briefly expressed her acknowledgments for the cordial vote of thanks passed to her. It had afforded her the greatest pleasure to assist the Committee in regard to the medals. She thought the proceedings at the South Kensington show marked a distinct step in advance of the former position of the B.B.K.A. The holding of the British Honey Exhibition last year in the Conservatory at Kensington was due to a very kindly act on the part of the Prince of Wales, which was not accorded to any other industry. She knew that the show was admired very much, and she thought that the Prince had given a substantial proof of his appreciation of the movement by permitting the die which was used for the Colonial Exhibition to be placed at the disposal of the Committee. It was to be hoped that the medals would give pleasure to all the fortunate recipients of them. Since they last met, she had been asked to become President of the Middlesex Bee-Keepers' Association, and had complied with such request. Her ladyship concluded by expressing the pleasure with which she found herself amongst those who were devoted to the interests of the Association.

Great Tit Killed by Bees.—The great tit (Parus major) is a well-known enemy to the bee-keeper. First he comes to pick up the dead bees thrown out during the winter, and when these are exhausted he pecks at the mouths of the hives, and when a bee comes to the door to see what is the matter he snaps it, and flies on to the top of the hive or some convenient post, perhaps, and there dresses his prey preparatory to eating it, generally commencing by biting off the tail end of the bee, with the sting attached; this he never eats, but leaves it on the top of the hive or post. I was once very much annoyed by a pair of these tits daily molesting a hive, and not only killing a number of bees, but keeping

them in constant commotion at a time of year when they should have been at rest; so I set a small trap, used for catching mice, at the entrance of the hive, and in a very short time I saw one of the tits fly on to it and get caught by the leg, when immediately a number of bees rushed out and stung him round the beak and eyes, and in exactly four minutes he was dead. I ought to say that I should have put him out of pain at ouce only the bees were roused by finding they had got their enemy in their power, and had I interfered to do so I should have got well stung, so I ran to the bee-shed for my veil, but when I returned the tit was just dying. I do not think I have molested one of these birds since, the whole family are so useful and interesting; I always encourage them in the garden. During the present hard weather the great tit daily pays visits to the bee-hives. F. Boyes (Beverley).—Field.

Correspondence.

The Editor does not hold himself responsible for the opinions expressed by his correspondents. No attention will be taken of anonymous communications, and correspondents are requested to write on one side of the paper only, and give their real names and addresses, not necessarily for publication, but as a guarantee of good fatth. Illustrations should be drawn on separate pieces of paper.

Communications relating to the literary department, reports of Associations, Shows, Meelings, Echoes, Queries, Books for Review, Ec., must be addressed only to 'The Entron of the 'British Bee Journal,' c/o Messrs. Strangeways and Sons, Tower Street, Upper St. Martin's Lane, London, W.C.' All business communications relating to Advertisements, &c., must be addressed to Mr. J. Huckle, King's Langley, Herts (see 2nd page of Advertisements).

***In order to facilitate reference, Correspondents, when speaking of any letter or query previously inserted, will oblige by mentioning the number of the letter, as well as the page on which it appears.

OUR HONEY IMPORTS. The value of honey imported into the United Kingdom during the month of December, 1886, amounted to 1639/.

We are now in possession of the full returns for the past year, which are as follows:-

					£
January					424
February					451
March					2,722
April					1,113
May					1,541
June			• •	• •	2,900
July		• •		• •	6,505
August					1,255
September	• •			• •	2,812
October	• •	• •	• •	• •	1,257
November	• •	• •		• •	2,527
December	• •	• •	• •	• •	1,639

Total for the year £25,146

Comparing this total with the figures for which we have authentic data, we find that the total imports were as follows: ---

1883 1884 1835 61,3441. 33,7781. 62,3571. 25,1467.

It should, however, be remembered that the figures for 1883-5 are approximate only, the order from the Board of Trade to tabulate honey only dating from January, 1886. These latter, moreover, do not include the vast quantity of honey sent through Colonial Governments to the Indian and Colonial Exhibition. Honey will be included for the first time in the Annual Returns of Imports and Exports to be shortly published; and although we may expect the total to appear insignificant beside the immense sums paid annually for eggs, butter, &c. &c., the item will unquestionably be of consider able interest to the public at large, besides awakening beekeepers to the fact that we are still unable to entirely supply the home consumption. As some time may, however, chapse before these 'Annual Returns' are officially published, it has seemed to me better not to await them, but to send them to the Bee Journal made up as in former years .-- E. H. Bellairs, Feb. 18.

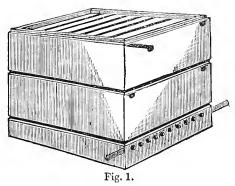

SIMMINS' 'UNION' OR 'UNIVERSAL' HIVE.

[830.] This hive has had three years of careful consideration, and was in the first instance developed because I had found the 'Standard' frame (14 inches by 81 inches) decidedly inferior to larger frames 1 had formerly used, either for the production of honey, or bees for sale. After various experiences, a frame 14 inches by 14 inches has been found the most appropriate, all things considered, as it enables a stock to build up more rapidly in early spring and gives greater security in winter, as the stores are arranged in the best possible position, in relation to the cluster.

As a single frame, the present 'standard' is too small; as a storifying frame it is too large; therefore a smaller extracting super is connected with the large hive, and which can be used both at the back and front of the

14 inch-by-14 inch frame, as well as on top.

The frames of this shallow hive (fig. 1) are 12 in. by 6 in. $\times \frac{7}{8}$; there are eight of them spaced rather more than the $1\frac{1}{2}$ in from centre to centre. By a simple metal key running throughout the length of the hive, the frames are all held securely in place, as the said key passes

through a saw-cut in each end of the top bars. There are plain metal ends on the frames, which are grooved to correspond with saw cuts, so that the key is entirely hidden. The key is entirely hidden from the action of the bees, and as the frames hang clear of each other, the weather has no effect upon the wood as with close-end frames, or broad shoulders when used in a limited space.

A novel feature in connexion with the shallow chamber is that the usual bee-space is at the top instead of at the bottom, as of old. The reasons for this are (1), to give greater strength in the margin above saw-cut in hive side; (2), to receive pliable honey board (Fig. 2 or 3) across and

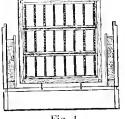

Fig. 2.

Fig. 3.

close on the frames as constantly recommended by us as the only means of totally excluding brace combs. course this implies that the extracting super can also be used independently of the large hive, similar to the Stewarton,' and with but a slight alteration in the position of the saw-cut, Heddon's half bee-space can be provided for those who desire to try inversion. At the same time the hive, as presented, can be used either way up, though I do not claim that any advantage is to be gained by inverting brood combs during the honey season. When used by itself the small hive has a sunk floor-board which acts as a permanent feeder, when inverted.

When either extracting or comb supers are used on end against the large frames (Figs. 4 and 5) the $\frac{3}{2}$ -in. space is placed next the latter. If on top, the same can also be done, though my own practice is to keep such the right

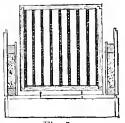

Fig. 4.

Fig. 5.

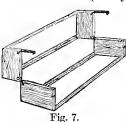

way up with the bars across those of the lower frames, close on to them; this also excludes brace combs when working for extracted honey, and when one has once tried the plan, he will never again submit to a clear beespace immediately above the brood frames. It is there alone that comb attachments are liable to be built, but any space allowed between further super additions are not subject to this annoyance. In following out this plan of working for the past six years I have not had a single piece of comb attached to our sections, as often

is the case on the underside of sections worked with the clear space under.

The comb super (Fig. 6) is also I4 in. by 14 in., con-

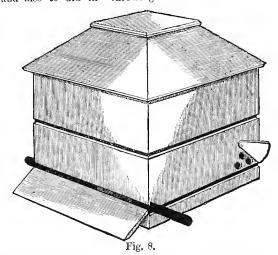

taining three skeleton folding frames (Fig. 7), enabling each set of seven $4\frac{1}{4}$ in, by $4\frac{1}{4}$ in, sections to be inverted

separately at will when full sheets of foundation are not I, however, prefer to fill the section with foundation, which gives a comb more perfect than a starter only, followed by inversion. The sections are securely keyed in position that the crate may be used on end with the large frames

and also to aid in 'throwing' out the bees without

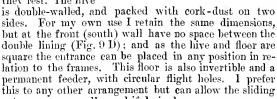

handling each section separately, though if supers be removed during the middle of the day a little smoke

will generally clear out most of the bees then at

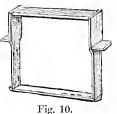

The large hive is (Figs. 8 and 9 A) 19 in. by 19 in. outside, and is arranged to take either the 17 in. or $15\frac{1}{2}$ in. top bars of the Standard frame, as in AB. With-

ont any alteration it also takes our large frames (Fig. 10), which have their 'lugs' placed down the side on the same level as those of a standard frame: thus they stand $5\frac{1}{2}$ in. higher, but to economise heat above the cluster and also to ensure that they hang 'true' it has been necessary to make these frames closeended above the level of the side walls upon which they rest. The hive

entrance as generally used if desired.

The large frames (Fig. 10) are set at $1\frac{3}{5}$ in from centre to centre as we have found this the best for a fixed

distance with a frame of this size, because in winter the cluster can be compact without spreading the combs, and the large surface of comb admits of sufficient stores being placed within easy reach of the same; in summer it presents the same advantage of contraction that I have practised with various frames for the

past ten years. Hence it is shown that few manipulations are necessary, and, when handled, one frame stands as two of the 'Standard' size.

The extracting super, with its frames keyed in position, was designed in the first instance to accommodate a new mode of extracting; the fixed combs, also enabling those hees to be 'thrown' out which smoking fails to drive down. No alteration is made in the distance from centre to centre of the shallow frames, when the same are used on a separate stand as a brood-chamber as well, as this arrangement permits of plenty of stores for winter, and more room for the bees to cluster between, as in this case the bee-nest is spread out horizontally instead of in an upward direction as in the deep frame. Thus, to suit their own particular formation, the deep and shallow chambers are each arranged to meet all necessary conditions without further manipulations.

Where the large frames are not desired the outer case will do for giving protection to the small hive, or the latter

can stand all the year round without other protection.

There are no plinths used anywhere about the hives, but the upper edge of each chamber has a 4-inch rabbet cut out all round the outside, thus forming a gutter to carry off any moisture and making it impossible for the same to penetrate into the hive.

The small hive has no dummies, but the larger one has one dry-sugar feeding dummy, and one plain dummy supplied with it; or two original dry-feeding dummies if Standard frames only are wanted.

All parts of the hives are tongned and grooved, so as to come correct to guage, that any one may buy in the flat and put them together at home.

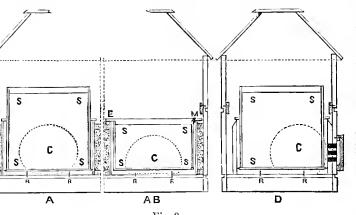

Fig. 9.

I have been fully aware that the greatest obstacle in the way of introdueing another frame would have been the loss of uniformity, seeing that the 'Standard' is so generally used, simply because it is the 'Standard,' and for that reason has been recommended by many, myself among the number, before I was really aware that I was using it at a serious loss. I

have accordingly ensured that the present hive will, without alteration, take in the same body (14\frac{1}{2} in. space) my new large frame, the 'Standard' frame with either 17 in. or $15\frac{1}{2}$ in. top bar, the erate of twenty-one sections as one large frame, the shallow chamber of eight frames as a combined frame; and, moreover, that the large frames may be used in any existing Standard hive, the latter also serving as a cover or shelter to the shallow hive, when used independently. Hence the hive is very appropriately called the 'Union,' or 'Universal.'—S. Šimmins.

A DISCOURAGED ONE.

[831.] I have received (on Saturday) my first discouragement in bee-keeping, and in the midst of my trouble I turn to you, in the hope that I may receive some small crumb of comfort. I may say that I had anticipated your appeal to the teachers of schools to take up the 'hobby,' and this gave me the more satisfaction to see the appeal. I had always a burning desire to be the possessor of at least one or two hives, but up till last back-end I was in the dark how to procure a hive.

Accident, however, threw an opportunity in my way; a friend, who had just made a good start, having to dispose of his stock by order of his employer. To make a long story short, I bought a swarm which had come away in May, and which my friend had hived in a box hive (not frame). My friend is one of the old school, on the verge of conversion, but a most enthusiastic beekeeper withal. I lend him my Journals each week, and they do a great amount of good, as there are a few of the old school here. Of course I cannot presume to educate them yet. To continue my story:-The hive is a box, with a hole in the crown for supering, and is enclosed in a substantial case, which I have packed with ehaff, and the whole has been kept 'dry as a bone.' During the long spell of snow my friend paid me a visit, with the sorrowful news that a neighbour had lost his stock (a weak one) through the ravages of mice, which had 'cleared the shop' of every bee. He thought it advisable to have a peep at my stock, to see how they appeared to be stocked. Of course, I need not say that he could not see much by taking off the bit of board which covered the hole, but he advised me to give them some syrup; and being only too thankful for advice, I gave about a pint, when I saw a warning against feeding with syrup in the Journal, and I at once discontinued. It occurred to me at the time that surely a swarm coming so early as May enght to be sufficiently stored,

even in a poor honey season, when they had been allowed to keep all their takings. I hope I have shown wisdom in deciding to let them alone till late next month, i.e., if I have any left. As you now know the particulars with respect to the constitution of my apiary (?), I will now tell my tale of woe. During the prevalence of the late cold and boisterous winds, I have kept the sliding doors closed up to about one bee-space. On Saturday last we had a grand spell of sunshine, though the wind was very cold. I left home for the day, leaving things as usual, and on Sunday, on taking a walk round my garden, I was staggered to see about a score dead bees lying in front of the hive. But oh, worse still. I opened the doors, and to my great horror I found the entrance crowded with dead or dying pets. The thought of it makes me ill when I recall it. I should think there were about one hundred dead, or dying. I cleared the entrance, of course, but I shudder to think of what may be the state inside. Can you account for it? What am I te do? I look about for some to advise me, but alas! I will await my next issue of the Journal with impatience. Perhaps, if 1 stop here, you will permit me to write to you again. I wish that box-hive far enough. Please give me a good dose of advice, but pray don't call me knobstick, and tell me to go out of the business.-Discouraged, Alderley, Crewe.

The syrup you gave during the frost would not have much effect upon the bees until warmer weather came. 'The grand spell of sunshine' aroused the semi-dormant bees, and, partaking freely of the syrup, excitement followed, when, rushing to the narrow entrance, a block took place, and many were suffocated. Your discovery of the state of things on the following day was fortunate, and, in all probability, saved the colony. Raise the hive from the floor-board about an inch, by gently inserting wedges on four sides, when you can clear out the dead bees and refuse by inserting a piece of stout wire, with hook at end. If you find *piles* of dead on the board, turn up the hive and ascertain whether the whole have perished. If you find few dead-say a hundred or twoclear them out, lower the hive gently to the board, keep the entrance at full summer width, not less than six inches, and give a cake of warm candy at the feed-hole. We do not think, however, that you will find the bees short of food, but you ought to be able to discover this by lifting the hive, and if you turn it up you may ascertain, to a certainty, their state.—Ed.]

EXPERIENCE OF A NOVICE.

[832.] Being a novice at bee-keeping, I should like to be allowed to give you my experience during the last two years, so that I may have the assistance of your valuable paper ere another season comes upon us.

I must begin by stating that I live in a neighbourhood not particularly well suited to bees, being near the sea, where high winds are prevalent, and the fields around chiefly occupied by broccoli and potatoes. Within a a distance, however, of from two or three miles there is a large quantity of both heather and gorse. Two years ago I commenced bee-keeping with three stocks, and did remarkably well, taking no less than 70 lbs. of honey from one hive and forty-eight sections from another. This determined me to increase my stocks, which I did in the autumn by means of driven bees. I opened the season last year with twelve stocks, expecting, before the summer ended, to take a large amount of surplus honey. Alas! I was doomed to disappointment. Up to the third week in June the bees did wonders. My hives were literally crammed with bees, all my hives were either doubled or had two tiers of sections. One hive I doubled and in addition added three crates of 21-lb. sections, and the whole were taken possession of by the bees. All seemed to be going on swimmingly until the end of June, when the honey flow almost ceased for the

season. I took a little honey from a few of the hives, but in August, when I came to examine the brood-nests, I found they were all empty, and the greater number of the sections were unfinished. I had to give each hive in the autumn I6 lbs. of syrup, and I found by October that hives which had contained enough bees to cover twenty frames only contained sufficient to cover six or seven. I successfully introduced, late in the season, a Carniolau and a Ligurian queen, by following Mr. Simmins' directious.

My stocks are at present all alive though not strong, covering about four frames on an average. I may say that I used no excluder zinc, so that the queens (all young ones) were able to roam about at leisure. I shall be very glad if any of your correspondents can tell me wherein I erred, and how I should act for the future.

My own idea is that the queens raised too large a number of bees, and that towards the end of the season, the honey harvest failing, this large number of bees exhausted the gathered stores, and then numbers of them perished prematurely, from having to range long distances in search of the sweets of life. Had I used excluder zinc, and confined the queen to so many frames, say ten or twelve, I believe the results would have been more satisfactory. I shall be grateful for any help your kind readers may be able to give me.—INQUIRER.

[There does not seem to have been any honey in your district after June, consequently when the flow ceased breeding also ceased, and we think you erred in not at this time removing your sections. If your colonies did not develope to their full strength before the honey flow commenced they could not store any, but in your case there does not seem to have been much honey to store when they had become strong. Last season was a bad one in most districts, and the one before an exceptionally good one. As brood-rearing with you ceased so soon it is not surprising that your colonies dwindled down by October. Breeding should have been encouraged by stimulative feeding, so as to have had a large number of bees to commence the winter with. The old bees died off naturally, and, unless breeding had been kept up, restricting the queen to a certain number of frames would not have assisted you.-ED.]

A VOICE FROM SUSSEX.

[833.] We are very, very sorry to inform you that the queen of our hive has been missing for a very long time, and we cannot tell what has become of her majesty. We are rather afraid that she has perished with her hive, for she had nothing but drones there. Could her parents tell us what we are to do, and where we might get another queen? Or, if the parents have another young princess to spare, we would gladly accept her as our queen, providing she will stay at home and attend to the duties of the hive. We do not mind what breed, or what colour, or what country, she may come from, provided she does not lay too many drones' eggs. Tell her there is plenty of good honey in Sussex, and plenty of good working bees, but no store-room. We will start the new hive with worker-comb foundation.—A Forest Bee, Sussex.

A VOICE FROM CUMBERLAND.

[834.] I am rather inclined to think that the Cumberland Bee-keepers' Association is in a somewhat similar position to that of the Yorkshire. Why such slow progress has been made I am unable to say, unless it is that those who should have been the principal workers are satisfied with the little knowledge they have got, and do not care to let it be known amongst their more unfortunate neighbours. I wish to ask the chief actors, or rather those who should have taken the more active part, why they did not continue and keep it on the move when there was every prospect of the Association doing

so well. At the commencement—that is, in 1883 some of those who took an interest in it did exert themselves a little in getting the Association into a workable form, and the number of members in a very short time was upwards of seventy. After the autumn of 1884 nothing more was done, or very little. Since then all has been darkness, and whether the Association is really dead or alive I know not; but there need be no wonder about it getting into such a low state when we have not a doctor in the county who is willing to come forward and give his advice, and try to stop the course of the disease. I have never once heard of a resident bee-keeper in Cumberland giving a lecture on beekeeping, except a cottage bee-keeper at Keswick; and I believe this is the only place where the annual meetings have been kept up. It appears that we have not got the right sort of workers in Cumberland who are willing to give a helping hand now that it is so much needed. We have in this county a very large number of beekeepers, and most of these keep their bees on the old barbarous system. I think by this time, if those connected with the Association had acted up to the spirit in which it was formed, some scores of those might have been induced to keep their bees on the humane principle. We have had neither lectures nor shows, except one tour through the neighbourhood by Mr. White and another by Mr. Sissons. After these gentlemen had livened things up a little I looked for some of our own members to follow their example. I see in the list of members the names of either seven or eight clergymen. Surely one might think that out of this number some of those reverend gentlemen would have taken a little more interest in it, and not allowed it to be neglected as it has been. We want a Raynor or a Bligh amongst us. If this had been the case Cumberland would have been in a more flourishing state than it is at the present time. I hope that another attempt will shortly be made to revive the Association, and not let it be said that a cottage hee-keeper is the only one that is anxious for the future prosperity of the Cumberland Bee-keepers' Association.—Worker Bee.

Replies to Queries.

, In their answers, Correspondents are respectfully requested to mention in each instance the number and the title of the query asked.

[818.]-In reply to 'R. E. Lloyd,' I have had some experience in varnishes, and I do not think there is any varnish or polish made (we must remember they are only gums in solution) that will withstand the salts or chemicals held in solution in water. To prove my assertion, let any one try the effect of a good strong solution of soda in water on any varnish or polish, be it on wood or your hands, and they will soon see how rapidly the gums are decomposed; but they must not neutralise the soda by the addition of I should recommend him to treat his vessel as I am doing Clark's patent feeder. I make them hot, and pour some melted beeswax in. It will not break off, and is just the thing .-- W. T. GREEN.

[826.] Crates of Thirty-five Sections. (West Somer-SET.)-Nothing is gained by having so many sections in one rack; the weight of rack is increased, this being a great consideration. A portion of the rack would have to be enclosed underneath, as it would more than cover the right number of frames for a brood-nest, hence there would be a great loss of heat. Work your bees on the storifying principle, not laterally, you will not be then far wrong.— W. B. Webster.

[827.] MOVEABLE FRAME-HIVE. (Douglas.)—To Major Munn is ascribed the making of the first moveable framehive, this being considered a failure, the date being 1841. Ten years after, Langstroth so improved on it as to make it practicable.—W. B. Webster.

[827.] THE FRAME-HIVE.—The moveable comb frame hive was introduced and improved upon by Mr. Langstroth about 1852.—J. D. McNally.

[827.] Inventor of Moveable Frame Hive. (Douglas.)-Huber is credited as being inventor of moveable frame (top bar); but Langstroth improved it by adding the end rails and bottom bar; although it appears to have been in use as early as 1675-6 by Geo. Wealer, as one author says, and probably even then an old invention. - EDWARD CLOWES.

[828.] Glass Hive.—About the first mention we have of glass hives were those used by Mr. Maraldi about the year 1777 for the purpose of watching how bees paired. Many eonjectures regarding the pairing of bees have been published; one of the most ingenious appears to have been suggested by Aristotle, and revived by Maraldi, the eelebrated inventor of glass hives,—John D. McNally.

[828.] GLASS HIVE. (DOUGLAS.)--Such a thing I have never heard of; if you mean an observatory hive, that is, a hive having glass inserted in portions of it for the purposes of observation, the first record that I can find is Huber .-W. B. Webster.

[829.] Poisonous Honey. (Douglas.)—According to my experiences, poisonous honey produced in England is a myth; I never trouble my head about such a thing when eating any description of English honey. Your second query has puzzled the greatest scientists, and eannot be satisfactorily answered. How is it that the goat, for instance, will eat leaves and thrive on them, whereas a horse, doing the same, would be killed? To bring it nearer to the subject, How is it that a very few people cannot eat honey, as it produces nausea? It doesn't with me.— W. B. WEBSTER.

Queries.

Queries and Answers are inserted free of charge to Correspondents When more than one query is sent, each should be on a separate piece

Our readers will greatly oblige us by answering, as far as their know-ledge and observations permit, the Correspondents who seek assistance. Answers should always bear the number and title placed against the query replied to. Any queries unanswered in this way will be answered

[835.] Artificial Swarming.—Who is reputed to be the first that practised artificial swarming?—EDWARD CLOWES.

[836.] Quieting Bees.-Who was the first that found out a method of quieting bees through the influence of smoke? -Edward Clowes.

NOTICES TO CORRESPONDENTS & INQUIRERS.

All queries forwarded will be attended to, and those only of personal

All queries forwarded will be attended to, and those only of personal interest will be answered in this column.

Letters or queries asking for addresses of manufacturers or correspondents, or where appliances can be purchased, or replies giving such information, can only be inserted as advertisements. The space devoted to letters, queries, and replies, is meant for the general good of bee-keepers, and not for advertisements. We wish our Correspondents to bear in mind that, as it is necessary for us to go to press in advance of the date of issue, queries cannot always be replied to in the issue immediately following the receipt of their communication.

E. Shotter. - Fowls. - Fowls rerely attack bees. Ours have the range of the apiary, and we have never seen them attack the bees. The most they do is to pick up an occasional drone when it comes across their path.

-Extracting.—It is better not to extract from COTTAGER. combs of the year, at least before the autumn, by which time they have generally become tough enough for extracting. The American flat-bottomed wired foundation is the best for the purpose. If this is used there will be no danger of breakage towards autumn, with We never use excluder zine. If brood is ordinary care. deposited in the upper storeys it is easy to remove it to the brood-nest below, and to remove the outer combs of honey from the lower to the upper chambers. Excluder zine disheartens the bees, and hinders free and hearty work. At least this is our experience, but it has its advocates, which are more numerous in America than in England. Wiring the frames, with a view to extracting, is better even than wired foundation. If your colonies are strong, when the honey season arrives, you may safely insert two or three frames of foundation, in each of your colonies, close to the brood-nest, and remove the frames displaced by these—provided they are free from

brood-to the upper chambers. These frames of foundation will be utilised for broad, since queens prefer, above all things, to deposit eggs in newly-built worker

A. W.—1. The sugar forwarded is not suitable for dry sugar feeding; Porto Rico is the best. 2. Enamel cloth, like sample, will answer your purpose. 3. For syrupmaking, Mr. Simmins uses Dutch crushed sugar, which, we note, he recommends in his advertisement to his eustomers; it answers its purpose well, but we prefer

Duncan's Pearl or crystallized sugar.

IGNORAMUS.—I. Age of Queens.—The first swarm, which you had in June, 1885, would have a queen of 1884. When that stock, No. 1, swarmed in June, 1886, the queen went with the swarm, No. 2; the second swarm had a young queen, No. 3; thus No. 1 and No. 3 have each a queen one year old, and No. 2 a queen three years old (unless she had been superseded by the bees, which is sometimes the ease). 2. American Bee-keepers' Magazine may be procured from Mr. Huckle, King's Langley, or from Messrs. Aspinwall & Treadwell, Barrington-on-Hudson, New York. 3. Symington's Pea Flour.—Yes, that will do very well for artificial pollen. 4. Measurements of Hive.—The only measurements which need be kept to are the width from side to side, 141 in., and the depth from the edge of sides on which the frames rest to the floor-board, which must be 8½ in. The length of the hive is a matter of detail, and regulated according to the number of frames you intend to nse. 20 in. for a single hive is a very convenient length. Refer to pp. 60 and 69, Vol. XIV. 5. Queenwasps.—It is early to see these upon the wing. Carrying pollen would show that the stock carrying it in has commenced brood-raising.

J. C. I.—1. Inverting Sections.—The object in inverting sections is not so much getting them filled quickly as having them fixed to the bottom securely. Turning them on one side would only accomplish this in a partial degree. Before trying either plan read 'Amateur Expert's' note in a recent issue. The advantage of reversing is very doubtful. 2. Wire-cloth Mesh.—Wire-cloth of 4-inch mesh is used by a few bee-keepers in America, and the inventor claims great results through the bees being able to form a solid cluster. This, however, like many other new ideas, requires proving before

it can be recommended.

J. B. S.—Bee Space between Bottom Bar and Floor-board.— Let there be $\frac{5}{16}$ ths of an inch only between the bottom bar of your frames and the floor-board of your hive, whether you use metal ends or not. This reply meets both your

East Lothian.—Transferring.—We suggest that you should stimulate the bees in the skeps, and get swarms from them as early as possible, and transfer twenty-one days after swarming. For method of transferring consult Modern Bee-keeping or Cowan's Beekeepers' Guide.

A. F.—Summer Shade for Hives.—If the hives are singlewalled it is very necessary that they be shaded in some way or other during the hot summer weather, otherwise the hees are likely to swarm. If the temperature rises rapidly above 95° swarming is induced, and this may be brought about if the hive is fully exposed to the sun, and its rays strike directly the thin walls of the live. If the bees are not ready to swarm they spend a great deal of their time outside when they ought to be working inside. Double walls are a protection. We do not think you have quite understood the outer cases alluded to. The hive we use is not double-walled, but by means of the outer cases we make it so. The hive itself, which has no top or bottom, stands on the floor-board, and the outer cases surround it. In winter the space between the hive and outer casing is filled with chaff, which is removed in the summer, and allows a free circulation of air between the two, especially if the latter be wedged up to allow the air to enter at the bottom. The outer cases are made of four boards nine inches deep, and are exactly like the hive, or like a box without top or bottom. They are made of half-inch stuff, and have a plinth round the lower edge, so that when one is put on the top of the other they are kept in position. One can be placed above the other to any height, and the loose roof

is then placed above them, just as is shown in the illusd tration on p. 12, which also shows the four hives places one above the other surrounded by the four outer case.

and covered by the sloping roof. With such hives there are too many bees to allow any snails to congregate; hut bees do use the space between, more especially at night, when they do not find room inside the hive. In very hot weather we put the outer cases one on the top of the other in such a way that there

is an outlet for the air between each. The sketch we give will illustrate our meaning. The shaded part represents the hive, and the outer lines the easings, as seen when looking down upon them from the top.

TRADE CATALOGUES.—We have received Trade Catalogues from Messrs. G. Stothard, Welwyn, Herts; T. B. Blow, Welwyn; E. C. Walton, Muskham; Simmins, Brighton.

Show Announcements.

July 11-15.—Royal Agricultural Show at Newcastle-on-Tyne. Entries close May 12. J. Huckle, Kings Langley. August 3-5.—Yorkshive Agricultural Society at York, Sceretary, H. L. Rickards, Poole, near Leeds.

MANIPULATE WITHOUT SMOKE!

WEBSTER'S FUMIGATOR

Entirely supersedes the Smoker, both in Simplicity and Effectiveness. No 'going out.' No tainting or soiling of combs. Always ready for use without any preparation, Can be carried in the pocket.

With Bellows, 4s. 6d.; postage, 4½d. Without Bellows, 3s.; postage, 3d.

Can be adjusted to any ordinary smoker bellows.

6 oz. Bottles of Agent—carbolic acid, oil of tar, and water, properly mixed—6d. each.

WEBSTER'S SWIVEL FRAME - LIFTER

WILL BE READY SHORTLY.

With this appliance, frames can be removed from hive, replaced and examined on both sides without inverting, with one hand, leaving the other free for manipulating, at the same time preventing soiling the hands with propolis.

W. B. WEBSTER,

SOLE MANUFACTURER AND INVENTOR, WOKINGHAM, BERKS.

AWARDS FOR FUMIGATORS LAST SEASON.

1st Prize Silver Medal, Royal Counties' Agricultural Show. Highest Award, Colonial and Indian Exhibition, London. 2nd Prize Bronze Medal, Colonial and Indian Exhibition, London.

2nd Prize Altrincham, Lancashire and Cheshire B. K. A.

LYON'S Patent METAL ENDS

THE only perfect pattern. The metal being flush with the inside of the Hive side, CANNOT BE FIXED TO IT BY PROPOLIS. All the so-called Improvements CAN.

The Special Alloy used allows them to be LIGHT YET STRONG. One gross weighs $5\frac{1}{4}$ lbs.

Price for 1887 5 6 per gross.

DR. PINE'S VEILS.

Prize Medal, 1879, for the best Bee Dress, The only Medal ever awarded to a Veil, **2**/**2** each, post free. Every genuine Veil bears the Registered Trade Mark.

DR. PINE'S LOTION.

The ONLY CURE for Stings, 1/8 per bottle, post free.

CHESHIRE CURE.

Guaranteed, with Directions, 1/2 per bottle, post free.

METHYL SALICYLATE, or 'APIFUGE.'

HIVE MAKERS supplied with SPRINGS, GLASSES for Sections, PHENOL, METHYL SALICYLATE, in bulk,

&c., &c., at lowest prices. F. LYON, 94 Harleyford Rd., London, S.E.

TO DEALERS.

CEND to A. F. HUTCHINGS for quotations of AMERICAN WHITE BASSWOOD ONE-PIECE SECTIONS of the finest manufacture and quality, 300,000 will shortly be on hand. Special terms for all Orders before March 25. Don't fail to get my prices before you Order elsewhere! Address, West Kent Steam Power Hive Works, St. Mary Cray, Kent.

OUR WAX AND HONEY IMPORTS.

Having been enabled in our last issue, through the kindness of E. H. Bellairs, Esq., Hon, Sec. of the Hants and Isle of Wight Bee-keepers' Association, to give the returns of the value of honey imported into the United Kingdom during the past year, and as we are now, by the official publication of the 'Annual Statement of the Trade of the United Kingdom with Foreign Countries for 1885,' in possession of the amount and value of the imports of wax for that year, we are in a position to compare these data with those of the respective preceding years.

The subjoined tabular statement specifies the foreign countries and the British possessions from which wax is exported, with the amount and value

of the same :---

i the same					
				ewts.	£
Germany				10,749	29,054
France `				1,244	6,088
Portugal				965	5,523
ltaly				666	3,978
Morocco				964	5,287
China				778	2,354
Japan				$6,\!115$	$12,\!883$
United Sta				2,911	17,639
Chile	***			499	3,461
Brazil			• • •	5.605	17,886
	C		•••

British W	est Indie			1,012	6,921
Other Bri				48	279
other in	cicii a osc	.ceetom	٠	40	210
Total fron	n British	Posses	sions	6,997	40,974
		Total	*	38,925	$\overline{149,253}$

It will be seen from the above that the mean value of wax per cwt. is 3l. 16s. 8d.; in the previous year it was 31. 14s. 10d. There has been a considerable increase in the amount received from the British possessions over the previous years. Wax is of various kinds-vegetable, mineral, and insect —and from the preceding statement of the value, we are able to deduce the nature, of the wax That from Japan is 21. 2s. 1d. per ewt.; from Germany, 27. 14s.; from China, 37. 0s. 9d.; while that from Italy fetched 51, 19s. 5d.; from the United States, 61. 1s. 2d.; and that from the British possessions averaged 51, 17s, 3d. We note that Holland, which figured as a contributor in the previous year, is absent from the list this year; while China and South Africa, which were absent the previous year, appear this year as large importers.

The following statement gives the value and amount of the wax exported from the United

Kingdom to the respective countries:-

			cwts.	£
Russia			 1.342	4,825
Germany			 3,561	13,827
France			 1,409	5,044
Other Forei	on Cou	ntries	 3,573	11,918
British Poss			 443	1,092
			10.328	36,706

Comparing the quantities of wax imported during the two preceding years, the results are,—

1885. 1883. 1884. 28.192 cwt. 28,258 cwt. 38,925 cwt.

The value of the above for the same years is,— 105.8137. 149,2537. 97,1427.

While the amount of the wax exported for the same vears is.

12,504 ewt. 10.378 ewt. 10,328 ewt. And the value thereof,-

36,4377. 36,7067. 41.3397.

From a comparison of the above we see that there was a considerable increase in the import of wax during the year 1885 over that in 1884, while that re-exported during the same years has almost remained stationary. It is evident that if it would pay bee-keepers to direct their attention to the production of wax together with that of honey,and we see that many practical bee-keepers are so doing,—there would be a market for it in this country. The amount of wax used in the production of comb-foundation by manufacturers alone is very large, and an attempt should be made by bec-keepers to raise a larger quantity in proportion to its requirements. The British Honey Company have done much in increasing the production of honey: could they not also find it to their interest to stimulate the expansion of that of wax?

In our last number Mr. Bellairs gave us, so far as he was able, the value of the imports of honey for last year and that of the three preceding years. The values for 1884, 1885, and 1886 are,—

1884. 1885. 1886. 62,357*l*. 61,344*l*. 25,146*l*.

Those of 1884 and 1885 are approximate only, and those of 1886 do not include the honey sent through Colonial Governments to the Indian and Colonial Exhibition.

For some years past we have been indebted to S. Seldon, Esq., of the Statistical Office, Customs, and to Mr. Bellairs, for the information that has appeared so regularly in our pages of the value of the monthly imports of honey into the United Kingdom; and we are sure that bee-keepers are fully sensible of their indebtedness to those gentlemen for the trouble they have so kindly From January, 1886, the imports and exports of honey will be found in the 'Annual Statement of Trade with Foreign Countries.' however, this Statement does not usually appear before the month of September, we are pleased to be assured by Mr. Bellairs that he will continue his good offices by forwarding month by month the accounts as he has done in previous years.

USEFUL HINTS.

Weather.—During the last fortnight the weather has continued cold, cheerless, and changeable, and our bees have been entirely confined to their hives, with the exception of one fine day which enabled them to fly freely and to display their numbers. 'All things come to those who wait,' and 'Post nubila Phæbus' is a true proverb in more senses than one. Soon, therefore, shall we realise that—

. . . 'Day by day New pollen on the lily petal grows, And still more labyrinthine buds the rose.'

COUNTRY LIFE.—After our experience of the dense London fog up to noon on the 17th ult., the day after our annual meeting, when gas and electric lights failed to dispel the gloom, and, unable to decipher the figures on the dial-plates, we were compelled to resort to the nearest policeman to learn the time, we congratulated ourselves in the words of our favourite poet,—

' O fortunatos nimium, sua si bona norint, Agricolas!'

And choked almost to suffocation, pitying the gasping Londoners while contrasting their state of existence with that of our own happy country fraternity, we exclaimed in fullness of heart,—

'We possess the flowers and trees, Modern hives and golden bees; Fruit and nectar, both divine, We shall reap at harvest time.'

And, finding on reaching our quiet country home, with its hive-scattered lawns and shrubberies, that the day had been one of brilliant sunshine, we were more than ever impressed with the truth of the old saying, 'God made the country, man made the town.'

ENAMEL CLOTH AND Illve-covering.—Although we have repeatedly explained the way in which we use the enamel cloth as a covering for hives, we are constantly asked for information thereon. Indeed the reiteration we are

compelled to use in this, our department-reiteration of methods of management, facts, advice, &c., &c., many of which have been ever present to our minds for well-nigh half a century, and have repeatedly appeared in the columns of our Journal, is one of our most irksome tasks; and yet, with the knowledge that all this repetition is absolutely necessary, we must not shirk a duty so obvious, asking only that our readers will exercise a little patience and forbearance towards our wanderings into 'devious paths and pastures new.' The enamel cloth we always use is American, and we place the enamelled or glazed side downwards upon the frames. These American cloths are sold by most English dealers in two sizes to suit small and large hives, and are neatly bound on two sides with strips of tin. In making winter preparations we place several thicknesses of felt, carpet, chaff-cushions, or both, upon the enamel cloth, and over all a weighted crown-hoard. These prevent all escape of heat, and we have wintered upwards of fifty colonies during the recent severe winter, and brought them safely through—thus far—without a single loss. The interiors of the hives are perfectly dry, combs and all, and the bees in perfect health, without a symptom of dysentery. Our apiary occupies a bleak position, some of the hives facing east and south-east, and the entrances have been kept at summer width, the narrowest being six inches, and others the whole width of the hive, while severe frost and snow, with easterly winds, have prevailed for many weeks.

SPRING EXAMINATION OF COLONIES.—Most apiarists recommend a thorough examination of all colonies at spring. Columella advised that the hives should be opened at spring, and all filth which had accumulated during the winter should be removed; and most modern bee-keepers follow his advice. Spring is rather a loose term, and allows a wide margin as to the precise time of this general examination. Our own idea is that the middle or end of the present month is soon enough, and that it should be performed in fine weather only. The that it should be performed in fine weather only. colonies should be disturbed as little as possible during the examination, and to this end we prefer the use of diluted carbolic acid in preference to smoke. (See Modern Bee-keeping, p. 29.) An old calico or woollen quilt steeped in the solution, and laid over the frames of the hive will effectually quiet the bees, when operations may be commenced. A spare hive and floor-board, perfectly dry and clean, should be placed on the stand of the hive under examination, the latter having been removed a couple of feet to one side. Leave the brood-nest until last, removing the surrounding frames on both sides one by one to the new hive. When the next is reached, if breeding is in progress, we prefer to transfer the four or five frames which compose it without separating them, which may easily be done by placing two short laths or thick pieces of wire under both ends of the frames and removing them altogether. It is not at all necessary to 'interview' the queen if you are convinced she is there and performing her duties. The outside frames having been replaced in their former position, division-boards may be applied as required, sealed honey supplied if needed, and the quilts returned. The signs of breeding will be occasional dead larvæ on the floor-board, eggs or broad in the comb, vigour and dash of the bees carrying in pollen, &c. The emptied hive, when scraped, disinfected, and dried, will be ready for the next operation. These manipulations must be performed quietly but quickly, giving no chance of robbing, to prevent which all frames not under inspection should be covered with the carbolised cloth. With a little practice it is surprising how quickly these examinations may be accomplished. When the enamel sheet is used there is great advantage in its lightness, flexibility, and in the non-adherence to it of propolis. It may be stripped off the frames quickly, and a slight spraying of weak carbolic solution will at

once keep the bees in check, when it should be allowed

to fall back into its place, and each frame may be uncovered separately as required. The condition of the colony as regards population, stores, brood, &c., should be noted either on tablets attached to the hives or in a book kept for the purpose, together with the date of examination.

ARTIFICIAL POLLEN, &c.—On every bright day bees will now be very busy on the crocus and other spring blooms, on which the scattering of pea or other meal will greatly assist them. A supply of water must not be neglected. Also on bright days remove hive-roofs, or covers, turning them up to the sun, but do not forget when night comes to replace them. Dislodge spiders, their eggs, larvæ of moths. &c.

their eggs, larvæ of moths, &c.

COMING CAMPAIGN.—These matters completed, a beginning will have been made for the approaching campaign, and bee-keepers and bees will have been aroused to make further preparation for reaping a future

harvest.

STIMULATING.—By 'stimulation' is usually understood a supply of food given in driblets, generally at spring time. The system has its advocates and oppospring time. The system has its advocates and opponents. The former argue that the bees and queen perceiving that food is coming in are incited thereby to earlier preparation for brood-rearing than would otherwise have taken place. The latter, granting this, are of opinion that the bees, stimulated to early brood-rearing, are induced to leave the hive in search of pollen, water, or food at unseasonable times and during the prevalence of cold spring winds, and so perish in numbers, being chilled and unable to reach their hives, hence follows spring dwindling with its attendant evils, until finally the colony is often lost. In our opinion spring dwindling arises chiefly from another cause, viz., dysentery or diarrhea. The intestines having become diseased by improper food, and too low a temperature, the vitality of the colony is reduced, and that to so great an extent that its members perish while in search of food and in the performance of their heavy spring labours. Once entered upon the downward road the final catastrophe soon follows, the brood-nest becoming circumscribed, no matter how prolific the queen may be, it gradually becomes less and less; eggs laid are neglected or devoured owing to the paucity of nurse-bees to incubate them, and the end comes through robbery, desertion, or death. We have never found judicious feeding of fairly populous colonies at spring injurious, but care must be taken to feed so sparingly that the brood-nest shall not become a repository for food instead of brood. Many colonies have at spring more honey than their wants demand. In such cases we prefer the repeated uncapping of a few cells near the brood-nest to give syrup, the stimulating effect being quite as great, and, as the brood is extended, the outer clogged honey-combs may be extracted and returned to the hive. This plan is productive of more extensive and more certain stimulation of brood-rearing than any other with which we are acquainted.

FOOD RECIPE.—The following recipe is recommended

by Mr. Heddon:-

'Into a boiling-pan put three pounds of water, heating it until it boils, and with a wooden spoon stir the water as you sift into it ten pounds of granulated sugar. When it is all dissolved, and the syrup is boiling, pour in one half teacupful of water in which has previously been dissolved a level teaspoonful of tartaric acid. Stir it a moment longer, and then remove it from the fire. Give the syrup warm (not hot).'

For spring use from four to six pounds (say pints) of water may be used. Duucan's Pearl sugar we think the best of any we have used. For stimulating, a bottle-feeder is best, and from two to six holes may be used, according to the size and needs of the colony. The food should be given warm at night to prevent robbing; and as a further precaution the entrance must be contracted.

COMMITTEE CRITICISED.—Since the work of the acting Committee of the B.B.K.A. is often freely canvassed and criticised,—not always in the most flattering manner,—the unbiassed opinion of an outside friend, who writes to us as follows, may fairly be given:—

'It strikes me that Captain Bush's view of reducing the qualifying subscription for membership on the Committee is the correct one. I cannot understand how a man can be expected to attend from twelve to eighteen meetings in the year, to travel, say, from fifty to a hundred miles (the double journey), and, in not a few cases, be obliged to undergo the expense of passing a night at a London hotel,—from inabilitity to reach his home,—and yet be unable to subscribe his pound to the funds of the Association! I do not wonder that you find a difficulty in indneing qualified men to give their time and money—no doubt, often at great incouvenience to themselves—at such a rate, in order to advance bee-keeping chiefly amongst cottagers, however favourite the pursuit may be. To me it speaks volumes for the patriotic spirit of our leading bee-keepers, that on such terms you are able to procure an acting Committee at all.'

To our friend we replied that—'The case being thus, all the more reason why members of Committee should be relieved from an annual subscription of one pound; in fact, that the argument cut both ways.' We do not anticipate, indeed, a revolution, from the reduction of the franchise, and believe that even universal suffrage will not destroy the edifice built upon a foundation so secure.

JOTTINGS BY AMATEUR EXPERT.

' Mel sapit Omnia.

Glorious weather for bees and bee-keepers! My queens are all breeding except one—that Holy Land—and all hives have plenty of stores and bees. But stores will decrease fast now, with bees active and queens breeding, let us remember. 'Expert-in-Chief' Baldwin predicts a good year, as bees have wintered well, if—that if is the rub—their owners will only give them proper care during the spring. Tell us, 'A. E.,' what is proper care? Meddle as little as possible, meddle as much as necessary, but always see to it, above all things, that they never for one hour are short of food right up to the time of the clover glut.

I hope the delusion of ever getting bees to store much from fruit-blossoms in England is about exploded by this time. An enthusiastic contributor to our Journal talked last year of getting one ton from this source alone, but I never heard that he succeeded. I shall be pleased to hear that his hopes were realised, as I could but admire his courage when he put the 'hope' in print, and must confess his courage alone merited success.

If you wish to live a life of peace now-a-days you must praise everything, and if you depart from that path the 'fortune of war' is your portion. Well, come war or come peace, I confess I deem it necessary to put in a word of caution to those who are young or unsuccessful at bee-keeping. As bad workmen complain of their tools, so unsuccessful bee-keepers hope to get on better if they get expensive and elaborate appliances and lives. And if they are readers of the B. B. J. they will find plenty to allure them into investing their money. Hive construction, like most things, has its cycles. We are emerging from the simple on to the elaborate; the last cycle of the elaborate reached its zenith about the year 1882, when we had hives with brass runners to support the frames, so that you might summer on the 'cool' system, and winter on the 'hot.' Hives with peep-holes' and glass shutters, trap-doors, knobs, and buttons and hooks ad lib., sections in front of them, sections 'in rear of them,' sections 'each side of them,' and crates of sections on the top. Added to this thero was excluder-zine here, there, and everywhere; and cushions enough almost to pad an ordinary armchair. They were things 'fearfully and wonderfully made,'

and the price of twenty such hives would build a

cottage.

But all this has given way in great part for a neat, simple class of hive, fitted with ten or eleven 'Standard' frames and good porches and roofs, and most of us have found that by good management with such hives we can more than double the record in bad seasons that we used to get when we used 'fads' and lots of manipulation, even if seasons were better. And now we are coolly asked to go back to this kind of thing again. The old birds won't be eaught with chaff, so I don't attempt to advise them, but to the yonnger I say, 'Save your money,' at least all of it except threepence; and with that go and purchase Mr. Cowan's new 'Guide-book Pamphlet' on Doubling and Storifying. I had hoped some one would have said a good word for it in the Journal long ere this.

Mr. Pettit, the President of the Ontario Bee-keepers' Association, has gone home from London to Canada a convert to its teachings, and in his Presidential address at Toronto the other day almost went so far as to beg of the Canadians to adopt it. Mr. Cowan has set himself the task of showing how 'honey can be produced profitably in this country at the present low price with very little trouble, and with very much less apparatus than is usually employed by bee-keepers;' and in my judgment he has succeeded admirably, and if you are bewildered by the allurements that are being spread around at the present time, there can be no better advice than is given in these sixteen pages of this pamphlet, for remember, 'It is the expensive appliances, frequently more for show than use, which run away with all the profit, and leave the bee-keeper at the end of the year with a deficit.'

Some are complaining that our 'Standard' frame is too shallow. The Americans and Cauadians have used a deeper frame for years, and their newest 'craze' is the shallow 'Heddon,' but our 'Standard' is a happy medium between the two extremes.

I wish I lived in Sussex, for having conquered my small world, I thought of sitting down to weep for other (bee) worlds to conquer; but however much I sympathise with 'A Forest Bee,' Sussex is too far away to get any help from—AMATEUR EXPERT.

ASSOCIATIONS.

LANCASHIRE AND CHESHIRE BEE-KEEPERS' ASSOCIATION.

The Annual Meeting of the above Association was held at the Bear's Paw Restaurant, Liverpool, on Tuesday, the 8th of February, C. P. Titherley, Esq. in the chair. Present: Rev. J. F. Buckler, Colonel Herne, Messrs. W. B. Carr, W. Lyon, W. Liddell, W. Caldwell, G. Roberts, W. L. Maclure, and F. H. Carr.

The accounts of the Association were presented to the meeting, and after the minute of the Committee with reference to the donation of 10% to the B. B. K. A. for the Royal Horticultural Show held at Liverpool had been read, they were passed unanimously.

read, they were passed unanimously.

The report of the Committee for 1886 was read by the Rev. J. F. Buckler, and passed unanimously.

The report states that the Committee have much satisfaction in noting the success which has attended the Association's work during 1886, which has been chiefly in connection with shows, viz.:—June 29th to July 5th, Royal Horticultural at Liverpool, in connexion with the British B. K. A. July 24th, Huyton and Whiston Cottagers' Horticultural Society. July 30th to August 5th, South Kensington Honey Show. August 2nd, Frodsham. August 5th, Barrow, Chester. August 25th, Handbridge, Chester. August 25th, Lancaster. September 9th to 11th, Manchester and Liverpool Agricultural Society's Show, held at Chester. As no

charge for admission could be made to the bee tents at the Liverpool Show, there was an outlay of over 10l., which was to some extent covered by special donations. The exhibit sent to South Kensington will long be remembered by those who saw it, as far ahead of any other sent to the county competition, which was the first held by the British Bee-keepers Association. The expenses connected with this exhibit were heavy, but having taken the first prize, and many members giving special donations to the cost, and as those who took charge of it worked gratuitously, the nett cost is a small charge on the year's accounts. Of the 283 members referred to in the Report for 1885, 105 have resigned; 60 have joined, leaving 238 members' names on the books, including 41 in the artizan and cottager list. The disposing of members' honey is a question which has had attention, and a good quantity has been sold at remunerative prices; and it is hoped the committee for 1887 will be able to arrange the sale of even a larger quantity. The committee think it well to put on record that the first conversazione held by members of the Association took place in December, 1886, and though the number present (about 60) was not as large as might have been expected from the long list of members, still, as a successful commencement has been made, they hope meetings of a similar kind will often be held in the future by the L. and C. B. K. A., as such meetings bring the members and their friends together. Through the kindness of examiners from the British Bee-keepers' Association, candidates had a chance of getting third-class certificates at the time of the Royal Horticultural Show held at Liverpool, and once since; but of the ten candidates who came for examination, only three obtained certificates. It is a great satisfaction to your committee that this year's work has been done in good harmony with the British Bee-keepers' Association.

Some alterations of rules were proposed by Mr. M'Clure.

The Patrons, President, and Vice-presidents were manimously re-elected. Rev. J. F. Buckler, Col. Herne, Messrs. W. B. Carr, J. M. Gibbs, Wm. Lees M'Clure, Geo. Roberts, Wm. Roberts, H. H. Williams, G. G. Parker, and George Aitken, were appointed the Committee for 1887. Wm. Lees M'Clure was appointed Honorary Secretary, and Mr. W. Tyrer, Treasurer. Mr. Wm. Lees M'Clure was appointed to attend the quarterly conferences in London; Mr. F. H. Carr, expert; Mr. J. A. Bally, auditor of the Association, and Mr. Gibbs was re-appointed Librarian. A vote of thanks was given to all the officers of the Association.

After the Annual Meeting a committee-meeting was held, when it was proposed and carried unanimously, that the Committee meetings be held on the fourth Monday of each month, except when that day falls on or after the 25th of the month, and in that event the committee arc to meet on the third Monday of the month.

WORCESTERSHIRE BEE-KEEPERS' ASSOCIATION.

The annual meeting in connexion with this Association was held on February 19, 1887, at the Guildhall, Worcester. The Rev. E. W. Isaac presided in the absence of the Mayor (Alderman Holland), and among those also present were the Revs. R. T. W. Brayne and W. M. Kingsmill, Mrs. Swinden, Messrs. H. Goldiogham, J. A. Watson, T. Cook, C. H. Haynes, J. Powell, G. H. Latty, E. A. Dimmock, A. Thorpe, A. E. Bryan, J. W. W. Boughton, H. W. Carey, J. Neal, A. H. Martin (Hon. Sec.), E. Davenport (Expert to the Association), &c.

The annual report stated that the work done during the past year had been curtailed owing to the apathy of the members themselves by the non-payment of sub-

scriptions, and by a want of interest shown in the promotion of the objects which the Association had in view. The number of members at the close of the year was 186. The total income had amounted to 551. 2s. 8d., and there was a balance of 81. 6s. 4d. in the hands of the treasurer, as compared with an adverse balance of 3t. 5s. 6d. at the beginning of the year. Early in April Mr. C. Brown resigned the appointment of expert to the Association. Mr. Davenport, of Stourport, who had held the office of expert to the Hants and Isle of Wight Beekeepers' Association, and had a first-class expert certificate from the B. B. K. A., was elected to the vacant post, and made a tour among the members. Owing to a want of funds, the committee were reluctantly compelled to abandon the holding of an annual show of bees, hives, honey, and apiarian appliances, and they wished to impress upon members that if one was to be held in the coming year a special subscription must be raised to defray the expenses of the same. The committee had determined to circulate the *Bee Journal* every fortnight among the members during the ensuing year. The committee regretted the removal from the county of Mrs. Piers F. Legh, who had given the Association most valuable help ever since it was started. In conclusion the committee expressed the hope that members would take more interest in the Association, and bear in mind that one of the main advantages to be gained from membership was that the members would probably learn something about bee-keeping themselves and might help to instruct others who know little or nothing about it.

On the motion of Mr. Latty, seconded by Mr. Cook,

the report was adopted.

Mr. Davenport (expert) said he commenced his tour of inspection among members towards the end of April, but owing to serious domestic affliction, his visits were considerably interfered with. In many instances he found very good results, which showed that in spite of indifference amongst some of the members the work of the Association had not been in vain. As to the future of the Association, it would require the united efforts of members if its prosperity were to be increased. Among certain things which he regarded as important, he suggested the division of the county into districts, with a secretary and adviser in each district. As to the bee tent, he thought the time was past when they could expect to make it a source of large profit at the various horticultural shows, and he suggested its being thrown open free of charge, and hoped that contributions would be voluntarily tendered. He thought that driving from the old skep should be abandoned to a certain extent, and more attention given on these occasions to barframed hives.

Mr. A. H. Martin said they were obliged to Mr. Davenport for his report, and he hoped that the work of the bee tent would be extended. With regard to throwing it open, he should like to see it sent to every village green in the county and demonstrations given to the villagers in the summer evenings. He much regretted that, owing to want of funds, their operations had been somewhat curtailed, but he trusted that the coming season would bring increased prosperity to the Association

Mr. Goldingham said that the Association was to a great extent a trading Association, and he considered the suggestion of throwing the bee tent open at horti-

cultural shows a very good one.

Earl Beauchamp was re-elected President of the Association, and the following were elected Vice-Presidents:—The Bishop of Worcester, Lady Hindlip, Lady Georgina Vernon, Lord Edward S. Churchill, Sir Richard Temple, Bart., M.P., Sir E. A. H. Lechmere, Bart., M.P., Mr. John Corbett, M.P., the Hon. G. H. Allsopp, M.P., and the Mayor of Worcester. Mr. T. J. Slatter was re-elected Honorary Treasurer, and Mr. A. H. Martin Honorary Secretary. Mr. A. H. Martin and Mr. C. H.

Haynes were appointed as representatives of the Association at the Conferences of the British Bee-keepers' Association.

The annual ballot for hives resulted in Mrs. Huddleston, of Dunley, Stourport, and Michael Portman, of

Astwood Bank, being the winners.

The Chairman said a most pleasing duty remained for him to propose a vote of thanks to their Hon. Secretary for the attention he had bestowed on the work of the Association, and they were all greatly indebted to him for all he had done. This was seconded by Mr. Goldingham.

Mr. Martin, in returning thanks, said he was one of those who believed that, although much had been accomplished in the past, there was a great future before the bee-keepers of this country. The great apiarian exhibition held last July, and the exhibition of the Ontario bee-keepers later in the year, at the Colonial Exhibition, should stimulate them to continue their exertions in the objects which the County Associations were endeavouring to promote. In conclusion, he proposed a vote of thanks to the Chairman for presiding at the meeting, and said that the committee must shortly meet to consider the suggestions that had been proposed for the working of the Association in the coming season.

MIDDLESEX BEE-KEEPERS' ASSOCIATION.

The Annual meeting of this Association was held on Thursday, February 10th, the Baroness Burdett-Coutts in the chair. Present: Dr. Rayner, Major Fair, Messrs. W. H. Kennell, W. M. Graham, J. Peers, T. Leadbitter, G. Henderson, O. Lambert, R. Rose, S. J. Gunn, G. Moyes, and the hon. sec. the Hon. and Rev. II. Bligh. The following resolution was carried unanimously:-'The members of the Middlesex Bee-keepers' Association desire to express the deep-felt sorrow and sincere regret with which they have heard of the sad news of the sudden and early death of their late secretary, Mr. Fox Kenworthy. They feel that the well-known excellence of his character, the deep interest which he took in the affairs of the Association, and his unwearied labours for it, will make his loss more keenly felt by They would give expression to their sense of gratitude which they owe to him for the present state of efficiency to which, mainly by his labour, the Association has been raised. They beg leave to offer to Mrs. Kenworthy and her family their sincere condolence, and to assure her of the very great respect and esteem in which the memory of her son is held by them.

The Baroness Burdett-Coutts was elected President for the ensuing year; Vice-presidents, Lord George Hamilton, the Right. Hon. S. H. Walpole, Sir J. Lubbock, the Hon. and Rev. H. Bligh, Mr. Nelson, and Mr. Lafone: treasurer, Mr. Rose; hon. sec., the Hon. and Rev. H. Bligh; provincial secretaries, Major Fair, and Messrs. Graham and Harris; committee, Messrs. Jones, Henderson, Zehetmayr, Mason, and Lambert; auditor, Mr. W. G. Jefferys; expert, Mr. Fewtrell.

Mr. Bligh presented the statement of accounts for the South Kensington show, and announced that the Baroness Burdett-Coutts had kindly cleared the deficiency amounting to 12*l*. or 13*l*. A vote of thanks to the Baroness Burdett-Coutts for her liberality and kindness

in presiding was carried unanimously.

The following is an abstract of the report:—Increase in the number of members, a growing interest in beekeeping, and a marked improvement in the method and practice of the beekeepers of the county, are among the satisfactory results which the committee are enabled to record in this their fourth annual report. The early months of the year were made use of for a series of lectures on beekeeping, most of them delivered by the Rev. W. E. Burkitt, Rector of Buttermere, Wilts, and

Secretary of the Wilts County Association, given at Ealing, Hampton Hill, Brentford, Pinner, Sulbury, Staines, Uxbridge, and Twickenham. As soon as the bees had got into regular working order, the usual spring tour was made by Mr. Fewtrell, B.B.K.A., firstclass expert, over the larger portion of the county; whilst Mr. Baldwin, Expert-in-Chief of the B.B.K.A.. broke up some new ground in the north-east corner of the county. In the general working of the Association the district system has been further developed, and the committee gladly record that three new districts are now efficiently worked, where a year ago little or nothing was being done. The number of members added during the year to the roll of the Association is perhaps the best proof of the advance which it has made. At the beginning of the year 1886, there were I39 members; there are 200 names upon the books now, or a net gain In the great exhibition of Honey and Beekeeping appliances at the Indian and Colonial Exhibition at South Kensington in the competition between the counties of England, our Association competed, and staged, as a single exhibit, 6 cwt. of honey (232 lbs. sections and 440 lbs. extracted), out of 9 cwt. contributed by 24 members for the purpose. Our exhibit did not take a prize; but, at the same time, was universally acknowledged to have been one of the most striking features of the show. Ten, at least, of the exhibitors will receive the large bronze medal given by the Executive of the Colonial Exhibition, and the rest will receive a certificate of merit. In the spring, the committee secured at second-hand, and at a very moderate outlay, a good manipulating tent, which for all practical purposes, was equal to new. This was brought into requisition at several flower shows. With a view to the increase in the number of members, and also to secure the early payment of subscriptions, the committee have determined to return to all whose subscriptions are paid by the 31st of January ten per cent in the shape of prizes to be drawn for at the annual meeting.

During the progress of the meeting the drawing for prizes took place. Ninety-seven members had qualified themselves to take part in the drawing, and the Miss Morgan, Bingham smoker; Miss Heyn, Benthall crate; Mr. A. Mitchell, Benthall crate; Mr. F. Hughes, crate; Mr. A. Mitchell, Benthall crate; Mr. F. Hughes, Benthall crate; Mr. Harveyson, Abbott cage; Mr. C. J. Athey, Abbott cage; Miss George, Bingham knife; Mr. Campbell, Abbott feeder; Miss C. Hale, Raynor feeder; Mr. R. Jonas, section crate: Mr. A. Stent, feeder; Mr. D. H. Durrant, feeder; Mr. W. Hinde, Bingham knife; Mr. W. Willan, atomizer; Baroness Burdett-Coutts, smoker; Mr. B. Johnson, wire veil; Mr. Wall, veil; Mr. Bligh, 100 sections.

BERKS BEE-KEEPERS' ASSOCIATION.

The Berks Bee-keepers' Association opened the campaign of 1887 by a social meeting at the Assembly Rooms, Friar Street, Reading, on Thursday last, February 24. A committee meeting was held previous to the social to elect a hon, secretary in place of Mr. J. Bowley, who has removed from the county, and we were pleased that the Rev. Roland Errington, Rector of Clewer, has kindly undertaken the duties of hon, secretary with Mr. A. D. Woodley, 26 Domington Road, Reading, as assistant secretary. That being the only item on the agenda paper a vote of thanks was accorded to Mr. Errington for consenting to take the office, the meeting adjourned sine die.

The social meeting opened at eight o'clock, and the spacious room was soon a busy scene inspecting the many interesting articles kindly brought by friends. Mr. Blow, of Welwyn, brought his new hive, recently limned in British Bee Journal, also one of his Carniolan hives with painted front, said painting representing the Old Testa-

ment story of the two she-bears tearing the children who cried to the Prophet, 'Go up, thou bald-head;' also several physiological subjects illustrating the honey-bee. Webster, Wokingham, exhibited his 'Jones-Heddon' hive, famigators, foundation, and frame-lifters, &c. Mr. A. D. Woodley, Reading, a new reversible crate, new cheap hive similar to the Sandringham hive, also a Combination hive, and miscellaneous articles and literature connected with the craft. Messrs. Abbott, Southall, sent a collection of small articles; a friend with a microscope and microscopic slides came in for a fair share of attention. There was the hearty grip of the hand by brother bee-keepers whom we had not met for a season, short lectures by bee-keepers of known ability, viz., Messrs. Blow, Webster, and A. D. Woodley, each illustrated by the magic lantern with photographic slides taken from the object depicted; selections of music in the intervals between the fectures by Mrs. Frank Cooksey, who kindly and ably presided at the pianoforte; comestibles, nearly all containing honey in some shape or form; and though we did not go the length of sweetening our tea and coffee with honey, we certainly enjoyed the delicious honey ices Mrs. Curry regaled us with. Miss Darvill, of Reading, had a fine display of sweets and sweetmeats, many of them containing honey. Mr. Blow's hive was considered a great advance on the Jones-Heddon for our climate and style of wintering, though the general opinion of the meeting, as far as I could gather by remarks passed by practical bee-keepers, was decidedly in favour of the English Combination Hive, which has been proved to be adapted to the requirements of the bees, as also of bee-masters for every style of supering either for extracted or comb honey, and the consensus of opinion on the 'Jones-Heddon' hive was to go slowly with it. Altogether a very pleasant and profitable evening was spent, and great credit is due to Mrs. Curry for the admirable way in which she superintended the affair from the beginning.—Your Correspondent.

OUR HONEY IMPORTS.

The value of honey imported into the United Kingdom during the month of January 1887 amounted to 7:30%. [From a return furnished by the Statistic Department, H.M. Customs, to E. H. Bellairs, Wingfield House, near Christehurch.

WHEN DOCTORS DIFFER WHO SHALL DECIDE?

[837.] Mr. Simmins, in his description of his very ingeniously contrived 'Universal Hive,' says: 'This hive has had three years of careful consideration, because I had found the standard frame (14 by 81 inches) decidedly inferior to larger frames I had formerly used. After various experiences, a frame I4 by 14 has been found the most appropriate, all things considered, as it enables a stock to build up more rapidly in early spring and gives greater security in winter, as the stores are arranged in the best possible position in relation to the cluster. Mr. Simmins says, 'As a single frame the present standard is too

small; as a storifying frame it is too large.

Mr. Cowan does not consider the standard frame too large for storifying, for, in his useful little pamphlet, Doubling and Storifying, he illustrates three or four hives high having standard frames, and tells us how large quantities of extracted honey can be obtained by stori-

fying with these hives.

Mr. Broughton Carr advocates the use of the Carr-Stewarton-size hive somewhat modified, having a frame 14 by $5\frac{1}{2}$, three inches less in depth than the standard. It is illustrated, and his management is fully described in the Bec-keeper's Record of January last. Mr. Broughton Carr is an old and advanced bee-keeper, and we have recently had an opportunity of witnessing the success of his system of management in the beautiful honey he exhibited in the county competition at South Kensington, and also of seeing the small frames of combs from which

the honey had been extracted.

Dr. Tinker, an advanced American bee-keeper, has given up the 'Gallup frame,' which is $11\frac{1}{4}$ by $11\frac{1}{4}$, and has adopted a shallower and longer frame, $9\frac{1}{5}$ deep by 143 wide. He says:—'I had abandoned side storing, and with that the "Gallup frame," as it did not present enough surplus room on the top of ten frames to correspond with the large amount of brood-comb below. The other objection was in the distance that the frame had to be lifted to get it out of the hive. The greater facility in lifting out a shallow frame will not be fully realised by any one till they try one by the side of a deep frame.' If this is felt in a difference of depth of $9\frac{1}{8}$ and $11\frac{1}{4}$ inches, how much more will it in the case of the standard 83, and Mr. Simmins' frame, 14 inches!

The reasons above given by Mr. Simmins for the necessity of changing from the standard to a much larger frame do not appear to me to be sufficiently conclusive to render such a change desirable. I have never had any difficulty in wintering stocks and building them up in spring, if they have not been robbed too much and have had ample natural stores to earry them through, and have not been disturbed during the winter. These stores would be in the 'best possible position,' the upper part of the comb in the standard frame as in the larger 14 by 14 frame; and if the hive has been properly prepared and contracted in the autumn, so that the bees have only just as many frames of comb as they can cover, with winter passages cut through them, a good queen and a dry hive, there should be no difficulty. The 'rapidly building up—in both cases, I presume—is done by judicious stimulative feeding and spreading the brood from time to time, as the bees hatch out to cover the combs and become erowded. If this system is correct I fail to see the advantage the larger frame has over the standard.

A hive containing ten standard frames, taking outside measurement of the two breeding surfaces of each frame, equals 2380 superficial inches; whereas a hive of six frames I4 by 14 equals 2352 inches, only 28 inches of surface less than the ten standard frames. Those who work for comb honey frequently reduce the breedingspace to nine and even eight standard frames. Taking the superficial area of the top of frames on which to place supers, we have in the case of the ten standard frames 217 inches, which would take the ordinary crate of twenty-one sections. In the case of the six large frames of Mr. Simmins, only fourteen sections could be placed without projecting beyond the area of these frames. I am aware that Mr. Simmins has had great experience with bees, although I do not recollect seeing his name as a large exhibitor of honey at any of our principal exhibitions. Perhaps he can tell your readers the amount of honey he has taken from hives having 14 by 14 frames, and the number used in each storey. The standard frame is now almost universally used in England; and, depend upon it, if the seasons are pro-

pitious, the management judicious, and the bres are not over-manipulated, as much honey will be obtained in a well-constructed hive with standard frames as in any other yet invented. I have been induced to make these few remarks knowing that there are a few-and I believe only a few-who would like another size frame adopted.—Joнх M. Hooker.

FOREIGN BEES.

[838.] The very important question as to the superiority, or otherwise, of foreign bees and their suitability to our climate, is one that can only be decided, I think, by experience; and that not of one or two bee-keepers merely, but of many in different parts of the country. Will you, therefore, grant me a little space in which to relate my own experience, premising that though I am not a beekeeper on a large seale-my stock rarely exceeding thirty hives at one time-yet I have for many years given very eareful attention to the subject, and know as much about it, perhaps, as most people?

My first Ligurian queen was purchased several years ago of Messrs. Edey, of St. Neots, and she was certainly all I expected her to be—gentle, handsome, and extremely prolific; and her progeny for several generations have retained their good qualities, and though, of course, crossed with the common black bee, were never especially fierce or unmanageable. I have some of this strain now, as good bees as one need have, but on the whole I have not found them better honey-gatherers than the native blacks, as they waste their energies in working and

breeding at unprofitable times.

I afterwards bought two queens, so-called Ligurians, of one of the most noted dealers-I won't now mention names-very handsome bees-one especially was of a lovely gold colour. But neither was so prolific as a common native queen. The progeny proved idle and fierce, and the next generation so bad every way, and especially so savage, that I was most thankful to root them all out and re-queen with anything I could get.

Last year I resolved to try Carniolans, having heard so much of their gentleness. So I applied early in the year to what I thought was the hest source of supply for a queen of undoubted purity and good quality, and one was sent me in due course. Imagine my disappointment at finding her bees about as difficult to handle as Cyprians! And I have since heard from the importer that it is very possible she is merely a hybrid. This is very satisfactory as an explanation, but it hardly consoles one for the loss of a season and the full price of a best queen.

I may add that my so-called Carniolan is extremely prolifie, and so also are two queens that I reared from her last autumn, all three have wintered well. All this goes to show that one may possibly get a good foreign bee. But in the present uncertainty as to quality, it is safer to stick to those of one's own rearing, as showing the difference between the two

races.

I may say that, at the present time—end of February in my own apiary all the bees of foreign extraction have brood in all stages, but the black stocks have not yet commenced to breed so far as I can tell. This is a cold situation on the Derbyshire hills. - George SHIPTON.

CANADIAN HIVES—CYPRIANS—CHAPMAN HONEY PLANT.

[839.] On p. 605 of last volume of B.B.J. appears a letter from Mr. C. N. Abbott, in which he says: 'A young friend lately arrived at Ontario; in his first letter to me, after having settled down, Nov. 20th, 1886, writes "A few days past I was at a show at Caledonia, but did not see any bees and hives (frame-hives) such as you have at Southall. The hives were very funnylooking objects, something like those of twenty years ago." These are but a few words, but to my mind they let in a deal of light on a big subject, as they show that the principles sought to be thrust upon English bee-keepers by our late Canadian visitors are not general in their own home counties, or surely at a large show there would have been a sufficient display of frame-hives, amongst the many, to have rendered the presence of ancient hives alone less remarkable, particularly to a young man who is not, and never has been, a beekeeper.'

Now I am not going to dispute the statement that there were funny-looking hives without frames at the show referred to—it is just possible that such was the case. We have in Ontario, as well as you have in England, eccentric people that do funny things, but the fact remains undisturbed that moveable frame-hives are not only generally, but universally, used by professional

bee-keepers.

That last-quoted remark, 'particularly to a young man who has not, and never has been, a bee-keeper, are but a few words, but to my mind they let in a deal of light.' It occurs to me that in all probability the young friend was looking at butter-firkins, washing-machines, or some other wooden ware. Such mistakes often occur. If Caledonia had a large show it was only so comparatively, for it is but a small place indeed.

I guess the most of us will agree that Mr. Abbott is about right about the stinging qualities of Cyprian bees; but is it not more than a year or two ago since

they were brought to England and Canada?

I feel quite sure that we all owe a vote of thanks to Mr. Abbott for the opportune warning he has given about the so-called Chapman honey-plant. The Committee appointed by the North American Bee-keepers' Association to report upon said plant ascribe to it all the characteristics of a much-to-be-dreaded noxious weed. They report that it is perennial, seeds itself, is a strong growing plant, will root out all other vegetation, and, I learn from another source, that stocks will not eat it. Now I submit that any plant answering to the above description must necessarily be a noxious weed, and yet the said Committee think there is no danger. What more could be said of sour-dock, ox-eye daisy, ragweed, pigeon-weed, Canada thistle, and many more troublesome weeds? I sincerely hope that those who contemplate buying or selling and scattering noxious weeds will think fairly before acting. Surely the farmer has enough to contend with already, and we bee-keepers should think a second time, and honestly too, before adding anything more to his already too heavy burden. -S. T. Pettit, Belmont, Ontario, Canada, January 25.

P.S.—I have just returned from a visiting trip through Kent, Essex, and Lambton, and find that those who winter out-doors begin to complain of too steady cold weather. We have just had a big thaw, but the weather was unsuitable for the bees to get a good flight. Most of us begin to think that in-door wintering is the only

safe way here.—S. T. P.

A BEEMAN'S TRIP TO AMERICA.

(Continued from page 7.)

MR. A. I. ROOT'S ESTABLISHMENT.

[840.] In my last I promised to give an account of my visit to Mr. Root at Medina, feeling sure that an account of the largest bee-keepers' supply in the world could not be without interest to your readers.

Although I reached Medina some time after working hours I found Mr. Root still busy in the office. The motto of the establishment is evidently 'By industry shall ye thrive,' for there was no encouragement either by example or precept for idlers. A ready welcome was accorded me, and the next few days were most

enjoyably spent in exploring the different departments and discussing the merits of the various processes. The little picture is a fair one of the factory as it was a few years ago, but it is now about double as large, and the substantial way in which it is built plainly shows the owner's confidence in the future of bee-keeping. The

first object of interest was a new engine of ninety horsepower and most improved construction, which had just displaced a smaller one and which was separated by a stout fire-proof wall from the wood-working department.

In this shop were machines for making nearly every wooden article that a bee-keeper could require. Two planers, half-a-dozen machines for different parts of section-making, a borer, and many saw-benches of different patterns were to be found amongst the number, and others were being fitted up, this shop being all new

and not yet in full swing.

A capital feature in this department was a system of big tin tubes which, being connected at one end with the furnace, and at the extremities with each machine, and being also in connexion with a centrifugal fan, carried away all sawdust and chips and put them right into the fire. Besides saving sweeping and stoking, the purity of the air, which this ensured, added greatly to the comfort of the workmen. Above this department were the paint and tin shops where there was every facility for turning out extractors, smokers, &c. In the base of the older building I found the engineers' shop, where skilled hands were fitting up saw-spindles, foundation-mills, &c.

The arrangements for cutting the rolls of the latter were most ingenious, but too complicated for description. There were also a machine for perforating zinc and one for grinding plane irons, the advantages of doing all possible work at home being fully recognised. idea was so thoroughly carried out, that not only was all the printing and bookbinding done on the premises, but there was even a machine for making envelopes. I will not tire you with details of my visits to the packing, printing, book-keeping, or similar departments, but after having refreshed at the 'lunch-room,' will pass on to the 'counter-store.' This is a feature which is greatly appreciated by bee-keepers living at a distance from towns, as the stock consists of hundreds of articles of domestic use, which such customers find it very convenient to order with their bee-goods, as the prices of all things are moderate, and their utility can be relied on. Of course one of the first pleasures of the visit was an introduction to Mr. Root's son, Ernest, to whom I am indebted for most of my information. The bees were naturally in winter quarters, so I could not see much of them. In the foundation-room there was also not much to be seen as most folks like their comb freshly made. Mr. Root's ideas on bee-keeping are so ably and frequently given in his Gleanings and in his A B C of Bee-culture, that any remarks on them would be tedious; but I would strongly advise all bee-keepers who have not seen the latter book to order it at once of their supply dealer as it is full of interesting matter of all sorts.—J. A. Arbott, Southall, February 1887.

INVERTIBLE HIVES AND HOW I USE THEM.

[841.] Will you allow me a small space in your Journal to say what hives I use and how I use them? Some seem to want some information on the plan. But, first, let me say to W. Soar that his cap won't fit, so he must please wear it himself or try it on some one else. I am not a hive-manufacturer, or have I any connexions with any, although I make my own hives and appliances, and look after my 200 stocks myself, so that W. S. need not be afraid of my grinding my axe at his expense, or at any cottager's; and had I seen Blow's British Heddon hive I should have given the same advice for cottagers to use it as I did the Jones Heddon. I have not seen what the thickness is to be of the imported hive. Has anybody told W. S. that it is to be the same as the one exhibited? I quite agree that it wants an outer case,—that I always use; so I believe you do, Mr. Editor, and I think there's no hive to equal it. And now to my mode of working. In 1885 I made up my mind to invert some hives, and the first were four straw skeps: that was an easy matter, as I had some straw skeps with cheese-boxes over them. This was done for the convenience of supering and feeding, as I had a hole in the top of the hive and the bottom of the cheese-box. Now, any cottager can manage this job, and the time to turn them is when the bees are ready to swarm and the flow of honey coming in. I use them in an outer case, and all is kept snug out of wind and rain. As I could not see what was going on in straw skeps, I thought I would try some bar-frame hives for that purpose. I made a few tenbar hives, rabbeting the sides double the proper depth, so that the tops of the bars were free from the floor-board when upside down. The frames had a bit of wood nailed to each corner, so they could be all wedged up tight together; these were inverted in outer cases. I examined the combs for brood and eggs before inverting, and four days after found eggs hatched out and brood going on all right. I have sent one of my frames to you. W. Soar might call on you and see it. - DEVONSHIRE Dumpling.

PHYSIOLOGICAL QUERIES, ETC. [824.]

[842.] 'Devonshire Dumpling' appears unable to see with his own eyes, as I have never said, 'I am making a hive like the Jones-Heddon.' One may well express astonishment at 'D.D.'s' advice repeated to cottagers, to try the invertible hives. To such bee-keepers I see no single point that can be recommended. Why, even its inventor has sent out a disclaimer of its supposed advantages (see 8I4), heralded into the world with a great flourish two seasons back; and thus it appears it is being rapidly modified out of existence in the land of its birth. No, 'D. D.', my definition of a suitable hive for cottage bee-keepers would be very far removed from such an expensive, purely experimental, and confessedly untried system—as far as this country is concerned—as the invertible plan.

There are others asking for particulars of 'D. D.'s' experience in inverting; and to say that the facts given bearing on this question are meagre is putting it too favourably—it amounts to nil. But instead, like a drowning man catching at a straw, 'D. D.' wants to know if 'I have had experience.' The question is quite unnecessary, as I started the discussion with an implied admission of having no experience, and I venture to say that not one bee-keeper in a hundred knows anything

about the matter from experience.

Where do we get our facts from? Why, Mr. Heddon himself has been honest enough to admit (and all will respect him the more) that, with one exception, the conclusions he arrived at in 1885 are erroneous, and this exception of inverting once only (brood-combs alone) to secure the complete filling of the frames is more than

likely to be accomplished without the necessity of inverting at all.—James Lee, Feb. 19.

THE NEW APIFUGE.

[843.] A few weeks ago I gave you a somewhat prosy statement of my views on a new compound, calculated to conciliate

'Our dear little friends, with the nimble tails,'

and I should not have troubled the fraternity further on the subject, had I not then stated that I was in treaty with a manufacturing chemist for its production, and that I would continue my experiments of last year (stopped, of course, by winter), as to its efficacy, at the

same time promising to report results.

I have now the highest pleasure in informing you that, after a slow and tedious process, success has been reached to a degree far beyond even my hope. I have, however, had to modify and alter my formula considerably, in order to make the apifuge a complete success. On Saturday last, I manipulated two hives, at 70° in the sun, and noticed this peculiarity about the bees on the approach of my hands:—They seemed charmed, and subsided amongst the frames, as boiling water subsides on the introduction of a spoon. A twelve-year old youth moved his fingers in the porch, to force the bees to crawl in and out through them during a vigorous cleansing flight; there was not a soupçon of a sting. I may say that another substance recommended for the same purpose as mine is so difficult to obtain in a pure state, and therefore of a sufficient strength to be useful, that I concentrated my attention on the production of a compound of such an exact undiluted strength that it can be taken into, and used in the apiary, with as much, and more confidence, than the best gloves. I needn't say that it is the *exact dose* in medicine which is beneficial. So with the apifuge. As I could not distribute it adequately, I have placed the sole agency in the hands of Abbott Bros., Southall.—R. A. H. Grimshaw, Cray Hill, Horsforth, near Leeds.

BEE-CONCILIATORS.

[844.] I am surprised that no one has protested against the use of apif-oh! I forgot, I must not use the t awful word; Mr. Abbott says it is 'Copyright' and Mr. Grimshaw tells me it is 'Registered,' so there is no knowing what pains and penalties are involved in the use of it—say 'anti-sting.' There is nothing which so impresses the spectators at a show as the unconcern with which the manipulators and the judges and others within the vail stand surrounded by bees and without getting stung. A common remark is that they must use something repugnant to bees. Hitherto this insimuation could be repelled, and the reply truly made that nothing was required but coolness and care. Alas! in future, when the subtle and peculiar odour of methyl salicylate pervades the tent, the soft impeachment can no longer be denied, and the charm attending the cool, careful manipulation of an expert will be gone. I well remember my first visit to Mr. Abbott in his little garden at Hauwell, where I, a perfect novice, stood quite unprotected while he opened hive after hive, lifted out frames, and, to my great delight, allowed me to do the same. There is nothing which tends to promote neat and careful handling of bees so much as the absence of protection and the full knowledge that carelessness and jarring will at once bring their punishment, and on the contrary, the use of anything which gives the operator a feeling that however careless he may be he cannot suffer for it, can only lead to a slovenly, slap-dash method. If the use of substances to prevent stings should come into general use the effect upon the rising generation of bee-keepers can but he to render them very unworthy successors of the present skilful manipulators.—F. Lyon.

NOTICES TO CORRESPONDENTS & INQUIRERS.

All queries forwarded will be attended to, and those only of personal interest will be answered in this column.

interest will be answered in this column.

Letters or queries asking for addresses of manufacturers or correspondents, or where appliances can be purchased, or replies giving such information, can only be inserted as advertisements. The space devoted to letters, queries, and replies, is meant for the general good of beckeepers, and not for advertisements. We wish our Correspondents to bear in mind that, as it is necessary for us to go to press in advance of the date of issue, queries cannot always be replied to in the issue immediately following the receipt of their communication.

- FAR NORTH.—1. Enamel cloth.—Glazed side next the bees.
 2. Uncapping.—Uncap a few cells of honey, occasionally, above the cluster of bees, or near to it. This may be done without removing the frames by using a little smoke or carbolic acid solution. If the outer combs contain granulated boney it is best to remove them, and to feed on syrup, otherwise let them remain. Uncapping, as advised above, is sufficiently stimulating without giving syrup.
- Rector.—1. Late Autumn Plants.—Batches of bee-flowers, such as borage, mignonette, phacelia, the sunflower tribes, and others, may be sown late in the season to produce autumnal blooms, but no appreciable amount of honey is ever obtained from garden plants, except in market-gardening and flower-seed-growing districts. Second crops of red clover and crops of buckwheat are amongst the best for yielding honey towards autumn. Candytuft, stocks, and sweet peas, sown late, will also yield autumn bloom. 2. Feeding with Salicylic Acid.—Salicylic acid, when mixed with dry sugar, would not be taken by the bees. The only plan of administering it effectually is either in syrup or by fumigation.
- T. Nixon.-1. Tar for Hives.-Six pints of gas-tar, one pint Stockholm-tar, and one pint of spirit of turpentine, form a good varnish for outdoor work. The tar should be heated and well mixed, and the turpentine added when cooling. A good recipe also is the following;—One gallon of gas-tar, one ounce of nitric acid, half pint of spirit of turpentine. The acid to be mixed in gradually. This composition, which dries quickly and sets very hard, should be well brushed on, after the manner of paint, and not too thickly, and it will not melt or become sticky with the summer heat. 2. Placing a small above a larger Hive .- By the plan you propose you would find great difficulty in removing the upper hive when filled, since brace combs would be built between the two hives. A much better plan is to put the large hive below the small one—covering up with strips of carpet and boards any parts which project beyond the upper and smaller hive-and to allow the bees to work down into it. Fill the frames of the lower hive with foundation, which will greatly expedite matters. No board is required between the two hives.
- H. W. D.-1. Members of County Associations,—Members of County Associations are entitled and invited to attend the quarterly and annual meetings of the B. B. K. A., but have not the right of voting; neither have their elected representatives this right. A subscription of five shillings per annum constitutes membership, and confers the right of voting on any question brought before the abovenamed meetings, and also gives one vote for each member at the annual election of the Committee of the Association. 2. Separators.—Tin separators are in common use between sections. The tin used should be as thin and light as possible. Many advanced bee-keepers advocate thin wood separators. Either kind may be perforated as desired. 3. Preventing Queen entering upper Boxes. —In tiering up, whether for extracting or for obtaining comb-honey, we never use excluder-zinc. Bykeeping the brood-chamber sufficiently large and free from storage of honey, and by giving room beneath it, in the form of 'ekes' or shallow chambers, with sufficient bottom ventilation, the queen, as a rule, may be prevented from entering the upper boxes and from leading 4. Stocking an Observatory Hive.—A small swarm will be required for an observatory hive of four frames. We should prefer nice, straight, newly-built combs to giving foundation, but either may be used. Shake the bees on a sheet in front of the wedged-up hive and allow them to enter at the bottom. If it is simply

- a case of transferring, remove the bees, with their queen, combs, and broad from the ordinary to the observatory hive.
- HONEY DROP.—The dust of lump sugar will make useful syrup; it is desirable that it should be as free from dirt as possible.
- John Bull.—Gloves.—Be a true 'John Bull,' and do without them. They are great hindrances to manipulation, and when once stung they retain the smell of the poison, and invite further attacks. The best gloves are the two pairs of fine cotton texture, well wetted with water. The Rev. W. E. Burkitt could supply you with the special information you require; the gloves mentioned by him were leather gloves, manufactured by a dealer in High Street, Andover. Some gloves have recently been imported from the Continent made of American cloth; but they look clumsy, and would be found awkward and troublesome in working with them. Now that Grimshaw's Apifuge and Lyon's Sting-Preventer are before the public, we should be pleased to have some independent opinion of their value.
- H. P.—1. Dry Sugar Feeding.—Mr. Simmins recommends for this purpose Porto Rico sugar: that you have forwarded is a sample of sugar called 'pieces.' If presented to the bees they will utilise it, but you cannot expect that the result will be so beneficial as the using of that which the experience of practical bee-keepers has found most serviceable. 2. Fertile Worker.—There can be no doubt of the presence of a fertile worker in your hive; and in due time we shall be pleased to receive the results of your experiments as to the full development of the drones so produced.
- Bee-ologist. British Wild Bees. Monographia Apum Angliæ, by W. Kirby; British Bees, by Lieut, Shuckard, with illustrations; Apidæ—Bees, by F. Smith, Brit, Mus. The above books are out of print, but may occasionally be found on book-stalls. The most exhaustive and complete work on wild bees is Apidæ Europææ. This is being published in parts at the present time; as a book of reference it is invaluable, and the excellent illustrations it contains are a great help in determining species. This work comes out quarterly, and the annual subscription is fourteen marks.
- R. Young.—Scotch Hire Manufacturers.—We have no doubt that there are in the north of Scotland numcrous dealers in bee-appliances; but though very desirous of giving all possible and all proper information to our readers, we consider that it is more the duty of bee-keepers in that part of the kingdom to advertise their wares in our Journal, than that our Journal should advertise them. The Journal has a large and an increasing circulation in Scotland, and we suggest that purveyors of appliances in that part would find it to their advantage and profit to make use of our Journal towards the development of their business.
- Welsh Novice.—Directly you commence to increase your stocks you reduce your yield of honey. If we could absolutely have the entire control of their swarming, we should—in order to get the greatest yield of honey—prevent such entirely, but this, up to the present, being an impossibility, we should manipulate our stocks that from those who show the greatest swarming proclivities, make our artificial swarms, and rear the queens from those who have the best storing qualities, not forgetting to rear the drones also from such stocks. You will usually find those two latter qualities go hand in hand.
- TMFFY.—1. Soft Warm Candy.—This is simply candy, made either by boiling and stirring while cooling or by kneading finely ground sugar in honey to the consistence of dough, warmed to about 80° before giving it to the bees. 2. Enamel Cloth is that used for chair-covers but without the imitation leather grain upon it. 3. Bees in Confinement.—Having kept your bees confined by perforated zine and fed (?) them with syrup during the winter, the wonder is, not that four lots are dead but that the other four are alive. Release the others at once and give them soft candy if they require food. 4. Location of hives.—You had better replace them on their stands as last year. Another winter leave them alone instead of moving them into a shed. 5. Erica vulgaris.

- J. G.—It is always a very delicate matter to interfere with the decisions of judges. These judges are not appointed to their arduous and often thankless position without much anxious thought. It would appear from your statement, and the subsequent act of the Committee, that in the instance mentioned the judge might have erred; but before saying that he had so done it would be just on our part to remember the advice, Andi alteram partem.
- H. C.—1. Dust thrown out by the bees.—The sample you send is simply the cappings removed from sealed honey in order to get at the contents of the cells, just as one throws away the cover of a pot of preserves. 2. Bec-tent at Horticultural Show.—You had better write to the Hon. Secretaries of the counties named, and arrange for the tent to be sent to your local show.
- C. Fox.-Whether you can make bee-keeping pay depends in a great measure upon yourself and the locality in which you are situated. You must not expect, if you purchase a few hives and give them no further attention, that you will make a living. We should advise you to get one or two hives only to begin with, and when you are able to manage them properly to go in for more. In this way you may be better able to judge whether you are fitted to undertake bee-keeping on a large scale. The Heddon hive is not suited to this climate, and if you wish to use it, you must have an outer covering for winter. We advise you not to go in largely for these hives until we have had some reports of their success in England. A simple hive with Standard frames is all you need for storifying. We did not find the shallow frames a success for this purpose. If you will say what other questions you wish answered, we shall be pleased to give you all the belp we can.

Received from Mr. Alfred Rusbridge, The Apiary, Sidlesham, Chichester, for the library of the British Bee-keepers' Association a copy of the Tidsskrift for Biavl, or the Danish Bee Journal for the year 1886. It contains a translation of Mr. Rusbridge's book on bee-keeping. In comparing the translation with the original many words appear very similar in sound, although the characters differ. H. R. H. the Princess of Wales has been pleased to accept a copy of both. In the Tidsskrift we notice a description of Mr. Cowan's hive with illustrations, articles on bumping, and translations from the British Bee Journal.

Show Announcements.

Giving Name and Address of Secretary, Date and Place of Show, Date of Closing Entries. Terms: Three Insertions and under, Two Shillings and Sixpence; additional insertions, Sixpence each. No charge made to those Associations whose Shows are announced in our general Advertising Columns.

July 11–15.—Royal Agricultural Show at Newcastle-on-Tyne. Entries close May 12. J. Huckle, Kings Langley.

August 3-5.—Yorkshire Agricultural Society at York, Secretary, H. L. Rickards, Poole, near Leeds.

Business Birectory.

For the use of Manufacturers and Purchasers of Bee-

keeping Appliances.

The Name and Address and Business of any Manufacturer will be inserted in this List, under one heading, for One Pound per annum. Additional headings, Five Shillings extra. Advertisers in 'The Bee Jounnal,' whose orders amount to Five Pounds per annum, will be inserted Free.

Carriage not paid. A Queen arriving dead, if returned at once, will be replaced without charge. Terms, Cash. Be particular to give the exact Address and Name of the Station. Queens rearied by selection. Five per cent discount on an order for 10 Queens or Colonies at a time; 10 per cent if 20 Queens are ordered; 15 per cent on 50; and 20 per cent on 100 Queens or Colonies ordered at one time. Write, if possible, in French or German. We have been acknowledged as the sole successors of the late A. Mona by the official Federal Gazette. See notice in British Bee Journal (page 424 of 9th Sept. 1886).

MANIPULATE WITHOUT SMOKE!

WEBSTER'S FUMIGATOR

Entirely supersedes the Smoker, both in Simplicity and Effectiveness. No 'going out.' No tainting or soiling of combs. Always ready for use without any preparation. Can be carried in the pocket.

With Bellows, 4s. 6d.; postage, 4½d. Without Bellows, 3s.; postage, 3d.

Can be adjusted to any ordinary smoker bellows.

6 oz. Bottles of Agent—carbolic acid, oil of tar, and water, properly mixed—6d. each.

WEBSTER'S SWIVEL FRAME - LIFTER

WILL BE READY SHORTLY.

With this appliance, frames can be removed from hive, replaced and examined on both sides without inverting, with one hand, leaving the other free for manipulating, at the same time preventing soiling the hands with propolis.

W. B. WEBSTER,

SOLE MANUFACTURER AND INVENTOR, WOKINGHAM, BERKS.

AWARDS FOR FUMIGATORS LAST SEASON.

1st Prize Silver Medal, Royal Counties' Agricultural Show. Highest Award, Colonial and Indian Exhibition, London. 2nd Prize Bronze Medal, Colonial and Indian Exhibition, London.

2nd Prize Altrincham, Lancashire and Cheshire B. K. A.

LYON'S Patent METAL ENDS.

THE only perfect pattern. The metal being flush with the inside of the Hive side, CANNOT BE FIXED TO IT BY PROPOLIS. All the so-called Improvements CAN.

The Special Alloy used allows them to be LIGHT YET STRONG. One gross weighs $5\frac{1}{4}$ lbs.

Price for 1887 5 6 per gross.

DR. PINE'S VEILS.

Prize Medal, 1879, for the best Bee Dress, The only Medal ever awarded to a Veil, **2**/**2** each, post free. Every genuine Veil bears the Registered Trade Mark.

DR. PINE'S LOTION.

The ONLY CURE for Stings, 1/8 per bottle, post free.

CHESHIRE CURE.

Guaranteed, with Directions, 1/2 per bottle, post free.

Methyl Salicylate, or 'Sting Preventer.'

HIVE MAKERS supplied with SPRINGS, GLASSES for Sections, PHENOL, METHYL SALICYLATE, in bulk, &c., &c., at lowest prices.

F. LYON, 94 Harleyford Rd., London, S.E.

TO DEALERS.

CEND to A. F. HUTCHINGS for quotations of AMERICAN WHITE BASSWOOD ONE-PIECE SECTIONS of the finest manufacture and quality, 300,000 will shortly be on hand. Special terms for all Orders before March 25. Don't fail to get my prices before you Order elsewhere! Address, West Kent Steam Power Hive Works, St. Mary Cray, Kent.

SUGGESTIONS FOR SCHEDULES,

The time is drawing near when the committees of the various Associations will be taking into consideration the task of drawing up their various schedules for the regulation of their annual shows, and it may not be considered inopportune to throw out a few suggestions or hints which may be of some assistance to them in this duty. Bee-keeping cannot now be considered to be in its infancy; it has been developing in experience for some years; the lessons of the past should not be lost upon us, and we are all desirous that our apicultural system should be approximating the goal of perfection. Admittedly there are still before us many debateable points. We are not all in agreement respecting the highest points in judging either hives or honey. In time these differences may possibly be adjusted, and these points solved. It would be an advance in that direction if, as suggested at the last annual meeting, the Committee of the B.B.K.A, could see their way to draw up some simple rules for judging, which from such a quarter would be sure to find acceptance with the several affiliated Associations.

During the past year discussions have arisen in our *Journal* which have proved of the greatest utility, and viewing these with an editorial eye, it may be allowable while the committee of the B.B.K.A. are pondering over the above matter to throw out a few hints pro bono publico.

The little contretemps at the Indian and Colonial Exhibition was not without its benefits. The county competition was an experiment which in its results more than surpassed the most sanguine expectations of its promoters. It was difficult—it having been a first endeavour—to know how the scheme would work, and therefore it cannot be wondered at that all was not right, that the judges' work was not the acme of perfection. It has simply shown us, as might have been anticipated, that on a future occasion a few slight alterations will be necessary in the details to render such an exhibition more complete.

Turning to the last annual meeting, Mr. Burkitt's resolution will have its results. We feel sure that gentleman had no desire to throw more work on the officers of Associations; he may have had in his

mind's eye cases which have come under his own notice, where there has been a long list of rules, and the judges have received copies just as they were beginning their arduous duties, without time being allowed to grasp some of the more minute details. To overcome this difficulty, let us suggest that it would be wise if secretaries were to forward to the judges a copy of the rules a few days prior to the show, so that they could make themselves thoughtfully and thoroughly acquainted with them.

Another point which occurs to us relates to Rules for judging, suggestions for judges, &c., are all very well in their way; but, after all, it is able and experienced men that are required, men who know their subject, and are well up in it, men who are known to give their judgment to the best of their ability;—men in whose verdict all will be ready to acquiesce. Of late the cry has beenloud and urgent—that the B. B. K. A. should frame rules for judging, so that any one may undertake the duties of a judge. But unless such judges were able to give a reason for the decisions they may arrive at, there would still be much dissatisfaction. The result of a show is not merely for the present, it influences the direction of the work of the bee-keepers for the future season, therefore much necessarily depends on the confidence that can be placed in the opinions of the judge. We would say to the various associations, Follow the example of other societies, and obtain judges well qualified for their work.

Another suggestion, and we have done for the present. Offer, in future, medals for the encouragement of the production of wax and the use of honey in various forms. Comestibles of all kinds with honey as an ingredient are now numerous, we are glad to say. Honey in medicine is regaining its proper footing, and honey is being utilised in many other ways; and now, when considering what to do with our increased productions of honey, we would desire especially to direct the attention of committees to this matter. Don't forget to encourage all the utilities for honey; offer prizes for honey comestibles, honey medicines, and have a separate class which will cover anything worthy of commendation in which the products of the apiary are employed. By such encouragement fresh channels will be opened, larger quantities of honey will be disposed of; and need we say prices will improve, and bee-keeping considered one of the most profitable of industries?

ASSOCIATIONS.

GLOUCESTERSHIRE BEE-KEEPERS' ASSOCIATION.

This Association held its Annual Meeting on Thursday, February 24th, at Gloucester. Report was read showing increase of members, &c. Financial statement closed with a working balance in hands of treasurer. Permission was given for the formation of a Bristol district association under their enterprising local secretary, Mr. Appleton, which it is hoped will much assist in the better working of that portion of the county. Received with regret the resignation of the Hon. Secretary, the Rev. John Turner, Mr. Slade, of 12 Promenade Villas, Cheltenham, being appointed Hon. Secretary.

IRISH BEE-KEEPERS' ASSOCIATION.

The Annual General Meeting of the above Association was held on Thursday, February 24, at 2 p.m., in Dr. Traill's Class-room, 35 Trinity College, H. Chenevix, Esq., J.P., in the chair. Present—Miss E. E. Rutherford, Miss Violet Knight, Dr. J. Purser Allen, Messrs. J. M. Gillies, J. Edmondson (treasurer), C. F. Knight, J. K. Milner, Walter J. Stanford (hon. secretary), and M. II.

The following is an abstract of the report adopted: 'The heavy debt of 30% carried into last year's accounts from 1885 has, owing to the great liberality of a few gentlemen, been cleared off. The Committee made arrangements to send an exhibit of Irish honey to the British Bee-keepers' Show at South Kensington. Only four members, however, availed themselves of the facilities offered, owing to the extraordinary lateness of the season; and three exhibits of I-lb. sections, and two of 1-lb. bottles, were delivered at the show from Ireland, and with these five exhibits one second prize and two highly commended in a class of forty-two entries, and one highly commended in a class of thirty-eight, were secured; honours equivalent to 80 per cent of the Irish exhibit. The only appearances of the bee tent this year were at Dunadry, co. Antrim, on July 26th, and at the Giant's Causeway, Portrush, on July 27th. After much difficulty a honey market was at last started in Dublin for members of the Association in August. The committee were fortunate in securing the services of Messrs. Carton Brothers, 17 Halston Street, as agents, to whose untiring energies the success of the scheme is largely due. Fourteen different members sent up honey amounting to 1228 lbs., for which a total of 50t. 9s. 10d. was realised, or an average of 9.86d. per lh. Two conversaziones were held during the year, in June and November, which were well attended. Several interesting and instructive papers were read, and various other subjects of apiarian interest were freely discussed and appliances exhibited. The list of members now numbers eighty-three, of whom six are life members, and seventyseven annual, as against three life members and 106 annual in 1884, and four life members and sixty-three annual in 1885. It will be seen, therefore, that though there was a very heavy fall in 1884-1885, we are again on the rise slowly, having added sixteen to our test lesings lest year with transfer. total since last year, with twenty-eight new subscribers. Several new names have already been received for 1887. They also desire to bring under your notice that this past year the Government have for the first time included apiculture in their annual agricultural returns, thereby proving how important a part of the industry of the country it is considered. Ireland having taken the lead in this important matter it is much to be hoped that England and Scotland will very soon follow her example.

The financial statement shows that the income from annual subscriptions for 1886 amounted to 237. 11s. 6d., as against only 177, 9s, 6d, for the year 1885. Besides this there were special donations towards paying off the outstanding accounts of the Association amounting to 19t. 10s. and also 3t. 18s. Cd. from sundry sources, making a grand total of 471, 9s. Of this 121, 5s, 11d. was expended to meet the current expenses of the year, and 301. 0s. 3d. to pay off the Association's debts, leaving a balance in the treasurer's hands of 5l. 2s. 10d.

The following were elected to serve as officers for the ensuing year: —President, the Lord Ardilaun; Vice-presidents, the Rev. R. Bellew, W. J. Bramly, Esq., the Rev. Canon Proctor; hon. treasurer, J. Edmondson,

Esq.; hon. secretary, II. Chenevix, Esq., J.P.

A vote of thanks was accorded to Mr. Stanford for his services as hon, secretary during the past year, which

was duly acknowledged by that gentleman.

The committee for 1887 are,—the Rev. P. Kavanagh,
Messrs. Walter J. Stanford, J. K. Millner, Dr. Traill,
Messrs. M. H. Read, J. M. Gillies, C. F. Knight, R. Sproule, Dr. Allen, Dr. O'Farrell, J. S. B. Vanston, the Rev. T. Lindsay, Edward Byrne, J. P., John Jones, M.D., S. K. Twigg.

It was moved by Dr. Knight that steps be taken by the incoming committee to place the Association on a more representative basis by conferring powers on district branches to nominate a member or members for election on the general committee and by indicating clearly on the voting papers that such members had been so nominated. This was seconded by Mr. Gillies and passed.

It was moved by Dr. Knight that District Associations

be formed throughout Ireland.

Mr. Stanford objected to District Associations being formed at all at present on the grounds that the Irish Bee-keepers' Association itself was not strong enough to subdivide into smaller associations. He suggested that the matter should be allowed to drop for another year. Mr. Read said that local secretaries would meet the requirements of Irish bee-keepers at present. Mr. Chenevix was of the same opinion. After some discussion, therefore, the motion was withdrawn.

It was moved by Dr. Knight that steps be taken by the incoming committee to carry out the plan of the Cottiers' Fund. This should be done by some few members each sending a name of a suitable cottager in their neighbourhood for approval to the committee, who should select one or more of these names and supply them as funds permitted with the appliances neces-sary to start bee-keeping. The members who nominated the chosen ones to become responsible for repayment in easy instalments for the appliances furnished. This was seconded by Mr. Stanford and passed.

The meeting adjourned with a vote of thanks to the

Chairman.

Weight of full Bars of Comb before Slinging and AFTER. (STANDARD SIZE.)—I thought it might interest some readers of the Bee Journal to know this. Last year I weighed one box of ten bars, the top storey of a hive:

'GLOVES.'—A Suggestion.—Cut off the finger-ends of the gloves, if not quite prepared to manipulate without some protection, then if desirous of making doubly sure of being unharmed, a very small application of Grimshaw's 'Apifuge' ought to suffice.—C. A. J.

Correspondence.

The Editor does not hold himself responsible for the opinions expressed by his correspondents. No attention will be taken of anonymous communications, and correspondents are requested to write on one side of the paper only, and give their real names and addresses, not necessarily for publication, but as a guarantee of good faith. Illustrations should be drawn on separate pieces of paper.

Communications relating to the literary department, reports of Associations, Shows, Meetings, Echees, Queries, Books for Review, &c., must be addressed only to 'The Editor of the 'British Bee Johnal,' clo Messrs. Strangeways and Sons, Tower Street, Upper St. Martin's Lane, London, W.C. All business communications relating to Advertisements, &c., must be addressed to Mr. J. Huckle, King's Langley, Herts (see 2nd page of Advertisements).

***In order to facilitate reference, Correspondents, when speaking of any letter or query previously inserted, will oblige by mentioning the number of the letter, as well as the page on which it appears.

THE NEW RACES AND THE BEST MEANS OF INTER-BREEDING AND SECURING FERTILISATION.

Cyprians.

[845.] The recent statements of Mr. F. Benton in reference to these bees will have interested many: but I do not see why he should fear that others may say he is actuated by interested motives. We all know that his motives are honourable, and if there is one man more capable than any other of forming a correct opinion of these bees it is himself. I believe that, as a rule, beedealers, as well as manufacturers, recommend an article because they honestly believe it to be of value, and I would ask, Who is there better able to judge correctly than those who provide for the many? I know that there are others who hold their peace, fearing they will be unsidered 'interested'; but, friends, if your opinion is worth anything at all, by all means let us have it. The majority will believe in your sincerity. Time proves all things, and truth will prevail.

I am afraid Mr. Benton has not had the recompense he deserves for all the trouble and expense he has been at in bringing the new races more prominently before the public, and placing Cyprians in particular more within reach of those who can afford to pay for them. The price has been high—too high to enable bee-keepers generally to adopt them; but I feel certain, could he but see his way clear to make a considerable reduction from his charges,

the demand would be so much greater as to fully repay

The reports regarding the temper of Cyprians have been so conflicting it cannot be wondered at that so much uncertainty exists in regard to them. The bad opinion, as expressed by some, results from one of two causes; either through careless handling, or the beekeeper has hybrids, which he persists in calling 'Cyprian's.' If we speak of Cyprians, once and for all, let it be understood that we mean what we say. Cyprians are not hybrids, and hybrids are not pure Cyprians. This seems plain enough, but, strange to say, a well-known writer in another journal speaks of the doings of his Cyprians: but he tells us they are descended from a queen he had ten years since. I wonder how much Cyprian blood there is in those bees at this day? I have no doubt his bees were benefited by the introduction of Cyprian blood at that time, and I am certain are the better for it now, but why call them 'Cyprians,' after being crossed and re-crossed as hybrids through several generations? Again, a noted Scotch bee-keeper has strongly condemned 'Cyprians,' though at the same time showing good results from them; but in private conversation he has informed me that he had never been stung by the pure bees, but the hybrids were hard to deal with.

The Rev. G. Raynor has had a lengthened experience with these bees, and continues to speak well of them; but I believe he has had some trouble with dysentery. It would be interesting, therefore, if that veteran beekeeper could give us a little information as to the hive he uses for wintering; and how the frames, &c., are

arranged.

We have heard of the grand results gained by that practical bee-keeper, Mr. Cowan, from his Cyprian (?) stocks. Now, I may be mistaken, but I have reason to believe that in his apiary it would have been the exception rather than the rule to find pure Cyprians; and if the Editor will kindly put us right, upon this point, it will be satisfactory to all, and particularly to myself, as I do want to get at the bottom of the whole question. Let us know only what are being called Cyprians, and what not; then we can clear away this mist overhanging that remarkable race.

Mr. Blow, of Welwyn, after all the the trouble and expense he was put to in bringing over many stocks, condemns them utterly. Though on one occasion it will be remembered he had to flee from the enraged bees without obtaining what he had bargained for, he says he had no difficulty in managing them abroad; but arrived here he could do nothing with them. His experience simply shows that it does not do to buy stocks indiscriminately. What is wanted is an established and permanent modern apiary in Cyprus, where year after year the disposition of the respective colonies may be tested, and breeding be carried on only from the most docile, of course having regard to working qualities as well. Another of our well-known bee-keepers has long since given Cyprians a bad name, but I am aware that hybrids resulting from indiscriminate mating had something to do with his verdict. It is within my knowledge that the same gentleman, not more than a year since, bought many stocks from an apiary where only hybrid Cyprians are kept, and in hives with frames so propolised that the average bee-keeper would hesitate before at-tempting to remove one. I had some of the same, and all were transferred to new frames, while with one or two exceptions they were as peaceable as Ligurians. Those that did sting were no worse than a Ligurian hybrid stock, from which I removed the queen because of their vicious nature.

I have had many pure Cyprians, and not one stock but what could be handled without smoke at any time of the day, dull days or fine days, in season or out of season, without receiving a single sting. They rest more quietly upon the combs under manipulation than any other bees I have seen: they are the best of honeygatherers, exceedingly prolific, and under proper management give no trouble in swarming, while not the least of their good recommendations is their extreme beauty. Upon examining a hive of these bees, proceed

as follows:

1. Peel the quilt back with a firm but exceful motion, using no intimidant.

2. Wait a few seconds.

3. Make no hasty movement. 4. As with other bees, remove combs carefully.

5. In shaking them from the combs, as with any others, I never give a thorough shake to begin with. Give one or two gentle jerks, and then be as rough as you please.

Mr. Cheshire, than whom there is no more observant bee-keeper, will surely be credited. He considers that Cyprians are most amiable, judging from his own stocks, and having also examined those at my Rottingdean

apiary under varying conditions.

I have had Cyprians storing honey and breeding when Ligurians and common bees would be doing nothing; in fact, there never appears to be a time during the season when they cannot get a living. G. M. Doolitte, a well-known American writer, speaks well of their working qualities, and says what is quite true, that, unlike common bees, one may stand for hours by the

hive, and not one bee will attempt to sting. Unfortunately, his experience has been with one colony only, and, whether through wrong treatment or not, I cannot say, he condemus them as quite numanageable.

Mr. Heddon, another prominent apiarist in the States, condemns them without trial, and draws some very erroneous conclusions from the statements of others, who have had but one or two queens; and it is even open to

doubt whether such were pure.

Perhaps the worst failing Cyprians have is that they use a great deal of propolis, often of a very dark colour. Their cappings are thin, and lie close upon the honey, giving the same a dark, damp appearance, and therefore they are in both respects quite unsuitable for section work. They are also almost certain to start fertile workers, if by any means the queen is removed; but this appears to be no trouble, as such subside immediaely upon the introduction of another laying queen, while

there is no attempt to molest her.

It has been stated that they breed too late in the season, using up all their stores, and also that they winter badly: but this is entirely a fault of those making such statements. I have long since been told that Ligurians also disposed of their stores in like manner, but if the apiarist persists in giving them a small daily supply during the autumn, of course brood-rearing will be continued. Give them the whole of their winter stores, or the quantity necessary to complete such, in the course of two or three days, at the end of August, if you like, but never later than the latter part of September. Never mind if some brood is thrown out to accommodate it, so that every comb is almost solid with sealed food; then leave them alone; and I have yet to see the stock so treated which did not soon cease breeding entirely, finding nothing more was to be had.

With the more prolific races it does not do to commence slow feeding, even as early as the last of August, when a colony does not appear to have quite enough store to carry it through, as all will simply be wasted, and the strength of the stock as well. Let no one say I am wrong in advising the destruction of the brood in such cases. I have seen it done by the bees on their own account when storing naturally late in the season, sometimes as early as the middle of August, and nothing would induce such colonies to breed again until after the 'turn of days,' though headed by young and prolific queens, and in the following year giving a good account

of themselves.

Now, how about dysentery, or bad wintering qualities? Strange as it may appear to some of your readers, I have always found this more prevalent with double-walled hives, and where the frames run across the entrance. But too often there is hardly sufficient space for a bee to crawl under the frames; bees die and drop to the floor-board, get into a mass, and block up such a shallow space. A warm day comes, and the bees have all they can do to find the entrance, while many wander about in an excited state, soon to drop among the heap upon the floor, daubed by their own excrement and that of others, which should and would, under proper conditions, have been voided while upon the wing. The living do not, because they cannot, remove such a mass of corruption, which is being rapidly added to, because of insufficient ventilation and the foulness of the hive. The stronger the colony thus situated, the more certain and rapid is its destruction, unless the evil be remedied at an early stage. Hence we see why the more prolific races, being in larger numbers during winter, suffer from dysentery when improperly hived.

The too-small space under the frames is the rule, rather than the exception. I have on many occasions drawn attention to this matter, and have given a full half-inch as the space to allow when hives are first made, though in winter several inches would be better. The more room given there, the cleaner will be the floor;

better ventilation will be secured, and the health of the bees maintained in consequence, more particularly if the frames stand 'end on' to the entrance, facing the mid-day sun. Do this as I have done, and you will have no more complaints to give about the wintering qualities of Cyprians.

The beginner should on no account obtain Cyprians, as he is sure to get a mixed race which will give him trouble; but the man of average experience, who can in a measure direct the breeding department, will find the introduction of these bees of immense value, making his stock more substantial, and causing his returns to be more certain; as a cross with this race gives that equal and general good condition of stocks, hitherto found wanting in every apiary, large or small.

In future papers we will talk about those hybrids, and how to get in them all the good qualities of the Cyprians, without their faults, and without that stinging pro-

pensity characteristic of hybrids as generally known, and which, through careless observation or heedless expressions, have often been the cause of giving pure Cyprians a bad name.—S. SIMMINS.

[For two years we had twelve pure Cyprian stocks from imported queens purchased of reliable dealers, and should have had no difficulty in keeping the race pure to this day had we wished to do so. Of these queens we destroyed several the first season, because they did not satisfy us, and did not come up to our Italians, and these we replaced by others, some imported and some bred at home from selected stocks. From our experience of home-bred queens, we believe in them, and also that any one taking the trouble can secure pure fertilisation if he wishes. When we speak of Cyprians we also mean the pure race, and for two years pure Cyprians with us were the rule and not the exception. Our correspondent has had, we believe, considerable experience with these bees, therefore we are glad to find he does not differ from us as to their not being suitable for beginners; but we do differ from him most distinctly as to the reason. Why is a beginner sure to get a mixed race which will give him trouble? Does Mr. Simmins wish us to believe that Cyprian queens as imported and sold by our respectable dealers are a mixed race? Mr. Benton we know supplies Cyprians; does he mean that a beginner purchasing queens sent over by him would not get the pure race? Our experience is that pure Cyprians vary considerably in temperament, and that very bad-tempered bees may yet be perfectly pure. The experience of the leading bee-keepers confirms this. As Mr. Simmins has appealed to Mr. Cheshire's statements in support of his arguments, we would point out their value by showing that he also gave them a bad character; and if our readers will refer to the discussion on Mr. Blow's paper, on p. 29, Vol. x. British Bee Journal, they will find the following words of Mr. Cheshire's:— The third queen, which he got from the north of the island of Cyprus, raised bees of a dark colour. This last queen sent by Mr. Benton was going on fairly well. She was extremely small, her bees were small though bright. With regard to the tempers, the queen (the third in number that came into his possession) had raised bees that were not generally irritable, but if they were disturbed they were furious beyond expression. On one occasion when he transferred a swarm from one hive to the other, he was stung at least a hundred times during the operation, they were utterly uncontrollable; yet these bees pre-viously had been easily handled. Mr. Cheshire's considering Cyprians most amiable is so diametrically opposed to his own statements respecting their temper, that we have no doubt our readers will be able to reconcile them somehow. We have only to repeat what we have said over and over again, that Cyprians vary in temperament, and some better selection must be adopted before we can hope to have nothing but amiable bees,

THE REVERSIBLE SECTION RACK.

[846.] This section rack has been designed to minimise manipulation with the 1½" section, for when with a crate of these sections one full one has been taken off the hive, and when no separator had been in use, the remainder must be moved up so as to have sections filled out to the same extent opposite each other. With this rack the whole sections are filled in and the crate full comes off at one time wholly finished.

There is a second advantage gained by its use (this is connected with the open-sided $1\frac{\pi}{4}$ section); it is that the brood-nest can be contracted in the honey flow, the queen kept out of the sections without use of excluder zinc, and a full bee passage of a quarter of an inch allowed the bees to the sections, by which, and with plenty of room in the sections, it is expected the bees will be prevented from swarming, and that as much comb honey will be stored as would be in frames

worked for extracting.

The principle is very simple; it is applicable to all sections without or with separators of only same size as section with which they are employed; it is also applicable to all section-crates which are slightly wider than the sections contained in them. But the sectioncrate for which it has been especially designed is the Raynor-Benthall pattern, made a 1" wider than the open-sided section on each side, to allow of bee passage round, and prevent pop-holes through the combs. Eight $1_4^{3''}$ sections fit in the space of seven two-inch wide; these eight are divided into two equal portions, the sections in each of which are clamped together by four slips of angle tin covering the four corners, and clasped or bent down over the narrow part of end sections at both top and sides. The opening at top and bottom of these sections is $\frac{1}{16}$ or excluder zinc size, that at the sides a quarter of an inch wide. When these racks are first placed in the crate, the $\frac{1}{16}$ opening is down, and when the comb is drawn out and a little honey stored in the centre of crate, the two racks are reversed and the sections previously on the outside are now brought to the centre, and when a little honey is again stored in these, the racks are turned on their sides, and as the queen can now do no damage, a full 1" beespace passage is allowed to the bees to work in the sections. By means of these racks every section in the hive can be placed directly over the centre of the brood-nest, or within the width of a section of the centre, and it is about the centre of the hive the chief storage and sealing over is done. One of Mr. Simmins's separators with a half bee-space added at the corners at each side would be required at the centre, when the end sections had not been evenly drawn out, and at the ends a half bee-space of $\frac{a}{3}$ must be added to face of boards closing up, when they touch the sections. The ledges for the sections to rest on are rectangular tin tunnels, inverted sides $\frac{1}{4}$ deep, width $\frac{3}{4}$; these are tacked underneath to sides of crate, which are 41" deep, the onter side of crate being flush with side of tin tunnel.

If there are any advantages in inversion of section honey-comb, these racks seem to overcome the drawback to inversion of crates of them at one time, which drawback is that all the combs not being in the same state of development at same time, and in consequence it is difficult to know when to invert: Mr. Heddon seems inclined to find fault with inversion altogether on this account. With the racks there is no difficulty in securing the fitness of the comb and finding out the time for that purpose, shortly after the outside sections have been placed in the centre, the racks should be filled with sections of same standing, and fit for inversion. Should anyone interested in this crate or rack not thoroughly understand it I shall be most happy to explain everything required, and should a demand arise

for either rack or crates, I should place samples in the hands of a manufacturer and have them made in quantity.—W. B., Patrickswell, Limerick.

IN THE HUT.

' Where the bee sucks, There lurk I.'

[847.] I purpose, with your permission, to send you occasional notes, criticisms, suggestions, and hints on bee topics amongst the Horsforth bee-keepers, who I find are in the habit (like some kinds of bees) of resorting to secluded and solitary nooks, in which they may discuss their hobby free from the ken of the outside world. In such a nook is 'The Hut,' which I ought to try and describe to your readers, for, if I mistuke not, its seclusion, or at least the seclusion of its inmates, is fated to experience fierce assault 'in the coming by-and-by.'

(When people think

'A chiel's among 'em takin' notes, An' faith he'll prent it,'

it may be as bad for the chiel as for Stephenson's coo!)
Picture a sharply-sloping hillside in Airedale, well sheltered by woods of beech, birch, sycamore, and hazel on all sides but due south. A clearing of half an acre or so is utilised as a bee-garden (how much nicer bee-garden sounds than apiary!), and along the western side, under the protection of a hedge against that bête noir of black bees—the north-east wind, a row of hives is ranged. They are unlike 'the great Orion, sloping slowly to the west,' but resemble somewhat true orthodox Christians in sepulture in that they possess in their arrangements this relic of Paganism—on the re-awaking resurrection of early spring, they shall greet the great sun-god at his rising.

On the northern side of the clearing is a wooden hut, quite open on the south side, provided with a firmly fixed table, and canvas-covered, hay-stuffed seats, which at this season are highly charged with elements productive of rheumatism and hæmorrhoidal disturbance; so, like the objectionable dishes in Mark Twain's book, those seats are 'passed,' in favour of the table. Here, in the hut, midst bosky wood and mossy boulders, the calumet of peace is smoked, with perhaps a wandering Jew (W. J.) in perspective, probing about and pottering under stones for ants' nests, or else amusing the blue tits

with shot from his catapult.

High noon, an hour before, and one after, are marked by incisions cut in the table on the line of reflection east by a sharp-edged supporting pillar, and it is by the decisions of this homely sun-dial that adjournments are made. So you see all discussion is at present perforce standing, that is, when there are several subjects on foot, and frequent reference has to be made to the standing orders of the Association of which these happy bee-ists are members. Hearty jokes (artichokes, if you will) are anything but rare in this bee-garden, and are as freely taken as given. I do not, of course, impute to anyone the taking of 'what isn't his'n'; acting on the motto 'Honi soit qui mal y pense,' which, being freely translated and pronounced, meaneth 'Honey and soot killed Mally (local for Mary) Spence.'

In one debate as to the best material for smokers, a Hutite suggests that cigars are best, when obtainable, but for old hands an efficient substitute may be found in good tobacco. Seriously, chemists frequently get corrugated paper as packing for bottles, and most of them will obligingly hand it over to us. A better thing, however, is old cord trousers (cut into strips, and rolled the size of the smoke-chamber), those of juveniles being much relished and preferred, or abhorred, by the bees.

There is one thing, we *framewell* (Yorkshire dialect), to succeed with in this part—we use only one kind of frame—'Abbott's broad shoulders.' It has been found

so convenient, when a vagrant swarm has hived itself in a decoy, to trundle the lot home again at nightfall, paying the owner the cost of the hive. One can, besides, 'help a worn and weary brother,' with a frame or two of drawn-out foundation, when packing-up for the heather, and so on.

Moral:—Have as much uniformity as you can in forming district associations; the co-operative system of purchasing will then come into play.—X. Tractor.

THE ONE-AND-THREE-QUARTER SECTION.

[848.] It might not be amiss now that the time of preparation has come for securing the results of next honey season, to review the objections raised against the disuse of separators, and reconsider the claims of the 1³/₄ section as being the best for storage of its surplus

The disuse of separators is objected to,—Firstly, that

comb-honey.

without their use the comb is irregularly scaled over; secondly, too bulged for glazing; thirdly, that in packing for transit the combs frequently touch one another; and lastly, that in unpacking it is difficult to know which comb to take out first without eausing damage. It has been proved that 'perfectly level 1\(^2\) sections can be worked without separators.' (See Mr. Grimshaw's letter, No. 690, page 537, B.B.J. of last year.) This success, probably, was in a honey-glut, or good honey year, the indispensables of level hives and careful manipulation being also observed; but it is not to be expected that in a bad year or intermittent honey flow, when work has to be done piecemeal, that the same symmetry of proportion can be preserved by the bees; for such times, and to bring the 14 into general use, Mr. Simmins has invented a separator (and allowed me to call the attention of bee-keepers to it), that, while it allows of the same full appearance of the section, as if no separator had been used, ensures a perfectly even section—one fit for glazing and exhibition at all times. This is accomplished by thickening the corners of the separator at point of contact with the section the $\frac{3}{32}$ nds of an inch on each side, or faths of an inch, a full bee-space altogether. Thus the face of comb is brought within a half beespace of outer edge of section. But this separator is not recommended when it can possibly be done without, as it is found the comb-honey harvest is greatly increased where no separator had been used. With regard to bulging too much for glazing, this seems but to improve the appearance of the section should it occur, for we read of some of those worked without separators, that were at the Canadian Exhibition— better than which eyes need ne'er wish to look upon; too bulged for glazing, but all right for the fancy boxes.' With two tacks or small serews through the eardboard into the wood, the comb is kept at any required distance from the glass; and the cost of those boxes can compare favourably with glazing when the time occupied by the latter is taken into account. In packing in travelling crate, there is no danger of the combs touching one another, for if packed in them in the same way as they had been in the erate on hive, there must be a bee-space between each two combs; and in unpacking, were the erate made a little longer than the enclosed sections, and the same arrangement used as in that on hive-a board with wedge, or board alone to close up—there would be no difficulty, on removal of this board, in knowing which section to take out first. Why was it that, whereas in Canada separators are in general use (see Mr. M'Knight's letter in B.B.J. of Nov. 11th last), nine-tenths of the *ections at the Colonial Exhibition were produced without their aid? Our Canadian friends knew very well that when worked without separators, sections both look and sell better. At the close of the honey season, when it becomes necessary for the bee-keeper to have his sections sealed over quickly, the lainch, with the usual separator, makes a narrow section, one well suitable for that purpose. Thus we see the I_4^a inch is the best suited section for great produce; the best in appearance for sale and exhibition, and a good narrow for use at the close of the honey season. The best section therefore for general use, and one well suited at all points for storage of the surplus comb-honey of the coming season, appears to be the I_4^a inch wide, worked either with or without separators.—W. B., Patrickswell, Limerick.

THE NEW APIFUGE.

[849.] Mr. Lyon (p. 99) having thrown down the gauntlet by writing satirically of the fact that I have deemed it necessary to make it 'registered,' I am reluctantly compelled to take up the challenge in order that your readers may not be misled, and that your oft-quoted motto 'suum cuique' may not be prostituted by one who seems desirous of 'ploughing with my oxen.'

one who seems desirous of 'ploughing with my oxen.'
In speaking of 'apifuge' he says, 'Oh, I must not use
that awful word, '&c., &c. He was not always so sensitive, and must know that he can use it, but not to sell

his goods by.

No sooner did my article appear on the exhaustive experiments I have made than Mr. F. Lyon began to advertise methyl salicylate. No sooner did an advertisement of Grimshaw's apifuge appear than he followed by using a word to sell his goods by, which word he knew I had coined or invented. This manceuvre being stopped by a letter from me, he now, like a familiar rodent in a corner, proceeds audaciously to lead the readers of the B.B.J. into believing that methyl salicylate is used in the manufacture of 'apifuge,' for he says, 'Alas, in future, when the subtle and peculiar odour of methyl salicylate pervades the tent,' &c., &c., when at the same time he has not a shadow of evidence, either in my writing or speech, nor evidence in any way, to support him in his assumption. Is not this 'trying to sharpen his axe on my grindstone?' Or perhaps is it a 'ballon d'essai' to try and ascertain what apifuge is composed of by a negative process of getting me to deny erroneous assertions? We thus see how really necessary it was for me to register the apifuge, attended, as inventors in bee-keeping are, by ever-vigilant outsiders.

I tried methyl salicylate and it failed. It failed also when Mr. Cheshire got stung on the knuckle whilst manipulating the 'awful example' the Rottingdean demons. It failed when Mr. Hart gave Mr. Cheshire his bottle of it, saying, 'he reckoned nothing of it' (vide conversazione). It failed also because (vide Mr. Cheshire's book) it is so 'liable to be terribly adulterated and weakened' that its price to-day goes from—well, very,

very low up to 32s, per pound.

The last sentence in his letter is too rich to be passed over, so I will give it in extenso:—'If the use of substances to prevent stings should come into general use, the effect upon the rising generation of bee-keepers can but be to render them very unworthy successors of the present skilful manipulators.' And this comes from him who sells a lotion professing to be the only cure for

stings! How absurdly inconsistent!

Again, what is there 'slovenly or slapdash' in a method which allows naked hands, and gives perfect protection against stinging, besides a feeling of ealm confidence even in times of accident? I think the 'charm attending the cool, careful manipulation' is on my side. Cyprians, Syrians, or Ligurian half-breds, it matters not which of these: one can have the really best workers with perfect impunity. For myself I do not see that apifuge is anything but a boon to the vast majority of bee-keepers, amongst whom we may dare to include some timid or nervous ladies (of course there are no nervous men!), gloved and gauntleted up to the elbows, to say nothing to those to whom a sting or two is a serious matter on account of their extreme suscepti-

bility. For example, I wish Mr. Lyon had seen my hand after using Dr. Pine's lotion for two days in my attempts to reduce the swelling from one sting I purposely obtained in his honour on Saturday, February 26th, in order to test its efficacy; whilst Mr. S. Abbott was trying in vain to get stung (after using apifuge, which is not repugnant to bees) by a tribe of demons we disturbed by kicking the hive, he playing an imaginary piano on the alighting-board with his fingers, and pushing two or three bees in at the entrance as he crushed them.

Surely Mr. Lyon is prepared to admit that beekeepers do get stung, and don't like it, else why his

lotion?

Ah! does not the *crux* of the whole thing rest here, that it is a contest for very existence by the law of natural selection between—

Grimshaw's Apifuge, an alleged perfect preventive, and Cr. Pine's Lotion, an alleged 'perfect cure?'

Prevention being notoriously better than cure, do you see that 'Othello's occupation's gone' if my stuff win the contest?—R. A. H. GRIMSHAW, Cray Hill, Horsforth, near Leeds.

AN APHFUGE.

[850.] Some two years ago I came across a receipt to prevent mosquitos and other insects from biting travellers in hot climates, so thought it might also prevent bees stinging. I have used it two years when manipulating and consider it a great preventive against being stung. I also apply it to any one that gets stung and it has proved very effecacious. One ounce ecdar oil, one ounce olive oil, mix and rub a drop or two on each hand when manipulating.—J. W. L.

ARE INVERTIBLE HIVES WATERTIGHT?

[851.] May I be allowed to ask Messrs. Neighbour and Sons to explain in your columns how they mean the rain to be kept out of the hives figured on the first page of cover of No. 244 of the B. B. Journal? The advertisement says their 'British Invertible B. F. Hives' are 'adapted to our British climate;' but I doubt it, unless the hives be sheltered by a shed or placed in a house. The hive seems a good one, and from the illustration (which I hope you will transfer to your columns that it may be preserved with the volume when bound) easy to manipulate; but unless it can be made watertight at the joints where one box sits on the other I shall not like to risk a colony of bees in it except in the height of a very dry summer.

To a bee-keeper like myself, who makes his own hives, but recommends to his friends and correspondents good and simple hives no matter who is the maker, the question is an important one. I am constantly being asked and written to about the best hives to purchase, especially by beginners in bee-keeping, and I should not like

to be wrong as to the properties of the hive I recommend. I am afraid, that, in the recent craze for invertible hives there is a danger of losing sight of the essential qualification of hives being thoroughly weathertight at all seasons. And so many new things have, during the last ten years, been pointed out, and urged upon us and then allowed to pass silently into forgetfulness, that one cannot swallow all at once the doctrine—untried and unproved—that we must convert all our trusty bar-frame hives in which our bees have done so well for many years, into invertible hives or we will be left behind the times as to bee-keeping.—II. W. Lett, M.A., Aghaderg Glebe, Loughbrickland, Co. Down.

THE STANDARD THE RIGHT SIZE.

[852.] The bee season is approaching, and bee-keepers are considering which system of management to employ.

Some will adopt the invertible system, but the majority I think will go very slowly in that direction, and many will not move at all, since they profess their in bility to see how any good can result from turning so many thousand head of broad upside down. At present there seems but little evidence pro or con either in England or America, and therefore all must watch and wait.

The interchangeability of the different parts of hives seems to me to be the leading idea, and not merely their invertibility, in Canada, and the same idea has been advocated by Mr. Cowan for some time. The same idea produced the Association standard frame—a frame too large for some, and not large enough for others, so that I presume it is just the right size. There are frames of three sizes to select from, the diminutive, the medium and the gigantic, and each size has its advocates. Many, no doubt, would like to give the shallow frame a trial, but do not see buying new hives for the experiment; and to such I say there is no need to do so, as they can be worked in the hives now in use, whether comb or extracted honey is desired.—A. GREEN, Selston, Alfreton.

ROOFS OF HIVES.

[853.] In a book on pigeous I have seen a recommendation for making travelling boxes out of paper in order to combine lightness with strength in the follo ving manner. Dissolve one ounce of Scotch glue in twenty ounces boiling water, and the last thing before n-ing stir into it a little at a time twenty grains c'irome alum dissolved in ten ounces more of hot water. This will entirely prevent the glue being ever affected by damp and keep the whole manufacture hard and stiff, but no more must be prepared than can be used at a time, as when once cold and stiff no amount of heat will re-dissolve the glue. Sufficient sheets of any waste paper can be glued together and left to dry in a press. I should like to try this plan for making roofs of hives, but have failed to obtain the ingredients necessary. I therefore take the liberty of asking if any readers of the Brit's's Bee Journal could inform me where the chrome alu n can be got. I presume that best Russian glue would do in the place of Scotch glue mentioned .- J. B. BUTLER, Bristol.

DEAD QUEEN.

[S54.] I started bee-keeping about seventeen months since, and on the whole, have been very successful. Last season I had three frame-hives, from which I obtained nearly two hundredweight of honey, mainly by following minutely the instructions in your Journal. I venture to say that you do not possess a more devoted admirer in the British Islands than your humble servant. I look to you as my père in the bee line, and your Journal co mes as a 'boon and a blessing' every week, to delight the heart and relieve the monotony of my existence as a certificated teacher in a remote country Board School.

Fired by the above success, I determined to have a Ligurian stock of bees, so last season I obtained from Mr. Simmins a splendid queen, which I introduced about 6th September, 1886, to a strong stock of brown bees, covering about ten to twelve frames, quite thick. I afterwards gave the same stock 15 lbs. of syrup, by rapid feeding from five holes. On 19th January, Ligarian bees were on the flight-board, and flying about freely.

To-day I picked up my Ligurian queen, on the ground before the hive, apparently quite dead. Temperature 42° Fahrenheit, by mercurial thermometer in shade. No sun, slightly mizzling with rain all day. I picked her up at twelve in the middle of the day. Temperature at 7 a.m. same day was 40° Fahrenheit, so there could have been uo sudden rise of temperature. I could not believe for some time it was the queen, I was so struck with my loss. However, I took her into the house, and

held her in my hand before the fire for nearly an hour. She just moved a leg or two, showed her sting, and became quiescent. Is she dead, or only a case of suspended animation? I send her to you by this post, to see if you, père editor, can tell me the cause of death, or how it was. Are they getting ready for swarming, and thrown out a surplus queen? Is my hive queenless? what am I to do? See what my ambition to have a Ligurian stock has come to. I now have eight blacks and brown stocks, and one stock of half blacks and half Ligurians. If they have no queen, will they rear one now? What was she doing outside the hive:

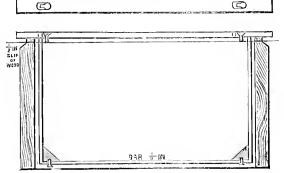

Please help me out of my dilemma. I await your verdict with interest. I believe two weak stocks, that are covering six or eight frames, better than joining; I don't want to join.—Chas. J. Jelfs, Dodford, Broms-grove, Worcestershire, 18th February.

Your Queen-bee is as dead as Queen Anne. It is impossible to say what was the cause of the queen's death. Sometimes bees will supersede a queen, without any apparent reason, and it is probable that yours are raising a queen. As you do not wish to unite, on the first suitable opportunity examine the colony, and, if you find queen-cells in progress, use your discretion as to allowing it to stand. Were the case our own we should certainly unite it to our weakest colony, first cutting out the queen-cells. If there are no queen-cells, uniting is the only alternative, since it is too early to obtain queens, and, if this were possible, the risk of introduction now would be great.

For your consolation, however, we may state that, in March last, a strong Italian colony, in our own apiary, taking a fancy to change its queen, destroyed her, and raised another in her place, which mated successfully about the middle of April, and is now a most prolific breeder, and a beautiful queen in size, shape, and colour. It must be noted, however, that drones were plentiful in our apiary at the time this queen matched.—Ev.]

REVERSING FRAMES.

[855.] I beg to take the opportunity of writing to you, in reference to the article which appeared in the B. B. J. of December I, 1886, on 'Reversing Frames and Hives,' in which you were of opinion that if reversible frames were to come into general use, a simple appliance must be used that will utilise our present frames and in no way interfere with their size, with which I quite agree. I now submit to you the following simple plan, whereby any one might try reversible frames for a few pence. I first cut off the ears of the top bar, then glue

in little angle pieces in the angles at the bottom of the frame, so as to strengthen the bottom part of the frame, which also forms a hold for screws which are screwed in about half an inch from the sides of the frame. I get out a new top bar, which may be either broad-shouldered or metal-ended, and in this bore two holes of the size of the head of the screws, and from these holes are two

wedge-like slots, which, when the bar is pushed, tighten both the bars. This same top bar would do for any frame, and section-cases, if worked in the rear of the hive, might by the same be inverted and kept in position. -R. G., West End, Bodmin.

'CROAKING QUEENS' (203.)

[856.] 'Amateur Expert,' in 'Jottings' for the 3rd ult., 'hopes that all who own "croaking" bees are satisfied with Mr. Grimshaw's excellent paper on the "Vocal Organs of the Bee," and that they will endeavour to notice the different "croaks" in future, and, moreover, that none of them will ever "croak" themselves.

I read Mr. Grimshaw's paper with considerable interest, and I beg to assure your facile and racy correspondent that—as in the past, so in the future—the different 'croaks' will receive their due share of notice from me at least. 'A. E.' hopes that all who own, &c. This is pressing into the service the whole army of bee-

keepers—a mighty host!

An attentive examination of the paper in question discovers nothing that in any degree militates againstmuch that favours—the possibility of the existence of such a sound; and this whether we investigate and analyse the minute anatomical structure and arrangement of the spiracles and their relations to the wings, or simply follow Mr. Grimshaw in his description of some of the sounds. 'We all know,' says he, 'the lazy contented boom of the drone as contrasted with the whizz and whirr of the disturbed honey-gatherer. We recognise the contented hum of the quiet prosperous hive in opposition to the sharp "poop! poop!" of the lost queenless hive.' Now this sharp 'poop! 'poop!' is clearly a species of 'croak.' It is just possible, however, that this 'poop! poop!' sound or croak is never uttered by a queenless stock. 'Stahala,' quoted in the Journal of the 10th ult., states that the sound "H-u-u-u-u-u-u!" is produced by queenless stocks both in summer and winter,' a very different sound from 'poop! poop!' 'Stahala' furthermore adds, 'A loud "wuh-wuh-wuh!" is only heard when breeding is going on, but never when the hive is queenless or has an unfertilised queen.' This 'wuh-wuh-wuh!' or rather, to give it its proper pro-nunciation, this 'yuh-vuh-vuh!' is the abrupt croak, rattle, or drum-roll that I have on former occasions described as peculiar to the queen, and, as I have never heard such sound emitted by a virgin queen, possibly peculiar to one fertilised. It does not, however, necessarily follow that an unfertilised queen is, anatomically, incapable of uttering such sound, but only that her condition and surroundings, in the virgin state and in the fertilised, differ, and that the necessity for the emission of this sound is, therefore, in the former state absent.

This, Sir, is an apparently trivial subject upon which to write, but occasionally great truths and important facts are evolved and receive their elucidation from very small data, and I consider it the duty of each of us, no matter how humble-so-ever his intellectual status, to do

what he can for the general good.

Finally, being of a somewhat hopeful disposition and temperament, I shall perhaps the more easily put into practice 'A. E.'s' last piece of advice—viz., 'never to croak.'—Edward C. Anderson.

SYRUP FEEDER.-I think my own syrup feeder is the simplest and best. I find tumblers and tin lids about the house that fit each other. Bore five small holes in the tin lid near the centre, fill the tumbler with the syrup, put on the lid and turn down on the stage, which is placed over the feed-hole. The stage is a square piece of wood 3 of an inch thick, about 11 inches square, with a round hole in it 12 inches across, and covered with perforated zine, cut with seissors and nailed on. No shovel is required, not a drop is spilt, and the tumbler can be turned up any time, and be refilled before it is quite empty.—Beeswing.

Review.

DAS BIENENWACHS UND SEINE VERWERTUNG by J. Dennler. Published by the author at Enzheim. There have been a good many pamphlets on the uses of honey as food and medicine, but up to the present time, with the exception of what is found in large and costly books, nothing has been done in a separate and cheap form to bring the utility of wax before the notice of the public. Occasionally we have seen articles exhibited in which wax was used, and after our visit to the National Exhibition in Zurich, in 1883, we described in the British Bec Journal the fine collection of things we saw there. That wax has a variety of uses not generally known, we were convinced by the fact that there were no less than twenty-two articles in which it formed an ingredient, or in the manufacture for which it was used. These were 1, glass engraving; 2, painting in wax colours; 3, wax modelling; 4, bleached wax; 5, cosmetique; 6, wax for waxing thread; 7, corking wax; 8, preparation for waxing floors; 9, wax salve; 10, wax plaister; 11, solution in benzole: 12, various forms of wax tapers; 13, cold cream; 14, mould of teeth; 15, anatomical preparations in wax: 16, meerschaum tubes; 17, collar glazed with wax; 18, wax matches; 19, comb foundation; 20, candles; 21, medals; 22, photography. Such being the various uses to which it can be put, it is with pleasure that we welcome the appearance of this pamphlet, which commences by giving a history of the production of wax, then its conversion into foundation, and its uses in the household, and, lastly, its uses as a medicine. We find a description of the best way of obtaining the wax pure, and how to detect its adulterants. M. Dennler is well known as one of the editors of the Elsass-Lothringische Bienenzritung, is the chairman of the Strasburg section of the Bee Society, and has taken an active part in disseminating a knowledge of bee-keeping. He is also one of the lecturers of the Society, and it gave us great pleasure when we visited him at Enzheim to find that he practises in his apiary what he preaches out of it. His other occupations prevent him keeping more than twenty hives, and most of them are of the Baden type. He told us he had three harvests of honey during the season; first, fruit trees in April, which give the honey a slight-rose coloured tint; second, Trifolium incarnatum, from the end of May to the middle of June, this honey has a yellow tinge; third, linden, which has a yellowish hue. With the multiplication of bee-keepers a larger quantity of wax is required for foundation, and it is therefore important that there should be no waste, and even the oldest combs contain something worth getting out of them. How it is to be done this pamphlet explains, we therefore recommend it, and shall hope, from time to time, to give our readers some useful extracts from it.

Replies to Queries.

[835, 836.] (Edward Clowes.)—Your two queries are most difficult to answer. The possibilities of artificial swarming were known to the ancients; whether they practised it or not it is impossible to say; but no doubt they did. In order to give you some idea as to how long smoke has been known as an intimidant to bees, I may mention that Johnstone, in his travels in Central Africa on the Upper Congo, found that many tribes here were bee-keepers, suspending their hives—made of rushes—on the branches of trees, and using smoke when taking the honey. When did this commence? Here we find totally uncivilised people, having had no possible chance of intercourse with civilisation, practising a method which we, in our self-sufficiency, consider ourselves the introducers of. The partially civilised natives of India use smoke in taking the nests of Apis dorsata and other varieties.—W. B. Webster.

Queries.

Queries and Answers are inserted free of charge to Correspondents When more than one query is sent, each should be on a separate piece of paper.

of paper. Our readers will greatly oblige us by answering, as far as their knowledge and observations permit, the Correspondents who seek assistance. Answers should always bear the number and title placed against the query replied to. Any queries unanswered in this way will be answered by the Editor and others.

[857.] Would any reader of the *Bee Journal* say at what distance Ligurians should be kept from blacks to keep them pure?—J. W. L.

[858.] How far off might I place a nucleus hive with a young queen from an apiary of a dozen hives and expect to get her fertilised?—J. W. L.

[859.] Will some one kindly tell me the best way to pack bees in Combination hive to send by rail? Will the bars want any fastening put to them? also if it will be best to let them travel by night or by day? May they be sent by passenger or goods train? Any information will oblige.—H. B.

Echoes from the Pives.

Cambridge, February 1st.—Bees have been flying freely during the past week from my hives, many of them visiting a large tub of rain-water which stands a short distance from the hives. The bees appear very healthy, fly strongly and without falling to the ground, as often happens, after they have been shut up in the hives for a long time by stress of weather.—J. S.

February 26th.—A most lovely day, the air filled with the joyful hum of bees. Examined all my stocks, eighteen in number, all perfectly healthy and strong. Eggs in all, hatching brood in several; in one hatching brood in three frames the centre patch as large as a saucer, young bees flying. The greater part of the stocks were made up of condemned bees in September, packed for the winter between cork-dust dividers, made so that the cork-dust can be emptied and dry sugar substituted; frames covered with American cloth, and over that trays three inches deep with eanvas bottoms, filled with cork-dust. Frames parallel to the front of hives.—F. L.

Upton, St. Leonard's, Gloucestershire, Feb. 28.—Examined my thirteen hives this day. All single-walled Simmins's hives §" thick, except one. Seven had enamel cloth on all the winter, the remaining six carpet and chaff cushion. Bees all dead in three hives owing to weakness or insufficient stores, the remaining ten in good condition, though stores almost exhausted. The surviving ten stocks consist of one Cyprian, two Carniolans, one Ligurian, three Hybrids, three Blacks. Of the three last stocks two were blacks and one hybrid.—E. Wilkins.

Goole, March 5,—During the last two or three weeks tho weather has been all that could be desired—beautiful, warm, bright days, which our pets have made the most of, carrying in a quantity of water and artificial pollen which we have supplied, as there are no flowers yet in bloom. We have not lost a single hive this winter up to the present, and I think it is not at all probable that we shall (thanks to the Journal), as all have plenty of sealed stores, and the bees are in good condition. Let us hope that we may have a better honey season this year than last, for some of our hives had to be fed up for winter as they had not been able to gather sufficient stores, let alone surplus, and we had very few swarms, although all the stocks were strong.—A. WOODDEAD.

The Mall House, Lismore.— Our daffodils (the Irish daffodil) have been out a few days, and are crowded with bees. In view of the fact that our blossoms and vegetation in the south of Ireland is at least ten days or a fortnight ahead of England, I do not think it amiss to begin a very gentle stimulation about March 1. The celandine is out now, and daisies in abundance, gorse in quantities, erocus, daffodils, heath in gardens (snowdrops over), seillas, and primroses both wild and in gardens, and the laurustinus, are sheeted with bloom. The ribies will be in bloom in less than a week. Under these circumstances I think a

little gentle stimulation advisable, especially as some of my stocks are a trifle short of stores. I shall be glad to know your opinion. Last year we had no honey stored in May, but the year before, which was an average fine spring, I had a beautiful crate of sections finished by May 25. Last year one terrible storm in May destroyed all the fruit-tree bloom and made an end of the apple crop, pears, &c. I observe the bees much prefer the white and purple and purple striped crocuses to the common yellow ones. quantities of each, but see the bees frequenting the former in much greater numbers. There is a very large pale purple striped variety, that they seem to prefer to any other.—F. W. C.

[Your season is exceptionally early; at least a month earlier than ours. In mild weather you may safely begin to stimulate. If any are short of food feed copiously, giving sufficient room in the brood-nest by occasionally adding empty brood combs as required. We shall hope to hear of your success in reaping a bountiful barvest.—Ed.]

NOTICES TO CORRESPONDENTS & INQUIRERS.

All queries forwarded will be attended to, and those only of personal

All queries forwarded will be attended to, and those only of personal interest will be answered in this column.

Letters or queries asking for addresses of manufacturers or correspondents, or where appliances can be purchased, or replies giving such information, can only be inserted as advertisements. The space devoted to letters, queries, and replies, is meant for the general good of beckeepers, and not for advertisements. We wish our Correspondents to bear in mind that, as it is necessary for us to go to press in advance of the date of issue, queries cannot always be replied to in the issue immediately following the receipt of their communication.

- J. S. S.—1. Cowan's Hives.—In hives of this character having no shoulders to the frames, the quilts should be large enough to completely cover the frames and also rest upon the sides of the hive. This will prevent the bees getting up. 2. Examining Hives .- When opening bar-frame hives smoke at the eutrance is not necessary, a little blown under the quilt will have the desired effect.
- M. F.—Bees in town, a mile from open country.—There is no reason against bees doing fairly well. Scores, or perhaps hundreds, of stocks are kept in the suburbs of London; depending for their living almost entirely upon flowers and trees in gardens, and hardly ever getting to really open country.
- J. Turncock, Jun.—The sample of sugar forwarded is that recommended by Mr. Simmins for dry-sugar feeding. You will find it serve your purpose.
- C. A. T .- Loss of Queen .- It is almost impossible to say the cause of the death of your Italian queen. Since worker bees-her progeny-appeared three weeks ago, it is evident that breeding had been carried on during the winter and in severe weather, which is a bad sign in an autumnally introduced queen. Imported, or travelled queens are rarely long-lived. Death might, however, have been caused by robbing—by which in the spring queens are often destroyed; or it may have arisen from old age. If you left the hive raised from the floor-board for any length of time, it is most likely that robbing was the cause of the misfortune. At this time the bees are very eager to appropriate their neighbours' stores, that it is unsafe to open a hive at all during the hours of flight; and the evenings at present being too cold for manipulation, it is best to leave the bees alone, save to supply food where it is required. 2. Bacillus depilis.—The disease of your other colony is, from your description, Bacillus depilis. Clear out the dead bees and feed at night with warm phenolised syrup, according to Mr. Cheshire's recipe; or with salicylised syrup, according to Mr. Cowan's. We have cured with both.
- W. Baker.—Loss of Queen.—You do not say whether you opened your hive to give the candy. However, that may be, we think the encasement of your queen arose from the entrance of strange bees into the hive, alarmed and chased, by which the queen rushing wildly to the entrance was surrounded and encased by her own bees, for protection from the enemy. On the entry of strange bees into any hive, its rightful occupants will always enease their own queen to preserve her life, and on the departure of the intruders, will release her uninjured. You did quite right to reseue and return her to the hive. In future, feed at night, and cover up securely, to prevent

- any scent of food escaping, which entices other bees to attack. It might, however, chance that the queen was aged, and about to be superseded by the bees. If so, you will probably find her dead body cast out of the hive. We advise you not to disturb the hive again.
- Samuel Watson.—I. Loss of Queen.—The peculiar hum to which you allude denoted excitement arising from the loss of the queen. It is impossible to assign a cause for her death without a knowledge of the previous history of the colony. At this season old queens are often dethroned, from the loss of fecundity, and young ones raised in their place. 2. Mr. Abbott publishes a number of leaflets on bee-keeping. 3. We are pleased to hear that you are working for the good cause.
- J. C. R.—Transferring.—1. Do not attempt to transfer before the middle or end of April. We should prefer allowing the hives to swarm, and to transfer three weeks after swarming. If you follow this advice set the swarms on the stands of the old stocks, and remove the latter to a new position until you transfer them. 2. We prefer Ligurians to Carniolans. 3. The time of the honey harvest in your locality depends, as in other places, on weather, and on the kind and quantity of hee forage, such as fruit bloom, and early nectar-yielding plants. In an early season it will probably commence about the end of April; in a cold late season about three weeks later.
- J. H. W .- Moving Bees from one side of high close fence to the other. -- If you do it now you will lose a few bees, but not many. Put small skeps on the old places to collect stragglers, and in the evening return them to the hives. If you delay, your best plan would be to shift them along by degrees until behind the new position, as in your sketch, then mount them up on a stand to above the fence, turn them round by degrees to face the other way, and then lower them to their permanent places.
- Sagged Down Combs broken down in Autumn Carry the hive indoors, pass a piece of wood under the ends of all the frames and lift them bodily out. Then separate the fallen combs and tie them into the frames. Use smoke to keep the bees quiet.
- F. J .- 1. Making Candy .- If you follow the instructions in Modern Bee-keeping you will get it right; but, if you burn it, it will not set hard, and it will be moreover bad for the bees. 2. Drone (?) on Flowers.—You must have been mistaken in the insect which you saw.
- W. G. CAMPBELL.—Les Abeilles, Organes et Fonctions, by Maurice Girard, is published by J. B. Baillière et Fils, 19, Rue Hautefeuille, Paris: London house, 20 King William Street, Strand. The price of the book is fr. 4.50.
- A Beginner.—1. Sugar.—The sugar enclosed is suitable for dry-sugar feeding. 2. Stimulation.—We prefer syrup to dry sugar for stimulation. It should be given warm and at night from a bottle feeder. A pint every three or four days is sufficient. 3. Natural Pollen.—With plenty of hazel in bloom within half a mile artificial pollen is not necessary. Whenever bees have access to abundant natural pollen they will neglect the artificial.
- E. Lupton.—Fighting.—The bees dragged out from the hives nolentes volentes are undoubtedly robbers, but so persistent are they in their evil course that they will attack again on getting free from their pursuers until at length they pay forfeit with their lives.
- J. C. AND SON.—The sugar is suitable for dry sugar feeding, but not for making syrup on Mr. Simmins' plan: Mr. Simmins uses for this latter purpose Dutch crushed. See his advertisement.
- C. A. Jones.—We always bind up the advertisements with our volumes. With the contents to each number and the copious index we have a full synopsis of the contents of each volume.
- Bernshire Hog.—We believe that the pay of an expert varies from 5s. to 10s. a-day with expenses. We consider you would have no difficulty in estimating the value of your time in rendering assistance to those who may require it. We did not require your postscript to prevent us from falling into the possible mistake of supposing you belonged to the profession mentioned.
- R. T. S.—Red clover (Trifolium pratense) is not of much use to common hive-bees; their proboscides are too short

to reach the nectaries. Ligurian and Eastern bees are able to work upon it, as also humble bees.

Welsh Novice.—The conditions being in both cases identical, you may calculate that the average yield per hive in an apiary of 100 would be equal to that in one of twelve.

J. H. M.—We suggest that by stimulating the bees in your skeps you should get swarms as early as possible, and after twenty-one days transfer. The directions in Modern Bee-keeping are so precise that we do not think you would find any difficulty in driving.

H. E. S.—There are no symptoms of foul brood in the portions of comb forwarded.

Received price list of Apiarian Appliances manufactured and sold by Wm. M'Nally, Glenluce, Wigtownshire, N.B. A bottle of Grimshaw's Apifuge from Abbott Brothers.

MANIPULATE WITHOUT SMOKE!

WEBSTER'S

Entirely supersedes the Smoker, both in Simplicity and Effectiveness. No 'going out.' No tainting or soiling of combs. Always ready for use without any preparation. Can be carried in the pocket.

With Bellows, 4s. 6d.; postage, 4dd. Without Bellows, 3s.; postage, 3d.

Can be adjusted to any ordinary smoker bellows,

6 oz. Bottles of Agent-carbolic acid, oil of tar, and water, properly mixed-6d. each.

WEBSTER'S SWIVEL FRAME-LIFTER

WILL BE READY SHORTLY.

With this appliance, frames can be removed from hive, replaced and examined on both sides without inverting, with one hand, leaving the other free for manipulating, at the same time preventing soiling the hands with propolis,

OUTLINES OF BEE-KEEPING FOR BEGINNERS.

(Continued from page 67.)

III.—BEES ARE ABLE TO STING.

I. Worker and queen bees are furnished for their defence with a stinging apparatus, whose principal

parts are the sting and poison-bag.

2. The poison is a clear liquid, and is introduced through small openings in the sting into the wound when stung. After a few moments there is a sensation of heat, and this spot begins to swell, the swelling spreading to the surrounding parts. If children are stung on the head, very often the whole face becomes swollen, and it takes several days for them to recover.

3. With grown-up people, after they have been stung several times, the effect produced is less marked, until, with very few exceptions, the parts stung no longer swell, and the bee-keeper is said to be sting-proof. Where stung, there is still the sensation of pain, but this passes away without any

swelling,

4. When stung, remove the sting as quickly as possible with the point of a pen-knife, and wipe the place with a handkerchief moistened in water. A little honey put on the wound gives relief, but it should not be rubbed, as this helps to spread the

poison and causes more irritation.

5. The poison (called *formic acid*) has a peculiar smell, which can be recognised when one is stung. It is this smell that makes the bees angry; therefore, when working amongst them, always have a pail of elean water handy, so that you can plunge your hands into it to remove the acid. For the same reason, care must be taken not to crush a bee. If it is absolutely necessary to kill one, its head should be squeezed.

6. When a bee persists in buzzing round the bee-keeper's head, he must move away quietly, and when at some distance from the hive, it will generally leave him. If the bees are angry in consequence of having their hive upset, they should be sprinkled freely with water, poured through the fine rose of a water-can, or with a syringe, before

anything further is done to them.

(To be continued.)

WOIBLET SPUR EMBEDDER FOR FIXING FOUNDATION.

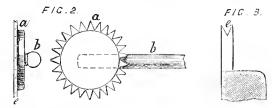

When we attended the Conference at the Indian and Colonial Exhibition on the 6th October last we introduced to the notice of the British and Canadian beekeepers present an apparatus invented in Switzerland for securely fastening foundation in wired frames (see British Bee Journal, 1886, page 474). As we have since received several inquiries about this apparatus we will give our readers a description of it.

Fig. 1 shows the instrument one half its actual size, and

which consists of a brass toothed wheel a, working on a centre at d, fixed on one side of the wheel to a rod b, driven into a wooden handle c.

In fig. 2 the principal parts are shown full size. The

diameter of the wheel across the teeth is $\frac{13}{16}$ of an inch and the width of the toothed part is $\frac{1}{3}$ of an inch. There are twenty-six teeth, which have a \mathbf{V} groove at their edges e, fig. 2. This is also shown at e in fig. 3, in which one of the teeth and a portion of the wheel will be found enlarged four times. Fig. 4 shows the double

F1G.4.

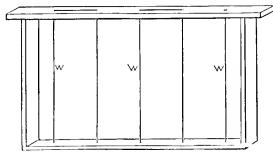

dots made by the teeth, full size and also their exact distance from each other.

The frames have to be wired with No. 30 tinned wire, as in fig. 5. Five wires are sufficient, although six are better, and are frequently used. The top and bottom bars are pierced with small holes by means of a fine bradawl. The frame is then placed over a board which fits it exactly and is \(\frac{2}{3}\) of an inch thick, having two pieces nailed on the back, as in fig. 6, and first recommended by Mr. Abbott many years ago for fixing foundation with his wax-smelter. We then proceed to put in the wires and fix each end by turning it down and driving a wooden peg into the hole, which can then be cut off level with the surface of the bars. The wires must be drawn pretty tightly, and it is for this reason that we put the

board inside the frame. If we did not do so the tightening of the wire would curve the top and bottom bars inwards, but the board prevents this taking place. The frames now wired are ready for the foundation.

Place a sheet of this on the board and over it put the wired frame so that the foundation touches the top bar.

Have a lighted spirit-lamp by the side of you, and in the flame heat the wheel of the embedder and place the **V** groove on the wire. Then run the wheel along from one end of the wire to the other. The heat melts the wax at each point, which cools as fast as the wheel travels

forward, and the wire will be found covered with wax, because the teeth are so close together. The operation is completed so rapidly and perfectly that no one who has once used it will ever think of employing any other

means of embedding wire.

We have been particular in describing the method of working, because it is different to the ordinary way of cmbedding, where the wire is only pressed into the foundation at intervals of $\frac{1}{2}$ inch to one inch and not covered with wax, and also we are anxious that a good thing should not be discarded because it is not properly understood and incorrectly described. Mr. Cheshire has figured something of this sort, and has given instructions for using it, which are likely to mislead, for such an embedder as he shows could not possibly work as it is intended to do. He was at the Conference and we showed him the instrument, which was the first ever shown in England, and he pictures a thing with a wheel 11 inches in diameter and with only nine teeth instead of twenty-six, and those nearly $\frac{1}{3}$ th of an inch wide instead of $\frac{1}{3}$, and $\frac{3}{8}$ from point to point. His description is so amusing that we cannot refrain from giving it in his own words. In Bees and Bee-keeping, page 208, he says: 'Some use the wheeled apparatus (fig. 60). The method of operation is obvious. The wheel, which is stellate, is growed at the edge, so as to hold the wire beneath and between the cutting points (pp). As the wheel is driven the wire in short lengths is pushed down into the body of the wax. The foundation is now very securely held, but it cannot be safely given in all cases without attachment to the top bar.' It may be obvious to the writer, but we know such an apparatus could not be used in this way without damaging the foundation and doing more harm than good. Surely the Swiss apparatus ought to have been correctly described, or if it was not understood. as appears to us was the case, it should have been left We wonder if the writer has ever tried the method he describes and who the 'some' are who use the embedder he figures. The beauty of the Swiss invention is that the teeth being so fine and close together the

wire is entirely covered with the molten wax (without even disfiguring the foundation), and not pushed firm into the body of the wax, and it thus gets over a serious objection which formerly existed to wired foundation. We recollect some years ago when it was first introduced we objected to it after trial, because we found that where the wire had not been covered with wax the bees did not use the cells through which the wires passed. A striking instance of this came before our notice at a show, we think at Windsor, where in a large observatory hive of Mr. Abbott's make we called the attention of the Rev. G. Raynor to the fact that in combs perfectly filled with brood there were lines of empty cells corresponding to the wires in the foundation. Since that time such foundation has been greatly improved and the wire is now properly embedded, but still it has to be fixed to the top bar, and even then the combs can never be so firmly fixed in the frames as when the frames are first wired. Foundation in wired frames embedded with the Swiss embedder requires no other fixing. The instrument is the invention of Monsieur Woiblet, and he calls it the 'Woiblet spur' from its resemblance to one. When alluding to it we shall in future always call it the 'Woiblet Spur Embedder.'

USEFUL HINTS.

WEATHER.—Easterly winds and frosty nights, with days of mist and fog, have fallen to our let of late. Possibly the best weather for the bees. Days of brilliant sunshine and unseasonably high temperature in February and March have never in our experience preceded a bountiful summer. 'Better have the cold weather now, sir, than later,' says our weather-wise factotum in his oracular manner. Whether the old saw-' Mists in March mean frosts in May '-will prove correct of the present season we shall be able presently to note; but, certainly, an English month of May without frost, and free from the 'Blackthorn winter,' would be next to a miracle. The great advantage of a cold and backward spring is threefold:—(I), Ardent bee-keepers are unable to manipulate the bees to their hearts' content; (2), vegetation is in abeyance until there is little fear of later frosts nipping the fruit in the bud or bloom; (3), there is no inducement to the bees to wander forth and perish in search of non-existent pollen and nectar. We can always supply our bees with flour-cake, artificial pollen, candy, syrup, water, and all other good things at home, and so encourage their breeding propensities to the full extent. Then, when the good time comes, our hives, teeming with population, will render a good account of the deliciously scented clover fields and other nectaryielding crops.

Apifuges. - In our early days we knew an 'aged Corycian who possessed a few acres of barren land, too poor for ploughing, unfit for cattle, herds, or flocks, or for growing vines; yet this old man cultivated white lilies, poppies of every shade of colour, and other plants in which his bees delighted. He was the first to hive the spring swarms, the first to squeeze the luscious honey from the combs in autumn.' He kept one hundred hives, on the old-skep-natural-swarming system, and managed them all himself. The bees paid his rent, and maintained his family. Indeed, he was one of the most successful bec-keepers we ever knew, but he used no apifuge—neither veil nor gloves. Stripped to his shirt, with bare, brawny arms and bronzed chest and neek, from early moru to dewy eve he lived amongst his bees. Him have we often seen covered with living bees, hiving swarm after swarm in quick succession, unmindful of their stings, and happier far than kings. He used no apifuge—no Put the bees to flight for him.

HONEY A STING AVERTER. — Allurements he preferred. Arms, face, and neck, were all besmeared with liquid honey, until they glittered in the sun

like varnish, and him the bees never stung. Why should not our lady bee-keepers—and timid gentlemen, too—anoint the hands with a little honey—the smallest quantity will suffice, and wear a veil? How changed are we! Begloved, bevoiled, apifugated, we go forth conquering and to conquer. But why squabble about a technical scientific term? The despised dead languages of aucient Greece and Rome are not so poor and circumscribed that they cannot supply a duplicate.

METHYL SALICYLATE, OR KENTRAPONE?—Let Mr. Lyon take heart. We do not wish to 'put the bees to flight.' Fugitive swarms and deserting colonies are not so rare that we need desire to increase their number! Let him call his 'Methyl Salicylate' 'Kentrapone,' which is simple Greek for 'sting-averter,' surely a more appropriate term than 'Apifuge' or 'put-the-bees-to-flight.' This newly coined word, we presume, is formed after 'Febrifuge,' or 'put-to-flight-the-fever.'

APIFEBRIS, OR BEE-FEVER.—But is not this rather dangerous ground? There is such a disease as 'Apifebris,' or 'Bee-fever.' Alas, how many a poor wife prostrates herself—a suppliant with votive offering praying that her lord may be restrained from spending all his time and means on the new-fangled 'apistical appliances' (forgive the 'apt alliteration's artful aid'). Or it may be that the wife is bewitched—for sometimes, 'though hardly ever,' the lady becomes the enthusiast, although we should never be so ungallant as to accuse her of harbouring 'a bee in her bonnet'—then the husband, perchance, becomes the deprecator, since there are few households in which both husband and wife are smitten with the disease, or can afford to devote all their time to 'apifuges,' et hoc genus omne. By the way, we never chance to meet a gentleman, now-a-days, who confesses himself ignorant of the ancient classics, however much he may despise them. The schoolmaster is, indeed, abroad.

Brood-Spreading.—Whether any disturbance of the brood-nest of a colony of bees during the spring months, or, indeed, at almost any other time, is advantageous or disadvantageons is a moot question. Our own opinion is that, unless in very exceptional cases, more harm is done than benefit derived. And this opinion seems to be fast gaining ground amongst skilled apiarists both at home and abroad. We do not mean to assert that in able and experienced hands, during suitable weather and under favourable conditions, it may not sometimes be done with advantage, but we have almost invariably found that, given a strong healthy colony, with a prolific queen at its head, and sufficient stores, the increase of population is greater when the nest is left undisturbed than when brood-spreading is practised. The brood-nest is always globular in shape, and in whatever manner it is attempted to spread it, this shape or form must be destroyed. If you place an empty comb in its centre, you divide it into two portions, and the bees into two clusters, one of which retains the queen. If you place the outside combs, each containing very little brood, in the centre, you destroy the circular form of the nest. If you turn round, or reverse (not invert) any of the brood-combs, again you destroy the globular form. And in all these cases you remove a portion of the brood away from the stores prepared for its use, since pollen and diluted boney are always placed in the cells around the outsides of the nest and the cluster of bees, the former taking exactly the shape of the latter.

When the combs range from front to back of the hive, and a southern aspect is given, the nest will always be found on the south side, immediately over the entrance, because that is the warmest part of the hive, and consequently best adapted for brood-rearing; and if care be taken that the combs, outside and behind the nest, are not too heavily clogged with honey, any surplus which might interrupt the extension of the nest

laterally, or backward, will quickly be removed by the bees, and the cells having been thoroughly cleaned out and polished, the queen will find ample room for increasing the nest to the full extent of her powers, and tho opportunity of keeping it in the particular form which she and her children instinctively prefer. These remarks relate to the spring months, as a matter of course, since when the summer is advanced, and surplus-boxes are in position, brood-spreading is no longer thought of, as we assume the brood-chambers to be full of eggs and hatching larve.

There are experienced apiarists who persist in spreading brood, but they are few in number. Professor Cook simply adds empty combs as needed, placing them next to the brood, which can hardly be called spreading. Mr. Miller does very little in this way, but when he adds extra combs he generally adds them outside the brood-nest. Mr. Demaree does not spread brood because he believes that his bees build up more rapidly by being allowed to follow their own instincts, which lead them to concentrate and pack closely the brood in the early season. If he thinks the brood-nest too much contracted he adds combs at the side of the brood as fast as the bees can cover them. Mr. Brown considers that the 'spreading-brood furor' has consigned many colonies to the shades. Mr. Hutchinson does not approve of the so-called brood-spreading: if extra combs were needed he would put them at the side of the brood-nest. Mr. Heddon does not practise it, but prefers sectional brood chambers, and when required adds an empty comb chamber below the full one, which has no tendency to cool the nest, but the spreading system, he thinks, has. Mr. Pond does not use spreading at all, but prefers building up by adding frames of broad from other colonies, considering the main point to be, keeping the brood in the centre of the cluster, so that it may have all the heat possible. And Mr. Newman, the editor of the American Bee Journal, from whence these views are selected, believes that spreading brood is often disastrons, especially when practised by any but experts. The above-quoted authorities are practical, experienced beekeepers, in most cases conducting large apiaries.

Again, during our entire bee-keeping experience we have always kept some half-dozen colonies in skeps of medium size, from which we take natural swarms, and these colonies have, almost without an exception, given us earlier swarms than frame-hives. Why is this so? Simply because the brood-nest in skeps cannot be disturbed either by spreading broad or hy other manipulations. With us, too, these colonies winter remarkably well, no matter how severe the winter may be. Why? because there can be no escape of heat or moisture through the thickly propolised interior of dome and sides of their domiciles, nor can their combs be pulled about in the autumn and the propolis broken up or removed altogether, under the idea of 'winter preparation, putting into winter quarters, &c., &c.' We are really inclined to the opinion that the bane of modern apiculture is too much interference with the internal arrangements of the hive at unseasonable times and for purposes to be deprecated. But, even so, we are by no means unmindful of the great advantages of moveable comb-hives over those with fixed combs, when rightly and carefully worked

and manipulated.

Frame-distance.—When preparing frame-hives for winter, we contracted, by division-boards, each of four hives, containing strong colonies, to six frames, placing a strip of wood \(\frac{1}{4}\) inch wide, and of the same thickness and length as the top bars of the frames, alternately between the broad-shouldered frames, thus rendering the distance from centre to centre of frame 1\(\frac{2}{4}\) inches. These colonies were the first to rear brood at spring. By the middle of last month their combs were filled with sealed and hatching brood to an extent far surpassing other colonies located in similar hives with

combs at the usual space of $1\frac{1}{2}$ inches, and we were obliged to add, at the sides of the brood-nests, frames of sealed honey. We attribute this early breeding to the bees being able to keep up a higher temperature by clustering in thicker 'seams' in the wider spaces than those wintered on frames at the ordinary distance. Here, then, is surely a hint for enabling bees to pass safely through a winter of long-continued cold. A space of $1\frac{1}{4}$ inches, or at most $1\frac{3}{8}$ inches, from centre to centre of combs in the brood-chamber during the honey season, is better than $1\frac{3}{2}$ inches, since the bees are thereby prevented from storing honey in quantity therein, and are driven upwards and compelled to store in the supers. But this view applies only to the production of combhoney in preference to extracted.

CAUSE OF QUEENS DYING.—For several weeks past we have received numerous queries as to the loss of queens -queens cast out of the hives dead, and iu some cases queens of last year, in others last year's imported queens, without any apparent cause, and often leaving abundance of brood in the hive. Without an exact knowledge of the history and conditions of the various colonies bereft of mothers, it is impossible to assign a But, generally speaking, there are three very common causes of queen-destruction at spring: (I.) Keeping hives open too long a time when manipulating on a fine day while bees are in full flight, thus allowing the entrance of strange bees, and consequent encasement and death of queen. (2.) Careless feeding, by which robbing is encouraged. And (3.) encasement by her own children of an aged and effete queen, which terminates in her death. When a queen ceases to lay, or produces drone eggs only, the usual method of despatch is by encasement, i.e. hugging to death. We know that a theory has been started that bees encase their queens in order to urge them on to laying, and sometimes, while so acting, with the best intentions, kill them unintentionally. In that theory we do not believe.

FEEDING AND STIMULATION.—While concluding these hints, reports of a fall of snow, from eight to ten inches deep, in Scotland, reach us, and snow is falling thickly in our eastern counties, with bitterly cold north-east winds, and sharp, frosty nights. Where feeding is a matter of life or death, let warm, soft candy still be given. During such weather it is useless to offer syrnp, since the bees will not take it, but candy will be joyfully accepted. The beginning of next month will be soon enough to stimulate, except, perhaps, in southern districts. In this we must be guided by the weather and the forage, since no general rule can be laid down to meet all cases. Reserve and disinfect all combs upon which colonies have perished, if not too old and clogged with pollen, storing them in a dry place, and keep them free from moths. These will be found very useful for swarms, for extracting purposes, or for enlarging brood-nests. other work preparatory to the quickly approaching season, such as providing section-racks and hives, and inserting foundation, should now be pushed forward without delay. Keep all colonies as warm as possible by adding extra quilts and coverings during the cold weather. By these means breeding will be encouraged and population increased before the honey season arrives.

JOTTINGS BY AMATEUR EXPERT.

'Mel sap t omnia.'

I hope the various Hon. Secretaries and Committees will profit by the excellent advice given them by the Editor in current number of the *Journal* on the question of show schedules.

Our esteemed friend, the contributor of 'Useful llints,' gives us a quotation from a letter he received as to committees, &c. I presume none but a party of English gentlemen would do the work as our committee and officers do theirs. It is a characteristic of our

nationality, and it will be a bad day for our country when such cease to be found. The extent of their subscriptions is an index of the length of their purses, and not of the depth of interest they feel in the objects of our Association. There are many amongst us in humbler walks of life, working in less prominent spheres of beekeeping whose interest and self-denial equal, or even exceed, these gentlemen's proportionately, and that is my chief reason for wishing to remove all fancy qualifications. We should have 'one man one vote,' and 'miversal suffrage,' and never fear but that only those who have time and money to spend in the service of the Association and are above suspicion, would get elected on the Committee.

Our versatile friend, Mr. Grimshaw, has turned from poetry to 'wrangling' (nothing offensive is meant by the word). He complains of another sharping his axe on his grindstone; well I complain that Mr. Grimshaw has sharped his axe on our grindstone and got us to turn it while doing so. I refer to the gratuitous advertisements he has got in the form of letters in the Journal, on the sole assumption of his invention being such a blessing to bee-keepers. Of course he has perfect right to his 'invention,' whether it be artificial 'wintergreen,' or the word 'Apifuge.' But if he is going to sell hardware, he should live at Birmingham. I am one of not a few of those who contend that all honorary officers of associations should not have the shadow of a suspicion of being a dealer. Here is Mr. Grimshaw in Co. with a great firm for the sale of an article which his official position gives him an opportunity of pushing; it stands to reason that the other goods made by the same firm will be pushed at the same time; we get the thin end of the wedge—unintentional I have not the least doubt, but none the less true—from 'X.-tractor,' one of his friends with him 'In the Hut.' Mr. Cheshire's experience of 'Cure for Foul-brood' may be of service to Mr. Grimshaw, he will find it in a recent number of B, B, J.

Our Berkshire friends are good at 'Comestibles,' they seem to have made their late Annual Meeting a jovial

'picnic,' and a very bright idea too.

The Rev. H. W. Lett, M.A., asks if the 'Invertible Ilive' is water-tight. I remember the question was put to Mr. Jones at our late great Conversazione at South Kensington, and he replied, 'Yes!' which brought out the retort, 'It would not be in our climate,' and immediately Mr. Jones—who is nothing if not keen at parrying an awkward question—said, 'Water in Canada is as wet as it is anywhere.' But we must not forget the Canadians winter in cellars.

I notice the Editor's reply to our disconsolate friend, 'Chas. J. Jelfs.' May I suggest she succumbed to the pressure of breeding, as many queens do in early spring, and such queens if they do not die are speedily 'improved' out of existence by the bees in a most summary manner. The Syrians and Cyprians are especially good at this work. Join them, Sir! join them! never caudle queenless stocks this time of year, nor any other time if

you wish to make bee-keeping pay.

Dear 'Bees-wing' thinks his own feeder is best after all,—of course he does, and so it is. I am glad to find he puts his wits to work to contrive a feeder out of a few simple things that he has to his hand, instead of spending a half-crown in one. A day labourer came to me to-day with a pardonable glow of pride, to ask my opinion of a feeder he has schemed, and considering his scanty advantages, very clever it was, as I told him.

In the Canadian *Bee Journal* for February 16th, fifteen of the principal bee-keepers of Canada and the United States of America give in answer to a 'Selected query' as to the best cure for foul brood, and not one of them seems ever to have given salicylic acid or phenol a trial. Rather slow this for our Transatlantic friends!

As to virgin queens 'croaking' I would refer our

'hopeful' correspondent 'Edward C. Anderson' to the remarks made by Mr. Hayiland at the late Conversazione as reported in the B, B, J_{ij} , and remain 'croakingly' -Amateur Expert.

ASSOCIATIONS.

YORKSHIRE BEE-KEEPERS ASSOCIATION.

CRAVEN DISTRICT.

A meeting of persons interested in bee-keeping was held at Skipton on Saturday, March 5th. Bee-keepers from Bolton-by-Bolland, Bradley, Cononley, Gargrave, and Skipton, were present, and Mr. Tordoff, Gargrave, was voted to the chair. It was decided to form a branch of the Yorkshire Bee-keepers' Association to be called the 'Craven District Bee-keepers' Association.' The annual subscription was fixed at half-a-crown, and persons wishing to join the Association are requested to communicate with the Secretary. The following officers were appointed:—President, Rev. A. P. Howes (rector of Bolton Abbey); Hon. Treasurer, Mr. G. H. Tordoff (Gargrave); and Hon. Secretary, Mr. J. Dodgson (Skipton). An executive committee will be elected at a meeting of members to be held the first Saturday in April.

HANTS AND ISLE OF WIGHT BEE-KEEPERS' ASSOCIATION.

SWANMORE BRANCH.

The above Society has just completed a series of lectures on bee-keeping for the benefit of cottagers, &c., in the above district, at Bishops Waltham, Droxford, Botley, Swanmore, Exton, Corhampton, and Curdridge: the lectures being given by the Rev. W. E. Medlicott, Hon. Treasurer; Mr. H. W. West, Hon. Sec.; and Mr. C. Martin, the Hon. District Adviser.

The subject at all the lectures was thoroughly well handled, the lecturers lucidly explaining the methods of right and wrong dealing in the manipulation of the hives, and showing the great advantage attached to the modern mode of bee-keeping over the old barbarous one of murdering the bees at the end of summer. The lecturers were assisted by a fine set of slides showing every phase of bee-life and bee-keeping, a splendid set of diagrams, and bar-frame and other hives. audiences showed great interest in the subject, and an addition to the number of members has been the result.

IRISH BEE-KEEPERS' ASSOCIATION.

A committee meeting was held on 7th instant at 35 Trinity College. Present: Dr. G. P. Allen (in the chair), Dr. Traill, Dr. O'Farrell, Messrs. Vanston, Read, Milner, and the Hon. Secretary. It was determined to hold a bee show in July or August. Arrangements were made for the printing and distribution of leaflets pointing out the advantages of belonging to the Association, and of a new circular relating to the sale of members' honey.

CHEAP WAX EXTRACTOR.—I am very much obliged to you for inserting my query (No. 774), as by that means I have found the article I want, namely, a cheap wax extractor, and Killick's answers the purpose well. It is, as is said, a great boon to cottage bee-keepers, although it would be useful to one possessing, say, thirty or forty stocks. All you have to do is to put it in a slow oven with any old combs on the top and a little water in the pan, and in about an hour all the wax is run from the combs into the The plan far exceeds either Mr. Webster's or 'Amateur Expert's' process, as there is no mess, and by putting it in a slow oven the wax is not discoloured and turns out in a cake when cold, -A. S.

Correspondence.

The Editor does not hold himself responsible for the opinions expressed by his correspondents. No attention will be taken of anonymous communications, and correspondents are requested to write on one side of the paper only, and give their real names and addresses, not necessarily for publication, but as a guarantee of good faith. Illustrations should be drawn on separate pieces of paper.

oe arau on separate pieces of paper.

PAINTING INTERIORS OF WOODEN HIVES.

[860.] I was very glad to read the 'Useful Hint' at page 70 about painting or varnishing the interiors of I have always painted the whole of the wooden hives. insides of my hives-two coats of ordinary oil paint-I am not particular about the colour, but I take care to rub it thoroughly over every part of floor-board, brood nest, super cover, and roof. This I did with the first wooden hives I made, now many years ago, and I have advocated the practice in every lecture I have had the pleasure of giving on modern bee-keeping in different places throughout the counties of Down, Antrim, Armagh, and Tyrone. Most bee-keepers, like Mr. Pettitt of Dover, have exclaimed against the practice, but I remain unshaken in my advocacy of it. What led me to it was because a new straw skep is invariably varnished with propolis as soon as possible by the bees; and reasoning as to the why and wherefore, I saw that the moist vapour which rises from the hive would condense on the propolised or painted surface and quickly run down where the bees could use it with their food, or it would escape at the entrance and do no harm. Whereas I observed in hives with unpainted interiors that the moisture in cold weather sank into the wood and saturated it, whereby the bees were kept in an unnatural damp house for the winter months. Of course in dry warm weather it makes no matter, but our climate being mostly damp we have to provide for it. Then I tried the experiment myself, with the result that in hives whose interior is painted the quilts and winter packing remain always dry and sweet, while in one hive which I keep for curiosity with an unpainted interior I have to change the quilt and packing several times during each winter. Then as to the paint on the inside being injurious to the bees, which has been urged against my practice, why I have changed a strong colony into a bive on the second day after the interior had been painted, and I never had a better producing stock than it was immediately afterwards. All I look to is that the paint be quite dry. Moreover, it is a curious fact that bees are attracted by fresh paint. I observe that whenever any painting is being done outside my residence the bees quickly find it out and visit it, but for what purpose I am not in a position to decide. This partiality has been noticed long since, see for instance some correspondence about it in Vol. xiv. of Science Gossip for the year 1877. A couple of years ago I read a paper before our North-East of Ireland Bee-keepers' Association, in which I advocated on the above grounds the painting the interior of all wooden hives, but I was condemned by all my fellow bee-keepers. I rejoiced, therefore, when I found the Editor of the British Bee Journal telling how good it is to make the wooden hive as to its inside as comfortable as the bees make the skeps of straw.

As I am not ashamed of my opinions I have no occasion to adopt a fictitious name.—H. W. Lett, M.A., Aghadery Glebe, Loughbrickland, Co. Down.

CYPRIAN BEES.

[861.] I notice that in your last issue Mr. Simmins speaks strongly in favour of these capricious insects, but I hope 'our Editor's remarks will be sufficient to prevent any one being misled. In case they are not so I will add some of my experiences. These were not with one stock but with many, all of them headed by queens imported direct from Mr. Benton; though when an experienced apiarist gets one stock and finds it 'quite unmanageable,' he has every reason for believing that an increase would not be productive of benefit in that direction. Possibly my difficulties may have been the result of improper treatment, though 1 am generally considered to handle bees as well as most folks, and everything connected with their importation made it to my interest to make the best of them, as, whatever other faults they had, they were certainly profitable to sell, and had I been unscrupulous enough to recommend them they would no doubt have paid well; but, as Mr. Simmins remarks, some manufacturers, &c., only recommend what they honestly believe to be good, and I believe the firm I belong to (Abbott Brothers) are generally put in that class. Truly some statements were made at first based only on the reports of Messrs. Jones & Benton which had to be contradicted, but there was no intentional deception in this. I have found that while the Cyprians are in small colonies only, or while the hives contain only young bees, they may be easily handled, but that whenever a stock is in condition to work a super or store surplus honey it is as dangerous to handle as a bombshell.

As 1 at first devoted all my spare time to raising queens I had no strong stock to handle, and therefore could not fully appreciate their temper, but my subsequent experience is as much as I want. I remember one operation in particular. I had to remove a queen from a full colony and felt determined that it should have every chance of behaving well. Having put on a new straw bat and veil, and a freshly washed holland jacket, made on purpose for handling bees, with tightly-fitting waistband and belt, the attack was made very much as directed by Mr. Simmins, without smoke.

The combs were handled in turn, the queen caught and carefully put in her box; but here the trouble began. The bees suddenly found some flaw in my management, though I cannot say where; and though I had only to put the combs up together and replace the quilt, I was forced to retire twice before I could do so. The bees rose in a cloud and attacked me on all sides. Stings on the hands did not much matter, but when busybodies force themselves between one's coat-buttons and explore until they find a tender spot, it is more than a regular bee-man cares about. The second attack was made with the addition of string tied round the ankles, india-rubber gloves, and a smoker, but even thus armed I could not stay within range long enough to put on the quilt. Their resentment was now at its height, and a poor sparrow who settled near them was violently attacked and barely escaped with his life. Even when I considered all was over, and I had, after rest and refreshment, retired to my bedroom, an unsuccessful pioneer flew out on the removal of my waistcoat and attacked me with spirit. I do not say that Cyprian bees cannot be handled any more than I would say that tigers cannot be tamed or bomb-shells charged, for I have sometimes managed them very pleasantly, but I would strongly advise any one who has anything to do with them to be prepared for a desperate battle at any moment. J. A. Abbott, Southall.

NOTES ON BEE-HIVES.

[862.] In the issue of the British Bee Journal for March 10, the Rev. H. W. Lett, M.A., asks Messrs, Neighbour & Sons to explain how they mean the rain to

be kept out of their 'British Invertible Bar-Frame Hive. Unless their hives are sheltered by a shed or placed in a honse, he doubts their 'being adapted to a British climate.'

Messrs. Neighbour & Sons state their hive, No. 100 of their latest catalogue, or the above, will surpass all imported ones, because made to suit the British climate.

From an inspection of the illustration and accompanying description of it, it is not surprising that such an inquiry should be made, nor would questions about the inferiority of the patent Heddon hive be more remarkable, after a careful reading or study of Success in Bee Culture, by Mr. Heddon, containing so admirable a description of the Heddon new hive and system.

Mr. Cheshire states, on page 90 of Bees and Bee-keeping, Vol. ii., that Mr. D. A. Joues, while retaining the specialities of the Heddon hive, has introduced several modifications, which will be generally accepted as improvements. Several of the largest British bee-keepers, manufacturers, and appliance-dealers, have decided not to supply the patent 'Heddon hive,' one dealer is ready to make a 'Heddon hive;' another says, the Success in Bee Culture is the best thing he has read, taking into consideration all things; while another wishes for Mr. Heddon to give up his serews and close-ended frames.

As so much has lately been said in the $B.\ B.\ Journal$ about the pet Standard frames, and so little about the size of the patent Heddon frame, it would be interesting and useful to compare these sizes together with the new 14×14 in. frame of Mr. Simmins and the frame of Messrs. G. Neighbour & Sons. The $4^1_1\times4^1_2$ in. section seems to have a controlling power over the Heddon frame, but not entirely. When the Heddon sized frame is worked à la Heddon, it will be difficult to equal. The size and arrangement of the frames of Messrs. Neighbour do not at once appear to do so; and I do not think that Mr. D. A. Jones's arrangements are equal to those of Mr. Heddon.

It should be well understood that some frames are right for surplus honey, some for rearing bees, and some for a medium course; would it not be well to arrange for these purposes the frames in the following order respectively, viz., Heddon, Simmins, and Standard, because a specialist will always have some colonies doing one thing and some another?

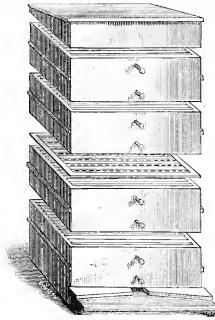

I am quite aware of the disadvantages, or more correctly the inconveniences, of having various-sized frames in an apiary or in this country. I also know a great deal of the sentimentality as well as the good connected with the Standard-sized frame; but I believe the time is coming when honey-raising will be developed into an industry on a different footing to what it is now, and upon more scientific principles. I am afraid the time is past when the cottager is the pet object to stimulate to walk in the better way, for will it really pay him to really keep all the bees he can at the present prices and low, falling prices of honey? Cannot good Mr. Simmins or someone give a lesson on raising wax? Cannot a few lessons be given on bee-breeding, and upon other subjects we are so much in the dark about?

As it would take a small pamphlet to go over the Heddon system seriatim I shall forward, with your kind permission, other notes occasionally; but it would be well to compare the floor-board and stand of the two hives in question (quite different in illustration), as well as the roofs of each. It should be mentioned or noted, that Mr. Heddon uses a shade-board which is kept in place by means of a large stone, and is to my mind evidently superior, as it protects the hive from undue heat in summer, and would act as a slope to turn off any rain encountered in this climate.—T. Bonner-Cham-

BERS, F.L.S., March 11.

IS NEIGHBOUR'S BRITISH INVERTIBLE HIVE WATERPROOF?

[863.] In reply to the Rev. II. W. Lett's inquiry in the previous number of your Journal, we beg leave to say that undoubtedly the best protection for such a hive is inside a bee-house or within an outer covering, but our notion has been that the British invertible hive may be kept in the same way as bee-keepers are in the practice of keeping the original and well-known Stewarton boxes, which are of the same thickness of material, and where the owners either provide protection from weather according to their own taste, or, as is the ease in some instances, leave the hives exposed. Mr. Lett is no doubt apprehensive that the rain will gain

The British Invertible Bar-frame Hive.

access at the crevices. To guard against this we make the boxes to fit as close as possible together, and recommend that the roof be made secure by first putting on two coats of paint, and whilst wet stretching unbleached calico, then, when dry, adding two more coats of paint. We are about adopting a waterproof wrapper for the sides, which we think will be an improvement and supply the double purpose of keeping the hive thoroughly dry throughout the year, and also form a desirable shade during the hottest part of the summer.

This extra protection can be either carried out by the purchasers or supplied by us direct at a fractional additional cost; and if it prove as satisfactory as we anticipate, we will, with Mr. Editor's permission, publish a fuller description in a future number of this Journal.—Geo. Neighbour & Sons, 149 Regent Street, London.

INVERTIBLE HIVES.

[864.] Having recently procured one of Neighbour's Invertible hives, which is alleged to have been adapted to suit the British climate, I was a little disappointed in finding it very imperfect as to the resistance of wind and weather, and indeed but little better suited for outdoor use here than the new Heddon Invertible hive.

If this hive were allowed to remain unprotected in those parts where the several boxes rest on each other, the rains of this neighbourhood would penetrate to the inside in a few minutes, and in the event of its being left in this place without the boxes being attached firmly to each other by some means, the whole affair would soon be blown into the lake piecemeal.

Notwithstanding the various opinions pronounced on the merits and demerits of the peculiarities of this new hive, I incline to think that under intelligent manipulation it will become a success.

Mr. T. B. Blow has corrected one of the deficiencies alluded to, in his new invertible hive, and the size of the frames adopted by him is also an advantage as compared with other hives of this class, but the new hive still remains imperfect for outside purposes, in the want of due protection from beating rains.

Seeing how much interest appears to be felt in the Heddon Invertible hive, it is much to be desired that any new version or modification of it which may yet appear may be free from the defects pointed out, and the communication on this subject by the Rev. Mr. Lett, in your last issue, is very timely.—W. J. M., Loweswater Hall, Loweswater, Cumberland.

APIFUGE AND METHYL SALICYLATE.

[865.] Mr. Grimshaw's letter resembles the wail of a peevish child who fears the loss of a new toy. Let him not be troubled, I do not covet his 'Apifuge,' neither have I attempted to deprive him of it.

I have not his faculty for saying very little in a great many words, but, lest it should be thought that I am quite swamped by his exuberant verbosity, I should like a few words in reply.

Mr. Grimshaw is rather egotistical in assuming that my actions are in any way influenced by his. Let me assure him that his doings and writings are quite unimportant to me.

I happen to employ methyl salicylate in my own business, buying it in a pure form in quantities. Therefore, finding there was likely to be some demand for it, I offered it for sale, but not before the season commenced. If, in the meantime, Mr. Grimshaw wrote an article, that was no fault of mine, and no reason why I should abstain from offering it. If it proves to be useless, no one will buy it, and Mr. Grimshaw cannot complain.

The word Apifuge is not 'copyright,' that term only applying to designs and literary compositions. Hence my ironical remarks which have so stung Mr. Grimshaw. If he will refer to Act 46 and 47 Vic., cap. 57, sec. 105, he will find that he is liable to a penalty of 20l. for applying the term 'copyright' to an article not legally entitled to be thus termed. He might have also noticed that in my advertisement of 24th February, I placed the word 'Apifuge' in inverted commas, to indicate that it was not my term, but quoted from someone else. I do not want to know the composition of his preparation; if I did I should take more direct means than the roundabout way he suggests.

It matters not whether the smell pervading the tent be that of methyl salicylate or of any other compound. The taunt will still remain unanswerable that the bold operators have besmeared themselves with some substance to protect them. While discoursing upon the ease with which bees are subdued and rendered harmless by smoke only combined with care and skill in manipulation, I must confess I am too dense to see any inconsistency in my raising a protest against the use of these substances merely because I happen to be the proprietor of Dr. Pine's Lotion. It may seem inconsistent to decry an article which I offer for sale, but although my personal opinion is against the use of these substances, many may differ from me and wish to purchase methyl salicylate, not knowing where to procure it.

I am sorry my lotion failed to cure Mr. G., possibly the wound was poisoned by his 'Apifuge.' The lotion is intended to cure the effects of stings, not those of poisonous substances. It would not have commanded a sale for ten years if not found efficacious.—F. Lyon.

Replies to Queries.

[818.] Varnishing galvanised Iron Reservoir. (R. E. Lloyd.)—I should not recommend varnishing the galvanised iron reservoir you have in use. Is there any objection to coating it with white enamel, such as used in baths, saucepans, &c.? I have had no experience with this, but should fancy it would be far preferable to a zinc vessel or to one varnished.—J. T. Pattison, Cheshunt.

[853.] Chrome Alum.—Mr. J. B. Butler, Bristol, can procure chrome alum of any dealer in photographers' necessaries; it is used in small quantities by makers of dryplates, and has the property of rendering gelatine or glue insoluble. Bichromate of potash, of any chemist, and many other chrome salts, have a somewhat similar effect. I think Mr. Butler's suggestion a good one, and well worth a trial. Any good glue would do, but common glue, being adulterated with other gunmy substances, would not be rendered sufficiently insoluble.—J. A. Abbort, Southall.

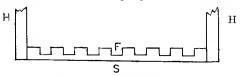

[853.] Any good gluc, size, or gelatine will do, and bichromate of potash can be obtained at any chemist's who supplies photographers. The process is the same as used in carbon photographic printing, and to render the glue insoluble, should, when dry, be exposed to full daylight. It is not sensitive while wet. The mixture would keep good for a week or more if kept wet in a cool place, or if dry, excluded from light and air, or the article could be made of plain glue and paper, allowed to dry, and then saturated with a cold solution of the bichromate.—H. M. Appleton, Bristol.

[857.] Pure Liqurians. (J. W. L.)—You would have to keep them at least from two to three miles away; even at that distance they will occasionally get cross-fertilised. Hybrids are usually splendid workers.—W. B. Webster.

[857.] (J. W. L.)—You must put Ligurians quite five miles from blacks to keep them pure. You may put your nuclei any distance from three yards to one mile for the purpose mentioned.—AMATEUR EXPERT.

[858.] Pure Fertilisation. (J. W. L.)—Any distance from a yard to two miles; but then there is no certainty that a drone from this particular apiary will be the selected one, as there may be other apiaries within a mile or two.—W. B. Webster.

[859.] Packing Hives. (H. B.)—Cut a piece of wood the exact length to fit inside the hive, as seen in the sketch. The hive walls are represented at H H. In the piece of wood cut as many notches to fit the bottom rails of the frames, as seen at F, as you intend to send bars in the hive; this keeps the bottoms of the fames from oscillating. Now fix the ends of the top bars by putting a fine screw down through each into the top of the hive-walls; this will make the frames a fixture. If you put nails instead of screws, you will have a fine opportunity of testing the efficacy of Mr. Grimshaw's 'Apifuge.' Now fasten a strip

of perforated zinc over the entrance, remove all the quilts, and fasten a sheet down on the tops of the frames so secure as to be only removed with tools, and so that no bees can possibly escape. You do not say how far you intend to send them, nor when. You must choose suitable weather, so that the bees do not get chilled; and if it is in the hottest of summer you must so pack the lid of your hive separate that the railway people cannot put it on, and so smother the bees. Goods train will do if sent in a covered truck, but more care is taken by passenger trains. By taking the extra precaution of binding each comb with two 'foundation fixers,' bees so packed have been carried on a three hundred miles' journey in the month of August by—Amateer Expert.

[859.] Packing Bees. (H. B.)—Tie two thin tapes round each frame, as in transferring; nail two pieces of wood along the ends of the frames on top, so as to fix the frames

tightly together and prevent them rocking; in place of the quilt, fix a flat board having an oblong hole at least three inches wide, and of sufficient length to cover all the frames, a strip of perforated zinc being tacked on top to cover same; fix a piece of the same material over the entrance, which should be at full width; serew the body to the floor-board and the roof to the body; cord firmly and label 'Live Bees, with Care,' 'Not to be roughly handled, or thrown down.' More ventilation will be necessary in warm weather by increasing the size of the hole in the board on the top of the frames,—W. B. Webster.

Queries.

Queries and Answers are inserted free of charge to Correspondents When more than one query is sent, each should be on a separate piece of paner.

of paper.

Our readers will greatly oblige us by answering, as far as their knowledge and observations permit, the Correspondents who seek assistance.

Answers should always bear the number and title placed against the query replied to. Any queries unanswered in this way will be answered by the Editor and others.

[866.] Water for Bees. Would some bee-keepers kindly tell me how I can make a watering-place for bees that would look a little ornamental, as well as being useful, and they would much oblige—J. F.

[867.] Bell Glass to hold 35 lbs. Will any of your readers give size of hell-glass inside measurement to hold 35 lbs. of honey-comb worked in it?—A Subscriber.

Echoes from the Pives.

Keswick.—Supplying Bees with Artificial Pollen.—The weather here has been most favourable for our little pets. We have had a few dull days, but as many bright and sunny. Bees have made the best of it, though there has been very little to be done in collecting natural pollen. Palms are not yet quite in bloom; crocuses are the only plants that are of any value to the bees. I have given them flour in crocuses, but filling them with artificial pollen occupies too much time, so, as soon as they were working well on the crocuses, I made some little cups out of yellow paper, and put a crocus flower in them to attract their attention. These artificial cups I make about an inch in diameter, and a little more in depth, but it does not matter about the size; when larger they hold more flour. They are much better than crocnses when a few scores of them are planted here and there among the natural blooms; the bees collect it out of them much quicker, and at the same time there is no waste as with the flowers. I noticed some of my best stocks going in their hives at the rate of ten bees per minute laden with this artificial pollen. These cups are simply made by clipping pieces of paper $3 \times 2\frac{1}{2}$ inches. take something the shape of a trowel-haft, lap one half of the paper round the tapered end, and twist the other, and it is made. A small piece of stick can be tied to it, or it can be stuck in the soil without. This will be a nice occupation for the lady bee-keepers.—R. Philipson.

Swannore, Bishop's Waltham.—I am glad to report on

Swanmore, Bishop's Waltham.—I am glad to report on the whole fairly favourable weather for the bees. On many days during the past fortnight they have been enabled to take good, healthy, cleansing flights, and to-day, March the 9th, I see they are carrying pollen—a favourable sign at this time of the year. I have seen a good many stocks during the past week or so, and I am very glad to note that as a rule bees in this district have wintered well; in my own no trace of dysentery, or in fact anything wrong. I find, however, that the consumption of stores has been considerable, and feeding will shortly have to be started in some cases; I am not, however, an advocate for early feeding, except in cases of necessity.—H. W. West.

East Yorkshire, Beverley.—My bees, fifty-eight stocks, have wintered well without a single loss, notwithstanding that nearly a dozen of them are small lots with young queens in makeshift hives, and during the great storm we had in late autumn several of these were either blown over or had their covers swept off with the gale, and four of them had all their quilts and coverings blown away, leaving the bees exposed to a downpour of rain; still they are looking healthy, and have been carrying in pea-flour in quantities during the last week or so. These nuclei are

kept, of course, to nnite to any stocks that may chance to become queenless; but should they not be required for this purpose I shall have no difficulty in building them up into strong colonies by the time of the white clover honey harvest. Those colonies, thirty in number, which were at the heather are remarkably strong, and have been breeding ever since the frost and snow left us early in January. Mine are English bees, which for honey gathering and sealing, quietness under manipulation, freedom from robbing, and hardiness, there are no foreign bees to compare with them.—F. Boyes.

Ripon.—Invertible Hives.—I have just come in from shading my hives and spreading hay round about them, as we have had a very deep snow last night, and the sun is now shining bright and hot. My fourteen hives have wintered well on my plan (see B. B. J., January 20th), and I do not see any difference between those in double or single-walled hives. Talking about hives, I have never seen anything, while mentioning invertible hives, about the upward slope of the cells. We used to read about 'beautiful provision of Nature,' 'worderful instinct of bees,' in that the cells all had this upward slope to prevent the honey running out. Now it is proposed to invert the cells, what will be the result? I should say thin honey would run out, and the bees, after disgorging it, will have to make a clean bolt before the honey follows them. Nothing would induce me to use an invertible hive, or even section crate. I never have any difficulty in getting my sections well filled, and without pop-holes, but then I keep my bees nusually strong (see B. B. \hat{J} ., January 20th), and that is the whole secret of it. I had dozens of sections last year that I could not tell the top from the bottom of. But the times go very fast now, although we have already goue back to the crownboard, or rather American-cloth, which has the same effect, viz., stopping upward ventilation. Some years ago we were told that the crown-board was the cause of dysentery, and I believe myself that such was the case, but no doubt we shall hear more about the enamel-cloth in times to come. Dysentery, as we all know, is caused by dampness, and if you had a large room badly ventilated, and with a small fire, it would probably be damp. In the same way as a small fire will not warm or dry a large room, so the heat from the bees will not warm and dry a large hive, and I therefore prefer the ordinary quilt, with a much-contracted hive—seven Woodbury frames—for wintering, and I never have dysentery in my hives, although I do not use cork, or any other cushions, and many of my hives are of only halfinch board.—ARTHUR J. H. WOOD.

The Apiaries, Glenluce, Wigtownshire, March 9th.—Travelling south this morning from Glasgow to pay my brother's apiaries a visit, I have just arrived, after a somewhat long and wearisome journey and intense cold, notwithstanding the day is lovely with bright sunshine overhead. All my brother's bees have wintered well, and to-day they are busy working on the crocuses and snowdrops, carrying in pollen. I examined fifty stocks, and found the bees very healthy and breeding. Should the season turn out good, we may expect to hear of some good results from this district. All my brother's bees are the common blacks, his hives being mostly made for extracting on the storifying or 'tiering-up principle. The apiaries, which are considered the largest in Scotland, are at all times open for inspection, and those visiting the locality will find it instructive to give those apiaries a visit and learn the method pursued by Mr. Wm. M'Nally, in Scotch bee-keeping.—J. D. M'N.

NOTICES TO CORRESPONDENTS & INQUIRERS.

Letters or queries asking for addresses of manufacturers or correspondents, or where appliances can be purchased, or replies giving such information, can only be inserted as advertisements. The space devoted to letters, queries, and replies, is meant for the general good of bee-keepers, and not for advertisements. We wish our Correspondents to bear in mind that, as it is necessary for us to go to press in advance of the date of issue, queries cannot always be replied to in the issue immediately following the receipt of their communication.

- J. B. S.—Bees Starved.—Your bees have died of starvation. In their chilled and weakened condition they were unable to leave the cluster to take advantage of the proffered candy. Your assistance was rendered when it was too late.
- O. B. T.—'Brood Chamber—Shave off.'—We do not find any reference in our issue of January 27th to the subject

- of the above heading—nor in any recent number. If you refer to stimulation by uncapping sealed honcy near the brood-nest, it may be done now, at any time during fine weather, by turning back the quilt, and uncapping a few square inches of comb above, or on either side of the brood-nest, close to the cluster of bees. Breaking the caps of the cells by scratching will do equally well.
- E. W. P.—Removing Hives.—If your bees are in framehives procure frames, made of laths, to fit the tops of
 your hives and tack upon them strong coarse canvas.
 Remove the quilts and screw down the canvas-frames on
 the tops of the hives, having first closed the hiveentrances. A strong screw, on each of the four sides
 of the hives, driven into the floor-board will render all
 secure. Each hive should be 'corded' in the manner of
 a box, for convenience in earrying, and must travel right
 side uppermost. If skeps, invert, tie canvas over the
 mouths and let them travel inverted. See also 'Packing
 Hives, p. 122.
- W. MITCHELL.—1. Bees. The bees marked 3 are but a slight remove from black. Supposed Palestines are hybrids, far removed from pure. Supposed Italians are but little different to blacks. When dead, bees are always shrivelled up, but if forwarded alive in Benton, or similar cage, a more satisfactory investigation could be made. 2. Simmins' Hive Cover.—You will find the cover as made for hive 17½ in. square will also do for 17 in. frame-hive, if the outer dimensions do not exceed 19 iu. If larger, then add the greater length required to both long and short side. Cut one piece carefully, and then mark off your board with that, reversing each time. For mitres bevel off to § in. on underside.
- C. A. J.—Removing Frames from Full Hive.—If the foundation is properly fixed by insertion in saw-cut or otherwise, and the hive is perfectly level, the comb will be built evenly by the bees. To secure the correct distances between frames many devices are employed, such as staples, broad shoulders, metal ends, &c. To overcome the difficulty of removing the frame from a very full hive, make the hive wider (or longer) than the ten frames required, and insert two division-boards, one on each side, and fitting close all round; and then, by removing one of these when examining a hive, you obtain space and avoid all danger of injuring your bees or your queen.
- WESTBOURNE.—Straining Extracted Honey.—If the honey is thick from suspended pollen no amount of straining will clear it. If it is required to remove the fragments of wax, if left at rest for a few hours they will float, and cau be skimmed off.
- W. F. A.—1. Stocks Travelling by Rail.—The safety depends upon the packing. Skeps should be tied over with cheese-cloth or paper-hangers' canvas, not with sacking or any close-textured material, and travel upside down, the top resting upon a ring of hay or straw to prevent jarring; a rope put round to form a handle to hit by is an addition to the chance of safety. Bar-frame hives must have the quilts, &c., removed, and replaced by a square of open material, the frames kept from moving by two slots screwed firmly across the whole of them, the entrance closed by perforated zinc. If pads of hay enclosed in canvas are fixed to the bottom boards to prevent jars, and rope handles to lift by, it will be all the better. See above, reply to 'E. W. P.' 2. Cost of Carriage.—You had better inquire at the station at which the bees are to be sent or delivered.
- H. Mee.—Queen jound alone.—It is a case of robbery, the other bees having been killed or joined the robbers. Keep the queen warm, with a few workers to take care of her, and some food, and she may survive to be united to another stock which you may find queenless.
- T. R. Garton.—The standard frame of the B.B.K.A. is 14 inches long by 8½ deep, the top bar being 17 inches long, ½ ths of an inch thick, the bottom bar ½ th, the side bar ½ th, the width being ½ ths of an inch. Between the bottom of the frame and the floorboard a passage of ½ inch should be left. The distance between the tops of frame and the rack should not be less than ½ th, and not more than ½ ths of an inch. Number of frames should be from ten to twelve, according to district. The size of frames arrived at, you will be able to ascertain the dimensions of the

frame-block; you will find very full directions for making frame-blocks in British Bee Journal, Vol. III., page 6.

frame-blocks in British Bee Journal, Vol. III., page 6. Wax.—Galvanised piping will not be deleterious to the wax.

M. H.—Spreading Brood.—Under no circumstances must you spread the brood now; wait until the middle of April, and even then it is a risky operation for an amateur. Do not change the bees from one hive to another until warm weather sets in. In doubling, the combs without the bees, but with brood and eggs, are added over another strong stock; this must be done just before the honeyflow commences, the bees shaken from such combs being treated as a swarm; that is, supplied with foundation as you have no spare combs.

Wneatfield.—1. Eggs.—It is an established fact that the eggs to produce either queen or worker are identical.

2. Royal Jelly.—It is a peculiar—we might almost term it lacteal—secretion of the worker bees.

3. Queen Depositing Eggs.—The extremity of her body is inserted into the cell.

4. Use of Formic Acid.—This statement of the gentleman has been greatly ridiculed, although he does not say that formic acid is used in capping the honey-cells, but simply injecting it into the honey contained therein.

Dumfries.—1. Yes. 2. Of no use, it being much too early to get the queen fertilised. 3. Unite the queenless stock to another having a queen. 4. Such hives are too cumbersome, and you would do well to discard them. Ont-of-door wintering in single chaff hives—i.e., double-walled hives packed with chaff—is successful in North America and Canada, although cellar wintering is much more general. We should very much like to know how you would succeed if you could possibly try this latter plan in your district.

IGNORAMUS.—Your bees have died of the disease called Bacillus Gaytoni, or depilis. See reply in our last issue

to 'C. A. T., p. 112.

W. T.—1. Dry Sugar Feeding.—The important thing is to get a sugar which is as far as possible free from chemicals as well as from those dyes which are used to make sugar bright yellow or snow-white. For dry sugar feeding the order of merit might thus be arranged,—Porto Rico, Barbados, Jamaica, and such other old-fashioned raw sugars. If therefore, as you say, you have a difficulty in procuring Porto Rico, proceed to Barbados, and so on. 2. Preventing Queen from ascending into Supers.—The use of excluder zinc under the sections is for many cogent reasons undesirable. Allow not less than a quarter of an inch and not more than three eighths between the rack and frames.

F. W. C., Lismore, and R. Philipson, Keswick.—The heath forwarded is Erica carnea.

An Amateur.—1. The terms 'bar-frame hive' and 'moveable-frame hive,' apply to the same kind of hive. 2. The Cowan hive is obtainable from C. T. Overton, Lowfield Apiary, Crawley, Sussex, to whom apply for prices.

H. W. Perkins.—Robbers attacked your hive in great numbers, and the bees, unable to defend themselves,

were obliged to succumb.

W. H. A.—1, Transferring —It is sometimes recommended that this should be done tweuty-one days after swarming, when there will be but little brood in the hive; and if you swarm the stock artificially it would be the same. It is not at all necessary, however, to wait for swarming, either natural or artificial, if you take care not to chill the brood. Choose a warm day, and either drive the bees out, or, which is by far the better plan, remove the combs by 'bumping;' lift them out one at a time and tie them into the frames, shake the bees off the second and succceding combs on to the first placed in the bar-frame hive, putting each frame of comb into it. As tied in by this plan the brood and bees are not separated for many minutes, and no risk of chilling is incurred, as is the case when all the bees are driven out and not returned until all the combs are tied in, as usually recommended. 2. Utilisation of Combs stored with Syrup.—These may be tied into frames and given to the bees, either in the hive or behind the divider, to be cleared out.

Amateur Naturalist.—Loss of Queen.—Please refer to 'Useful lfints, p. 118, where you will find similar cases

to yours argued at some length. Your hive being queenless, your best plan will be to join it to another.

M. E. M.—We prefer sample No. 1 for dry-sugar feeding. For syrup feeding use Duncan Pearl or American Granulated.

CORRECTION.—Gloucestershire Bee-keepers' Association, p. 104. The local secretary for Bristol district is Mr. J. B. Butler. Mr. H. M. Appleton is a member of the Committee of the Gloucestershire B. K. A., and local secretary to the Bristol district of the Somersetshire B. K. A.

RECEIVED from Mr. H. Dobbie, Cringleford, Norwich, a collection of seeds of border annuals, with a packet of Chapman honey-plant.

Received from G. Neighbour & Sons, 149 Regent Street, and 127 High Holborn, their trade catalogue of hives, bees, and appliances, 70 pages.

Show Announcements.

EXAMINATIONS.

Upon reference to the report of the last Committee Meeting of the B.B.K.A. (see page 127), it will be found that the annual examination of candidates desirous of gaining first or second-class certificates will be held in London on Wednesday, April 20th. The examination will be open to all candidates who have already obtained a third-class certificate. An entrance-fee of five shillings will be required from each candidate. Candidates intending to compete must give notice to the Secretary, J. Huckle, Kings Langley, Herts, on or before Wednesday, April 13th.

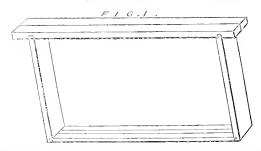

IMPROVEMENTS IN FRAMES AND SECTIONS.

We have had forwarded to us for inspection some frames and sections patented by Mr. James Lee, containing improvements which promise to be of use to bee-keepers. For some years bee-keepers have been using dovetailed sections, or those in one piece with **V** or square grooves, which, if care were not taken in the folding, sometimes broke and became useless, and unless very accurately made, were often not square.

This invention is an improvement which is a decided step in the right direction; and if Mr. Lee's ideas are correct, which trial will be able to prove, we shall be able to secure some of the advantages claimed for the invertible hive without any of its disadvantages.

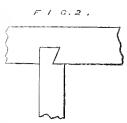

The frames, sections, and hives, are all put together without nailing, and the principal improvement consists of a 'continuous dovetailed groove' with tongued ends to fit. By referring to the illustrations the method of construction will be more readily understood. Fig. I shows the frame, and fig. 2 is a full-sized diagram of the joint in a standard frame. The top rail of the frame is in two parts, with the dovetail grooves on the underside which receive the ends of the bars tongued to fit these grooves. The lower ends of the bars have similar grooves and receive the bottom rail, which is also in two parts.

For putting the frames together a frame-block is used, and with it the frames are completed, and foundation fixed very rapidly. In using the block one half of the top bar of the frame is dropped into

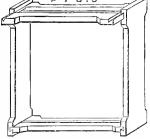

the groove made to receive it; the sides are next added, the dovetails being pressed down as far as they will go. One of the halves of the bottom rail

is then slipped into the groove at the bottom of the side bars and pushed down. The foundation is then laid on, covering the half top bar, and passing half over the bottom rail. The second half of the top bar is then pushed down and pressed tightly on to, and securely

fixes, the foundation. The other half of the bottom rail is also put in its place, but allows the foundation to hang loosely, to allow of stretch ing, there being a space of $\frac{\pi}{10}$ inch full between and also to prevent bulging, Mr. Lee being of opinion that this will

opinion that this will secure well-filled frames without any enecessity for inverting them. The top bars are also slightly convex on their inner edges so that they give an equal grip throughout when pressed tightly home.

Sections are made on exactly the same principle, fig. 3, and are also put together on a block. The top and bottom rails are in halves, and foundation is to be placed filling the sections, and secured by

driving the half rails down. It will be seen that there are passage-ways on all the four sides. In use they are fitted into the frames which have passages cut out of top and bottom rail to correspond with those of sections. These are placed with the longest sides next the top and bottom rails so as to have a \frac{1}{4} inch space between them, and they have a passage-way at the ends, like in those of of Mr. Sambels (see page 59 of Journal). separators, which are also like those shown by Mr. Sambels, have openings corresponding, forming permanent passage-ways for the bees, and with full sheets of foundation perfectly filled sections will be the rule without the necessity of popholes. This is a very important consideration, and if it is as successful as Mr. Lee thinks it will be, a great point will have been gained. The frames which hold the sections have the half-bee space at top and bottom, so that they can be used for storifying, the separators spring on, and their points fit into grooves in the side bars. When filled, the sections can be placed on their projecting ends, and in case of a bruised cell the section itself would not get covered with sticky honey, and the foundation showing through the top rail, can be covered with a label. Hives and section-racks are made on the same principle of continuous dovetailed grooves and tongues, and are intended to be sent away in the flat, and put together without any nailing. Mr. Lee has also sent an ingeniously constructed box for the carriage of sections. Three sides fold up, and by means of three loose pieces which are pushed into the grooves, the box is completed.

The workmanship is all that can be desired for accuracy and finish, and the whole method of puting together so simple, that with the block even quite a novice could not go wrong. If they can be manufactured at a reasonable price, and Mr. Lee assures us that they can be made to compete successfully with the Americans, we are sure these improvements will be appreciated by British

bee-keepers.

SLOTTED DIVIDERS.

We desire to call attention to the illustration of an article designed by Mr. T. B. Blow, of Welwyn, Herts, which will be found of service to producers of comb honey. It is a slotted divider, for

use more especially with the 4 bee-way sections. By its use the bees have free access to every part of each section, and thus popholes and other imperfections may be avoided. A form of slotted divider was mentioned both by Mr. Corneil and Mr. Jones, but the great drawback stated by them was the expense of production. This, we understand, has been got over by Mr. Blow, who has provided special machinery to produce these dividers.

They are produced either in wood or metal. The slots, too, can be made a little wider than in illustration, so that ordinary 2 bec-way sections can be used. These, then, have almost equal advantages with 4 way ones.

BEES-WAX AND ITS CONVERSION INTO MONEY.

By J. Dennler, President of the Strassburg Enzheim Bee-keepers' Association; Editor of the Elsas Lothringer Bee-keeper; Author of Honey as Food and Medicine, and Honey and its Use.

HISTORICAL.

Bees-wax was known in ancient times. The Bible tells us of a land flowing with milk and honey; and where there was honey, there must also have been wax. Pliny speaks of white wax, and in the time of Dioscorides wax was rolled into sheets after a method described by him.

At that time materials for lighting made out of wax fetched a high price; they were used at divine service, and the consumption which was at first comparatively small, was afterwards increased by the spread of Christianity. The bleaching of wax was at that time followed as an independent trade, and one sees how extensive it was by the fact that towards the end of the seventeenth century there were in Hamburg above fourteen bleaching-houses for wax. Certainly, with the exception of oil and tallow, as well as the inevitable torch, no other material for lighting was known except wax, and wax could only he used by very rich people.

Even princes who allowed themselves this luxury (as it was then held) were accounted extravagant. But, besides for tapers, wax was used in still larger quantities for the representation of artificial flowers and fruits, which were much used as ornaments for rooms, for artificial flowers made of stuff were not then known.

The Reformation dealt a great blow to the wax trade, in that the Evangelical Church did away with tapers at

their divine service.

By the introduction of sugar bee-keeping was decreased still more, and the production of wax was reduced to a minimum. As important competitors of wax, there appeared in trade the wax obtained from various plants and minerals, such as stearine, paraffine, kerosine, and others, which lowered still further the price of bees-wax.

Germany has always produced a very much-prized wax for technical, medicinal, and artistic uses, as well as the various Austrian provinces and Switzerland. Turkey is said to produce the best of all known sorts of wax. Turkish wax is also the dearest; usually bright red in colour. France produces a large quantity of splendid wax. Closely following the French comes the Spanish, in cakes of from $2\frac{1}{4}$ to $3\frac{1}{2}$ lbs. in weight. Italy produces large quantities of excellent wax. Of the various kinds of wax other than European, the West Indian, Egyptian, and Barbary wax are highly prized.

THE PRODUCTION OF WAX.

Bee-keepers, and amongst them Swammerdam, Maraldi, Réaumur, and others, were for a long time of opinion that the bees collected the wax directly from the flowers (Swammerdam: Biblia Natura: Maradi: Observations sur les Abeilles: Mémoires de l'Acad. des Sciences, 1712; Réaumur: Histoire Nat. des Abeilles.) But the experiments of Hunter have shown that the bee plays by no means so simple a part in the production of wax, for this great anatomist, as long ago as the year 1702, gave a description of the segments of the bee's abdomen, by which the wax is separated into small scales (Philosoph. Trans., 1712), an observation which Huber of Geneva confirms in his Nouvelles Observations sur les Abeilles, II., chap. 1. Already in 1864 (1664?) Martin John had made the same observation.

(To be continued.)

ASSOCIATIONS.

BRITISH BEE-KEEPERS' ASSOCIATION.

The first meeting of the newly-elected Committee was held at 105 Jermyn Street, on Wednesday, March 16th. There were present the Hon. and Rev. H. Bligh, the Rev. Dr. Bartrum, the Rev. F. G. Jenyns, the Rev. F. S. Sclater, the Rev. G. Oddie, Captain Campbell, H. Jonas, J. M. Hooker, W. O'B. Glennie, Treasurer, and the Secretary. Letters were read from the Rev. J. L. Seager, the Rev. Geo. Raynor, Captain Bush, and Dr. Walker, regretting their inability to be present.

It was resolved unanimously that Mr. T. W. Cowan be appointed chairman, and the Hon. and Rev. H. Bligh vice-chairman, for the ensuing year. The following subcommittees were appointed:—Finance: the Rev. Dr. Bartrum, the Rev. F. G. Jenyns, and Mr. H. Jonas. Educational: the Hon. and Rev. H. Bligh, the Rev. Dr. Bartrum, the Rev. Geo. Raynor, and the Rev. F. G. Jenyns. Exhibitions: the Rev. F. S. Sclater, the Rev. J. Lingen Seager, Captain Bush, H. Jonas, and J. M. Hooker. County Associations: the Rev. F. S. Sclater, the Rev. J. Lingen Seager, Captain Bush, Rev. G. Oddie, and Dr. Walker.

An application from Mr. H. Bunbury, of Bury St. Edmunds, requesting the B.B.K.A. to undertake an exhibition of hives, honey, &c., in connexion with the Suffolk Agricultural Society in June next, was considered. It was resolved that Mr. Bunbury's application be acceded to subject to terms to be arranged. The Exhibitions Sub-committee were requested to prepare a suitable schedule in accordance with the amount proposed to be expended.

The following resolution passed at the Annual General Meeting of the members, was referred to the Exhibitions Committee, with the request that they should report thereon at an early date, viz., 'That the Committee be requested to draw up a form of rules for exhibitions, with a view to establishing uniformity at all shows throughout the counties—a recommendation being added that shows should be advertised as held under the B. B. K. A. rules.'

It was resolved that the date for the annual first-class examination to be held in London should be fixed for Wednesday, April 20th, the date of the next quarterly meeting.

MIDDLESEX BEE-KEEPERS' ASSOCIATION.

Committee meeting on the 16th, at 105 Jermyn Street. Present, Hon. and Rev. H. Bligh, in the chair, Major Fair, Dr. Raynor, Messrs. Jonas, Kennell, Gunn, Hasluck, Campbell, Leach, and Graham.

The general routine business having been disposed of, it was resolved that the M.B.K.A. defray the expenses of a lecture on bees to be delivered at Southgate by Mr. Sambels on the 24th inst. That the silver and bronze medals of the B.B.K.A. be allotted to the N.E. Province for competition this year at a show to be held at Palmer's Green on the 8th and 9th July, in connexion with the Wood Green Horticultural Society's Show, and that 4l. be added thereto towards additional prizes.

The following representatives were elected to serve on the Committee of the B. B. K. A., Dr. Rayner for N.W. Province, W. M. Graham for N.E. Province.

SURREY BEE-KEEPERS' ASSOCIATION.

On Saturday, I2th inst., the above Association held their eighth annual meeting at the Royal Arms Coffee Tavern, North Street, Guildford. There was a large attendance, and John C. Ramsden, Esq., of Bushridge Hall, one of the vice-presidents, took the chair. Amongst those present were Mrs. Maclear, Messrs. S. Wellings, F. H. Lemare, and J. Harrison (district secretaries), Mr.

Thos. Chapman (chairman of the committee). Mrs. Tickner, Mr. E. Daw, and Captain Campbell, were also present

The Secretary (Captain Campbell) read the report of the Committee, from which it appeared that 140 new members had joined during the year, and the Association now numbers 420 subscribers and donors. The county was divided into districts, of which ten are already organized, including Guildford and Godalming, Croydon, Sutton, Leatherhead, Haslemere, Abinger and Wotton, Cranleigh, Chohham, Camberley and York Town, East Molesey and Surbiton. Bee and honey shows and lectures had been held at various localities during the year, besides the annual county show at Leatherhead on the 31st July last. The Association also took part in the National Exhibition of British honey in the Winter Gardens of the Albert Hall, South Kensington, when a magnificent display of British honey from nearly all the counties of England was collected, and at which fifteen bronze medals were awarded to the county of Surrey, besides the silver and bronze medals and certificates of merit of the British Bee-keepers' Association for the Leatherhead show. The financial statement was then read, showing a sum of 8%. IGs. 3d. due to the treasurer, but with assets to the value of 371. in property of the The report and statement of accounts Association. were adopted and officers re-elected, and after the usual vote of thanks to the Committee, office-bearers, &c., the Chairman presented the medals to those of the exhibitors that were present, including Captain Campbell, amidst the cordial cheers of the meeting. Mr. W. B. Webster of Wokingham was then invited to exhibit and explain some inventions and appliances in bee-keeping, and described some new methods adopted in bee-culture. Coffee and tea were served, and after some pleasant conversation on bee matters, the meeting concluded with a hearty vote of thanks to Mr. Webster for his interesting remarks.

FORMATION OF EAST LOTHIAN BEE-KEEPERS' ASSOCIATION.

On Friday, March 4th, a meeting of those favourable to the formation of an association for the purpose of promoting the study and practice of bee-keeping was held at Haddington - the Rev. John Kerr, M.A., Dirleton, in the chair. The Chairman, after explaining the objects of the meeting, stated that he had already received letters from over thirty gentlemen in different parts of the county, who were ready to join such an association as was proposed, and that, in addition, he was aware of others being favourable, who had not yet sent in any letter to that effect. Besides the primary purpose of such an association, it was also intended to arrange with certain merchants in the different towns in the county to dispose of the honey grown by members of the association, so that bee-keepers who were members might have no difficulty in finding a market for their honey. The meeting then agreed to form an East Lothian Beekeepers' Association, and appointed office-hearers as follows:-Hon. President, Sheriff Shirreff; President, Rev. Mr. Kerr, Dirleton; Secretary and Treasurer, Mr. James Ovens, Haddington; who along with the following gentlemen-Messrs. J. Stirling, and Adam Paterson, Haddington; Bertram, Gifford; G. T. Clarke, Kirklandhill; and Barnes, Innerwick—form the committee. After hearing several letters, all advocating the formation of an association, the meeting considered the draft rules of the Association, which were remitted to the committee for revision and for presentation to a future general meeting of the Association for final adjustment. Some conversation then took place among those present on the proposal contained in the rules to have shows of honey and exhibitions of bee-keeping appliances in connexion with the shows of the East Lothian Agricultural Society and the Horticultural Society, of which the members present heartily approved.

Correspondence.

The Editor does not hold himself responsible for the opinions expressed by his correspondents. No attention will be taken of anonymous communications, and correspondents are requested to write on one side of the paper only, and give their real names and addresses, not necessarily for publication, but as a guarantee of good faith. Illustrations should be drawn on separate pieces of paper.

Communications relating to the literary department, reports of Associations, Shows, Meetings, Echoes, Queries, Books for Review, &c., must be addressed only to 'The Entron of the 'British Bee Journal,' c/o Messrs. Strangeways and Sons, Tower Street, Upper St. Martin's Lane, London, W.C.' All business communications relating to Advertisements, &c., must be addressed to Mr. J. HUKLE, King's Langley, Herts (see 2nd page of Advertisements).

** In order to facilitate reference, Correspondents, when speaking of any letter or query previously inserted, will oblige by mentioning the number of the letter, as well as the page on which it appears.

SECTION-CASES AND SECTIONS.

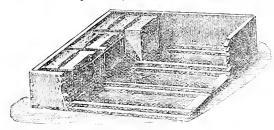

[868.] The time is fast approaching, notwithstanding the frost and snow we have had during the last week, when bee-keepers should lay their plans and provide themselves with all the requisites for the coming honey season. It is not an uncommon thing to put off obtaining these until they are wanted. The bees swarm, and the supply dealer is written to and expected to send hives at a minute's notice in which to put the bees. The honey barvest finds us without sufficient section-cases or sections with foundation fixed ready to use when they are required, and a quantity of the early and best honey is put in the brood frames, the queen has not sufficient space of comb in which she can lay, and the desire to swarm is the result. This fever once started it is difficult to stop, although had additional room been given at the proper time, either by adding another storey of frames for extracting, or by tiering up crates of sections, in most cases it would not have arisen; the bees would have been content to have gathered all the honey they could if they had supers to put it in and the queen had not been crowded, and had sufficient space to lay in.

Those who intend working for honeycomb, and have not sufficient crates for tiering up, will do well to decide at once the sort of crate, the size and width of sections,

and whether they will use separators or not.

There has been a great variety of section-crates exhibited during the last summer, and several of the best have been illustrated in the B. B. Journal.

I now propose to call attention to what appear to me the good or weak points they possess, and I also send a woodcut of a super-crate, in which I think most of the

desirable parts are contained, and which I will describe hereafter.

The crate Mr. Dines exhibited at Norwich, and of which you gave a cut on page 508, was one of the first that claims the advantage of being capable of inversion. The depth of case gives a half bee-space at top and bottom in addition to the depth of the section used. In preparing for putting sections in position, the case is placed over a piece of wood of the thickness of the half bee-space required; the sections and separators are then adjusted, and are kept in position by a board, which is tightly pressed against the sections by screws; this is the only support they have. Should there he the least shrinkage of the sections, they would drop on the excluder if one is used, or, if not, then on the frames,

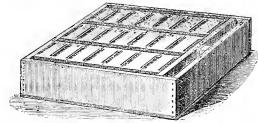

crushing any bees there may be between. The screws are also liable to become set tight.

The crate exhibited by 'Amateur Expert' at the last Conversazione, and illustrated on page 59, also depends entirely on the screws for keeping the sections in position. The bee-space is kept by having a loose related frame, in which the case stands, keeping it the proper distance from the excluder or frames below, the case proper being exactly the same depth as the sections used. This case has pieces of wood on the sides, between which the separators go, and, being notched out to correspond, form passages for the bees to pass along. There are also two holes in the separators opposite to where the sections touch each other. This improvement of the separators by having these holes in it is not a new idea. I pointed this out on page 558, as it was previously illustrated by Mr. Greer in Gleanings on page 689, but Mr. Sambels tells me he had not seen it at the time he suggested it as an improvement to Mr. Corneil's super. There is a difficulty in getting the separators in and out without removing several of the sections, and in taking out sections they would be likely to fall and irritate the bees.

Mr. Corneil's super was well described at the time it was illustrated on page 531, and is to my mind the best invertible crate for L_2^1 -inch sections, but it has the same difficulty as that of 'Amateur Expert' in the removal of

separators.

Mr. Neighbour's invertible super crate is a very good one; the sections are supported by metal ribs both top and bottom, and whichever way they stand can with a little care be inverted; even without the serews the sections cannot drop and stop the bee-space, and is readily tiered up. This is one of the best; but it lacks the bee passages, which I think a great point. The section crate here shown is similar to that illustrated in *Modern*

Bee-keeping; but by adopting the separator of Mr. Greer, without otherwise altering the arrangement, we have a crate possessing all the good points contained in the others, except that of reversing. It will be seen that the sections do not touch each other or the ends of the crate, being kept apart by quarter-inch strips of wood on which the separators rest. These separators have holes through them, corresponding to the spaces between and at the end of sections, and can be removed at pleasure if sections are used. Having entrances on the sides as well as top and bottom, in addition to the passages, the bees can cluster round all the sections, and pass from one to the other without difficulty, and thus do away with their need for popholes to get from one side of the comb to the other. They can be tiered up three or four With regard to sections, I think that the best width for them is $1\frac{3}{4}$ inches wide, with entrances on all sides; and I would on no account advise the giving up of separators. If, however, some bee-keepers would like to try without them, they must be very careful that the sections stand perfectly level on the hive, - J. M. HOOKER.

CYPRIANS.

[869.] I have to thank the Editor for his reply to my request, but I am afraid he did not quite understand me. He should know that I had not the slightest intention of implying that any dealer would supply hybrids for

pure queens, and I am quite sure none of the readers of the Journal will consider that I so intended it to be understood. What I did mean is only what I know to be the case. It is a fact that many obtain one or more pure queens in the first instance; they rear others from these, and get them hybridised, and yet without intending to give a false impression, speak of these as of the

pure race.

The Editor tells us that for two years it was the rule for his apiary to consist of pure Cyprians; thus it is left for us to understand that during other years my application would be found correct, and that it was the rule for hybrids to predominate. However, what I wish to arrive at is the comparative merits of the pure and hybrid bees. For my own part I do not look upon Cyprians as suitable for all purposes, but value them very highly for extracting, and more than any kind for crossing with other races. I am pleased to find that the Editor is at one with myself as to the superiority of home-reared queens, but there are very many who cannot be satisfied unless they have an imported queen. Of course one must import for breeding purposes in the first instance, but those who obtain only one or two of any kind rarely have the opportunity of thoroughly testing any particular race, and as a matter of fact the number who can or do secure pure fertilisation is very small indeed.

Though I have not under my own management found Cyprians to vary in temper I have given the opinions of others, and have shown that the 'better selection' desired by the Editor is to be obtained by establishing a permanent apiary in Cyprus under such efficient management as Mr. F. Benton could give, if only he could rely upon someone to take charge during his enforced absence, but this unfortunately he has not yet been able to do. Such selection can be made at home, but as yet many bee-keepers cannot be so persuaded. In quoting Mr. Cheshire's earlier experience with Cyprians the Editor only states what that gentleman has himself recently told (Vol. II. Bees and Bee-keeping, Part I.), where also will be found Mr. C.'s present opinion of them, which is decidedly in favour of Cyprians as imported at this day. —S. Simmins.

It is very difficult, indeed, to understand what the gentleman mentioned really does mean. He gives nothing but what was already known, both as regards their management and temper, but this is what he does say: 'But I "speak that I do know and testify that I have seen" in adding that, although now and again a vicious Cyprian stock is met,' &c., and 'Cyprians have faults in our climate, as well as excellencies, quite outside the question of temper; but their surpassing leveliness of form and colour would induce some to keep them, especially if their disposition could be reckoned upon, and to this end irritable colonies, whenever discovered, should be re-queened.' If his opinion was, that they were as amiable as our correspondent suggests, there would have been no occasion to say anything about their disposition being reckoned upon. We usually consider amiable people those whose tempers can be depended upon, and those whose bad tempers may break out at any unexpected moment as the most dangerous of all, whatever their other qualities may be. Bees are no exception. Still, Mr. Cheshire may consider bees with such treacherous dispositions amiable. Mr. Abbott's experience (page 120 B. B. Journal) is both instructive and interesting, and should serve as a caution.—ED.]

CYPRIAN BEES.

[869.] Readers of the Journal will be greatly obliged to Mr. Abbott for his letter respecting these beespersonally I was delighted to read it. I think Mr. Abbott hit the nail on the head when he spoke of weak colonies being easily handled; this is so with all

bees I fancy, but when we get a hive crowded, say on twenty frames, if they have any nastiness about them it is then they show it.

I had an idea we had done with these bees years ago; what is it that is bringing them to the front again? their good qualities or the dealers? The same may be said of the Carniolans, they were dismissed long ago, but it would appear that as soon as any one gets a quantity of them for sale we hear of them as being very active, very hardy, and great honey gatherers.

What has become of the British bee? not 'black,' please, we do not call a brown horse 'black;' and what has our native bee done that it is no longer worth mention in the Journal? Is it not too bad that dealers should be trying all they know to drive it out of the country simply because they cannot make it profitable to sell the queens? and what do people think of themselves who purchase these foreign bees and locate them against their neighbours' apiaries, and by so doing turn all the bees in the district for miles round into hybrids? and we know what hybrids are. Is such a proceeding considered a neighbourly act? Bee-keepers must have a very queer sense of justice if they think so.

Is it not time someone spoke out about these things? and why do we nearly always read of these foreign bees in the Journal as 'golden bees?' No doubt they are golden to those who sell them, but I fear the purchasers soon find the gilt rubbed off. It seems to me that unless these bees have something more than colour to recommend them the public will at last get their eyes open (they have had them closed frequently by these insinuating devils) and will in future use more caution in introducing them into their gardens, except of course those who like well stinging, plenty of robbers to annoy their neighbours and themselves, with plenty of queens (pure no doubt) to sell at exorbitant prices, and so bring discredit and disgust on bee-keeping generally. - F. Boyes, Beverley.

GLASS IIIVES.

[870.] It seems to be taken for granted that Maraldi was the inventor of glass hives. Was he? I doubt it. It is true that M. Figuier in Les Insectes says, 'All the fables, all the hypotheses spread about and cherished by the ancients respecting these industrious little insects were dissipated in a moment, when, by the invention of glass bee-lives, first made in the beginning of last century by Maraldi, a mathematician of Nice, we were enabled to observe their operations and habits. Thanks to the invention of Maraldi,' &c. Arthur Murphy, the well-known translator of Tacitus, wrote at the latter end of last century a poem, *The Bees*. It is simply a translation into verse of the fourteenth book of the *Prædium Rusticum* of Vanière the Jesuit. In the preface, Murphy says, 'Maraldi, a famous French philosopher, was the first that invented glass hives, and through that transparent medium was able to observe the manners, the cenius, and all the labours of those wonderful insects. He published his account in the Histoire de l'Académie Royale des Sciences on the 6th of November, 1712. Vanière professes to have collected his materials from Maraldi, and has done them ample justice.' Both in the poem itself, and in the précis of it, it is asserted that the bees carry the wax upon their thighs, and, in fact, Maraldi and he knew no better than their predecessors. I possess a little work by the Hon. Robert Boyle, Fellow of the Royal Society, entitled, A Disquisition about the Final Causes of Natural Things, and printed in 1688, written really to oppose the philosophy of Descartes. There is a passage in this work which seems to prove that Robert Boyle had a glass hive in his house some twenty-four years before Maraldi's was heard of. It is this: 'Divers strange things are deliver'd, not only by poets, but by more credible writers, about the wonderful sagacity and government of bees, in point not only of economy, but of politicks too. But the I shall not build anything upon the authorities that I myself suspect, yet, having had the curiosity to keep for a good while in my closet a transparent hive, whence there was a free passage into a neighbouring garden, and having thereby had the opportunity to make frequent observations of the actions of these little animals, and particularly to see them at work, about making their combs and filling them with honey, I confess I discover'd some things that I did not believe before, and was induc'd to look upon them as very fit instances of creatures endow'd with natural instincts and providence.' Now two things are clear from R. Boyle's work-1st, That he had a glass hive (perhaps he invented it) long before Maraldi; and, 2nd, that he believed, as Maraldi and Murphy did, that the bees collected wax, and carried it home on their legs.—J. Lawson Sisson.

FOUNDATION.

[871.] The price of pure bees-wax being now so much higher in price than it was a few years ago, and foundation being so much lower, seems to give one the idea that this contradiction must be the result of either a very 'long profit having been made in earlier days or a substitute for bees-wax being used now. I am well aware it is so in some cases, but all must not be 'tarred with the same We are all aware of the absolute necessity of having pure bees-wax only in our foundation. I have had inquiry after inquiry made to me as to the cause of foundation sagging to such an extent as to cause the total destruction of stocks, and where, in response to my wish, I have had a sample of the foundation sent to me, it has usually been found to be adulterated. Mr. O. Hehner in the *Bee Journal* of last spring gave a rough test, which he said at the time was not to be entirely depended upon. I should now like to add to this test another one, which I think if acted upon will prevent any unsuitable foundation being foisted upon bee-keepers and so ruining many of their prospects during the ensuing season. Perhaps the practice of scenting foundation is not of very great moment; foreign wax has not the aroma of English, and the first thing an amateur does when looking at foundation is to place it to his nose and take a long, long sniff. 'What a nose it has got!' is his exclamation. Yes it has, but much too strong and pungent for a genuine odour. So you see some manufacturers must pander to the tastes of their customers a little. The fault of adulterated foundation is its inability to stand the internal heat of the hive at breeding time, and when laden with honey, brood, and bees, down it comes on the floor-board in a perfect 'conglomeration of wax, bees, brood, and honey. Now the melting point of pure bees-wax is 146 degrees Fahr., and this is where our tests should be directed. If the foundation will stand I45 degrees before it melts it will stand the heat of the hive at breeding time, unless the stock is placed in the broiling sun with entrances nearly closed, under which conditions wax, either pure or otherwise, will melt.

The difficulty is the knowledge how to make this test, and I will now explain how it can be done at a nominal eost. The appliances necessary are, -a thermometer that will register 200 degrees Fahr, or over; this can be purchased for 1s. 6d. and can be tested as to its accuracy by immersing it in water gradually brought to the boil, and then noting whether it registers 212 degrees Fahr or if it will not register as high a degree as that try it with boiling spirit-rather dangerous without proper appliances; this boils at 176 degrees Fahr.;—a capillary tube, this can be made, but they are very cheap, by drawing out a thin glass tube made hot in the gas or spirit-lamp; -an empty condensed milk tin and an empty lobster can without top or bottom: this latter is your stove; your fire must be a lamp of some description. Place the lobster can on the table, out of any draught, and put

your lamp inside; see that it has ventilation, or it will not burn; now place the milk tin on top and nearly fill it with warm water; have your capillary tube ready, melt a portion of the wax to be tested in an old spoon and fill a portion of the tube; now tie this piece of tube to the bulb of the thermometer with a piece of cotton, plugging the ends of the tube; then immerse it in the water, allow the water to get gradually hot, and when the thermometer registers 146 degrees Fahr., if pure, the wax in the tube will assume suddenly a transparent look; it has melted.

You must not with these rough appliances be particular to one degree, but it is sufficient to gain a knowledge as to whether the foundation is fit to use or not. Don't forget that there must be no draught, or your thermometer will jump up and down like a jack-in-the-box.-W. B. Webster.

NOTES ON CARNIOLAN BEES.

[872.] Perhaps the following may be interesting to some of your readers; but I hope to supplement it at

some future time with other particulars.

On Saturday last I received, through the kindness of Mr. T. B. Blow, Welwyn, by letter post, ten Carniolan worker bees in a common lucifer match-box. were, to all appearance, quite dead; but, accidentally placing the box containing them near a window, through which the sun was shining very brightly, they soon recovered and began buzzing and humining about quite joyously. I might here say what struck me at once was their large and powerful-looking wings, and their beautiful and symmetrical appearance. The thorax is entirely covered with a rich pubescence or fluff, like a beautiful sealskin in appearance; the ehitinous case of the abdomen is of a beautiful ehestnut colour, with rings or bands similar to the thorax in colour, only a shade lighter. Two of the Carniolans were selected, and placed under a thin tumbler glass with two black bees, which I at once took from a hive, selecting a young black and one more advanced in life; they were now supplied with food—the Carniolans having been without since leaving Mr. Blow's apiary. On Sunday evening one of the blacks (the younger one) died, and on the following morning its sister perished. One of the Carniolans died on Tuesday morning, the other during Tuesday night or early on Wednesday morning. Does not this show a great amount of physical strength in favour of the Carniolans? By microscopical and geometrical examination I find the area of wing surface greater in the Carniolans; and, upon eareful weighing, that the ten Carniolans weighed twenty grains, while the blacks only balanced sixteen grains.

Mr. Bennett, whom I mentioned in your issue of the 27th January, and who had never seen a Carniolan bee previously, at once saw the distinguishing features I have mentioned, and expressed himself that Carniolan bees and black bees should not be compared for beauty—the

blacks being much inferior in this respect.

I think it is one of the first points in beauty of bees the amount of pubescence upon the thorax—and it is only fair to Mr. Blow for me to add, having imported a good number of Ligurian or Italian bees from various dealers in Italy and Switzerland, that the stock I purehased from him surpasses them all in this particular .-T. Bonner-Chambers, F.L.S., March 5th, 1887.

JUDGING HONEY, &c.

[873.] I was exceedingly glad to find from the report of the annual meeting of the B. B. K. A. that it is intended to draw up a form of 'rules for exhibition.' The subject of judging honey is a very difficult one to deal with, and probably it would be almost impossible to formulate a code of marks such as has been suggested from time to time in the British Bee Journal for colour,

consistency, &c. But I think that this would be a very suitable time for the B. B. K. A. to print (together with the rules for exhibition) a series of hints, which would be alike useful to exhibitors and country judges. It is of great importance that it should be known what are the most desirable points to aim at obtaining when we exhibit at shows, and at present it is almost impossible to know to what standard we should try to attain. These hints might be as short and concise as possible for easy reference, but at the same time should be sufficiently explicit, for example, for an exhibitor to form a clear idea whether he had better send to the shows a light or dark sample of extracted honey, if in other respects his samples are the same. If the committee of the B. B. K. A. would undertake this task I am sure many bee-keepers would greatly esteem their labours.— EDWARD J. GIBBINS, Neath, March 4.

DO BEES HEAR?

[874.] This seems to be an undecided question at present. I read on page 58, February 10th, a very interesting discussion on vocal organs of bees by Mr. Grimshaw. I have a strong opinion that bees do not hear; they will respond to the slightest touch or shake, but will not respond to the report of a gun a few yards off. I have often fired a gun close to my hives, which makes no impression whatever, but driving a heavy-loaded wheelbarrow close behind them will at once arouse them. Then comes the question, How do they communicate? which would be very interesting to our readers. Mr. Baldwin gives his experience of trying to make bees raise queens while the queen is present by dividing the hive with perforated zinc, and the bees did not attempt to raise queens. My experience was last summer with a hive doubled for extracting. The hive being very strong in bees at the close of the honey harvest, I thought I would try the plan to make two lots of them a week before I made an entrance between the two storeys, to get the bees a little used to the two entrances. I then lifted the queen with bar into the upper box, placed a square of perforated zinc between the two boxes, and they at once commenced to raise queens. The hive with the young queen has wintered up to the present. The one with the old queen a friend is in possession of, so I cannot form an idea as to the way of their communication. -T. Dunster, Staplehurst, Kent.

APIFUGE.

'Hang out our banners ou the outward walls; The cry is still "They come." —Macbeth.!

[875.] Like King Dick, I find there are two, yea, three Richmonds, in the field.

'Useful Hints' (the calm, respected 'Useful Hints') takes me to task on the suitability of the word 'Apifuge.' Now if he will refer to p. 38, present vol., whereon I answer Mr. A. Green on this subject, he will find me state that the verb fugio bears other constructions than simple flight; it also means to avoid, forbear, &c.: res me fugit, the thing escapes my notice, I do not perceive it, am not aware of it; populus tamen vidit id quod fugit Lycurgum. And I used the verb in the sense that bees would avoid a substance on which apifuge was rubbed, and forbear to sting if they did alight. I am sure your esteemed 'U. H.' would not of set purpose lead your readers into the error that apifuge puts the bees to flight, and so on, for it seems to me that is the only sense his words can be read in. It would in that case be an act of gross injustice to the article which is before the public, and of which much more, I can assure you, is destined to be heard. The simple fact is, bees pursue their ordinary avocations when it is used, and take no notice of intrusion. As to the word Kentrapone, or sting-averter, this is trying to knock one bogey down

in order to set up a more hideous one with a vengeance. Kentrapone (if that word were adopted) would not turn I have admitted that there may be a more stings aside. suitable word than mine, but it has to be found yet, meantime 'Apifuge' will easily carry the burthen of a somewhat lame name. If 'U. H.' will insist on being so intensely literal in his translation,-

Febrifuge does not literally put the fever to flight (a

remedy for abating the violence of fevers).

Vermifuge does not literally put the worms to flight (but is a medicine for expelling worms).

Galactofuge does not literally put the milk to flight (a

remedy which decreases the secretion of milk).

As Mr. Lyon's actions, in my opinion, do not coincide with his utterances, the only part of his letter I will notice is his last paragraph, wherein he says, 'I am sorry my lotion failed to cure Mr. G., possibly the wound was poisoned with his Apifuge. The lotion is intended to cure the effects of stings, not those of poisonous substances.' Reader, is this not stabbing a man behind his back, is it not a stab in the dark? In his previous letter he insinuated that Apifuge is methyl salicylate, without a particle of evidence. This week he insinuates it is poisonous. Would that some substance were invented as a preventative against the poisoned arrows of our loving fraternity — some scorpiofuge, Mr. 'Useful Hints,' eh?

Well, I suppose I must reply and say that Apifuge is not poisonous, and that my hands had not touched it. I could retort on Mr. Lyon if I so pleased by opening up

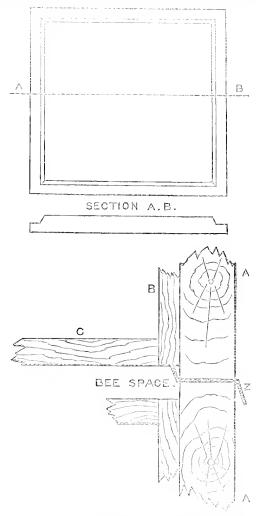

the question of 'Ac, Acet.'
'Amateur Expert' (this was the most unkindest ent of all), in a vigorous, manly, stand-up attack upon me, hints that I either have made, or shall make, use of my official position to push the sale of this apifuge, and refers to gratuitous advertisements I have got in the shape of letters to the British Bee Journal. Now, since my article was (or intended to be) brought out for sale I have only written once on this subject (p. 99, excepting of course my reply to Mr. Lyon's attack on me, to which I was reluctantly driven in self-defence), and this once was in fulfilment of a promise made in your columns to report the results of my efforts. I think if 'A. E.' had looked at the prominent advertisement of my agents he would have thought twice, and found second thoughts best, before ascribing to me such meanness as this. Even if such were the case, apifuge would only be having accorded to it the same notice which is given to Dick, Tom, and Harry's hives and appliances week by week. notice that 'A. E.,' too, falls into the error that the new substance is artificial wintergreen. It is not. I am not going to sell hardware,' any more than Messrs. Cowan and Cheshire (forgive the comparison) sold hardware by inventing and naming their respective hives and discoveries; therefore my residence in the Birmingham of bee-keepers must be postponed. Did you mean Coventry, 'A. E.?' Et tu, Brute?

Mr. Cheshire's conduct with regard to his cure for foul brood was my very model, even though it ended for him so pecuniarily unsuccessful, which would not have been the case had he not had 'the wreckers on his coast.'

Now if your readers will not again accuse me of seeking free advertisements, I will give you a short history of my conduct as regards Apifuge:—About two months ago I wrote a long article on my experiments and efforts to have made a certain substance, &c. I told your readers everything I could on the chemistry of the how and why, without (then) any mental reservation or equivocation whatever, never thinking of having to baptize the child as well as to bring it into the world. About three weeks after that, at the Conversazione, I had pleasure in submitting the first little drop which had been made (about half-an-ounce) to the B.B.K.A., and this I shared after the meeting with Mr. Stanford, Irish Hon. Sec. I then kept back nothing from you, except certain alterations in my formula, saying my happiness consisted in being able to say that the substance could now be produced. Up to that moment I had no thought beyond presenting the discovery to the beekeeping world. At this point, however, I was compelled to overhear this remark, 'The proper thing for Mr. Grimshaw to do is to get a quantity and distribute it:'—my business engagements forbade this. The next morning, Thursday, I read in B. B. J. 'A Disclaimer' from Mr. Cheshire, and (acting upon his example) I went on the Saturday to Southall, and placed the whole question in the hands of respectable agents in whom I have implicit confidence. I hope, however, my results will be different from his.—R. A. H. Grimshaw, Crag Hill, Horsforth, Leeds.

BRITISH INVERTIBLE HIVE.

[876.] I noticed H. W. Lett's letter in the *Journal* wherein he asks if Neighbour's British Invertible Hive is watertight at the joints. As I have purchased one of

Device for making Heddon Hive watertight between storeys and for supporting frames.

A, side of hive; B, end bar of frame; C, bottom bar of frame; Z, loose zine frame between each storey, also support to frames whether inverted or not.

the above hives I am able to say that it is not, neither is the original Jones-Heddon Rive. I have designed a simple device which will make both the above hives watertight, and it will also form a support to the frames whether inverted or not. Please find sketch enclosed, which I hope will make it easily understood.—J. Hall, Station Hill, Wigton, Cumberland, March 10.

THOUGHTS ON CURRENT TOPICS.

[877.] I have been thinking that as I had a few moments at my disposal I would send a few lines to the Journal in case you may have room for them.

WAX AND HONEY IMPORTS.—We are very much indebted to the kindness of Mr. Bellairs, and to yourself, Mr. Editor, for the information you from time to time give us in regard to the imports of honey and wax into this country; but it strikes me there is a something which we do not clearly understand respecting these products, nor why the foreigners should be able to send us such a quantity when we here cannot dispose of our stock. It might be interesting to know how much of the wax is animal and how much vegetable; and, again, how much of the honey is manufactured, say, the product of man, and how much pure honey, the product of the bee. The latter is a weighty question just now, when English honey cannot find a market, whilst every large town is swamped with foreign compounds called honey.

STANDARD FRAME.—I think it would be a pity to alter this now, unless some very grave objection can be urged against it. A deeper frame would be much more liable to break down. The only fault I find with it is that it is hardly strong enough, and the top-bar should be broader.

WINTER PASSAGES.—I consider these all moonshine if stock are properly looked to in the autumn. I never use them now, and never feel the want of them; they are a source of weakness to the combs.

INVERTIBLE FRAMES.—Novices beware, or you are going to be caught in a trap here; look out for collapse of new combs, endless trouble, and much cost in new frames, &c.

Spring Examination of Colonies.—If all be going on right, let well alone. No colonies should yet be short of food; if they are, it is bad management. First week in May is early enough to remove bees and combs into clean hives; to those who think of doing so now, I say, Don't.—F. Boyes, Beverley.

Review.

Nouvelle Flore four la détermination facile des Plantes sans mots techniques, avec 2145 figures inédites. Par Gaston Bonnier, Professeur de Botanique à l'Ecole Normale supérieure, et Georges de Layens, Lauréat de l'Institut (Académie des Sciences). Paris: Paul Dupont, éditeur, £1 rue J. J. Rousseau. Price 4 frs. 50 cs. (about 4s.)

It will need no apology in introducing this book to our readers. There is a growing desire amongst our bee-keepers to know something about botany, but it has been a subject not so very easily learnt, and unless the study had been commenced early in life there was very little chance of getting even enough knowledge to determine with eetainty the name of a plant. Much of this difficulty has arisen from the scientific language of the books, which has frightened many who could have made the study both agreeable to themselves and others. There are many who do not wish, nor have the time to go deeply into the subject, but who would still like to be able to find out the names of some of the plants they see, if it could be done easily. This is just the book for such.

Some of the prefatory remarks are so to the point that we translate the author's own words. They say:—
'When we first commenced the study of botany and wished simply to find the name of a plant we remember the difficulties which we encountered. The little know-

ledge we had acquired before, in reading the elementary botanical works, were hardly of any use for our nurpose. In fact, the authors of most of the floras have a special language so mixed up with technical terms, that to find the explanation of them at every moment a special vocabulary has to be referred to. The descriptions are full of scientific Latin and ancient medical terms. It is, so to speak, a new language that has to be learned, and it is the same in every work. This is the principal obstacle which those who wish to occupy themselves with Lotany have to encounter.'

Many will be ready to endorse these remarks of the

learned authors.

Now the book which we have before us gets over these difficulties, and will enable any one with a very little knowledge of the subject to derive much pleasure and pick up instruction in an easy manner.

In the first place all technical terms are avoided as far as practicable, and in the second any words out of the

common that are used are explained.

The work consists of 270 pages, and to facilitate reference there are 2145 original illustrations of the special distinctive characteristics of plants. The plan adopted is that of synoptical tables, and inquirers are passed on by easy questions from one to another until they arrive at the name of the species they are examining. Let us, for instance, take a strawberry blossom and see how easy it is to determine its name accurately by means of these tables.

We first refer to the 'General table' on page 19, and we find two questions asked there, namely, is it a plant with flowers or without? We find our plant has a flower, and the first question resolves itself into two others: Are the stamens and pistils on the same plant, or on different plants? We find our flower answering to the first, and here again two questions follow: Are the flowers salitary or united in clusters? Again the answer to the first brings us to two more, and so on until we get to the end, where we find that our flower belongs to plants with petals separated; and here we are referred to the next table, where, after answering one or two questions, we find the flower belonging to the rose family on page 49. This table, in addition to the questions has illustrations of each genus, and we soon find it belongs to the genus Fragaria or strawberry, and on page 51, to which we are then referred, we find the specific name. It takes much less time to find out the name of a plant than we have taken to describe the plan, and we were astonished at the rapidity when we put it to the test on several plants. Our readers may object that we have already used technical terms in mentioning petals, stamens, &c., but every word of this sort is explained, and illustrations accompany the explanations, so that a child can understand them. At the end of the book there is an alphabetical index of all the species of plants, and what makes it of special value to bee-keepers is, that all the flowers visited by bees are marked with a *. This from such authors as these is of no inconsiderable value, for M. G. de Layens is well known as a leading, and one of the most observant bee-keepers in France, the author of l'Elevage des Abeilles, and who assisted M. Gaston Bonnier in his researches on the nectaries of flowers, especially in connexion with bees. M. G. Bonnier is also well known as one of the leading French botanists, and as author of several botanical works as well as Les Nectaires which is one of the most important of those written in connexion with the mutual relations of insects to flowers. Those of our readers who know the French language would do well to get the Nouvelle Flore because in it they will find nearly all the plants we have in England. In the British flora there are only about 150 plants not found in France, and of these 100 belong to Scotland and Ireland, so that for England the flora is nearly complete. Of course it contains a great many not found in Great Britain.

We have every confidence in recommending this work, more especially as flowers are so pleasantly associated with bee-keeping. Some of our happiest days have been spent in botanising, and we have found it a recreation as beneficial to health as it is enchanting.

LECTURE ON BEE-REEPING.—At the Savings' Bank, Faringdon, on Monday evening, March 14th, Mr. A. D. Woodley, expert to the Berkshire Bee-keepers' Association, gave an interesting lecture on 'Bee-keeping,' his remarks being illustrated by magic-lantern slides, exhibited by Mr. E. Wright, who kindly lent his lantern for the occasion. Mr. G. J. Haines took the chair, and there was a fair attendance.

Replies to Queries.

[866.] Water for Bees.—(J. F.)—A small ornamental flowerpot-stand, to hold one pot, having a hive trough round the pot filled with clean moss; this has a very mee effect, the moss making a good landing-place for the bees. Fill the trough with water as well as moss, and put a nice shrub in the pot. A small ornamental fountain, the water running over virgin cork and moss, would look pretty.-W. B. Weester.

[867.] Bell Glass to hold 35 lbs.—(A Beginner.)—The rule for finding contents of spheroid is

(diameter² x fixed axis);

therefore for bell-glass will be

 $\frac{3\frac{1}{7}}{c}$ (diameter² × fixed axis) ÷ 2.

In this case

 $\frac{3\frac{1}{7}}{6} \, (12^2 \ {\rm ins.} \, \times \, 30 \ {\rm ins.}) \div 2 = 1131 \frac{\pi}{6} \ {\rm cubic \ ins.}$

The space occupied in a hive to contain 35 lbs, of honey is about $8'' \times 13\frac{1}{4}'' \times 10\frac{1}{4}'' = 1113$ cubic inches. The bellglass, if a spheroid, should be 12" base × 15" high, but its form would be a matter of taste and convenience. -- W. M. GRAHAM.

yibes. Echaes from the

Bishop's Waltham, March 15th.—Since writing my last, we have had a radical change again in the weather to intense cold on Saturday 12th, nine degrees of frost, Sunday ten degrees, Monday at 11 p.m. twelve degrees, and as I write this (Tuesday) there are two inches of snow on the ground, and it is still snowing, the three previous days have however been lovely and warm during the middle of the days, and the bees have fairly revelled in the snow-

drops and Arabis.—H. W. West.

Wadhurst, March 16th.—I have kept bees for years on the careless system, but your Journal has infused into me a zeal for the work, and I hope to succeed. I think the storifying system likely to answer; the best results I saw last year among all the condemned bees I took, was from a skep placed on the top of a new empty skep in the autumn of 1885; it was literally filled with pure white honey, and why may we not expect results quite as good from barframes? May I ask if Ligurians are good on ordinary clover? [Yes.—Ed.] I shall amuse you, perhaps, by telling you I have made some iron hives; they seem to do well, I allow 2½ inches for cork-dust all round, they are not likely to blow over. I thank you for your kind replies to our many questions.—Vulcan.

'Honey Cott,' Weston, Learnington, March 21st.—Almost the whole of the month, thus far, it has been very severe, with a deal of snow threatening, though very little has There have only been a few solitary half hours really laid. or so that bees could venture out, to get a little pollen or water; they have scarcely had a chance at the crocuses, though they have been in flower a long time. Have just been up among the bees now, at noon, on the first day of spring, so-called, but searcely a bee to be seen or heard; not very promising or cheering: but, as in the case of Picciola. the prison flower, we must hope and tell our neighbours also

to hope. - John Walton.

Revlin House, Donegal, March 14th.—My bees have wintered so far very well, notwithstanding the rather severe winter, heavy snow, and slight frosts. Bees carrying in pollen on 19th ult., and every fine day since. I began to stimulate on the 6th inst., did not do so last year till the 23rd March. I have not had a look at them yet, as there have been some cold days, especially the last few days, sharp frosts and some snow, and very cold east wind. I have an Observatory hive with two frames, which I used for raising queens, and having left a young queen in it, I thought I would see if it would winter outside, and I find it has survived so far, not having enough honey, I put some candy on top of frames, which was their principal food. Gooseberry bushes are out in blossom here, but am afraid the frost has injured them.—George Turner.

NOTICES TO CORRESPONDENTS & INQUIRERS.

Letters or queries asking for addresses of manufacturers or correspondents, or where appliances can be purchased, or replies giving such information, can only be inserted as advertisements. The space devoted to letters, queries, and replies, is meant for the general good of bee-keepers, and not for advertisements. We wish our Correspondents to bear in mind that, as it is necessary for us to go to press in advance of the date of issue, queries cannot always be replied to in the issue immediately following the receipt of their communication.

- H. W.—Bees Fighting after Uniting.—The camphor smell of one stock may have led to the disaster, and there may have been some fault in your method, which you did not notice.
- H. W.—The pattern of enamel cloth will be found to answer your purpose. The shiny side is to put next the frames.
- H. A. P.—There are no symptoms of foul brood in comb forwarded; it is a case of chilled brood.
- M. D.—The piece of comb received is old, and many of the cells are full of last year's pollen, but the comb is healthy and may be used without prejudice to the bees.
- New Beginner.—Transferring.—Yes, you may transfer to the larger hive, but it is best to wait until the middle of next month, and, even then, to transfer indoors to prevent robbing. For 'Transferring' see Mr. Cowan's Guide Book, or Modern Bee-keeping.
- A. M. M.—1. Crooked Combs.—Since you say the combs are too irregular to be transferred, it is best to allow the bees to swarm naturally, and three weeks afterwards to remove the bees in the old hive (cutting away the combs) and to place them on foundation.

 2. If your stocks have sufficient food they will do well enough presently. It is too cold for them to fly much, and there is but little forage to entice them forth.

 3. Hires Invertible.—Either of the invertible hives you name are improvements upon the American, and are better adapted to this climate. Are you aware that the frames are close-ended and difficult to manipulate?
- C. A. J.-1. Artificial Swarming.—There is no necessity for giving a comh with brood in the case you mention, as there are already five in the hive, and the chances are that some of the brood will not have hatched out. Besides, the hive will already be in the position of an established stock, having a large population of old bees, as well as large numbers of young ones which could not fly. It is very different with a nucleus where there are not many bees, and most of these old, except the few that had hatched out from the comb of brood inserted when first the nucleus was formed. 2. Nucleus Swarming. -There is no need to cage the queen in the stock removed, because the flying bees of the nucleus are very few in number, and will be returning, probably laden, to a hive full of bees, capable of protecting their queen from the few strangers should they be unfriendly. other hand, although the bees of the stock will be also returning laden to the nucleus, they will be so numerous as to quite outnumber the small population of the latter. Therefore, in order to avoid the risk of losing the young queen, we prefer to cage her. 3. Carbolic Acid. - We quite approve of carbolic acid, if used with care. Four tablespoonfuls to one quart of water are the usual proportions. The Rev. G. Raynor, who has used it for upwards of twenty years, recommends the following solution: 1\frac{1}{2} oz.

Calvert's No. 5 carbolic acid, $1\frac{1}{2}$ oz. glycerine, and 1 quart of warm water. Great care must be taken in using, as it is very poisonous. 4. Salicylic-Acid Solution.—During all the years we have used it we have never had such a growth as you mention. It is possible that your acid may be impure, as it is frequently very much adulterated. The pure acid is largely used as an anti-ferment. We should not use the solution, but prepare another, 5. Borax.—The sample of powdered borax which you send is correct. Borax, which is biborate of soda, can be called 'soda borax.'

INQUIRER.—Bees in a Loft.—Without doubt bees may be kept, and prosper, in a loft, care being taken that the hives are not too crowded, and that the bees have free means of ingress and egress. The plan suggested will be found to work very well.

MANIPULATE WITHOUT SMOKE!

WEBSTER'S FUNIGATOR

Entirely supersedes the Smoker, both in Simplicity and Effectiveness. No 'going out.' No tainting or soiling of combs. Always ready for use without any preparation. Can be carried in the pocket.

With Bellews, 4s. 6d.; postage, 41d. Without Bellows, 3s.; postage, 3d.

Can be adjusted to any ordinary smoker bellows.
6 oz. Bottles of Agent—carbolic acid, oil of tar, and water,
properly mixed—6d. each.

WEBSTER'S SWIVEL FRAME - LIFTER WILL BE READY SHORTLY.

With this appliance, frames can be removed from hive, replaced and examined on both sides without inverting, with one hand, leaving the other free for manipulating, at the same time preventing soiling the hands with propolis.

OUTLINES OF BEE-KEEPING FOR BEGINNERS.

(Continued from page 115.)

IV.—How to Manage and Control Bees.

I. The honey-bee has become a domesticated animal; it accepts the dwelling which we select for it, and takes the food we provide it with; becomes used to the care and attention we bestow, but does not learn to know its master, and if he disturbs its dwelling, or interferes with its flight, will sting him just as readily as it will a stranger. It goes its own way, interferes with no one, and will not allow any one to interfere with it. Fright and fear are the means by which bees may be controlled. (The Eastern races are an exception, but as these are not suitable for beginners, we shall not refer to them.)

2. Many bees are very quiet, and with gentle handling much can be done with them; more especially is this the ease with pure Carniolan and Italian bees. Others are not so manageable, and we have to resort to other means. Smoke or carbolic acid frightens bees, and they immediately rush to the cells to fill themselves with sweets.

3. Before examining a hive blow a little smoke in among the bees. Whatever has to be done should be performed as rapidly as possible, and if any operation takes a long time it will be necessary to give more smoke. Quiet manipulation will generally prevent bees becoming angry, but should they show their tempers they can be subdued by giving them, from time to time, more smoke.

4. For this purpose a smoker should be used, Brown paper, rags, old fustian or sacking rolled up. lighted, and put into the barrel with the smouldering end downwards, will answer the purpose for supplying smoke, and will keep alight for a considerable time. Care must be taken not to give too much, so as to stupify the bees.

If carbolic acid be used the treatment must be different. A solution is made by mixing four tablespoonfuls of No. 5 Calvert's carbolic acid in one quart of warm water, shaking it up well. With a goosequill apply some of the solution to the alightingboard and round the entrance, as well as a little within. If a skep is to be examined, turn it up

carefully and spread over it for a few seconds a piece of thin calico moistened slightly with the solution, when, on its removal, it will be found that the bees have run down amongst the combs. For moveable comb-hives raise the quilt slightly at one end of the hive, and apply the feather dipped in the solution along the tops of the frames, or the calico may be spread over them the same as described for a skep.

6. As carbolic acid is a poison, great care is required in its use, and should any of the solution come into contact with the hands they should be immediately rinsed in clean water. Should there be any cuts or cracks on the skin still greater care

must be taken.

7. During great heat, causing much perspiration, and in very windy weather, when the bees are blown about and the smoke driven away, they should be left alone.

8. Bees do not like bad smells; dust or dirt and dark colours irritate them. Human breath is also offensive to them. Persons dressed in dark clothes and having dark hair are more liable to attack than those having light hair and wearing light-coloured

garments.

9. Beginners who have not yet got used to stings should provide themselves with a veil to protect the face. This can be made of coarse black net, one yard by eighteen inches. Fasten the ends together, run a hem round the top, insert an elastic, and draw it up until it fits round the crown of a The rim of the hat keeps the veil from the face, and the lower end can be tucked in under the coat about the neck.

V.—The Different Bees found in a Colony.

1. The bee is a sociable insect, and cannot live long by itself. Many bees live together and form a society called a colony. In the colony is found one large bee which may be recognised by her form, size, and colour, being longer and of more slender structure, with comparatively shorter wings than the others. This is the queen; she is the only fully developed female who lays all the eggs, and is the mother of all the bees in the colony. She passes through various changes from the time the egg is laid to leaving the cell as a full-grown insect in from fifteen to seventeen days, and can live five years, although she usually serves the bee-keeper only for two to three years.

2. The other bees are the workers; upon them devolves all the work of collecting and defending their stores, building comb, and feeding and protecting the brood. They are females, but are undeveloped as far as regards their reproductive organs. They mature in about twenty-one days from the day the egg is laid, and fly out for collecting in from eight to fourteen days. Those hatched in the autumn generally live through the winter, but during the summer, when they have much work to do, they usually live from six to eight weeks.

3. During the swarming season there appear male bees. These are called drones, and are recognised by the noise they make when flying; they are more bulky than the queens and larger than the workers; have no stings, and do no work. At the end of the swarming season, when their services for impregnating the queen are no longer needed, they are driven forth by the workers. In queenless hives they remain sometimes until the

following spring.

4. Sometimes what are known as fertile workers are found in queenless colonies no longer having the requisite means of producing a queen, but from the eggs they lay only drones proceed.

USEFUL HINTS.

Weather.—The present March will long be remembered as one of the most severe on record. Frosts, snowstorms—snow lying to a depth of eighteen inches—gales, almost hurricanes, have prevailed; and 25 degrees of frost have been registered sufficient, we fear, to kill in many cases the embryo buds on the fruit trees, if not the embryo brood in our hives. But we have only neighbour's fare, since we are told that the experience is the same 'from Northern Denmark to Southern Spain.' What all this portends it is difficult to foretell, but we trust a fine summer and a good season for the bees will follow. Every gleam of sunshine, and every opening flower, is utilised by the bees, but we hear complaints of dysentery and the loss of many colonies. Feed, feed, is still the order of the day, since there is very little either in field or garden upon which the poor insects can regale themselves.

Heddon and Stewarton Hives.—Some doubt seems to have arisen respecting the weather-proof qualities of Mr. Neighbour's Heddon Hive. For many years we kept bees in Stewarton hives, having no outer cases, in sheltered position, without any protection whatever, and we never found the wet to penetrate. The bees propolise the boxes so firmly together, stopping even the smallest chink, that it is next to impossible for the rain to enter; and with a well-made, well-painted Heddon

hive we should have no fear of weather.

Foundation and the Woinlet Spur.—We are indebted to Mr. Cowan for his lucid description of M. Woiblet spur for embedding wire in foundation. The one he kindly presented to us is beautifully finished, and works well on the plan suggested. Over a spirit-lamp, we keep boiling water, in which to dip the instrument, in preference to heating the wheel in flame. Unfortunately all plans of wiring frames, and embedding the wires in foundation, occupy much time, and we have little doubt that the rapidity and ease with which wired or unwired foundation can be inserted in Mr. Lee's new frames and sections will obtain for them almost universal acceptation. We much wish that dealers could supply foundation in sheets $13\frac{1}{2}$ in. $\times 8$ in, which is not wide enough to pass through the

bottom bar of the standard frame. Wired foundation, being an American production, we fear some time must elapse before sheets of the former size can be procured, but Mr. Neighbour informs us that he will procure them with the least possible delay, and no doubt our other firms will do the same. Mr. Cowan has alluded, in his article on the Woiblet Spur, to the combs built upon wired foundation in Mr. Abbott's observatory hive exhibited at the Windsor Show, which was held on the 13th July, 1880, and we well remember the circumstance to which he refers, viz., that in the combs filled with brood there were lines of empty cells corresponding to the wires in the foundation. Since that time, as Mr. Cowan justly observes, the wired foundation has been greatly improved, and we have used it for the last four or five years in our own apiary with complete success, never finding it to bulge, or break down, under the weight of the bees in the hottest weather, nor have the queens ever refused to breed in the cells through which the wires pass. Formerly the wires were too numerous, being at one inch distance only, and they were untinned, and so liable to rust. Now they are placed at double that distance, are well tinned, and much reduced in substance. The foundation is flat-bottomed and light, but the bees draw it out into combs as quickly as they do other kinds, and moreover it has this advantage over unwired, that the combs may be safely passed through the extractor as soon as built, without fear of breakage. The only drawback with us has been that in some cases the bees have refused to carry down the combs below the foundation-sheets, that is, within an inch of the bottom bar of the frame, thus causing too much space at the bottom of the hive and waste of room. But with broader sheets, to pass through the bottom, and topbars also, according to Mr. Lee's plan, we anticipate obtaining perfectly straight combs, and frames as well filled as by inversion. Mr. Lee has conferred a great boon upon our fraternity in general, and we trust that he may reap the benefit to which this invention, as well as his antecedents, fully entitle him. To those, to whom time is not an object, and who prefer the wired frame, we recommend the Woiblet spur.

Syrup and Candy.—We are often asked what are the relative values as regards weight and quantity of hency as stored by the bees, and sugar syrup prepared from the common recipe of 10 lbs. of sugar to six pints of water. Roughly speaking, this quantity may be taken as 16 lbs. of syrup, and it is calculated that in consuming, ripening, and storing, the bees will reduce it to 10 lbs. of food, which are equal to about the same quantity of honey. Other circumstances must, of course, be considered, such as the time of year, the strength of the colony, whether it is breeding, whether honey is obtained from the fields, &c., but, as a general rule, we have proved by experience that it is tolerably correct. We still continue to feed on soft candy, introducing a small quantity of pea-meal, and a little salicylic-acid solution. Finely powdered white sugar and liquid honey form the staple of the candy, which the bees take with evident approval. This food excites less than syrup, and there is not so great a desire, or necessity, to leave the

hive as when feeding on the latter.

ROBRING.—Bees are so much inclined to robbing now, that where feeding is in process the utmost care is necessary. Colonies being fed should be watched, and if much excitement is noticed contract entrances and use freely carbolic solution.

Cyprians and Syrians.—On the vexed question of the qualities of the Cyprian bee we are often asked to state our experience, which extents over a period of the last five years only. In April, 1882, we introduced our first imported Cyprian and Syrian queens, and, classing both races in the same category, related our experience, after nearly a year's trial, in the monthly issue of the B. B. J. of February 1st, 1883 (Vol. x. p. 212). Recent

experience has led us to modify the views there expressed, which were summed up thus—'(1.) Extremely prolific. (2.) Excellent honey-gatherers. (3.) Extremely vindictive, and difficult to handle. (4.) More liable to disease than other races, especially to dysentery.' Although we have not bred the two races pure, to any large extent, we have always kept a few colonies of each, and have used imported queens occasionally, beside our homebred purely fecundated ones.

Our opinion under the heads 1 and 2 remains unaltered. As regards fecundity Syrians, perhaps, yield the palm to Cyprians, but both are extremely prolific, and their crosses with the black bee can hardly be Their honey-gathering qualities are of the first order, and they constantly work later in the day than the black bees, and in weather when the blacks remain at home. For extracting purposes, in our opinion, they, especially the Cyprians, have no equal, but in working sections they use so little wax-barely half as much as blacks-and the capping is so light and thin, rendering the comb in appearance dark in colour, and the honey liable to ooze, that their sections cannot compete with those of the blacks, although the honey is of

equal, and often of superior quality.

Under heading 3 our opinion is modified. When once aroused, by careless handling, smoking, or otherwise, no words can express their persistent anger. But there is no necessity for provoking them. Truly, they are not the bees we would recommend to a novice who is always manipulating and smoking his bees. Smoke, whether much or little, they resent most furiously. Smoke we never use now, having entirely discarded it, and given away our smokers. A little weak solution of carbolic acid is all we use, and, more often than not, we dispense with that. Gentle, quiet handling-even under the provocation of a sting or two-in four cases out of five, is all that is necessary. If by any untoward chance their anger is aroused, a light sheet, sprayed with carbolic solution, and thrown over the open hive, will in a few minutes allay their anger. For our own part we would rather manipulate Cyprians and Syrians than blacks and hybrids, although, by using the same means, there is no difficulty with either. A little discrimination in this, as in all other matters, is advantageous. For instance, as Mr. James Abbott truly observes, small colonies are more easily handled than large ones, and he might have said that large, prolific colonies defend their broad and stores far more vigorously than weak ones. But this is a truism which applies to all races, even to the quiet, tame, spiritless Carniolans. Our first experience in manipulating Cyprians was with smoke, hence we were led to describe them as 'extremely vindictive.'

Fourthly, we spoke of them as liable to disease,

especially to dysentery.

Since those words were penned we have not met with a single case of dysentery, or any other disease, in Cyprian or Syrian colonies. If our readers will turn to the reference we have given above, they will find the case described which led us to the erroneous conclusion that these Eastern races were especially liable to dysentery. The summer of '82 was cold and wet, and consequently very little honey was stored in our apiary. The first Cyprian queen was introduced in April, so that before the colony was completely exprianised the middle of June had arrived. After that date the weather was so unsettled that, without feeding, the bees could scarcely collect sufficient food for daily use, and the honey was thin and poor in quality. No wonder, therefore, that bees brought from the fine and warm climate of Cyprus should succumb to dysentery under such disadvantageous circumstances. All this teaches us that it is unwise to give a decided opinion upon any matter before a full and sufficient trial has been made. Had we possessed our present experience that loss would never have occurred, since it might easily have been prevented by checking late breeding, and exchanging a few combs of unsealed sour honey for ripened sealed combs. We hope the day is far distant when these excellent and beautiful bees shall be discarded from English apiaries.

Last autumn we obtained two imported Cyprian queens from Mr. Benton, and these are now reigning over strong colonies, and doing as well as we could wish in all respects. We prefer, however, home-reared queens -with an occasional importation-if only we can get them purely fecundated, but, surrounded as we are by bees of all races, mongrels included, it is only by practising the Köhler method that we can attain our object. That process is a slow one, and often requires much time, which can be ill spared during the busy summer months.

It is with much pleasure, therefore, that we are assured that Mr. Simmius possesses all the requirements for pure fecundation, and we shall hope in future to draw chiefly upon him in preference to rearing our own queens, since, most certainly, we do not intend to give up either the Cyprian or Syrian races.

Both are most valuable if used only for purposes of crossing. There is no finer bee in appearance, and for work and hardiness of constitution, than the Syrio-black

Apifuges.—Noting Mr. Grimshaw's reply to our remarks on his newly-coined term, 'Apifuge,' we have to say that we had not read his letter (B.B.J., page 38) before those remarks were written, but we do not see that his derivation from fugio, instead of fugo, as we supposed, improves his position. From childhood we have been fully aware of the difference in meaning between fugio and fugo. Using the former in the sense of 'to escape,' we cannot see that the word will bear the meaning which he intends. For instance, we have the word 'centrifugal' (from centrum and fugio) 'flying from a centre, —(Skeat), and the expressions 'avoiding,' or 'escaping from,' the centre, make no real difference. The verb fugio' throws its action on centrum, and in apifuge fugio must transfer its action to its object, apis, and the meaning will be 'flying from the bees,' whereas if fugo had been used we should have had the meaning of 'putting the bees to flight,' in nnison with 'vermifuge' and 'febrifuge.' A word must bear the meaning which its construction warrants, independently of the intention or wish of Mr. Grimshaw. Both 'vermifuge and 'febrifuge' are formed from fugo (not from fugio), and, we presume, the authors of these words thought fugo the most suitable or they would not have selected it. Professor Skeat, in his Etymological Dictionary, tells us that 'febrifuge' is derived from 'febri-s, fever; and fugare, to put to flight, and he gives the meaning of 'febrifuge' 'fever-dispelling.' Mr. Grimshaw says 'febrifuge does not put the fever to flight'-i.e., does not dispel it—but merely 'abates its violence.' Nuttall, in his last edition, and all other lexicographers with whose works we have any acquaintance, are in agreement with the Professor, who is the great authority at both Universities. The same also may be said of 'vermifuge.' When Mr. Grimshaw says 'vermifuge does not literally put the worms to flight, but is a medicine for expelling worms,' surely he is quibbling. No one supposes that worms possess wings; neither when an army is put to flight does any one credit its individual soldiers, or the army itself, literally with possessing wings. To expel, or drive away, means, therefore, to put to flight, so long as the beings acted upon are living. We have no doubt whatever that Mr. Grimshaw 'used the verb in the sense of to avoid,' but it seems to us a mistake to do so, since, so far as we are aware, there is no precedent for such usage in conveying the sense he wishes.

But we come now to a more important matter still. In all seriousness surely Mr. Grimshaw does not mean to promulgate, or perpetrate, such a macaronic solecismsuch an etymological monster—as 'Galactofuge,' a thorough mengrel, half Greek, half Latin ($\Gamma \acute{a} \lambda a$, gen. $\gamma \acute{a} \lambda \iota \kappa \tau o c$, milk, and fugare, to put to flight). And he says it only 'decreases the secretion of milk!' Well, in our simplicity, we should have thought driving away a part of the milk was much the same as preventing its secretion. Surely he must drop the initial syllable 'Ga' to agree with the terminal 'fuge' from 'fugare.' 'Kentrofuge' would be less barbarous and less hideous.

As regards the suggested word, 'Kentrapone,' or 'Kentrepone,' our 'Authority' condemns it as 'hideous with a vengeance.' Perhaps his ear has not become attuned to the Greek language. To our feelings it is, to say the least, as euphonious as 'Apifuge.' Its derivation from $\tau \delta$ $\kappa \dot{\epsilon} \nu \tau \rho \sigma \nu$, a sting, and $\tau \rho \dot{\epsilon} \pi \omega$, to turn aside, is very simple, and the euphony, to our ears, is pleasing. A friend, however, suggests 'Kentrotrope' as a better word, and more in accordance with usage and analogy. Therefore, if anyone wishes to adopt it, let him do so, or shorten it to 'Kentrope,' and he will have a much better word than 'Apifuge,' notwithstand-Mr. Grimshaw's dictum. But if all are declined we shall not grieve overmuch.

There is no plant of the scent of which bees are more fond than of that of the herb balm (melissa).* The plan of rubbing the hives with this plant before hiving a swarm, prevailed almost universally in olden time, and even now we often use it. A solution of a little honey and water, scented with the essential oil, essence, or extract of balm, will form a better lotion for the protection of the hands and arms than all the modern 'fuges' with their abominable stench; and the cost is a mere trifle.

We commend to our youthful readers the fable of 'Cupid and the Bee,' with its excellent moral.

'Cupid, one day, not perceiving a bee which rested upon a rose, was stung upon his finger, and, uttering cries of pain, he flew to the beautiful Cythera† exclaiming, "I am destroyed, O mother, I am destroyed, and thall surely die; a little winged serpent, which the country people call a bee, has stung me." To him Cythera replied, "If the sting of a bee, O Cupid, causes so much pain, how much, think you, do they suffer upon whom you hurl your darts?" (Anaereon, Ode XL.)

Foreign.

ITALY.

Chevalier L. Sartori, of Milan, was, a few days ago, favoured with the visit of two Japanese delegates, viz., Messrs. G. R. Hida and H. Danke, Counsellers of the Japanese Ministry of Agriculture and Commerce. The distinguished visitors had not been long in Mr. Sartori's well-known apiary before it became evident that they were not novices in matters connected with bee-keeping, us their numerous and pertinent inquiries plainly testified. Nothing, it appears, escaped their observation, and much interest was exhibited when examining the new large plates recently published by Mr. Sartori, with explana-tions in four languages. In fact, before bringing their visit to a close, they left an order for 400 sets of these illustrations for the Government of Japan, upon which notes will be inserted in the Japanese language. Of course, the natural beauty of the Italian bee was, of itself, an object of no small interest, and a few stocks were ordered for shipment to their country. They were, however, not a little surprised when Mr. Sartori placed before them two large plates illustrating Japanese beekeeping. Before leaving, they expressed themselves highly pleased with what they saw in Mr. Sartori's noted establishment.—Apicoltore.

AUSTRIA.

Next month an apiarian exhibition will be held in Vienna, and such a large number of exhibitors intend to compete, native and foreign, that the extensive premises of the Botanical Gardens will hardly afford room enough. The hives wherein 'the little busy bee has improved each shining hour,' from the earliest period of bee history down to the present day, will form an attractive section of the exhibition.—Daily Telegraph.

SWITZERLAND.

NEW EXPERIMENTS CALCULATED TO ASCERTAIN THE PROPORTION OF HONEY USED BY BEES IN THE PRODUCTION OF WAX.

In making the experiments which I am going to describe, I have not made it a point to ascertain whether or not bees build their combs more economically with one kind of sugar than with another, my object having been simply to arrive at the quantity of honey used by hees working in an apiary at their free will, and at a season when they take to comb-building with more readiness than in any other.

The experiments hitherto made in this direction differed so much among themselves that it was impossible to arrive at a reliable conclusion. It is this fact which induced me to recommence these experiments, taking for basis the various plans previously adopted. But at the very outset two questions arise which in practice have often been confounded, but which must be distinctly

separated, viz.:-

1st. Even when honey is plentiful, it is not advantageous to induce bees to produce wax, although it may be done at a small cost, because, in the first place, if only a few empty frames are given to a strong colony among a good supply of ready-made comb, within which to store the incoming harvest, and yet to find sufficient scope to give vent to their comb-building propensity, they would be almost sure to build drongcomb. On the other hand, if plenty of comb-building is given them by reducing them, as it were, to a combless swarm, they would no doubt build numerous workercombs, but they would not have sufficient cells wherein to store the incoming honey, the production of wax not being in proportion to the collection of honey. Therefore, at the time when honey is plentiful, it is not advisable to set bees to comb-building. 2nd. When, on the contrary, the honey yield is great, is it advantageous to set our bees to produce wax? This is the point I have tried to solve.

The basis of what was considered to be the best experiments made consisted, briefly put, of selecting two stocks, say Λ and B, of the same strength, one of which — Λ , for instance — was supplied with empty frames, and the other, B, ready-built combs. Λ little later on, the honey gathered by B is weighed; the same with that found in Λ . This done, the quantity of wax produced is ascertained; the difference between the weight of the honey compared with that of the wax produced represents the proportion between the honey and the wax. This method is, however, incorrect in several respects.

1st. Even supposing that by some chance one queen were as prolific as the other, they would not lay the same number of eggs within a certain number of days, because one of the hives afforded, from the very first day, all the desired accommodation for egg-laying, which would not be the case with the stock whose combs are built at a slow pace. Therefore, at the end of the experiment there will be more broad in one than in the other; hence a difference also in the consumption of honey, a difference which is left out of reckoning, and—

2nd. It was generally supposed that by choosing from

^{*} Greek for bee.

[†] Cythera (Venus), an island lying S.E. of the 'Peloponnesus (modern *Cerigo*) in which Venus was especialty worshipped; as she was also in Cyprus, whence we obtain our beautiful yellow Cyprian bees.

an apiary two stocks, apparently of the same strength internally, and of similar activity externally, one could compare the work done by either of them without risk offering to any great extent; but very frequently this is not the case as I will presently show.

Having examined two stocks, which for the present purpose I will call No. 1 and No. 2, and having, more-over, ascertained that the strength of the latter was about twice that of the former, I reduced them both to the condition of a swarm. The bees, finding themselves now free to set about bringing in their harvest, under identical circumstances—for both hives had been deprived of their brood—at the closing of each favourable day I used to take the exact weight of the honey brought in. No. 1 had stored kilos 2,140, and No. 2 kilos 2,030, that is, nearly as much as No. 1, whereas it ought to have gathered only about half that quantity. This year M. Bertrand witnessed results similar to this, in the opposite direction. A stock of his had gathered kilos 37 of honey, whilst another, of about the same strength, had brought in, during the same interval, kilos 18. question with me now is, not to find how to explain this, but rather to show that all experiments having for basis the simple comparison of actual work done by two colonies of the same strength cannot be relied upon .-G. DE LAYENS.

(To be continued.)

LECTURE ON BEE-KEEPING.—SOUTHGATE BRANCH OF THE M. B. K. A.—A fecture under the auspices of the Middlesex B. K. A. was delivered at the Village Hall, Southgate, by Mr. John P. Sambels, on Thursday, 24th March, on 'Bees and Bee-keeping.' Owing to the inclemency of the weather the attendance was not so large as could have been desired, but those present were well repaid for their trouble, if one can judge by the interest shown. The subject, it is needless to say, was treated in the lecturer's usual happy manner, and he kept his audience spellbound during one hour and a half. The appliances used in the illustrations were lent by Mr. P. P. Hasluck, the hon. Secretary of the Southgate Branch of the Association, and Mr. Sambels kindly exhibited an invertible section crate designed by himself, and some specimens of Canadian honey. At the conclusion of the lecture the Rev. James Baird, President of the Southgate Branch, proposed a vote of thanks to the fecturer, which was heartily accorded by those present. It is to be hoped that this lecture, and the coming show on the 8th and 9th July next, will give a great impulse to bee-keeping in the neighbourhood.

A Hint.—Bee-keepers would do well to oil the leather parts of their smokers to prevent cracking. Castor, train, sweet, or olive oils will do. One in the Leather Trade.

How to Embed Wire in Comb Foundation without a ' Woiblet Spur' or any Embedder .- Wire frames, and procure board to fit as in ordinary fixing. Lay foundation on the wet board, resting on a stool convenient to a clear charcoal fire. Heat the frame over the fire and press down while heated upon the foundation, and it will be embedded at once. Half-a-dozen may be fixed by this method, while one could be done by the 'Spur.'-Expedites.

KEEPING RAIN FROM THE BRITISH INVERTIBLE HIVE.-The Rev. H. W. Lett asks how the rain is to be kept out of the British Invertible Hive. As they are at present constructed this is impossible without affording the hives some outer covering. But why should there not be a double fillet fitted to all the joints. The simplest way is this:-Rnn a plough one inch deep along both top and bottom of every box, and then plane down the outer edge 3 inch; then make a double fillet to fit into the plough of upper box and hang over the edge of lower box. By this means I think damp and draught may be excluded.—C. W. Scott, Bray, Ireland.

Eucalyptus Honey.-M. Guilmith, the French traveller, while on a journey in Australia, discovered some bee-hives in a gigantic eucalyptus-tree, of 120 metres in height. The honey was strongly scented with the perfume of the flowers of the tree. Professor Thomas Karraman has examined it, and believes it to have beneficial medicinal properties.— Hull News.

Correspondence.

The Editor does not hold himself responsible for the opinions expressed by his correspondents. No attention will be taken of anonymous communications, and correspondents are requested to write on one side of the paper only, and give their real names and addresses, not necessarily for publication, but as a guarantee of good faith. Mustrations should be drawn on separate pieces of paper.

be a arm on sparate precess of paper.

THE NEW RACES, AND THE BEST MEANS OF INTER-BREEDING AND SECURING FERTILISATION.

Syrians.

[878.] Notwithstanding statements to the contrary, I have not, with any race of bees, known individual colonies to vary in temperament. Just as I have found the disposition of any one queen's progeny in the first instance, so the same character has been continued throughout. The only difference at all discernible is that, generally speaking, bees are more easily handled when building up in spring, than at any other time.

Any sudden exhibition of ill-temper from a stock otherwise found to be of gentle disposition, can only be caused by some oversight on the part of the operator, some hasty movement, or crushing of bees, as it would be unreasonable to suppose that even those of the most amiable disposition would not use that defensive weapon ever at command in case of carelessness being at any time shown by the bee-keeper. More often than not, however, the first object attacked would not be the operator, but some person or thing not quite so near. It is a remarkable fact that in handling various colonies time after time without being stung myself, the same bees have attacked chickens near at hand; and I believe it is generally understood that while subject to the beemaster, no robber dare approach the open hive without The foregoing then shows being immediately attacked. how much depends upon the bearing and manipulation of the bee-keeper, even where gentle bees are concerned. They are quiet under the hand of man, but will submit to no other interference.

Now I do admit that, generally speaking, different colonies vary in temperament as compared with each other, though as yet I have not found it so with Cyprians. Syriaus vary in this respect to an extent which seems almost incredible. The most vicious colony I ever met with is one I now have of this variety, and the temper of this individual stock never varies, nor does that of another not quite so bad. I do not condemn Syrians because I have among them the worst-tempered bees I ever had, for having others of this kind that can be handled absolutely like flies, it is quite evident that the bad temper need not be perpetuated.

The foregoing shows conclusively how entirely wrong are those who condemn any particular variety, because the one or two imported queens they had purchased happened to throw vicious workers. Those who rear these bees in their native land must, in their own interests, breed from amiable stock, and in course of time no more queens that produce vicious stocks will be sent out.

At first sight Syrians appear rather dark in colour as compared with Ligurians, though having the same number of yellow bands, but unlike the latter they are yellow on the underside of the abdomen.

Syrians are good workers, but not as generally so as Cyprians, and being less beautiful than the latter, I have

decided not to keep them extensively, but shall probably continue to experiment with about a dozen colonies, as they may possess some unexpected qualities which might be of advantage in crossing with other races.

It has been said of these bees, that, more than any other kind, they will breed heavily into late autumn, but from my own experience, I can state, as a fact, that this peculiarity has been entirely overcome in the same manner as I recently pointed out in connexion with

Cyprians.

It should be hardly necessary to state that the treatment recommended in these papers refers solely to stocks in normal condition, or such as are populous and well established, headed by queens raised or imported not later than June. Nothing but absolute starvation will stop the laying of a young Syrian raised towards August: and queens of these more prolific races ought not to be obtained after midsummer, unless they be such as were reared early, or during the preceding year.

It has on several occasions been stated that when young, Cyprian and Syrian bees can be handled very easily; but is not this the case with all bees? In speaking of the disposition of any kind, is it not implied that one is speaking of an average working stock which therefore includes bees of all ages? How then can the comparison with older bees show that the latter are unmanageable because of their age? Again, why are vicious bees easily managed if in nuclei? I tell you, friends, that if bees are vicious as a populous colony, nothing will alter that disposition. As a matter of fact, I have on several occasions made up nuclei from ill-tempered Syrian colonies, which were occupying three chambers, and none of the nuclei were in the least better behaved than the parent colony. On the other hand, I have built up mild-tempered Syrians from nuclei into populous colonies, when they were equally as well disposed as at first.

Palestines.

These, often called 'Holy-Lands,' are sometimes confused with Syrians. Bee-keepers should endeavour to correct this mistake as the two are quite distinct. Palestines come from the Holy Land, while Syrians are found much farther north. The former are exceedingly beantiful, being even more yellow than the Cyprians, and having also a quantity of grey hair about the body; the drones also are very yellow, whereas Syrian drones can hardly be distinguished from blacks in many instances.

I have had no Palestines for the past six years, as my experience was not at all favorrable with them. They develop fertile workers and supersede queens to an alarming extent; but there is another peculiarity about them which I have not found with the most savage Syrians, and that is a very unpleasant habit of biting one's fingers during manipulation. I believe Mr. Benton, also, does not recommend this variety, and though they are fairly good honey-gatherers, for my own part I shall not again keep them.—S. SIMMINS.

'APIFUGE.'

[879.] In common I doubt not with most practical bee-men, I have been amused at the storm which has raged around this word, both as regards its meaning and also its utility. Of the first I will say nothing, but as regards the second, I think we want something more than the sanguine expectation of its inventor. At present, the notion of a substance that will prevent stinging savours too much of the ignorant prejudice one so often meets with in the bee-tent, which found expression from the Cornishman, who thought he had been defrauded, when he exclaimed, 'He guv they bees chemicals.' For my own part, I confess to an utter inability to believe in any substance checking a bee that has made up its mind to part with its 'business end.'

Having experienced many thousands of stings, and observed the conditions under which they were administered, I am convinced that nothing short of absolute prevention in the shape of external protection will deter a bee whose mind is made up. He flies straight at his goal as an arrow from the bow, and is generally in such a hurry, he fails to strike home true, but entering obliquely, a large part of the venom is wasted. Your bee that hesitates is 'lost' (as a patriot), and once settled on hand or face, is as safe as a fly, be you dressed with 'Apifuge' or any other 'chemical,' or with honest clean water. If this is not the experience of all who have studied the matter, I am much mistaken. We shall be glad to hear the last of 'Apifuge' as another of those treacherous traps for impoverishing humanity, and giving point to those angry growls from disappointed reformers who only desire in taking up beekeeping to benefit their tenants.—E. II. Bellaries.

GLASS HIVES.

[880.] The Rev. J. Lawson Sisson has rightly questioned M. Figuier's assertion that Maraldi was the inventor of glass hives, and quotes Robert Boyle as having kept bees in these homes some twenty-five years earlier, namely, in 1688. But the truth is glass hives were invented much earlier than this, how much it would be difficult to say. Pepys tells us in his *Diary* 5th May, 1665, that 'after dinner to Mr. Evelyn's, he being abroad we walked in his garden, and a lovely noble ground he hath indeed. And among other rarities a hive of bees, so as being hived in glass, you may see the bees making their honey and combs mighty pleasantly.' As this was written very nearly 100 years before the description of Maraldi's glass hive was heard of, we have another instance of the Gallic tendency to appropriate to themselves whatever inventions have been made for advancing human knowledge. Without claiming the invention as exactly English, it is desirable to protest, seeing how frequently foreigners, and especially our nearest neighbours, ignore the researches of our own countrymen in the department of science.—E. II. Bellairs.

HIVE COVERS, &c.

[881.] In answer to those correspondents who wish to know the best plan for keeping wet out of the joinings of hives when storified, and also for keeping the wind from blowing them apart, I find a good plan is to put a beading round the lower part of the upper hive of $\frac{3}{4}$ in.

A

wood, of course flush with the live bottom, bringing it well to a point (see sketch at B). Being \(^3_4\) in. wood it keeps the drip well off the hive. By putting a small button at A in the middle of the top of each side, which will turn up under the beading, the hives are kept well together.

Instead of the heading, and a plan I much prefer, is to make some of Simmins's covers of an extra size. These come well down over the sides, forming a good shade in hot weather

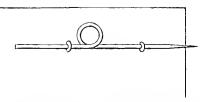

and keeping off even a driving rain. I made three for myself last year, and there has not been a sign of dampness inside them, while many other roofs, with plenty of slope and apparently perfectly sound wood, are unaccountably damp inside. I consider them the best covers out, and they also fit either skeps or any sized wooden hives.

I found out a little plan the other day which answers admirably for fixing dummies in any part of the hive. I got some large pins and twisted them in the middle into a loop, and by putting a small staple on each side of the centre of brass wire—which clench on the other side

of the dummy—a small bolt is made which the least pressure against the sides causes the dummy to be held in its place, and it also has the advantage that it lifts with the hive when the latter is propped up during a honey glut in hot weather.

You can make your hives double-walled on two sides by this plan, and make use of the same sides in contract-

ing the hive for winter.

Cut the pins' heads off. The least touch of the points keeps the dummy in position. Drive the staples close down on the bolt.—ARTHUR J. II, WOOD, Bellwood, Ripon, March 15.

NOTES ON BEE-HIVES. THE HEDDON NEW HIVE.

[882.] On page 620 of Gleanings in Bee-Culture for 1884, the Editor, Mr. A. I. Root, says:—

'I am very glad indeed to note the disposition among bee-keepers of forbearing to copy the works of each other, patent or no patent. The supply-dealer who would unhesitatingly copy something well known to be the property of another, without getting the privilege of so doing, by purchase or otherwise, would very tikely lose more than he made, so strong is the disposition of our people to give honour to whom honour is due.'

That hero of American apiculture, Father Langstroth, penned Mr. James Heddon the following last year, which is published by his permission:

'He who makes an important invention and patents it, is a public benefactor, and no one who calls himself an honest man should attempt to infringe upon his rights.'

The following are the plain patent claims of the invention of Mr. Heddon:—

'1. Set screws, used in combination with brood or surplus frames, and an outer case, for the purpose of supporting said frames, when inverted.

'2. The use of one-half bee-spaces, when united with each other to form a whole bee-space of about three-eighths of an inch.

'3. A brood-chamber of a bee-hive made in two or more horizontal sections, for the purpose of interchanging, or

alternating said sections with each other.

'4. The combination of frames filled with combs, by inverting, and a case closely fitting the ends of said frames, all in such a manner as to leave few or no lodging-places for bees when we desire to shake them out of said case and from among the combs.

'5. The combination of my sink, break-joint, honey-board, with a double brood-chamber, as described.'

The above are the main functions of the late invention, but what they will hold no one knows, as it has not yet been tested in court. Mr. Heddon hopes no one will ever know; and hopes the sentiment of the progressive beekeepers of the age will never sustain an infringement of his late invention to compel him to ask the aid of the law.

Patent law declares that the maker, user, or vendor of a patented machine, or manufacturer, are each and severally liable to prosecution for infringement.

'The price of an individual right to make for one's own use, and use the new hive, or any of the special features of the invention, is §5.'

'Any hive containing even one of my principles, although it may not have the appearance or the name of my hive, will be no less an infringement.'

Messrs. Geo. Neighbour & Sons inform me their British Invertible Hive is, in several respects, similar to the 'Heddon,' but not as imported. I find in their advertisement of 20th January in the British Bee Journal that for 17s. 6d. they offer a complete live suitable to inter on the summer stand, but now in a more recent issue of the B. B. Journal they state for an additional fractional cost they will add to the roof, and a wrapper is in preparation for it.

It is stated in America that the benefits accruing from a use of the genuine new hive are as much greater than those of the Langstroth as the Langstroth are superior

to the old-fashioned bee-gums.

A correspondent under the letters 'W. J. M.' in last week's issue evidently has his bee-hives in an unsuitable locality, and I very much doubt whether he has ever seen one real genuine imported Heddon hive much less having a perfect acquaintance with the new system à la Heddon, as I am informed that there are not half-a-dozen imported Heddon new hives in this country. How can any person pass judgment upon a hive they have never seen, and which they do not understand?

Will Messrs. Geo. Neighbour & Sons be so good as to state how their British Invertible Hive is superior to that of the new hive, and how it is similar yet different to the imported one; and will good Mr. Editor say if he considers there is any danger of infringing Mr. Heddon's rights by using such hives in this country?

Future notes will deal more particularly with the system of management.—T. BONNER-CHAMBERS, F.L.S.,

March 18th.

[We do not consider that Mr. Heddon has any patent rights in this country.—Ed.]

SMOKER FOR BEES.

[883.] In the British Bee Journal, issued on 27th January last, eareful directions for making a smoker are given, and in the issue of 17th instant I notice that Mr. Cowan is about to publish Guide-book No. II.—How to make a Smoker.

Now, as I had found by experience, before the first-named date, that my Bingham smoker was liable to fail me by eeasing to keep alight at critical moments, I had thereby been moved to make a smoker from first principles and remedy its defects, and have succeeded, as I think, in considerably improving on the details of the Bingham type. I venture to think that a description of my most successful smoker may not be unacceptable to your readers.

(1.) My bellows are without valve. Sticking a piece of paper over the Bingham valve will convince the most incredulous that that valve is useless. No one will deny that it adds something to the trouble and expense of manufacture. If experience is not enough, common sense will suggest that air will not lift a valve when it can get in without doing so at the blast-pipe. Lastly, trial will prove that the valve is worse than useless, since it will be found, in ninety-nine cases out a hundred, to allow air to escape from it that ought to be forced through the smoker.

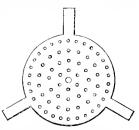

(2.) The grating of my Bingham smoker has only seven and a half holes not obstructed by the bars that

are riveted across it to keep it in place, while my new smoker has the whole area of its grating $-2\frac{1}{2}$ inches diameter -full of holes, the supporting arm being cut out of the same piece of tin as in sketch. And subsequently turned up at right angles.

The above two improvements are, I submit, of vadical importance but

of radical importance, but my smoker has others which are convenient if not essential. These are:—

(3.) The diameter of the barrel is increased to 21

inches to allow another cylinder to be placed inside it

carrying the fuel.

(4.) The fuel is contained in a separate tin cylinder inch less diameter than the barrel, slipped ready loaded and lighted into the latter. This keeps the outer barrel cool, and allows two or more loaded interior cylinders to be kept ready for instant use. The interior cylinder is kept out of contact with the barrel by having a few V cuts made in it with a cold chisel while the tin is flat, the points of these V's being subsequently sprung outwards to project beyond the general outline of the interior cylinder and to touch the barrel. The space thus secured between the barrel and interior cylinder is most valuable in reducing the temperature of the smoke.

(5.) In place of the hand-guard, my smoker has its barrel covered with a layer of cord neatly wound round it to act as a non-conductor, and this is overlaid with longitudinal strips of mahogany, which are secured by brass bands, just like the 'lagging' of a steam cylinder. This effectually keeps heat from the hand, and presents

a handsome appearance.

I have no anxiety now about my smoker being ready whenever I want it.—T. I. N.

IN THE HUT.

'Where the bee sucks There lurk I.'

[884.] Alas! the hut has been passing through a stage of spring repairs, and the garden-gnome has altered the position of the gnomon of our extemporised snn-dial.

A strange smile, and a sickly, flits over the rotund and jovial countenance of a luttite, as he sees week by week a notice that the Yorkshire Agricultural Show will be held next August, and here we are in the midst of a snowstorm, with the glass at 30° (and 20° during the night) accompanied by a howling north-easterly gale.

Poor bees! your lot is indeed a hard one! After having been tempted and treated on the 3rd and 4th inst., to a feast of pollen and pea-meal, alluringly laid out for you in the golden chalices of the crocus by your ever attentive servant, man, the cup is dashed from your lips, and to-night you will have to beat a retreat up into the honeyless attics of your cells;—attic bees indeed! The wind and sleet are whirling round your porches, and dare you, at your peril, to come round the corners of your stores, or, shivering and shaking, down you will drop. Rough Rab was right when he said,

'The best-laid schemes o' mice and men gang aft agley.'

Reader, have you ever seen anyone in a fit of ague? If so, watch a chilled bee and note the similarity of the symptoms. If the bee be not a little martyr to rheumatism when chilled, my name's not 'X.-Tractor.'

N.B.—(Don't dismiss the idea as unworthy of serious consideration.) Salicylate of soda is almost a specific for rheumatism in animals and men; should not, therefore, the salicylic acid in the artificial food of our bees be the preventive against that chemical change in their life-fluid by cold which, in the human subject is made known to us by an attack of rheumatism, sciatica, lumbago, or whatever special form of the same thing as our own pet little weakness?

We must remember that the rationale of salicylic acid as a preventive and cure of foul brood has not been worked out yet. I am much mistaken if it will not read somewhat like this:—The microbe of foul brood finds it impossible to 'increase and multiply' as it would like, in an antacid condition of the blood. If we get a chill, saccharine substances in the blood become by some means so turned into acids, that we begin to feel that pain which I call rheumatism. Now

microhes in the body of the bee, and elsewhere, have the power of turning saccharine fluid into acids. Ergo, I think, if impropitions weather chill the blood of our bees, their bodies are more susceptible, and prone to attack from those myriads of microbe germs (Saccharomyces mycoderma, mycoderma aceti, &c.), constantly on the look out for those starved and atonic subjects, which are ever the first prey to disease.

I notice that at Horsforth onr bee-hives are not subjected to freezing temperature until December 1st, falling to 16° by the 3rd, 10° of frost just before Christmas, 16° on New Year's day, and 23° of frost on January 17th. The coldest in February was 16° on 10th, and 12° of frost on March 12th. Altogether the season up to now has been exceptionally regular and even, both extremes being gradually led up to. I think it is the 'sudden change' which does the mischief, as the boy said when he fell off a wall.—X.-Tractor.

MY EXPERIENCE.

[885.] Being a constant reader of your Journal I notice all reports and experiences are of a very bright character. My experience of bee-keeping is anything but bright, and I think this spring I am nearly cured of bee-fever.

In 1884 I obtained one skep, which had two swarms, and I purchased one swarm in bar-frame hive, which made four lots. The skep I transferred into bar-frame hive, and I put the two swarms into bar-frame hive. I took 6 lbs. of honey, the first and the only honey I have had. I will say nothing about the expense, as yon, a bee-keeper, know what it is to purchase nine stocks and hives, and sngar by the cwts., for I have given them plenty. I have only had two cases of starvation, and these were cases of robbing.

There is something very interesting about a bar-frame hive I had in 1885. It was queenless. I gave a frame of eggs April 19th, 1886, and they hatched three queens April 30th, and May 3rd—drones must be flying in April—I found one dead outside. On May 19th there was fifteen inch super of eggs and brood, and on June 24th I took out this young queen and some of the young bees on two sealed brood combs and put them into observatory hive, and put them into my sitting-room, and enjoyed, and learned, a very great deal about the habits of bees. The hive at once formed queen-cells and hatched a queen, which was laying well in the autumn. The young queen in observatory hive, after laying well and getting strong, emigrated, I don't know where, and left me empty hive. I did not give ventilation enough, so she moved her household.

In 1886 I was going in largely; all my hives were well stored with sealed stores. I set them in one long row, from north to south, facing east, well sheltered from north and east. I put a tiled house over the whole length, and put carpenters' shavings round the outside of the hives in the house, and covered the whole of the roofs of the hives over with leaves, and left them for

the winter perfectly dry.

The result was eleven stocks dead, and all of them with sealed stores, so it was not starvation; the remaining six bar-frame hives very weak. One I have examined and put in a clean hive, as it was very foul; the queen seemed strong, but very few bees, but plenty of stores. The only return I have had is 6 lbs. honey, the pleasure of the Observatory hives, and plenty of stings in driving, enough to make me sting-proof. I have doubled the hives when strong, and some I have put supers on top, and the only time the bees would go up into them was when I put my finger there.—John S. Browne, Albury Heath, Guildford, March 21st, 1887.

[With the letter a stock list was enclosed confirmatory of the above statements, -Eb.]

BEE TENT.

[886.] It is so much more convenient and comfortable to deal with one hive, and one cluster of bees under control by smoke, than to have to deal also with homing bees of the same hive, or with homing or robber bees of the other hives not under the influence of smoke, that I determined to think out a tent of cheap and easy construction.

I made a clothes-horse of three folds or frames, large enough to enclose a hive, myself, a friend, and a small table; and high enough to allow me to stand up when roof is spread. Mosquito net, of the size of each frame of the horse, is sewn into a margin of tape, and this tape is hooked on to small screws on the frame; thus back and two sides of the tent are formed. A piece of wood, of the same thickness and length as the other cross bars of the frame, has a loop of strong tape (webbing) nailed on at each end. This loop is hig enough to slip over the projecting top ends of the fronts of the side frames. On this piece of wood is nailed a piece of calico, rather bigger than the square formed by the three folds and the connecting cross piece. Holes strongly bound with tape are made in this calico at the points where, when stretched as a roof, the side frames meet the back frame, so that when the cross piece of wood is looped over the frames in front, the calico stretched tightly will let the holes fit over the tops of the frames at back and thus form a roof. Strips of cloth from corner to corner diagonally are securely sewn to strengthen the roof to prevent the frames from getting much out of square. For the door, or entrance screen, a piece of mosquito net, rather larger than the corresponding pieces on the frames, is nailed to the front cross bar, and allowed to droop to near the ground: on its edge near the middle, and near the bottom, pieces of tape are sewn for tying the door in windy weather, if necessary, to the side frames.

The tent is now complete with roof, door, and sides; and can be moved from place to place as it is; or by simply pushing up the back corners of the roof, and raising and removing the cross bar, the roof and door can be rolled up on the bar, and the three frames can be folded, either with or without the net on them, and the tent can be stowed away until again wanted.

If more economy is needed old calico instead of net could be used. I use calico for the top as desirable in showery weather or in light rain. I use net for the sides to get air freely, and to allow friends to see the manipulations. With many hives I think this tent will be found useful and cheap. I will not dwell on the pleasure of receiving the warm thanks of the housewife for the nice clothes-horse so kindly made her; all that goes without saying.—T. I. N.

BRITISH AND AMERICAN INVENTIONS: BEE PASSAGES AND SLOTTED DIVIDERS.

[887.] In your Editorial remarks in last year's Journal, p. 567, you say, 'We do not forget, too, that the Americans have taken a great many ideas from us, which, unfortunately, they do not credit us with, and we are frequently amused and have often alluded to inventions brought out by them long after they have been in use in Europe.' In these remarks I quite agree, but whilst knowing this, let us not fall into the error ourselves and give Englishmen the credit of originating 'ideas' when precisely the same things have been previously done by Americans and even illustrated in some of their periodicals.

On p. 125 in last week's Journal, after describing some of Mr. James Lee's patented inventions, speaking of his section, which, when in position, of themselves give passage-ways between the sections, and also between the outside of the crate and the sections, you say, 'and they have a passage way at the ends like in those of Mr.

Sambels (see Journal, p. 59).' Now these 'side-passages,' as they are called, are an American invention and were first brought into general notice in England by Mr. S. Corneil, when he exhibited and explained his super crate at the meeting on October 20th, which was illustrated in the Journal of the 18th of November, p. 531. If you compare this with that shown on p. 59, you will see that so far as the side-passages are concerned Mr. Sambels has simply copied that of Mr. Corneil, although 1 do not think the latter gentleman was the originator of them, but that it was the invention of Mr. Oliver Foster, of Mount Vermont, Iowa (who, I believe, was also the first to use sections open on all sides).

These passages are formed by nailing two strips of wood on the sides of the crate; whereas the top and bottom of Mr. Lee's sections project, and when brought together the bee-passages are formed without any extra pieces being nailed to the sides to interfere with the removal of the separators, as in that of Mr. Sambels.

Separators.—You also say 'the separators, which are also like those shown by Mr. Sambels, have openings corresponding, forming permanent psssage-ways for the bees.' Here, again, let us not claim this as an English invention. I mentioned, on p. 558, that it was not new, 'having seen it described and illustrated in one of the American bee papers.' In last year's Gleanings, p. 698, Mr. W. H. Greer, of Paris, Tenn., U. S. A., referring to Mr. Foster's open side-sections, says, 'Ever since I became acquainted with the open-end section I have felt that it was "the thing," but in practice I met with difficulties. It seemed to be intended to be used without separators, and, in consequence, with sections both wide and narrow, I had bulged comb, so I have attempted to devise a separator that could be used with open-end separators; and here it is—

Tin separator, expressly for use in sections, with openings all round.

'The slots are intended to match with the edges of the sections, and will enable the bees to have the same free communication that they have without them. I think the slots in the separators should be \(^3_4\)-inch wide.'

So far as the side-passages and the openings in separators are concerned, I think I have shown that the Americans have the priority of invention. At the Conversazione on the 6th of October, held at South Kensington, I exhibited a crate of sections having separators with openings like that of Mr. Greer. In the Journal of November 18th there is a wood-cut showing a suggested improvement by Mr. Sambels, afterwards alluded to by me on p. 558.

With Mr. Lee's sections, as illustrated, and also in the crate on p. 128, described by me, the passages are not only at the sides but there are passages between the sections from end to end corresponding with the openings in the separators (which is not the case either with Mr. Greer's or Mr. Sambels'), there will therefore be no occasion for pop-holes.—John M. Hooker, 76 Tyrwhitt Road, St. Johns, S.E.

PAINTING HIVES INSIDE.

[888.] There is no doubt that the unprotected wood of the hive absorbs moisture, both from the hees and from the air which enters the hive, which moisture is very objectionable both in frosty and in dry weather. The bees by ventilating their hive can drive out moist air and get in dry air, in dry weather; but if the wood of the hive be wet the dry air admitted becomes moist

and tends to produce mildew, and is, I have no doubt, a

source of dysentery.

All my hives are covered inside with a good layer of shell-lae varnish (made by dissolving shell-lae in methylated spirit to produce a solution as thick as thin cream), and put on with a brush. No moisture can be absorbed; no comfortable cracks or corners for insects are left; and the nice clean appearance of the wood remains Honey is easily wiped away, and propolis removed with facility by a rag soiled with turpentine or kerosine, neither of which will touch shell-lac. I consider this varnish much better than paint for interior of hives. -T. I. N.

Honey Beer .- Boil two handfuls of hops in five gallens of water for fifteen minutes, then strain into an open vessel, let it cool down to 100° Fahr., then mix four pounds of honey with it, and add one or two cupfuls of fresh hop yeast, cover up, and let it work from twenty-four to thirtysix hours, skim off as often as seum rises; roast halfcupful of yellow sugar till it becomes brown, then dissolve it again with water, add this to the beer to give colour; then draw off into bottles or casks and cork well. In two or three days it will be ready for use. This will make a most delicious and cooling drink for farmers and fieldlabourers in haying and harvest time. Cappings will do just as well, and even better, than honey. When they are well drained of their honey, throw them into a tin pail, pour boiling water over, so that the wax will melt; let cool, remove wax, strain and prepare as above, adding less or no honey at all .- Canadian Bee Journal.

Queries.

Queries and Answers are inserted free of charge to Correspondents When more than one query is sent, each should be on a separate piece

When more than one yeary is some of paper.
Our readers will greatly oblige us by answering, as far as their knowledge and observations permit, the Correspondents who seek assistance. Answers should always bear the number and title placed against the query replied to. Any queries unanswered in this way will be answered by the Editor and others.

[889.] Bee-hives.—I should be very much obliged if any of the readers of the B.B.J. who have seen bee-houses either on the Continent or in this country would give me as many details of construction as possible. I want a house to hold 150 hives, at least. I particularly desire to know how near tegether bives may be placed, so as to avoid queens mistaking the right entrance. Also, what height from the ground is most desirable? Would it be any harm if I put the hives alternately one foot and two feet from the ground? By this means I should get the entrances mere separate.—Edward J. Gibbins, Neath, March 26th.

[890.] Has any bee-keeper tried mixing formic acid with syrup for autumn feeding, and in what proportion ?-H. W.

Echoes from the Pives.

Carrick-on-Suir, Ireland.-I have just had a look over the hives-ten bar-frame and one skep; the latter was a late swarm. Finding it rather light about a month ago, I cut a hole in crown and put candy on it. This did some good, but unfortunately I did not supply another cake in time, and lost the steek, which was a pity, as there was a nice patch of brood showing all was well. Must be more careful next time. The others are all strong, the weakest covering five frames fully. This has been my second year in the business, and I like it very much. I have got over the trouble about stings, and don't mind a few now. The above skep is the only loss I have had yet. My bar-frame hives are all my own make, and I never had an opportunity of visiting a bee-tent or seeing hives, &c.; the little I know is from Cowan's Guide and the Bee Journal. I am sorry to have to report a great many losses of stocks among my friends. I saw about twelve bar-frame hives and six skeps lost already, and I heard of more. Some that I examined had the frames full of dead brood, which, I think, was from autumn dwindling. I enclose a queen and workers from one, and would like to know what you think of them.—John Barnes. [The bees forwarded are black or British bees.]

NOTICES TO CORRESPONDENTS & INQUIRERS.

- I. Harvey.—Non-Swarming.—The garden position would be most conducive to non-swarming; beneath the zine roof (if not too near it) to honey-getting. Why not try both?
- WINDERMERE.—I. Enamel Cloth.—Do not remove the cloth. The moisture is a sign that the bees are strong in numbers. A chauge of floor-board will be an advantage. 2. Frame Distance.-We advise you to make your frame distance 13 inches.
- Angler.—The sample of honey forwarded is thin and has little body. The honey has lost much of its flavour through having undergone a slight fermentation.
- Expensifuge.—1. Cowan Hive.—In Cowan's Guide-book, in the chapter entitled 'Hives,' you will find such full instructions for the making of these hives that you will find no difficulty in their manufacture. 2. We are pleased to receive your appreciation of our pamphlet, Doubling and Storifying. 3. The suggestions contained in your letter will receive our best attention.
- R. Westlake.—The sample of sugar is not 'the most suitable for feeding bees at the present time without being liquefied.' We should advise you to procure Porto Rico or Barbados for dry sugar feeding.
- K. Drummond.—The sample, No. 1, is the preferable for dry sugar feeding.
- W. Baker.—Your hive now being queenless, your best plan would be to unite it to another stock when convenient.
- R. T.—We should think that the drone observed by you had not lived through the winter, but is a young drone of this season. The date of its appearance as given by you is very early for the presence of drones.
- W. P. Meadows.—It is not stated on p. 126, that Mr. Blow was 'the first to make sletted dividers;' it is specially mentioned that these were shown by Messrs. Jones and Corneil, but that Mr. Blow had designed a form of dividers which would be of service to the producers of comb honey.
- R. T. A.—The address of Mr. Fred. Enock, the mounter of microscopical objects, is Parelles Road, Miranda Road,
- C. B.—The subject of dry sugar-feeding will be found fully treated in previous numbers of the Journal, more especially,—Vol. XIII., No. 147, 'Another Point Gained;' No. 156, 'Dry Sugar Feeders;' Vol. XIV., No. 162, 'Sugar as used in Apiculture;' Vol. XV. No. 238, 'Singar Indicate in Feeding'. Simplicity in Feeding.
- Novitas.—1. Carniolans and Ligarians.—Other things being equal we consider that you will find the Carniolans the better honey-gatherers. 2. No particular advantage would arise from the cross of Ligurians and Carniolans, as the two races are too nearly allied. 3. Your suggestion is not practicable.
- A. F., Ellis E.C., and Others.—Woiblet Spur Embedder.— The description should be sufficient to enable any one to make the embedder correctly, and we have no doubt some of our dealers will advertise it. It is made by M. J. A. Woiblet, Sanges, Neuchatel, Switzerland.
- H. R.—Bees in Lofts.—Many experienced bee-keepers have found it more advantageous to keep bees in the open than in lofts, and have therefore discontinued the practice. The homing instinct of bees would be as true with holes in walls leading to their domiciles as with the entrances of hives in a garden or a field. The overcrowding in our reply had reference to the desirable facility of the bee-keeper in his manipulations,
- JOHN ORR.-Woiblet Spur Embedder.-There is really only about I of an inch at the top where the wheel will not reach, and this can easily be pressed in with the fingernail, so that there is no necessity for a second instrument to finish off with. We do not think the work could be so rapidly done with the tool suggested as with a wheel.
- John Dixon.—Ants.—Ants do not generally trouble bees to any great extent, though we have heard of a few instances where their presence has been disastrous, but the hives in such cases must have been very weak.

Show Announcements.

June 23, 24.—Suffolk Agricultural Show at Bury St Edmunds. J. Huckle, Secretary.

July 11-15.—Royal Agricultural Show at Newcastle-on-Tyne. Entries close May 12. J. Huckle, Kings Langley.

July 20-22.—Lincolnshire Agricultural Society at Spalding. Entries close July 4. R. R. Godfrey, Secretary.

August 3-5.—Yorkshire Agricultural Society at York. Secretary, H. L. Rickards, Poole, near Leeds.

Finest CYPRIAN Queens.

DIRECT by MAIL from CYPRUS to any Address in EUROPE. From 1st MAY to 30th AUGUST.

For I or 2 Queens (if ordered at one time), each 14/-,, 3 ,, 4 " 13/-" 12/-,, 3 ,, 4 ,, ,, ,, 5 ,, 6 ,, ,,

For Countries out of Europe add 50 ,/° to above prices. All Orders to be accompanied by a Remittance.

My Queens are all very prolific, long-lived, and much larger-bodied, than the majority of those supplied by others, as they are reared naturally, under the swarming impulse, in April, May, and June, from the strongest of my forty colonies of Bees kept in double-walled moveable frame-hives, and all having choice Queens, which produce workers so gentle that they can be handled without smoke, and even without a veil on the face, just as I do myself (see Mr. S. Simmins' statements on page 37 of his work entitled, A New Era in Modern Bee-keeping). This is principally owing to the fact that I have weeded out from my Apiary all such Queens which appeared to be weak or producing troublesome workers. Address-

M. G. DERVISHIAN, Larnaca, CYPRUS. A 2375 For Reference, address Imperial Ottoman Bank, Larnace.

HOW TO MAKE AN EXTRACTOR, AND A BELLOWS SMOKER.

By T. W. COWAN, F.G.S., F.R.M.S.

Post Free, Sixpence Halfpenny.

J. HUCKLE, KINGS LANGLEY.

SIMPLICITY-EFFICIENCY-STABILITY-ECONOMY.

Send 1d. Stamp for Illustrated, Descriptive, and Instructive Circular.

UNIVERSAL HIVE. Address simply— Factory, BRIGHTON.

MANIPULATE WITHOUT SMOKE!

WEBSTER'S FUMIGATOR

Entirely supersedes the Smoker, both in Simplicity and Effectiveness. No 'going out.' No tainting or soiling of combs. Always ready for use without any preparation. Can be carried in the pocket.

With Bellows, 4s. 6d.; postage, $4\frac{1}{2}$ d. Without Bellows, 3s.; postage, 3d.

Can be adjusted to any ordinary smoker bellows.

6 oz. Bottles of Agent—carbolic acid, oil of tar, and water, properly mixed—6d. each.

WEBSTER'S SWIVEL FRAME-LIFTER

WILL BE READY SHORTLY.

With this appliance, frames can be removed from hive, replaced and examined on both sides without inverting, with one hand, leaving the other free for manipulating, at the same time preventing soiling the hands with propolis.

W. B. WEBSTER,

SOLE MANUFACTURER AND INVENTOR, WOKINGHAM, BERKS.

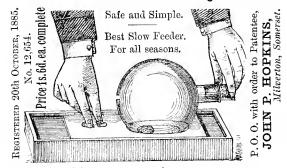

AWARDS FOR FUMIGATORS LAST SEASON.

1st Prize Silver Medal, Royal Counties' Agricultural Show. Highest Award, Colonial and Indian Exhibition, London. 2nd Prize Bronze Medal, Colonial and Indian Exhibition, London.

2nd Prize Altrineham, Lancashire and Cheshire B. K. A.

NOTICE TO DEALERS.—In thanking my numerous Patrons, I beg to say my SECTIONS are on the way, and will arrive in London shortly. The following sizes in stock:— $\frac{1}{4} \times \frac{1}{4} \times 2$, $\frac{4}{4} \times 4\frac{1}{7} \times 1\frac{1}{2}$, either open top or at all four sides. $5\frac{1}{4} \times 6\frac{1}{4} \times 2$ and $6\frac{1}{4} \times 5\frac{1}{4} \times 2$, open top. 1\frac{1}{2} Sections same price as 2". Order at once, or you may be disappointed, having received a large number of orders. Address A. F. Hutchings, West Kent Steam Power Hive Works, St. Mary Cray.

Patent Bee Feeder.—Removing the Flask.

Or for giving warm syrup in cases of dysentery.

DEUTSCHE ILLUSTRIERTE BIENENZEITUNG.

Sample copies sent on request.

Also, 'DER PRAKTISCHE IMKER.' Compendium of Rational Bee-culture, by C. F. H. Gravenhorst. Third enlarged and improved edition, with fifty-two new original Pictures, and a frontispiece. Price 4 marks (4s.), stitched; well bound, 5 marks.

C. A. Schwetschke & Son (M. Bruhn), Brunswick,

FIRST CLASS Open Sided $4\frac{1}{4} \times 4\frac{1}{4} \times 1\frac{3}{4}$ V-cut one-piece SECTIONS. From American steamer direct, 1l. per 1000; 10s. 6d. for 500, less for larger lots. Address R. White & Co., Importers Fort Etna, Limerick. The Trade supplied.

CLASS HONEY JARS a Speciality. Write for Price List, sent Free. Address Fredr. Pearson, Stockton Heath, Warrington.

MPROVED British Bee-keepers' BAR-FRAME HIVE, made of One-ineh Well-seasoned Wood, Eight Frames, Waxed, Quilt, Walker's Feeder, Excluder Zinc, Floor-board, Waterproof, and Cover. Hive complete, 5s. cach. Directions for Management, 1d. Address Isaac Hale, Maker, Horneastle.

LYON'S Patent METAL ENDS

THE only perfect pattern. The metal being flush with the inside of the Hive side, CANNOT BE FIXED TO IT BY PROPOLIS. All the so-called Improvements CAN.

The Special Alloy used allows them to be LIGHT YET STRONG. One gross weighs $5\frac{1}{4}$ lbs.

Price for 1887 5/6 per gross.

DR. PINE'S VEILS.

Prize Medal, 1879, for the best Bee Dress. The only Medal ever awarded to a Veil, **2/2** each, post free. Every genuine Veil bears the Registered Trade Mark.

DR. PINE'S LOTION.

The ONLY CURE for Stings, 1/8 per bottle, post free.

CHESHIRE CURE.

Guaranteed, with Directions, 1/2 per bottle, post free.

Methyl Salicylate, or 'Sting Preventer.'

HIVE MAKERS supplied with SPRINGS, GLASSES for Sections, PHENOL, METHYL SALICYLATE, in bulk, &c., &c., at lowest prices.

F. LYON, 94 Harleyford Rd., London, S.E.

The oldest Weekly Bee Paper in the World.

THE AMERICAN BEE JOURNAL

Established in 1861.

Price 6s. 6d. per annum, post free.

SKEPS, FOUNDATION, &c.

Dealers and others apply for List (110 Illustrations),

G. STOTHARD, WELWYN, HERTS. A 2324

Eighth Edition. Fifteenth Thousand.

EE-KEEPERS' GUIDE BOOK. Containing Management of Bees in Modern Moveable Comb Hives, and the Use of the Extractor. By Thos. Wm. Cowan, F.G.S., F.R.M.S., &c. With numerous Illustrations. Fcap. 8vo., price 1s. 6d.; or in cloth gilt, 2s. 6d. Postage 2d. To be had of Houlston & Sons, Paternoster Square, all Hive dealers, Secretaries to Bee-keepers' Associations, and of J. Huckle, British Bee Journal Office, Kings Langley, Herts.

French Edition, price 1s. 8d., now ready.

BRITISH BEFJOURNAL

Communications to the Editor to be addressed 'Strangeways' Printing Office, Tower Street, St. Martin's Lane, w.c.'

[No. 250. Vol. XV.]

APRIL 7, 1887.

[PUBLISHED WEEKLY.]

Editorial, Hotices, &c.

WHAT SHALL WE DO WITH OUR HONEY?

This question has been asked times without number, and vaguely replied to in as many different ways. 'Sell it, of course,' would be the ready and common-sense response of the apiarian who keeps bees for profit. But do the producers always go the right way to work to attain their object?

Honey at present is not a daily article of food, and is by no means a household requisite; but, 'It should be,' says every reader of the Journal; and 'These are my sentiments,' re-echoes the honey producer. 'Every Association is endeavouring to advocate this,' replies a third. But, in our opinion, much depends upon the bec-keeper himself. 'How so?' we fancy we hear a score of enthusiasts exclaim. To such we remark, 'Be patient.'

Honey was used by the ancients as a daily article of food; but gradually, through causes too well known for repetition here, it discontinued to be considered a domestic requisite, and till within a few years since was looked upon more as a luxury. Happily this state of affairs is slowly vanishing, and by the many laudable endeavours of lecturers and writers in bee periodicals, the good properties of honey and its great value as an article of diet have become more widely known. 'If this is the case, why trouble yourself any further?' would be the taunt of the near-sighted critic; 'bide your time, and the demand and production will equalise themselves.'

In this go-ahead age this will not answer; we must ever push on; failure in one direction must only stimulate to redoubled perseverance in another. We must create a demand for honey, and if we succeed in this before long we shall find the production barely equal to keep pace with it. At one time the great importations appeared likely to swamp our little industry. Prices, it is true, have gone down, but parallel with this, the brimstone pit is dying out: a more humane system is practised; larger quantities of honey are produced of a quality which will hold its own against all comers, and bee-keeping is steadily becoming a national industry.

Bee-keepers talk of honey as food, &c., but in

how many cases is it absent from their tables, how little is it used by them! To such we should say, 'Practise what you preach.' 'All very well, Mr. Editor, but our bees must pay the rent.' How much better than buying butter at 1s. 6d. per lb. (often nothing better than butterine), cheap jam, sugar, &c.—injurious to health—if some of the honey were used in the house, and the money which would have been spent on the above commodities saved for the rent. Health would be maintained, and, in the end, a better price would be realised for the remainder of the stock of honey.

It is reckoned that there are about ten thousand members belonging to the various Associations. Many are non-bee-keepers, but then there are apiarians who are non-members, so if we look upon this number as producers of honey we shall be well within the mark. Now, if our advice is taken, and we average the consumption at half a cwt. for a year per household (being a trifle over one lb. per week), we shall at one sweep dispose of the large amount of 250 tons. We feel confident that all would be the richer by this, and that the results would prove more than satisfactory.

JOTTINGS BY AMATEUR EXPERT.

'Mel sapit omnia.'

I beg to congratulate Mr. James Lee on the latest evolution he has given us from his fertile brain. It is very elever, and I hope he will not be disappointed as to price of production. I am sorry they cannot be produced in bulk in time for this season. My congratulations extend to Messrs. Neighbour also for bringing him to the fore after a season of comparative obscurity.

Mr. F. Boyes wants some one to 'speak out' about foreign bees. He says, amongst other things, 'Carniolans were dismissed long ago,' &c. Allow me to tell that gentleman that Carniolans are the bees of all others for timid bee-keepers. They are probably not the best honey-gatherers, but they will require some beating at that; and as to gentleness, they are far and away ahead of all kinds. I need not say I never sold a bee or a cent's worth of appliances as a dealer in my life, so that his other remarks do not apply to myself; and I am all the more free to recommend them, especially as we are likely to be able to get a better article imported than formerly.

During the past week I have been into the country north of London amongst the Middlesex bee-keepers; they are developing an amount of energy that speaks well for the future of their Association. Very gratifying it is to hear a departed friend for whom one has great regard spoken well of when going over the ground after him. I felt it so in respect to the late Mr. Fox Kenworthy, so bright and cheerful, but quiet and unassuming as he was, for whom one could have wished a long life of usefulness, but early called away to—

'That great cloister's stillness and seclusion,

By guardian angels led,

Safe from temptation, safe from sin's pollution, He lives.'

I see my friend, Mr. Graham, has given 'A Beginner' the size of a bell-glass to hold 35 pounds of comb honey. Will 'Beginner' kindly say what he will take for it

nicely filled and sealed?

Mr. Webster does good service by pointing out that 'scent' is no guide as to the purity of foundation. Many boil their wax, especially if it is adulterated, in honey for the very purpose of giving it 'a good nose.' I know of a fine batch of paraffin wax boiled in lime honey, and sold as bees-wax to a dealer, but the purchaser was too keen to be caught so easily, and, moreover, had too great a regard for his reputation in the matter of bees-wax.

Here are a few extracts from the Canadian B. J. of March 2nd in reply to a query on inverting frames:—

Dr. Duncan. - Never tried them.'

H. D. Cutting.— Bees doing well enough without it, so do not practise it.'

II. Couse.—' Do not use reversible frames.'

Judge Andrews.—'I avoid the use of any lumbugs, hence do not know what auties the poor bees may cut up, but suppose they might possibly retain their usual common sense—would not do useless work!'

common sense—would not do useless work!'

Dr. Thom.—'Never used them, cannot afford to "advance" fast enough to throw away hives every year

or two when new are placed on the market.'

S. T. Pettit (President Ontario B. K. A.)—'Never tried them, and thinks he never shall; knows he is out of fashion, but fashions change, and is strongly of opinion that if he remains where he is with respect to invertible hives, in a few years he will be in fashion again. The word inversion has another meaning than that intended for it to convey here, but we may all better understand the other meaning later ou.'

Rather warm of the 'Judge;' fancy I would like to spend an hour with him. 'Peck-a-boo' is giving a very interesting account of the visit of the Canadian delegates to England in the C. B. J. week by week. Read it!

Send Mr. Grimshaw to Coventry! Dear me, no! He is far too good a fellow for that. Our humourous friend, the Rev. J. Lawson Sisson, tells me 'I hit the nail on the head in a way I little thought, Birmingham is the place for hardware.' I am slow at puns, so give it up. Mr. Grimshaw has had his revenge: I will tell him a secret ('A. E.' does not want a Febrifuge, 'Useful Hints.') The lady that is queen in my hive suddenly developed an interest in the B. B. J., so during my absence she got the first reading of Mr. Grimshaw's letter, and exultingly met me with, 'Mr. Grimshaw says you are a "Brute," and so you are, three of you to set on one.' Latin was ne part of a lady's education in the good old days when Mrs. 'A. E.' went to school. 'A house divided against itself—-'

But Mr. Grimshaw has fallen into a slight error. Messrs. Cowan and Raynor and some others have always freely given the result of their brains to bee-keepers, merely giving the patterns of their new appliances to some one of the many manufacturers whom they can recommend as giving good work at a fair remuneration, but they have no agents for, nor pecuniary interest in, the sale of any of the appliances that bear their names. Mr. Cheshire adopted a course similar to Mr. Grimshaw with regard to his 'Phenol,' with the result that he got disappointment and annoyance where he hoped for, at least, some slight remuneration. I certainly did not wish to

impute meanness to Mr. Grimshaw, but only wanted to keep him clear of what will probably mar his future career of usefulness to the Association.

Thus far last week, but was crowded out in the cold. Arbitrary people are Editors—at least some of them; but the (B) world goes round as usual, although it left behind—for one week at least—AMATEUR EXPERT.

BEESWAX AND ITS CONVERSION INTO MONEY.

(Continued from page 126.)

Beeswax then is not found ready-made in nature, but is a production of the bee's body; it is like honey, an organic production, and not a mechanical or technical one. Wax is formed in the body of the working bee, of third honey, and pollen. But it is not formed involuntarily, as every well-nourished animal body forms fat, but voluntarily, viz., it is formed when the bees wish to form it, viz., when they have taken fluid honey, and pollen, in a larger quantity than they need for their own bodily nourishment, and the surplus is neither given as food to the brood, the queen, nor the drones, but is retained, further digested, and allowed to pass into the blood-vessels, in order to be organically, chemically distilled there, and to be separated as a kind of fatty matter by the segments of the abdomen.

The wax leaves the separating organs in a fluid state, and solidifies in the form of small transparent white little scales, five-cornered, shiming like mother of pearl, about two square millimetres in size, as are found in large numbers on the floor-boards of a strong building

colony.

When the bees want to build a comb, they hang together in the form of a bunch of grapes, by which a certain amount of order is observed. The bees do not hang irregularly one npon another by their hooklets or their feet, but the whole bunch is formed by the bees holding together in the form of a chain. The great heat generated in the bunch of bees facilitates the separation of the wax from their bodies.

Newly-built combs vary in colour from a light yellow to an orange red. It is remarkable that a light yellow wax comes from dark kinds of honey like, for instance, heather honey, and a dark orange red wax from white

honey, as, for instance, vetch honey.

This circumstance, which Mons. de Layens, a well-known bee-keeper and author in France was the first to notice, led this sagacious inquirer to think that the colouring of the wax is probably owing to the pollen, which was also chemically proved last year by Dr. A.

Von Planta, the famous Swiss chemist.

Beeswax consists of two different combinations. It is a mixture of cerotinic acid (cerin), which is soluble in alcohol, and of melissin or myricin, which is only slightly soluble in alcohol. Besides these constituents beeswax contains organic colouring matter, as well as other organic matters, which latter are separated in the purifying. The colouring matter bleaches best in the clear sunshine, when quite pure the wax forms a completely white, colourless, and tasteless mass, which in thin scales is very transparent, shows a splintery fracture, and at 20°C. assumes that peculiar kneadable condition which is especially described as 'like wax.' The melting point of wax is very high, between 63° and 64°C., and the latter is a good means of recognising the genuineness of the production, together with the specific weight, which lies between 0.965 and 0.969.

The preparation of wax not only makes great claims on the vital powers of the bees, but also costs them, as well as the bee-keeper, much honey. It has been calculated that for one pound of wax, from ten to fifteen pounds of honey are needed, without counting the loss of time caused by the building. Von Berlepsch makes the proportion from 13 to 1, Dr. Dönhoff from 14\frac{1}{3} to 1,

and Cowan estimates the production of wax at 20 to 1. But 20 lbs. of honey are worth 20 marks, while for 1 lb. of wax one gets only 2 marks. A judicious bee-keeper will see by these figures how valuable good combs are.

(To be continued.)

GLEANINGS.

In the Bee-keeper's Guide, M. Mahin says that in the breeding season there is little difficulty of getting rid of fertile workers, but late in the season when broodrearing in normal colonies has ceased, and queens cannot be reared and fertilised, the difficulty has been found to be much greater. It is a remarkable fact that colonies having laying workers will continue to raise drone brood long after breeding in other colonies has ceased. In fact he does not know that they would cease at all until so reduced in numbers that they could no longer care for their abnormal broad. He has discovered a method by which a queen can be introduced into a laving colony having laying workers at any time. He puts a young impregnated queen in a cage that contains food enough to last an indefinite time, and then cuts out a piece of comb in the centre of the space occupied by brood, and inserts the cage in its place. The hive is then closed and left undisturbed for about eight days, when he opens it and fixes the cage so that the queen could find her way out, and as quickly and with as little disturbance as possible closes the hive up again. He says he has reason to believe that this plan, if earefully followed, will always succeed.

In the Bee-keepers' Magazine J. Aspinwall, in speaking of the colour of wood from which sections are usually made, says he has his doubts as to white wood being the best. He says that when a jeweller wishes to exhibit the beauty and the brilliancy of his diamonds, or the purity of his pearls, he does not place them either on a linen sheet or a white velvet cushion. He groups them artistically upon a dead black cloth, and goes so far as to paint the outside and the inside of his show-window a deep black. The darkest buckwheat, he says, would look white if it could be got into ebonized sections. Propolis would not show so much on such a section. Although an extremely white section may be beautiful to look at alone, when contrasted with the honey it contains it must be admitted that it detracts from the beauty of the latter, and were the section dark-coloured, the honey would look all the whiter. Buckwheat, he thinks, would command one cent or two per pound more could we make it appear lighter by contrast with a dark section. He thinks it worthy of a trial in the markets.

In the American Bee Journal the Rev. L. Johnson says that the reversible hive has only been tried by its inventor and one or two others for two seasons. These men are practical apiarists, and in their hands it has done well; but when others, with less knowledge and without properly understanding what is intended by this hive, undertake its use, it may receive a backset from which it may not recover for years. He is in favour of making every progressive step in bee-keeping that is possible, but so much enthusiasm often ushers in a new thing as to do it harm. He urges bee-keepers to earefully ponder before doing away with the old, tried, and profitable standard hives which we now have and adopting something we do not yet understand. Take hold cantiously, and let those who have the time and money with which to experiment enjoy the benefits for a time.

In the Bulletin de la Société d'Apiculture de la Somme, Ph. Jacques Baldensperger, who resides at Jaffa, says that during the months when the sun shines he has not much time to spare. This is from the beginning of March, when the bees prepare for swarming and collect honey from orange-blossoms; after this yield of the month of April, comes a moderate harvest in May from Barbary fig, and in July the principal harvest in the

year is collected from thyme, which is as good as that from orange. Between the harvests the time is spent in rearing Palestine queens, as well as Syrians at Beyrouth, at the foot of Mount Lebanon, a journey of twelve hours by steamer from Jaffa, and with sending them off to England, America, and a few to France and Germany. England takes more than all the other three countries put together; and it is there that bee-keepers have properly appreciated the value of the Oriental races—the typrian, Syrian, and Palestine bees. He spends his time in Jaffa from October to June, and in Jerusalem from July to September.

In the Journal of the Royal Microscopical Society we find that Professor G. A. Barbaglia has examined the chemical constituents of wax found chiefly on the upper sides of the leaves of Boxus sempervirens, and finds that, like Chinese wax and bees-wax, it contains palmitic acid.

Foreign.

SWITZERLAND.

NEW EXPERIMENTS CALCULATED TO ASCERTAIN THE PROPORTION OF HONEY USED BY BEES IN THE PRODUCTION OF WAX.

(Continued from page 139.)

I will now explain, therefore, what were the circumstances I placed myself in when I undertook my experiment.

1st. My stacks had been allowed to work freely in the apiary, without interferences, so that that nothing could be altered in the natural order of their duties.

2nd. My experiments were made at a season when temperature was high (maximum at least 20° Centigrade), this being the temperature which bees, in their natural state, choose for the production of wax.

3rd. I had also selected for my experiments a season when honey was rather scarce, so as to be sure that the stocks which were building, as well as those which were not, had sufficient room in their combs for storing all the honey they could bring in.

4th. I experimented on two stocks of my apiary which differed in strength as well as in quantity of brood, but which, judging from external appearance, both worked with about the same amount of energy.

Now, these two stocks, which I will here call A to the strongest, and B to the less stronger, were both reduced to the condition of a swarm. To A seven built frames were given, beween which I inserted empty ones. This I did in order to feel that the bees were obliged, as it were, to build, and that at the same time there was a sufficiency of built combs to receive the incoming honey, and that, moreover, the egg-laying propensity of the queen would not be checked for want of room. To B I gave eight ready-built frames; here the bees could not build combs for want of space.

5th. I made two experiments, one after the other, and each one lasted exactly eight days. At the end of the eighth day all the combs were taken away from the hives and replaced by others, but the order was reversed; here, then, B was placed in the necessity of building combs, whereas A was prevented from doing so. This crossing syst m is an important one, as it permits, whilst experimenting on any two hives, of obtaining data for comparing, by simply adding, at the end of the experiment, the differences which are noted between them.

6th. At the conclusion of the experiments, the honey collected by the colonies A and B (which did not make any wax) was added together; so was also the honey of the colonies A and B (which made wax). Lastly, the quantity of wax made by the two colonies was added together. Owing, however, to great dampness, the honey gathered during the sixteen days of the experiment contained a considerable quantity of water, consequently at the end of the time none of the cells had been sealed

up. The honey, which was very thin, contained, therefore, more water than that in the sealed-up cells. In order to neutralise this misleading circumstance, I ascertained the thickness of the sealed-up honey as well as that of the thin liquid one (honey) which had just been brought home. This done, I added a sufficient quantity of water to the honey which had been sealed up by the bees, until it had been brought to the same degree of thickness of that which had not been sealed up. By these means I was enabled to arrive at the extra quantity of water contained in the honey which had just been gathered, and I deducted this quantity of water from my calculations. Finally, the difference in the quantity of honey gathered by the stocks which built combs and that of those which did not build indicated the weight of the honey consumed in the production of a given weight of wax.

7th. During the sixteen days my experiments lasted, the queens did not lay a uniform number of eggs, as they were not of identical fecundity. Nor did it happen that during the same period the laying of eggs by these two queens did progress with the same disproportion; as a result of this, in the stocks which had not been building, 16,064 eggs (were laid, whereas in those which had been building, the number of eggs laid was 16,634, or as near as possible the same number. This small difference of brood represents a quantity of honey consumed the weight of which must be added to that gathered by the stocks which had been building comb. But as the eggs did not open until the end of three days, and that it was only then that they began consuming honey, the number of larvæ which had been fed was 358. It is the honey consumed by these that must now be arrived at.

According to the investigations made by Berlepsch, 47 grammes of honey and pollen would have sufficed to feed these 358 larvæ until they closed themselves up in their cell. Other experiments, made by myself, show that to feed their brood bees use about as much honey as pollen, consequently 25 grammes will be the maximum quantity of honey used up by my bees in the partial feeding of this brood, of which only a few cells were scaled over.

We find, therefore, that the difference in the quantity of honey gathered was one kilo and 202 grammes. That of wax produced 191 grammes. My bees had, therefore, used 6 grammes, 3 of honey in order to produce one gramme of wax.

In previous experiments my bees had started combbuilding on eight frames, and as the honey yield was an indifferent one, with the exception of the first day, they built almost worker [comb throughout—I say almost, or nearly so, because in a corner of the largest comb there were to be found a few drone-cells; the latter had been built the first day, when the honey yield was greatest, almost two kilos having been brought in.

It will be seen, therefore, that in practice it is possible to get bees to build worker-combs rather economically by feeding them with a cheaper kind of honey, say some of the foreign kind, to be had on the Havre market at from 50 to 60 francs the 100 kilos. But, to obtain this result, three things are essential, viz.:—

1st.—A rather poor yield of honey.

2nd.—The removal of all the brood-combs of a hive, to be replaced by empty frames, the latter to be placed between the full ones. The brood-combs removed, will be given to a weak stock.

3rd.—Never to induce comb-building unless when the temperature is high.—G. DE LAYENS, Bulletin d'Apiculture de la Suisse Romande.

ITALY.

According to our contemporary, the *Apicoltore* of Milan, the Co-operative Bee Association of Molisana, called the *Società anonima cooperativa per l'apicoltura*

Molisana, was bold enough a little while ago to spend 1920 lire for a model apiary, the management of which has been entrusted to a noted expert, Signor Ferdinando di Jorio di Spinete, and now has invested in addition thereto the following sums in connexion therewith, viz.:

	Lire.
For the purchase of 64 stocks	2400
For the purchase of 20 ditto in common skeps	400
For the registration, &c., of the Society	115
Sundry duties	50
Bee implements	85
Office expenses	50
Insurance, &c	20

It is reported, adds the same journal, that there is every reason to anticipate a fair dividend at the end of the coming season.

Total 3120

Curiesities of Bee Life. — This formed the subject of a very instructive and interesting lecture delivered on Friday night, March 25th, to the members of the St. Silas' Mutual Improvement Society by Mr. R. A. Grimshaw, of Horsforth, member of the Naturalist Society. The chair was occupied by Mr. B. Holgate, and there was a large attendance of members and friends. The lecturer observed that the honey-bee seemed to be developed under a never-erring guidance into a creature gifted with something much higher in the mental scale than instinct—nothing short of reason could account for the many marvellous things it performed. He then entered into a lengthy and elaborate description of the peculiar functions of the queen-bee, the duties of nurses or new-hatched bees, the keeping watch over the hive by seutinels, or stay-at-home bees, the expelling of drones on the approach of winter, and the duties of the feragers, or workers, which commenced in spring by visiting the earliest blossoms for pollen or bee-bread, which they used in the rearing of young bees, and collected in a receptacle on each hinder leg. The process of gathering the nectar from various flowers, of storing it in the cells of the hive, and of its ultimate conversion into honey, were next minutely described by the lecturer. The subject of swarming was next touched upon, the lecturer remarking that a strong hive or stock of bees consisted of some 30,000 or 40,000 werkers, &c., and as it took 5376 bees to weigh a lb. of themselves they will weigh about 6 lbs. The operations of the bees throughout the winter were next touched upon, showing how they cluster on the hency-combs somewhat iu the shape of an inverted saucer. The lecturer concluded by remarking that in whatever direction we turned our studies we perceived the marvellous wisdom of the Creator in previding for the wants of all living things, both great and small, as completely in the minutest degree as for man himself, and that everything in nature had been fashioned in a marvellously intricate festoen of harmonious dependence and enjoyment, yet everything existing for the glory and praise of the Maker of all things.

Lecture on Bee-keeping.—A lecture, under the auspices of the Werking Man's Club, Ascot, was delivered at their cemfortable Hall, Ascot, by Mr. W. B. Webster, on Monday evening, March 28th; the chair being taken by the Rector. The Hall was well filled with a very appreciative audience, among them some very old skeppists, who expressed great astenishment at the results which Mr. Webster shewed ceuld be produced by the modern system. After a hearty vote of thanks to the lecturer the company spent some time in examining the different appliances shown, some converts being the result.

HIVE CONSTRUCTION.—Mr. Cheshire, in Bees and Beekeeping, and Mr. Raitt, in the Bee-Keepers' Record, gives the honour of an improvement in hive-construction to Mr. J. H. Howard, Helme, England, which in my humble opinion ought te be given to my neighbour, Mr. Andrew Buchan, Dalkeith, Scotland. The improvement referred to is described by Mr. Raitt in the following words: 'The mere recently made ones avoid the necessity of outside plinths to cover joints—a clumsy plan at the best—by having all their parts made to break joint in the solid wood. Thus the hive preper covers the edges of the floorboard, each hive section does the same to the one below,

and the roof similarly fits on above.' This description equally applies to Mr. Buchan's Midlothian storifying hives, designed by him in 1885.—WM. Purves, Dalkeith.

'BEE Bobs.'-In some districts swarms are secured by preparing a hive and placing it on a small table furnished with a white cloth, some little time before the swarm comes off. If this plan is reliable, it might be adopted for making the 'hive' into a 'Bee Bob' by dropping in block, then fix three legs made $4 \times 3 \times \frac{3}{4}$ thick, feet pointed or spiked, then make a 3-inch round hole in each leg at a suitable distance from the top of each, through which pass two garden sticks (the legs arranged tripod fashion), one stick passes through the holes in the two legs, the other through No. 3, its end resting on the cross stick, on which place the floor-board. Bore a small hole in the top of each leg, through which pass a short wire pin put in at an angle upwards to penetrate the skep. If the swarm do not accept and are about to settle on a bush the tripod may be carried at once to where the cluster is forming, if it can be placed over the cluster the greater chance they will ascend, or if not, may be caused to go up by the aid of smoke or a feather dipped in the carbolic mixture.—W. G.

Moving Bres .- I should like to suggest to any one about to move bees, if obtainable to secure a donkey and truck for the purpose. I have just moved my apiary about $2\frac{1}{2}$ miles, four hives at a load, without any other preparation than perforated zinc over the entrances. I have not one item of damage done to them. The slow and short steps of a donkey make him the most suitable for this purpose. My moving was done each evening, after the bees had gone to rest.—C. H. BICKLEY.

Correspondence.

The Editor does not hold himself responsible for the opinions expressed by his correspondents. No attention will be taken of anonymous communications, and correspondents are requested to write on one side of the paper only, and give their real names and addresses, not necessarily for publication, but as a guarantee of good faith. Illustrations should be drawn on separate pieces of paper.

Communications relating to the literary department, reports of Associations, Shows, Meetings, Echoes, Queries, Books for Review, &c., must be addressed only to 'The Editon of the 'British Bee Journal,'' clo Messrs. Strangeways and Sons, Tower Street, Upper St. Martin's Lane, London, W.C.' All business communications relating to Advertisements, &c., must be addressed to Mr. J. Huckle, King's Langley, Herts (see 2nd page of Advertisements).

***In order to facilitate reference, Correspondents, when speaking of any letter or query previously inserted, will oblige by mentioning the number of the letter, as well as the page on which it appears.

R. R. GODFREY'S GUIDE FOR JUDGING HONEY,

[891.] I have occasionally noticed in Bee Journals expressions of dissatisfaction from correspondents with the awards made by judges at some of our exhibitions. Possibly they may have had just cause for being dissatisfied. On the other hand, I may remark, it is no unusual occurrence to find exhibitors dissatisfied when they have no reason to be so. That errors in judging do occur few will deny; and with a view to lessening such I have prepared the enclosed Guide, which I venture to think will (if followed) be effective.—R. R. Godfrey,

Points to be considered in the Judging of Extracted or Run Honey, with a Standard of Mark's obtainable for each point, and remarks on quality desirable as a standard of excellence.

DO BEES HEAR? [874.]

[892.] This must ever remain but an hypothesis, since we cannot obtain absolute proof of the theory; yet the doubts as to their power of hearing may be reduced into such small compass by evidences in favour of the affirmative side, that it may almost be considered as an established fact that bees do hear.

Primary and almost satisfactory testimony is offered by the knowledge that bees possess (1) vocal organs and (2) organs justly supposed to be annal because of their peculiar anatomical construction, differing as these latter do from the touching, the smelling, the seeing, and the tasting organs. Now if we have our five senses, all of which we use, and the bee has quite similar mechanism to our own, which we admit it uses in four

out of the five cases, is there not strong prima facie evidence that it uses the fifth (the hearing) sense, especially as it uses its correlative the vocal organs?

In a general survey of animated nature one may find individuals of sex not using organs with which nature has provided them, but never do we find any species endowed with any complete (that is, not aborted) apparatus which does not, as occasion requires, call such apparatus into play. Here we have hollows on the antennæ of our bees; a thin film or diaphragm is stretched across each hollow, and opposite and in contact with this film is the end of a nerve connected with the brain. Given a suitable, perfect, useful apparatus, and the use of it follows. Given a chronometer, and its use follows as a logical sequence.

Mr. Dunster (874) cannot get his bees to show him any response to the report of a gun, but does he give any outward and visible sign that he hears it? Sir John Lubbock found it necessary to qualify his opinion against bees having the sense of hearing hy saying that his evidence was only of a negative kind—that he does say they cannot hear, but only he cannot make them

give evidence of it.

To simplify the question of auditory operation, or hearing, may we begin by requiring, as the only conditions—(1) a vibrating, (2) a conducting or transmitting, (3) a receiving medium? (It is not necessary that air should be any of these.) Let us place the car on a railway metal at the end of a tunnel, and we can hear a train enter at its other end; the end of a long rod or table, will show us that once the power of hearing be given, the means may vary, but each goes to prove the existence of the sense. The blows of an axe or spade vibrate the earth and send the mole downinto its deepest chamber. The same blows send up the worms who think the vibration is caused by the burrowing of their enemy the mole. Reasoning thus, some birds actually stamp the ground in order that they may get a meal of worms. Thus the moles and worms hear, as do the bees when the slight touch or shake, or the heavily laden wheelbarrow, Mr. Dunster speaks of, are brought into play.

There are very many instances quoted of bees hearing: a very telling one being given by Mr. Cheshire, who saw a small knot of bees in an obscure part of the tent commence ascending, immediately the swarm in a driving operation began running into the upper skep. When a skep of bees is thrown on to the sheet in front of a frame-hive, the instant those nearest to the door get on the march there is a sound we all hear and know, which puts the lot to the 'right-about, quick-march' in This movement is so sudden the desired direction. that the peculiar merry hissing or hushing sound is in all likelihood the signal to march; and although the crowd is so great that the citadel gate will not admit them, march they will 'onward and npward,' like so many silly bees as they are, just because they are told to, exactly as they will commence fanning in the most absurd position just because the word was passed to fan or they heard some sisters fanning. I contend that bees do hear.—R. A. 11. Grimshaw, Crag Hill, Horsforth,

near Leeds.

SLOTTED DIVIDERS.

[893.] On page 143 of B.B.J. (887), Mr. Hooker has given your readers his version of 'slotted dividers,' amongst other matters, claiming them as an 'American invention.' I will endeavour to give the facts about them, so far as I am concerned.

When Mr. Corneil exhibited his super crate at the meeting on October 20th last year, the moment he sat down, I stepped up to him and suggested cutting slots in his dividers, and that gentleman's reply led me to the conclusion that the idea was as new to him as it was to

myself, as I had not up to that time been so fortunate as to see it in *Gleanings*, nor was I aware until a fortnight since that Mr. Hooker had brought out a new section crate, so that Mr. Hooker did not help me towards the idea. I exhibited my new crate at Hertford, and Mr. Corneil, who was my guest at the time, said nothing to lead me to judge that he had seen or heard of the idea across the Atlantic.

I was careful at the Conversazione in Jermyn Street (see B. B. J. page 60) as to what I claimed as my 'inventions,' and Mr. Hooker, who sat opposite me at the time, said nothing about his own crate or the idea being an American one; and if Mr. Hooker thought the idea worth anything to bee-keepers, I am surprised that he did not bring it to our notice before.

I am pleased the idea is likely to become general; my thanks are due to Mr. James Lee for giving credit to where—as far as he was concerned—credit was due.

where—as far as he was concerned—credit was due.

Mr. Hooker should be satisfied with describing his own super without disparaging other people's; what he said about the sections falling out of mine when the screws were loose was 'bogie.' I think I satisfied the Southgate bee-keepers on the 24th ult., that a fair amount of jarring could not jar them out. As it happens it does me no injury as I have no pecuniary interest, but we look for some observance of the golden rule.—J. P. Sambels, Cole Green, Hertford.

NOTES BY THE WAY.

[894.] From 'Useful Hints' notice concerning improvements in frames and sections I for one was anticipating something far beyond the construction given in the Editorial illustrated in issue of March 24, and I am bound to say that in neither frame nor section is there aught original save the adapting of the running dovetail joint and the bottom rail as a foundation guide. This latter in practice will prove a sad mistake. So far as providing for full sheets of foundation in the bar-frame practically wiring is preferable. But here let me ask, is it wise to exclude drone-rearing in drone-cells proper? also can drone-rearing be frustrated entirely, even though all worker-cell building may be tried a compulsion? My experience has proved otherwise. Then why not slightly encourage nature's effort and allow for the same? mention this, as a special feature is noticed that combfilled frames will be the result with 'Lee's' frame. Such may be, for a first season, and perchance many dwarf drones attending, where a brood-chamber is completely furnished on such principle; but has ever any bee-master found the standard frame in successive use, that the bees respect an even and well comb-filled frame? Therefore, as passage-ways more or less through, below, and at side of combs, are shown a necessity in positive use, why at the start completely ignore them?

I give an illustration showing a frame which in practice will compare more than favourably with 'Lee's.' The top

with 'Lee's.' The top bar and sides are grooved to just where the latter diminish. The foundation can be placed into

groove either before or after the bottom (dovetailed) rail is added. A slight addition of molten wax holds foundation secure; and is the latter cut at corners, as shown, here drone-cells proper are found constructed in most cases with a young queen to suit and satisfy all her need.

The thickness of top bar between sides is ½ inch, and shouldered as the Sitamins' frame, for the 3 inch lug, just keeping the latter always to size for those who prefer metal ends, and at the same time the top bar is strengthened by an extra thickness, nor is it an already weak bar; still further weakened by separation. Again

with a sheet of foundation held as shown all sufficient room for expansion is allowed; and if it is of such strict necessity to have a comb-filled frame, just run the first season without the bottom rail, and after the bottom edge of worked down comb has been cut away to receive the same put the rail in place: but this is a useless work, as I have before remarked.

Again, as to sections. Dear me! little did I think a six-piece section would be heralded in as a step forward, when the four-piece section and double top rail sections for holding the foundation, making a five-piece section, had fallen away, giving place to the one piece V cut; and I certainly felt we were going backward when I

made the four-piece section, of which I send you illustration. This section the four sides are grooved to receive the foundation, as shown. The foundation is cut by a special tin die to exact size, and at same time the centre bee passage is also cut, which allows of expansion until such time the bees have made sound and strong the same

by extended cells.

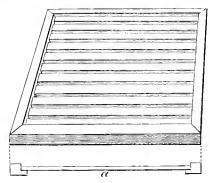

Now we come to slotted dividers. Well, here I think Mr. Hooker's letter, No. 868, proves design and originality, neither is there anything in providing 'special machinery for their production. 'Dies' for the same long ago I could place my hand upon not many miles from here. These in wood especially, with much other which is now agitating the new hand, will be tried and found wanting; many old hands, who could produce honey under every disadvantage, will abide well-nigh stationary in limited trial only. Mr. J. Hall, No. 876, gives an ingenious one way watertight joint, but how about the 'tother way up?' Mr. F. Boyes (877) entirely I endorse. Last, though not least, Mr. W. B. Webster, 871, on 'Foundation.' Has he a foundation for asserting the company of the second of th that one, or more, or the whole of British foundation-makers are dishonest? Would it not be far wiser for him to give his tests (of which there are several more simple and less inexpensive than his last) and so expose the guilty, rather than say all 'must not be tarred with the same brush,' yet still leave us all liable to suspicion? Were we all near Mr. W. no doubt he would not go to Mr. Grimshaw for help, but have to find the oldest of all 'fuges,'-Refuge,-from the angry storm.-J. H. Howard, Holme, Peterborough.

CRATES AND SECTIONS.

[895.] As economy is a great point to be considered in bee-keeping in order to make a profit at the present, and in all probability future, low prices and slow sales, it has long since occurred to me that a single-walled hive for summer use, having a good watertight outer case, to be packed with chaff, &c., if it should have to be wintered out-of-doors, would be the most economical as well as the most useful; in fact, just such a bive as that described by Mr. McKnight, of Ontario, on page 72 of this *Journal*. The body of the hive might be made of one inch and \(\frac{3}{4}\) inch wood with \(\frac{1}{2}\) inch rabbets in the former to take a standard sized frame (but with top bar only $15\frac{1}{2}$ inches long). Such a hive with ten frames and a thin dummy would be $16\frac{1}{4}$ to $16\frac{3}{8}$ square, still there would yet exist the crate difficulty, outside lifts and deep roof, being required if we use the $4\frac{1}{4} \times 4\frac{1}{4}$ sections, unless we reduced the length of the frame so as to make the hive about fourteen inches from side to side (outside measurement). To avoid this we could increase the length of the 1-lb. section to five inches, making it $3\frac{5}{8} \times 5$, which with $\frac{3}{4}$ inch wood used for crate would make just $16\frac{1}{4}$ inches. A 2-lb. section for this sized crate would be 7×5 , and if a half-pound is required $3\frac{5}{8} \times 2\frac{1}{2}$,

The kind of crate I would prefer would be one similar to the one exhibited by Mr. Sambels, being the height of the section only, but without the inside fillets, and having strips of tin at the sides and two angle tins, thus—1 in the centre to support the sections.

I send herewith an illustration of a frame to form a bee space for this kind of crate, and at the same time to

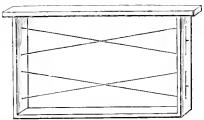

prevent the sections from being propolised, and think the only explanation 1 need give is that the strips of wood $I \times \frac{\alpha}{2}$ rest on a rabbet shown in section of frame. They are placed about $\frac{\alpha}{2}$ inch apart and immediately over the interstices of the frames below, and may be fixed or loose. A strip is shown in the section of frame at α .

In regard to the divider, shown on page 126, allow me to suggest that the side slots need not be more than one inch long, which would be quite sufficient for the bees to pass, and sections for use with such a divider having slots only one inch long at the sides would give more strength to the lug at the corner, being less liable to break away, and would keep the heat in better. I suppose sections will now be made some with slots on the right side only, some with slots on the left side only, and some on both sides.—A. T. Wilmot, St. Albans, March 26.

THE WOIBLET SPUR EMBEDDER.

[896.] It was with great pleasure that I read your description of the 'Woiblet Spur,' as I can quite believe it is exactly what most bee-keepers require. There are, however, one or two matters connected with its use to which I should like to draw your attention and that of the readers of the B. B. J.

1st. The method of wiring frames as described by you, viz., carrying the wire from the top to bottom bar would, as a rule, be a failure, owing to the bottom bar in most of the frames sold by dealers being too weak to keep the wire tightly stretched, for as soon as the board (Fig. 6 in your description) was removed the bottom bar would be bent towards the top and the wire would thus become slack. Under these circumstances I always lace my frames from side to side bars, as in sketch, placing the sheet of foundation between the

wires and fixing it to top bar, and then twisting the ends of wires together until they are quite tight, so that there are two wires on either side of foundation.

I have up to the present (for want of such an apparatus as the Woiblet Spur) pressed the wire into the

wax with the point of a small bradawl, first warming the sheet of foundation; and although the wire has not been covered with wax, I have always had the cells drawn out and used as readily as those which the wire (Wilson's of Oakham) did not cross, as I shall be happy to prove by sending a frame of comb for your inspection. In fact, unless the comb is closely examined and held before a bright light no one could tell that it had been wired. I used frames of foundation wired in this manner last year for extracting without a single comb giving way.

The description you mention as given by Mr. Cheshire is certainly surprising as coming from a practical beckeeper; but a drawing in one of the dealer's catalogues is still more absurd, for if the apparatus is anything like the drawing, the wire would be pressed into the foundation by teeth about an inch apart and nearly half an inch across, and of such a large size that I should expect they would punch a hole in the wax on either side of the wire.—HAROLD ADCOCK, Middleton, North-

ampton.

CROAKING QUEENS.

[897.] On page 110 I am slightly misquoted by a slip of Mr. Anderson's pen. The expression I used in my paper was, 'We recognise the contented boom of the quiet prosperous hive, in opposition to the sharp "poop! poop!" of the lost queenless bee.' Your correspondent makes me say the lost queenless hive. The notes I allude to are well represented by the upper G of the tenor singer, and are produced by keeping bees prisoners under a glass after destroying or changing their characteristic aroma by feeding on peppermint syrup; the noises are are made both under the glass, and whilst trying to escape by flying against the window-pane.

Some time ago when this subject was before us in your columns I told you on my part I had distinctly traced the croaking in a hive to the striking of wings against the hard shining surface under an Americancloth quilt. It was a drone; 'I see'd him do it.' We can imitate him (or the other bees) with a pen or peneil held in one hand, one end near a window pane, a sheet of paper, or wood, and by playing the 'devil's tattoo' with the fingers of the other hand on the pencil, so that its end strikes the object, we may account for many noises heard in hives produced by blows or vibrations of wings, which are often mistaken for voice tones. I am quite with Mr. Anderson as to the importance of studying minute details in any branch of science, and we have only to refer to the works of the 'early fathers' in beekeeping to find justification in discussing apparent trivialities, indeed we need none.—R. A. H. Grimshaw, Horsforth, near Leeds.

NOTES BY WOODLEIGH.

[808.] EXCLUDER ZINC.—Could we not dispense with the cross pieces left in a sheet of excluder zinc as now made and have the width only, and let the slots run from side to side? I should think stout wires stretched in an iron frame the proper distances apart would not be such an impediment to worker bees to get through as the flat zinc, the iron frame could easily be made the size of a 21 lb. section crate. If, as I suggest, with zinc, the sheets would require to be thicker, or it would bulge and not answer the purpose intended.

Instinct.—Do Bees Talk?—Last summer I had a fine bell-glass filled, as I thought, from external appearance, with splendid honey, but when I came to take it off the hive I found the centre of it full of brood in all stages of development. I had taken the precaution to use excluder zinc, and so of course did not expect anything of the kind, although I could not account for a few drone bees walking leisurely about in

the super a few days before I removed it from the hive, but thought perhaps the excluder had dropped off the rabbet on one side and so given them access to the dome; but when I got it into a back room, where I always manipulate my large supers, I found the zinc in place just as I had put it before it was put on the hive, though a glance told me the super was spoiled by brood, among which was a number of drones. The queen must have got through the excluder zine shortly after the super was put on, and when through had not been able to get back into the body of the hive, and here confined in a bell-glass she had done her best to carry on the wellbeing of the colony though on a limited scale. But why all this description, you say, about a broody super, that is a common occurrence? Yes, sir, it may be a common occurrence, but the following remarkable incident I noticed helps to prove that bees must have a language, or some means of communication that is not known to us at present. Here in this bell-glass were drone bees that had been bred in it, drones that had never seen the light of day, had never used their wings, could not, by actual sight, know the shape of the outside of the hive or the position in which it was situated or in what it differed from others in the same row or apiary, unless it was communicated to them by worker-bees who were able to pass the excluder, or by other drones that were bred in the hive below from eggs deposited by the queen before she got up into the super. Yet when I removed the board with zine centre from the bottom of the super the drones took flight through the partly open door and instead of flying to one of the fifty busy hives immediately in view of the door they very quietly careered round to the side of the house to their own hive, although the row of hives-of which theirs was number one of the row—was not in view from the door through which they made their exit. Now how shall we account for the above unless bees do communicate their ideas to each other, or that they had in this instance given the drones instructions by some means as to the latitude of their domicile while still prisoners in the super? The only other alternative we have in the case is, that the drones were piloted to their right hive by worker bees who had left the super before them and were still flying about round the partly open door, or else it must have been the sounds of distress that were uttered by the bees of the hive on the loss of their food, brood, and queen, as I think I have made it plain that when I removed the super I had all the brood and queen with it. I know the hive was in great commotion at the time, and the hive, though not visible from the door, is only a few yards from it; and if bees have a language and are able to lament when a great disaster occurs to the colony, then probably the sounds of the sisters' voices in great distress attracted the sympathies of their big burly brothers the drones, and acted as a beacon light does to the lost mariner.—Woodleight.

SIZE OF FRAMES.—ARTIFICIAL POLLEN.

[899.] I observe that the size of bar-frames is sometimes discussed in the Journal, my experience has been that hives containing ten of Abbott's large tapering frames give at least 20 lbs, more honey per hive than hives containing ten Association frames. These large hives winter well with all the frames in; mine appear now almost as full of bees as they are at swarming time, judging by the numbers that come out on fine days. I have not opened out a hive yet; they are covered first with enamel cloth, then thick felt, then an inch thick board, with a feed-hole through all these layers, and finally plenty of flamel felt, and chaff-cushions on the board, which feels quite warm under the cushions. Fearing some of them might be short of food I took off the perforated zinc which covered the feed-hole, intended for syrup feeding, and am now giving them tumblers of raw West India sugar turned over

the feed-hole. I can see when to renew it, and some hives are very hungry. After the bees had finished all the pollen in the crocuses, I spread honey very thinly on small pieces of board and dredged a good layer of pea-flour over it, and placed these some distance from the hives; they soon cleared the boards, and doing this rather late in the day I saw no robbing set up.

Do you approve of it? The floor-boards seem quite

dry as far as I can see without much disturbance.

BEESWING.

We think the device is one to be commended for its simplicity and efficiency.—Ed.

HONEY MARKET.—OBSERVATORY HIVE.

[900.] Several of your correspondents, in writing to the Journal, complain of having no market for their honey, and if they have they require to sell it at a very low price. Then others say they have a good market and get a good price, by doing all they can to make a

market among their friends and others.

Now, I think a good plan for creating a honey market would be for bee-keepers to exhibit their honey, bees, &c., at the horticultural shows generally held in their own village every year. I believe that if the committee of such shows were approached in a proper manner they would be very happy to assist bee-keepers by giving them accommodation at their shows, and if this were done the bee-keepers in their own village could often very have a very nice display of honey, &c., and they also could explain to the people going the round of shows various matters in connexion with bees and bee-keeping, and in this way it would also prove a greater attraction to the flower shows. I would like if some of your numerous correspondents would give us their opinion about this, being better able to write and advise than I am in connexion with this matter.

Another request I would ask of some of the readers of the Journal-if any of them would be kind enough to give a description of how to make a simple observatory hive to hold either two or four standard frames, suitable for the exhibition of bees at a flower show, as I would like to try and make one, so as to have it ready for the horticultural show in our village, at the end of the season, as I intend to get up an exhibition of bees, honey, and appliances, along with other two or three bee-keepers this year.—Thornton Hamilton.

LOSS OF LIGURIANS FROM MISMANAGEMENT.

[901.] It was in July, 1886, the exact date was the 5th, on opening one of my hives-to which I had lately introduced a laying queen, which I expected to find, by that time, presiding over a goodly quantity of brood,—to my dismay, I could discover neither brood, nor eggs, neither after searching over all the combs could I catch a

glimpse of the queen.

Now, having, for some time, wished to possess a Ligarian hive of bees, I determined to procure a queen of that race, and so immediately posted down to a reliable dealer, for that purpose. I obtained a fine healthy, lively one, which had, I was informed, only arrived from Italy three days previously. When I arrived home it was too late to introduce her, so 1 postponed the operation until the next day.

On the following morning on opening the hive, to which I had intended to introduce her, I discovered, by the unexpected presence of eggs in the combs, that their queen was unmistakably present; so not wishing to destroy her in order to introduce the Ligurian queen, I procured a couple of pounds of bees without a queen, introduced my Italian to them, and hived them on four frames of foundation.

I stimulated them with syrup, until, with the addition

of two frames of hatching broad, I had eight combs pretty well covered with bees, and almost one mass of brood by the middle of September, when I commenced the autumnal feeding in conjunction with my other

At the end of September I examined all hives before packing for the winter; my English and cross-breds had sealed the syrup up well, and were in splendid condition; but on opening the Italian hive, I found that, instead of storing the syrup, they had converted the combs into a mass of brood, with but little sealed stores; so I had to continue feeding them now with thicker

syrup and more rapidly.

On examining them on 15th October, I found they had only about 20 lbs. of stores in the six combs to which I had contracted them, and that each comb had about 1 lb. of unsealed food; I added a frame of capped stores weighing 5 lbs. taken from another hive, and I intended to extract the unsealed honey; but being away from home except at the end of each week, I had no favourable opportunity of doing so, so wintered them as they were. If I had known what I do now, I should have carried the hive indoors, extracted the uncapped honey, added candy to make up the deficiency in their stores, and then returned them to their stands in the

All went well, or apparently so, until the last day of the year, when I discovered on my daily inspection of the hives, about fifty dead bees on the alighting board in front of the entrance to the Italian hive, and I saw at once that dysentery was the cause. The next day, another batch of fifty was removed from the entrance, and the hive was carried indoors. An empty hive was prepared ready to transfer the combs and bees into, with chaff-cushions contracting the hive so as to contain only four frames. The next morning the room containing the hive, which only registered 32°, was heated by a stove to 60°; the combs were removed, the unsealed honey extracted, and the bees which still remained alive, about 10,000, were shaken into the clean hive. Candy was placed over the frames, and a chaff-cushion on top. There were about 5000 dead bees on the floor-board of the old hive.

The hive containing the surviving bees was then removed to a dry, underground cellar, registering 38°, where they remained until 5th February, the temperature varying from 36° to 47°; the dead bees raked from the bottom of the hive also varied with the weather from 4 to 12 per diem, more dying when the temperature was high; this was no doubt caused by the bees being enticed out by the warmth, and not being

able to find their way back in the dark.

On 5th February the thermometer registered, in the open, 40° at 9 a.m., and 50° at 3 p.m.; the warmth also in the cellar making the bees uneasy, and, consequently, the mortality great, I removed the hive to its old stand in the open, and the bees had a cleansing flight. I noticed that, while the warm weather lasted, the deathrate, now they were in the open, had decreased from ten to five per diem.

The weather soon, however, changed cold again, and perhaps my wisest plan would have been to have again removed the hive to the cellar, still I hoped that, having pulled through so far, they would continue to do so until the weather permitted my uniting them to another hive. However, the heavy fall of snow in the night of 14th March, and the accompanying frosty nights, and sharp east winds, proved too much for them; and they succumbed, on 17th March, 1887, the victims of mismanagement on the part of their owner.

Moral: Do not stimulate too late in the season. Always extract all unsealed stores before wintering.

Perhaps from my trial of them, I may not be accurate in my impression, that Italians do not cap over their honey so well as other races, and that the capping is very thin and unsuitable for sections. I can, however, affirm that no quieter bees to the manipulator could exist, although they were most vigilant in defending their hive from robbers, when they were strong and in health.

It has been complained in the Journal that we only hear of successes, and not of disappointments, and for that reason I have penned the foregoing; however, a person must be indeed courageous to sign his name to a confession of this description. I therefore, ever hoping, sign myself—Nil Desperandum.

Review.

THE BEE-KEEPER'S HANDY BOOK. TWENTY-TWO YEARS' EXPERIENCE IN QUEEN-REARING. By Henry Alley, Wenham, Massachusetts.—Practical bee-keepers well know the importance of queen-rearing as a branch of apiculture, and here we have a work treating especially of this subject. Mr. Alley, who is the present editor of the American Apiculturist, has had twentyseven years' experience in bee-keeping, twenty-four of which have been devoted to queen-rearing; and as he is acknowledged by American bee-keepers to have produced and reared more queens than any other breeder, he may be regarded as one speaking with authority. In former editions the largest part of the book was devoted entirely to queen-raising, but as the author found many who purchased it were not experts in bee-keeping and desired more information suited to beginners, he has, in response to a request, enlarged his work and given, at the commencement, practical instructions in bee-management. The first part consists of 175 pages, and contains everything it is necessary to know to become a good bee-keeper. Mr. Alley is one of those who gives 'honour to whom honour is due,' and in the descriptions of hives and appliances, great care is taken not only to describe them correctly, but also to give the names of inventors as well as the names of the various bee-keepers whose opinions he quotes. Amongst the hives described are the Langstroth, Quinby, Baystate, Van Deusen-Nellis, Shuck's Universal and Invertible, the Heddon-Langstroth, and many others, of which also illustrations are given. A chapter is devoted to invertible frames, in which he says, 'The idea of reversing the hives for tiering np and other purposes, is not by any means new or original with the present generation, having been practised and strongly advocated by a successful Russian apiarist in the eighteenth century, and claimed by him to be one of the most valuable features of his hive." Who will say after this that there is anything new under the sun? There is also a useful chapter on combfoundation making, and tests for bees-wax are given, which will be appreciated by manufacturers. Feeders and appliances of all sorts are described, and valuable hints will be found on wintering. The last chapter of about a dozen pages is on bee-pasturage. The second part is devoted entirely to queen-rearing, and Mr. Alley adopts the motto, 'Better, not cheaper queens,' with which we entirely agree. This subject occupies about ninety pages, and is treated by the author in a most practical manner, showing his complete mastery of it. The system has already Leen briefly described by Mr. Blow in his article 'Amongst the Queen-raisers of North Italy,' on page 96 of British Bee Journal for 1886, and some of the illustrations there were from Mr. Alley's book, although by some oversight their source was not acknowledged. We shall on some future occasion hope to give extracts, and describe more fully the methods he so warmly advocates. This book should be in every bee-keeper's hands, and will prove a valuable addition to our bee literature being honestly written by a practical beekeeper, who gives his readers the benefit of his experience. This work is a handsome octave volume of 269 pages, beautifully printed and copiously illustrated.

Echoes from the Bives.

South Derbyshire, March 29th.—Have not had the heart to send an 'Echo' ere this, as I could scarcely conceive a more unfavourable spring for bees. A month of sharp frost followed by three weeks of cold, rough winds disposes of most of February and March. To-day, however, the wind has dropped and the sun shines warmly, so that there is a general exodus of bees. I have taken the opportunity to glance through my hives and put them straight for work. For the time of year I never before saw so little brood, my hand would easily cover the patches, though there appears to be about the average amount of bees. Out of twenty hives, I have lost one through starvation (and robbing, too, I fancy), and one is queenless. I purpose trying the 'let-alone' system this season, allowing no brood spreading, simply to add combs outside the uest and to feed when necessary.—M. J. Astle.

North Leicestershire.—April 1st and not a leaf to be seen; crocuses just well up; snowdrops and aconites gone. The snowdrops bloomed and faded almost unvisited by the bees, who have only had four really good days foraging, viz., February 22nd and 27th and March 26th and 29th. Stocks continue strong, but require feeding to prevent the destruction of brood.—E. B.

Woore, April 4th.—On April 2nd I examined three framehives, found new-laid eggs and hatching brood; colonies very healthy, but getting rather short of food; have commenced to feed to day.—J. S. L.

NOTICES TO CORRESPONDENTS & INQUIRERS

M.E. Kirk.—Fighting.—The excitement, which you describe by saying, 'The hive was almost covered with bees,' probably arose from the bees rejoicing and 'playing' in the glorious sunshine. You did wrong in removing the quilts and enlarging the entrance, thus giving free entrance, above and below, to the bees from your other hives, against which it was impossible for the attacked colony to defend itself. At this time of year the heat is never so great as to be injurious to the bees, and being unable to obtain honey from the fields they were only too happy to obtain such an opportunity of robbing a neighbour as you presented to them. It is possible, but not likely, that the first excitement might have been caused by a small colony having deserted its hive, and settled on the outside of yours, with a desire to gain admittance, but the former explanation is far more probable. We do not think much damage is done except the loss of a few bees. The bees would encase their own queen to preserve her from the stings of the intruders. It will be well, however, to obtain an interview with her majesty on some fine evening when bees have ceased to fly, and also to notice whether the colony works vigorously, and carries in pollen, when the weather permits. Contract the entrances of all your hives to about two inches in width, so that if a spirit of robbing has been engendered each colony may be able to defend itself.

W.H. Jenkins.—I. Section distance.—Section-racks are made to receive either three or four rows of sections of seven in each row, and to cover the top of a hive containing ten standard-frames. If three rows (twenty-one sections) are used, spaces sufficiently wide between the rows (say, 1 in. full) are allowed for convenience in removing and inserting sections while the rack is in use. If four rows are preferred (twenty-eight sections), with the view of a better retention of heat, the rows must touch each other, or nearly so, and the rack will project slightly over the sides of the hive. These dimensions refer to 1-lb, sections = $4\frac{1}{4}$ " \times $4\frac{1}{4}$ " \times 2". 2. Slot width.—The width of 'slots,' or passage-ways, cut out of dividers for single sections, should be one bee-space, i.e., a quarter of an inch full, and these should correspond with the side passages of the sections, supposing the sides of the sections touch. If the tops and bottoms of the sections project a half beespace beyond their sides, thus forming a full bee-space between the rows of sections, the openings in the dividers must still be \(\frac{1}{2} \) in., and must stand opposite the spaces between the rows. 3. Wintergreen. — Amongst essential

or volatile, oils, oil of wintergreen (Gaultheria procumbens) is synonymous with the oils of partridge-berry, methylosalicylic ether, and salicylate of oxide of methyl. This 'Oleum gaultheriæ' (Pharmacopæia of United States) is procured from the leaves, or the whole plant of Gaultheria procumbens, a herb common in North America, and known also by the names of 'box-berry,' 'chequerberry,' 'partridge-berry,' 'mountain-tea,' and 'wintergreen.' When diluted it is agreeably fragrant. When mixed with a dilute solution of potassa it solidities to a crystalline mass (salicylate of methyl and potassa) from which the oil may be again separated by the addition of an acid. Salicylic acid may be obtained from this 'Oleum gaultheriæ' by acting upon it with a strong and and hot solution of potassa, and afterwards separating the acid as before. But the greater part, if not the whole, of the salicylic acid of commerce, is now obtained by Professor Kolbe's method, which consists in acting on sodium carbolate with carbonic acid. See 'Cooley's *Cyclopædia*.' Oil of wintergreen, pure and simple, we do not advise you to give to bees in syrup. It is much better and safer to keep to the solution of salicylic acid as recommended in Mr. Cowan's Guide-Book, p. 151.

O. W.-Food for the present Season.-The candy made as you propose will do, but we should substitute pea-flour for ordinary wheat-flour. The best method of feeding for a busy man is the dry sugar plan. Cover a frame both sides with the thin board nsed for picture-books, leaving an inch space open at the top of one side. Fill the trough thus formed with Porto Rico sugar and use as a dummy. Crowd the bees so that they are in contact with the feeder, and place enamel cloth on top of the frames to condense moisture.

INQUIRER.—We have not advanced so far in our endeavours to nuravel the mysteries of the physiology of the bee as to be able to determine whether the eggs and grubs in the pieces of comb forwarded are the progeny of a fertile worker or a fertilised queen.

E.—The comb forwarded shows chilled brood much de-

composed, and requires vigilant watching.

INSECTS.—The two insects are drones, and being very small, they have most probably been bred in worker-cells.

R. T. S.—We have no experience of caraway as a bee plant. You will be able to tell whether it is of value to bees at the time it is in flower.

C. H. B.-We do not think that the sample of sugar, stated by your grocer to be Porto Rico, but which we call 'picces,' would be found suitable for dry sugar feeding. We would recommend you to get pure Porto Rico or Barbados for this purpose.

W. G. C.—Honey.—The sample of honey labelled 'Edward Pink & Sons' has been submitted to Otto Hehner, Esq., analyst, and his reply is, 'The sample consists of genuine honey.

J. A. Watson.—We suggest that you should forward a sample of the honey to Mr. Hehner for analysis.

EUCALYPTUS HONEY.—With reference to the short paragraph in B. B. J. of 31st March about Eucalyptus Honey, our readers may be interested to know that it can be obtained of the British Bee-keepers' Stores, 23 Coruhill, E.C., who, we are informed, have recently received a consignment.

Show Announcements.

Finest CYPRIAN Queens.

DIRECT by MAIL from CYPRUS to any Address in EUROPE.
From 1st MAY to 30th AUGUST.

For 1 or 2 Queens (if ordered at one time), each 14/-, 3, 4, 7, 13/-, 5, 6, 7, 7, 7, 7, 12/-

For Countries out of Europe add 50 ° to above prices.

All Orders to be accompanied by a Remittance.

My Queens are all very prolific, long-lived, and much larger-bodied, than the majority of those supplied by others, as they are reared naturally, under the swarming impulse, in April, May, and June, from the strongest of my forty colonies of Bees kept in double-walled moveable frame-hives, and all having choice Queens, which produce workers so gentle that they can be handled without smoke, and even without a veil on the face, just as I do myself (see Mr. S. Simmins' statements on page 37 of his work entitled, A New Era in Modern Bee-keeping). This is principally owing to the fact that I have weeded out from my Apiary all such Queens which appeared to be weak or producing troublesome workers. Address—

M. G. DERVISHIAN, Larnaca, CYPRUS. A 2375 For Reference, address Imperial Ottoman Bank, Larnace.

NOTICE TO DEALERS.—In thanking my numerous Patrons, I beg to say my SECTIONS are on the way, and will arrive in London shortly. The following sizes in stock:— $1\frac{1}{4} \times 4\frac{1}{4} \times 2$, $4\frac{1}{4} \times 4\frac{1}{4} \times 1\frac{1}{2}$, $4 \times 4\frac{1}{2} \times 2$, $4 \times 4\frac{1}{4} \times 1\frac{1}{2}$, either open top or at all four sides. $5\frac{1}{4} \times 6\frac{1}{4} \times 2$ and $6\frac{1}{4} \times 5\frac{1}{4} \times 2$, open top. $1\frac{1}{2}$ Sections same price as $2^{\prime\prime}$. Order at once, or you may be disappointed, having received a large number of orders. Address A. F. Hutchings, West Kent Steam Power Hive Works, St. Mary Cray.

THE AGE OF WORKER-BEES.

While there are many points in the physiology of the honey bee waiting to be determined by the painstaking efforts of the curious searchers after knowledge, one of the questions which for many ages puzzled the minds and baffled the researches of philosophers and students has for many years received a satisfactory solution. We refer to the once-vexed question of the longevity of workerbees.

In a very early number of the British Bee Journal (Vol. I., p. 46), in reply to a question respecting the age of the worker-bee, the Editor was able, with a full degree of authoritativeness, to give the following reply:—

'The introduction of a Lignrian queen to a full stock of black bees proves that the life of bees in summer is very short. As it may be presumed that the black queen continued to deposit eggs up to the time of her removal from the hive, it must be evident that black bees will continue to hatch out until the expiration of the next twenty-one days at least. From that period, and not until then, will it be possible for any young Ligurians to emerge, but after that date the blacks will die, and the Ligurians increase so rapidly that in a few weeks the hive will be almost entirely populated with the latter. We think we may safely say, if the exchange of queens is effected during the height of the breeding season, that three months after the birth of the first Ligurian bee not a single black worker will be found in the hive.'

But we believe it would be interesting,—at all events to beginners in bee-keeping,—to trace back and recapitulate the origin and circumstances by which our present knowledge on this question has been attained, and to note the continuous steps which have led from the darkness of ignorance to the light of truth and the assurance of fact.

The views enunciated by ancients and moderns to very recent times on this subject were not determined by ocular demonstration, but were vague gnesses and foundationless conjectures. This arose in a great measure from the nature of the hives in which the bees were domiciled, preventing their owners from investigating their interiors.

Ancient writers who have touched upon the longevity of bees have constantly and persistently

confused the duration of the existence of communities and that of individual bees.

We are indebted to the philosopher Aristotle, who flourished about 384 B.C., for the knowledge that prevailed in his days of the natural history of animals. In his works, in all probability were incorporated the floating ideas that writers previous to him had accumulated. A portion of his Natural History of Animals was devoted to bees; and in touching upon the age to which bees attained, he extends it from six to ten years. Virgil says that bees reach the seventh summer,—

'Neque enim plus septima ducitur æstas.'

Columella speaks of the duration of their life as being ten years; but the construction of his language inclines us to think that he refers rather to the existence of the community (examen) than to that of individual bees.

The long period assigned by the ancients to the existence of stocks is not far from correct if the hive be not changed or the combs renewed, as the accumulation of the cocoons or silken pellicles with which the cells are successively lined, and the excrement of the larvæ left behind each lining, gradually render them unfit for their use as brood-cells. Dr. Hunter found three of these linings deposited in a single season, and counted upwards of twenty in the cells of an old comb, which, taking the average of three generations yearly would make the age of the community about correspond with that stated by some ancient writers.

There are many instances on record of the lengthened existence of a stock in the same domicile. Mr. Espinasse tells us that he once took a hive which had stood fourteen years, having found it very weak, and yet during the previous summer it had thrown off a swarm. Della Rocca says that he has known hives in Syria continue in a flourishing state from forty to fifty years. Butler mentions that some bees had their location under the leads over the study of Ludovicus Vives in Oxford, and remained there from the year 1520 to 1630; in the latter year it had been found necessary to renew the leads, when the bees being disturbed, 'an incredible mass of honey was taken.' Monffet supposes that bees may live thirty years, and says he knew a stock that continued in the ceiling of the Duchess of Somerset's house more than three decades of years, and questions whether they died of age at all.

Dr. Butler, in his Feminine Monarchie, with a nearer approximation to the real fact, says, 'The truth is, a bee is but a year's bird, with some advantage.' Thorley, in his Melissologia, says, 'Observe with some strictness a hive of bees in July and you may perceive many of them of a dark colour with wings rent and torn, and in September not one of them to be seen; and in my opinion a bee lives no longer than two summers; yet that is a long life if compared with wasps, the drones, silkworms.'

The erroneous supposition which had for so many ages prevailed respecting the bee being a long-lived animal has in these present days been disproved; and this 'curious areanum in natural history,' as Dr. Evans styles it, has been 'unlocked.'

The change in the form of hives, the advent of Ligurian bees into this country, and the introduction of queens of this race, have for ever settled the duration of the life of the worker bee. Every beekeeper is now-a-days able to substantiate for himself the truth of the statement we have given from the Bee Journal. The short life of the worker-beeduring the summer months is due to the hard work it has to perform, and during the honey glut 'the three months' is even reduced from six to eight weeks; but if bees are hatched in the autumn they will live during the winter and commence the work of the hive in the spring,—so extending their life from eight to nine months.

If any of our readers are disposed to study this question further we would desire to direct them to an exhaustive and painstaking paper in the sixth volume of the *Transactions of the Entomological Society*, p. 226, written by one who nobly served the cause of apiculture in his time and generation,—the late Mr. J. G. Desborough, of Stamford.

USEFUL HINTS.

Weather.—Weather still cold and ungenial. Wednesday, March 20th, and Sunday, April 3rd, were the only days, since writing our last Hints, on which the bees were able thoroughly to enjoy themselves. Those were days of brilliant sunshine and high temperature, and colonies displayed themselves in full strength, carrying home large quantities of pollen from various sources, but chiefly from the willow. Storms, wind, snow, hail, and rain, have been frequent, and although fruit trees give promise of profuse bloom, at present we have none open except on peaches and nectarines, and our spring is a late one.

Food AND BACILLUS.—Now we are feeding on syrup, salicylised or phenolised, for we thear that *Bacillus alvei* has appeared in our neighbourhood, and that *Bacillus depilis* is very prevalent. Does not the latter lead up to the former, or rather is not this 'bee-dropsy,' as it used

to be called, incipient foul brood?

Probably the skilled in this matter will tell us that the bacilli are not the same. Wherever the one has prevailed, in our experience, the other has not been far distant. We strongly advise all, as a precautionary measure, to use one or other of the above-mentioned remedies. If careful to use the exact quantities prescribed (see Cowan's Guide-Book, pp. 151-3), our bees consume the food as eagerly as they do plain syrup, and there can be no question of either acting as an antidote.

Breeding and Stimulation.—A sufficient supply of food is now a matter of the utmost importance, the consumption in all flourishing colonies being greater

than ever. Often during this month have we known large colonies brought to the verge of starvation, and not unfrequently to perish, from lack of food, while the owner has flattered himself that 'a week ago they had enough for a month's consumption.' Surely it is better rather to overdo than to underdo in an unpropitious season like the present. Bees, like young plants, and all young animals, should 'be kept going on.' Any check to growth, or semi-starvation, is certain to result in loss to the owner.

It is well to keep the nest, at present, between division-boards, giving a frame of comb, containing a little sealed honey, at the sides, as more room is required, and to keep all colonies as warm as possible, in regard to quilts and covering, feeding at the top from a good

heat-conserving feeder.

From colonies wintered on more combs than required—their outside frames being clogged with granulated, or partly granulated, honey—it will be of great advantage to withdraw such outside combs, to pass them through the extractor, and to return them to the hives for the bees to clear out. We have found no kind of spring stimulation equal to this; and the method is perfectly safe, since it affords neither encouragement to robbing nor inducement to the bees to fly abroad in unseasonable weather. The honey thus obtained is of second-rate quality, but when rendered fluid by heat is useful in a variety of ways for home consumption.

Stimulation, in other cases, should be carried on as before, by breaking the capping of cells near the

nest.

SWARMS—NATURAL AND ARTIFICIAL.—Probably the advocates of artificial swarming ontnumber those who prefer the natural system. The objections to the latter are said to be uncertainty, inconvenience, waste of time, nudesirable increase, loss of swarms, multiplication of small and useless second swarms, settling in inconvenient places, refusal to swarm at all, and remaining idle at home, &c. Bearing all this in mind, we have never seen artificial swarms work with half the energy of natural ones, and the queens reared under the natural impulse are almost invariably the longest-lived and the most prolific. The management of an apiary must, of course, be conducted according to the intentions of its owner, whether, for instance, it is worked for the production of comb or extracted honey, for increase with a view to the sale of bees or for queen-raising, or even for a combination of all these points.

But whenever it can be arranged to indulge, without actual loss, the natural instinct or propensity to swarm, we strongly advocate doing so. Much depends on weather. In some seasons there is very little disposition to swarm. In others, it is next to impossible to prevent the issuing of swarms from half-finished supers, notwithstanding that plenty of room has been given in all directions. In 'U. H.' of April 15th last (B.B.J. vol. xiv. p. 162), we gave, under the head of 'Preventing After-swarms,' a modified plan of the Heddon system, which we have practised successfully, and which gratifies the natural instinct for swarming, either with or without increase, and while working for comb or extracted

honey.

With slight alteration, or adaptation to circumstances, we think the plan would prove successful in all cases. For example: when a swarm has been installed in the position of its parent, with the rack of sections over it, brood-combs, minus queen-cells, at an interval of a day or two may be transferred from the latter to the former, more room being afforded, and an additional rack added, so that a constant addition of young bees is made to the swarm at the expense of the parent colony, which, no increase being desired, is not allowed to rear a queen, or to do so in nucleus only. Under the swarm-preventing plan, when a swarm is put back, and the queen-cells are cut out, the bees work with little or no energy, and

more often than not, sulk, and refuse to work at all; and swarming is prevented at the loss of honey. When 'putting back' is practised, it is always best to give room below the nest, by nadiring with a small sectional hive, about 6 in. deep, containing frames of 4 in. depth, placed at $1\frac{1}{4}$ in from centre to centre, and having full sheets of worker-celled foundation; and drone larve should be destroyed when excising queen-cells. At the same time more super room may be given if honey is coming in fast.

Mr. Demaree states that, if he wishes to prevent further increase, he places his swarms on half the usual number of Langstroth frames (equal to about seven English standard frames), using only 'starters' in them, and fills up the space at the sides of the frames with division-boards standing a half inch apart. Over all he places queen-excluder zinc, and upon it sets the first tier

of surplus cases.

By this management the whole ferce of the new swarm is spent in producing surplus, and comes out as a mere nucleus, being disposed of, as such, at the close of the season, either by uniting or allowing it to perish. The parent colony is allowed to raise its queen, and is retained in stock. If increase is desired he hives the swarms on full sets of frames (equal to twelve English standards) filled with worker foundation, and gives the colonies abundance of room as fast as they require it,

practising the tiering system to supply their needs.

If the queens are old there will be danger of swarms issuing, but, as a rule, no swarms will issue from new colonies if the queens are satisfactory to the workers. This influence, or queen condition, gives the key to the situation. In practising this plan the swarm should occupy the position of the parent colony, the latter being removed to a new stand. If the queen which leads off the swarm is more than two years old, the introduction of a fertile young queen would go far to prevent all probability of swarming.

To practise either of these systems to the greatest advantage, fertilised young queens should be introduced to the parent colonies immediately after swarming, and shortly afterwards surplus eases given. By these plans, whether increase is desired or not, the natural instinct of the bees is gratified and the swarming energy is utilised, a far more satisfactory practice, to our ideas, than the usual artificial system of 'making two out of three,' &e.,

recommended in our English apiaries.

Lose no time in completing all possible preparations for the coming season.

ECHINOPS SPILÆROCEPHALUS.

This plant which is just now all the rage amongst American bee-keepers, and has been by them called the Chapman honey plant, owing to it having been introduced by Mr. Chapman for this purpose, is a native of southern Europe and Western Asia. The name is derived from echinos, hedgehog, and ops, appearance, referring to the globular and spiny character of the flower. The English name is Great Globe-thistle. It belongs to the order *Compositæ*, composite flowers. The plant is bushy, with stems from four to six feet, and alternate leaves, green and slightly hairy above, whitish and downy beneath. They are large, pinnatifid (i.e. divided half-way to the midrib in segments in a feathery manner), sinuate (with a enrved margin), with unequal segments, and slightly spinose (hard-pointed lobes). The stems are erect, branched, and streaked with longitudinal lines. The flowers are globular, of a very pale blue, and the plant continues in bloom from July to September. The lowest florets expand first, and the others continue to do so in succession, so that each flower is a considerable time before it is fully blown. It is commonly grown as an ornamental garden plant, and at a distance resembles a gigantic and handsome thistle. It grows without care, and almost any waste place will do, although it thrives better in a light calcareous soil. It is visited by the honey-bee as well as by humble bees

We and wasps. have grown it as an ornamental plant for some years, and it is easily cultivated in shrubberies, and, where hoeing is frequent, as in well-ordered gardens, can be easily kept within bounds. Whatever it may be as a honey plant in other pla-ees, we cannot call it a first-class one in our district, and so far, we have only placed it in the second rank amongst bee flowers. do not recommend its extensive cultivation, for it is useless as a fodder plant, and we doubt if it will answer to grow for honey alone. The seed can be sown from April to June in a bed, and then pricked out in October, from two feet to two feet six inehes apart. When

the plants are fully established they can be propagated by division of the roots in the spring. It is a perennial

and is sometimes called Echinanthus.

Another perennial plant, much handsomer, belonging to the same family, is *Echinops ritro* (Small Globethistle), which grows only from two to three feet high, and has smaller heads of flowers of a deep azure blue, with a metallic lustre.

ASSOCIATIONS.

BRITISH BEE-KEEPERS' ASSOCIATION.

The next quarterly conversazione will be held at 105 Jermyn Street, on Wednesday next, the 20th inst., at six p.m. Members desirous of introducing subjects for discussion, or submitting new and useful appliances for consideration, should lose no time in communicating with the Secretary. Arrangements have now been made by the Committee to give awards of merit to useful inventions which may be submitted from time to time for consideration.

The annual first-class examination will be held on Wednesday the 20th inst. Due notice of time and place of meeting will be given to each candidate.

The usual quarterly meeting of County Representatives will be held at 105 Jermyn Street, at five p.m. on the same day, when the subject of the rules for the management of County Shows, in accordance with the resolution passed at the annual general meeting of the members, will be considered.

IRISH BEE-KEEPERS' ASSOCIATION.

A meeting of the committee was held on the 5th inst. Present: Dr. J. P. Allen, in the chair; Rev. P. Kavanagh, Messrs. Milner, Edmondson, and Reid, Dr.

Kuight, and the hon. secretary (Mr. Chenevix). The hon, secretary reported that the guarantee fund reached at present the amount of 14t. A further amount of 10s. was contributed by a member of the committee. The schedule of prizes for the Association's forthcoming show was settled, but the place and date of the show were referred to a sub-committee. Another sub-committee was appointed to prepare plans for model hives, and draw up a scheme for enabling members to obtain them on specially advantageous terms.

Correspondence.

The Editor does not hold himself responsible for the opinions expressed by his correspondents. No attention will be taken of anonymous communications, and correspondents are requested to write on one side of the paper only, and give their real names and addresses, not necessarily for publication, but as a guarantee of good faith. Illustrations should be drawn on separate pieces of paper.

Communications relating to the literary department, reports of Associations, Shows, Meetings, Echoes, Queries, Books for Review, &c., must be addressed only to 'The Editor of the 'British Bee Journal,' 'c/o Messrs. Strangeways and Sons, Tower Street, Upper St. Martin's Lane, London, W.C.' All business communications relating to Advertisements, &c., must be addressed to Mr. J. Huckle, King's Langley, Herts (see 2nd page of Advertisements).

*** In order to facilitate reference, Correspondents, when speaking of any letter or query previously inserted, will oblige by mentioning the number of the letter, as well as the page on which it appears.

THE NEW RACES AND THE BEST MEANS OF INTER-BREEDING AND SECURING FERTILISATION.

CARNIOLANS.

[902.] As a pure race these are the nearest possible approach to an 'all-purposes' bee. They can certainly be improved by crossing, but in their purity a remarkable race is presented, possessing nearly all the good qualities of every other race combined, with almost none of their defects. They have been considered by some to be the common black bees, but only a very careless observer would call them one and the same. The white pubescent bands on the abdomen of the Carniolan are broad and very clearly defined, while near the junction with the thorax there is a faint copper colour on the upper part of the first segment.

Some of the queens are very similar to those of the black races, but they are more generally tinged on the abdomen with yellow, while others are quite yellow. All, however, produce workers of the typical kind. The queens are exceedingly prolific, giving this race great advantage over the blacks, though in some respects they have points of value in common with that kind. For instance, they produce very white comb honey, and

use but little propelis.

Carniolans winter perfectly, with little or no care on the part of the bee-keeper, being very restful during the longest spells of cold weather. They have, therefore, great vitality, and I will tell also why they keep up their numbers at all times, and what makes them appear even more prolific than they really are: it is their longevity. My own experience has shown that in both summer and winter these bees live longer than any others. This quality alone is a grand recommendation, and to see stocks come out in spring stronger than they were when settled down for winter is with them the rule, and but seldom the exception. That they are little inclined to sting is another of their good qualities, and one which probably more than anything will bring them

into favour, more especially with beginners.

It has been said that their one fault is excessive swarming, but this has not been my own experience, and I do not see why, under proper management, any trouble should be found in that direction, especially if young

queens are kept.

Hints have been thrown out to the effect that they gather no more, if as much, as blacks or Ligurians, but, as a matter of fact, I have known them in nearly every instance do far better than either of the above side by side in the same apiary.

Statements have been made to the effect that the new races are being praised to the exclusion of the natives. In the foregoing papers I have given an impartial opinion, showing the good qualities possessed by each variety which are certainly worth perpetuating. My experience has not been with two or three queens, or colonies of each, but with many stocks, which have been subjected to careful observation. One correspondent thought we had heard the last of these bees long ago, but I would remind him that Cyprians, Syrians, and especially Carniolans, are all gaining ground; they have come to stay, but it would be unreasonable to expect to hear the last of them before the beginning was told.

As to our English bees being neglected, I have always been a strong advocate of their best qualities, and I may presently have some things to tell of them that the same correspondent had not even dreamed about nor imagined. We do not certainly call a brown horse black, but why does he call a black bee brown? I consider my own eyesight to be as good as any, but I have yet to see the brown bee spoken of by himself as the

British bee.—S. SIMMINS.

MR. LEE'S FRAMES AND SECTIONS.

[903.] I am sorry that my frames and sections, as illustrated in the British Bee Journal, p. 125, do not come up to Mr. Howard's anticipations as expressed on

p. 150.

Mr. Howard—who has wares of his own to advertise -at the same time would naturally feel a little jealous of the praise my inventions have received from practical men of such standing as Mr. Raynor, Mr. Cowan, Mr. Broughtou-Carr, Mr. Cheshire, and Mr. Raitt, whose opinions are not influenced by having axes of their own to grind; and I do not think your readers will be ready to take his interested opinion, in preference to that of the above well-known gentlemen—who have given a very favourable criticism in the B. B. J., The Record, and in Bees and Bee-keeping—after having seen them and put them together, which Mr. H. has not.

Mr. Howard asks, 'Is it wise to exclude drone-rearing in drone-cells?' If Mr. Howard wishes to encourage

drone-breeding in the hive, full sheets of drone foundation can be fixed in my frames as easily as full sheets of worker. Neither is it original, but ancient history, for the bee-master to cut out in suitable positions, either foundation or perfectly built comb whenever desirable for

the encouragement of drone-breeding.

In my simplicity I have always been under the impression that one of the things most desired by the beemaster was to have all his frames completely filled with comb, and securely fixed on all sides. The strong point mentioned in favour of inversion was, that the combs were thereby built to completely fill the frames, so that they were, among other advantages, not liable to be damaged when the honey was extracted.

I claim that by using my frames and fixing full sheets of foundation in the frames as they are put together, there is no need for 'a slight addition of molten wax' to hold the foundation secure. Taking the frames in the flat, three of my frames can be completed—comb-foundation and all—ready for putting into the hive in the same time as one ordinary frame where it is 'molten wax'

holds foundation.

At the present price of honey, and a possible chance of its being lower (let us hope not), we shall have to simplify and cheapen all our appliances, and economise labour in every way that we are able. And I hardly think using frames 'the first season without a bottom rail, and after the bottom edge of worked-down comb has been cut away to receive the same, put the rail in place,' as mentioned by Mr. Howard, as necessary, 'to have a comb-filled frame,' will conduce to that economy of time,

and commend itself to bee-keepers generally.

With regard to what is said about my sections being six-piece sections, and not being in advance of the fourpiece, or the V-cut one-piece sections; I hope you will not think I am taking up too much of your valuable space, but I feel called on to make a few remarks. In the first place, the four-piece sections were difficult to keep square, and frequently when filled and were being taken out of the crate they would come apart and spoil the honey-comb. The one-piece sections frequently break in putting together, and the time required for fixing foundation, are both drawbacks to them.

Although my sections have six pieces, I can prove by ocular demonstration that they can be put together, and foundation securely fixed, without the aid of molten wax, either as starters—within a inch of, and with a narrow strip at bottom (after Mr. Corneil's excellent method)—or with full sheets securely fixed on two sides, in less than half the time the one on the four-piece sections. They are much stronger when put together, and are not liable to break as is the case with the others. When placed side by side a bee space is left between the sections from end to end of crate, so that the clustering is most thorough and complete.

I am quite content that my frames, sections, &c., should be judged on their own merits by impartial judges, and do not feel disposed to run down the manubringing mine before the public. Time proves most things.—James Lee, 43 Glycena Road, Lavender Hill, London, S. II.

R. R. GODFREY'S HINTS TO JUDGES.

[904.] Following my last on points to be considered in the judging of honey, &c., I pen a few plain and simple hints for consideration by judges new at work, and which may not perhaps be passed altogether unheeded over by those more experienced. I hope I may not be thought intrusive or irksome to your readers and that some profit may result from my remarks. You will have my best thanks for placing them before my brother judges through the medium of your Journal.—R. R. G.

Gentlemen accepting an engagement to act as judges at any of our exhibitions should at the earliest opportunity procure a copy of schedule of prizes, conditions, and regulations, and make themselves thoroughly conversant with them. If in doubt of the meaning of any particular clause communicate with the secretary on the day and hour fixed for the exhibition, repair to the scene of action and report themselves. Should it be that all is not ready to commence judging (and it does more generally so happen) take a stroll and view the surroundings. Don't stand by to witness unpacking and staging. Avoid giving the slightest cause for suspicion of having a knowledge of ownership of a single exhibit. Should, however, all be in readiness, procure judge's book, and ascertain from the secretary if all exhibits in competition which are staged are in conformity with the rules and regulations of the Association. If any irregularities be pointed out (as is not unfrequently the case at our exhibitions) and are left open, ask the committee to consider them, and if desired to do so assist them in arriving at a right decision. Get well acquainted with the order and position of the various exhibits. This may be better and more speedily done with the assistance of the secretary or staging committee. All being so far understood, and the building cleared of all persons except the officials engaged, commence the duties and get done as quickly as after due examination of the respective exhibits will admit of. After the award-cards are placed walk round and compare notes, the duties being

thus completed. If time admits use the opportunity to assist the committee in entertaining visitors, interview any critic or be interviewed, and subdue if possible discontent whenever noticeable, - R. R. Godfrey, Grantham, April 6.

FOUNDATION.

[905.] My letter (871) in this Journal, wherein I gave a test for detecting impure foundation, was written simply for the benefit of bee-keepers, and not for the purpose of instruction in making a chemical analysis of wax. I maintain that by using heat as the test we arrive at a sounder knowledge as to whether our foundation will stand the temperature of the hive; such a test is without doubt the best for that purpose. I really, myself, do not mind if another substance other than wax is used, providing it will answer the bees' purpose for comb-building, and stand the heat so as not to break down or stretch; but this substance has yet to be discovered.

I will now give further tests as to wax. First, by the sense of touch. 'Pure wax should not be unctuous to the touch; 'this is readily detected after feeling paraffin wax and is a very good off-hand test, although not to be depended upon without considerable experience. 'Pure wax should not yield more than 3 per cent to cold rectified spirit, and nothing to water or to a boiling solution of soda; the two latter fluids after filtration neither being turbid nor yielding a precipitate on the addition of hydrochloric acid. Boiling water, in which it is agitated, is not, when cooled, rendered blue by iodine. Specific gravity 0.950 to 0.970.' Now a lot of the above is just Greek to many bee-keepers, and all, except touch, cost money to perform, while the heat test costs nothing. I presume this is a fair translation of 'less inexpensive.' As even if you purchase your thermometer—a brewer will readily lend you such an one-you have your eighteenpence worth still in hand, as well as your glass-tube for further experiments. I am extremely sorry that I have raised the ire of Mr. J. H. Howard in giving the information contained in this letter (871), my regret being more profound, as this is the first 'growl' that I have experienced after the many communications that I have contributed to these columns: but nemo mortalium omnibus horis sapit, perhaps I did wrong in giving it.— W. B. WEBSTER,

BIRDS EATING BEES.

[906.] As this is just the season at which I find birds most apt to eat bees, and as I dare say the usual controversy as to whether they kill working bees or not will soon set in, I write to give my experience this year, as yet, which exactly coincides with that of the last two years, for which time I have closely watched the move-

ments of birds about my hives.

The only birds I have ever detected killing my bees are three kinds of tits, the coal-tit, blue-tit, and great-tit (there are long-tailed tits about, but I never saw them eating a bee, dead or alive), and chaffinches. The tits begin earliest. In January last, when we had a couple of fine days, in which the bees took cleansing flights and cleared out the accumulated dead bees from the hives, I saw four coal, two blue, and one great-tit eating the dead bees as fast as they were brought out. I watched them very closely, and for the first day or two I could not see them make any attempt to catch a live bee; but after a little while, when the dead bees were all gone, I saw two of the coal-tits and one blue catching bees, and immediately shot them. None of the others which had been so much about the hives while the dead bees were plentiful seemed to touch the live ones, though I have little doubt they would have joined the others if they had been let continue at their work. I do not think any birds touched my bees since till last Wednesday, March

30th (perhaps they may have done so on Tuesday, but I did not see them). On that morning, before ten o'clock, I saw a blue-tit killing bees at the hives. My son immediately shot him. The hives are in a small garden, with a range of two-storey offices at the west, a wall ten feet high at north and east, and a low wall at the south. Most of the hives are in a row, about fifteen feet from the north wall, and the rest a little in front of them, and when the bees are flying well from fifteen hives they go in a continuous stream over the top of the east wall, as there is a quantity of hazel in full flower in that direction. The blue-tit had hardly been shot when a pair of chaffinches took their post on the top of the wall, and commenced flying up at, catching, and eating the passing bees as fast as ever they could. They were immediately shot, and before half-past eleven o'clock six others shared the same fate; but though the place all about is literally alive with chaffinehes, no others have since molested the bees. I find this to be the case every year; a few individuals take to killing the bees in exactly the same place just at this season in bright, dry weather, when the bees are flying in numbers and while the other insects are rather scarce, but the general run of the chaffinches do not touch them, and when once there are plenty of small insects flying they let the bees alone entirely; but if the first that attack the bees are not at once shot they cause a much larger number to follow their example, and the execution which a single chaffinch in a favourable situation can do is wonderful. Once while my son was running into the house, about twenty-five yards off, for more ammunition, I saw a cock chaffineh kill and eat nine bees. Chaffinches never come down to the hives like the tits.

I have just given my actual experience, such as it is, and for what it is worth. This place literally swarms with all kinds of birds, and chaffinches are, if anything, the most numerous. I really do not think that the number that kill bees is much, if anything, more than one per cent of the entire number about. As I have said, I immediately execute any individual convicted on satisfactory evidence of killing bees, but I never do so on suspicion. I think that if other bee-keepers would closely watch the dealings of birds with their bees, they would come to the same conclusion that I have, that it is absolutely necessary in the interests of their bees to kill immediately any individual birds that take to killing bees, but that to try to exterminate the birds about their hives because some individuals of the same species kill bees is useless cruelty.

I may add that I have never seen any bird kill bees in summer when drones are flying, but I dare say that if the birds which kill bees at this season were left alive they would do so, and, most likely, prefer drones; and I am strongly inclined to suspect that those birds that kill drones in summer, when insects are plentiful, have killed workers in spring, when insects are scarce. I do not believe that a swallow ever killed a bee. There are no flycatchers here.—G. J. H., April 4th.

THE NEW JAMES-LEE FRAME.

[907.] In answer to a correspondent, James Lee states,—that the sample frames he has made on his new plan are of both pine and line. As regards strength, the following extract from Mr. Cheshire's *Bees and Beekeeping*, vol. ii., p. 194, will fully answer:—

Two practically essential questions at once suggest themselves: Is the foundation firmly held? and is the frame thus pushed together sufficiently solid for work? The result of experiment is far more to the purpose than a statement of opinion. Two sheets were tested. The first remained unmoved until the strain reached I9 lbs.; it then broke, part being left in the eleft: the second, at 15 lb. parted at the side, some portion being withdrawn, and some left in the eleft. The weight was distributed by

clamping the sheet. The rigidity of the frame is remarkable, and its accurate make prevents any trace of winding. The dovetail, also, has great holding power. The lighter, invertible standing frames were more easily tested than the standards, and here the dovetails bore an average strain of 52 lb. before the side bar was broken from its place.

The lighter frame referred to is made of pine, on the same principle as the Standard. The latter is equally as strong, where the strength is most required, i.e. the top bar, and the bottom dovetail will be found more than equal to what it has to do. These frames will be brought before the quarterly meeting of the B.B.K.A. on the 20th inst.—J. L.

SLOTTED DIVIDERS. [893.]

[908.] On page 150 of the B. B. J. Mr. Sambels says, I have given my 'version of slotted dividers, claiming them as an 'American invention;' and goes on to say, 'I will endeavour to give the facts about them,' as if what I had written were not the facts. I quoted from 'Gleanings' ipsissima verba, and gave the woodcut also to show priority of invention. Although Mr. Sambels had not up to that time been so fortunate as to see it in 'Gleanings,' or to see the crate I exhibited at South Kensington on October 6th, the facts remain the same; it is no new version of mine. I do not for a moment wish to contend that the idea of 'slotted dividers' is not original with Mr. Sambels, or that he ever saw or heard of them before: but he is not prior in such invention, this is all I have said.

With regard to the crate itself, the one I exhibited is precisely similar to it, and has equally all the faults pointed out by me on page 128; the only difference being in the way the bee-space is obtained. I used one of Heddon's excluder honey-boards; Mr. Sambels had an arrangement of loose rebated frames, like that used by Messrs. Abbott in their invertible crate exhibited at the Colinderies (for which they obtained a medal), with the omission of the metal ribs in the centre that sup-ported the sections. The systems of screws and pressure board are just the same as that exhibited by Mr. Dines at Norwich, illustrated in November number of the B. B. J., page 508. The side passages and the arrangement for supporting the dividers are like those in Mr. Corneil's crate, with the addition of the slots which, in my case, were copied from Mr. Greer. Mr. Sambels is surprised I did not say anything about my crate when he exhibited his. The fact is that I did not think the idea was worth anything to bee-keepers;' and having adjusted the sections in it a few times, I made up my mind, as I since told Mr. Henderson, that although I had it I should never use it, there being so many crates that were more easily manipulated and better in every

Mr. Sambels says, 'as it happens it does one no injury as I have no pecuniary interest.' I can assure him I should be sorry to say or do anything knowingly that would injure him or any man. I should also be sorry to see others give up useful appliances which they have, for new ideas which will only give disappointment; and I think it is the duty of those having some experience to give a word of caution. Satis verborum.—John M. Hooker.

NOTES BY WOODLEIGH, [891 & 893.]

[909.] I am very pleased to see our veteran friend, R. R. Godfrey, to the front re the Judging Question, and as the time is drawing near when we shall have to submit our exhibits to the judgment of those who ought to be experts in the art, as a bee-keeper and also an exhibitor of some years standing I thank Mr. Godfrey for his synopsis on judging honey and appliances, and consider it a long stride toward the goal.

I should think the ideal bottle or jar of honey should

contain, say, the six good points, and each point should be represented by an *equal* number of marks, say, twenty-five each, and then the judges could credit the number according to merit on each point of the exhibits submitted to them up to the maximum number, twentyfive on each points, or 150 on the whole, six points to a

perfect sample of honey.

There is one more point in judging which Mr. G. does not notice, but which, in my opinion, goes to the root of the matter, and has been the cause of much heartburning among exhibitors in the past, and that point is, that judges should make themselves acquainted with the rules and regulations of the show on which they are going to adjudicate. I consider judges should endeavour to meet the wishes of donors of prizes for a specific exhibit, and also be bound by the rules and regulations as much as exhibitors are; and, again, when schedules state expressly and unequivocally for what a prize is offered, I myself think the terms of the schedule should be respected and acted on by the judges.

[893.] Mr. Hooker and Mr. Sambels may both be

[893.] Mr. Hooker and Mr. Sambels may both be right as to slotted dividers. Mr. Hooker speaks of them as an 'American invention,' and Mr. Sambels gets the assertion mixed up with Mr. Corneil, the Canadian. There may be many inventions known to Americans and unknown to Canadians; in fact, we here, though divided by a wide tract of water, have equal, if not greater, facilities for knowing American ideas as our Canadian brethren, though the division between their two countries may be of a more skeleton form than a slotted divider.—WOODLEIGH.

CANADIAN EXPERIENCES.

[910.] On page 94, current year B. B. J., 'Amateur Expert' is mistaken in supposing that I am a new convert to the tiering-up or storifying system for securing largo crops of best honey. I have practised it and advocated it for some ten years or more. But the idea of placing a portion of the surplus combs under the brood-chamber is new to me, and I am free to admit that I am indebted to Mr. T. W. Cowan's Guide-book Pamphlet, No. 1. for that idea.

It may be of interest to some of your readers to know that I have ever since commencing bee-keeping used a frame $13\frac{7}{8}$ inches deep and $14\frac{3}{4}$ inches wide, and I wish to say that in my experience a frame of that or similar dimensions has but one redeeming quality, viz., no pollen will ever find its way into the sections. But I think its disadvantages are many:—1. In order to prevent the combs from breaking down some supports must be given them. 2. They are difficult to lift out without hurting bees, and that makes them sting. 3. The large square shape makes them awkward to uncap for the extractor. 4. From the fact that the queen does not seem to care to occupy the lower corners of so deep a frame, more dronecomb will be built than in shallow frames, for workercomb is built in nearly every case only when the bees are followed closely by the queen. 5. I think the bees go up more readily and work more earnestly and fill both sections and extracting combs fuller over shallow frames than over such deep ones. 6. And last, but not least, a hive built to accommodate a frame from 12 to 14 inches deep presents too small a top for surplus receptacles.

I would just add that in this country opinions differ, but I think the most of us agree that a hive with frames from 9 to 10 inches deep will winter fully as well as that of a deep frame, and build up just as rapidly in spring.—S. T. Pettit, Belmont, Ontario, Canada, March 25.

APIFUGE.

[911.] In your answers to correspondents on page 100 you invite 'independent opinion of its value,' and as Mr. Grimshaw has been attacked in your recent issues by those who have certainly not tried the substance, I think

in common justice to it a few words from one who has will be seasonable.

A few days ago I opened a hive for a thorough manipulation, having previously rubbed a few drops of apifuge on my hands, the result being that during the whole manipulation there was not the least attempt at stinging, in fact, all the sting seemed taken out of them by the agreeable odour it possesses; the mere fact of spreading the naked hands over the frames caused the bees not to boil up and take a vagrant flight, but simply to recede quietly to about one inch below the top-bar, just where they ought to be. I removed the dummy and examined each frame separately, having neither veil, gloves, nor smoke, with the thermometer at 60°, and can only come to this conclusion that to the majority of bee-keepers apifuge cannot be other than a boon.—
Arthur Henderson, Upperhead Row, Leeds, April 2.

SUNDRY EXPERIENCES WITH BEES.

[912.] As I have received many useful hints about bees from your numerous correspondents, and many interesting details as to their habits and rather eccentric behaviour, perhaps a few of my own observations and experiences may be interesting to the readers of the Journal. Having early learned the advantages of giving plenty of room to strong stocks, even before I adopted the bar-frame hive some eight or nine years since, I have seldom been troubled with too many swarms. The year before last, however, several very strong ones would come out, and one of these I lost, and this one made me know how far bees could fly upon occasion. On going home from my work on Saturday, at about two o'clock, I noticed a strange commotion in one of the hives and immediately after a large swarm issued which I watched in expectation that it would settle, but noticing that the centre of the circle was gradually shifting down a field joining my garden, I got at once over the fence and followed at a gentle trot down the field, all the while saying to myself, 'Now, if I had not been at home this swarm would have been lost.' Instead, however, of settling, as I expected they would, in the fence at the bottom of the field, they kept steadily on in their circular dance across three or four more fields and a part of a common, and appeared to be flying direct to a large tree about a mile from where they started, but instead of settling there they turned at right angles from this tree in another direction, taking in their course across a field of wheat.

Thinking I might do some damage to the wheat, I hesitated to follow them. It is said that 'he who hesitates is lost.' Whether this be so or no my bees were lost to me from that moment, for they appeared to be making their way to a coppice stretching on for several miles, and though I searched and made inquiry among the cottagers near, I never found them. The interesting point in this is, how many miles must these bees have flown? As they were flying in circles all the time it must have been considerable. The next morning I was about taking a walk with my son, to see if we could find the vagrants, when another swarm issued from a hive near, and this, we found, had settled very high indeed in an elm-tree, near by my cottage, and at the extreme end of the branch quite out of reach. This, however, we hived very easily by passing the clothes-line over a branch above, and by cutting the branch off on which the bees had clustered they were gradually lowered and shaken over the bars of a hive prepared for them, scarcely a bee being lost or injured. Of course, care had to be exercised that the branch did not suddenly

I mention this as there have been some suggestions as to preventing bees from flying so high, which might not always succeed, even if you were watching at the time.

—C. Shufflebotham, Coventry.

RESUSCITATION,—A WRINKLE.

[913.] It may be of interest to state how I recently rescued a stock from almost certain non-existence.

On hurriedly examining my seven stocks in beginning of February I found that one of two that I had wintered on candy alone had almost finished its cake, and I at once determined to try the Simmins plan of placing sugar over the frames. This I did, but as I subsequently found, put back the quilt rather negligently, thus allowing the heat to escape. A fortnight later, seeing that the bees of this stock did not avail themselves of a fine day to have an outing, I examined again and found the sugar untouched and the bees with only a glimmer of life in them, many indeed dead. I was in a fix. Take them into the house I could not, for the other members of the household are by no means in love with my pets. Suddenly I struck upon an idea and forthwith put it into execution. The sugar was taken off-a small quantity of granulated honey placed near end of frames instead—the quilt placed and (this is the idea) a heated brick laid on the quit. In a few minutes I was satisfied that the scheme was a success. The colony was saved,—Welsh NOVICE.

FOUL-BROOD, &c.

[914.] Foul-brood is not a pleasant subject for beekeepers, but it is a very necessary one sometimes to face, for it causes immense discouragement and loss. I have long recommended my parishioners to take up bee-keeping as a pleasant and profitable occupation for their leisure hours; but foul-brood has wrought such havoc amongst us, that I have had cause to regret that I have ever done so. I should, consequently, be truly glad if some simple and certain method of cure could be found out, and also if the subject could be brought forward

still further in your columns.

Finding the disease reappear in my own apiary last year, I procured a salicylic funigator, but was surprised at its costliness—too much, by far, for a poor cottager. I used it perseveringly, and it certainly seemed to check the disease, as I have not seen as yet any sign of its having spread beyond the two hives, adjacent to each other, in which it first appeared; but whether it has cured it remains to be seen. I opened the diseased cells as far as possible, and the salicylic fumigation appeared to dry them up. I also poured into them syrup medicated with Cheshire's prescription; and kept in each hive a lump of camphor. Examining these two hives on February 21st, to see how they had passed through the winter, I find that, although one appeared to be strong and in a healthy state, the other had dwindled down to a mere handful of bees, without a queen, although I gave it a new queen late last autumn; so I united the two together.

On a former occasion, when troubled with this annoying disease, I destroyed hives, frames, and combs, isolated the bees, and commenced altogether afresh; but I hope that this will not be necessary this time. The hint given by the writer of 'Useful Hints' as to the 'use' of a piece of calico saturated with a solution of carbolic acid, I found extremely 'useful' last year; it not only dispersed the bees quickly from full sections, but it also, several times, acted admirably instead of smoke, and quieted some fierce Ligurians when smoke seemed useless. Many other hints given in the Journal are very valuable, and the kindly feeling shown by your correspondents, and their willingness to help one another, are, I think, very pleasing. I cannot help hoping that, with a little further advance, a few more difficulties removed, and a few more 'Useful Ilints,' bee-keeping may attain a position and success which it has not yet obtained in this country.—RECTOR.

P.S.—I intend to try a Jones-Heddon hive this year; the principle of it seems excellent, but I doubt its adaptation in its present form to our climate.

NOTES ON BEE-HIVFS.

PAINTING THE INTERIORS OF WOODEN HIVES.

[915.] From careful experiments for some time past, especially during the whole of last winter, confirming them by tests during the present one, I come to the conclusion that there is not the slightest necessity nor advantage in either painting, varnishing, or otherwise coating the interior of hives. The use of propolis is not to condense aqueous vapours, as Rev. II. W. Lett supposes or intimates in his recent communication to the British Bee Journal, but to close up chinks, to keep out enemies and robbers, to cover rough surfaces and objectionable ones, to preserve the interior from decay and from the attacks of animal and plant life, and par-

ticularly to keep out currents of air.

Bacillus Gaytoni is all fudge—it is true, however, that such symptoms described under this heading, or Bacillus depilis, appear, but my experience and experiments point undoubtedly that these are brought on and are the results of bad and imperfect ventilation. Bees do not cluster in the manner stated on page 117 so much for the reasons there stated as for the fact that that part of the hive is nearly always best ventilated and free from draughts. A cold draught is as destructive to the health of bees as it is to our own. But when the air is not renewed in a hive of bees, and their exhalations condense into water during cold weather, the bee-hive resembles a damp cellar; the honey, souring in those combs on which the bees cluster, gives them dysentery and other disorders. We need not wonder what killed the bees when we had covered them

During the past year I found a colony of bees in a flourishing condition, the combs of which were suspended from the surface of a beam of timber in the open air, at the Fridd Farm, Tref Eglwys,—they had reared a large quantity of brood, and collected from eight to nine pounds of honey for future use, and all done in a very exposed position. Of course, this does not prove that protection from the British climate is not necessary, and of no advantage; but I have found several similar examples, proving that propolis is not necessary to condense aqueous exhalations and other vapours in order to supply them materials to use their honey when in a candied condition, at any time. A damp atmosphere is not necessary and helpful to bees to rear brood; the air in the hive should be as pure and dry as we require for our own room at all times. A painted or varnished interior tends to lower the vital energies of the bees, and lowers the temperature of the cluster—even when there is a proper entrance to the hive. The best covering for an interior would be a layer of cork. We should go a step further back than the straw skep to study the interior of a hive, i.e. to a hollow tree, or to a hollow wall. The straw hive of old, as long as it is new, is known to be the best of all wintering hives, but it is no better than a wooden box so soon as its inside is covered with propolis, excepting that it is not likely to be displaced internally so much by its meddlesome owner, and that the bees generally have time to arrange their waxworks to properly ventilate or turn the air-currents. The following is a good rule: 'Have a strong colony with plenty of honey, and the air in your hive as pure and dry

as you require it for your own room.'
I consider an oil-cloth a most dangerous winter covering. An excellent cover is a straw mat. In order to keep the straw from being glued over, a piece of linen cloth or calico should be kept next the bees. A box of chaff, or, better still, a box of cork-dust, might be substituted for the straw mat, over any of which should

be placed a flat board under a heavy weight.

Having regard to your space, I am sorry I cannot detail my experiments to show how sensitive bees are to atmospheric influences and temperature. I think we can safely lay it down as an axiom that bees do not use their own condensed exhalations, and that such exhalations are highly injurious to them, if allowed to remain in their hive; furthermore, I am sure these are easily demonstrable facts. Great care should be exercised in uniting several lots of condemned bees at end of each season.—T. Bonner-Chambers, F.L.S., March 24th.

HIVE CONSTRUCTION (P. 149).

[916.] I do not know for how long the honour of the improvement, consisting in avoiding plinths, has been ascribed to either Mr. Howard or Mr. Buchan. But this I know. That for at least ten years 1 have made my own hives without plinths, by placing the floor-boards inside the outer walls and the roofs outside them. My plan is fully described and illustrated in the Journal, vol. xiv., p. 57.—F. L.

Replies to Queries.

[889.] Bee Hives.—(Edward J. Gibbins.)—See Bee Journal for Jan. 21st, 1886, Feb. 4th, 1886 (86), and Root's A B C of Bee Culture. The same question was answered for you by several bee-keepers in March, 1886. Mr. Simmins, of Rottingdean, has a very large bee-house. Perhaps he would give you better information.—W. B. Webster.

[890.] (H. W.)—Although I have never tried mixing formic acid with syrup with the idea of preventing or curing foul brood, I find there is considerable chemical affinity between formic and carbolic acids; the formula of formic acid being CHO HO, that of carbolic C₆H₅HO. The Bari and other tribes of the Soudan consider that milk is rendered more wholesome by washing their milk vessels with the excreta of the cow. A similar course may be beneficial to the bees, formic acid being their excreta; but I should prefer waiting evidence before applying these means.—W. B. Webster.

Echoes from the Hives.

Honey Cott, Weston, Leamington, April 11th.—There have been but a few nice days lately that bees could fly; it has been dull, with a north-east wind that has cut without mercy. To-day (Bank Holiday) the wind is keen from the east, but the sun is warm, and the bees have taken advantage of it, and have brought in pollen in quantity. The first thing in the morning I regaled them with pea-flour, for which they have a great liking. I have examined a good quantity of stocks, and taken spare combs away, but to say that all stocks are strong would be too much to say, though I have some good stocks. Even those that had the most food some time back have used it up very much. The palm is not much out at present, and no blossom scarce as yet, only a few blossoms in a sunny corner, though there is great promise when the plums and appletrees do come out.—Joun Walton.

North Stafford, April 11th.—Yesterday being a nice sunny day, I noticed my bees (blacks) at most hives bringing in a moderate supply of pollen, which, I imagine, must be gathered chiefly from the palm willow, so I thought to-day being fine I would venture an examination of them, and found brood in various stages and quantities from small patches on a single comb to three almost filled combs. All bees appear healthy in both my fourteen bar-frame hives and five skeps, the latter of which are all driven bees. I have lost two stocks, one disappearing suddenly and mysteriously, leaving sealed stores, the other perishing, as I think, for the want of winter passages in two centre combs in a spell of hard weather, all bees being dead with plenty of sealed stores in rear combs.—E. C.

NOTICES TO CORRESPONDENTS & INQUIRERS.

F. Girdlestone.—Inverting Skeps.—The skep, after inversion, is sunk beneath the level of its original stand, the same entrance being used. There have been scarcely any details as yet published. In your district there was

- a very bad honey crop last season. If you had fixed some pieces of comb in the super the bees would have worked. We had a similar case, but within half an hour of placing foundation in the supers they were busily engaged drawing it out, and they filled it in ten days. Why not use bar-frame hives? You have greater control over your bees.
- INQUIRER.—1. Hire-roofs.—If you make each division of the hive to overlap the one underneath, and have the roof perfectly sound and watertight, your hives will keep quite dry. 2. Queens.—Unless the alighting-boards of your hives touch the ground, which must be perfectly free from grass or weeds, you will lose the queen, as even under these conditions she sometimes fails to get back into the hive unless you are there to look after her. 3. Uniting.—Unite to another stock, caging the queen for greater safety. This must be done on a nice warm day. 4. Enamel Cloth.—If your stocks are strong, hives watertight, and plenty of ventilation, the enamel cloth will not be damp. Have you plenty of warm covering over the enamel cloth?
- J.—1. The 'W. B. Carr' metal ends can be used with Lee's new frames. 2. The wire may be obtained from the dealers in bee appliances. 3. Mr. Lee's address is attached to his communication on p. 160.
- J. Orr.—A reply to your question by Mr. Lee will be found on p. 162.
- M. E. M. and J. G.—The samples of sugar forwarded would be found servicable.
- M. O.—The comb forwarded was not affected by foul brood; the special appearance of some of the cells was caused by a coating of mildew on the pollen through damp. We should not destroy the combs. Rub them with a soft brush, and spray with salicylic acid, and return to the bees.
- T. G. Barlow.—W. P. Meadows, Syston, Leicester.
- John.—Abbott Brothers, or W. Baker, Muskham, Newark. W. H. Hughes.—The syrup prepared according to the recipe is quite innocuous; the disaster has probably resulted through the rustiness of the feeder; we should suggest that the feeder be changed at once.
- J. W.—The principal use of metal ends is to keep the correct distances of frames; though for many reasons at times advanced bee-keepers find it desirable to dispense with them. The metal ends mentioned will be found as serviceable as any others in the market. Both metal ends and broad-shouldered frames have their special advantages.
- A. P. J.—The bees do not appear to have died of dysentery. You have taken the wiser course of altering your mode of feeding. Some of our correspondents have experienced the same difficulty with feeding bees in the manner mentioned. The sugar forwarded is not that which we would recommend
- W. M.—Foul Brood.—Use the Cheshire Phenol Solution as given on p. 153 of our Guide Book.
- J. W. H.—1. Bees by the side of a Railway.—It would not be advisable to place them so close as to be shaken by passing trains. The small number of bees on the wing caught by the trains would make no practical difference.

 2. 1½ inch Sections.—You may do without separators, but some care is necessary to prevent some of the combs being built out too far at the expense of the adjoining ones. 3. Foundation.— Seven sheets to 11b. is quite heavy enough. The sample you send is dark, but the wax is pure and it will answer very well for stock hives.

 4. Sections in Frames.—The 4½ × 3½ × 1½ would not fill standard frames exactly. You would find giving the sections in racks in the usual manner better than several frames of six sections each.
- M. E. K.—There is every probability that your queen is in full performance of her maternal duties. Nothing can be done for the 'handful' of queenless bees left in the other hive.
- C. C. M. -1. Providing the queens are young—last season's —you have every chance of obtaining a surplus.
 2. Read The British Bee-Keepers' Guide for transferring. As soon as warm weather sets in.
 3. A frame of brood would be

of much service, if you can spare it from other colonies and there are sufficient bees to take care of it. You should not examine colonies for sealed brood in January, they ought then to be left entirely undisturbed.

J. A. Watson.—The sample of Californian honey is, we should say, some that has been a long time in the country; and a sale not having been effected at the original price it has been reduced to that at which it has been offered to you.

Received two pieces of comb, but with no accompanying letter or address.

Received from Mr. J. H. Howard, Holme, Peterborough, and Mr. W. P. Meadows, Syston, Leicester, their 'Appendix of Modern Bee Appliances.' This catalogue, containing many important novelties and improvements, is well worthy the attention of all bee-keepers.

Received from Thomas G. Newman & Son, Chicago, Ill., their Illustrated Catalogue of Bee-keepers' Supplies for 1887.

Erratum.—P. 141, col. 2, line 4 from top, for inter read winter.

Heddon Hive.—I notice in this week's B. B. Journal that J. H. Howard says on page 151, 'Mr. J. Hall, No. 876, gives an ingenious one-way watertight joint, but how about 'tother way up?' Mr. Howard evidently does not fully grasp my idea. There is no 'tother way up' to trouble about, as the loose zinc frame has not to be inverted at all, but always remains in the position shown in sketch. However, I don't think it is worth while spending much time in trying to improve the Heddon hive, as I expect it will soon be a thing of the past.—J. H.

Show Announcements.

June 23, 24.—Suffolk Agricultural Show at Bury St. dmunds. Entries close June 16. J. Huckle, Secretary. July 11–15.—Royal Agricultural Show at Newcastle-on-Edmunds.

[IMPORTANT NOTICE.—In offering Home-reared Queens, it should be distinctly understood that only purely mated Queens are sent out. Hybrid crosses are so named, and are mated as stated, in connection with respective prices.

THE BRITISH EMPORIUM

QUEENS, NUCLEI, and SWARMS.

No Foul Brood either in my own, or Foreign Apiaries from which my Imported Queens are obtained.

CARNIOLANS.

Imported Queens, 10/6, Home-reared, 7/6 each.

These have nearly all the good qualities of every other race combined, and none of their defects, while they winter better than any, are very gentle, and good workers; also beautiful in appearance, having several broad white bands on the abdomen.

An impression prevails that these bees swarm to excess, but as the demand has been greater than the supply, and there were no queen-raisers in their native land, the probability is that many old queens have been sent over, and hence undue swarming has resulted; but with young queens, which alone I send out as 'home-reared,' this race, judging from my own and several friends' experiences, can be restrained from swarming, however energetic the queen may be.

Having an excellent stock of these bees on hand, during the season I shall be raising queens on a large scale from selected imported mothers of different strains, particularly from two referred to below as 1 and 2; and having many others from which I am breeding thousands of fine drones, I am enabled to offer queens which will produce some of the choicest pure stock yet seen.

CARNIOLAN BREEDING STOCK FOR 1887.

No. 1. Imported Yellow Queen, selected from a large number for fine appearance, turned out exceedingly prolific and produces bees of good colour. Daughters of same are either yellow or ringed, and therefore readily found among workers.

No. 2. Imported, and of another strain; produces some dark queens, but generally 'ringed' or yellow-banded. Workers very good. During season 1886 this queen produced more bees, and the latter more honey, than those of any other stock in the same apiary, consisting of Ligurians, Hybrids, and Syrians; though when imported in Autumn of '85 she was placed with rather a weak lot.

My drones are reared from still another strain, and from stock which in 1886 drew out foundation and stored heavily during the latter part of August (no heather). While therefore 1 offer the purchaser young queens bred from stock of good character, my arrangements provide for an infusion of fresh blood; advantages which are not to be obtained with imported queens of any one strain bred for many years in the same district.

CYPRIANS.

Home-raised Queens, 10/6.

These are the most beautiful bees yet cultivated, and can be handled without smoke. They are exceedingly good honey-gatherers, but are suitable only for extracting purposes, as their cappings are not of good colour.

Cyprian Queens crossed with Carniolan drones, and Carniolan Queens with Cyprian drones, 7/8 each.

The former are very desirable bees and more hardy and energetic than pure Cyprians.

The latter are the best 'all purposes' bees known, and

are sure to give satisfaction. Any other cross with Cyprians can be supplied, but I cannot undertake to supply those not mentioned at short notice.

My Cyprian Queens and drones are reared only from stock which can be handled like flies at any time, whether honey is being brought in or not, so that both the pure bees, and those crossed with Carniolans, will be gentle in dis-

SYRIANS.

These are not recommended, but can supply them bred from gentle stock, and crossed with Cyprians or Carniolans

LIGURIAN, OR ITALIAN ALP BEE.

Imported or Home-reared, 7/6 each.

My Imported Queens are from very choice strains, and have been much admired.

Those raised at home are bred from a queen whose bees last season gathered over 50 lbs. in seven days, and gave the largest increase in the same apiary.

BLACK STRAIN.

HIGHEST RECORD! 200lbs. COMB HONEY!

Bearing in mind that many still prefer the old Black race, I am breeding from a strain, respective stocks of which have

produced (No. 1, '85), the mother colony 150 lbs. comb. (No. 2, 1886), 198 well-finished sections, 60 others partly filled, and the stock combs at end of season one solid block of honey.

(No. 3, 1886), first swarm, 78 lbs. comb.

I offer young Queens of this strain mated with drones from either choice Carniolan or Cyprian stock, as may be desired, at 7/6 each with usual guarantee.

SWARMS BY THE POUND.

NUCLEI. 21/- Bees on 3 combs in Standard frames Three-pounds weight 10/-,, 2 ,, ,, ,, ,, ,, 1 ,, ,, ,, Single pound ... 8/-Half-pound ... 6/6 4/-

The above rates include packing and free delivery up to 10 lbs, weight. Add cost of Queen required in each instance,

TERMS: STRICTLY CASH WITH ORDERS. Address-

S. SIMMINS, ROTTINGDEAN, BRIGHTON,

Finest CYPRIAN Queens.

DIRECT by MAIL from CYPRUS to any Address in EUROPE. From 1st MAY to 30th AUGUST.

For Countries out of Europe add 50 ° to above prices.

All Orders to be aecompanied by a Remittance.

My Queens are all very prolific, long-lived, and much larger-bodied, than the majority of those supplied by others, as they are reared naturally, under the swarming impulse, in April, May, and June, from the strongest of my forty colonies of Bees kept in double-walled moveable frame-hives, and all having choice Queens, which produce workers so gentle that they can be handled without smoke, and even without a veil on the face, just as I do myself (see Mr. S. Simmins' statements on page 37 of his work entitled, A New Era in Modern Bee-keeping). This is principally owing to the fact that I have weeded out from my Apiary all such Queens which appeared to be weak or producing troublesome workers. Address—

M. G. DERVISHIAN, Larnaca, CYPRUS. A 2375 For Reference, address Imperial Ottoman Bank, Larnace.

NOTICE TO DEALERS.—In thanking my numerous Patrons, I beg to say my SECTIONS are on the way, and will arrive in London shortly. The following sizes in stock:— $4\frac{1}{4} \times 4\frac{1}{4} \times 2$, $4\frac{1}{4} \times 4\frac{1}{4} \times 1\frac{1}{2}$, $4 \times 4\frac{1}{2} \times 2$, $4 \times 4\frac{1}{2} \times 1\frac{1}{2}$, either open top or at all four sides. $5\frac{1}{4} \times 6\frac{1}{4} \times 2$ and $6\frac{1}{4} \times 5\frac{1}{4} \times 2$, open top. $1\frac{1}{2}$ Sections same price as 2''. Order at once, or you may be disappointed, having received a large number of orders. Address A. F. Hutchings, West Kent Steam Power Hive Works, St. Mary Cray.

Patent Bee Feeder.—Removing the Flask.

Or for giving warm syrup in cases of dysentery.

The best Journal of its kind, edited and published by the renowned C. F. H. GRAVENHORST, Brunswick.

DEUTSCHE ILLUSTRIERTE BIENENZEITUNG.

Sample copies sent on request.

Also, 'DER PRAKTISCHE IMKER.' Compendium of Rational Bee-culture, by C. F. H. Gravenhorst. Third enlarged and improved edition, with fifty-two new original Pictures, and a frontispiece. Price 4 marks (4s.), stitched; well bound, 5 marks.

C. A. Schwetschke & Son (M. Bruhn), Brunswick.

Eighth Edition. Fifteenth Thousand.

DEE-KEEPERS' GUIDE BOOK. Containing Management of Bees in Modern Moveable Comb Hives, and the Use of the Extractor. By Thos. Wm. Cowan, F.G.S., F.R.M.S., &c. With numerous Illustrations. Feap. 8vo., price 1s. 6d.; or in cloth gilt, 2s. 6d. Postage 2d. To be had of Houlston & Sons, Paternoster Square, all Hive dealers, Secretaries to Bee-keepers' Associations, and of J. Huckle, British Bee Journal Office, Kings Langley, Herts.

French Edition, price Is. 8d., now ready.

CLASS HONEY JARS a Speciality. Write for Price List, sent Free. Address Fredk. Pearson, Stockton Heath, Warrington.

MPROVED British Bee-keepers' BAR-FRAME HIVE, made of One-inch Well-seasoned Wood, Eight Frames, Waxed, Quilt, Walker's Feeder, Excluder Zinc, Floor-board, Waterproof, and Cover. Hive complete, 5s. each. Directions for Management, 1d. Address Isaac Hale, Maker, Horncastle.

WOIBLET SPUR! WOIBLET SPUR!!

A JUBILEE PRESENT.—HUGHES' EMBEDDER SPUR, equal to the WOIBLET SPUR. Having
a large number now nearly completed, I can supply them
at the low price of 6d. each. CARLIN CUTTER same
price. The two combined 11d., postage paid. Orders
executed in rotation. Address A. Hughes, Stonehouse
Apiary, Halstead, Kent.

[Published Weekly.]

Editorial, Hotices, &c.

EXTRACTED OR SECTION HONEY?

April is now well advanced, and the weather still continues unfavourable for the bees. Bitter east winds still prevail, varied occasionally by northeast. The past winter truly has been most trying. Everything is backward, vegetation is almost at a standstill, although fruit trees are doing their very best to show signs of life. All things, however, come round to him who will but wait; and when our patience is well-nigh exhausted we may expect the welcome spring, and with it renewed animation in our apiaries.

With the honey season of 1887 (shall we call it the Jubilee year?) now so close on us, many apiarians will be excreising their minds as to which is better to work for—'Extracted or Section Honey.' Given as a fact that there are tons of the much-coveted nectar secreted in the season without any trouble on our part, but provided by an all-wise and bountiful Creator, and that we have strong and healthy colonies to gather it, it rests with the bee-keeper for the most part to decide whether sections or liquid honey will return him the more profit.

If we are to listen to our Canadian friends sections must be the rule, as we have been told that they have secured the markets in England for extracted honey, and in future British beekeepers must depend solely on comb honey for their profits.

This information we accept with all due courtesy and caution. But we have it from good authority that English honey is holding its own in spite of all opposition, and is now sought after and appreciated as it should be.

Judging from the number of new methods and appliances introduced since this time last year, many stocks, and perhaps apiaries, will be devoted to trying which is really the best, and we shall be pleased to chronicle results at end of season.

But we must not on this occasion step aside to spy into experimental apiaries in this year of joy and jubilee. Judging from the diminution of importations it clearly demonstrates that British honey is pushing its way into the markets in which we were told it could never gain a place.

British honey is very different from what it used to be when our Journal was first started; good and clean honey used to be the exception, but now it is almost the rule. We are confident that there is a profitable and a ready market for both extracted and section honey; in some places the former, and in others the latter, will find the readiest sale, whilst in others an equal quantity of each will be required. It will be wise for bee-keepers to study their markets and work accordingly. Some apiarians are beginning to lose heart and to say with the low prices of honey bees will not pay. But such are, we venture to say, mistaken, as with present quotations very excellent returns can be made from this pursuit. We have lately heard that agriculture being in such a state of depression farmers are advised to look more closely into the smaller industries of the farm. We are reminded of the large sums of money annually sent out of this country for the millions of eggs exported from France. We are told, on the other hand, that the French are a thrifty nation and are content with small profits; be this as it may they manage to get no unworthy sum in return. Poultry-farming pays we have not the slightest doubt, but it cannot be for an instant compared with bee-farming. With this last there is not much trouble; not a great outlay; no three acres required; no rent to pay for pasturage. The bee is free to wander where she likes, visiting this bright flower and that fragrant bush, performing many duties, gladdening man's heart by her joyous hum, and returning to her master with her rich store. The channels for the disposal of honey are now so multiplied that the bee-keeper is saved the trouble of hawking it about.

We are confident that even with existing circumstances bee-keeping can be made to pay, and pay far better than any other industry, and we cannot do better than re-echo the French Bishop's advice to his poor elergy, and to say to all in search of a means to increase their incomes, 'Keep bees, keep bees.'

ANNUAL EXHIBITION OF THE ROYAL COUNTIES AGRICULTURAL SOCIETY.

We have pleasure in announcing that this Society, which has by its liberal assistance to the bee-keeping industry, established a reputation second only to the R. A. S. E. for importance amongst bee-keepers and others, intends holding its 1887 Show at Reading, in

the latter part of June. Last year the Show was held at Portsmouth, and the Hants B. K. A. succeeded in organizing a very large and important honey department. This year the Berks B. K. A. have invited the Hauts Association to assist them in organizing a still larger Joint Exhibition, and already preparations are on foot for ensuring a thoroughly representative exhibition. A liberal schedule is being arranged, and the work of arrangement, &c., has been entrusted to a joint committee consisting of—(Berks) Mrs. Curry, Rev. R. Errington, Messrs. F. Cooksey, H. Fewtrell, W. Woodley, A. D. Woodley; and (Hants) Rev. W. E. Medlicott, Messrs. H. W. West, Evan Maberly, and E. H. Bellairs.

BEESWAX AND ITS CONVERSION INTO MONEY.

By J. DENNLER.

(Continued from page 147.)

It is to the interest of every bee-keeper to seek to protect his combs from the ravages of the wax-moths. These moths, of which there is a large and small kind, lay their eggs in the combs, or in the débris of the bee-hives. It is the larvæ which come from these eggs which spin round the comb and eat it. It is specially the large kind of larvæ which very much increase the difficulty of preserving the combs. The right means of getting rid of them or killing them consists in hanging up your stock of comb in hermetically sealed boxes, and in the hot time of year burn a piece of sulphur in it every three or four weeks. One can also protect the combs from the wax-moth by hanging them up in very airy places.

ARTIFICIAL COMBS.

There came a time when the bees did not content the demands of the bee-keeper in what refers to the accuracy in the building of the rows in the middle of the comb, and the habit of the bees in beginning to build their comb on the ledges and the sides gave some bee-keepers the idea of providing the middle of the small frame and wood for the comb with a sharply projecting cage of wood (Giebelhausen and Böttner). A line of wax was also recommended (Dr. Honert). The bees were to build regularly on it. Sometimes they did and sometimes they did not. Tongs, also, were prepared which represented the pressure of the cells on the little pieces of wood (Wilde).

Otto Schulz writes (History of Artificial Comb) that it certainly succeeded in inducing bees to build straightly by time-wasting manipulations, yet all one's wishes were not fulfilled, and the vexation was especially great when the bee-keepers in the early spring put in a little frame provided with a pressed-out piece of foundation and at the beginning of the building perceived that principally

drone-cells were being built.

The carpenter, Mehring, of Frankenthal in the Palatinate, was the first to have the happy idea of constructing a pair of plates of wood with the corresponding indentations of the foundations of the cells, with which he pressed out in wax the first partition walls of the comb. Dümmler in Homburg, Kunz in Jagendorf, Sand in Gundau, Peter Jacob in Fraubrunuen in Switzerland, perfected the ingenious discovery of making, and soon provided very useful wares. But it was Otto Schulz, of Buckow, who, later on, brought the artificial combs to a perfection hitherto maintained. Since then he has never been unfaithful to his principle—to establish a product of blaneless perfection at a low price and in great quantities. That this undertaking has grown in the hands of the 'Bee-lord' (literally the bee-village-amgistrate), as our manufacturer is called in the bee-

world, is to be seen by the fact that his business increases every year, and that, for instance, in 1885, he produced and despatched about 18,000 kilogrammes (a kilogramme=2½ lbs.). Competition was not wauting. Artificial comb manufactories shot up like mushrooms from the ground in the two last decades. Of the best known we may mention in Germany, Friedrich in Griefswald, Hermann Bruder in Waldshut (Baden), A. Herlikofer in Gmiud (Würtemberg), Adam Wendler in Sauer-Schwafbenheim (in Rhenish Hesse), Voight in Bahn (Pomerania). In Austrian Hungary, Anton John Wagner in Vienna, Joseph Ludwig, the Master Carpenter of Moravian Bee-keepers' Union in Brünn; in Switzerland, Siegwart in Altdorf (Uri), Hermann Brogle in Siesseln; in England, Abbott of Southall, London; in America, Ch. Dadant of Hamilton (Illinois).

By the recent discovery of an artificial comb-presser bee-keepers are enabled to press out for themselves the artificial combs they require, instead of selling the wax they have got at ridiculous prices. Rietsche in Bieberach (Baden) supplies such presses, as well as Hermann Greve, in Neu-Bradenburg (Mecklenburg), and Ihring and Fahrenholz, in Berlin. The Italian hand-presser of Guazzoni, who also invented the wax-holder, is a very practical hand-presser (see illustration in the original). Of course in the home manufacture of these artificial combs one must not expect first-rate goods, for every trade needs long practice, and a bee-keeper will seldom attain to this in the manufacture of artificial comb if he has only to produce what he requires for his own wants.

(To be continued.)

Foreign.

TASMANIA.

From the Hobart Mercury of the 19th of February we take the following cutting:—'St. David's Club.—The usual weekly meeting was held at eight o'clock last evening in the club-room. Present-the Dean (in the chair), Revs. G. F. M. Fielding, G. W. H. Dicker, G. A. Breguet, Mr. B. T. Solly, and other members. The business of the evening was a lecture by Mr. Fielding upon "Bees and Bee-Culture," a subject upon which the rev. gentleman is somewhat an enthusiast. He gave a resumé of what is now termed the "old-fashioned" method of bee-keeping, passing on to speak in detail of the various steps and stages which have brought beeculture up to its present pitch of perfection. Dividing the hive into the three divisions of queen, workers, and drones, the lecturer described how the work of the hive was carried on, how certain laws were conformed to, the industrious and ingenious habits of the inmates, &c. A feature of the lecture was the exhibition of the many and varied contrivances for facilitating the storage and yield of honey, together with different breeds of bees. A vote of thanks was heartily accorded the lecturer, and the meeting adjourned.'

[We hear also from other sources that Mr. Fielding has delivered courses of lectures on the improved methods of bee-keeping, in Tasmania. With their fine climate, and the introduction of modern appliances, and the 'different breeds of bees,' our Antipodean daughters bid fair to equal, if not to surpass, the mother country.—ED.]

NEW ZEALAND.

Humble Bees.—The *Dunstan Times*, New Zealand, of February 4th, reports 'that a humble bees' nest is to be seen in a garden at Oteknike,' and says, 'The *Oamaru Mail* states that these useful insects have made their appearance throughout the district with remarkable suddenness.'

[We congratulate our brethren at the Antipodes that

after so many trials, extending over a long course of years, the introduction of the humble bee is at length un fait accompli.—Ep.]

A VISIT TO THE MATAMATA APIARY.

The following is taken from the New Zealand Herald of March 6th, 1886:-

'Amengst the several rural industries now being carried on at Matamata, there is none more generally interesting to visitors than that of apiculture. Beefarming has now become an established in lustry in England, America, on the Continent of Europe, and in Australasia, and deservedly so, for very few industries connected with rural pursuits have made greater progress during the last few years, or shown better results when systematically carried out. The importance of apiculture as an industry attracted the attention of Mr. J. C. Firth, who, with his characteristic enterprise, started the nucleus of a bee-farm some three years and a half ago, with Mr. Hopkins, the well-known apiarist, as manager. The result has proved the good judgment of Mr. Firth, for instead of the whole of the honey that is secreted in the clover blossom now "wasting its sweetness on the desert air," as formerly, many tons are annually harvested, which find a ready market, at a remunerative price. There is one thing worthy of mention. The honey raised at Matamata is without doubt equal to the best raised in any part of the world. That is the opinion of everyone who has tasted it; and the demand for the "Tower brand" of honey is increasing so rapidly as to

warrant the further extension of the apiaries.

'Connected with the management of the apiaries, of which there are two at present, there are two substantial buildings—one containing a large workshop, in which the hives, frames, and other appliances are made, a honey-room for storage of honey, a fumigating room, and an office. The first thing that struck us on entering were the large stacks of 2-lb. tins of honey—close on 10,000. These had been brought from the principal apiary, and were ready for soldering, preparatory to heing labelled and cased for market. At the time of our visit the season's crop of honey was nearly all in, and this will amount to about ten tons-the produce of 200 hives—an average of 100 lbs. per hive. What an enormous quantity it seems to be gathered by such little workers; well may the honey bee be held up as a pattern of industry. In the fumigating room, which for the nonce had been turned into a wine room, we were shown a number of casks containing fruit wines, mead, eider, and vinegar in a state of preparation. These had been made principally with honey, and gave promise of turning out excellent in quality. The honey used in their manufacture had all been obtained by washing the cappings of the combs; the portion shaved off before extracting the honey from them, and which is useless, for market. Mr. Hopkins, the manager, is of opinion that were mead, honey, and fruit wines, honey vinegar, and other such like products obtainable, an immense demand would soon spring up for them. We have no doubt that this might be made a very profitable branch of bee-keeping if bee-keepers would but turn their attention to it. It would not only be the means of utilising a vast amount of surplus honey, but a great tenefit would be conferred on humanity by placing within reach some wholesome, health-giving beverages in place of the vile compounds now sometimes sold as wines. There is no reason why we should not again revive some of those ancient beverages, such as mead, metheglin, miodomel, so highly prized when honey was considered as an indispensable article of food for man, before sugar took its place.

'The other building is used for manufacturing combfoundation. To those of our readers who have not seen this artificial aid to bees, we may explain that comb-foundation is sheets of thin beeswax impressed

with the bases of the honey-cells, thus forming a foundation upon which the perfect comb is built. Usually these sheets are made about $16\frac{1}{3}$ inches long, 9 inches wide, by one-eighth of an inch thick. These are fastened in small wood frames, and placed in the hives for the bees to finish. It is calculated that for each pound of comb-foundation used there is a saving of 15 lbs. of honey, to say nothing of the numerous other advantages gained. Four of the latest and most improved machines for making it are in use at Matamata, and, in fact, everything that can be devised for purifying the wax and manufacturing a first-class article. Some idea of the progress of bee-culture in Australasia may be formed when we state that in 1879, when Mr. Hopkins first commenced to manufacture comb-foundation for sale, about 300 lbs, were sufficient for all demands; the demand has steadily increased since, and the sales this season amount to five tons. That made at Matamata is in use throughout the whole of the Australasian colonies, and what appears very remarkable is, that several beekeepers who have gone to the expense of procuring machinery, &c., for making comb-foundation, have found that it pays them much better to send to Matamata for what they require, even to sending all the way from Queensland for it.

'The home apiary, situated near to the manager's, is a small one of about thirty hives, principally devoted to queen-rearing. Here we saw a large number of miniature or nucleus hives, in which the young queens are reared and kept until they are required. Until quite lately none but pure Italian bees were kept and bred in this apiary, but in December last some pure Cyprian queens were imported from Messrs. Neighbour and Sons, the well-known English apiarists. These for the time were located here for the purpose of having the young queens reared from them mated by Italian drones, as the progeny from this cross are now considered to be the best working bees cultivated. There is no danger of any queens reared at this apiary being mated by drones other than those bred there, as the nearest bush is at least five or six miles away, and the nearest apiary is two and a half miles distant. Queens are sent through the post to all parts of the colonies in small ingeniously contrived cages made for the purpose, and will travel over a twelve

or fourteen days' journey confined in the mail bags with very little risk of dying.

'The "Burwood Apiary," situated some two and a half miles from the "Home Apiary," is devoted to honey production. The hives—about 22 in number—are set out in long rows in an enclosure of about an acre, surrounded by pine-trees, and are well sheltered. The extracting-house, where the honey is extracted from the combs, stands nearly in the centre of the hives. At the time of our visit extracting was going on. One man manipulates the hives, removing the full frames of honey and replacing them with empty ones. These are placed in tin baskets and taken to the extracting-house, where another man with a peculiar knife resembling a narrow trowel, and called an uncapping knife, shaves off the cappings of the cells into a large can, the combs are then placed in narrow wire cloth baskets which are fixed to a frame-work in the extractor; the framework is then made to revolve rapidly by turning a handle, and the honey is thrown by centrifugal force from the combs against the inside of the extractor. When one side of the combs are emptied they are turned and the other side extracted. From the extractor—which stands on a platform about four feet above the floor-the honey runs into a triple strainer and from there into the honey tank, capable of holding about 3000 lbs. Here it is allowed to remain for a day or two to get thoroughly ripe, when it is skimmed and run off into tins for market. The combs—which are not injured in the least by the extracting process—when emptied are given back to the bees to refill, and emptied again and again. This system of

taking honey is a vast improvement on the old-fashioned way of sulphuring the bees and breaking up and straining or squeezing the combs. By the latter method the delicate flavour of the honey is destroyed, and in fact usually it is not fit to eat; but by the method described the original aromatic flavour which makes fine honey so delicious is preserved and it is kept from all foreign substauces. One peculiarity about the Matamata honey is its rapid granulation and very fine grain. In the hottest weather it granulates in about three days and from the time it is extracted, and in more than one instance this season it would not run from the tank thirty-six hours after being taken from the comb. When placed in a dish on the table its colour and grain give it the appearance of butter, from which it is sometimes difficult to distinguish it.

'Mr. Hopkins informed us that the past season has been a very fair one throughout New Zealand for bee-keepers, and that he estimates the season's crop at over 300 tons for this colony. He thinks the Auckland province alone will have produced nearly one half of that quantity. Altogether, we look upon the industry of apiculture as one of much importance to the State, and well worthy of any direct encouragement the State can give it. We congratulate Mr. Firth on his enterprise and the example he has set to other colonists to "go and do likewise."

CANADA.

SENDING HONEY TO ENGLAND.

A meeting of the directors of the Ontario Bee-keepers' Association was held on the 16th of March at the Albion Hotel, Toronto; S. T. Pettit presided. We extract the following account of the meeting from the Canadian Bee Journal:—

The President explained the object for which the meeting had been called, viz., to decide in what shape our honey should be put up for the English market, and whether or not the Association should undertake to handle the productions of its members.

The first question decided was, that glass was the package to be adopted and that the probable size was

one pound.

The question of the Association's taking hold of the matter then came up, and, after much discussion, Mr. Corneil intimated that the Association was not incorporated as a trading hody, and unless they procured a special clause enabling them to do this they could not undertake the work. This was concurred in by F. H. Macpherson.

It was decided, however, that the honey must go to England in bulk, to be put up there in the style of package in which it is intended to reach the customer. The package considered most suitable for shipping it was the 60 lb. tin, such as we make and sell, and which was used for the bulk of the extracted honey which the delegates took with them last summer. It seemed to be generally considered that no honey should be shipped to commission men, and that the work would be a matter of private enterprise.

Mr. Corneil advised mixing our honey and blending the flavours to make one uniform brand or flavour. It would be much easier to control the market and keep the reputation we had gained, than by attempting to keep on the market three or four different flavours of honey; and in this Mr. Pettit agreed, with the proviso, of course, that no dark honey must be sent or mixed.

Mr. R. F. Holtermann, in a letter written subsequently to the above meeting, informs us 'that a meeting has since been held by a county association, at which a resolution was passed urging the Ontario Association to reconsider the matter, promising at least 10,000 lbs. of honey on the spet if season permitted, providing one of the four directors would go which had the work in hand last year, and take the honey to England. The Ontario Association has an annual grant of \$500; it is proposed

that this be taken to defray the expenses of the director, and the balance of expenditure and payment for time be shared by the contributors. What effect this will have time will tell.

R. McKNIGHT.

In the same number we find an interesting memoir of one of the Canadian Delegates to London, Mr. R. McKnight, whose genial bearing and marked intelligence will be in remembrance by those who were present at the Conversazione at South Kensington, or who visited the Canadian Honey Exhibition. We have much pleasure in transferring this memoir to our columns:—

R. McKnight was born in the County Down, Ireland, in the year 1836, and like many of his fellow-citizens before him he left home and friends at the early age of 19 years, and hied himself to Canada, via New York, which port he arrived at about the latter part of the month of June, after a six weeks voyage. While in the city of New York he engaged with the captain of a whale-ship to go to the Polar seas on a whaling expedition, but through some delay in the ship's sailing he broke off his engagement. Leaving New York he came West, and in the township of Tossoronto, County of Simcee, he found employment in a saw-mill. His history shows the ambitious desire of our friend, and to this ambition and a desire to 'stand on the top of the heap' may be ascribed his success in life. Six months in his mill life brought him 'to the head of the class,' and the mill was placed in his charge, and was conducted by him for three years. In 1860 he left the saw-mill and took charge of a school in the adjoining township of Essa, where he remained for three years. Leaving Essa he came to Tecumseth, where, in a school only two or three miles from this village (Beeton), he taught another three years, and during this time he secured the highest grade of a first-class teacher from the County Beard. He then bade good-bye to the school-room and entered the military school at Toronto, and in the following spring he hade his adieus to the latter, carrying with him a cadet's commission. The mercantile business then received a share of his attention. He opened a general store in the little village of Markdale, County Grey, where he remained for two years, then selling out and removing to Cookstown, County Simcoe, where he added the drug husiness to his general stere. Tiring of the life of a hachelor he decided to join the army of benedicts, and found his partner in life in the person of Miss McLean, of Elm Grove. In the spring of the year his store and dwelling were destroyed by fire, everything being consumed. He succeeded, however, in paying up every dollar of his indebtedness, and he was hard pressed by the wholesale houses with whom he did husiness to rebuild, they promising to give him all the necessary support, but he decided it unwise to bother himself with heavy liabilities, and the following fall he moved to the then rising village of Meaford, where he went into the drug and grocery business. It was not long before he became one of its most enterprising citizens, taking an active part in everything pertaining to the advancement of the village. Three years later he was selected by the Reform Convention of East Grey to contest that intensely Conservative constituency against Mr. Flesher, but he was beaten by some 600 votes. At the next election he was again chosen to fight the battle of his party against his old opponent, and this time he reduced Mr. Flesher's former majority by 300 votes. Some two years after this, Mr. Scott, the local member for North Grey, was unseated and disqualified, and he was asked by the Reform Convention to go up and contest that riding. Here, again, he was handicapped,—heing practically an outsider, while his opponent, Mr. Creighton, the present member, was editor and proprietor of the Owen Sound Times, and was well known throughout the Notwithstanding all this, Mr. M. was only defeated by 59 votes. During all these contests he lost

no friends in his own party, but gained many personal if not political friends amongst his opponents. Shortly after his contest in North Grey the Registrarship of the County became vacant by the death of the incumbent, and Mr. M. was offered and accepted the position.

This removed him from the arena of politics and gave him leisure to practise other pursuits for which he had a strong liking—notably floriculture and horticulture. His home at Owen Sound testifies to his taste and skill in both. Nor does he confine himself to his own home pursuits, but in everything for the good of his town he takes a lively interest. He is at present president of the Mechanics' Institute, a member of the Board of Education, also of the Board of Health, is one of the executive committee of the Board of Trade, and an active member of the Masonic fraternity, indeed his is a busy life.

As a hee-keeper he has had about seven years' experience, and he is fairly well known as one of the leading apiarists. He has been one of the leading spirits of the Ontario Bee-keepers' Association, being present at the convention held in Toronto, when it was first organized, and he presided over the deliberations of that meeting in the City Hall for three evenings. He was elected the Sec.-Treas. of the newly organized Association, and on him devolved the perfecting of the organization, which he did thoroughly and well. For two years he held this position, and during that time edited the Bee Department of the Canadian Farmer. The following year he was elected president, and he has been on the executive committee ever since. colonies now number 175, the product of two hives bought seven years ago. In the meantime he has sold perhaps \$200 worth of bees. He was appointed one of the delegates to represent Ontario's honey display, and it was a most fortunate thing that Mr. McKnight was appointed one of the Commissioners at the Colonial. The magnificent display of honey was due in a very great measure to his efforts, as after a fair trial we all found that he possessed the art of staging the goods to the best possible advantage, and we think we may say without fear of contradiction that he has no superior, if an equal, in this line.

To him alone was left the entire arrangement of the display, and the bee-keepers of Ontario should feel very grateful for his untiring efforts in watching and carefully keeping the display up, changing it from day to day and from week to week, making it always look fresh, as if just placed in position.

He not only worked in the honey building, but frequently spent hours after midnight with the pen to maintain the honour and reputation of the bee-keepers of Ontario. He made many warm friends while there, and after he left many a kind word could be heard from those who regretted he had to leave so soon.

BERKS BEE-KEEPERS' ASSOCIATION.

The Windsor branch of the above Association held their second social gathering at the Albert Institute, Windsor, on Tuesday, April 12th. At half-past six a committee meeting was held, when it was resolved to hold the Annual Show at Windsor this year in conjunction with the Prince Consort's Association meeting. It was also resolved, on the motion of Mr. G. P. Cartland, that the balance-sheet should be printed and circulated among the committee before the annual meeting of the Association in January each year. At the conclusion of the committee meeting, the public were admitted. Among others present were, Mr. G. P. Cartland, Mr. Darby, Mr. Sevenoaks, Mr. W. Carter, Rev. R. Errington (Hon. Sec.), Mr. A. D. Woodley (expert), Mr. W. Woodley, Mrs. Curry, Messrs. Gower, G. and Il. Willis, J. Smith, D. Smith, R. Brown, and others. Mr. Sevenoaks exhibited some appliances, and Mr. A. D. Woodley introduced a very neat metal section

case. The section slips into the case, the bottom and sides of which are solid, and then the top, like that of an ordinary tin canister, fits on, and the thing is complete. They are painted in four colours, and when stained in any way can be washed.

Miss Goring very kindly presided at the refreshment stall, and in the course of the evening Mr. Woodley gave an address on 'The Relation of Bees to Fowers.' The

company separated about 10 p.m.

LECTURE ON BEE-KEEPING.—An interesting lecture on 'Bees and Bee-keeping' was delivered on the 12th inst., m the School-room, Badsworth, Yorkshire, by Mr. R. A. H. Grimshaw, of Horsforth, Co-Secretary of the Yorkshire B. K. A. The chair was taken by Lieut, Colonel Ramsden, of Rogerthorpe Manor, who introduced the lecturer to an appreciative audience. The usual diagrams, frames, sections, combs, &c., were exhibited and explained, but the chief aim of the lecturer was directed to the great advantages of the frame-hive over the old dome-shaped skep (all the beekeepers present, we may remark, were skeppists), and the almost national necessity there was of farmers availing themselves of every opportunity to eke out their incomes in these times of agricultural depression and competition. It was argued that if bees did not yield us one drop of honey it would still, indirectly, well pay the agriculturalist and fruit-farmer to keep bees in such a rich pastoral district, because of their services in fertilising and crossfertilising the clovers and fruit trees. Mr. Grimshaw strongly urged his hearers to form themselves into a village bee-club or branch association, fixing their subscription at, say, 2s. 6d. each per annum, out of which they should buy a hive of Association Standard size from which they could take a pattern if they desired to make their own. Frames could be bought cheaper and truer than they could be made, and should, at all hazards, be of a uniform size in each apiary or bee-garden; indeed, if they were to form a society, they should keep one uniform size in the whole district if possible, for lending, giving, and selling facilities. This hive could be offered as a prize to their own members at the local show. He also recommended them to subscribe 5s. 5d. per half-year for the British Bee Journal, which could be passed round for reading among the members. They should, besides, send up for a copy of Modern Bee-keeping, which could be read aloud—a chapter at a time—at their monthly meetings, to be followed by discussion. From the enthusiasm of Mr. Tyne, the schoolmaster at Badsworth, and others, it is very probable these suggestions will be at once earried out.—Great eredit and praise are due to Lieut, Colonel Ramsden, for the large-heartedness and public spirit he has shown in his efforts to benefit those near him by arousing the desire to 'go in' more for the scientific, or modern aspect of beekeeping. The usual votes of thanks were passed and truly acknowledged.

Lecture on the Honey Bee.—On Wednesday evening, April 14, at the Biological Room in the Yorkshire College, under the presidency of Mr. H. Bendelack Hewetson, M.R.C.S., a lecture was delivered by Mr. G. H. L. Rickards, M.R.C.S., on 'The Honey Bee and Bee-keeping,' before the Leeds Naturalists' Club and Scientific Association. After describing in popular language the life-history of the bee, and the internal economy of the hive, the lecturer explained the modern appliances for bee-keeping, illustrating this portion of his remarks by reference to a large collection of hives and other implements which had been kindly lent by Mr. W. Dixon of Beckett Street. The lecture was listened to with the greatest interest by a large number of the members and their friends, and at the conclusion several questions were asked, and replied to by the lecturer.

EMBALMED IN HONEY.—'When he dies (the Hpoongee or Buddhist priest) he is embalmed in honey six months; then in great pomp and state his body is burned. The honey is sold, and by some is much esteemed for its supposed healing properties. It is said to find its way into the bazaar market, and European officers who will eat Barman honey are not to be found.' (Extract from a letter of an officer from Burmah in the *Irish Times* of April 9th, 1887.)—Moral (for the British public): Don't eat Burman honey.

Correspondence.

The Editor does not hold himself responsible for the opinions expressed by his correspondents. No attention will be taken of anonymous communications, and correspondents are requested to write on one side of the paper only, and give their real names and addresses, not necessarily for publication, but as a guarantee of good faith. Illustrations should be drawn on separate pieces of paper.

Communications relating to the literary department, reports of Associations, Shows, Meetings, Echoes, Queries, Books for Review, &c., must be addressed only to "The Entron of the "British Bee Journal," clo Messys. Strangeneaus and Sons, Tower Street, Upper St. Martin's Lane, London, W.C.' All business communications relating to Advertisements, &c., must be addressed to Mr. J. Huckle, King's Langley, Herts (see 2nd page of Advertisements).

**In order to facilitate reference, Correspondents, when speaking of any letter or query previously inserted, will oblige by montioning the number of the letter, as well as the page on which it appears.

OUR HONEY IMPORTS.

The value of honey imported into the United Kingdom during the month of March, 1887, amounted to 1114/.

Particulars of the QUANTITIES of honey imported into the United Kingdom during 1886 and whence.

[From Returns furnished by the Statistical Department H. M. Customs to E. H. Bellairs, Wingfield House, near Christchurch.]

'MEL SAPIT OMNIA.'

[917.] I am glad to have an opportunity of acknowledging the debt that I, in common with the readers of the B.B.J., owe to the writer of 'Useful Hints' for his most interesting dissection of the now notorious word 'apifuge.' It is well for us all (considering the countless number of new words that are necessarily introduced into our language from day to day) that those who coin or introduce them should be subjected to the searching criticism which the author of 'apifuge' has encountered in your columns. When, however, he is accused of 'promulgating or propagating a macaronic solecism,' in inventing another term (Galactofuge) which is rightly called 'an etymological monster, I should think he must have felt as guilty as if he had committed the seven deadly sins all at one time. How many of your readers could explain the meaning of a 'macaronic solecism?' Who would not be nervous if such an epithet were hurled at his head? The expression is a perfectly correct and proper one, but I suspect that it puzzled most of those who noticed it, and I confess that I was glad to have the 'Imperial' at my side to test its accuracy. The author of this overwhelming epithet has evidently been engaging in the word-competitions that

have been so popular of late.

My chief object, however, in writing to you is to inquire the meaning which is intended to be attached to the words which appear so often in your columns, 'Mel sapit omnia.' I have always thought the expression a doubtful one, but I should like to know the meaning intended to be attached. 'Sapere,' connected with the Greek σαφής, first of all means 'to taste,' or 'to have a taste or flavour of' a thing, so that 'Mel sapit emnia' must be explained, 'Honey has a taste of everything.' But does it taste of everything? Some amusing passages might be quoted where the word is used in the sense of to smell of, but the expression cannot be intended to mean 'honey smells of everything.' chief and ordinary meaning of the word sapere, as used in countless passages by a wide range of authors, is 'to be wise, sensible, discreet,' and not a few of your readers will at once recall the line which every student of Horace must remember, typical as it is of 'the peet of middle-aged men,' 'Dulce est desipere in loco'—' Sweet it is to lay aside one's wisdom at the fitting place and time.'

It is evident that the anthor of the phrase does not use 'sapit' in the ordinary or neuter sense, so that we must continue our search for the proper meaning. Sometimes the word is used in the sense of 'to know,' 'to understand' a thing, as in a passage quoted by Cicero, and worthy, I think, of quotation in your columns: ' Qui sibi semitam non sapiunt, alteri viam monstrant'— 'Those who know of no by-path for themselves are showing the road to the other.' And a passage from the Epistles of Horace may also be quoted:-

> 'Quum tu . . Nil parvum sapias et adhuc sublimia enres.'

'When (or while) you have no taste for anything trivial, and still care only for lefty themes.'

Thus, then, I am at a loss to comprehend the meaning of the expression as used in your columns' Mel sapit omnia. It cannot be 'Honey knows or understands everything.' I suspect the writer intends it to convey the meaning 'Honey gives wisdom to everything,' a meaning that it cannot for a moment bear. There is a passage in the Vulgate (St. Matt. xvi. 23, St. Mark, viii. 33) in which the words occur 'Tu non sapis ea quæ Dei sunt'—'Thou savourest not' (R.V., 'mindest not') 'the things that be of God.' This quotation, however, does not help us in any way. We come back then to the meaning, the only meaning which I think the words can bear, 'Honey has a taste or flavour of everything;' and such a sense seems to me simply to approach the absurd. Others, however, may take a different view, and I trust some further light may be thrown on an expression which appears to have been accepted as correct for a considerable time.—Oxoniensis.

EXPERTS' VISITS.

[918.] May I ask you for advice or arguments, more conclusive than my inexperience can as yet furnish me with, wherewith I can combat the strange antipathy some of our bee-keepers show to the bare mention of the preposed experts' visit?

I have no wish to force such a visit on them, but when my duty leads me to go the round of our members and take down the names of those anxious to gain more experience by such means, or of those who are proud to let the expert see what progress they have made from year to year, I am here and there nonplussed by an unexpected answer such as this: 'No, thank you; no expert's visit for me. I don't held with that constant pulling about of one's hives, chilling of brood, and bringing foul brood about. Foul brood was never heard of before these new-fangled frame-hives came into use; there is no such thing ever known in straw skeps.

How far can it be proved whether foul brood did or did not exist in former times? Surely it may have done so, but was simply never taken notice of, and in most cases probably burnt out by the old-fashioned custom of killing off all but the best and strongest stocks.

If this question has already been well thrashed out in your Journal, I beg you will kindly excuse my repeating it, for though I have read it diligently for about a year, I find myself as greatly puzzled this season as I was last to give an answer to these same members.—L. S.

Fonl brood, though not so called, has existed from remote times, many apiaries having been depopulated by its inroads. It has, we believe, been more common in modern days, but we have at the present day more means of eradicating it. We are afraid that experts are not so careful as they ought to be. In visiting apiaries infected with foul brood, they cannot be too careful in washing their hands and cleansing all the appliances they have had in use.—ED.]

IN REPLY TO NOTICES IN B. E. J. OF APRIL 14.

[919.] Echinops Sphærocephalus.—We had a specimen of this on our Wilts' Trophy' at the South Kensington Bee Show last summer. During the whole time it was daily visited by a small humble bee (only one) about 10 a.m. He was very punctual, and was seldom seen again the same day; he came again when we were packing up, and hovered about for some time searching for it in vain.

Birds eating Bees (906).—Some twenty-five years ago, I watched a blue-tit (early in the year) tapping at a hive door. He snapped up the first bee that came out, carried it off to a post, held it down with his claw, pecked at it, ate it, and returned for another; this went on for nearly half-an-hour. On examining the post, I found seventeen bee-stings which he had left. So I am convinced that some blue-tits, at all events, eat live bees. I can say the same of swallows and sparrows, both of which every year I watch flying over and round my hives (especially when approaching showers cause the bees to hurry home), and unmistakably catching them as they fly.

Reply to C. Shufflebotham (912).—During the swarming season, I usually keep a bucket of water and powerful garden syringe near my hives, if a swarm seems inclined to go off my own premises, I throw a jet of water into the air so that the falling spray may sprinkle them, which causes them to settle very quickly. I believe this is a very old, but effectual dodge.—W. E. BURKITT.

THOUGHTS ON CURRENT TOPICS.

[920.] Foreign Bees.—Thanks, 'Amateur Expert.' I said nothing against the gentleness of Carniolan bees, I took that to be pretty generally known; and as to timid beekeepers, they never entered my mind when I penned my letter against the indiscriminate introduction of foreign bees to the annihilation of the British bee. Of course bee-keepers must have their 'fads,' and possibly Carniolan bees in a good district in the sunny south may gather enough to keep them through the winter; therefore, if 'Amateur Expert' has the happiness to live in that favoured portion of our island, I say by all means recommend these bees, but to those who unfortunately have to exist in what is proverbially known as the coldest part of this country—the eastern side of Yorkshire—I say, keep to the British bee, which is indigenous to the country, has withstood all the vicissitudes of our treacherous chimate for countless generations, and is, therefore, the survival of the fittest in the struggle for

CROAKING QUEENS.—I gather from Mr. Grimshaw's letter that he does not believe that queens 'croak,' but attributes the sound to 'a drone striking its wings against the hard shining under-surface of American cloth.' Well, now, that may be a solution of his case, but it does not satisfy me, for I have heard the noise, an unmistakably loud croak, frequently in my hives, not often twice in the same hive, but always under similar conditions, viz., when manipulating with smoke and when the bees were pretty much subdued, and this in hives where no American cloth was used and when there were no drones in the hive; every one knows the peculiar cry of distress of a bee when caught between the quilt and a frame, in closing up the hive: but the croak I have heard has sounded sometimes deep down in the centre

of the hive. I believe it to be the queen because I never heard the noise made by more than one bee in each hive at a time.

PEA-FLOUR. —I find the best way of giving bees peaflour is to purchase, for 6d., from the grocers, an empty sugar-cask, with one end knocked out, then to drive a stake into the ground and fasten the eask horizontally on to it with the open end having a southern aspect. Now put into it a tray or shallow box, in which place the pea-meal and put a few branches inside on which the bees can climb to rub and clean themselves and transfer the flour to their pollen-baskets. The advantages of this method are that a sudden shower of rain cannot spoil the flour, as it does if given in the open; the bees are sheltered from rough winds, mice cannot climb up into it, as they will into almost anything to get pea-meal, of which they appear to be very fond; and, lastly, should the weather suddenly become very cold and the bees be unable to get out to the meal, it will be there for them when it changes.

Water.—Bees must have water in the spring. I give it them by filling those large earthenware covers used for skeps and placing them on a sunny, sheltered border. I then sift out the 'dust' of what is called 'cork-dust' and lay a good stratum of these cork chips on the water, which they absorb and form a floating scum, whereon the bees alight and drink in security.

SMOKERS.—'T. I. N.' has some practical remarks on these, which one wonders manufacturers of them have not discovered before. I can fully corroborate him in regard to the uselessness of a valve; mine broke, so I blocked up the hole and used it all last year without one, and it seemed to go much better.

Drones.—I am quite of Mr. Howard's opinion that we ought not to exclude drones from hives, having practically solved that point to my own entire satisfac-tion. I will cite a case or two. Having a hive that usually lay dormant a long time in the spring, but which when it did start generally outstripped most of the others, I thought it would be well to have plenty of drones in it to fertilise young queens, so introduced two full sheets of drone-comb into the centre of the cluster, besides which it had already its own ordinary quantity along the bottoms and edges of the other combs. The result was that it abounded with drones all the summer, but it gave the greatest weight of honey in the whole lot. Last year I again let it have all this drone-comb, and again it turned out one of my very best honey-producers. Another hive, driven bees from the same district, had two sheets of drone-comb given it, as I was anxious to perpetuate this strain of bees, which I fetched from the highest and coldest spot on the eastern seaboard of Yorkshire; and this hive also did well, filling and sealing every comb in the doubling box and giving two or three crates of sections besides. Pray let us hear no more about useless drones.—F. Boyes, Beverley.

CROAKING QUEENS, (897.)

[921.] Mr. Grimshaw, on page 152, draws my attention to a slight slip of the pen in my communication upon this subject, inserted in your issue of March 10th. The expression used by your correspondent was, 'We recognise the contented boom (or hum?) of the quiet, prosperous hive in opposition to the sharp "poop! poop!" of the lost queenless bee.' For 'bee' I substituted 'hive,' as indeed I remarked, it appeared to be an error, possibly a printer's.

I am obliged to Mr. Grimshaw for the correction. It enables me to recognise the sharp 'poop! poop!' he speaks of, which, under the circumstances he mentions, I have many times heard uttered. But this is a very different sound from the croak, ruttle, or drum-roll I attribute to the queen. The latter sound is quite an octave lower, far more rapid in succession, and even to

be differentiated from the croaking noise referred to by him, and pointed out by me in my first communication, viz., that produced by the wings of a bee when fixed between the quilt and a frame top-bar, and which ceases, as I then observed, upon the release of the bee.—Edward C. Anderson, Lydgate House, Wolsingham, April 12th.

BEE-WAY SECTIONS.

[922.] Apropos of four bee-way sections and slotted dividers, I think it would add greatly to the usefulness of both if the slots were divided into two. The division in the bee-space of the section coming against the division in the slot of the divider would then prevent the latter from warping, which, in its present condition, it will be certain to do. With four bee-way sections now in use the same result may be obtained by driving a small wire point into each side of the section. Of course the tops and bottoms of both sections and dividers will remain the same as at present. I enclose drawings to explain my meaning.—W. H. Dolan, Loose, Maidstone.

FRAMES AND SECTIONS.

[923.] Rather mean to say, 'An axe to grind,' and that motives other than interest in what is practical should be imputed. I might retort that same purpose, adding that while I turn and grind alone, the many worthy ones named are turning the stone, while Mr. Lee grinds the axe of another in his own interest. Nor should Mr. Lee be too confident I have not seen his productions. Now, friend Lee, your application of the 'bastard dovetail' to the standard frame is of merit; but this application alone is all you can claim as original to your frame and section. Saws vertical, and running at the degree of angle desired, cut both groove and tennon,-your work testifying the same; and such is a joint of 'ancient days,' but of later days produced in many a joiner's workshop as described. To proceed. As honey-production in general is the main object in bee-keeping, I am surprised my query re drones is answered as it is. To the practial apiarian the question gave its own answer, and in frames it was not a question of drone production, hut the uses of a frame and foundation compelling in the right direction-not all drone-cells, nor quite all worker either. I am much obliged for the information; it is 'ancient history' that foundation and built comb have been cut for given purposes by the bee-master.

Again, defending the wrong principle of guiding the bottom of foundation with a split bottom rail, by bringing the merits (?) claimed for inversion to the rescue, is merely proving this bottom rail guide to bar-frames of theory only, nor does it add to the merit of its principle by quoting me; that which I wrote as an illustration showing how useless it was to work for comb-crammed brood frames, and Mr. Lee might have been sufficiently charitable to quote this is useless work. Now foundation held only between a split top bar, in either frame or section, may stand a test without the hive; but within! the precaution of molten wax, or a couple of brads, may not be great loss of time in adding after all, nor expense either. In practical test the principle has been tried and found wanting, nor would I ever risk wood and founda-

tion alone within the hive.

If Mr. Lee will defend his frame and section by actual apiary work and experience, not forgetting that split rails, glass rails, and projecting ends for bee-spaces are not quite 'ancient,' but fast becoming so, we may both get out of the 'shop' into the apiary, and there discuss bee spaces, completing, clustering (?), the merits (?) of inversion, right way up, and the right way to bear no ill impression of any man.—Jони П. Номако.

FEEDING WITHOUT FEEDERS.

[924.] Now that the time for spring stimulation has come round, a suggestion as to a very cheap and simple method of feeding, which dispenses with all appliances and preparation, may prove acceptable to bee-keepers. It is to take an empty comb, and, laying it flat on a table, place a heap of moist sugar* on it. Spread this with a knife or with your hand, so as to fill the cells on one side, taking care not to bruise or ent the comb. There is no need for ramming the sngar down into a hard, solid mass, as filling the cells up level is all that is wanted. If the bees have any difficulty in liquefying the sugar, the comb can be well sprinkled with water, either before or after filling; I think before would be preferable. The reason for filling only one side of the comb is that, while filling the other side, a quantity of sugar would fall out again from the side previously filled, and it is also unnecessary, for as many combs as desired could be so stored and given to a hive.

Before returning the comb to the hive, brush or shake off all loose surplus, so as to avoid its falling on the floor-board, and thus being wasted. Place the sugared combs in the hives towards the ontside of the nest, but inside the division-boards, with the full side towards the cluster, as the bees always prefer to have the empty face of a comb outwards. I think one standard frame so filled will last a breeding hive for about a week, but am not quite certain as to the exact time. I think, too, that this way of feeding will be found to cause little, if any, more excitement than uncapping sealed honey, and that as the sugar is already stored in the combs, the bees do not trouble to remove it to another part of the hive, but use it as required, consuming it in preference to breaking into their stores of sealed honey. I cannot vouch for the perfect accuracy of this view of the bees' proceedings, as I have not observed them closely enough for this; but I can say that I am now using this method, and find it to answer satisfactorily. It is very similar to the method advocated by Mr. Simmins, but dispenses with the dummy as an unnecessary expense; herein I think is the only difference in the bee-keepers' method of proceeding.

How this method would answer for autumn and winter feeding I cannot say, as I have only tried it this spring, but should think it would do, providing the hive was kept reasonably dry, so as to prevent the sugar from absorbing too much moisture, and so flooding the hive with syrup. For this purpose, I should propose filling only the upper portion and ends of the central combs, or turning their sugared face towards the hive walls; the outer combs being arranged

as before mentioned.—Student.

STEWARTON HIVES.

[925.] Several new designs in hives have been given lately, so I think I will also give mine, and ask public opinion on it, if you will favour me. To begin with, I secede from the bar-framist, because my experience has, so far, taught me that I can succeed just as well without them. My Stewartons are just as strong, if properly managed, as my bar-frame hives, and they give me just as much honey, but not in so saleable a form. Also, the Stewartons, owing to their thin sides, require an outer case. The frame-hives take a lot more work for the same results, and are clumsy to take to the heather. I have tried to remedy some of these defects in my new hive. I have not made it specially invertible, because it only with deep frames that inverting is required. With shallow frames we can transpose, which is far better. The body-boxes are six inches deep, and fourteen inches in diameter inside, and fitted with nine or ten fixed bars. The sides are a full three-quarters of an inch thick, and have a peculiar arrangement to prevent wet

^{*} I use white at 1½d. per lb., and find it answer very well.

getting in at joints. Either section-boxes or extracting-supers may be used above, all having this joint. For my own part, I work only for sections. It would be interesting if Mr. Cowan would say what the difference between working his Stewartons and bar-frame hives is I mean in building up in spring. Which get strong quickest, and with what attention? I think this hive would do well for cottagers and others, who never make a good job with moveable frames. Not that I have had any experience with this hive, or intend to go in largely with it. My idea is to try and get sections as easily as possible. The cover for above hive is the same as Mr. Simmins's, and a very good form I find it, and not very difficult to make.—Ggorge D. Clark, Kirklandhill, Dunbar.

[The arrangement alluded to for keeping out the wet consists in having a V groove on the bottom edges of the hive-sides, and bevelling off towards the outside the top edge. Our frame-hives are always the forwardest, and are ready for honey-gathering first, but they have an advantage in the moveable combs which enable us to assist them more than we can the others, and therefore they are much quicker in building up in spring.—ED.]

THE NEW RACES OF FOREIGN BEES.

[926.] I did not intend writing any more on this subject, but I see Mr. Simmins, in an addendum to his article on Carniolans, does me the honour of making some remarks on my letter.

He first says he has given an impartial opinion on the different varieties of foreign bees—of course I do not for a moment doubt him when he says so, but a naughty little bird in flying across my garden whispered that his very glowing articles on these bees, appearing simultaneously with his full-page advertisement directing people where to go to get them, may possibly create in some refractory minds the very smallest semblance of a doubt on this point. I should be sorry if it did, and had I bad my gun I should certainly have shot that nanghty little bird for its impudence. Since then a neighbour informs me that he heard it whispering in his garden that it believed Mr. Simmins had made an omission when he stated it was 'unreasonable to expect to hear the last of these bees before the beginning was told,' and that he ought to have said his beginning, for, continued the little bird, have we not had our Cowan's and our Raynor's, and many others' opinions years ago?' That little bird is becoming incorrigible, and I shall certainly make it my duty to shoot it the first chance I have.

When Mr. Simmins writes, 'I may presently have some things to tell of English bees that the same correspondent (myself, readers) had not even dreamed about nor imagined,' I must tell him I shall be delighted to learn these things, if they are worth knowing, about our British bees—not 'English,' please, that would be too selfish a definition—but he must be careful what he states about me, I am a very queer man, and have dreamt some very funny things at one time and another; and as to my imagination, it, probably, I fear, doesn't soar so high in regard to foreign bees as his own, yet it is not given either to him or any one to define its limits on British bees or anything else. He continues, 'We do not certainly call a brown horse black, but why does he' (1) 'call a black bee brown? I consider my own eyesight to be as good as any, but I have yet to see the brown bee spoken of by himself as the British bee.' I certainly did not expect to see this from Mr. Simmins, whose writings are generally so practical, particularly in regard to the management and manipulations of the hive, and I can only account for it by supposing that he either meant this as a joke or he is totally colour-blind, for surely no one with the smallest knowledge of colours will call our native bee 'black.' I spoke of our native

brown bees as 'British,' for do we not all know that every animal, whether beast, bird, or insect, which breeds naturally in this country is called 'British?'— F. Boyes, *Beverley*.

BEE-FLOWERS.

[927.] A valuable shrub for bees, which I think has not been mentioned in the Journal is the Tree Box (Buxus arborescens) and is worthy to be noticed as a fitting companion to that beautiful ornamental shrub Berberis Darwini. Both are excellent for bees, but the tree box, coming into bloom some time before the latter, is, I think, the more valuable. It has been in flower here for more than a week, and has been crowded with bees all day long, whenever the weather would permit them to get to it.—F. Boxes, Beverley, April 18th.

NOTES BY WOODLEIGH.

[928.] Separators.—May I ask if it was the fault of your engraver that the feet of the separators were not shown in the engraving some weeks ago in your columns, or did 'A. E.' intend the strips or small fillets nailed on the inside of sides of crate to take the place of feet and carry the separators between them? I have been in communication with bee-keepers on the same subject.

I have always used thin sheet zinc for separators and cannot see any objection to its use as such. Something has been said about using perforated zinc for separators. I cannot see any advantage there can be in the perforated over the plain, in fact I think there would be a great disadvantage in giving the bees peep-holes at each other while busy at work (it would lead to needless gossiping). Then another asks if excluder zinc will do for separators. I have not used it for such a purpose. Can anyone that has enlighten us as to the plain or corrugated surface of the sealed sections when it has been used?

Pea-Flour.—I find Symington's patent pea-flour the best for artificial pollen, or Brown and Polson's cornflour and the pea-flour mixed; the bees take it with avidity and it is a great saving of bee life. The above flours are both impalpable powders and easily worked up by the bees.

Propolisation.—If the wood bearings for frames are lubricated with black lead, no propolisation will take place and no obnoxious emanations will exude from it as from tallow.

Porous Quilts.—Our theories and practice change almost as quickly as the seasons or the fashions. How short a time ago—vide previous vols. of B.B.J.—leading bee-keepers were advocating porous quilts and covers, now it is impervious American cloth and a resinous composition for hive interiors. Mutatis, &c.

FOUNDATION.—Wanted, some inventors to turn their inventive genius on super foundation-making, and give us a foundation that leaves no thicker midrib when worked out than the bees do in the natural comb, also a good tough strong foundation that will not sag, or break out in the extractor. Could not some textile base be used after the method of Abbott's wooden base foundation? What kind of foundation do our Canadian friends use?

A VARNISH for hives warranted to fill cracks if used as directed. Take two gallons of gas tar, boil for four hours, take from over the fire, add by stirring balf a gallon of turpentine, then boil again for half an hour or cound apply while still het.

so, and apply while still hot.

Wasps.—The erratic specimen of wasp (?) (813) that deposited the eaterpillar in the crevice was not the Vespa vulgaris, but a smaller kind of solitary insect, closely allied to the V.v. in shape and colour, but very different in its habits and actions. I had three of the same kind of insects under observation last summer and I am looking forward to the sequel this coming season.

The bee noticed by Harold Adcock visiting the bobbin

was not the honey-bee, but the solitary bee that generally builds its nest in a small hole in mud walls, &c., and a very wonderful provision of nature in connexion with this kind of bee is that it prepares its nest, then deposits an egg, inserts some food, then another wad of pieces of leaves, then another egg and more food, and so on, yet the last egg deposited, perhaps four or five days after the first, developes and arrives at maturity first.

INVERTIBLE HIVE.—I think the patent invertible hive of the Jones-Heddon type must be getting rather shaky after the rough handling it has received from British beekeepers, considering how slight the material was from which it was constructed, and I shall not be surprised if it follows in the wake of a large majority of its predecessors, whose only chronicle of existence is the archives of the Patent Office. Our thanks are due to Mr. Hooker for the trouble he has taken in enumerating the number of American hives that have been patented. One would judge by results that the Patent Office gets the lion's share of the profits. I should expect, from the advice given to cottagers to invest in cheap Yankee invertible hives by 'Devonshire Dumpling,' that D. D. must of necessity be a townsman who does not know anything of the capabilities of cottage bee-keepers, who has never had opportunities of mixing with them, or knowing how difficult it is to induce them to adopt the modern system, even with hives that have been worked in their own gardens, but to advise cottager Smith to buy a Jones hive, and then tell him that his neighbour Robinson had one last season, and that when his bees had worked out and built the comb to the top bar Robinson turned his hive 'topsy-turvy' for the bees to build the comb to the bottom bar, why, my dear D. D., he would consider you were the inventor escaped from Colney Hatch .-Woodleigh.

QUERIES BY A BEGINNER.

Now, Mr. Editor, please answer these Few simple inquiries about my bees.

Suppose it's winter time, with a deep snow, And a bright sunshine sends light from below,

Tempting the bees to fly forth from their doors, What is the remedy? Suppose it pours,

And the wet penetrates clean through the roofs, Are outside plinths all wrong? What are your proofs?

Suppose, when spring has come, robbing is rife, Would it be well to stand by with a knife

And kill the robber bees? If a queen dies Is it a matter to cause much surprise?

Should tomtits kill the bees, fat toads, or mice? Dear Mr. Editor, what's your advice?

If wax-moths eat the comb what is the cure? Will chalk lines keep off ants? are you quite sure?

As for the moths and ants, why don't the bees Tackle such feeble foes as these with ease?

Should hive have legs or not? square legs or round? Are they not steadier down on the ground?

How many stings shall I have to endure Before I cease to swell? fifty, or more?

What's the subscription I should have to pay To join as a member the B. B. K. A.?

What are the benefits I should derive? Would some one teach me to manage a hive?

And, Mr. Editor, one question more, Which you've not answered yet, am I a bore? ROBERT S. ROUTH.

Will some kind friend, by pen or mouth, Give full replies to Mr. Routh?

Queries.

Our readers will greatly oblige us by answering, as far as their knowledge and observations permit, the Correspondents who seek assistance. Answers should always bear the number and title placed against the query replied to. Any queries unanswered in this way will be answered by the Editor and others.

[929.] Can any reader of the British Bee Journal inform me whether foul brood is known to exist anywhere near Ettington, a village six niles from Stratford-on-Avon, Warwickshire? I have been offered some skeps as a gift, but would not take them if this disease is common in the locality.—E. J. Gibbins, Neath, April 13th, 1887.

Echoes from the Pives.

East Yorkshire.—Since my last report we have had very variable weather, cold frosty nights and snow, as well as a great storm which could not let my hives alone, but blew the tops off two of them, and sent all the coverings into the next parish. As I did not go down until the following evening I fear these two lots have got a nasty chill to their brood. Now we are having a rather long spell of harsh, icy, north-east winds, with strong sunshine, but, being dry, not altogether unfavourable for bees. My own were never looking so forward and well, breeding going on extensively all round; every hive (fifty-eight) in good condition, with fertile queens, all carrying in pollen and water daily. 1 find 1 lb. of peaflour last them nearly an hour to carry in, and 4 or 5 lbs. per day would not satisfy the n, so eager are they for it, showing how largely breeding is going on. At night some of the hives, cold as the weather is, are humming as if it were May, with perspiration issuing from the entranees. I saw the first drone yesterday, April 10th. -F. Boyes,

Muskham.—The weather here has been very severe for the last eight or nine weeks, and there are no signs of a change. Hardly a day since Christmas have bees been able to get an airing, for the days have been dull and cold with easterly winds and severe night frosts. Numbers of stocks have been lost owing to scantiness of spring stores, the cold having been so protracted. I think there will be few May swarms in Notts, as there are no signs of drones yet. I am glad to be able to say I have not seen nor heard of one case in this neighbourhood of that dreadful disease foul brood. I hope that the coming season may be more favourable than the last, and that bee-keepers may have large crops of honey from their 'Jubilee Bees.'—E. C. Walton.

NOTICES TO CORRESPONDENTS & INQUIRERS.

All queries forwarded will be attended to, and those only of personal

interest will be answered in this column.

Letters or queries asking for addresses of manufacturers or correspondents, or where appliances can be purchased, or replies giving such information, can only be inserted as advertisements. The space devoted to letters, queries, and replies, is meant for the general good of beckeepers, and not for advertisements. We wish our Correspondents to bear in mind that, as it is necessary for us to go to press in advance of the date of issue, queries cannot always be replied to in the issue immediately following the receipt of their communication.

E. J. G.—The sample of sugar received is that which is called in the trade 'pieces.' 'Pieces' are the drainings of sugar refineries, and though made to look very nice, they do not have much of the saceharine element in them. They are a far remove from Porto Rico, and other primitive West Indian sugars. The bees will utilise the sugar, no donbt; but the experience of bee-keepers teaches that that sugar is the best which is most beneficial to the bees; and, therefore, Porto Rico and other like sugars are recommended.

Forest of Dean,—Superabundance of Stores.—The bees have consumed the eardy in preference to the sealed honey which from your description, is aphidian. We advise you to extract the outside combs—up to the broodnest—and to return them to the hive. If more food is required, feed slowly on syrup, say in a week's time after extracting. Keep plenty of warm covering over the frames.

W. T. C.—Clustering Outside.—The internal heat of the hive, caused by the excitement of the bees during re-

moval, was the reason of the bees hanging from the alighting-board. If you had raised the skep slightly from the floor-board, after placing it in position, there would have been no 'lying out.' It is probable that a little breakage of comb-honey may have occurred during removal which would increase the heat and excitement. There is no cause for alarm. Judge of the quantity of stores by the weight of the skep, and feed if necessary.

- D. Matier.—I. Smoker.—We scarcely understand what you mean by a 'fumigator.' If you mean for injecting the fumes of salicylic acid into foul-broody hives, we do not think an ordinary smoker could be so used successfully. There are, however, searcely any limits to the invention of the present age. 2. Extractor.—As a general rule, the specific gravity of heather honcy is too great for any extractor thoroughly to relieve the combs of it.
- R. C .- 1. Changing Hives. Transferring colonies to clean hives may be done on any fine day; towards evening when bees have ceased working, is the best time. Let it be done quickly but quietly, removing the central frames of the brood-nest without separating them, and, when all the frames have been transferred, brush out of the old hive on to the top of the frames any bees remaining. The old hive should be displaced by the new one before commencing the operation. 2. Stimulating.—Stimulation may now be commenced.
- A. E. P.—The pieces of combs sent are not affected by foul brood; but portions of the combs are in a very sad condition, and should be at once melted down.
- E. M. L.—The method proposed by you is practicable. The combs being attached to the sides of the hive, the cutting off the tops of the combs will not prejudice the operation. But we would suggest that you should make an artificial swarm by the ordinary method.
- H. W. D.-We are not able to distinguish between the eggs and grubs of fertile workers and those of fertilised queens. The fertile worker lays her eggs sporadically, the queen regularly.
- C. A. J.—Many eggs in one cell.—This frequently happens; but there is nothing to be apprehended from that cause. We should say that your queen is healthy and in good condition.
- JOHN ORR.—Woiblet Embedder.—We are not aware that Mr. Root has described such a tool. The embedder shown in his book is not used hot as you propose, but is made of a hoop of tin with pieces of tin soldered on at distances of about half an inch to one inch apart and is used cold, the wire being pressed into the body of the wax foundation. One reason for thinking a wheel will work quicker is that when the V groove in one of the teeth is once placed on the wire the Woiblet embedder can be run along it without removal, whereas the form you suggest being only a segment of a circle to embed a wire 81 inches long would necessitate its removal several times, as we presume from your sketch you do not propose to make it the length of the wire.

Received from A. F. Hutchings, St. Mary Cray, Kent, his 'Illustrated Price List of Improved Bee-hives and Appliances required in Modern Bee-culture.' Pp. 16. A very useful and compact catalogue. Also some samples of sections recently imported from G. B. Lewis & Co., America.

RECEIVED from Mr. A. D. Woodley, 26 Donnington Road, Reading, Expert of the Berks B.K.A., some samples of a new style of section case. These are made of tin and glass, with a tight-fitting lid which keeps the whole compact. With glass in front and back they are well suited for purposes of exhibition. We consider them to be superior to the ordinary cardboard cases, which are easily damaged by any leakage of honey; but Mr. Woodley's cases can easily be washed and used again. They are durable, cleanly, and neat. They were exhibited at the meeting of the Windsor Branch of the Berks B.K.A. and much appreciated by those present on that occasion.

We have a small quantity of surplus seeds of the Echinops sphærocephalus, or Chapman's Honey Plant, which we should be pleased to distribute amongst bee-keepers who would take an interest in its cultivation. Apply to Editor.

Finest CYPRIAN Queens.

DIRECT by MAIL from CYPRUS to any Address in EUROPE.

From 1st MAY to 30th AUGUST.

For Countries out of Europe add 50 ° to above prices.

All Orders to be accompanied by a Remittance.

My Queens are all very prolific, long-lived, and much larger-bodied, than the majority of those supplied by others, as they are reared naturally, under the swarming impulse, in April, May, and June, from the strongest of my forty colonies of Bees kept in double-walled moveable frame-hives, and all having choice Queens, which produce workers so gentle that they can be handled without smoke, and even without a veil on the face, just as I do myself (see Mr. S. Simmins' statements on page 37 of his work entitled, A New Era in Modern Bec-keeping). This is principally owing to the fact that I have weeded out from my Apiary all such Queens which appeared to be weak or producing troublesome workers. Address—

M. G. DERVISHIAN, Larnaca, CYPRUS. A 2375 For Reference, address Imperial Ottoman Bank, Larnaca.

Sectional view of New Patent Bee Feeder.

Simple, Safe, Clean!

BRITISH BEE-KEEPERS' ASSOCIATION.

Subscriptions for 1887.

We are desired to remind those Members who have not yet paid their subscriptions for the current year that they will confer a great favour upon the Committee by forwarding the same to the Secretary at the earliest possible date. As the Association becomes more dependent every year upon those who are more intimately acquainted with the bee-keeping industry either as manufacturers of appliances or as bee-keepers, it is hoped that all those so connected will give their support to the Association, and make its aims and objects known as much as possible.

It should be borne in mind that entries for the Royal Agricultural Show, to be held at Newcastle, close on May 12th. Application for schedules of prizes should be made as early as possible.

OUTLINES OF BEE-KEEPING FOR BEGINNERS.

(Continued from page 136.)

VI.—Bees Require a Dwelling to Live in.

1. The honey-bee does not like dirt, and it differs from ordinary domesticated animals kept in stalls and stables, by itself attending to the eleanliness of its own dwelling. It gets rid of its dejections outside of its residence, and when in health never soils the inside; it ventilates it and constantly renews the air, so that the newly-stored honey does not become contaminated by foul smells or unwholesome surroundings. A stall always has a bad smell, it is, therefore, not right to speak of a stall of bees (an expression not at all uncommon in some country districts). The dwellings in which bees live and build their combs are called hives.

2. Wind, wet, and cold, are injurious to bees; the hive must, therefore, be well protected against these. A good hive must be warm, have a good covering, and it must be placed in such a position that the keen north-east and the moist south-west winds do not easily find their way into the entrance-hole.

3. Hives are made of different materials and vary in shape. Those formerly in use were called *skeps*; although these are still found, and are extensively used by villagers, modern bee-keepers have adopted wooden boxes, as in every way preferable.

4. Skeps are usually made of straw, and are generally dome-shaped, or circular with flat tops, having a hole in the crown. They are worked on the swarming principle, and have fixed combs. The modern wooden boxes used for hives have even sides, generally at right angles to each other. In them the combs are moveable, and for this reason they are called moveable comb-hives. They offer greater facilities for manipulation than skeps; at the same time they present considerable advantages, and if managed properly, enable the bee-keeper to obtain a very much larger quantity of honey.

5. Besides skeps and moveable comb-hives, there are what are called *Stewarton* hives. These are also of wood and are eight-sided (octagonal). The central combs are moveable, the outer ones being fixed. Stewarton hives are easy of management

and give better results than skeps.

6. Wooden hives should be well made by a good carpenter, who is also a bee-keeper and understands the requirements of bees. Accuracy of workmanship is of the greatest importance, and the simpler the construction, the more easily will the hives be manipulated. The wood used must be well seasoned, dry yellow deal or pine free from loose knots and cracks.

VII.—THE COMB STRUCTURE IN A HIVE.

1. When a swarm is placed in a hive the bees constituting it begin to build combs. These are made of wax, which is secreted by the bees and appears in the shape of small, thin, five-sided scales between the rings on the under-side of the worker's abdomen. The wax is produced from the honey consumed by the bees, of which several pounds are required to yield one pound of wax.

2. During comb-building the bees hang quietly in clusters. They work up the wax-scales with their jaws, and, by adding a liquid (saliva), they knead the wax into a soft paste. Comb-building is commenced at the top and continued downwards, the central division wall or foundation being always begun first. This forms the basis of the cells, which are placed on each side in such a way that the base of one forms portions of the bases of

three on the opposite side. Two rows of such cells with a central division constitute a *comb*, and from this shape the cells fit so closely together that no room is wasted.

3. The cells are usually six-sided, and are not quite level, having a slight inclination upwards in the direction of the openings.

4. Only well-fed bees can make wax and build combs. When bees are queenless or food is scarce

combs are not built.

5. When bees are placed in an empty hive they at first build combs with small cells, called workercells; later, larger cells are constructed, and these are called drone cells. Sometimes the bees change the size of the cells on the same comb, and go from worker to drone, or from drone to worker; they then construct between them irregular-shaped cells, which are called accommodation-cells. The change is usually made in from one to six rows; these cells may be of almost any shape, and have sometimes five or seven sides.

6. Cells intended for brood are of two regular sizes; those in which workers are bred are one-fifth of an inch between the sides, and five of them measure one inch. Comb containing such cells is called worker-comb. Drones are reared in larger cells a quarter of an inch between the sides, four measuring one inch. Such comb is called drone-comb.

7. Brood-combs are of a certain thickness, worker-combs being about seven-eighths of an inch, and drone-combs about one and a quarter inch thick.

8. Both sizes of cells are used for storing honey, and these vary greatly in length. Should these honey cells be afterwards used for brood, they are reduced to the length required.

9. There are sometimes cells of a different shape called queen-cells. These are round, resemble somewhat an acorn, are about an inch in length, and one-third of an inch across. They usually hang with their mouths downwards, and are generally found at the edges of the comb.

10. Queen-cells are constructed of a mixture of wax and pollen, making them porous, and are covered with a number of depressions, which give them greater strength. The walls are thick and much material enters into their composition, which, as soon as the queen is hatched, is used elsewhere, the cell being cut down until it resembles a small acorn-cup.

11. The cappings of brood-cells are porous, and consist of a mixture of wax and pollen, those of honey-cells being made of wax only.

12. If the hives are furnished with strips of comb the bees will continue them down, and they will act as guides. Comb may be constructed parallel to the entrance or at right angles to it, the direction being determined by the guides.

(To be continued.)

W. P. MEADOWS' PATENT EXTRACTORS: THE RAYNOR AND THE GUINEA.

At the first Quarterly Meeting of the British Beckeepers' Association for 1886, held in London April 28th,

the first of these extractors was shown and a short comment made upon them in the *Journal* of May 6th. After a season's trial we again refer to them.

The principle upon which their merit consists is an onter cage of sheet-metal upon which are fastened strips of metal edgeways to form a rest for the wire mesh necessary for the honey-comb to rest upon. These strips edgeways offer no resistance to outflow of honey, at the same time do not allow of the wire hulging, although the wire-netting used is finer than that used in the old form of extractor.

The way they are made also prevents the splashing of honey. The metal revolving cage receives it and carries it into bottom of cylinder, at the same time effectually stops draughts to comb and chill to brood.

The users of these machines signify their approval of them, and the numerous prizes they gained last summer attest their value.

The principle was originally applied to 'The Raynor,' but Mr. Meadows informs us he has adapted it to his Guinea and Little Wonder, and already has sent out a large number of extractors fitted in this way.

USEFUL HINTS.

Weather.—The month of May, the swarming month, is close upon us, with weather still cold and changeable, and but little forage for the bees. A long and trying winter, truly we have passed through, but genial showers and sunny days will soon bring forth our spring flora, and although the time of honey is not yet patience will assuredly gain its reward at last.

READY, AYE READY.—Only let us be ready when the influx arrives—ready in bees, ready in all that appertains to the storage of an ample and bounteous supply of the nectar of the gods.

JUBILEE DESIGNS IN GLASS.—In this year of Jubilee, many will be anxious to hononr our Queen by wonderful devices wrought in comb-honey; and glasses, with designs in comb-foundation deftly arranged, will, no doubt, be the order of the day, and when skilfully completed by the bees will form a great attraction at our principal shows.

QUEEN WASPS are showing themselves in numbers

about the hives, and our garden syringe is daily at work. The bloom on the gooseberry bushes is also a great attraction. Our young people succeeded in taking not a few in butterfly nets, and claimed the stipulated 'penuy per head.' Wasps in abundance towards autumn are undesirable for more reasons than one; and as a man is known by his companions, such likewise is the case with the bee. When seen with wasps, imbibing the sweet juices of the grape, the peach, and the nectarine, the bee, although comparatively innocent, receives the larger share of blame.

FEED is still our cry. The consumption by populous colonies is now great, and the income at present, in many districts, is small. The finest granulated crystal canesugar may be purchased at 2d. per lb.; who, then, would let their bees starve? Consider the importance of having the hives full of bees ready for the good time coming, when we may address the apiarist in the words of the poet:—

'Tityre, tu quod, apium somnos suadente susurro, Ad septum recubas, si placet esto deus.'

A pleasant and god-like occupation, truly.

Syrup may now be given rather thinner in consistency, and, in average weather, a quart weekly will generally suffice to keep a strong colony advancing. Give it warm and at night. Let there be no disturbance of the broodnest further than to add, in case of necessity, an empty comb on its ontside.

This treatment may be continued safely until the middle of May. In earlier districts, with fine weather and fruit trees in bloom, sections, or other supers, will

be required on strong colonies.

SWARMS.—Natural swarms in May will be 'few and far between.' We are intending to place our first on Lee's frames, and hope, and expect, to obtain perfect combs. Swarms in May are generally small, but with fine weather make splendid colonies, filling their hives with brood before the white clover harvest begins.

FOUL BROOD.—We have a word of exhortation on this subject for county experts, whose calling and status in the County Associations open to their inspection almost all apiaries. Surely these men should have a thorough knowledge of apiculture in all its branches, or

how can they advise others?

We hear mutterings of experts who do not know foul brood when they see it-of others, who never disinfect hands or clothes after manipulating foul-broody hives before proceeding to the next apiary; of foul-brood, which had never existed in a district, following in the wake of the expert. We hear that, in consequence of these reports, many apiaries are closed to the expert. And no wonder. One can scarcely imagine a more fertile means of spreading this dread disease than an expert's visit under such circumstances. There is no disease more contagious, and we have well-authenticated cases of its first appearance shortly after experts' visits. We wish to put this very strongly before all experts, who, as a rule, are a most respectable body of men anxious to advance the science of apiculture by all the means at their command.

There certainly ought to be a rule in all County Associations compelling experts, under a penalty, to thoroughly disinfect both hands and clothes after every visit. An outer dress, well saturated with a disinfectant, should be worn during manipulations, and the hands should be repeatedly sprayed with weak carbolic solution, or other disinfectant. An expert should be as careful not to spread foul brood in his district as doctors are to avoid earrying the infection of small-pox or scarlet fever from house to house. If some steps are not taken in this direction 'Othello's occupation will soon be gone.' We are strongly of opinion that this subject demands the careful attention of the General Committee of the central Association, and that it may well be discussed at the quarterly meetings of the county representatives. Until

some steps are taken we advise all experts carefully to disinfect after manipulating, no matter whether foul brood he present or absent. A spray disperser, very effective, strongly made and lasting, which can be applied to any ordinary bottle, is the one commonly used by gardeners under the name of 'Cooper's patent protector.' We have had one in use for five years, and it is still as effective as ever. Its cost is about 1s. 6d. or 2s.

Cypnians.—In our former notice of these bees several points were omitted to which we may now shortly refer. The flight of the queens is stronger and more rapid than that of black queens, and they are rarely lost on the mating flight, owing probably to these qualities. Indeed we do not remember losing a single queen on these excursions. These remarks are true also of queens bred from impurely fecundated mothers, which are usually very fine and large. Cyprians raise numerous queen-cells, more than are desirable according to our ideas, and they do not fill sections so well as other races, many of our I-lb. sections weighing 12 or 13 ounces only, and so strong are their breeding propensities that on one occasion when honey failed, they filled the

sections with broad and queen-cells.

Philology.—Our frater, 'Oxoniensis,' is shocked at the expression 'macaronic solecism,' and evidently feels for the anthor of 'apifuge' in having so awful an 'epithet hurled at his head.' Let us assure him, however, that the gentleman in question has perfectly recovered from the shock, since we had the pleasure of making his acquaintance at the late conversazione held in Jermyn Street, and found him smiling and agreeable, especially while discussing our late tournament, indeed evincing not the slightest symptom of any recent shock to the system! Our nerves certainly were extremely agitated on reading the monster 'galactofuge,' hence the 'overwhelming epithet' 'macaronic,' liuked with 'solecism,' arose to our lips (pen). Mr. Grimshaw assures us that he has not the honour of having coined the word. It is, we believe, in common use by the medical and chemical professions—more shame to them. 'Lactifuge' is, no doubt, the proper term to express the required meaning. As to the soft impeachment that we have been 'engaged in word-competitions,' we must beg to enter a disclaimer, utterly despising, as we do, such modern- Well, we had almost written another 'overwhelmer,' but we re-With 'Oxoniensis' in his remarks on the coining of words we are fully in accord, and they vividly recall to mind the controversy which ensued on the necessity arising for a word to express a message by wire on the discovery of telegraphing by electricity. The battle was between telegram v. telepomp. The late Mr. Shilleto, the noted Cambridge classical 'coach,' maintained that the meaning of the former word was inappropriate, viz., 'a written letter, sent from afar, and suggested that the latter meaning, 'a message from afar,' was the proper word; and although in our opinion he was perfectly right, his ruling was not accepted, the chief objection being that 'telepomp' would be shortened into 'pomp,' as in the case of 'omnibus' into 'bus,' and there might arise mistakes between 'pomp' and 'pump,' notably the 'Aldgate

We are not inclined to break a lance in defence of 'Mel sapit omnia,' which, as we have often wondered, has escaped notice so long. Probably 'sapit' has been credited with bearing the rendering 'flavours,' or 'gives a zest to,' which it certainly will not bear. A Mr. Mason, in a severe critique, published in the Canadian Bec Journal of February 23, upon a former communication to that journal by 'Amateur Expert,' improves upon 'Mel sapit omnia' by writing it 'Mel sanit omnia,' which he translates 'Honey heals everything,' but omis to say how he forms 'sanit' from the Latin verb 'sanare,' seeing there is no other from which it can be derived. But, perhaps, this is the latest American

discovery, or shall we say invention in the classical

A correspondent, in defence of 'Galactofuge,' reminds us that the generally accepted word 'Lactometer' has a Latin and Greek derivation. Here the proper word is 'Galactometer,' which is pure Greek, and no mongrel, being formed after 'barometer,' 'thermometer,' 'hygrometer, and a host of other words. What a pity that 'Scientists' will be so perverse! Our correspondent apparently does not perceive that

> 'Two wrongs don't make a right, Two blacks don't make a white.

Dr. Goodwin, Bishop of Carlisle, in a short biography of Dr. Thompson, the late Cambridge Professor of Greek, and Master of Trinity, relates the following anecdote:-'An inventor of some new contrivance desired to advertise his invention with some new Greek name, after the pattern of the Eureka shirt, the Eucnemida gaiters, and the rest. The Professor of Greek seemed to the inventor the proper person to whom to apply for help in the formation of his new name. Application was made, and, in answer, the Professor expressed himself in this fashion: "My business as Professor of Greek is, to the best of my ability, to keep the language free from impurities. To apply to me for a new Greek word is much the same thing as writing to the Archbishop of Canterbury and asking him to invent a new heresy. If, however," he added, "you must have a new name, take this" , and he then gave a most ingenious Greek compound, with a marvellous number of syllables, and by me quite unrememberable. Professor Selwyn told me the story and repeated the name; I wonder if any record of it exists. It was a rerbum sesquipedale (eighteen inches in length) beyond all mistake.' (Macmillan's Magazine, March, 1887).

Probably the word was of the same class, or similar to

'Aldiborontiphouskiphornihostikos,'

which is not quite eighteen inches long.

We trust our patient readers will pardon this long digression, particularly as we promise not to offend again, at least on any slight provocation.

JOTTINGS BY 'AMATEUR EXPERT.'

'Mel sapit omnia.'

I presume 'Oxoniensis' is not familiar with the motto of the Salters' Company, and its arms consisting of the three hard-boiled eggs. The Salters say, 'Sal sapit omnia,' inferring even such tasteless things as hardboiled eggs. I substitute 'Mel' for 'Sal,' intending that those readers of the B. B. J. that honour me by reading the emanations from my pen should also infer that these 'jottings' required 'savouring' with 'mel' to make them palatable. The reasonings from the classics I must leave some of my scholastic readers to answer. Λ very clever and practical working mechanic assured me in good faith last week that the schoolmasters had committed moral suicide; they had ventured beyond their depth in word-construction and pronunciation and were drowned. Be it so. Practical people that call 'a spade a spade' will suffer no loss.
The quotations from the Gospels of St. Matthew and

St. Mark rightly, in my opinion, give the sense of 'savour;' it was not that Peter 'minded not'—i. e., paid no heed to—the things of God, but that his conduct on that occasion did not 'savour' (to taste of) of

them, hence the epithet, 'adversary. But I was asked the meaning of 'Mel sapit omnia' last week in another quarter; and I, thinking the answer would better suit my questioner, substituted 'sweetens' for 'savours.' Honey sweetens everything. He looked thoughtful for a moment, and as his eyes met mine replied, 'Blowed if it does though, it don't sweeten my old woman none; she always is agoing on about the "blessed bees," the mess, the sugar, and the honey sticking all over the house.' Poor chap! he wants a febrifuge. A guest of mine refused to eat honey at my table recently because he feared it contained stings. assured him I had extracted them all, and so induced him to eat. Gentle reader, is it so with my 'jottings?' Whatever this errant pen runs on to jot, do believe there is no *venom* intended, but just sufficient 'formic acid' to keep the various matters treated on from 'fermenting,' and thus becoming unwholesome.

'L. S.' cannot get people to have the expert. Probably he is a good man, but I would greatly blame the people to take him on trust. I know a duly certified expert that did more harm to his Association in one week than four years have put right. You don't get people caught twice, and what earthly use is it sending bookworms to handle bees?

No, Mr. Boyes. I cannot allow you to back out of your strong remarks (869, page 129) about Carniolan bees, with thanks to me for telling you what you did not wish to learn, and the feeble admission that 'possibly in a good district in the sunny south they may gather enough to keep them through the winter.' On your own showing you have never tried them. I quite agree with your remarks on page 129, as far as they apply to Cypriaus, Syrians, and many strains of so-called Liguriaus (I say so-called, because I believe the Cyprians have been crossed into the Ligurians by some breeders to improve their colour), but to apply the same scathless condemnation to the Carniolans is unwarrantable. Try them in your cold east Yorkshire, and you will find them as hardy as your blacks (?), and, I repeat, they will require some beating as honey-gatherers; and if they hybridize your British (?) you will have no cause to regret it, either for temper, industry, or physique, and if you do not care to try them don't hinder others from doing so. Can't you get your little bird to whisper something as to my being the sixty-ninth cousin to the wife of some one that has some to sell? Shoot that little wretch at your first opportunity.

Gentle readers of the B.B.J. did you ever get a bee-keeper's nightmare? Has it ever been your lot to have a fine lot of bees given you by a friend? And when, with a glowing heart, you have acknowledged the gift by return of post, did you retire to bed—to sleep—perchance to dream—ah, horrid, horrid thought! Foul brood!! That gehenna of all scourges to bee-keepers, have they got it, and is that the reason your friend is so suddenly liberal? To refuse the gift would be to outrage friendship, receive them and so introduce the plague into your own neighbourhood, there to work ruin to your poorer neighbours, whom you love so well (?). Unhappy man that I am! Why did he make me the gift? Is it not better to endure the ills of outraged friendship than to cause your poorer neighbours to suffer loss? To look a gift horse in the mouth would be rudeness indeed; I must accept him, yes! And resort to phenol, thymol, salicylic, or carbolic, or, peradventure, burn them instantly on arrival without unpacking! Ye spirits of the night, keeping guard over my would-be slumbers, will you not dispel this phantom that banishes sleep from this throbbing brain? Tell me, is there foul brood to be found within six miles of the birth-place of the Bard? Happy thought! I will ask the readers of the B. B. J.!! How refreshing now does gentle sleep steal over these eyelids weary! To awake! Ah, there is the rub! To sleep and then to awake, write a letter to the Editor—the thought is charming!! why did it not occur to me before? And so, after two hours' fitful tossings, he sleeps well.—AMATEUR EXPERT.

A correspondent informs us that 'recently Mr. R. T. Andrews, Hon. Secretary of the Hertford District of the Herts B. K. A., lectured to the Herts Natural History Society on "Bees," and he out-Cheshired Mr. Cheshire by exhibiting some twenty diagrams of various parts of the bee, some of which were enlarged 8000 diameters and upwards.

BRITISH BEE-KEEPERS' ASSOCIATION.

Meeting of the Committee held at 105 Jermyn Street, on Wednesday, April 20th. Present: T. W. Cowan (in the chair), Hon, and Rev. H. Bligh, Rev. F. S. Sclater. Rev. F. G. Jenyns, Rev. G. Raynor. Captain Bush, Captain Campbell, J. M. Hooker, W. O'B. Glennie (treasurer), and the Secretary. Letters were read from the Rev. F. T. Scott, Dr. Bartrum, and Dr. Walker regretting their inability to be present.

The minutes of the last Committee meeting were read

and confirmed.

The Finance Committee presented their report recommending the payment of certain bills. The same were examined and ordered to be paid. In consideration of the balance in the Treasurer's hands being at a low ebb it was hoped that members in arrear with their subscriptions would kindly pay the same as early as possible.

A letter was read from Shropshire soliciting support to a proposed exhibition of honey, &c., at the Shrewsbury Horticultural Show to be held in August next, with the view of resuscitating the Shropshire Association. The application was referred to the County Associations Sub-Committee with power to make such arrangements

as might seem to them advisable.

The Exhibition Sub-Committee presented their report in regard to a code of rules for the management of County Shows in accordance with the resolution passed at the Annual General Meeting. These rules having been considered, they were referred to the meeting of county representatives for further consideration.

MEETING OF COUNTY REPRESENTATIVES.

Present: The Rev. E. Clay and R. King, Bucks; Mrs. Curry and W. B. Webster, Berks; Mr. Graham and W. Rayner, Middlesex; Rev. W. E. Burkitt, Wilts; C. H. Haynes, Worcestershire; W. L. McClure, Lancashire and Cheshire.

The minutes of the last Quarterly Conference were

read and confirmed.

The resolution relating to the preparation of a code of rules for the management of County Shows having been read by the Secretary, these rules were considered seriatim, and various suggestions made thereon, more especially in regard to the following points:—

(1.) That the rules should provide that all honey exhibited should have been gathered by bees which were the property of the exhibitor at the time the honey

was gathered.

(2.) That the paper edging covering the edges of

glazed sections should be white in colour.

(3.) In regard to the exhibition of run honey in white flint glass jars, Mr. McClure contended that this ought not to be insisted upon, as the expense of such jars placed an obstacle in the way of cottagers exhibiting honey.

Various other suggestions were made, and the rules were referred to the Committee for further consideration, to be ultimately published in the *British Bee Journal*.

It was pointed out that the rules would in no wise be compulsory, but were intended as a guide for the drawing up of schedules.

The second Quarterly Conversazione of the present year was held on Wednesday, April 20th, at 6 p.m., in the Board Room of the Royal Society for the Prevention of Cruelty to Animals, 105 Jermyn Street, when amongst the numerous audience of ladies and gentlemen were Mr. Cowan, the Rev. F. G. Jenyns, Mr. Hooker, the Rev. G. Raynor, Mr. Glennie, Captain Campbell, the Hon. and Rev. Henry Bligh, the Rev. W. E. Burkitt, the Rev. E. K. Clay, Mr. Grimshaw, Mr. McClure, Mr. Baldwin, Mr. Graham, Mr. Rayner, Mr. Webster, and Mr. Leigh.

Mr. T. W. Cowan presided, and in opening the proceedings, said that it was usual at their meetings to exhibit

new inventious and implements relative to bee-keeping, and to intro luce debateable subjects for discussion. He therefore invited any one present to lay before the meeting any matter in relation to bees or bee-keeping which he thought deserved consideration.

The Rev. E. K. Clay said that a farmer in his district complained that bees had destroyed his roses; also that, owing to the constant extraction of honey by the bees from white clover that plant was rendered useless to graze sheep upon, because the bees had robbed it of all nutritive power. *Prima facie* there appeared to be some force in the farmer's contention regarding the clover, but he would like to hear the opinions of persons better acquainted with the subject than himself.

Mr. Rayner said that the bees came to the flowers to fertilise them, after which the latter soon began to droop and fade, because the part they had played in life was

accomplished.

Mr. Webster thought it was a provision of nature that the flowers contained nectar in order to induce the bees to fertilise them. If there was no necessity to get the bee to the flower the nectar would not be there. When the flower fades it turns to seed.

Mr. Baldwin said if the nectar were not present it was a question whether any seed would be got from the flowers. He had never seen bees on roses except the wild rose. He had often wished those flowers contained

something for the bees.

Mr. Graham said that a friend of his had told him that the flowers would be preserved much longer if the whole of the pollen-masses were to be nipped off the blooms, which would continue to produce honey. He had tried the experiment with success, the blooms lasting five days, while in other cases they faded in six hours.

Mr. Grimshaw agreed that the roses were not destroyed by the honey bee. It was a mistake to suppose that the value of the clover was deteriorated by the visits of the bee. The contrary was the fact. As soon as the saccharine matter of the plant stopped flowing the seed increased, and was converted by a chemical process within the cells of the plant into nitrogenous matter. Thus the value of the clover was increased, and the weight of it per acre was considerably greater when bees were kept in the neighbourhood than in districts where they were absent.

The Chairman said that the question before the meeting had been thoroughly discussed in America; where it was generally the opinion that clover was improved by the visits of the bee. Mr. Clay could tell his friend the farmer that the small quantity of honey the bee took amounted to nothing; because in any case it would be evaporated before the clover was made into hay. The clover contained starch in the plant itself capable of being converted into sugar in greater quantity than the small portion of secreted nectar, which was evaporated. Fertilisation of flowers was not the only object for the presence of nectar, although that was one of them. The chief object of the nectar in the plant was to nourish the seed, or particular parts of plants. Nectar would be found secreted some time after the plant had been fertilised by the bee, and until the ovary had been developed to a certain extent. Then it ceased, because there was no longer any need of special local nourishment. There was no doubt that the nectar did attract the bees, and was to some extent there for the purpose of inducing them to fertilise flowers; but there were many plants which did not secrete nectar at all, and yet were visited by bees, and there were many which secreted nectar, though this did not in any way assist in fer-

The Rev. Mr. Jenyns, speaking as a rose-grower, said he never saw a bee upon the roses; and he felt quite sure that the bees could not be blamed for destroying those

A gentleman whose name did not transpire said he

thought the bees very seldom went to apple-trees. They favoured pear and peach trees, but very seldom apple-

Mr. Baldwin thought a great deal of honey was obtained from apple-blossom, at least that was his experience.

Mr. Webster endorsed this view, saying that he knew a gentleman who boasted of his success in growing

apples, which he attributed to the bees.

In reply to a gentleman who asked whether the fact that the blossom died off rapidly after the visits of bees was an advantage or not, the Chairman said that after the fertilisation had been accomplished, the object of the flower had been attained, and there was no longer any need for it.

The Rev. G. Raynor said his part of the country was noted for red clover. Some years ago he had about a score hives of Italian bees, and during one wet summer, the second crop of red clover, which was generally allowed to stand for seed, failed almost entirely throughout the country to yield any seed at all. The one exception to this was a farmer, whose farm was about half a mile from his (the speaker's) apiary, who succeeded in obtaining a good crop of seed, which he (the farmer) attributed entirely to the presence of yellow

The Rev. Mr. Clay said that in Buckinghamshire, where he lived, the hills were covered with box-trees, and he thought a great deal of early honey was derived therefrom, as the bees seemed very busy round those blooms.

Mr. Rayner said he had noticed the bees amongst the crocuses during the early spring-time. Those flowers very soon went to pieces after the visits of the bees.

The Rev. F. G. Jenyns, the Chairman, and Mr. Baldwin thought that a very small quantity of honey was obtained

from the box-tree, which supplied only pollen.

Mr. Grimshaw said a sure test of the presence of honey in the blooms was the odour which could be detected from a mass of them. When a distinct perfume was conveyed to the nostrils, either agreeable or otherwise, as in the case of mignonette or clover, there was no doubt honey to be found in the blossom, and that perfume was afterwards conveyed to the honey produced by the bee. He was inclined to the belief that box did not yield any honey at all, and he thought that the only odour it gave off was from the essential oil of the leaves; or it might be that pollen grains bursting on the sensitive parts inside the nostrils produced the impression referred to by Mr. Clay.

Mr. Webster said that very little honey was obtained from the willow, yet that tree emitted a pleasant odour.

Mr. Grimshaw would like to know if it was a debateable point whether the object of the nectar in the flower was not principally to tempt the visits of insects. He had understood the Chairman to dispute this, and he respectfully asked on whose authority the Chairman propounded an opinion at variance with the generally accepted view.

The Chairman said he knew perfectly well the generally accepted idea, namely, that the object of the nectar in the flower was to promote the fertilisation of the plant by insects. Darwin, Müller, and others, upheld that view, and he admitted that in many flowers it was the case; but the fact that an immense number of plants did not require insects at all for their fertilisation had induced another set of thinkers to believe that the nectur must be there for some other purpose. Gaston Bonnier and others had made many observations and experiments; and were of opinion that the primary object of the nectur was the nourishment of particular portions of the plant, and not fertilisation. That school of thought, amongst which he (the Chairman) was one from observation and experiment, had likewise come to the conclusion that in plants which were originally in-

tended to be self fertilised, the bees had induced an irritation by their constant visits until the incessant scratching of the plant bad caused a large quantity of nectar to flow, and have made the plant dependent upon insects for fertilisation. For instance, in Scrophularia nectar was secreted in abundance after the flower had been fertilised and the stamens and stigma had withered, but it served here for the nourishment of the ovary, and when it was no longer needed for this purpose the secretion ceased. There was no doubt that the constant irritation had produced diversity in the flowers. Now some flowers had arrived at a condition that they could not do without insect fertilisation, but he believed that they were not so originally. He admitted that the point was debateable, inasmuch as some of the great men referred to had differed in their conclusions on the subject; and that as many examples could be brought forward to show that fertilisation by insects was not necessary as the contrary.

Mr. Grimshaw thanked the Chairman for his able and

lucid statement.

The Chairman (T. W. Cowan) said: -- There is an important question I should like to bring before the meeting, and upon which a very interesting discussion might be started. It has reference to the food of the queen-larva (royal jelly), the food of the other larvæ, and also with respect to the digestion of such food. I am now in a position to give some recent investigations which will, I think, clear up those points conclusively. We have been taught for some time that the food which is given to the worker and other larvæ is partly digested in the chylestomach of the worker-bee; for this digestion, and the providing of this food, the young bees act as nurses. Dufour was one of those who taught this, although Swammerdam alluded to it before; and we have always accepted the idea that the larvæ were fed with this semi-digested food. Leuckart was also a partisan of this theory. However, when the glands were discovered, Leuckart thought he was not quite satisfied with this theory of semi-digestion, and he suggested that the larvæ were fed with a secretion from the different glands. In the honey-bee there are four pairs of glands; three pairs in the head, that is, two pairs in the upper part, and one pair in the jaws, and one pair in the thorax. Leuckart supposed that these glands furnished the food for the larvæ as well as the food for the queens. Schiemenz, who was a pupil of Leuckart, was induced to take up and investigate the matter thoroughly. He did so, with instructions from Leuckart to examine specially the functions of these glands in relation to the food, and he published the result of his researches in 1883. I have his work here with all the drawings, if anyone present likes to look at it. He went into the subject very fully indeed, and it is the most complete description of the glands we have. He came to the conclusion that the food was a secretion produced from the glands. For some years since 1854 Schönfeld has been at work likewise on this subject. He described the digestive system of the honey-bee particularly in the Bienenzeitung and his discoveries from 1854 to 1883. Below the honey mouth (Magenmund) there is a neck which connects the honey-stomach with the chyle-stomach, and from this mouth into the chylestomach there is a prolongation through which the honey and pollen passes from the honcy-stomach into the chylestomach; and Schönfeld, by experiments and microscopical examination, showed that this internal prolongation could be turned inside out or inverted so that the bee could disgorge the digested food from its stomach by way of the esophagus into the cells. These alleged discoveries were thought to be very singular by Leuckart, Fischer, Vogel, Dzierzon, and others, but they continued to insist that the food of the bee was a secretion; some were going so far as to call it Milchsaft, or milk food. Leuckart says that the food of the larvæ of the queen,

workers, and drones, is exactly the same. But Leuckart, in 1858, discovered that the food of the larvæ of workerbees was subject to some variation, that it was not always the same during the whole of its larval existence. For the first three days the food was liquid, and appeared like a secretion. After that pollen and honey were added to it, which could be detected by the microscope. The queen-larva, on the contrary, was fed with the same food throughout its larval existence, that is, from the very first day of the larva leaving the egg to the day it was sealed up; and he said it was owing to this that the queen was produced instead of a worker. The weaning took place on the third day, and it was exactly at this time that the ovaries began to make their appearance in the female bee, and by changing the food in the case of a worker this development was arrested and a worker produced, whereas by continuing the same food a queen was produced. The same thing took place with regard to the drone, except that instead of three days the drone was fed on the same food for five days. We have always hitherto been led to believe that this food was alike, at any rate during the first three days, and that the greater abundance given to the queen-larva produced the development more rapidly. Dr. A. de Planta has been at work for two years in trying to settle the ques-tion by analysing this food, and has had considerable difficulty in carrying out his investigations. Some idea may be formed of the magnitude of the work he has been engaged on when I say that he has had to operate upon I20 queen-cells, 4000 drone-cells, and 10,000 workercells. I believe only one chemical analysis of the food had been made prior to this, namely, by Schlossberger in 1871. He took all the food he could get hold of, put it together and analysed it on the supposition that the food was the same all through. Dr. Planta was not satisfied with that, and wished to settle the point by analysing the different foods separately, and his chemical experiments have confirmed step by step the observations of Schönfeld, and have shown him to be right. Dr. Planta analysed the substances contained in the queencells, worker-cells, and drone-cells, and the result of these investigations showed, as regards the different ingredients of the different foods, the following proportions:

> Albumen46.5 per cent for queens. 50.16 , workers workers. " 39.91 drones. ,, Fatty Matters...12 62 per cent for queens. 6.84 workers. ,, 7.85drones 22 2 2 Sugar17:90 per cent for queens. 27.65workers. ,, 1.17drones.

The above tables refer only to dried food. As regards the water contained in each food there is not a very great difference. The proportions are as follows:—

> 66.64 per cent for queens. 71.09workers. drones.

These figures show that the food of the queen contains less water than that of the drones or workers; and I dare say all of you know that the food in a queen-cell is much stiffer in substance, and is able to stick to the top of the queen-cell hanging down and to support the grub. With regard to albumen, you see the worker stands at the head, whilst in respect to fatty matter the queen is first, and the drones and workers in nearly equal proportions. In regard to sugar the workers are first, then comes the queen, and the drones have very little indeed. Drones are the fewest in the hive, and I think we must not grudge them the small quantity of honey they take, seeing that they get so little sugar during their larval existence. The figures I have given may not convey much to you, but with regard to richness of the food I may tell you that in 100 queen-cells there are 356 times more dry nutritive sub-

stances than there are in 100 drone-cells, or 232 times more than in 100 worker-cells. Then Dr. Planta tried another experiment, namely, in order to judge upon an equal basis he compared the dry substance in 100 grammes of fresh food. In this he found that it contained 4.92 grammes more of dry nutritive substance than 100 drone-cells, and 3:26 grammes more than those of workers. Testing in every way the food of the queen, there can be no doubt that it is the richest and hest from the commencement. Now, if the food were a secretion similar to milk, it would always be the same, or at least it would vary to a very trifling extent; but as it varies as greatly as Dr. Planta has shown, and has chemically proved to be different in its composition, there can be no doubt that it is a digested food elaborated in their chyle-stomach, and that the bies at will vary the ingredients thereof to suit their particular purpose. They can voluntarily add the necessary ingredients, such as pollen, honey, and nectar, more or less diluted with water. So far as can be ascertained there do not appear to be any particular bees set apart for the purpose of feeding particular grubs, but that up to a certain age the feeding capacity is the same in all cases. We suppose that the bees must have the voluntary power of supplying one kind of food or the other as may be wanted. This subject is a very important one, because upon it to a great extent is based the raising of queens. The question naturally arises, Are queens that are raised by natural means as good or better than queens raised artificially? Now, I always maintained, and I think I have good reason for maintaining, that queens should be raised from eggs, because they get the better food from the very first day when the eggs hatch. The analysis of Dr. Planta and the conclusions he comes to go a great way in favour of that theory. Queens must be better if raised on the best food from the commencement. I have known queens started on larvæ four days old. If a queen-cell is started after the fourth day there has been one day in which the development of the ovaries has been arrested, and she can never make a good queen. Also microscopically Dr. Planta has been able to show that the worker larvæ receive this digested food for the first three days, and after that pollen and honey; drone larve are reared after the fifth day; while the royal food is always a chyle food, and never has either pellen or water mixed with it .. I think I have now placed this matter before you as fully as I am able to do. It appears to me that we may now look upon this question as decided, namely, that the food is produced in the chyle-stomach of the bee, and is not a secretion. I do not wish it to be understood that the secretion of the glands has nothing to do with the food, because Schönfeld, Holtz, and others admit that the secretions from the glands are added to the chyle food, but are not the actual food itself, which consists of digested pollen and honey. The results of the investigations referred to will be published in Germany in about a fortnight's time, and I hope then to be able to say something more on the subject in the columns of the Bee Journal.

Mr. Rayner and the Rev. G. Raynor agreed that queens raised from eggs in the natural way were better than those raised from larvæ four days old.

Mr. Webster said that he had twenty or thirty queens raised artificially on Alley's system, and he could not detect any difference between them and those raised in the ordinary way.

Mr. Baldwin and Mr. Webster discouraged the raising

of queens in small colonies.

Mr. Grimshaw asked whether if the worker bees in feeding the larvæ mix their proportions in some injudicious quantities, the result would be that a fertile worker would be produced.

The Chairman said it was supposed that the workers who became fertile had received an extra large proportion of rich food. Instead of being weaned at the proper time, the rich food had been continued to them beyond that period. If a worker were fed thus for four days the organs would have one day's development. In an ordinary worker they were stopped on the third day.

After a few words from Mr. Rayner to the same effect, Mr. Webster asked whether the bees committed any depredations on fruit. He thought peaches suffered from

their attacks.

The Chairman said he thought bees would not attack peaches or grapes until after wasps bad penetrated the skin thereof and made a hole through which the juice could be sucked.

Mr. Webster was under the impression he bad seen bees go to sound fruit, make a hole, and suck juice therefrom, and this opinion was confirmed by a gardener he

The Rev. G. Raynor thought there must have been some wound in the fruit not noticeable. Perhaps the fruit was dead ripe, and the juices were oozing through the skin, in which ease the visits of the bees were accounted for. Bees had not the power to penetrate the skin of fruit.

Mr. Graham and Captain Campbell agreed with Mr. Raynor, and pointed out that the mandibles of wasps were much larger and more powerful than those of bees.

The Chairman said that the only fruit the bee could pierce was the raspberry, which was very thin-skinned.

The Chairman exhibited some section boxes prepared by Mr. D. A. Woodley for sale and exhibition purposes. Each one consisted of a frame-work of tin, with three sides turned up at the edges. Into that frame work the section with side glasses was placed, the whole being covered with a little cap, there being a margin of some width at the sides. He thought it a neat way of glazing and sending sections about; the price of them was not stated.

Mr. James Lee explained and exhibited a new system of hive-making, the principal feature of which appeared to be the ready, novel, and convenient way of putting together and taking to pieces the frames and sections, which were intended to be filled up with foundation, leaving no passage at the bottom.

The appliances were examined, and commented on at some length by several of the audience, the general opinion being favourable to Mr. Lee's exhibits, the Rev. G. Raynor and the Chairman endorsing that view

Mr. Hooker exhibited a super crate, for which he claimed some advantages. The bees could travel from end to end between the sections, and round the outside of them. The sections could also be got at and removed

by an instantaneous method.

Messrs. Abbott showed some useful American hives and frames, the principal merit of which was their cheapness, the price being 7.8. 6d. in the flat and 9s. 6d. made up. They also exhibited a novelty entitled a 'Jubike embedder,' made out of a clothes peg, and sold by the trade for 11d. This article was not manufactured nor recommended by Messrs, Abbott, but merely laid before the audience as a specimen of the inferior workmanship put in the market at the present time. An opal jar price 12d., an American uncapping knife, price 1s. 6d., and a small phial of Grimshaw's apifuge (a preventivé of bee-stings) were also exhibited by the same firm.

Samples of section crates with queen-excluders between each frame, specimens of simplex glazing, and improved drone-trap for preventing swarming, were exhibited on behalf of Mr. W. P. Meadows.

The Chairman showed the Woiblet Spur Embeddor, and produced two photographs of Forsay's apiaries in Switzerland, which he was sure would be interesting to all who were acquainted with the works of François Huber. One of the photographs showed the identical house in which Huber lived, which was now occupied by a large bee-keeper, who kept about 200 hives, and had not had a natural swarm for years. The second

photograph showed another apiary belonging to the same gentleman, and devoted entirely to queen-raising. Only Italian bees were kept at the latter apiary, which was five miles distant from the other one. It was pleasing to know that fifty years after Huber's death an enthusiastic bee-keeper lived on the spot where that great man had made all his observations. His (Huber's) grandson was a personal friend of the chairman, whom he called on in Lausanne and presented with a photograph of his grandfather taken from an original miniature.

Mr. Lee exhibited a portable box, provided with leather hinges, and which could be taken to pieces and folded up. It was designed for carrying sections with safety.

Mr. Baldwin moved and Mr. Graham seconded a vote of thanks to the Chairman, which was briefly acknowledged, and the meeting was brought to a close.

Correspondence.

The Editor does not hold himself responsible for the opinions expressed by his correspondents. No attention will be taken of anonymous communications, and correspondents are requested to write on one side of the paper only, and give their real names and addresses, not necessarily for publication, but as a guarantee of good faith. Illustrations should be diarn on separate pieces of paper.

Communications relating to the literary department, reports of Associations, Shows, Meetings, Echoes, Queries, Books for Review, &c., must be addressed only to 'The Editor of the 'British Bee Journal,' c/o Messrs. Strangeways and Sons, Tower Street, Upper St. Martin's Lane, London, W.C.' All business communications relating to Advertisements, &c., must be addressed to Mr. J. Huckle, Kiny's Langley, Herts (see 2nd page of Advertisements).

**In order to facilitate reference, Correspondents, when speaking of any letter or query previously inserted, will oblige by mentioning the number of the letter, as well as the page on which it appears.

THE NEW RACES, ETC.

[930.] Your correspondent (926) appears unwilling to admit that his fancy in regard to the colour of the British bee is an error, but nevertheless he will find few agree with himself on that point. I do know of one or two who have endeavoured to draw a line between what they were pleased to call black and brown bees; but such persons have generally been obliged to admit that there was really no such distinction when a little common sense was brought to bear upon the subject.

In his former letter the same correspondent expressed his opinion that we had long since heard the last of Cyprians, &c., but now he mentions Messrs. Raynor and Cowan as giving their 'last' years ago. Now, does he consider that both of these gentlemen have a decided preference for Cyprians? Why, then, does he make such contradictory statements—and how does be measure time? Does he suppose that even a decade of years is sufficient to establish the merits or demerits of any variety? Surely no shorter time can be allowed for a thorough and general trial. Prejudice never can be overcome, but many of the difficulties arrayed against those who introduce anything new can and will be overcome with regard to the new races of bees.

The survival of the littest! Oh, yes! of course the peculiar colour of the natives in your correspondent's own district must have something to do with their other remarkable qualities. He may be possessed of bees thus selected, shall we say, by Nature, or by the bee-keepers' own happy-go-lucky style of the let-em-alone policy? Really, I have something yet to learn, even in the matter of breeding, though I must confess I had been under the impression that practical bee-keepers were taking this matter of selection into their own hands, and, too, were doing it just a little bit better than Nature unguided.

Well, friend Boyes, suppose you have the survival of the fittest, you have but the best of one race only, and I agree with you a good sort at that; but you are not going to sit down and be satisfied when a little persuasion will convince you that there are better bees of

another sort, and you do not need to be told that even a combination imparts more vigour and brings more profit from the stock of whatever kind you may name. you be content to stay when but half-way up the ladder,

and say you have done? I think not,

And why that insinuation as to my impartiality? How much better had you come straight to the point, and have said out what you mean. Of course, I know full well that those who have no charity towards their neighbour will say as you insinuate. Now, let me speak plainly. My advertisements are in because it is the season for so advertising. My articles on bees are given now because I always do my best to give statements just when they will be appreciated, and I cannot conceive any better time than the present for explaining what I have myself gleaned from an extensive experience with the varieties of bres under consideration. What I have found to be of value in comexion therewith has been appreciated by myself, and if others wish to take advantage of such statements and to make a trial for themselves, the whole season lies before them, and they may get their queens from whom they will.

Mr. Boyes must consider that there are others beside myself who are in the trade; but why must one's statements be all for 'self?' Does he so lose faith in human nature that he cannot conceive a man giving an honest opinion? Even in trade, is it all for self? Far from it. First there is the deeply implanted instinct of selfpreservation—a man must work or die; and in working he labours for the good of all; each depends upon the other, and the whole community forms one vast 'mutual benefit 'society. Friends, may we have heard the last of such insinuations, which destroy all good feeling and disgrace the pages of the Journal, while forming no part of, but being one of the greatest hindrances to, a full and

fair discussion.—S. Simmins.

DE QUIBUSDAM.

[931.] It is some time since I found leisure to write under this heading, but as 'Oxoniensis' has touched a subject closely allied to 'Nomenclature' on which I once addressed you, let me follow him. Certainly it is difficult to assign a satisfactory meaning to mel sapit omnia, or rather to see how the combination of words can be used with any appropriateness. I feel that it would be rather straying away from the subject of bee-keeping if I said all I intended to with respect to the classical uses of the word sapere which 'Oxoniensis' quotes, but I should just like to suggest whether he is not a little inconsistent in his statements. In the first place, he says that sapere, connected with the Greek $\sigma a\phi \dot{\eta}^{c}$, means 'to taste 'or 'to have a taste or flavour of 'a thing, while afterwards he gives 'to be wise,' &c. as the chief and ordinary meaning. I accept the former, though the connexion with $\sigma a\phi \dot{\eta} c$ (clear or manifest) is not quite clear to me. I daresay 'Oxoniensis' is aware of the late use of the word in the sense of having an agreeable flavour, or of being pleasant to the mind. Like many Latin words its meaning seems to have wandered curiously to and fro between neuter to active, but the conclusion arrived at must I fear (for 'A. E.'s' sake) be accepted that mel sapit omnia will not stand criticism.

Though no doubt 'A. E.' will be the best exponent of his own meaning, it has always struck me that he did not mean to convey that 'honey had a taste' of anything, but that it yave a flavour, that an agreeable one to whatever it was used with. But it must be confessed that these qualifications are absolutely not conveyed by the words themselves.

By all means let us be correct in our mottoes and in our nomenclature, and with respect to the latter I should like to ask whether a hive intended to be turned topsyturvy is correctly named 'invertible,' as one able to be inverted? I am sorry I have not the 'Imperial,' but I

like the word less every time I see it. Verbal criticism is not the most agreeable occupation, but the word has to me an unacceptible, not to say an objectionible appearauce, and I do think that the use of the i instead of a is at least debateible, and if the spelling is wrong I hope it is even yet amendible.

l am glad that suggestions have been made for judging. This is practical; but rules as to colour and granulation, for example, must vary with localities. I should like to say more on this subject at a future time than you will bear with now. As I wrote a year ago on 'Croaking,' I may just say that when I heard it there was at any rate no American cloth on the hive. The tree box which Mr. Boyes mentions is certainly much frequented by bees in the spring, but its odour in passing is most offensive, and, knowing what privet is capable of, I am thankful that it does not bloom in the summer. I know of no one in these parts who is yet prepared to turn his frames or his sections upside down. (What a crash if we were treated so!) I, for one, am quite satisfied with present results and have no belief that the method will be found successful. Nor do I think these accurately designed bee-spaces can be maintained. Frames in the body hive will vary with the weight of honey, and so will the carriers of sections, whether metal or wood, and I mean to keep my sections together with springs, quickly set and quickly withdrawn, till screws with their objectionable projecting heads have become things of the past.

One word more. What a revolution from the oneway section sent me in mistake last year to that of fourway now advertised! I shall not be surprised if these cause trouble, giving less control over the bees when shifting and removing, encouraging more propolisation and sometimes inducing the construction of comb attach-

ments. We shall see. C. R. S.

NOMENCLATURE.

[932.] 'To your tents, O Israel.' To your dictionary, O erudite 'Oxoniensis.'

Our sapient critic confesses to have been right glad of his 'Imperial' at his side, and thinks he has scored two imperial p'ints in his pseudo-exhaustive criticism by managing, through its aid, to comprehend the meaning of 'macaronic solecism.' In order that he may look up 'all the fuges,' I will refer him to a lexicon by one Webster, Ed. 1836 (coch. amp. ter in die.)

The village lads here frequently capture a kind of bee which they call 'double stenged.' I think we have got such an one in 'Oxoniensis,' for his shaft (917) is split like that of our own worker-bee, and dug in somewhat at random, one half for me and the better half for 'Amateur Expert' (I hope his better half will give him, 'A. E.,' the moral support this time). I have but to deal with dart No. 1. I laid a trap and another fell into it. In one of the early lessons of manhood we were taught to be cautious, therefore, 'Oxoniensis,' when he attempts trenchant criticism, should read carefully and quote accurately before charging me with 'inventing another term Galactofuge,' and that 'he (myself) must have felt as guilty as if he had committed the seven deadly sins at one time. He says also that I should feel nervous with such a macaronic solecism hurled at my head; and, again, 'that the author of this overwhelming epithet [Galactofuge] has evidently been engaging in the word-competitions that have been so popular of late.'* Here comes the pit into which our 'Ox' has fallen. I did not invent the word Galactofuge, it is a common medical and dictionary term, as are Galactometer, Galaxy, Galactagogue, Galactia, Galactin, Galactirrhea, Galactocele, Galactites: it is as significant and common in its proper place as tonic,

^{*} Sec 'Useful Hints' on this, p. 181. The overwhelming epithet is 'macaronic solecism,' not 'galactofuge.'-ED.

diaphoretic, or purgative. Thus do I consign my critic, 'O.,' to the purgatory of etymological investigation; a further course of 'Imperial' will do good.—R. A. II. GRIMSHAW, Cray Hill, Horsforth, near Leeds, April 22nd

MEL ET SAL.

[933.] Evidently of late a spirit of fastidious hypercriticism has appeared in the pages of the B.B.J., which has resulted in the edification of a few, but which, I am afraid, has proved a bewilderment to the majority of your readers. The last aspect of this spirit has shown itself in an onslaught on the motto adopted by your interesting correspondent, the 'Amateur Expert.' 'Oxoniensis,' clad in the panoply of classicism, has run full tilt on our friend, who, though perhaps temporarily recoiling under the first fierce shock, will, I feel sure, speedily recover and be found with his front to the foe, with his banner bravely flaunting in the breeze, bearing the now familiar motto, Mel sant omnia, as brightly legible as ever. 'Oxoniensis' must feel much refreshed after his lengthened flight. I have found it very interesting to follow him in his gyrations. He has passed from sapere active to sapere neuter. He has pointed us to a rather dubious derivation, and has also directed us to a very pleasant compound. He has loitered in Tusculum, and tarried in Brundusium. He has interviewed rhetorician and poets. He has visited writers sacred and writers profane; and the result has been that the ground he has alighted upon is soft and uncertain. Within the narrow canons of criticism the deductions of 'Oxoniensis' may be entertained. But the limits of the lines drawn by classical writers are sometimes rigid and constrained. Could not 'Oxoniensis' (Almā Matre favente) widen his circle and extend his horizon? Latin need not necessarily be confined to classical writers: there was a Latin literature after they had passed from the scene. There is Latin patristic, there is Latin mediæval, there is Latin heraldic, and Latin is intimately connected with various sciences in recent times. Evidently Mel sapit omnia is a modification of Sal sapit omnia, which, though of post-classical origin, is an old and world-wide proverb, and is best known as the motto of an august and respectable City Company. 'A. E.' is not isolated: the contention does not only rest with him. Salt savours all things; and as this is true of the wider world, so Mel may be said to be the great inspiring power of the more limited bee-keeping world. Mel is the end-all and be-all of the industry and activity of the honey bee. Mel is the bright goal in prospect of all bee-keepers. Mel, we may safely say, has ever been that which has permeated and leavened the writings of 'A. E.'; and I trust that all that those engaged in beekeeping may say and write, do and think, will ever be savoured with Sal and sweetened with Mel.—T. P. ATTICUS.

MEL SAPIT OMNIA.

[934.] The motto of the Salters' Company (vide their hall in Cannon Street) is Sal sapit omnia, which I have always taken to mean 'Salt seasons all things.' Our triend 'A. E.' in using the modification Mel sapit omnia, intends, I suppose, to convey that his writings are all seasoned or flavoured with honey. I am curious to see the replies to 'Oxomensis.'—F. Lyon.

[922] Foul Brood.—From the applications for Cheshire cure, I could take a map of the United Kingdom and colour in the districts most affected by foul brood. One in particular I should shade in pretty heavily. I can tell Mr. Gibbins that I do not recollect (of course I cannot answer for others whom I supply in wholesale quantities) sending any to the neighbourhood which he names; I should therefore consider it clean.—F. Lyox.

NOTICES TO CORRESPONDENTS & INQUIRERS.

Letters or queries asking for addresses of monufacturers or correspondents, or where appliances can be purchased, or replies giving such information, can only be inserted as advertisements. The space devoted to letters, queries, and replies, is meant for the general good of bee-keepers, and not for advertisements. We wish our Correspondents to bear in mind that, as it is necessary for us to go to press in advance of the date of issue, queries cannot always be replied to in the issue immediately following the receipt of their communication.

Perflexed.—Transferring.—The young bees you describe as crawling on the ground had no doubt fallen from the combs, when transferring, on the floor-board, and being unable to remount had crawled out of the hive. On being again returned, still unable to mount the combs, they were extruded by the older bees. A very slight degree of cold chills young bees. You would have done much better to have transferred the whole of the frames, combs, and bees to the new hive, simply shaving off the excrescences. If the transferring was done in the open air, on a fine warm day, the absence of hives for a distance of one mile—or even of three—would not secure you from an attack of robbers, and it is not at all unlikely that your bees suffered from these, as well as from the other cause suggested.

Patience.—Bees dying.—The particulars you give are not sufficient to enable us to form an opinion as to the cause of your bees dying. Had you stated fully their antecedents, stores, kind of hive, and management we might have done so. From what you say we are inclined to think that the food given was insufficient and of too coarse quality; or dysentery may have attacked them. Study Modern Beekeeping or Cowan's Guide.

REV. J. H.—The seed forwarded under the name of Alfalfa from your son in America is Lucerne, which is quite common in England and on the Continent. It is a good honey-plant, but yields no pollen.

H.—The queen you send reached us too much dried up and shrivelled to speak with certainty. She is very dark, but we have seen many pure Italian queens quite as dark. You may judge better from her progeny, and if she was a hybrid there would be many black bees amongst the workers.

FAR NORTH.—Some disaster has befallen your queen during the winter season. She is evidently now a drone-breeder, and there is no probability of her restoration to her former fertile condition.

C. K.—In the locality where you are situated, without a tree or a shrub for swarms to settle on, you would find clipping the wings of the queen an advantage; but you must excreise great care in the operation so that her ovaries should not be injured.

J. Hewett.—1. Thickish brown-paper glued on the sides of sections would not answer the purpose of a divider. The bees would waste all their energy in their endeavours to remove it. 2. Your proposed plan of covering up the bees would not be practicable. The covering, be it a quilt or enamel cloth, must be placed on the tops of the frames.

E. P.—The two pieces of comb have come to hand. They are not affected with foul-brood.

M. H.—American cloth.—It is right to use the shiny side next the frames. But for moisture to come 'through the sides' of the hive, presuming they are of wood, cannot be owing to the use of the cloth. Probably the roof leaks and the water runs down the hive-sides. The cloth need not be taken off in hot weather, except to put on a rack of sections.

J. C. I.—Drones.—A stock which is ready to swarm always contains drones.

R. L. R.—Frames of comb filled with heather-honey.—If the bees will not clean them out, try the following plan:—Immerse the combs in water at about 90°, leave them until quite warm through, and lay them one at a time flat on the top of the frames, cover up warm with quilts. The honey will soon be carried down. When the lower-side is emptied turn the comb over, or else it will be destroyed, to get at the other side.

*** The length to which our report of the meetings of the B.B.K.A. has extended has obliged us to postpone several communications.

Show Announcements.

June 23, 24.—Suffolk Agricultural Show at Bury St. Edmunds. Entries close June 16. J. Huckle, Secretary. July 11–15.—Royal Agricultural Show at Newcastle-ou-Tyne. Entries close May 12. J. Huckle, Kings Langley. July 20-22.—Lincolnshire Agricultural Society at Spalding. Entrics close July 4. R. R. Godfrey, Secretary.

Finest CYPRIAN Queens.

DIRECT by MAIL from CYPRUS to any Address in EUROPE.

From 1st MAY to 30th AUGUST.

For 1 or 2 Queens (if ordered at one time), each 14/,, 3 ,, 4 ,, ,, ,, ,, ,, 13/,, 5 ,, 6 ,, ,, ,, ,, ,, ,, 12/-

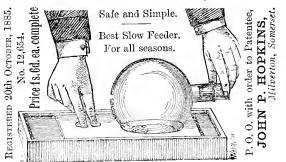

For Countries out of Europe add 50 ° to above prices.

All Orders to be accompanied by a Remittance.

My Queens are all very prolific, long-lived, and much larger-bodied, than the majority of those supplied by others, as they are reared naturally, under the swarming impulse, in April, May, and June, from the strongest of my forty colonies of Bees kept in double-walled moveable frame-hives, and all having choice Queens, which produce workers so gentle that they can be handled without smoke, and even without a veil on the face, just as I do myself (see Mr. S. Simmins' statements on page 37 of his work entitled, A New Era in Modern Bee-keeping). This is principally owing to the fact that I have weeded out from my Apiary all such Queens which appeared to be weak or producing troublesome workers. Address—

M. G. DERVISHIAN, Larnaca, CYPRUS. A 2375 For Reference, address Imperial Ottoman Bank, Larnaca.

Patent Bee Feeder.—Removing the Flask.

Or for giving warm syrup in cases of dysentery.

OUR WILD FLOWERS.

As with the soft zephyr or the tempestuous blast it is impossible to trace whence it cometh or whither it goeth, so with philanthropic objects it is difficult to point out the actual real good that may in the end result from praiseworthy endeavours. The snow-ball, so small at first, continually rolled over earth's winter's shroud, increases as it is pushed along till at length it becomes too unwieldy, and remains a mark of exerted perseverance. Societies are started with a primary object, and when their endeavours are being crowned with success, not unfrequently outsiders perceive that good is resulting in a direction never dreamt of by the original promoters. An instance of this has forcibly come under our notice in the objects of an Association called the Selborne Society. Its work is divided into several branches, but the third section, dealing with the protection of our wild plants and flowers, is the division that will prove of benefit to bee-keepers, and has been the means of calling forth our remarks on the present occasion. In one of the letters of the March number of a pamphlet published by that Society, the writer remarks: 'Our teeming population has been born of industrial prosperity, so that streets of dreary houses have spread over the land; large dis-tricts have been blasted with sterility by factories, minings, and smeltings, and year by year the orchis and primrose yield to the cabbage, favourite dells of the nightingale become cinderheaps, and bosky hillocks of the yellowhammer, "rows" and "courts." Rural England has shrunk and must shrink, but we still have a country of excelling beauty and variety, and to preserve this in the fulness of its riches against needless and wanton attacks is the work which the Selborne Society in its modest way would seek to further.'

The protection of wild flowers would indeed prove a great boon to bee-keepers, as, after all, the majority of those following the pursuit have to depend almost entirely on the flowers in our hedgerows, fields, and woods. Those possessing beefarms may plant, and with great advantage and profit, but by far the larger number of those keeping bees have neither the time, money, nor estate, to devote to the cultivation of honey-producing plants By the protection of our wild flowers not only will our charming country be beautified and men's hearts gladdened by the varied and rich hues of our flora, but great quantities of nectar will be produced, to be carried home by the bees, and so enrich their owners. Thus the Selborne Society, by their modest endeavours, will actually be assisting one of England's advancing industries, providing a source of income to many of its rural inhabitants, and doubtless doing good in a direction they could never have thought of.

Wild flora will always prove a profitable pasturage for our bees, as the cultivation of small gardens of flowers for our favourites is useless. Commons surrounded by woods are well known to make an apiary productive, those abounding with wild thyme and various other flowers which the seythe never touches are especially good. As Thomson says:—

'Here their delicious task the fervent bees
In swarming millions tend: around, athwart,
Through the soft air the busy nations fly,
Cling to the bud, and, with inserted tube,
Suck its pure essence, its æthereal soul;
And oft with bolder wing, they soaring dare
The purple heath, or where the wild thyme grows,
And yellow load them with the luscious spoil.'

HONEY AS AN ARTICLE OF FOOD.

We have much pleasure in transferring to our columns some well-timed remarks on the value of honey which appeared in the *Liverpool Journal of Commerce* of April 23:—

'The value of honey as an article of food is, we are afraid, only imperfectly appreciated by the public. Every one is ready to acknowledge its luscious sweetness, but comparatively few are cognisant of the fact that, in addition to this quality, it is in the highest degree nutritious. It is more aperient and detergent than sugar, and no healthier food can be found for children and those who cannot do with an excess of cane or other sugar. This needs only to be generally known in order to bring honey into more prevalent use than is the case at the present moment. Apart, however, from this primary domestic consideration, the matter has an important commercial aspect. Not long since we used to rely upon the production of our own hives; but this is now changed. With the increased facilities for transport and low freights it has been found a profitable business to bring the article from many quarters of the globe. California, Canada, Chili, New Zealand, Portugal, France, the West Indies, and many other parts are now laid under contributiou, and in some cases the trade has assumed enormous proportions, employing much capital

and labour. This is particularly the case in California, where it promises to become even more extensive in the future. Like many other products, however, honey has had to bear the brunt of the depression and competition of the present day, and latterly prices have not been remunerative to the producers, some losing as much as 50 per cent on their importations. This has been caused principally by the cheapness of sugar and the consequent low prices of preserves and other dietary articles into which sugar largely enters. Another factor is the want of a better knowledge on the part of the public respecting the value of honey as a wholesome article of diet, to which we have already alluded. Much has been done during the past few years to place it before consumers in a perfectly pure state, and the success which has attended the efforts in this direction is very gratifying, and will, no doubt, be in due time fully acknowledged by the public. Judging from the present position of the article, there can be no doubt that the bottom prices have been reached, and an advance is inevitable, as the producers show no inclination to sell at the late ruinous figures. In addition to this there is every prospect that the coming season in California will be a poor one, thus limiting the output from the most prolific source. What would tend to place the article upon a better footing would be an improved system of distribution, and that the public should be made more familiar with its value as a food product.

ROYAL AGRICULTURAL SHOW.

Our readers are reminded that the entries for the Royal Agricultural Show to be held at Newcastle-on-Tyne close on May 12th. Provision is made in the Schedule for the return of all fees for honey entered which the exhibitors may not be able to send for exhibition.

Honey-producers and manufacturers residing in the Northern and Midland Counties should give this Exhibition their best support.

SUFFOLK AGRICULTURAL SHOW.

A liberal Prize List for honey and bee-keeping appliances has been prepared in connexion with the Suffolk Agricultural Show to be held at Bury St. Edmunds. Entries close on June 6th.

Early application for Prize Lists of this and the preceding Show should be made to the Secretary of the B.B.K.A., J. Huckle, Kings Langley, Herts.

LINCOLNSHIRE AGRICULTURAL SOCIETY.

The first schedule of bees, hives, and beeappliances, which has reached us this year is that of the Lincolnshire Agricultural Society; and we hail it as the harbinger of the numerous apicultural shows which we hope will be held during this Jubilee year 1887. The Lincolnshire Agricultural Society have wisely entrusted the Bee Department to the Lincolnshire B. K. A.; and we feel sure that Mr. R. R. Godfrey and his experienced assistants will worthily discharge the trust thus reposed in them. It will be seen from our advertisement columns that the prizes offered for excellence in articles exhibited is rather in excess of those of the previous year. The Exhibition will be held in Spalding on Thursday and Friday, the 23rd and 24th of July. We hope the bee-keepers not only of the county, but of the United Kingdom, will assist and encourage Mr. Godfrey, and by their united efforts make the exhibition a great success.

Mr. Cheshire has requested us to state that his address in future will be Rosemont, Tweedy Road, Bromley, Kent.

ANSWERS TO MR. ROUTH.

Dear Mr. Editor, my name you will see Is quite a new one in the *Journal B. B.*, I've made an attempt, tho' living far south, To answer the queries of Mr. R. Routh.

Suppose it is winter, and sunshine bright, And snow reflecting into the hives, light, Tempting the bees to an unlucky flight, A zig-zag entrance will make it quite right.

A zig-zag entrance will make it quite right,
For seven long years bees I have kept,
And never yet had a quilt the least wet,
My covers stand on the hive sides exact,
And a plinth all around keeps as dry as my hat.

Supposing 'tis spring, and you've robbers, you think, Close the hives at eve with perforated zine; Next morn, if robbers are about quite thick, Sprinkle them well with powdered carbolic, Then, when they have gone their reception to brood o'er, Put a zig-zag entrance to each hive door. But I wouldn't advise—'twould worry my life, To stand by and kill each thief with a knife.

Should tomtits kill bees, as truly 'tis said, The safest remedy is one ounce of lead Administered sharply with powder so fine, And an unerring aim, as straight as a line.

If hive sides be stout, and entrances narrow, Neither mice nor fat toads will cause any sorrow. Queen-bees too will die, they cannot survive, If attacked by disease destructive of life; And this is a fact, not learned nor wise,

And therefore should cause not the least surprise.
If moth are in hives, your bees are not strong,
fet your hive full of bees and the moth will be gone;
Old, musty, house earpet for quilts, you will find,
Afford fine nurseries for all the moth kind.

A chalk line for ants is nothing but gammon, Might as well stop a whale with a rod used for salmon. Tho' I've ants all around, I ne'er found any wrong, If only my bees are kept thoroughly strong; But shoul I you by chance come across a big nest, A pot of boiling water will lessen the pest.

I prefer legs to hives, and have them male square, A foot or so from the soil, makes the bass more secure, As often when hives are close to the ground, A retreat for ants, slugs, and other insects is found.

The number of stings one would have to endure, To make him sting-proof, is rather obscure, I should say five stings a-day, for three weeks or more, Such as I've had to go through, would effect a sure cure, Whereas one sting would formerly close my eye for a day, Ten now make no difference, so I say sting away, But nine times out of ten, the stinging is due To bungling hands or the fear that you shew.

The subscription you pay to the B. B. K. A. Is just five shillings, so post it away
To Mr. J. Huckle, King's Langley, Herts,
And then you can have the advice of experts;
And if you're in doubt, and want their advice,
I'm sure yon won't have to write to them twice,

Now, Mr. Editor, my task is done, Will you kindly answer the last question. But perhaps you think—I feel rather sure—That Mr. R. Routh is not such a bore As your humble servant, a stranger to all, JNO. O. CLEMMOW, of Ladock, Cornwall.

[We have been not a little surprised at the number of poetical replies we have received to Mr. Routh's inquiries. We think, however, that the above, which was the first to come to hand, will be sufficient for our readers. Will our correspondents, A. E., W. W., G. W., F. L., J. L. R., J. H., T. M., and E. C., accept our thanks for the trouble they have taken and our regrets that we have not been able to avail ourselves of their appreciated versifications?—Ed.]

Foreign.

SWITZERLAND.

EXPERIMENTS CALCULATED TO ASCERTAIN THE WORK AND DEVELOPMENT OF BEE-COLONIES BY MEANS OF HIVES PLACED ON SCALES.

We have more than once pointed out the usefulness and interest that can be derived from a study of the variation in the weight of hives permanently kept on scales, particularly when the observer also notes, along with the changes in weight, those of the temperature, atmospheric pressure, amount of rain fallen, clearness or otherwise of the sky, changes and directions of the wind, the flight of bees, and, at the proper seasons, the flowers and trees furnishing a pasturage for bees. The Bulletin has occasionally reported extracts of our experiments, or of those made by some of our friends, and those who attended the 'Concours' held at Lucerne in 1881, or visited the Zurich Exhibition of 1883, will doubtless remember Mr. U. Kramer's beautiful graphic pictures, embracing several years.

At Mr. Kramer's suggestion, a few Swiss bee-keepers

At Mr. Kramer's suggestion, a few Swiss bee-keepers undertook similar observations, simultaneously, in the winter 1884–85. Two of these, viz., Dr. R. Kubli, of Grabs, St. Gall, and Mr. D. Reber, of Dreilinden, St. Gall, who had been able to continue their experiments throughout the year 1885, have published the results obtained, in a pamphlet of sixty-three pages, containing clear and minute explanations. This book, called, Beitrag zur Arbeitsleistung und Entwicklung der Bienenevölker, gives not only the historical progress of two stocks, with notes on the meteorological observations, on the flora, &c., but the authors have included many other interesting details, as well as remarks upon the construction and dimensions of hives, and the mode of using them.

They have divided the year into four seasons. The first, or the dead period, embraces the months of November, December, and January: the second period is that which precedes the season of early activity, say, February, March, and nineteen days of April; and the third, or the harrest period, comprises ten days of April, May, June, and July—that is to say, 103 days, during which the scales had shown increases of weight interleaved with decreases; and, finally, the fourth period, consisting of the months of August, September, and October.

	AT GRABS.	AT DREILINDEN.
Net Weights from	Kilos.	Kilos.
April 20th to 30th	8.640	0.570
May 1st to 31st	0.850	6.570
June 1st to 30th	31.900	12.300
July 1st to 31st	6.370	14.000
	47.760	33:440

It must be remarked, however, that the colony at Dreilinden threw off a swarm on the 9th of June weighing kilos. 2·720, which gathered kilos. 26 of honey. The heaviest day at Grabs was the 26th of June, when the scales registered kilos. 3¼, and at Dreilinden the 12th of July, which registered kilos. 2·200.

According to this report, the flowers which predominated at Dreilinden, as well as at Grabs, in April, were those of the cherry-tree, the cardamine, and the dent-de-lion; in May, the dent-de-lion and the apple-blossom, with the fir-tree towards the end of it. This fir-tree lasted till about the 8th of June, when there appeared the raspberries, white clover, and various other honey-producing plants. In July, the bees worked mostly on this white clover, lime-trees, and on a few other trees. The first hay was cut between the 10th and the 24th of June.

One of the studies one of the above-named gentlemen

made was to ascertain how much a colony consumes in one year. During three of the periods the scales gave precise figures, but in the harvest season the registrations were incomplete for those days when no honey was brought in, and they had to estimate the evaporation of water issuing from the stored honey.

Mr. Reber's register gave the following figures:— Days. Kilos. $\frac{2.210}{5.205}$ 25Winter period...... 90 average Period preceding harvest 80 65 Period after the harvest... 5.04355 12.458Period of harvest 103 36.940 estimated 360 49.398, or, say, 1 cwt. 365

M, Kubli had found in round numbers :-

Winter period	Kilos. 3.000 7.500 5.500	average	93 93 60
Harvest period	16·000 30·000 46·000	"	291

Here, at Nyon, we have no record of weights representing the whole season, and must therefore content ourselves with an approximate estimate. For the winter season our scale has given us kilos. 1 800. Sundry deductions made in April have given us 200 and 250 grammes per day; in May and June we were able to calculate a daily consumption of from 450 to 500 grammes; and about 50 to 60 kilos for the whole year. But our hives are much larger than those at St. Gall and our colonies are considerably stronger in the harvest season, The hives at Dreilinden measure 54 litres; those at Grabs, 70 litres. The body of our Dadant hives measures 66 litres, and each super 34 litres; and at harvest time our colonies occupy, besides the body, one, two, and even three of these supers, which brings up the total to about 100, 134, and 168 litres—occasionally a fourth super is required. As the harvest does not last here, at Nyon, more than twenty or twenty-five days, our course is well defined: we must stimulate breeding as much as possible in order to dispose of a strong army of workers at harvest time, even at the cost of a great

Now in localities where harvest is not limited to twenty-five days, but spread over 103, like at St. Gall, would it be just as advantageous to stimulate brood-rearing? This inquiry can only be answered by experience, but we are inclined to give an affirmative reply. A worker that can participate in the harvest will produce more than she will cost for rearing and keeping.

If the flora is poor, and the yield of honey limited, reduce the number of your colonies by half, and have them all the stronger in the same proportion at harvest time. You will then have the largest amount of honey brought in, as the number of outdoor workers will be all the greater in each hive, and you will have only half the number of bees to keep during the dead season. In conclusion we keep our bees from nine to eleven months in idleness, figuratively speaking, in order to have harvesters during over the remaining months. If ten colonies, able to develop themselves freely, can produce as many and more workers than twenty kept in small hives, it becomes advantageous to stimulate brood-rearing. The cost is less, so it is the room occupied by the bees, and the trouble is not so great. The principal conditions for the full development of a colony are, other things being equal, large combs and roomy hives. In winter, as well as in autumn, our stocks do not consume more than those

at St. Gall. It is mostly in April, May, and June, that the consumption of food is greatest, but at this season each reared bee is a producer.

The book in question contains a communication from Italy which, we think, will bear out our theory, as it originates from a locality where honey is scarce, and bees, by reason of their being kept in small hives with small combs, do not obtain their full development.

This question of development of colonies in its relation with the size of hives is an all-important one. Such competent and conscientious apiculturists like Mr. Kubli and Mr. Reber are in a favourable position to find a solution, and we earnestly wish they would give us the benefit of their experiments. But let us return to their interesting book.

The authors compare their results; examine the influence of the three principal factors, viz., flora, weather, and method of cultivation, not forgetting the style of hives used and the race of bees, and then try to arrive at results. We will limit ourselves to a few of the weak points to be noticed in their methods, viz.:—1. The hive at Grabs had thin walls and was not sufficiently protected against the cold. From November to end of March the consumption had been kilos. 7:400, whereas in that at Dreilinden, which was better protected in this respect, it was only kilos. 5:245. 2. Its interior arrangements, separating the brood-nest from the store-chamber, leaving only a small hole for communication, was a disadvantage. 3. The slinger was not brought into requisition often enough, or else the hive, notwithstanding its seventy litres capacity, was yet too small. On the 28th June, at the height of the harvest season, bees were hanging out.

With its fifty-four litres capacity the hive at Dreilinden was even more defective as regards room; the extraction of honey was insufficient and a swarm had issued. A queen requires, says Mr. Reber, a large number of cells to develop her brood in, and workers require a great many too, to store their honey in and to evaporate the excess of water which it contains. These authors do not consider swarming advantageous for the production of honey. There would be several other subjects in the pamphlet which might be pointed out, but we think enough has been said to show the usefulness of their undertaking, and we tender them our thanks on behalf of our bee-keeping fraternity.—Translated from the Bulletin d'Apiculture de la Suisse Romande for December, 1886.

ITALY.

According to the *Apicoltore*, Mr. G. Kandratieff, Director of the Imperial Opera of St. Petersburg, has availed himself of a short visit in Italy in order to make an inspection of the most important apiaries. Mr. Kandratieff is the proprietor of two large apiaries in Russia, one of about 300 stocks in the Caucasus and another of about 200 in St. Petersburg. Notwithstanding the great difference of climate between the Caucasus, where winter is almost unknown, and St. Petersburg, where it is both most severe and long, Mr. Kandratieff obtains, it appears, almost the same amount of profit in proportion from the one as from the other. It appears that Mr. Kandratieff is a perfect master of the Italian language and a constant reader of the *Apicoltore*, which has been his guide in his apicultural pursuits.

The same contemporary reports that Signor Sartori has contributed exhibits to a great bee show held this month at Vienna, with the main object of establishing a honey market for the convenience of the inhabitants of the Austrian capital and a means of facilitating the sale of honey now being produced in that country.

FRANCE.

The Société Centrale d'Apiculture et d'Insectologie of France held a meeting in Paris in March last. In the course of the proceedings it was stated that the Insect Exhibition would be opened on the 27th of August, and remain open until the 28th September next.

M. Savalle suggested that a committee of three members be appointed to visit and report upon the apiaries whose owners desired to compete at that Exhibition in the special class for 'well-managed apiaries,' but M. Ramé pointed out that such a course as that suggested by M. Savalle would involve the Central Association in greater travelling expenses than could conveniently be afforded, whereupon M. Hamet moved that the examination of such apiaries be entrusted to the local Societies near which the apiaries are situated. It was further ruled in connexion with this subject that such visits must be made before the 20th of September, to the end the jury may have time to examine the reports and arrange for the awards. Rules as to the manner in which the said reports are to be tabulated were drawn up and approved. As regards apiaries within a certain radius of Paris, a Committee of Inspection, consisting of three members, would, however, be appointed, particularly as in the course of the discussion M. Ramé remarked that there would be no difficulty to obtain from the Railway Companies a reduction of 50 per cent upon the rates for the members of their Committee of Inspection.

Subsequently the conversation turned upon an insect submitted by M. Crevoisier, of Havre, found upon his bees. This gentleman was of opinion that the presence of this insect caused a decrease in the numerical strength of his colonies. The insect was thereupon submitted to examination by means of a magnifying glass, and pronounced to be a specimen of the Braula cœca, and the general opinion of the meeting was that although the presence of these insects in large numbers was undesirable, yet it did not constitute an infectious disease, nor was it fatal to a stock.

Afterwards, in the absence of M. Bourgeois, who had failed to be present as promised, M. Hamet pointed out a novel application for a steam wax-melting oven, which he demonstrated can also be used as an economic incubator. It transpired in the course of conversation that at about the end of February last M. Bourgeois placed about twenty poultry eggs in his steam wax-melting oven, with the result that a dozen chickens were thereby obtained. M. Bourgeois fully believed, however, that had the temperature been more steady and certain precautions taken, which had been overlooked during his absence from home, every egg would have been successfully hatched.

 Λ general conversation upon sundry other matters brought a pleasant meeting to a close.

NORTH-EAST OF IRELAND BEE-KEEPERS' ASSOCIATION.

The Annual Meeting of the above Association was held at 41 Waring Street, Belfast, on Friday, the 22nd ult., at three o'clock. There was a large attendance of members, Among those present were W. J. Johnston, J.P., F. D. Ward, J.P., Rev. H. W. Lett, M.A., Riehard Niven, W. H. Phillips, W. E. Best, A. Morris, E. Malcomson, S. Cunningham, G. Hull, G. M'Neill, T. M'Henry, S. Refausse, &c. &c. The Rev. H. W. Lett, M.A., presided.

The Hon. Secretary (Mr. Paul M'Henry) read the Annual Report, which was of a very satisfactory character. The Financial Statement was equally satisfactory, showing the Association to be in a healthy condition. Mr. M'Henry stated that Sir John Lubbock, M.P., had consented to become an honorary member of the Association,

Mr. A. Morris, in moving the adoption of the Report. referred to the efforts the Canadians were making to advance bee-culture, and pointed out that they looked to this country as a market for their honey. He pointed out the difficulties which they had to contend with, and urged on bee-keepers the necessity for renewed exertions, He considered if bee-keeping could be made a profitable

investment that it should receive more attention than it

has in the past in this country.

Mr. F. D. Ward, J.P., in seconding the adoption of the Report, said although he only kept a few hives he believed bec-keeping could be made a profitable pursuit; he expressed the pleasure it gave him to be present at this year's annual meeting of the Association.

It was resolved that a Show be held this year, the 19th of August being fixed. A Committee was then appointed

to carry out the arrangements.

 Λ ballot was then taken for a bar-frame hive, presented to the Association by Mr. Niven, and Mr. W. J. Johnston, J.P., was declared the winner.

In the evening a Conversazione, under the auspices of the Association, was held in the Museum, where there

was a large attendance of members.

Tea having been partaken of, the Mayor (Alderman J. II. Haslett, J.P.) took the chair and delivered a brief address, in the course of which he referred to bee-keeping as an industry, and urged its being followed more by small farmers as a means by which they might augment their incomes. He also spoke of the efficient manner in which the Association was creating an interest in humane bee-culture and to the success which had attended its

The Rev. H. W. Lett, M.A., gave one of his very instructive lectures, which was listened to with much attention. In the course of his remarks he drew attention to the necessity of members trying to make a market for their honey in their own particular neighbourhood, and gave some instances which came under his notice where this had been particularly successful. He also drew attention to a plan which had been adopted with success in some parts of England, viz. of allowing the bee-tent to be erected in the grounds of some of the local gentry, on the occasion of fetes, &c.

Mr. A. Morris gave the result of his experience, and advocated bee-keeping to all those who had facilities for

keeping them.

The Chairman stated that he would be glad if any present, who were in doubt about their bees or management, would make use of the question box which had been provided, and any questions asked would be replied

to before close of meeting.

A number of microscopes were exhibited during the evening by members of the Association and their friends, and the slides illustrating the anatomy of the honey-bee and other insects were in great request. Mr. Smith exshibited some dead queens, workers, and drones, also some specimens of comb. with queen-cells, &c. &c. The Rev. specimens of comb, with queen-cells, &c. &c. H. W. Lett, M.A., exhibited the sheets published by the B. B. K. A., and described the same. Mr. W. Lonsdale, Lurgan, and Mr. Morrow, Banbridge, sent bar-frame hives of approved construction, which were explained by Mr. S. Hill and Mr. Paul M'Henry during the evening. Appliances were exhibited by Mr. Lonsdale and the Belfast Nursery Company, who exhibited some sections, glazed after the style advocated by W. J. Stanford, Esq., in the Irish Bee-keepers' Association Pamphlet.

A vote of thanks was passed to the ladies who had

acted as tea-makers.

The customary votes of thanks being passed, brought a very enjoyable evening to a close.

Long Words.—Apropos of the long names in your last issue, we have in our trade, Clark's Hoplemeuroma and Neurasthenipponskelesterizo, both of which by long practice we can 'speak trippingly' off the tongue.—Drugo.

DE QUIBUSDAM. -In my last I did not write that frames in the body hive will 'vary' with the weight of honey, but that they will 'sag.' I have since had an example. I took out a filled frame for the benefit of a hive the supplies of which were getting short. The top bar was of three-eighth stuff, but in the centre it had dropped one-quarter inch. What prospect then is there of our being able to preserve these exact bee-spaces so carefully provided ?-C. R. S.

Correspondence.

The Editor does not hold himself responsible for the opinions expressed by his correspondents. No attention will be taken of anonymous communications, and correspondents are requered to write on one site of the paper only, and give their real names and addresses, not necessarily for publication, but as a guarantee of good faith. Illustrations should be drawn on separate pieces of paper.

Communications relating to the literary department, reports of Associations, Shows, Meetings, Echoes, Queries, Books for Review, &c., must be addressed only to "The Editor of the "British Bee Journil," clo Messrs. Strangeways and Sons, Tower Street, Upper St. Martin's Lane, London, W.C." All business communications relating to Advertisements, &c., must be addressed to Mr. J. Huesle, King's Langley, Herts (see 2nd page of Advertisements).

**In order to facilitate reference, Correspondents, when speaking of any letter or query previously inserted, will oblige by mentioning the number of the letter, as well as the page on which it appears.

THE NEW RACES AND THE BEST MEANS OF INTER-BREEDING AND SECURING FERTILISATION.

HYBRIDS, BLACKS, &c.

[935.] We now have to consider the disposition and working qualities of the various crosses and the best means of ensuring the production of docile bees, without detracting from their value as honey-producers.

As it is intended to make use of the native race it will be well to first consider what they are capable of. Nearly all bee-keepers have a certain partiality for blacks, and it cannot be wondered at when we come to think of the beautiful colour of their comb-honey. They are also less inclined to swarm than any other kind, but the great reason for this is that the queens are not very prolific; and, in fact, it would be a serious error for any one to attempt to build up a large apiary with these bees and expect to make a fair profit at the same time, unless in an exceedingly good district.

Though they do not winter so well as Carniolan bees, they have great conservative energy, and are capable of maintaining a higher temperature than any. Hence the reason why they are such good wax workers, and why with comparatively small numbers a colony of blacks

readily takes to the supers.

On the whole (in their purity), they are not noted for the best of tempers, and besides being behind the foreign varieties in breeding they discontinue storing in the autumn, while the more prolific kinds continue to gather heavilv.

Many years' experience has shown me that to obtain thoroughly reliable workers producing comb of the first quality, one must take a black queen as a base to start upon, and crossing with drones of either the Ligurian, Cyprian, or Carniolan races, the latter by preference. We then dispose of the objections to the pure black, while retaining their good qualities. Though some believe they have cause to differ as to Cyprians, I have found the drones of each variety named carry a mild disposition to the hybridised workers. Indeed I have always found the drone to impress the disposition of the mother colony upon his progeny. Black drones should be rigidly excluded, as it is these crossing with foreign queens which have caused so much to be said against hybrids. Such a cross is of the worst temper imaginable, and though it may be pleasing for a beekeeper to raise queens from the valuable one he may have purchased, unless he can depend upon getting them purely mated he will do far better to raise plenty of drones from such and improve his natives, and so raise bees that he can easily handle.

If a good working cross is desired while one wishes to have colour as well, then take a Carniolan queen and mate her daughters to Cyprian drones. Though springing from a race not actually having yellow bands, this first eross will in many cases produce workers infinitely more beautiful than Cyprians themselves, as they have all the yellow and a great deal more down about them. In

some instances the first cross varies from Carniolan to Cyprian forms, and a second cross with Cyprians would

be desirable to get good colour.

If comb-honey be the object, however, colour from Cyprians must not be sought, as the nearer you approach to them the darker will be their cappings. It would be better in that case to cross once into Cyprian and back to Carniolan again, if blacks are not used; or begin on Cyprian queen and cross twice to Carniolan drones, the workers leaving nothing to be desired, putting colour out of the question.

With Ligurians proceed in the same way, crossing with Cyprian drones for colour, though, of course, the workers resulting therefrom would not give good comb. Carniclan or black queens with Ligurian drones would, however, give excellent bees for white comb-honey where

one will look only at the business point.

The crossing of two or more varieties will always give an improvement in the working capabilities of the bees, the main point being to make certain that the drones nsed come from good-tempered, and otherwise desirable stock. This is even more important than the disposition of the queen's colony.—S. SIMMINS.

BEES AND RIPE FRUITS.

[936.] I should very much like to obtain the opinion of bee-keepers on the point which I brought forward for discussion at the last Conversazione of the B. B. K. A. that is:—Do bees commit any damage to ripe fruit? I must say that it is with considerable reluctance that I hold the opinion that they do. Until last season I 'ran with the stream' of other bee-keepers and scouted the idea of such a thing happening, but, alas! my ideas received a sudden check, and I found my pets busily engaged piercing the skins of peaches and revelling on the sweet juice. At the Conversazione these opinions of mine were—Well, I was considerably 'sat upon,' but having recovered from the effects, I have risen again to the occasion.

Most of the arguments against such a bad practice on the part of the bees were based upon the assumption that their jaws were not strong enough to make a hole through a fruit skin as tough as that of the peach. I must emphatically negative this: even our friend, the Chairman, gave his opinion that they could pierce the skin of the raspberry, so partially negativing the idea that they could so pierce that of the peach. Has any bee-keeper placed paper in his hive? If not, let him do so, the bees will soon cut it up into small pieces and carry it thus outside. How about gnawing clean through the tapes after transferring? I veckon there's tougher work in these two cases than with ripe peach-

skins.

I now give an extract from Gleanings of the 15th April, 1887, from the pen of A. I. Root:— But if there are cracks where the bees can see through and smell the feed, they will often (at least in our apiary) bite away the solid wood until they can squeeze through where

cracks and openings are.'

Mr. Raynor also observed that the jaws of bees were much weaker than those of wasps. I am well aware of this, but that is no argument that it is impossible for them to break the skin of other fruit than raspberries. A gentleman gave it as his opinion that if I had taken a magnifying glass I would have seen a small puncture presumably made by a wasp beforehand. My eyesight is sufficiently good to detect the mark made by the first 'chop' of a hungry wasp's jaws, in several instances where I saw the bees commence gnawing the skin there was no such mark. I am well aware that the bees would sooner go to the part of the fruit that had been damaged beforehand, as a larger amount of saccarhine matter would be found there.

I am also aware that the infinitesimal amount of

damage—first damage I mean—committed by bees is as a grain of sand in a bushel compared with that of wasps; but this does not alter the truth of my assertion that bees can pierce the skin of peaches and some other fruits. I do not in the least wish to be dogmatic, but I feel confident as to their capabilities in this direction, if not in all cases their desires. I have written this letter, not for the purpose of publishing our pets' failings, but in order to lay before those who I find frequently complain of the presumed damage done to their fruit by the bees, the fact, that although they may commit a very small amount, the wasps are the chief culprits. If one entirely negatives their assertions of this damage you are simply laughed at as one not knowing much about bees.—W. B. Webster.

COUNTY EXPERTS.

[937.] Poor experts! foul-brood will be to you as an incubus like unto the bees. How I should like to meet the County Expert that doesn't know foul-brood when he sees it! What lucky experience!(?) But I know it to be a fact and can bear out 'U. II.'s' assertion. It is but a short time since I examined a colony that had been pronounced by a county expert (unqualified) quite healthy and flourishing, that was reeking with foul-brood; I pitied the owner who was elated at the expert's (?) report, but desired my opinion before giving vent to a very loud hurrah! The expression on her face when I showed her hundreds of foul larvæ, was indeed grievous. But, 'U. H.,' do you really think that one who has passed a second-class examination is as ignorant as this? If so, who are the 'eximiners?' remember being closely questioned upon this matter at each of the three examinations that I had the pleasure of 'going in' for. The fact is, it is only a few of our counties that have properly qualified experts, and I take it that in each case they should hold, at least, secondclass certificates; I do not mean to assert that there are not as good bee-keepers without a certificate as with, but such certificate is a guarantee as to their ability. District secretaries should, also—where they are presumed to give advice—hold third-class certificates; these are easily obtainable by any one having a good knowledge of modern bee-culture.—W. B. Webster.

GOSSIP.

[938.] It is a long time since I trespassed on the columns of the Bec Journal, and if I do so now I shall venture to put the blame on the present esteemed Editor. Last autumn, when I was 'doing' the Colinderies, I chanced to stumble into his company in the Canadian honey department, and will now offer my humble apology for interrupting his conversation with the gentleman in charge — Mr. M'Knight, I should presume from what I gather on page 170. Of course we were strangers, and I had to introduce myself as an occasional correspondent sometime before he became Editor, when he was kind enough to invite me to do so again.

As I have paid several visits to Canada, and have travelled the country from Quebec to the Falls of Niagara, I was naturally interested in seeing such a splendid collection of honey. My first visit was in 1858, my last in 1875, but during the whole time I never remember to have seen a single honey bee. I remember in 1873 inspecting a vast quantity of hives in the patent department at Ottawa, but at that time anything past the old straw skep was new to me. What a change in both countries in a few years! I hardly know which I am most afflicted with, the bee mania, the bird mania, or the wasp mania, all equally interesting in their way.

I should not have ventured to take up the pen had 1 not noticed the interesting article of 'G. J. 11.,' page 161. I am very pleased to say my experience with the birds

mentioned (all of which are residents with me) differs from his. I can honestly and faithfully declare that I have never been able to detect a single bird killing my bees. That the great tit is fond enough of bees I am well aware, but they only act as scavengers in picking up chilled or dead bees. Did G. J. II. ever try the effect of feeding the tit family? It is an old saying, 'If thine enemy hunger, feed him.' Give them a few bones to pick, or a lump of scrap suet suspended to peck at. It will afford amusement and pleasure, and they will amply repay for the little attention in destroying thousands of insect enemies in the garden, which I can vouch for by close observation. Again, there is no need to use powder and shot to destroy the tits, and probably fruit trees into the bargain, they will both build and roost on anything of a convenient size; I have taken them to lectures many a time in old boots, boxes, tea-pots, &c. There is not a 'darned' bit of pride in their nature, and they will put their trust in you and not be afraid; but do try feeding before killing them. It would occupy too much space to enter into the habits of each to relate the good they do in other

I have only met with one queen-wasp so far this spring.—Jas. IIIAM, The Wren's Nest, Astwood, Redditch.

THE WOIBLET SPUR EMBEDDER.

[939.] I have for a long time used wired frames, and have pressed the wire in the wax with the point of a knife; and although none of the wire has been covered with wax the queen has laid in every cell. Having seen Hughes' Embedder Spur advertised in the B. B. J., I sent for one, and I was highly pleased with its simplicity and also in the way it did its work; first warming the sheet of foundation in the sun, or by the fire, I could embed the wire with great ease and very quickly. I recommend my brother bee-keepers to give it a trial, and I think it worthy of high praise for its cheapness as well as for the way it works. By its means bee-keepers can save themselves much labour as well as time.—T. S.

FOUL BROOD.

[940.] I am much obliged to Mr. Lyon [992] for his answer to my query in B. B. J., April 21, respecting foul broad in Warwickshire. The expert of that county has also kindly written informing me that the district is quite clear of this disease. Allow me to express a hope, however, that Mr. Lyon will not too hastily infer that a district is infected because several bee-keepers have ordered bottles of 'cure.' I, for one, obtained a bottle so as to be forearmed in case the disease should appear, and doubtless hundreds of others have done the same. I am glad to say I have never had occasion to use it, and trust I never shall, but it is a satisfaction to know that a remedy is close at hand in case my bees ever require it. As may be seen on reference to former advertisements, when I buy swarms I stipulate that the seller's district shall be free from foul brood, and also that his apiary has never suffered from the disease. It is surprising how very many offers have fallen through owing to this latter clause. It is impossible to be too careful to avoid introducing this destroyer to a hitherto clean country. As an example, I may say I know a man who introduced an alien queen two years ago. Very shortly foul brood appeared, and in spite of all the many remedies, he was compelled to practically destroy his apiary of forty stocks. Unfortunately the mischief did not end here, for the infection was carried by robbers, &c., to the neighbouring cottagers' skeps, and thus the circle of an infected area ever grows larger unless prompt measures are taken for its eradication.

Mr. 'Amateur Expert' has a hearty laugh in last B. B. J. over my query, but surely it is a matter of grave

importance, worth considering. I had no reason to suspect any disease in Warwickshire, and had in fact examined the stocks offered to me a year ago, but as my friend does not personally manage his bees, I applied to the editor of the Bee-keeper's Adviser, and, as I have always experienced in all cases of difficulty, received through his hands the desired information.—Edward J. Gibbins, Neath, April 28.

CAN BEES HEAR?

[941.] Several letters have recently appeared in B. B. J. as to whether 'Bees can Hear,' to which I say Yes. I have been fond of bees over fifty years and a close observer of them. May I give three reasons for saying they can?

1. Last June I happened to have my head just in front of a Ligurian stock. I was very close and was looking into the entrance; there were probably about 100 bees sitting outside, not in touch of those inside. All at once I heard something like a hissing noise from inside the hive. The 100 outside seemed to hear this sound at the same moment that I heard it; they were on the move at once; a few seconds more and a fine swarm was rolling out of the hive.

2. Take a swarm into a straw skep when they are all in quiet. Shake them out in a lump on a cloth, stand the skep (with room for them to crawl into it) a few inches from the lump, then take a tablespoonful (or more) of bees, lay them down at the entrance of the skep, so that they are an inch or so from the bulk (or lump of bees), and there is no continuity of touch. Now if this spoonful of bees commence to enter the skep they will set up a humming noise, wherenpon the whole bulk seem to hear it at one; turn toward the skep, set up a humming and march straight for the same skep. Or try the same with a driven stock, then put down their own hive bottom board and all take a spoonful; put them on the alighting-board and you will get the same result, perhaps more instantaneously.

3. Eight or nine days after the issue of a first swarm go to the stock hive at night, place your ear against the back of it; and if they are intending to throw off a second swarm you will hear the well-known tooting or shouts of defiance from two or more queens. If you take time you will sometimes find a considerable number of minutes quite quiet, then one queen sets up tooting her note of defiance, and directly she ceases another queen from a distant part of the hive answers her back. I say they can hear one another and bandy the well-known tooting or note of defiance from different parts of the hive.—David Ovenden, Penge, S.E., 18th April.

HIVE CONSTRUCTION.

[942.] I beg to inform 'F. L.' that I too, for more than ten years, have had hives without plinths, the same as he describes; but neither 'F. L.'s' nor my own are interchangeable storifying hives. Mr. Buchan was the first to use a break-joint in the latter named hives as represented in-the margin, so as to make all the hive-joints without plinths, wind, and water-tight. For this original improvement in hive-construction he ought in common fairness to receive the honour due for it.—WM. PURVES, Dalkeith, N.B. 18th April.

SPARROWS AND BEES.

[943.] In B.B.J. (906) 'G. J. H.' gives his useful experience of 'birds eating bees.' May I add my London experience?

For five years, ending last February, I kept bees at Blackheath. My neighbours encouraged the London sparrow in a large growth of ivy, and during the entire

breeding season these sparrows committed havoc amongst my bees. They seemed to almost entirely rear their young with my poor slaughtered bees. The female sparrows seemed every year to commence this slaughter, and then the male sparrows seemed to act under the direction of their wives and set at this slaughter with a vengeance. These impudent sparrows would select a twig opposite a hive; they would settle on this twig, from thence fly straight at the hive-alighting board, take a worker-bee, settle on the ground, peck it to death quickly, carry it to their young, and be back in two minntes for another. Occasionally they would vary the diet with a drone.

Of all the birds in the air, I believe the London sparrow is the greatest enemy to bees kept in the suburbs.—David Ovenden, *Penge*, S.E., 18th April.

WIDTH OF SECTIONS.

[944.] Seeing that there is a good deal of controversy in the B. B. Journal respecting the best width for sections, I should like to state, through the medium of its pages, that I believe I was the first to import and recommend the use of the narrow section into this country. As many readers of the Journal know Mr. Froucrook took out a patent for the one-piece section with bee-ways and comb-grooves. Apart from the idea not being original, his specifications were so carelessly worded, that the sections could be manufactured in two, three, or four pieces, or in one, leaving out any one of the particulars mentioned, i.e., the comb-groove, &c. In the spring of 1883, Mr. Froncrook threatened to prosecute those who had manufactured and used any other one-piece section than his own. About this time I imported from Mr. Lewis the $4\frac{1}{4} \times 4\frac{1}{4} \times 1\frac{3}{4}$ section in one and two pieces. I quote the following from my catalogue, 1883: They are in two pieces and can be had either I_{\pm}^3 or 2 inches wide, but the former are to be preferred, as they do not require separators when comb-guide is used, and there is no escape of heat, or space between separators for bees to propolise. The bees are said to ripen and seal their honey faster in them.'
The same year the 'Royal Show' was held at York,

The same year the 'Royal Show' was held at York, and I entered for competition in the 10s. class a hive fitted with these narrow sections with close top, and I dare say Mr. Hooker will remember his remarks to me about them,—remarks not in their favour; for when I praised them, he seemed indignant at my opinion of the article: I did praise, having tried and proved their value, besides having heard them highly spoken of by many of my customers to whom they had been supplied. I believe these narrow sections give satisfaction in every case.—E. C. Walton, Muskham.

SUGGESTIONS.

[945.] The early spring months are very trying and often disastrous to the lives of our dear little bee friends. The outer surroundings of the hive have an important bearing on what may be termed the minor essentials to successful bee-keeping. Given a good aspect I would strongly deprecate allowing grass to grow near the hive in any shape or form, but if allowed to grow long and feathery, it is not only a great nuisance to bees in the summer months, but in the early spring is very destructive to bee life; in hurrying home from passing storms many drop in the long damp grass—get chilled—never to rise again.

Again, I have often noted alighting boards with a too sharp slope smoothly planed and painted, on which the bees cannot get foothold. I have grieved to see the heavily-laden bees after dropping on such alighting boards either roll off, or on the first attempt at walking make, not a step forward, but two backwards. To remedy

this evil take a coarse rasp, such as farriers use, and draw the teeth longitudinally from end to end. An ordinary pocket-knife with a sharp point will answer the purpose tolerably well by scratching the surface rather deeply.—James Lee.

FROM SKEP TO BAR-FRAME.

[946.] Being a bee-keeper on a small scale and a constant reader of the *British Bee Journal*, I thought I would write you a little about my experience as regards bees.

I have kept bees here for about ten years, both in straw skeps and in plain boxes home-made. To get the honey I used to sulphur them in autumn, till last spring, when our expert came here and put two of my stocks from straw skeps into a bar-frame hive; and during last summer I drove all the other stocks myself and placed them in bar-frames. Considering the season, I did very well with them, and find the bar-frame hives much better than straw skeps and much more profitable; but I think bees would winter better if the roofs and outside walls of the bar-frame hives were made thicker. The walls, say, I in. and roofs $\frac{3}{4}$ in. thick, of good, sound, well-seasoned deal and kept well painted with oil paint.

I think if bees were kept warm and dry during the winter we should not hear any more of foul brood, which I fancy is caused by having such thin boxes and getting damp inside. I packed my boxes between walls with hay chaff, and on the top I have one or more pieces of thin red woollen carpet for quilts with a good heap of chaff on the top. Being at my work close to my cottage I have time during the winter, when I get a nice warm day, to remove the roofs of hives and shake up the chaff if anyway damp. If the roofs feel damp inside I take them into my cottage and dry before the fire. I have not lost one stock this winter, and I have nine stocks now very strong, and two weak stocks; and the first swarms I get this season I shall bundle, queen and all, into my weak stocks to strengthen them. I intend doing away with chaff packing between the walls of hives next winter, as I think the bees would winter better with the air passing between walls.

I hardly ever get stung, as I never give my bees much chance to sting me. I bought a yard of strong black net and made it into a bag, which I put over my felt hat and tuck inside my vest; for the hands I have a pair of soft leather gloves, and on the end of the gloves I have the top part of a thick pair of old woollen gloves sewn on fast, which I draw well over an old coat right up to my elbows. Being so well protected I am the master of my bees any day, and do not want such nostrums as apifuge or sting-preventer, as my simple preventer is enough without those moonshines. About here people use washing blue, onions, turps, &c., those things are no doubt good in pickle, paint, and washing water, but for stings they are all bosh. Bees cannot abide me, and would push their tails into me very quickly if I were not in armour; and in my situation I have no fancy to go about with swollen face and black eyes, making me look as if I were related to Tom Sayers.—R. G., Coldra, Caerleon, Mon.

Poisonous Honey.—Much has been written upon the poisonons effects of certain plants, sometimes upon the honey, sometimes upon the bees themselves. Every schoolboy must remember the account given by Xenophon of the effect produced upon the Ten Thousand by the honey in the neighbourhood of Trebizond. The soldiers suffered in proportion to the quantity they had caten; some seemed drunken, some mad, and some all but died. (Anab. iv., S.) This quality in the honey has been referred to by Pliny and others to the poisonous nature of the rhododendron, which abounds in those parts; but from inquiries which we have made from

Dropmore and other spots abounding with this shrub, we cannot learn that any difference is perceived in the honey of those districts, or indeed that the common bee is ever seen to settle on its flowers. If the Kalmia latifolia be a native of Pontus, the dauger is more likely to have arisen from that source, as the honey derived from it has been known to prove fatal in several instances in America.

Bees Used in Warfare.—A small privateer, with forty or fifty men, having on board some hives made of carthenware, full of bees, was pursued by a Turkish galley manned by 500 seamen and soldiers. As soon as the latter came alongside, the crew of the privateer mounted the rigging with their hives and hurled them down on the deck of the galley. The Turks, astonished at this novel mode of warfare, and unable to defend themselves from the stings of the enraged bees, became so terrified that they thought of nothing but how to escape their fury; while the crew of the small vessel, defended by masks and gloves, flew upon their enemies, sword in hand, and captured the vessel, almost without resistance. It must strike the reader how well furnished this vessel must have been to afford on the moment masks and gloves for forty or fifty men. The following receipt to disperse a mob may, perhaps, be found useful. We have heard of a water engine being effectively employed in the same service. During the confusion occasioned by a time of war in 1525, a mob of peasants assembled in Holmstein, in Thuringia, attempted to pillage the house of a minister of Eleude, who, having vainly employed all his eloquence to dissuade them from their design, ordered his domestics to go and fetch his beehives and throw them in the middle of this furious mob. The effect was what might be expected; they were immediately put to flight, and happy to escape unstung.

Queries.

[947.] I have been making my own comb-foundation, but have had much trouble through its being too brittle, and in some cases breaks before I get it off the block. Will you kindly tell me how to make it more flexible and better to work?—John Dunning.

Echoes from the Hibes.

Hartlip Vicarage, Sittingbourne, April 18th.—Do you know that a Honey Company in Liverpool is selling excellent 'Californian' honey at 6d. per lb., carriage paid to this place. I am feeding my bees with it, outside their hives, as it has been much too cold as yet to handle them. This is a glorious day for them and they are working well, but what of to-morrow?—let Aix-les-Bains say, perhaps snow.

South Cornwall, April 22nd.—It has appeared useless to repeat the burden of the two or three 'echoes' a-week which have lately been sent, and of your own notes, but now that a few drops of rain are falling, the precursors, it is to be hoped, of copious showers, we may sound the note of hope. Notwithstanding the cold winds which have prevailed for two months, I am sure the bees have done their best. With plenty of tempting sunshine there have been some calm and mild days, and our little friends have carried in abundance of pollen, but certainly not much honey. It is very interesting to note (when one has leisure) the varied colours of the contents of their baskets. I have taken an opportunity of examining some half-dozen hives and find large patches of brood with many already vacated central cells. Some stocks were very strong and will soon require attention. Happily supplies are ample as yet, and I am glad that I left as much as I did of natural food. The blossom of bush fruit is very backward, and the few gooseberry buds which the bullfinches left me have had great difficulty in expanding. But now we shall be full of hope, and so may 'April showers bring forth May flowers.' C. R. S.

Kendal, April 30.—On examination of my hives on April 9th I found all had wintered well and were abundantly stored, but unfortunately one of them had lost their queen, so I put a frame of brood out of another hive in and they made a queen, but as there were no drones I sent to Mr. Simmins for one. She arrived on April 25; so I took the remaining brood out, and at night I kept the queen without food for thirty minutes, then I turned up the quilt in the centre, gave them a puff of smoke, let her run in and soon heard the sound of welcome. On the 28th I took a frame out and saw the queen moving about and a quantity of eggs.

—George F. Martindale.

Chippenham, Wilts.—A longer and more trying winter and spring for bees I never remember, neither do I remember a spring in which they worked less and were confined so much to their hives by ungenial weather. And yet they appear healthy and fairly strong. During the last week they have started in carnest and are evidently making great efforts to make up lost ground. I noticed to-day (April 30) the pollen-carriers from my strongest stocks were entering the hives heavily laden at the rate of thirty-five per minute, the weaker stocks not averaging more than fourteen per minute. I should like to know from other echoes if this is a fair rate of progress.—W. A. Warrilow.

Rempstone, near Loughborough, May 2.—All the colonies in this immediate neighbourhood are alive and able to kick, except a few bees which have either kicked the bucket or their interfering master. Many of the stocks are getting very short of food, and if not attended to promptly will starve or just be ripe for sections in August, after the honey flow. I saw the first drone on the wing on the 3rd of April. They are very busy just now (not the drones) on the gooseberry trees, and what pellets of pollen they bring home!—ARTHUR FELSTEAD.

[We appreciate your appended suggestion.—Ep.]

Harborne, Birmingham.—Considering the cold east winds and frosty nights we have had for so long, my hives are wonderfully strong, but not nearly so as they were this time last year. Every year at the beginning of April I crowd the bees into as small a space as possible, the strongest stocks only having six frames left them; then about a fortnight later I put back the surplus combs, one every week, in the centre of the brood nest, and it is really wonderful to see the energy with which these stocks work, in comparison with those left with ten or twelve combs. Yesterday, May 1st, they were hard at work bringing in pollen of all colours in great quantity, besides water, and honey from gooseberry and currant blossom. All we want now is a warm moist month to repay us, in some measure, for what we have gone through.—H. J. Sands.

Belfast, April 28th.—The reports that have reached me from all parts of this district are very favourable. Bees have wintered well and only want fine weather. I am sorry to say since Sunday last it has been more like midwinter than end of April; we have had hail, snow, and frost, with occasional bright sunshine. However, a change has taken place to-day, which I hope will continue, viz., weather warm and calm. Furze, willow, and dandelion, affording great pasturage if bees can only get out.—P. M·H.

NOTICES TO CORRESPONDENTS & INQUIRERS.

Letters or queries asking for addresses of manufacturers or correspondents, or where appliances can be purchased, or replies giving such information, can only be inserted as advertisements. The space devoted to letters, queries, and replies, is meant for the general good of bee-keepers, and not for advertisements. We wish our Correspondents to bear in mind that, as it is necessary for us to go to press in advance of the date of issue, queries cannot always be replied to in the issue immediately following the receipt of their communication.

- John Ross.—Fumigator.—Many of those who have made trial of Webster's fumigator prefer it to the ordinary smoker.
- A. Pinney.—Old Combs.—It would be very bad policy to put a swarm on mouldy combs and sour honey. Melt them down, and put the swarm on foundation. Very likely the sour honey killed your bees.
- E. Richards.—Fertile Worker.—According to your description the brood is that of a fertile worker. You say, 'there is a fine lot of bees;' are you quite certain that a queen did not escape your notice? Carefully examine

again, and if the colony is queenless almost your only plan will be to give a fertile queen caged on a frame of

N. Chapman.—Calvert's carbolic acid can be obtained from any chemist. Do not reduce the width of the frame shoulders; an inch and a half is the correct width. Your drones were early, but it is a good sign.

Primrose.—l. Glass Shade.—If the glass shade is of clear white glass and sufficiently strong it will make a good receptacle for comb-honey. No ventilation is required. Foundation starters, as guides for combs, are desirable. Packing.—There is no difficulty in sending swarms long distances. At this time of year there is considerable risk in transmitting colonies on combs. For packing, we must refer you to our back numbers.

- B. J. G .- Moth in hires .- Moth and grnbs are frequently found among the débris in a hive, and if not removed, as you have done by shifting the bees and combs to another hive, might attack such combs as are not covered by the bees. They do not injure the bees nor affect the honey, but destroy the combs if allowed to increase. Examine the combs, and if you see a whitish trail running across the cells at the bases, against the midrib, remove it with a pen-knife, and kill the grub which you will find in it. The bees will soon repair the slight damage to the combs. Strong stocks with the combs covered by the bees are safe from the attacks of moth.
- T. C. R.—Dead Larvæ and Young Bees.—The bees arrived so flattened as to be undistinguishable; but from your description it appears that some cold night the bees condensed themselves, and left the edges of the brood to be chilled, and these chilled bees are those which are being thrown out.
- T. Lightfoot.—1. Stimulating.—Syrup made from crystal sugar in accordance with instructions given in Cowan's Guide-book for spring feeding will suit you better than that made from the sugar you have sent. Porto Rico is a raw sugar suitable for dry-sugar feeding. 2. Method of Management.—Do not give the bees too much room and several of the stocks will undoubtedly swarm naturally. As they do so, divide the combs containing queen-cells and the young bees in the old stocks from which the swarms issue into nuclei. You will thus get queens raised under the swarming impulse, which are always the strongest and best. If they do not swarm naturally about the middle of July take matters in hand yourself by making artificial swarms from as many as you wish. You will thus get sufficient young queens with proper management to requeen all your stocks if you think well of doing so. Note. Be careful to do this before the queens have stopped laying, which they frequently do when the great honey flow ceases. 3. Comb-foundation.—Tried by the ordinary rough and ready tests your wax foundation seems good. We should not scruple to use it.

J. B. S.—Syrup in Rusty Tin.—The small amount of iron taken up by the syrup will not be injurious to the bees; still it is better to keep food or honey in earthenware or glass kettles.

W. H. V .-- Queen Raised in April.-If you or your neighbours have plenty of drones flying, she may be fertilised, but the weather is against it. You would have done better to have united your queenless stock at once instead of giving eggs. If she does not lay soon you had better unitc.

Brixton Turnover .- As the river has many tributaries, some clear and some muddy and turbid, yet still rolls on its seaward conrse, so bee-keeping is occasionally diversified by sundry disturbances, which, however, soon flit past, and the good work proceeds on its onward march.

TREVOR RAYNOR. - Age of Queens, -An old queen may be known by the worn appearance of her wings and by her movements not being so agile as those of a young one.

Mrs. Hay.—Use of Hive, &c., having had Bees affected by Foul Brood.—If you have many other stocks which are not at present affected, we should say that the value of one empty hive would not be worth the risk. If you decide upon using it, scald it well out with strong soap and carbolic acid and water. The combs should be melted down, and the syrup in them boiled before being given to other bees. The drawn-out sections would, if placed upon another hive, most certainly infect it, and these could not be disinfected without spoiling them, the wax had better be melted and the sections burned.

- Primrose.—Honey-comb Designs.—By referring to page 224 of previous volume, you will find a letter from Mr. Wm. M'Nally giving detailed instructions as to the method of making honey-comb letters and designs.
- G. G.—Patent Rights.—A hive being patented we conceive that you have neither a legal nor a moral right to make one without permission of the patentee.

Received from Mr. Harry F. Row, Braintree, Essex, his Illustrated Catalogue of Bar-frame Hives and Bee-keepers' Appliances. 24 pp.

RECEIVED from Mr. A. Cockburn, of Cairnie, by Keith, N.B., his Illustrated Catalogue of Bar-frame Hives and Apiarian Appliances for the practical and profitable management of Bees.

Received from Mr. C. Redshaw, South Wigston, near Leicester, his Illustrated and Descriptive Catalogue of Hives and Bec-keepers' Appliances. This Catalogue contains some specimens of the blue and gold labels supplied by Mr. Redshaw.

RECEIVED from Mr. A. Watkins, of Hereford, Schedule of Prizes for Show of Hives and Honey to be held at Ross, Herefordshire, in connexion with the Herefordshire Agricultural Society, on Tuesday, Wednesday, and Thursday, June 14, 15, 16.

Show Announcements.

June 23, 24.—Suffolk Agricultural Show at Bury St. Edmunds. Entries close June 16. J. Huckle, Secretary. July 11-15.—Royal Agricultural Show at Newcastle-on-

Tyne. Entries close May 12. J. Huckle, Kings Langley. July 20-22.—Lincolnshire Agricultural Society at Spalding. Entries close July 4. R. R. Godfrey, Secretary.

July 26, 27.—Warwick Agricultural Society at Suttou Coldfield. J. N. Bower, Knowle, Secretary.

July 27.—Bishops Waltham Show. (Hants and Isle of Wight Association). II. W. West, Hon. Sec., Swanmore

House, Bishops Waltham.
August 3-5.—Yorkshire Agricultural Society at York.
Secretary, H. L. Rickards, Poole, near Leeds.

From 1st MAY to 30th AUGUST.

For 1 or 2 Queens (if ordered at one time), each 14/,, 3 ,, 4 ,, ,, ,, ,, 13/,, 5 ,, 6 ,, ,, ,, ,, ,, 12/-

For Countries out of Europe add 50 % to above prices.

All Orders to be accompanied by a Remittance.

My Queens are all very prolific, long-lived, and much larger-bodied, than the majority of those supplied by others, as they are reared naturally, under the swarming impulse, in April, May, and June, from the strongest of my forty colonies of Bees kept in double-walled moveable frame-hives, and all having choice Queens, which produce workers so gentle that they can be handled without smoke, and even without a veil on the face, just as I do myself (see Mr. S. Simmins' statements on page 37 of his work entitled, A New Era in Modern Bee-keeping). This is principally owing to the fact that I have weeded out from my Apiary all snch Queens which appeared to be weak or producing troublesome workers. Address—

M. G. DERVISHIAN, Larnaca, CYPRUS. A 2375 For Reference, address Imperial Ottoman Bank, Larnaca.

'A MORE EXCELLENT WAY.'

While there have been various differences as to the appropriateness of the word 'Apifuge' as applied by Mr. Grimshaw to the composition he has brought before the public for quieting becs, yet there cannot be any divergency of opinion as to the desirability of having some such agent which will mollify the temper of bees, and which will engender a greater degree of confidence in the mind of the bee-keeper. If Mr. Grimshaw has been fortunate in making the discovery of such an agent, or even an approach to such a result, another hill-top has been gained, and great is the amount of gratitude which is due to him from all bee-keepers.

It is, indeed, a subject for wonder that so many generations should have come and gone, and so many ages rolled past, and yet the temper of bees seems as irascible as when David expressively said of his enemies that 'they compassed him like bees,' or when the Romans described them as animals ferce nature. With all our boasted advancement in science and civilisation, we have made little or no progress in the humane treatment of honey-bees. The means that we have taken to subjugate them All the coercion have not met with success. acts that we have promulgated,-all the coercion bills that we have issued, have not had the effect of bringing them to be the willing servants of man. They are still ready to fight, to the death, in defence of their 'hearths and homes.' From the time of Columella, and no doubt long anterior to him, we have been engaged in one continuous warfare against them. What numerous agents have we not employed to subjugate and bring them subservient to our dominion; and yet, with a bravery and a resolution that we must respect, they are still implacable and defiant. We have brought against them all the means which the ingenuity of man could devise. Volcanoes of smoke have been belched into their domiciles; 'tumultuous clouds, instinct with fire and nitre,' have been rolled into their midst; buckets of carbolic acid have been 'disgorged' in 'baleful streams' amongst them; they have been 'stupefied with the narcotic fumes of puff-ball; they have been rendered insensate by chloroform or ether; they have been smothered and suffocated, as Dr. Butler has it, with 'dank straw

or hav, with brimstone, bunk, puk-fists, touchwood, and mushrooms.' Smokers of all kinds, cold-blast and hot-blast, have been invented with a view to subdue them. Saltpetre, tobacco, wintergreen, oil of tar, brown paper, cordurey, fungus, and all other noxious and filthy substances, have been arrayed against the poor speechless sufferers. We have proclaimed that the object of our establishment of Bee-keepers' Associations has been 'the advocacy of humanity to that industrious labourer—the Honey-bee.' We have arrogated to ourselves a superiority in humanity to our predecessors, who with one act put an end to what they considered their surplus stocks. We have 'sat in the seats' of the Preventers of Cruelty to Animals. We have called the bees by most endearing names,—'our 'pets,' our 'favourites,' our 'dear little friends.' And yet what tortures have we inflicted upon the quivering creatures to make them feel that we are their masters! We have dosed and physicked, we have suffocated and asphyxiated, we have nicotinised and carbolicised them, that they,-cowed, subjugated, and demoralised,—should pass under our 'Caudine Forks!' And, let us ask against whom have we employed all this machinery? Against the little busy bees,'

> 'That with their pretty buzzing melody Came here to make us merry;'—

insects so 'fearfully and wonderfully made,' showing in so great a degree intelligence and instinct in their habits and in the architecture of their combs and cells that the very heathen attributed to them a divina mens* (a divine mind). And can we, who have attained with our greater knowledge a further insight into their wondrous structure, —their arteries, their nerves, their tissues, their spiracles, their eyes, and their whole physiology, resist saying, 'The Hand that made them is Divine?' And yet in how sad a method have we treated this reflex of Divinity! We sorrowfully confess that these deeds have been done in our 'times of ignorance,'—'our salad days when we were green in judgment.' Let the time past suffice us to have wrought in this misguided fashion, and let us acknowledge that a new light has beamed upon us. The darkness of the long night is yielding to the dawn of a brighter and happier day.

Mr. Grimshaw has appeared as a pacificator; he desires to establish an *entente cordiale* between

^{*} Virgil, Georgic iv. 220.

us and our bees; he points out 'a more excellent way' of treatment. He has inaugurated a new era.

He is the prophet of a new evangel.

We have been experimenting with the 'Apifuge' on a stock which was vicious in the extreme. The effect on the bees was sedative, taking from them the disposition to attack and sting. It had no repellent power, the bees fearlessly approached it, and seemed desirous to examine this new agent. Having satisfied themselves of its innocuousness, and even its pleasantness, they resumed their work as if saying, 'The good time has come.' The substance is not displeasing; and washing the hands in warm water will readily take away any odour.

Ladies and beginners in bee-keeping will hail the 'Apifuge' as a good friend, removing their fears and creating a pleasant confidence. It will be the means of vastly increasing the number of bee-

keepers.

We have received several testimonials from those who have given the Apifuge a trial. We have already on p. 163 given the testimony of a correspondent who says 'that during the whole of the manipulation there was not the least attempt at stinging,—in fact, all the sting seems taken out of the bees by the agreeable odour it possesses.' 'C. A. J.' says she would wish to add her testimony to that of the previous writer: 'I have tried it on two occasions, and the result was exactly the same as that described by that correspondent.' 'A Lady Amateur' writes:—

'I should like to add my testimonial to Mr. Grimshaw's Apifuge. It seems to me simply perfect. I have manipulated my bees without veil or gloves, and have not received a single sting. I was attacked by one angry bee in the face, but it was sufficient to raise my hands to my face to protect me. One great advantage is that it gives me entire confidence. I had lost mine to a great degree, having once been attacked by a whole hive when driving bees.'

We have received other testimonials, but our space will not permit their insertion; at the same time we shall not be surprised to hear of some failures.

We think that there can be little doubt, on the whole, as to the virtue and the value of the discovery made by Mr. Grimshaw. 'He that hath deserved should bear the palm.' Let Mr. Grimshaw bear the palm, and have all the honour and reward that he deserves.

THE YEAR OF JUBILEE.

The air is resonant with sounds of loyalty. From every city, village, and hamlet, there are stirrings of mind and heart to mark this year with some remembrance as a year of Jubilee. Church and State, all grades and conditions of men, are earnestly desirous to raise some monument which will cause them to remember this the fiftieth year of Her Majesty's reign.

We conceive there is no class or body of men among Her Majesty's subjects who are more solicitous of evincing their loyalty to their Queen than bee-keepers. With the community at large they have that respectful feeling towards a sovereign whose reign has been one of peace and of progress in all the arts and sciences; and in their hearts, as in those of others, a sense of gratitude is alive to Him who has spared her as their ruler for so many years, and under whose mild and gentle sway Britain has made such wonderful progress among the nations of the earth; and the hope is in every heart that her life may be long spared to reign over a loyal and contented people.

We bee-keepers may be but a 'feeble folk,' yet we consider there are special reasons why we should not be behindhand other communities in raising our voices in welcoming this auspicious year.

From Her Majesty, and from many members of the Royal family, we have received many tokens of the interest they have taken in our special industry. We have several members of the Royal family acting as Presidents of the County Associations. We feel that we were deeply indebted to the Prince of Wales for his kind and gracious permission in holding our long-to-be-remembered show at South Kensington; and the presence of Royalty has been frequent at the bee-departments of numerous agricultural shows.

From the study of the economy of the honey-bee there is much to incite bee-keepers in their devotion to their Queen. In the constitution of our realm, and in the order of government by bees, there is much that is congruous and parallel. The bees have, says Shakespeare, 'a king,' (i.e. a queen) 'and officers of sorts,'—they have a ruler in whose welfare they take an intense interest:—

'They link with industry the loyal mind.'

The prosperity of the hive rises or falls with the health and condition of the queen. Again, Dr. Butler, in his *Feminine Monarchie*, says:—'The bees abhor polyarchy, as anarchy, God having showed in them unto men an express pattern of a perfect monarchy, the most natural and absolute form of government.' Together with bees we have had a 'feminine monarchy,' and we all have good reason to rejoice that that monarchy has continued with so much benefit for the long period of fifty years.

Should we not then, in some direct manner, take our part in the general rejoicings which are sounding from every quarter of the Queen's dominions? We conceive that there will be no dissentients in this, and that all are anxious to commemorate the year of jubilee. The question is, How can this be best effected? We should suggest that the Committee of the British Bee-keepers' Association should forthwith meet and give this matter their best and most earnest consideration. Having resolved on some mode of honouring the event, it might be requisite to call a general meeting of the members of the Association and to ask their assistance in carrying out their views.

Bearing in remembrance the happy meetings that bee-keepers held last year at South Kensington, and feeling assured that bee-keeping derived a great and continuous impetus from that show, and that it is always desirable to keep bee-keeping before the eyes of the public, we would suggest that this year should not pass away without holding a similar exhibition to the South Kensington, improved upon

by all the experience of the past.

The question would then arise, Which place would be most suitable for the show? We would suggest that, if possible, it should be held in connexion with the American Exhibition, which will doubtless this year be the great outstanding attraction in the metropolis. We know the difficulties which stand in the way of accomplishing our sug-We are aware of the great difference between the two undertakings, the South Kensington and the American—the one in a great degree was public and philanthropic, the other is a purely commercial and private speculation. But as all obstacles were overcome in obtaining permission to hold the show at South Kensington, and we found ourselves amidst Indian and Colonial objects, so the unexpected may again occur, and there may be a possibility of seeing bee-keepers among Americans during the coming season.

We leave the suggestion in the hands of the Committee, convinced that whatever is practical will be done by them, not alone for the progress of beekeeping, but to show the loyalty of bee-keepers to

their Queen and Sovereign.

NOTICES.

Our readers' attention is called to the fact that the date for closing Entries of the Bury St. Edmunds Show has been changed from June 16th to June 6th. The date has been altered to suit the arrangements of the Suffolk Agricultural Society, in order that the exhibits of honey, &c., might be published in the general catalogue of the Exhibition of Stock, &c.

Entries for the Royal Agricultural Show close to-day. Post entries at double fees will be received up to June 1st.

USEFUL HINTS.

Weather.—With the exception of an occasional day of sunshine, the weather still continues cold and ungenial, with frosty nights, easterly winds, and cold showers.

Forage.—Fruit trees are full of bloom which has little chance of unfolding itself, and there is little beepasturage at present available. Our apiary is surrounded with numerous poplars, of four different species, which are full of bloom, shedding their catkins all around, on which the bees feast with evident satisfaction, appearing to prefer working upon the fallen ones to those still hanging upon the trees. Beneath the trees the ground is covered with bees busily at work with merry hum, while scarcely a bee is to be seen upon the trees.

Probably the pollen is more easily collected from the withering bloom, and exposure to the cutting winds is avoided. Furze, dandelions, blackthorn, and a few other wild flowers, are all our forage at present. When Eurus ceases to blow we shall hope for hetter times. No honey has yet been carried into our hives, but stores are still plentiful within, and the population increases so rapidly that our forwardest colonies are ready for surplus cases.

FEEDING out-of-doors we do not recommend. The disadvantages, in our opinion, far outweigh the advantages. Our objections are: 1. It encourages a desire for pilfering. 2. The fighting over the exposed food is considerable, consisting of a series of single combats. 3. Bees, when laden with food, often become chilled and unable to reach their hives. 4. All bees, say within a radius of a mile, discover the exposed food, and if foulbrood exists in the neighbourhood, are tolerably certain to communicate it. These, we think, are weighty reasons against the practice of out-door feeding, when compared with the peacefulness and quiet of top-feeding for each colony separately from a good heat-conserving feeder. If comb-honey be the food there are plenty of topfeeders in which it may be given, such for instance as Neighbour's, or it may be laid over the feed-hole and covered. All syrup should be phenolised or salicylised, since foul broad at this season is especially to be dreaded, and therefore to be guarded against.

ENLARGING BROOD-NEST.—The brood-nest, in prolific colonies, should be continually enlarged by the removal of outside combs which are honey-clogged, passing them through the extractor, and returning them to the hives, when they will quickly be utilised for brood-rearing, and will supply a stimulus to the bees, but too much room must not be given, indeed, very little more than can be filled. 'Crowding' the bees is a most important principle, which must not be neglected until the hives are quite full of bees and forage is plentiful in the fields, when

supers should be given without delay.

GIVING SUPERS.—The enlargement of the upper parts of the combs with new wax is a sure sign that more room is required, and super arrangements should be made, uncapping a few cells in the upper parts of the combs before placing sections in position.

COMB HONEY, during the early part of the season, in our opinion will pay better than extracted, since it is the finest in quality, keeps a long time free from granulation, and is liable to no admixture of aphidian excretion, which spoils so many late supers. Our fruit and hawthorn honey we often keep a whole year-and have kept it two years—without the slightest granulation. We do not work, therefore, for extracted honey in the early season, but delay our doubling operations until the first supers have been removed, preventing swarming, by giving room above and below the brood-nest, with ample ventilation in hot weather. If the bees, not withstanding all these precautions, will persist in swarming-which very rarely happens,—we adopt one or other of the plans described below which gratifies the natural desire for swarming, and keeps up the working energy at fever heat.

The forwardest and strongest colonies having received snpers for storing from fruit and other early bloom, the second-best should be stimulated, and assisted by all possible means; weak colonies which are unlikely to afford surplus should be united to the stronger ones, thus forming populous stocks by the time of the arrival of the white clover honey. Or if preferred two moderate-sized colonies may be united, and supers given a couple of days

afterwards.

Suppose, now, that all surplus arrangements, intended at present, are complete and that our bees are at work in the sections. These must be carefully watched, and as soon as the cases are about two-thirds filled they should be raised and a case of empty sections placed beneath each, thus affording space between the partly filled cases and the brood-combs, an arrangement which will generally satisfy the bees at the critical moment when the swarming fever is most likely to seize them, and will afford them ample opportunity for expending their energy in the storage of honey, instead of frittering away the precious moments in the vagaries of swarming.

Any sections in the upper cases which are finished and well sealed should be removed, and their places taken by those nearly completed, the gaps being filled by empty ones, always keeping the cases containing most honey at the top. To an exceptionally strong colony space may also be given below the brood-chamber by inserting a shallow chamber containing frames of from four to six inches deep with full sheets of foundation.

This system will generally prevent swarming, but occasionally -so strong is the impulse of nature-that in

spite of every precaution a swarm will issue.

NATURAL SWARMING.—Then let us suppose that one of our strong colonies, having accepted and commenced work in its supers, casts a swarm. What course shall we take? When the swarm has settled, sprinkle it slightly with water from a garden syringe to prevent its rising again, and to cause it to cluster more closely while you are engaged in arranging the hives. Returning to the parent-hive, remove the surplus cases, and from the brood-chamber take all the frames (except two, well filled with brood, but without queen-cells) and, placing them in an empty hive, close up with division-boards and remove the hive to a new position. Add to the two frames of brood, left in the parent hive, on each side, sufficient frames, containing full sheets of foundation, to fill the hive; place zinc-excluder upon the frames and return the surplus cases just removed, wedging up the brood-chamber a couple of inches in front. Now hive your swarm in a zinc pail, throwing over it a thin cloth or small sheet, and, carrying it to the parent hive, cast it down in front of it, watching until you see the queen enter, and hastening the ingress by guiding it with a carbolised feather. A few minutes will suffice for the operation, and the swarming impulse being satisfied, the work will be continued in the section cases with even greater diligence than before. The part removed to a new position may either be allowed to raise its queen and to form a separate colony, or it may be broken up and its brood divided amongst other colonies. If the former plan is adopted a good colony will usually result, and there is no fear of its casting a second swarm, as all the bees, save the nurses, will have returned to the parent hive. When we desire no increase, we leave as many as four frames of brood in the hives, to which the swarm is returned, placing them alternately with full sheets of foundation, being particularly careful to remove all queen-cells, and strengthen other colonies with the remaining sheets of brood. There is another plan which succeeds equally well. As soon as the swarm is well out, and has compactly clustered, keep it quiet as before by using a garden syringe. Remove all surplus cases from the parent hive, and, taking out every frame from the brood-chamber, destroy all queen-cells save one well formed and perfect. Replace in the parent hive the frame having the queen-cell and three others in the same position towards each other as they occupied before with adhering bees, brood, and honey. Fill up the brood-chamber with frames containing sheets of foundation, or preferably with comb already built, and let the hive occupy the same position as before. a new hive and place therein the remaining six or eight frames, whichever it may be, filling up with frames of foundation, and place it in a new position, with the surplus cases upon it, and a sheet of excluder zinc between. Now hive the awaiting swarm in a zinc pail as before, carry it to the new hive in the new position, and cast it out in front of it, carefully guiding in and hastening its entrance. In this case, as in the former, the swarming impulse will have been gratified, and work will be carried on with redoubled energy. Either plan may be varied by giving more or less brood to the swarm in accordance with the intentions of the owner as regards increase of colonies or otherwise. Whichever plan is used, the queen will soon be at work, and the bees will be storing honey in the sections more rapidly than before swarming for the simple reason that they have no other place in which to deposit it, but the hest of all is that the swarming propensity will have been indulged, and to those who have never tried the system the manner in which the bees work will be a new experience. Provided the queens are not more than two years old, and are prolific, there will be no further attempt to swarm or to supersede them.

PREPARATIONS.—Let there be no delay in any preparations still required. Hives and section cases, all ready primed with foundation, should now be in store, ready at a moment's notice, for, notwithstanding the lateness of the season, natural swarms may be cast earlier than expected. When queen-cells are in progress, bees, like time and tide, wait for no man, and makeshifts are not desirable. Early swarms will often store more section-honey than old stocks, and with a market glutted with American and other extracted honey, good sections will hold their own, and will always bring a fair return sooner or later.

ASSOCIATIONS.

NOTTS. BEE-KEEPERS' ASSOCIATION.

The annual meeting of this Association was held at the People's Hall, Heathcote Street, Nottingham, on Saturday, May 1. Mr. P. Pilgrim, of Shelford, presided, and amongst those present were:—Messrs. Brearley, A. Felstead, A. Simpson (Mansfield Woodhouse), E. C. Walton (North Muskham), J. Colgrave, Allsebrook, Turner, and Marriott. Mr. F. H. K. Fisher, hon. secretary pro tem., said that he had been asked to officiate for Mr. E. Ferneyhough, who through pressure of business had been unable to attend to the work incident to his acceptation of the post of honorary secretary and treasurer. He (Mr. Ferneyhough) was not able to be present at the meeting, and had not as yet prepared the statement of accounts. There was still a balance on the wrong side, but it was considerably less than that of last year. Up to some short time ago he was in hopes that there would be a balance in hand, because so little had been done by the Association last year. They had a great many members -109—last year, and the only business was that done at the Mansfield Agricultural Show, where they had a beetent, and a few prizes in connexion with other shows. Messrs, Morris and Place last year offered the Association the use of their mart for the purpose of holding a honey fair, but this matter had fallen through. The prizes won at the Mansfield Agricultural Show were in the hands of Mr. Barron. The holding of a honey fair ought to be one of the points to be taken up strongly by the committee this year if they went on with it. Members stated that the chief difficulty they had in connexion with beekeeping was getting rid of their honey. If a fair was held this would be done away with. In conclusion, Mr. Fisher stated that Mr. Ferneyhough (Radcliffe-on-Trent) had promised to get his accounts properly made out in a few days. Mr. F. H. K. Fisher (Farnsfield) was appointed secretary, Lord Newark president, and Lord Charles Bentinck, Mrs. Robertson (Widmerpool Hall), and Mrs. Hole (Caunton Manor), vice-presidents. Mr. E. C. Walton, of North Muskham, was re-appointed manipulator and lecturer at shows held in connexion with the society. The following were appointed on the committee for the ensuing year:—Revs. T. B. Garland, and H. P. Ling; Messrs. A. Felstead, T. Rose, W. Silver, Mrs. Wotton, Marriott (Nottingham), Brearley (Carlton), Godfrey (Langley), Gosling (Arnold), R. Turner, and E. Ferneyhough (Radcliffe). A vote of thanks was accorded Mr. E. Ferneyhough for his services as honorary secretary and treasurer, and a similar compliment to the chairman closed the meeting.

YORKSHIRE BEE-KEEPERS' ASSOCIATION.

A Committee meeting was held on 30th ult. at Leeds. W. Clark, Esq., in the chair.

After transacting the usual business it was decided to print Mr. Grimshaw's suggestions on the formation of district associations, and to send the circular to each member of the Y.B.K.A. asking them to get the same inserted in the best local paper of their own district.

The committee were also informed that the Hon. Secs. were waiting a reply from the Saltaire Exhibition Committee to their offer to give lectures and manipulations at regular periods during the forthcoming exhibition. Since the last meeting a new district association had been formed at Horsforth (Hon. Sec. Mr. Burniston), and another at Skipton (Hon. Sec. Mr. Dodgson), and there is every probability that others are in course of formation.

Specimens of Cyprian, Syrian, Ligurian, and other bees preserved in spirit by Messrs. Abbott Bros., Southall, were exhibited by Mr. W. Dixon.

The customary vote of thanks terminated a highly successful meeting.

LOWESTOFT BEE-KEEPERS' ASSOCIATION.

The annual meeting of the members of the above Association was held on Thursday afternoon, May 5th, at the Public Hall, the Rev. C. T. Scott in the chair. A very satisfactory report was read by the Honorary Secretary, Mr. L. Wren. The balance-sheet showed that the receipts for the year, including balance from last year, were 201. 0s. 8d., and that there was a balance in hand of 4l. 9s. 5d. The re-election of the old committee took place with the addition of Messrs. K. Rix and S. Cox, and the committee's report was unanimously adopted. Mr. Wren was also re-elected expert, secretary, and hon treasnrer. Mr. Wren read an excellent paper on the 'Management of Bees for Profit.' The Chairman proposed a hearty vote of thanks to he expert, which being seconded by Mr. Thornhill, was carried nem. con.

Correspondence.

The Editor does not hold himself responsible for the opinions expressed by his correspondents. No attention will be taken of anonymous communications, and correspondents are requested to write on one side of the paper only, and give their real names and addresses, not necessarily for publication, but as a guarantee of good faith. Illustrations should be drawn on separate pieces of paper.

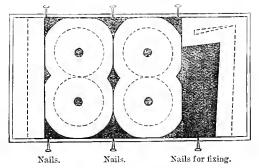

Communications relating to the literary department, reports of Associations, Shows, Meetings, Echoes, Queries, Books for Review, &c., must be addressed only to "The Editors of the "British Bee Journal," clo Messrs. Strangeways and Sons, Tower Street, Upper St. Martin's Lane, London, W.C. All business communications relating to Advertisements, &c., must be addressed to Mr. J. Huckle, King's Langley, Herts (see 2nd page of Advertisements).

***In order to facilitate reference, Correspondents, when speaking of any letter or query previously inserted, will oblige by mentioning the number of the letter, as well as the page on which it appears.

HONEY-COMB DESIGNS AND LETTERS.— BEE-HOUSES.

[948.] From the great number of letters I have received this spring asking how to prepare supers of letters to put on the hives, and this being the Jubilee of our Sovereign the Queen, there seems to be a growing

Dotted lines show the foundation view under side,

appreciation as to how to build them. With your permission I here subjoin a drawing of the figures 1887

with further note how to build these. It will be to the advantage of your readers to look over my article on this subject in B. B. J. of May 20th last year, page 224.

To begin I here show a super $16 \times 8 \times 3$ inches deep. Two of these supers cover ten frames as one super, the black marks show where the blocks are put in, to prevent the bees from missbaping the figures; the dotted lines show the foundation fixed in centre of each figure, one inch of a guide is sufficient. The blocks are fixed from the outside with nails or brads, and when the super is filled and sealed it is then taken off. The blocks being removed leave the 1887 completed. As I mentioned before these letters and figures do not as a rule pay. However, last year I had built on one hive, before the end of July, the words, 'Scotia,' 'Caledonia for Ever,' 'Dumfries Show, 1886.' With the former one I gained first prize at Dumfries Show and at all places wherever shown. With the others I secured premier medal for display of honey, these being prominent in the exhibit, which paid me. When the word is too long it has to be built in more supers, thus 'Scotia' is in two supers, and 'Caledonia' in three.

I hope I have made all plain, and will be pleased to answer any question on the subject through the columns of B.B.J.

Bee-houses.—I have just made one, and have placed it out two miles from my home apiary to hold twenty-two hives. Size of house, 9 feet 6 inches \times 6 feet 6 inches \times 7 feet high. There is no floor in it, and the hives sit on stands on ground, four on each side and three in the end. The door is in the other end, the top row of hives, 3 feet 6 inches from ground, are similar to bottom. I leave here abundance of room to manipulate and storify if required with room to store spare hives and appliances and all secured with lock and key. I have not the least doubt but bee-houses can be made to pay in the hands of an expert, as I have wrought them for several years on a smaller scale. The cost of fitting up a house something like myown should be about 3'. 10s., or say 3s. 6d. per hive; any cheap hive will do for the inside. Scantling of timber for same is framing of 3×2 white pine; boards of dressed yellow $\frac{e}{5}$ sarking, joints covered with strips $1\frac{1}{2} \times 1\frac{1}{2}$; roof of $\frac{e}{5}$ sarking and covered with Willesden paper, two-ply, the whole painted three coats white lead paint. One has here a substantial building to keep hives. I know the advocates of bee-houses are in the minority of bee-keepers, but I have found these houses so far profitable.—WILLIAM McNALLY, Glenluce.

POISONOUS PLANTS.

[949.] I may be allowed to add a fact on your interesting reference to the poisonous nature of certain plants, &c. (see p. 198). Some few years since I had unusual facilities for observing bees working on rhododendrons, azaleas, and kalmias, that I can confirm the inference you have drawn, 'That the common bee is scarcely or never seen to settle on these plants.' In these species, with their numerous varieties, nectar is secreted in abundance, and proves for humble-bees a veritable land flowing with honey. One of its components must be something akin to alcohol (in bee-life) as the nectar has a similar effect on the humble-bee as this spirit on the human species. These bees visit and collect the nectar with extreme avidity, and it has such an immediate effect that, as a rule, they are apparently thoroughly intoxicated by the time their honey sacs are full. In walking through grounds extensively planted with the above, and when in bloom, I have frequently seen upwards of a dozen in this state, tumbling and rolling over in a most comical fashion, vainly attempting to take flight; although I cannot say for how long this fit of inebriety continues.—James Lee.

BRITISH BEES. (930).

[950.] As a bee-keeper of thirty years I cannot allow even Mr. S. Simmins to libel our British bees by describing them as black without protest. There is in some parts of the country a race of small degenerate bees of a very dark colour, but there is also in every county to be found a fine handsome race of native bees, similar in colour to the Carniolan, and without a particle of foreign blood in them. If Mr. S. has never seen them I can tell him of a gentleman, well known as a first-rate bee-keeper in the county of Lincoln, who has carefully avoided all foreign strains, under the belief that some day the pure British bee would become a valuable article in the bee-market. The small darkcoloured bee referred to I attribute to the fact that in some parts bees have been known to occupy a hollow tree or a church roof for a great many years, and with constant breeding in the same combs, the cells of which become both small and black, the race degenerates; but to describe such a bee as the true type of the British, would be about as truthful as to describe the race of men who work in our coal-mines as a type of British manhood.

If I did not know Mr. S. personally, I should think he was joking on this subject. THOMAS F. WARD, Church House, Highgate, Middlesex, May 2.

LEE'S SECTIONS—APPLIANCES—FOUL BROOD.

[951.] Having had Mr. Lee's new sections submitted to me some time ago, I have been intending to write a few words with regard to them, but have not found time to do so. I fear now that anything I might have said has been forestalled in the Journal. The principle seems to me decidedly an advance forward, which is more than can be said of many new inventions nowadays; and, as Mr. Lee suggests, I believe that the bees will not be inclined to make 'popholes' in sections of this kind. With regard to the price, I cannot think that they can be made to compete with the cheap rate of the ordinary ones; but, personally, I fancy a small extra cost will in the end repay the purchaser.

I should advise the use of these sections, giving the bees a passage above and below, and not at the sides. From your article I gather that you would so use them, but Mr. Lee himself thinks the space is better given vertically (i.e. the long strips form the top and bottom of the sections). One drawback to this would be the loss of surface on the top of the frames, as much of it would be covered by a vacuum. I find hees fully appreciate a direct passage of this kind, and fill the sections more fully and with greater speed than those in ordinary use. I should like to write at greater length on this subject, but

I must not trespass at present on your space.

May I add a few words on another topic? Many letters have appeared of late in your columns (written chiefly by novices) finding fault with goods supplied to them. Being in no way connected with the trade, but having had occasion for many years to use the hives and other appliances of most of our leading dealers, I wish to bear testimony to the uniform excellence of the things they have sent me.

One word, in conclusion, to those who have had no experience with foul brood. Be very careful in equalising stocks, that diseased combs are not put into hives which are in a healthy condition. The disease, which is most prevalent at this time of the year, is spread in this way much more than is generally recognised.—A. G. RAD-CLIFFE, East Grinstead, May 6.

THE COMING BEE.

[952.] The following from the pages of Dr. Jessop's new book Arcady, one that should be read by every

parson and landholder in England, is too good not to be read in the B.B.J.:-

"I'm an apiary, sir," said a shiny being who called upon me the other day. "A what?" "An apiarist is, I believe, the more correct term, sir; and I am collecting orders for my new hives." How that man did talk! He had got hold of some scheme, and I am seriously informed it is actually a feasible one, for increasing the normal size of the common domestic bee (Apis ignoratissina) by somehow knocking two cells into one, and producing a sort of double-barrelled bee, "and adding enormously to your stock of honey, sir." It appears that we can absolutely increase the size of our bees indefinitely, and that the men of the future will have hives as roomy as an omnibus. Appalling prospect! Think of a bee as big as a rat bouncing into your greenhouse, bellowing hoarsely while he ravishes the orchids, or flopping into the nursery sugar-basin, glaring with his huge eyes at the terrified baby. Edith Evangeline—for Sara Anns have gone to a better world—would drop down inane, a lump of hysterical despair. We shall have to suppress these things by Act of Parliament at last. Meanwhile my shiny friend does not lack for orders, and if he has his will he will speedily improve off the face of the earth the little busy bee whom we used to sing of, and because we sang of, to love.

Joking apart, Arcady is a book to be closely read, pencilled, marked, and carefully digested by every one who realised the width of the Doctor's remarks in his capital article in the Nineteenth Century of March last.—Rector, Buckland Filleigh.

IN THE HUT.

[953.] Two huttites at the end of March got summary (yes, the weather also gave summery) notice to remove their hives from a garden in which they were placed. Lucky for them it wasn't later. Willy-nilly, out they must go; for the ancient gardener really couldn't stand 'em (the bees). The difficulty was they had only about three hundred yards to go, and bees were all flying, and carrying in pollen from the willows; so the rule—not the two-foot rule, but - the two-mile theory, was to be

By the aid of a hand-barrow and plenty of tobacco much may be accomplished, and this was done so successfully that on examining the spot afterwards instead of it proving a veritable necropolis, there were not found so many as a dozen bees out of near a dozen hives. There are now two more sceptics in the world as to the degmas of our bee books.—(Is not skeptic a better word than skeppist in these philological days?) The explanation that the dead bees might be 'what Moses was when Abram built de ark—thar or thar'bouts' availed not.

In 'Echoes,' p. 154, a correspondent finds 'new-laid eggs' in his hive. We know what he means, but to the ex-bee-mundane mind it must read very funny. 'A. E.' recently found fault with me for mentioning broadshouldered frames, and now another huttite invites him to tell us of a better if he can and it shall have a fair trial, as it was only after mature deliberation that we determined to replace all frames by these.

A hint to those who intend to transfer his bees and combs to other frames for uniformity's sake:—If the transfer be to smaller-sized frames, fasten, with a tack, a bit of wood under each projecting shoulder of the empty frame so as to lengthen it (it will thus not drop down into the hive); comb or foundation being duly fixed, insert one or two judiciously, near centre of brood-nest taking out the two outside empty combs, shaking or brushing off any adhering bees, the rest having been driven towards broodnest by a little smoke. Now at leisure these combs may be cut to fit tightly into the smaller frames, securing them with a couple of tapes; and, in a few days, this process may be repeated till all are done, always having care to work the old frames to the outside so that they

may be pretty clear of brood and bees. Finally, the whole transfer may be made into the clean hive in a few minutes some fine day, without having a row, or danger

of chilling brood or robbing.

I hope our readers will not forget, in fixing foundation in sections, that the top quarter of the section may be split by a penknife, the foundation inserted in the slit and the fixing up completed without the aid of Parker fixer. No wax running, running the risk of unfixing the foundations of the dental mechanism of the unfortunate whilst eating section honey.

The Woiblet Spur Embedder! Is this an equestrian term? I saw that spur on the table at Jermyn Street on 20th ult., and it was indeed a 'Wobbler' at one end with a tin Carlin cutter at the other, so that when using the cutter the spikes of the 'business end' would wobble into the palm of the hand in a highly successful manner.

Seriously, it is a most useful little implement.

Mr. Bellairs starts a new theory:—'The hee which hesitates is lost, and cannot sting.' Huttites well appreciate and are grateful for statistics of honey imports, but they cannot take this on. Their bees often meander leisurely about, searching for a nice place, and finding one they deliberately lay hold of the skin, as it were, with able the calm determination and vigour Mr. B. would exhibit in putting on a Wellington boot. In short, they sting à la belle air, but not à la Bellairs. 'O Sophonisha! Sophonisba O!'

Our dear 'Useful Hints' in his remarks on experts last week makes us smile all over. Fancy an expert entering one's bee-garden clad in a diver's dress, or divers dresses, well saturated with water containing a disinfectant, frequently asking a kind attendant to 'spray' him! I should think if he asked him to spare him, his request would be far likelier to be complied with. Fancy expertinchief B, being thus sprayed; his nose in the air snifftering in the carbolic fumes as some other old war-horse would smell the battle from afar! And then what has to be done unto him who standeth and manipulateth in a cold or damp smit? Who is to pay his doctor's hill for rheumatic fever?—X-Tractor, Horsforth.

BEES AND RIPE FRUIT. (936.)

[954.] I noticed bees attacking ripe fruit last year during very dry weather when mignonette and other bee-plants were quite neglected by them. I thought perhaps the flowers were too dry to attract the bees, and had them well watered in the evening. Next day the bees had neglected the fruit entirely, and were quite busy amongst the mignonette.—H. C.

HONEY AS FOOD FOR INFANTS.

[955.] I was glad to see your remarks on honey as food in to-day's paper, and can give a good instance of its value. We have a *fine* infant just being weaned. His food was sweetened with honey while the supply (the last pot) lasted. When the supply was gone, the food was sweetened with *sugar*, and he was troubled with sickness after every meal from his very strength and heartiness. I scoured the country, and secured more honey, on using which again all sickness ceased. This is worth knowing by all (or rather, I should say, the *few*) mothers who have the sense to look after their children properly.—PATER.

HUMBLE BEES.

[956.] I am a bee-keeper, but it is only of Humblebees. My father has some hives which really were bought for me, but I found the honey-bee is not to be played with, so I resigned from that part of bee-keeping. Last summer I had my humble-bees. They were jet-black, with a dark-red abdomen. I have tried to find

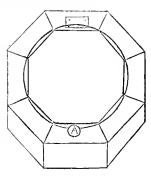

out the name of this bee, but did not succeed. I also had the queen of my small stock, of about fifty bees, and she was distinguishable by her shiny abdomen, which was bare,—not covered with hairs, as the workers were. I also had what I called drones in the same hive, and they were yellow and black bees, but with a red abdomen. Perhaps you would like to know what sort of a hive I had. It was a clock-case, with the works taken out, and for the doorway was a hole where the catch had been. Here is a sketch of my hive.

I read in the B. B. J. of a children's column being proposed, but I am sorry to never have seen any appearance of it. I would willingly be one of the correspondents.

But to return to my

narrative.

While I was looking in my hive once, I saw a bee busy opening one of the oval cells which contained young grubs, and presently, up comes another bee (which I

judge was the queen), and drove it away, after which it proceeded to fasten up its young. When it had finished, it went away again. Soon after, up came the other bee, and began opening; then the queen chased it away, and while it was chasing the other one, other bees came and continued opening the cell. So Mrs. Queen had her work set, but finally she drove them all away. Can you tell me the reason of such proceedings?

My bees also carried in pollen, which they stored in

cells and sealed, as well as honey.

When winter came on, I took them into the attic, to try and keep them till spring, but did not succeed. Could you tell me how I might keep them alive through winter? I am going to try again this next summer.— Darcy R. Grimshaw (age 13), Horsforth, Leeds.

[We have been very much pleased with your letter. It gives tokens of an observant mind; and when you grow older you will continue to find much that is lovely and wonderful in the works of Nature to engage your attention and to fill you with good thoughts. We cannot explain the opening of the cells containing the larve, but perhaps humble bees, like wasps, destroy the larve towards the middle of autumn. It is only the fertilised females survive the winter, and they speud the winter away from the parent nest. We shall be pleased to hear from you again.—Ed.]

SPARE COMBS.

[957.] I have just had your pamphlet on Doubling and Storifying, which, I presume, was written principally for the benefit of amateurs like myself; but there is one difficulty connected with it which I should be glad if you can help me in getting over. I must state first that I have only been keeping bees in bar-frame hives for two years, and have now nine stocks, all, I believe, healthy and strong; but I have no spare combs, and you state that in order to work this syssem to the best advantage it is necessary to have a large number of frames of empty comb. I shall be glad, therefore, if you will state in the next number of the Bee Journal how these can be best obtained, whether it would be right to give the strongest stocks foundation at once or later on, and whether syrup or dry sugar would be best give them at the time.-William Holman.

[You can give your strongest stocks comb-foundation to work out. If they are strong enough, we should

place a hive filled with frames of foundation below the stock. This will give them room, and they will build downwards. As the brood in the upper storey hatches out, if any honey is coming in, the cells will be filled with it, and the lower storey used for brood. When there are bees enough to fill the two storeys, put a third, also filled with frames of foundation, at the bottom. In this way you will soon get a stock of combs. You can feed with syrup as long as the bees are not able to get enough food, but stop as soon as they de. See also page 103 of Cowan's Guide-Book.]

CALVERT'S SOAP.

[958.] I am glad to see mentioned in the Journal of the 28th ult., under 'Useful Hints,' that you recommend experts to disinfect their hands or clothes after manipulating foul-broody hives before preceding to the next apiary. This I think extremely necessary, and can recommend for such a purpose a seap manufactured by Calvert & Co. for doctor's use, and sold in small tablets in a tin bex that can be put in the waistcoat pocket.

I have for some time used their carbolic soft soap for washing out the interior of my hives each spring. I am thankful to say we are not troubled with foul brood here, but I mention the soap for the benefit of my fellow-beekeepers.—B. LE NEVE FOSTER, Ewhurst, nr. Guildford,

May 4.

HOW LONG DOES A WORKER-BEE LIVE?

[959.] I can state as a positive fact that I have several, probably some thousands of bees in my apiary at this moment who cannot be less than twenty months old. The proof is this. In October 1885 I took away the queens from the two orange-banded—probably Ligurian—stocks in my garden. There has been no other foreign queen in the apiary since that time. They killed the brown queens that I gave them, and in April 1886 were broodless. I gave each of these hives at that time a frame full of brood from other hives, hoping they would hatch ont queens; but no, in May they deserted their hives, quartering themselves, with or without invitation I cannot say, on their neighbours, No. 7 and No. 2, for whom they did a great deal of light skirmishing duty during last summer. To-day about one bee in every ten in No. 7 is orange-banded. I have not observed No. 2 quite as closely, but I see plenty of them there also on the alighting-board. These have all certainly survived their second winter, and I do not observe that any of them yet have that dark, polished appearance which I take to be a mark of a very old bee.—C. C. James, Papworth St. Agnes Rectory, May I.

[Is it possible that the queen in No. 7 has been crossed with a Ligurian drone? We have never heard of such a case as worker-bees living for twenty months.

—ED.]

TRANSPARENT ROOFING.

[960.] The squire of my parish has just sent me own a pattern of Miether, Robbins & Co.'s transparent wire-wove roofing for my sheep-houses. I think it would be found suitable for roofs of hives. I intend to try it; it is a non-conductor. Sheets five feet by four feet, price sixpence per square foot. Their address is 83 Upper Thames Street, London.—Recton, Buckland Filleigh.

What Bees Gathen.—One remarkable circumstance about bees is the number of commodities of which they are either the collectors or confectioners. Besides honey and wax, there are two other distinct substances which they gather—bee-bread and propolis. Before we knew better, we thought, probably with most of our readers, when we saw a bee 'tolling from every flower the virtuous sweets,' with his legs full of the dust of the stamens,

that he was hurrying home with the wax to build his cell, or at least with the material wherewith to make We thought of Titania and her fairies, who for night tapers crop their waxen thighs,' and many other pretty things that poets have said and sung about them; or, if in a more presaic mood, we at least conceived that, if not furnishing fairy candles, they were laying the foundation for what Sir F. French calls 'the gentleman's lights.' No such thing. Their hollow legs were filled with the pollen or farina of flowers, which has nothing whatever to do with the composition of wax, but constitutes the ambresia of the hive-as honey does its nectar-their bee-bread, or rather, we should say, beepap, for it is entirely reserved for the use of their little ones. Old Butler had so long ago remarked that 'when they gather abundance of this stuff (pollen) they have never the more wax; when they make most wax they gather none of this.' In fact they store it np as food for the embryo bees, collecting from thirty to sixty pounds of it in a season; and in this matter alone they seem to be 'unthrift of their sweets,' and to want that shrewdness which never fails them, for they often, like certain overcareful housewives with their preserves, store away more than they can use, which, in its decomposition, becomes to them a sore trouble and annoyance. They are said always to keep to one kind of flower in collecting it, and the light red colour of it will often detect them as the riflers of the mignonette bed; but we have seen them late in the season in layers of different colours (not collected at the same time probably), and sometimes their whole body sprinkled with it, for they will at times roll and revel in a flower like a denkey on a dusty road.

PROFITABLE BEE-KEEPING.—'My object is to induce cottagers living in the country to keep bees; first of all, as a means of eking out a too scanty livelihood, and, in the next place, as a rational amusement and most in-structive pursuit. There are, in fact, within the reach of our labouring population few pursuits so interesting and so profitable as this of bee-keeping. It has this further advantage, that it demands comparatively but little attention, and interferes with no other occupation or duty. Nor is the capital required to commence beekeeping beyond the reach of our labouring poor. swarm in May, a straw hive or skep [or bar-frame hive] in which to put the bees, and an old bench, or the stump of a tree, with a hackle to shelter the hive, are all the needful stock-in-trade of the adventurous bee-keeper. A little saving on the part of an industriens man will soon supply what is wanting. To wealthier bee-keepers I would suggest the gift of a swarm as one of the most satisfactory ways of helping a poor family, where there is sufficient intelligence and a disposition to pay attention to the bees. But when once the bees are there, and well established, all expense ceases. With moderate but sufficient care they eight in a year or two to pay the rent of house and garden, and add, besides, many little comforts which few of our labouring poor are able to command. It is surprising how few bees are kept in England, compared with the number of hives one sees in other countries. Thus we import from abroad immense quantities of honey and wax every year, while many hundreds of tons of these commodities are left ungathered in our own fields and woods. A bountiful Providence has given to us no lack of the "fatness of the earth," which honey and wax may most fitly be called. In some years it superabounds in most astonishing quantities, but too often there are no labourers to gather in the riches, and they are lost. Even where bees are kept they are frequently mismanaged, if not utterly neglected; so that not a tenth part of the honey is harvested which might be collected.' After telling how, in a single season, he obtained 2 cwt. of honey, besides the wax, from seven hives, without destroying the bees or depriving them of their winter supply, the rev. gentleman adds: 'I would

say, then, to our cottagers in town and country, " Keep bees." Everywhere, save perhaps in London and a few other large cities, bees may be kept profitably—in some places, of course, more profitably than in others. On an average, every stock-hive that has well survived the winter should yield, in tolerably good seasons, from ten to twenty pounds of honey in caps or boxes, without destroying the stocks. It will thus be seen that ten hives, at this rate, should yield 51, to 101, per annum, supposing the honey to fetch only ls. per lb. I repeat. therefore, to our cottage friends, "Keep bees." Let me add, "Take care of your bees." It is worth while to manage them well; the more you look after them, without over-much meddling, the better they will pay. The bee-master's eyes should be frequently upon them, especially in the busy swarming time. Here his wife and children may greatly aid him by their watchfulness. Lastly, I say, "Never destroy your bees." The practice of "burning" or "brimstoning" bees is about as wise as killing a goose for her eggs. A more wasteful or mischiprons proceeding them, never was to say not been referred. chievous proceeding there never was—to say nothing of the cruelty of it. Those murdered bees—as many of them as survived the winter-would have been as industrious as ever on the return of spring, and have well made up to their master for his kindness in sparing their lives. Of course it follows that, if hives are never to be destroyed, the bees must not be robbed of all their stores: there must be moderation in plunder. Some honey must be left in the hive to keep them alive and in health during the winter and early spring months. Sound judgment, too, must be exercised as to the time when to rob them, as well as the quantity which may safely be taken.'—REV. P. V. M. FILLEUL.

Echoes from the Pives.

Bererley, April 29th.—Again I have to report favourably of my bees, notwithstanding the very cold wind, which has kept them more or less at home since my last report, except when the sun shone. However we have just had three consecutive sunshiny days, with the wind, although cold, very moderate, and with the gooseherry-trees, &c., in full flower; the bees have made the most of this favourable time, pouring into the hives laden with pollen and honey, and the perfume can be smelt yards away. Finding that some of my strong hives had risen considerably in weight, I examined a few of them and found combs filled from top to bottom with new honey, of course unsealed, the strong perfume telling plainly from whence gathered. Some of these hives are crowded on eleven and twelve standard frames, and should we have fine weather I must give more room either in the shape of more combs or sections. I hesitate to give crates of sections on account of the sharp frosty nights, and the consequent difficulty the bees have in building comb; neither can I extract the honey, it not being sufficiently ripened. This is just a time when great care is needed, as should we have cold set in for any length of time, as we had last year, the bees will want all their The difference between my strong hives and weak ones is plainly shown at dusk, for while the former are roaring like a furnace, the latter are still as death.—F. Boyes.

Broadstairs, Kent, May 7th.—The weather has been rather cold lately, and I do not remember having so much rain at this period for some years; Broadstairs being, as a rule, the last place for rain. The old local proverb runs, 'When England wrings Thanet sings.' I have doubled the two strongest stocks (covering nine frames each), placing brood combs in doubling-box, and sheets of foundation below in body-box. By-the-by, is 'doubling' the best term for so treating a hive; should it not be 'ekeing?' Those stocks covering six or seven frames I hope to double in about three weeks time; and shall try a couple with quarter-inch starters in body-box as a non-swarming safety-valve, treating the stock as though no empty space existed below. The stocks generally have wintered very well, thanks to the kindly attention of our local expert during my ab-

sence. I cannot say I have been uniformly successful in making stocks from condemned bees. One lot has a patch of brood about four inches diameter, and just enough bees to cover it. They are now packed up, with cork-dust to the right of them, cork-dust to the left of them, cork-dust in the front of them, cork-dust at the back of them, cork-dust on the top of them. All this cork-dust absorbs the sun's warmth in the day time, and gradually gives it off at night; and I think with a few frames of hatching brood from another stock that lot ought to pull up. Gooseberry bloom is nearly over, apples just beginning. As for wasps, though in the garden a great deal I have not yet seen a single specimen.—T. W. Oetzman.

North Leicestershire, May 7th.—Everything is very backward here for the time of year, and the bees do not seem to make much progress, as there has been very little weather fine and warm enough to tempt them ont. To-day—at least, during the morning—they were working hard on the lesser celandine, currant, gooseberry, and plum blossoms, and arabis. Nothing else ready.—E. B.

'Honey Cott,' Weston, near Leamington, May 9th .- After many changeable and stormy days, we seem to have drifted into some nice weather for our bees, which they have thoroughly enjoyed. With plum-trees in full bloom, dandelion coming out, wood anemone, and other flowers, there is a prospect of a good start for the season. I have found in several instances, where the bees had enough food and were left to their own sweet will, that they have not bred up so well as others that have been stimulated; whereas, in a few other cases, those with plenty of food have done exceedingly well. There has been any amount of young bees showing themselves during the last fortnight. Have been transferring a few stocks that I bought last autumn, and hope, with a little attention, to build them up in time for the clover. Am hoping to do a little spreading of broad if the fine weather continues, though it is just possible we may have (as we generally do) blackthorn winter .- John Walton.

Belfust, May 6th.—Since my last, I have been doing 'Amateur Expert,' and I found lots of brood and plenty of stores in several of the hives visited. I am glad to say a favourable change has taken place in the weather, which is now warm and showery and bees are doing good work. I have tried my stock on the dry sugar (Porto Rico), and will be able to report favourably or otherwise later on, have fed my thirty hives (which I was fortunate enough to bring through the winter) on dry sugar for stimulating; and if it is what is claimed for it, it will do away with one of the troubles of modern bee-culture, viz., making syrup for a number of hives.—P. McHenry.

NOTICES TO CORRESPONDENTS & INQUIRERS.

Letters or queries asking for addresses of manufacturers or correspondents, or where appliances can be purchased, or replies giving such information, can only be inserted as advertisements. The space devoted to letters, queries, and replies, is meant for the general good of beckeepers, and not for advertisements. We wish our Correspondents to bear in mind that, as it is necessary for us to go to press in advance of the date of issue, queries connot always be replied to in the issue immediately following the receipt of their communication.

- H. L. S.—The sample of enamel cloth has been received, and it will prove serviceable.
- T. Nixon.—1. If your queen is now laying only drone eggs, there is no prospect of her being refertilised. Being a young queen, her ovaries have been injured in some way. You must unite or get a fresh queeu. 2. If your bees are obtaining a sufficiency of natural food, you have done right in stopping the supply of artificial.
- H. G. Birch.—Doubling.—If you place a hive full of bees above or below, you should spray them with scented syrup as you propose. It is much safer to place the frames alternately, and unite in the usual manner. The old queen of 1885 is worthless, and you would get nothing for her.
- F. Nell.—Chapman Honey Plant.—We are not surprised that you cannot get seed in Sheffield, and that no plant of this name is known. There is, in fact, no plant of this name here; and it has been named Chapman Honey Plant because Mr. Chapman is supposed to have been the first who called attention to it as a honey-yielding

plant. You will find it is perfectly well known by the English name of 'Great Globe-thistle,' or by its botanical name of *Echinops spherocephalus*. We have plenty of English names for flowers without adding to the confusion by introducing new ones given without any sense or reason. We send you some seed.

H. J. Knight.-1. Dry Sugar Feeding.-Mr. Knight appears to have fallen into the error of making his bees rely upon dry sugar during winter. The process is in many quarters greatly misunderstood; and as the originator of the system, I am glad of the opportunity to warn the uninitiated, and to repeat what I have many times stated, that bees cannot exist upon dry sugar as their only winter food. In fact, neither that nor candy should be given until the approach of spring, unless in cases of extremity; and on no account ought a stock to begin the winter with either. Porto Rico does well as a winter food, but it must be stored by the bees as syrup by the end of September. As soon as all surplus honey is removed in autumn, start with dry feeders; and then if in some cases there is not sufficient store, feed rapidly with syrup, so that the bees may settle down quietly before October comes in. Such store should last till April, when dry sugar may again be resorted to with advantage. 2. Feeding Swarm hived on Combs.—A swarm hived on combs would be far better without feed of any kind, as a rule; but if the weather is very bad, a lump of Porto Rico over the feed-hole pressed down tight would keep them going, while the cells would not be clogged with syrup —S. Simmins.

W. S., Aboyne.-1. Dead Queen.-See answer to W. P. When manipulating during spring the bees will occasionally 'ball' the queen; if she is killed her body would be cast out of the hive. There is a very good chance of a virgin queen getting fertilised now, although less probability in your locality. 2. Bees.—The bees sent are Ligurians, of course it is impossible to say with certainty unless a description of the other bees in the hive is sent.
3. Laying two or three Eggs in Cells.—This is not unusual, and is more observable when her laying space is re-

W. P.—Death of Queen.—Weak starving colonies frequently vacate their hives and join other stocks, the queen of this colony is refused admission, and is cast to the ground, or the queen has been found past work, and has been dethroned; this may be the case with yours. Examine your stocks and note whether queenless or not.

J. H. D.—1. Stimulating.—It will be quite sufficient for stimulating purposes to uncap your honey cells once aweek; in fact this plan would be better than syrup feeding. 2. Moving Hives.—Yes; if the hive is very strong and on the point of swarming. Empty combs are preferable to foundation, give two combs of brood if possible.

BEES - Novitas. - Italian Hybrids. - The bees sent are Italian hybrids; the colony may have got hybridised whilst in your possession. Any of the various bee-appliance manufacturers advertising in these columns. It does not follow that because your hybrids are so vicious that all are so, we have some very gentle Italian hybrids; they are splendid workers.

R. E. C .-- I. Cowan Hive damp .-- You do not say what kind of quilt you use. It is clear that the dampness in the inner hive arises from condensation of the vapour which, from defective ventilation, cannot escape. Musty Smell in Feeders.—As the food is consumed, air, to take its place, enters from the hive; and as this must smell musty from the damp, the smell is accounted for.
3. Leaking Raynor Feeders.—The cause is most probably badly-fitting caps to the bottles. If air can enter except through the holes, it will allow the food to run out. 4. Spare Combs.—The granular dust which you find in the bottom of the box may be owing to the pollen being attacked by mites. 5. Drone Brood in Worker Comb. This seems to point to some injury to the queen, as she is in her second year only. Perhaps in a short time she may discontinue drone-egg laying. If she does not, she must be removed. 6. Queen Raising.—Even if you have no opportunity of raising queens to replace old ones in the best manner, you can with little more trouble do

better than you do. Instead of killing the old queen, and allowing the bees to raise one from her eggs, after four days destroy all commenced cells, and give them a comb of eggs from a young and vigorous queen. You will get a better queen raised. If your stocks are strong and drones flying, you may do it now; and your young queen will be in lay when the honey flow is on. If you delay, you had better leave alone until after the flow. 7. Varnishing Interior of Hive.—There seems an advantage in having a clean, washable surface; and as to impermeability to air, there can be very little difference, if any, between half-inch wood varnished and unvarnished.

J. Brown.—The probability is that the bees were starved, and therefore deserted the hive.

P. Robbin, and H. Worth.—The portious of comb forwarded were not affected with foul brood, but with chilled brood.

H. O .- Put the foundation in the saw-cuts, and wire from side to side as proposed.

From M. A. de Zoubareff we have received a pamphlet on honey and its uses, entitled, Myod kak peishcha e kak leakarstvo. This will be a very useful little pamphlet for the bee-keepers of Russia to distribute, as it sets forth the various uses of honey, with recipes gathered from English, German, and French works. The same author has also sent us the numbers of the Russian Bee Journal for this year, entitled, Roosskee ptchelovoodnee liestok, of which he has become the editor after the death of Professor Boutleroff. The Journal comes out monthly, is well got up, and carefully edited, and will be sure to do good to bee-keeping if the future numbers are as carefully written as those we have seen. We shall have occasion sometimes to give extracts from them.

We have received from Mr. Francisco F. Audreu a pamphlet in Spanish, entitled, La Apicultura Mobilista en Espana. It consists of 38 pages, and is an introduction to bee-keeping in moveable comb hives. As improved methods of bee-keeping are just now being introduced into Spain, this little pamphlet will be useful in giving an outline of the subject, and we wish it every success.

Received Schedule of Prizes from the Leicestershire Beekeepers' Association of the Exhibition of Hives, Honey, and Appliances, to be held at Ashby-de-la-Zouch, on July 28th and 29th.

Received Schedule of Prizes of Aberdare Horticultural Society's Show, to be held at Aberdare on Thursday, August 18.

We have received from Mr. Leslie Tait, Foveran, near Aberdeen, specimens of sections manufactured by him. They are one piece V-grooved, with and without beepassages on all four sides, and also two-piece dovetailed sections. They are made of different qualities of wood, and the prices range from 15s, to 24s, a thousand.

Received from Messrs, Abbott Bros, a sample of a material for aprons, shirts, quilts, tent-screens, &c. lt has for pattern cells with queen, worker, and drone.

We understand that Mr. John D. McNally, a member of the family of McNally, well known in the Scottish apicultural world, has been appointed one of the correspondents for the bee department of The Farming World, formerly the Scottish Agricultural Gazette.

Show Announcements.

Giving Name and Address of Secretary, Date and Place of Show, Date of Closing Entries. Terms: Three Insertions and under, Two Shillings and Sixpence; additional insertions, Sixpence each. No charge made to those Associations whose Shows are announced in our general Advertising Columns.

June 15, 16.—Wilts Agricultural Show. Rev. W. E. Burkitt, Secretary.

June 23, 21.—Suffolk Agricultural Show at Bury St. Edmnnds. Entries close June 6. J. Huckle, Secretary. July I1-I5.—Royal Agricultural Show at Newcastle-on-

Tyne. Entries close May 12. J. Huckle, Kings Langley.

July 20-22.—Lincolnshire Agricultural Society at Spalding. Entries close July 4. R. R. Godfrey, Secretary.

July 26, 27.—Warwick Agricultural Society at Sutton

Coldfield. J. N. Bower, Knowle, Secretary.

July 27.—Bishops Waltham Show. (Hants and Isle of Wight Association.) H. W. West, Hon. Sec., Swanmore House, Bishops Waltham.
Angust 3-5.—Yorkshire Agricultural Society at York.

Secretary, H. L. Rickards, Poole, near Leeds.

Business Directory.

The Name and Address and Business of any Manufacturer will be inserted in this List, under one heading, for One Pound per annum. Additional headings, Five Shillings Advertisers in 'The Bee Journal,' whose orders amount to Five Pounds per annum, will be inserted Free.

MANIPULATE WITHOUT SMOKE!

WEBSTER'S

Entirely supersedes the Smoker, both in Simplicity and Effectiveness. No 'going out.' No tainting or soiling of combs. Always ready for use without any preparation. Can be carried in pocket.

With Bellows, 4s. 6d.; postage, 41d. Without Bellows, 3s.; postage, 3d.

Can be adjusted to any ordinary smoker bellows.

6 oz. Bottles of Agent-carbolic acid, oil of tar, and water, proportionably mixed—6d. each.

NOW READY.

WEBSTER'S SWIVEL FRAME-LIFTER

With this appliance, frames can be removed from hive. Examined on both sides and replaced without inverting, and with one hand only, leaving the other free to perform any manipulation, at the same time preventing the soiling of hands with propolis. 1s. 6d. each. Postage 3d.

Send for ILLUSTRATED CATALOGUE of all descriptions of Appliances. Post free on receipt of post-card.

AWARDS LAST SEASON.

1st Prize, Silver Medal, Royal Counties' Agricultural Show. Highest Award, Bronze Medal, Colonial and Indian Exhibition, for Bee Subjugators.

2nd Prize Bronze Medal, Colonial and Indian Exhibition, for useful Inventions introduced since 1883.

2nd Prize, Altrincham, for useful Inventions.

For I or 2 Queens (if ordered at one time), each 14/-

13/-,, 3 ,, 4 12/-,, 5 ,, 6

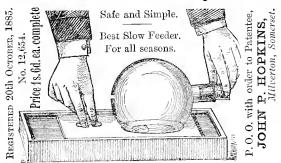

For Countries out of Europe add 50 , of to above prices.

All Orders to be accompanied by a Remittance.

My Queens are all very prolific, long-lived, and much larger-bodied, than the majority of those supplied by others, as they are reared naturally, under the swarming impulse, in April, May, and June, from the strongest of my forty colonies of Bees kept in double-walled moveable frame-hives, and all having choice Queens, which produce workers so gentle that they can be handled without smoke, and even without a veil on the face, just as I do myself (see Mr. S. Simmins' statements on page 37 of his work entitled, A New Era in Modern Bee-keeping). This is principally owing to the fact that I have weeded out from my Apiary all such Queens which appeared to be weak or producing troublesome workers. Address-

M. G. DERVISHIAN, Larnaca, CYPRUS. A 2375 For Reference, address Imperial Ottoman Bank, Larnaca.

OUTLINES OF BEE-KEEPING FOR BEGINNERS.

(Continued from page 180.)

VIII.—HIVES WITH MOVEABLE AND FIXED COMES.

1. According to the old style of bec-keeping a swarm was placed into a skep, and the bees were allowed to fill it with combs, which they built in any direction they liked. In such skeps the bees attach the combs to the top and sides, so that they form part of the dwelling and cannot be removed from the hive without cutting them out; boxes were worked in a similar way. This is

ealled the fixed-comb system.

2. According to the improved modern system of bee-keeping, the swarm is placed into a box fitted with frames, to which are fixed, on the under side of the top-bar, strips of comb, or comb-foundation, which guide the bees and induce them to build their combs in the direction in which the bee-keeper wishes them to be. The bees do not attach the combs to the sides of the hive, but build them inside the frames. These frames of comb can be easily taken out, their position inside the hive altered, or they can be removed and replaced by others. This is called the moveable-comb system.

3. In order to derive the greatest advantage from the moveable-comb system it is very important that only one size of frame be used in the apiary, and this must fit into every hive.

4. The British Bee-keepers' Association adopted some years ago a Standard frame, which has come into general use, and we advise the beginner to use no other. The outside dimensions are 14 inches long by 8½ inches deep, the top bar being 17 inches long, 3ths of an inch thick, the bottom bar ½th of an inch, and the side bars ¼ of an inch thick, the width being 5ths of an inch.

5. The hives should be made so as to leave a $\frac{1}{4}$ of an inch passage at the ends of the frames, and not less than $\frac{3}{8}$ ths inch at the bottom. The dimensions of a hive to suit the Standard frame would be $14\frac{1}{2}$ inches wide and $8\frac{7}{8}$ ths inches high, inside measurement. The length will be in proportion to the number of frames used, allowing $1\frac{1}{2}$ inches for each frame. The hive can be extended to take any number of frames, but generally

ten or eleven are used. For a ten-framed hive, placing them at $1\frac{1}{2}$ inches from centre to centre 15 inches will be required, and this space will easily take eleven frames when they are wanted closer together, or at a distance of $1\frac{1}{4}$ inches from centre to centre.

6. The frames are frequently provided with broad shoulders, or metal ends, to keep them the proper distance apart, and these have entirely superseded distance-pins, nails, staples, screw-eyes, &c., used formerly so extensively abroad and adopted by some bee-keepers here. Metal ends are made of different patterns, Carr's having the advantage that the bee-keeper is able to alter the distance of the frames from 1½ to 1¼ inches from centre to centre.

7. The projecting ends of the frames rest on the top edges of the hive, which is here $\frac{3}{8}$ -inch lower than the sides. When the frames are in the hive the top edges of this and the upper sides of

the top-bars will be level.

8. One or two division-boards are necessary for each hive, so as to be able to reduce its size to the strength of the colony. The division-boards fit close inside the hive, and are placed on either side of the frames, the hive being made a little longer to receive them.

9. A moveable bottom board must be provided as well as an entrance at least 8 inches long and gths of an inch in depth. This entrance can be closed more or less as needed by means of slides or blocks. In front of the entrance an alighting board should extend to some considerable distance, and slope to the ground.

10. Over the tops of the frames is placed what is called a quilt, usually consisting of a piece of unbleached calico, and three or four thicknesses of drugget, or a chaff-cushion, box, or some suitable

warm material.

11. The hive must have a roof constructed in such a way that there will be room under it for placing a feeding bottle or racks of sections (to be described later). A box similar in size to the hive will do, with strips of wood nailed on the lower outside edge, to prevent rain driving in at the joints. The sides and back can be cut down, to give an inclination to the boards fixed on it so that rain will run off the roof at the back, instead of dropping in front of the entrance. The boards should project at least 3 inches all round, and the roof must be made waterproof.

12. A single hive consists of one box fitted with frames, division-boards, roof, &c. A storifying hive is composed of two or more such hives placed one above another, with one roof over them.

13. The more carefully the hives are made, and the more accurately the frames fit, the greater will

be the case of manipulating them.

14. If the bee-keeper wishes to make his own hives he had better purchase a good one as a pattern, but in any case he would do better to procure the frames of a hive-maker, unless he has special tools for making them accurately.

15. Good hives are now so cheap that it will hardly pay the bee-keeper to make his own. The prices range from 10s. to 15s. for such a hive as we

have described.

IX.—WHAT BEES CARRY INTO THE HIVE.

1. Bees do not require to be fed daily like other domestic animals, but collect their own food. They store more than they require for their own use, and only require the bee-keeper's assistance if he takes too much from them, or the season has been a bad one. They live upon the sweet juices of plants, which are converted by them into honey, the fertilising dust of flowers (pollen) and water.

2. The best food for them is the *nectur*, which they find in the flowers of many plants. They, however, also collect the sweet juices which are found on the leaves of some plants, and even the liquid exercted by insects, such as the *aphis*, which collects on the leaves. This is called *honey dew*.

- 3. From these juices the bees make honey. They convert the nectar into honey by adding a liquid secretion (saliva) which has the property of changing the cane sugar of the nectar into the grape sugar of honey. The quality of the honey depends, like milk, upon the raw material from which it is made; that from nectar being the best, whilst that from honey-dew is usually very dark and inferior in flavour.
- 4. Sweet liquids are swallowed and carried into the hive by the bee in the *honey sac*; water is also carried in the same way, whereas pollen is packed in hollows on the hind-legs called *pollen baskets*.

5. Bees also collect a resin-like substance called propolis, which they obtain from the buds and limbs of trees. It is used to seal up every erevice

about the hive.

6. When the bees return to their hive laden, they disgorge the honey into the cells. Both honey and pollen are stored for future use. Water and propolis are used at once, not stored in the cells, and are only collected as they are wanted.

X.—SWARMS AND SWARMING.

1. If, in spring, a colony has its hive full of comb containing brood, is crowded with bees and tood is coming in plentifully, it makes preparations for sending off a swarm. Queen-cells will be constructed in which an impregnated egg is placed. In three days the egg hatches, and a grub (harva) crawls out; this is fed on rich food for five days, after which it no longer requires feeding, and is scaled up by the workers in its cell, where it spins a cocoon, and changes into a chrysalis. In about

sixteen days from the time the egg was laid, the queen, in a perfect state, is ready to leave the cell. The young queen makes, with its jaws, a circular cut in the cell-cap, forces it open, and crawls out. The old queen does not usually wait until this takes places, but generally soon after the queencell has been sealed over, selects a fine day, and between the hours of ten o'clock in the morning and four in the afternoon, leaves the hive with part of the population. This is called swarming.

2. The bees which leave with the old queen form with her the *jirst swarm*, the hive from which they left being the *stock*. In a good season, if the stock be strong, other swarms will issue as the queens mature and hatch out. These are called *casts* or *after-swarms*. Casts have young queens, and are therefore generally better than first swarms, pro-

vided they have plenty of bees.

3. The first cast or second swarm usually leaves the hive on the ninth day after the first, but occasionally sooner. Sometimes third, fourth, and fifth swarms may be thrown off at intervals, generally, of one or two days. These usually contain so few bees that they are worth very little, and should be united to others.

4. In the south of England, in favourable seasons, swarming begins about the end of April, but is sometimes delayed until the middle of June. In the North and in Scotland swarming takes place much later, frequently not beginning before the

end of May.

5. Early and large swarms are profitable; late and small swarms are worth little, although by judicious management they can be built up into strong colonies before the winter.

(To be continued.)

BEES AND HONEY.

The honey-bee has been an object of great interest from the very earliest ages; the most ancient historical records make frequent reference to it. 'A little balm and a little honey' formed part of the present which Jacob sent into Egypt to Joseph in the time of the great famine. The 'busy bee' figures also in Greek as well as in Hebrew history. The little creature has given a name to many females of high degree. The Hebrew name of the bee (Debôrah) was given to Rebekah's nurse, as also to that magnanimous prophetess whose courage and patriotism iuspired the flagging zeal and waning energies of her dispirited countrymen. The Greek name of the bee (Melissa) was given to one of the daughters of Melissus, king of Crete. It was she who, with her sister Amalthea, is fabled to have fed Jupiter with the milk of goats. She is said, also, to have first discovered the means of collecting honey from the stores of the bec, while some ancient writers inferred that she not only bore the name, but that she was actually changed into a bee.

Another Greek story tells of a woman of Corinth, also bearing the name of Melissa, who, having been admitted to officiate in the festivals of Ceres, the goddess of agriculture, afterwards refused to initiate others, and was torn to pieces for her disobedience, a swarm of bees being

made to rise from her body.

The old Greek name for the bee seems to have fallen into disu-e in this country as a name given to females, though there can be no reason why its use should not be revived, for it is at least as melodious as the Hebrew name of the same significance, still applied to many a

matron and maiden—a name which is expressive of honeyed sweetness, as also of unwearied energy and un-

tiring industry.

Those who have had personal knowledge and experience of hee-culture will bear out the remark that bees are not particular as to the size or the position of the home in which they choose to dwell, so that it suffices for them to carry on with security their wonderful operations. In their wild state, cavities of rocks and hollow trees are alike available; and in their domestic conditions they have no preference for a straw skep over a wooden box, nor for the wooden house over the straw castle.

The bee, which, while under proper control and management is one of man's best friends, proves, when assailed by him in any way, a terrible adversary. Allusion is made to this by Moses in his story of what befell the Israelites in their wilderness sojourn: 'The Amorites came out against you, and chased you as bees do, and destroyed you.' The strength and force of their sting is such as to enable them to pierce the skin of the horse and other large animals and kill them. Their ordinary speed when in flight is from sixty to eighty miles an hour, and they have been known to fly past the windows of an express train when travelling at full speed in the same direction. The manner of attack is to dash straight at the object aimed at; and commonly when excited by the presence of some unknown spectator, and especially by the intermeddling of some undexterous or mischievous person, they will attack the face, aiming especially at the eyes. When, therefore, the thousands especially at the eyes. When, therefore, the thousands which inhabit a single hive are aroused by the sound of alarm, well understood by all the inmates, to repel an invader, they sally forth with a courage and determination which none can withstand, attacking their foes on every side with a fury it is impossible to resist. King David must have witnessed just such a scene, which he reproduces in his description of the fierce attacks, the determined onslaughts of his bitter and unrelenting foes: 'All nations compassed me about . . . they compassed me about like bees.

Somewhat recently, the mishap of a porter in handling a box of bees in transit by railway created an amusing and rather alarming scene at the station. There was a general stampede of passengers and officials flying in every direction, chased by the infuniated bees. It was only when some one, skilled in the management of bees, catching the queen and placing her in the box, restored confidence and quiet, for, flocking loyally to her standard, the whole colony returned to the case, which was in due time forwarded to its destination. But even this was a small affair compared with what is related in ancient history of persons being driven from their habitations. and the inhabitants of an entire town being compelled to flee before myriads of bees. Elianus, who flourished about 200 A.D., gives an instance of this in one of his seventeen books on animals. Mungo Park, too, the African traveller, mentions a modern instance which took place near Dooproo: 'We had no sooner unloaded the asses than some of the people, being in search of honey, inopportunely disturbed a large swarm of bees. They came out in immense numbers, and attacked men and beasts at the same time. Luckily, most of the asses were loose, and galloped up the valley; but the horses and people were very much stung, and obliged to scamper off in all directions. In fact, for half an hour the bees seemed to have put an end to our journey. In the evening, when they became less troublesome and we could venture to collect our cattle, we found many of them much string and swelled about the head. Three asses were missing, one died in the evening, and another next morning. Our guide lost his horse, and many of the people were much stung about the head and face.

The fierceness and unrelenting cruelty of the ancient Assyrians, and the terror with which their swarming multitudes filled the inhabitants of the lands they invaded

have caused them to be likened to bees in their muchdreaded attacks on such as have aroused their anger: 'And it shall come to pass in that day that the Lord shall hiss for the fly that is in the uttermost part of the rivers of Egypt, and for the bee that is in the land of Assyria. And they shall come, and shall rest all of them in the desolate valleys, and in the holes of the rocks, and upon all thorns, and upon all bushes.' The 'hiss' was simply a call, in allusion to the note of the queen-bee, as she issues her royal mandate to her ever royal subjects to prepare for action. It has also been supposed to allude to a custom prevailing in very ancient times in connexion with bee-culture, or honey-raising in the neighbourhood of rivers. During the dry season, a number of hives would be placed on a flat-bottomed boat, in the charge of an attendant. Very early in the morning the boat would begin the day's voyage, gently gliding down the river, the bees sallying forth with the sun to collect their golden stores and deposit them in their several hives, which they commonly know by some mark. The innumerable flowers on the banks of the rivers offered them a fine harvest-field. At the approach of evening, the well-known whistle or 'hiss' of the care-taker—a decent imitation of the queen's own call-would bring them back to their hives in multitudes, when the boat would be paddled back to the farm or other place of rendezvous.

As an article of food, and as much-valued and even royal luxury, honey has been used from the remotest ages. Nor was it much, if any, less in request as a healing medicine for both inward and outward application. And though it may have fallen somewhat into disuse in these days, when many good things are overlooked, and when the artificial too often supplants the real, it may be safely predicted that the wide and rapid spread of bee-culture will induce a return to some of the wiser uses and methods and forms of adoption employed by our early forefathers, as well as stimulate to the new applications and new developments of its wondrous

powers. When and by whom mead or metheglin was first made from honey, could not be easily determined. The two words are not unfrequently applied to the same liquor; but that is not correct, as they are dissimilar. Both, however, are made from honey, sometimes also from the refuse or washings of the comb. Queen Elizabeth had such fondness for metheglin as to prescribe carefully how it should be made and with what variety of herbs it should be flavoured. In Wales, it long continued to be held in high esteem; and its various beneficial properties have been quaintly set forth in a letter addressed to Clifte the historian by the learned Welshman, Rev. James Howells (born 1594), brother of Thomas Howells, some time Bishop of Gloucester and Bristol. The uniqueness of the communication is the apology for its quotation in full:-

Sir,—To inaugurate a new and jovial new year unto you, I send you a morning's draught (namely, a bottle of metheglin). Neither Sir John Barleycorn nor Bacchus hath anything to do with it; but it is the pure juice of the bee, the laborious bee, and king of insects. The Druids and old British bards were wont to take a carouse hereof before they entered into their speculations; and if you do so when your fancy labours with anything it will do you no hurt; and I know your fancy to be very good. But this drink always carries a kind of state with it, for it must be attended with a brown toast; nor will it admit of but one good draught, and that in the morning; if more, it will keep a-humming in the head, and so speak much of the house it eame from, I mean the hive, as I gave a caution elsewhere; and because the bottle might make more haste, have made it go upon these (poetic) feet:

J. H. T. C. Salutem et Annum Platonicum. The juice of bees, not Bacchus. here behold, Which British Bards were wont to quaff of old; The berries of the grape with furies swell, But in the honeycomb the graces dwell.

This alludes to a saying which the Turks have, that there turks a devil in every berry of the vine. So I wish you cordially as to mean auspicious and joyful new year, because you know I am, &c.

Metheglin is no doubt a healthy beverage, containing an admixture of milk. Pallus Romulus, when he was a hundred years old, told Julius Cæsar that he had preserved the vigour of his mind and body by taking metheglin inwardly, and using oil outwardly. Metheglin and mead may be made very strong, and of course, they both contain some amount of alcohol. In Virgil's days, metheglin was used to qualify wine when harsh. He writes of

'Huge heavy honeycombs, of golden juice, Not only sweet, but pure, and fit for use; To allay the strength and hardness of the wine, And with old Bacchus new metheglin join.'

Mead or metheglin was the nectar of the Scandinavian nations which they expected to drink in heaven, using the skulls of their enemies as goblets. Thus we read in Penrose's Carousal of Odin:

'Fill the honeyed beverage high; Fill the skulls, 'tis Odin's cry! Heard ye not the powerfut call, Thundering through the vaulted hall? Fill the meathe, and spread the board, Vassals of the grisly lord!—
The feast begins, the skult goes round, Laughter shouts—the shouts resound.

In England at the present time, mead, like many other old and excellent domestic compounds, has passed almost entirely out of use. In very few houses could it now be found. Here and there in a farmhouse where old customs linger, it may still be had; and it is still used for colds and other complaints, both in the case of men and cattle.

The revival of bee-keeping and the conduct of the enterprise on scientific principles will restore honey to its wonted place in the domestic economy; and if carefully studied and thriftily managed, the cultivation of bees and the product of honey may be made to form not only an important article of food and a considerable item of domestic revenue, but an ample source of amusement, and means of recreation healthful alike to body and mind.—Chambers' Journal.

THE SONG OF THE BEE.

Hail to thee, Little brown bee!

After the winter long, I love to hear thy song, To see thy shapely form, when the March sun lies warm Upon thy prison-home, tempting thee forth to roam; Thou bringest joy with thee, thou little busy bee.

I hear thy morning psalm amid the downy palm— Now distant, now more near, faintly, then rising clear— Telling forth the measure of thy toilsome pleasure; Thon workest merrily, thou singest cheerily.

From golden crocus-cup gold-dust thou gather'st up, Which, by true instinct led, thou dost transmute to bread: Ah! thou alchymist bold, couldst but thy song unfold Some of the mystery wrapped in thy history!

Herald of spring art thou. The robin from his bough Sings loud, but what cares he how many flowers there be? Strangely the cuckoo eries, the lark thrills from the skies, But only thou dost sing for the earth's blossoming.

And when May, 'the merry month,' decks the wild cherry, And makes the orehards gay; and all the fields display Their wealth of colouring; and white-robed hedges fling Their fragrance on the wind,—thou think'st it all designed

Especially for thee, and sing'st for very glee! Swift on the heels of May the summer comes, each day Bringing thee new delight; upsprings the clover white, Whose dewy depths distil rich nectar—Drink thy fill!

And then, full soon, July; the great sun mounts the sky And pours his fervid beams downright, and nature seems To sleep, not a bird sings; and yet the still air rings, To the accustomed ear, with music, loud and clear:—

For why? 'The limes are out!' and everywhere about The honey-laden trees flit honey-laden bees, The solitary song swells to a chorus strong, And sun, and bees, and flowers, rule the enchanted hours.

Then the brief summer wanes; days shorten, night regains Lost hours; a little while the purple heather bell Glows on the distant hill, and then the song is still, The merry toil is done, the shapely form is gone.

Farewell to thee, Little brown bee!

-W. H., Dorking.

FRANCE.

Societé Centrale d'Apieulture et d'Insectologie.—This Society held another meeting in Paris on the 20th of last month. The communications handed in from several correspondents showed that the mortality of

stocks during March and April has been very great, even in apiaries where want of food was out of the question. It appeared, from the general tone of the remarks made, that many of the stocks which have succumbed gave no sign of decline in February, but, generally speaking, their populations dwindled away afterwards, and their queens died. The Professor of Luxembourg stated that, in his opinion, this was to be attributed to two causes, the first being that the majority of the queens which had died must have been old, and the second must be found in the fact that this year the cold lasted much longer than usual.

Among the communications received by the Society there was one from the Ministry of Agriculture enclosing a copy of his *Statistique Agricole* for I885, from which it appears that the value of the honey exported during that year was 936,236 francs, and the imported

753,196 francs.

M. Hamet mentioned that wax from French colonies competed against that produced at home. The chairman suggested that it would be well to ascertain if this was a fact, and if so, to agitate for an import duty like

in the case of wax from foreign countries.

With reference to the prizes which are to be awarded this season for 'well-kept apiaries,' M. Sevalle proposed that Messrs. Asset and Saint-Pée be added to the committee. The chairman replied that by adding the name of M. Sevalle himself, the author of the proposal, the com-

mittee would be constituted.

M. Ramé stated that a bee-section had been formed for the great Exhibition of 1889, viz., Group viii., class 76, to be called 'Insects utiles—Apiculture—Sériciculture, Sc., et Insectes nuisibles.' The committee appointed in connexion with this branch will be composed as follows:—Chairman, M. T. Blanchard, a member of the Institute; Vice-President, M. Ramé, a member of the Société d'Apiculture et d'Insectologie; M. F. Henneguy, Professor of the Versailles School of Horticulture; M. Balbiani, Professor at the College of France; and M. E. Menault, Inspector of Agriculture. Subsequently M. Ramé pointed out that bee-keepers intending to exhibit in that Exhibition should send in their declaration or application for space this year, to the end a suitable spot could be secured.

The chairman pointed out that, for the time being, bee-keepers should devote their attention to the preparation of exhibits for the September show.—Apiculteur

of Paris.

ASSOCIATIONS.

LANCASHIRE AND CHESHIRE ASSOCIATION.

Mr. W. B. Webster of Wokingham will lecture on behalf of the above Association, in the Market Hall Coffee Tavern, Corn Market Street, Lancaster, on Friday evening, May 20th, at seven o'clock. The chair will be taken by the Rev. J. Bone.

WARWICKSHIRE BEE-KEEPERS' ASSOCIATION.

The annual meeting of the Warwickshre Bee-keepers' Association was held at the Grand Hotel, April 28th. The Rev. Canon Evans presided; and among those present were Mrs. Allen, Mrs. Ward, Mrs. Stuart, Miss Keyte, the Rev. W. K. Suart (Iccturer), Messrs. J. N. Bower (hon. secretary), J. R. Inglethorp (assistant secretary), Jacob Rowlands, J. Y. Young, J. Cook, E. M. Pearson, C. Butler, J. Burman, E. Johnson, Ward, T. Warburton, and C. W. Summerskill (expert). The committee reported that there was a steady and increasing progress of the society. During the year more work had been done than in any previous year,

and the society might be congratulated on its Notwithstanding this, it would be seen by the box sheet that there was a pressing need for further and mcreased subscriptions to the society, otherwise some of its most useful operations, particularly as to expert's tours, would have to be curtailed. The receipts from all sources, including balance from last year, amounted to I24l. 3s. 6d., and the expenses to I34l. 6s. 7d., making a deficit of I0l. 3s. Id. This deficit was accounted for by the increased endeavours of the committee to render additional help to bee-keepers by carrying out the autumn tour of the society's expert as well as the one in spring. The committee sincerely hoped that this deficit would at once be cleared off by members assisting in obtaining new subscribers, and by outstanding subscriptions for the past year being paid up. The bee tent had visited, in connexion with horticultural shows, the following places:—Kenilworth, Harborne, Quinton, Handsworth, Ullenhall, Nuneaton, Bedworth. The county show was held at Nuneaton on August 31st and September I, in conjunction with the Warwickshire Agricultural Society. This was the largest show the society had held since its formation. The silver medal was awarded to Mr. D. Ingleby, Knowle; bronze medal to Rev. J. Sunderland, Eggington Vicarage; certificate to Mr. B. P. Walton, Weston. The judges were: Hives and appliances, Major Deykin and Mr. C. Butler; honey, Rev. J. E. Sale and Mr. J. Burman. It was proposed to hold a series of lectures in various villages through Warwickkshire during the coming spring, when all members residing in the neighbourhood were requested to attend. In concluding their report the committee begged to thank Mr. A. H. Foster for kindly placing his office at their disposal for committee meetings, Mr. J. Lawrence Hawkes for his service as auditor, the Rev. W. K. Suart for kindly lecturing in Birmingham, the judges who rendered their services at the county show, and other gentlemen who had in other ways rendered valuable assistance to the Association. The Chairman, in moving that the report be approved and adopted, said he was present at a meeting of the society at Leanington two years ago when prizes were distributed by Lord Leigh, and he was struck with the interest which seemed to be taken in bee-keeping. At the same time he was very much disappointed at not seeing more of the cottager classes present to carry off the prizes. There seemed at the present stage of the society rather a preponderance of middle-class members who carried off the prizes, but it was nothing more than might be expected. Cottagers as a class rather waited to see experiments tried by other people before they ventured themselves on an occupation of this kind. He had no doubt, however, if the Association persevered, the interest of its work would soon reach the humbler stratum of society whose welfare really the members of the society had mostly at heart when they joined. In a few years they would find the cottagers stimulated by the success of their neighbours, although they did not belong to the same social class, embarking upon this most interesting-and he trusted it would be to them profitable—pursuit. The Rev. W. K. Suart seconded the motion. He remarked that the adverse balance was not due to bad management or lack of members, but the society had so enlarged its sphere of work that the expenses had been proportionally increased. The resolution having been carried, the officers of the society for the ensuing year were elected. At the close of the business of the meeting the Rev. W. K. Suart gave a most interesting lecture on the external structure of the bee, illustrated by a series of cleverly-executed diagrams. Votes of thanks to the lecturer and chairman were passed. The ballot for three hives then took place, which hives were won by Mr. C. W. Bird, Kinwarton, Mr. W. Hill, Chilver's Coton, and Mr. T. Huxley, Erdington. Mr. Bower urged those present to do all in their power to get new subscribers, and condemned the

action of a few former members who had left the society after acquiring sufficient practical knowledge to start bee-keeping.

HAWKSHEAD AND DISTRICT BEE-KEEPERS' ASSOCIATION.

The general annual meeting of the members of the above was held in the Town Hall, Hawkshead, on Saturday evening, the 30th ult. Mr. James Postlethwaite was voted to the chair, and proposed, whilst Mr. Joseph Coward seconded, that Lientenant-Colonel Sandys, M.P., be president for the ensuing year. It was proposed by Mr. Isaac Postlethwaite, and seconded by Mr. Rogerson, that Mr. William D. Heelis be Hon. Secretary, and Mr. Lister Hon. Treasurer. The following were elected members of the Committee:—Alr. Wrigley, Mr. Horrax, Mr. John Abbott, jun., Mr. George Rigg, Mr. James Postlethwaite, Mr. John Burrow, sen., Mr. Thomas Walker, Mr. Joseph Coward, Mr. James Rogerson, Mr. Isaac Postlethwaite, Mr. Cornelius Coward, Mr. James Leviston, Mr. J. N. Fell, Mr. W. A. Rushforth, Rev. W. P. Dawe, and Mr. William Carter. It was proposed by Mr. Isaac Postlethwaite, and seconded by Mr. George Rigg, that the Secretary convey to Mr. William Feilden Whittaker, who was obliged to sever his connexion with the Association in consequence of his leaving the neighbourhood to go abroad, the cordial thanks of the members for all that he had done in promoting the Association. The first committee meeting was fixed for the 11th June.

The Show will be at Ambleside this year.

IRISH BEE-KEEPERS' ASSOCIATION.

The Committee of the above Association held a meeting on the 3rd inst. Present, Mr. Read, in the chair; Dr. Knight, Dr. Allen, Dr. O'Farrell; Messrs. Gillies, Milner, Vanston, and the Hon. Secretary. Mr. O'Reilly of Sans Souci, Booterstown, was unanimously co-opted a member of the Committee. It was resolved to hold the Association's Show at the Salthill Gardens, near Dublin, on the 9th and 10th of August.

Correspondence.

The Editor does not hold himself responsible for the opinions expressed

The Editor does not hold himself responsible for the opinions expressed by his correspondents. No attention will be taken of anonymous communications, and correspondents are requested to write on one side of the paper only, and give their real names and addresses, not necessarily for publication, but as a guarantee of good faith. Plustrations should be drawn on separate pieces of paper.

Communications relating to the literary department, reports of Associations, Shows, Meetings, Echocs, Queries, Books for Review, &c., must be addressed only to 'The Editor of the British Bee Journal,' clo Messes. Strangeways and Sons, Tower Street, Upper St. Martin's Lanc, London, W.C. All business communications relating to Advertisements, &c., must be addressed to Mr. J. Huckle, King's Lungley, Herts (see 2nd page of Advertisements).

****In order to facilitate reference, Correspondents, when speaking of any letter or query previously inserted, will oblige by mealioning the number of the letter, as well as the page on which it appears.

THE WINTER IS PAST?

[961.] 'Time works its changes,' is a saying as trite as it is true. When last I wrote you Canada was wrapped in a mantle of snow; her lakes and rivers bound down, or bridged over, by ice twelve to eighteen inches thick. To-day the lakes are open. The whistle of the steamboat is once again heard in the harbours of her inland waters. Her rivers, untrammelled, roll seaward, swollen by innumerable streamlets which carry down in liquid form the crystallised covering that lay lightly upon the face of the country for months past. The feathered songsters (most of them migratory) are again carolling in her woods and orchards. Insect life has revived and is again on the wing. The familiar hum of the honcy-bee falls upon the car of the apiarist with a sweetness, if not

a harmony, surpassing that of the Eolian harp. They have passed some five months of 'hibernation' will) in happiness and contentment. Some, of course, have passed to the bourne from whence no bee returns. The mortality, however, has not been greater than might have been expected.

The autumn flowers of last year were barren of nectar. Little or no honey was stored after August, and bees, if not fed, were put into winter quarters with scant provision for carrying them through till spring flowers furnished a fresh supply. This is the only cause from which I hear of loss being sustained. Some of my own bees have perished from starvation. Not being at home last autumn their wants were not well attended to, and their mortality has been greater than is usual with me. About twelve per cent of those wintered in my beehouse are defunct. Of fourteen stocks wintered outside in my home apiary only six survive—another proof to me of the advantages of indoor wintering. The outside hives were quite as well supplied with stores when put away as were those in the bee-house, yet the proportion of loss by the latter method of wintering was six times as great as that in the former. The average consumption of stores when placed in the bee-house does not exceed eight pounds per hive during a confinement of five months, while it requires nearly three times that quantity to bring them through when kept on their summer stands.

I have had a marked proof of the advantages of ample unoccupied forage-ground during last season. neighbourhood in which I live is slightly overstocked with bees. My increase at home was about seventy-five per cent by natural swarming. Last spring I moved twelve of my weaker stocks to my farm, some thirteen miles distant. There are no bees but my own in that neighbourhood. Those twelve increased to forty-two, and I took as much honey from them in proportion as I did from those at home. Forty out of those forty-two came through the winter in fine condition. They were kept on their summer stands, with precisely the same protection as the fourteen at home got—that is, they were prepared in the manner described by me in my last letter. I intend to profit by this experience, and have made provisions for moving a portion of those now at home into the country before swarming time. I shall thus have three yards to look after this summer.-R. McKnight, Owen Sound, Ontario, April 30th.

BEES AND RIPE FRUITS.

[962.] Mr. Webster asks if any bee-keeper has placed paper in his hive. Some years ago I fitted up four or tive sections for a last effort late in the season. They were not in a crate, but tied together and placed on the top of one of Mr. Lee's old hives I think. But the point is that the end of one was secured with a piece of good stiff cardboard, made fast with gummed paper, and the bees ate a hole through. Paper they will make light of. During a very busy season I once left a swarm on the ground for three or four days with an old table-cloth under them. They gnawed away a hole as large as the top of a hat. That they feed on raspberries, I suppose, I must believe. My people who pick the fruit tell me so, not heeding my assurance that they would not have any to pick but for the bees, et id genus omne; but whether they make the first puncture is more than I can say, and I do not see that it is of much consequence. We rob them, don't we?-C. R. S.

BEES EATING FRUIT (936.)

[963.] I have been growing fruit and keeping bees for about forty years, but I have never known bees to eat ripe fruit. I have had much trouble to keep wasps from ripe grapes, peaches, &c., indoors. I have netted the ventilators to keep the wasps out, but I found if I could exclude robins and tomtits the wasps could not penetrate the skin, consequently they could not damage the fruit. The bird alights on the top of the bunch of fruit, and pecks several small holes, after which Mr. Wasp can operate, and after the syrup has run from his work on the other part of the fruit he can penetrate it and go on bravely. I have no doubt there are numbers of your readers who have noticed pears and other fruit pecked in the manner described round the stalk, and that is the spot where Mr. Wasp starts operations.— JOHN MOORE.

HUMBLE-BEES.

[964.] The opening of cells containing new-laid eggs by worker humble-bees was well described by Huber in 1801. Mr. Darey Grimshaw would, I think, read his account with very great interest but for two drawbacks, it is difficult to get at, being in Vol. VI. of the Linnean Society's Transactions, and it is in French. Whether anything has ever been written on this subject I do not know. Huber noticed this habit in nests of red and black humble-bees. The name of Mr. Darcy Grimshaw's bees, at any rate, I have little doubt is Bombus lapidarius. In two colonies of these same bees I have seen what Mr. Grimshaw describes, with this exception that the cells contained new-laid eggs and not young grubs. My observations do not go so far as Huber's, but so far as they go they agree with his. He found that the workerbees try to open those cells only which contain newlaid eggs, that the mother has to defend them during the first day only; that the workers who endeavour to open the cells are fertile workers, who, if they get their own way, eat up the eggs, and themselves lay others in their place, and these produce drones only. Huber describes these fertile workers as quarrelling and eating up one another's eggs after he had removed their mother.

Do other kinds of humble-bees quarrel in this way? So far as I am aware scarcely anything is known of the

habits of humble-bees.

The boxes I kept the bees in had for their sides a 1-lb. section, a fixed wooden bottom, and a moveable glass top. The chief difficulty in watching a colony is that if moved 300 yards, or even three miles, most of the bees will not leave their new position. The great John Hunter in springtime made places for the humblebees well provided with moss and covered with moveable slabs. In these several queens built.—G. D. HAVILAND, Warbleton, Hawkhurst.

W. B. C. END.—THE APIFUGE.—SECTIONS.

[965.] May I advise 'X-Tractor' to give the W.B.C. end a trial before fitting up entirely with Abbott's broad-shouldered frames? The possibility of drawing the frames closer together, and so preventing honey storing 'below-stairs,' is a great advantage, and even if he does not approve of this, it is a handy and useful

appliance, and inexpensive as well.

I have been trying the apifuge, and am delighted. The smell is by no means disagreeable, and I rubbed a little on my neck and face, and worked without a veil with perfect immunity. The stock which I handled first comes of an awful race, well known here as 'reg'lar devils, sir, beggin' your pardon,' and they certainly maintained their reputation last year. A gentleman who was looking on, and had somewhat boastfully declined the use of a veil, saying, 'I'm not a bit afraid, bees never sting me,' had ruefully to confess, with the Captain of the Pinafore, that they 'hardle ever' did a minute later, and bore evident marks of my bees demoniacal tendencies on his face for some days after.

I should like to suggest caution in accepting Mr. Radeliffe's conclusions. 'The principle seems an advance,' 'I believe the bees won't make so many popholes,' 'I fancy extra cost will repay,' are hardly the sort 'I believe the bees won't make so many popof testimony I like to see, and I should certainly require something more definite before discarding our old friend the V-cut sections. I am rather struck with the four bee-way sections, however, and am inclined to try a few by way of experiment.

Honey is being brought in in small quantities in this part of the world, and as the weather is just now glorious, and apple-blossom opening fast, I have ventured to super my strongest stock, having ten frames below 1-inch apart, with the W.B.C. ends on.—TREVOR

Saynor, Plymstock, South Devon.

THINGS IN GENERAL, BY WOODLEIGH.

[966.] Mr. Webster (937) first pities the county experts re the possibilities of their propagating foul-broad during their tours, then expresses a wish to meet the county expert who is not familiar with the pest, evidently implying that said expert is a rara aris, yet in his very next sentence he gives the thrust to the hilt into some poor nameless county expert whom he terms unqualified. In behalf of the unqualified county expert, may I ask Mr. Webster if the weather was such that enabled the said county expert to examine the said foul-broody hive, or was it so cold that the unqualified one took a mere eursory glance at the exterior of the hive, and because a few bees were visible at the entrance, or maybe disporting themselves in the fitful sunbeams, the county expert gave the welcome report of 'All's well?' Perhaps Mr. Webster will notify to the said county expert, whoever he may be, as to his gross mistake in his report and give him a chance of explaining.

Though I boast of no scroll of parchment endorsed by the great and leading lights of our 'art,' yet I yield the palm to none in the practical part of the business, even to the inclusion of a knowledge of foul-brood; fortunately for me my knowledge of the dreaded pestilence was not acquired in my own apiary; and if care and circumspection will prevent its introduction there, I intend giving it a

Mr. Webster asks the pertinent question, Who were the examiners, if a second-class expert does not know foul-brood when he sees it? Mr. Webster must know that many a shallow pate gets through an examination by the aid of a good coach, and also what numskulls one meets with in every walk of life, who have all scrambled through some kind of examination and are in and hold their present position and emoluments by virtue of their parchments, and not because of either the quantity or

quality of brains contained in their craniums.

I notice in our 'Report' that I am appointed District Secretary for my part of the county, and no doubt I am expected to give advice, and now, after giving advice gratis for some years past as free as water to all and every one who has asked for it, to know that my advice is empirical, that I am not duly and properly qualified,-in fact, that I am not a regular certified practitioner, but only a quack. Bee-keepers of my district and acquaintance, beware of W. Woodley.

I have grown a few plants of Echinops Sphærocephalus, the Chapman honey plant, for several years, and it certainly is a favourite flower with the bees; but I do not consider it so good as borage, as it only produces one cluster of blossoms, while borage grows and blooms for a month in succession.

I think the suggestion of the sowing of bee-flowers in waste places a good one and worthy of the support of Bee-keepers' Associations, at the same time I think we must endeavour to propagate kinds that will not prove a nuisance to our best friends the farmers.

Apifuge, like everything else in the world, has its

failures as well as its successes. A lady I know tried it, discarded her gloves, anointed her hands with the apifuge, went valiantly to work, and received six stings during manipulation of first hive, lost all faith, washed her hands, donned her gloves, and proceeded with examination of No. 2, wiser, if not with more comfortable feelings.

I can endorse friend Webster's assertion in 936, having seen in 1884 a large bed of strawberries in front of an apiary cleared nearly by the bees there. There is no doubt that bees are able to pierce the skin of the ripe strawberry. Wasps are very strong in the jaw, I have seen a prisoner wasp bite a horse-hair through at one grip like a pair of nippers.—WOODLEIGH.

SPARE COMBS.

[967.] I query whether it is at all necessary to have any spare old combs when working on your doubling and storifying system. Last year I piled up one of my hives on to forty-two frames of which only six or seven were old combs.

I find that a good queen lays in every cell of foundation as soon as it is worked out, except of course just at the corners, whilst with old combs at first she only lays a round patch in the centre. For extracting I prefer new combs if not laid in. Last year when extracting the top storey of ten frames spaced about $1\frac{3}{4}$ inches, I always found I got just over forty lbs. (averaging four lbs. a frame), the middle frames having about six lbs. in each; and though all new combs, the only breakage I had was the top bar of one frame. (I took 130 lbs, from this hive last year, all collected between June 24 and August 9.)—E. B. Downer, Surrey.

CONDEMNED BEES.

[968.] In the Journal of this date, I notice Mr. Octzmann of Broadstairs says, 'I cannot say I have been uniformly successful in making stocks from condemned bees.' I am sorry to say this season I am bound to bear him testimony. I usually take a large quantity, but whether from too contracted a circle, and they wend their way home again, or whether last fall the bees were more worn out than usual, somehow or other I have fewer good lots. I always give them combs of honey to save additional labour and my several lots together. Maybe I am not as careful of the queens as I ought to be. I solicit correspondence hereon. — Rector, Buckland Filleigh, N. Devon, May 12.

LEE'S PATENT FRAMES.

[909.] Several inquiries from correspondents relative to the above, and as they are now in commerce, I would beg leave to advise those who are desirous of letting the foundation hang half through the bottom rail to use the wired, as I wish it to be distinctly understood that I do not guarantee the unwired not to bulge if such foundation is passed between the halves of bettom rails. Experiments are being carried out with unwired foundation in four apiaries, but owing to the backward season the tests have not yet been made. To prevent any misunderstanding, I would add that unwired foundation fixed within a 4" of the bottom bar is held securely, and from its peculiar grip, perfectly straight and without the faintest sign of buckling.

Although generally understood, it is a fact worth repeating, that in all cases hives should stand perfectly level at right angles to the frames; if this important feature is neglected more or less imperfectly built comb is the result.—James Lee, 43 Glycena Road, Larender Hill, S.W.

CARNIOLAN BEES.

[970.] 'Amateur Expert' has evidently put a false construction on my letter (p. 129), on Cyprian bees. If he will read again he will see there is but one sentence which applies, or at least which I intended to apply, to Carniolan bees, viz., that 'I had an idea they were dismissed years ago;' and I must say that I can scarcely divest myself of that idea still, seeing that these bees have been before the public so long, and it is only new lately that anyone seems to have recommended themat least I have carefully read the Journal for some years, and this is the impression left on my mind. I suppose it was open to me as well as to every other reader to express an opinion without raising the ire of anyone else; but 'Amateur Expert' seems to me a little pugnacious, and withal, I fear a little inconsistent: he was down on to Mr. Grimshaw like a thousand of bricks about grinding his axe, &c., re Apifuge, but though he sees others grinding away weekly he says nothing.

I have not tried Carniolans myself, though at one time I was strongly impressed with a desire to do so, but as my inquiries gave me such poor encouragement, except as regards swarms, I gave up the idea. A friend of mine, well experienced in bee-keeping, equal in fact to an 'Expert,' has tried them side by side with his natives, with the result that he got plenty of bees, but not an ounce of honey. Will 'Amateur Expert' please state the heaviest weights of honey taken from two or three of his best hives of Carniolans last year? I consider the concluding sneer he gives me anything but well-timed and in no way warranted by anything I have said in regard to

him.—F. Boyes.

THE NEW RACES, &c.

[971.] Mr. Simmins is quite right; I refuse to admit that brown is black. It does not matter to me who agrees or who differs with me; it is a question of principle, not of persons. But I must ask Mr. S. not te class me with 'those persons whom he has known, and who have endeavoured to draw a line between what they were pleased to call black and brown bees. I have not tried to make any such distinction; in fact, I was quite maware that there were two varieties of our native bees, therefore his allusion to 'a little common sense' (a commodity of which I fear we are all more or less deficient) has no application in my ease.

Now what did I write against foreign bees at all for? Certainly not with the remotest idea of doing harm to anyone, but solely from a desire to prevent the extermination of our British bees. For many years I have paid a good deal of attention to natural history, and, knowing the baneful effects which have followed the indiscriminate introduction of alien species into new countries, I looked upon it not only as the right, but the duty, of every bee-keeper to caution the inexperienced in these matters. Could those who introduce these bees into new districts keep them to themselves it would be different; they might keep scorpions if they liked, so that they did not let them loose to do others harm, but I think a great responsibility attaches to them when it is borne in mind that the purity of all their neighbours' bees is destroyed, which some probably have spent considerable time and trouble in selecting, as far as they were able, for their good qualities. I am sure I should not feel comfortable if I thought I had been the means of turning all the cottagers' bees in these parts from gentleness into demons, for be it remembered that many of these poor people keep their bees close to their own doors, and have children daily playing near them. -F. Boyes.

AN EXPERTS SPRING TOUR.

[972.] I have just been making my spring tour among the members of our Association, and I am happy to say

that with very few exceptions I found the bees in excellent condition; notwithstanding the long winter and the adverse weather the stocks, as a rule, are strong and in a forward condition. I met with the first natural swarms of this season on Tuesday, the I0th inst., at Peopleton near Pershore. Of course I took off my hat and paid my dutiful respects to the queens who had sent off, so far as I knew, the *first* swarms in this year of jubilee. And fine swarms they were too, completely filling the skeps in which they were placed.

I have not met with the sightest trace of foul brood in any part of the county; but, of course, I must speak on this subject with bated breath, for has it not been asserted in the Journal that all experts do not know it when they see it, and possibly I may be one of them, and yet I flatter myself by thinking I know a little about it? Have I not seen it? Have I not smelt it? Have I not suffered from it? and have I not subdued it more than once? I testify what I do know that in no apiary that I have visited this season have I found foul brood.

I cannot, however, positively assert that our county is entirely free from this pest, because there are many bee-keepers who do not belong to our Association, whilst there are a few members whom I have not yet visited, but up to the present we can show a clean sheet, which I think is cause for gratitude. In one or two instances I have found the bees hard at work in the sections storing honey, gathered from the fruit-blossom which abounds in some parts of this county.

On another occasion I may have something to say on the subject of honey, as I find from certain 'opinions' of professed judges that they do not know everything, and consequently are not always right in the opinions they express.— E. DAVENPORT, Expert to Worcestershire B.K.A.

BEES NO RESPECTERS OF PERSONS,-The Viceroy of India (Lord Dufferin) and his staff had a singular experience at Dehra Doon recently. His Excellency and suite attended service at the church—or, to put it more correctly, went to church for the purpose of attending service—and soon after entering the sacred edifice were alarmed at hearing a great commotion outside. The disturbance arose, it proved on inquiry, from the fact that a swarm of bees had attacked members of the Viceroy's bodyguard and others outside the sacred edifice. The Viceroy and his party had, fortunately, got into the church, and the doors were closed. The bodyguard escort ontside fled. A horse belonging to an officer of the Goorkhas was so badly stung that it lay down, and the bees would not leave the poor animal till they lighted a fire round it and drove them away. Ladies and children shricking, horses plunging and bolting—the confusion was The bees chased the church-goers for a quarter immense. of a mile down the main road. A Correspondent hears, but eannot vouch for the fact, that the Viceroy himself on leaving the church, did get one sting in the back of his neck. I saw the party retreating in a closed earriage, not attended by their bodyguard. When the harvest moon arose, shedding her mild beams over the walls of the Dehra ehnrch, one window was still in the occupation of the enemy who had inflicted so serious a defeat on the Supreme Government itself.—Daily Paper.

STUNG BY BEES.—We see, in the Annual Report of the London Guarantee and Accident Company for 1886, that a banker, 'stung by bees,' received as a solatium 6l.; an anctioneer, who was stung by an insect, had the same amount awarded to him.

BIRDS AND BEES.—From my own experience I think Mr. Hiam is right. Give the birds a few crumbs and they will not toneh the bees. I have 'swarms' of birds; my one hive is surrounded with nests, but not a bird has touched the bees. They do not seem to look at them. The bees are well and happy in the midst of swarms of birds of all sorts. I fear Mr. Ovenden's London sparrows are starved.—H. ROBERTSON, Parkwood, Torquay, May 10th.

Quern.

[973.] Arsenical Fumes.—A few bee-keepers in this district are much exercised about their bees, owing to the erection of buildings for arsenical purposes. It is rumoured that in the process of burning the fumes escape and cover the surrounding neighbourhood. The bees, attracted by the sweets, repair to the spot and suck it in and become poisoned. Could any of your correspondents give any information on this matter, and what would be the radius that such an operation would be effective to the destruction of bee life?—John Brown, Lewanwick, Launceston.

NOTICES TO CORRESPONDENTS & INQUIRERS.

Letters or queries asking for addresses of manufacturers or correspondents, or where appliances can be purchased, or replies giving such information, can only be inserted as advertisements. The space devoted to letters, queries, and replies, is meant for the general good of bee-keepers, and not for advertisements. We wish our Correspondents to bear in mind that, as it is necessary for us to go to press in advance of the date of issue, queries cannot always be replied to in the issue immediately following the receipt of their communication.

- Novice.—Weak Stocks.—I. Unite the weak stocks and feed. Buy swarms. You would find difficulty in purchasing established colonies at this late period. 2. Yes; a 3-lb. swarm, if possessed of a young and vigorons queen, may be built up, say from the early part of June, into a sufficiently strong colony to give a good account of the heather harvest.
- M. T. W.—Brood, Strength of Stocks.—1. Drone brood is often mixed with worker. There is evidently an intention to swarm, and probably the queen is aged and will be superseded at swarming time, or soon afterwards. 2. Four standard frames full of brood betoken a fair-sized colony, which will increase rapidly and become populous by the time of the chief honey flow.
- E. S. A. G.—Spiders.—There is nothing unusual in a spider killing a bee, for when it gets into the web it is powerless. Spiders are reckoned amongst the enemies of bees and are mentioned as such in bee books. Old sacks over skeps frequently harbour spiders, should be constantly examined, and the spiders destroyed.
- W. MITCHELL.—Foundation.—There is much time saved by giving full sheets of foundation, and we prefer them to strips. We have never found bees object to wired foundation. If they do not take readily to the foundation you have, try the ordinary foundation and wire your frames yourself.
- R. L. Richardson.—Unfinished Sections.—If you give the bees the unfinished sections they will complete them. We should cut off the eappings about 4-inch down, the eells will then be drawn out and completed. They will contain different sorts of honey, and if you do not wish this, cut the combs down to midrib; or it would be better still if you reserved those containing heather honey to be completed with the same at the moors.
- Ammeur Bee-reefer.—Removing Bees.—You must take your bees at least two miles in an opposite direction to the clover fields, and after a few days you can move them to the clover. As you are only one mile away, if you moved them at once many bees would return to their original place and would be lost. Were they ours we should not move them at all as they would find out the clover if the weather was fine, even from their present position.
- O. W.—Bell Glass on Bar-frame Hive.—It would be a much better plan to use an adapting board with a hole almost as large as the bottom of bell glass, this hole to be covered with excluder-zine as the queen is much more likely to pass up into bell glass, on account of the size of this hole, than into sections.
- F. Lester.—Introducing Queen to two Weak Stocks.—By all means unite the two stocks, and when they have settled down, say in three days, remove the queen and introduce the Carniolan.
- G. G.—Your bees are British bees.
- F. W. C.—The comb forwarded contained chilled broad, not foul.

G. Lindsey.—The comb is not affected with foul brood; it is a case of chilled brood. Spray the combs with salicylic acid solution, or place a piece of camphor in the hive.

E. Girbins, Neath.—1. Carbolic Fumigation.—We never experienced such a proceeding on part of the bees, as they always commence gorging, presuming there is uncapped lioney in the hive; place a few drops of common liq. ammonia on sponge. 2. Foundation Fixed with Woiblet Spur Embedder.—There is no necessity for inserting the foundation in saw-cut, neither is there for melting wax; the wires hold the foundation firmly.

CYMRO BACK.—1. Queenless Hive.—If your hive had been queenless all the summer, they would have entirely dwindled away long before August. The absence of queen renders the bees more suitable. 2. Capped Brood.—This may be known by the cappings, which are convex and have a dull appearance against honey cells, which are coneave, and have a shiny appearance in consequence of their cells being capped with wax, whilst brood-cells are capped with pollen and wax mixed. The brood-eells are situated in centre of comb, the honey-cells partially surrounding on top and sides. 3. Driving partially-filled Skep.—This is always difficult, as regards the time occupied in so doing; they should be 'bumped.' This plan is much easier than driving in nearly all cases. 4. Irritability of Bees.—This varies very much, according to the weather; on warm, sunny days they are gentle, on cold, rainy ones the reverse. 5. Doubling.—This should be done with two strong colonies about a week before white clover blooms, if this is your chief supply. To perform this, remove the brood combs-after shaking all the bees off, back into their hive—from one hive and place them on top of the hive to be supered; the bees hatching out make a very strong colony; as the cells are thus emptied they are refilled with honey, which will then be coming in plentifully. 6. Two Weak Skeps.—Unite the two skeps by placing one on top of the other with a piece of excluder-zinc between; allow only one entrance, that of the bottom hive, and remove queen from upper one; to make matters more certain, scent both lots with thin syrup, in which a few drops of essence of pepperment has been put.

F. D. S.—Wax-moth.—The 'long grubs' you describe are the larvæ of the wax-moth. They must be destroyed, either by crushing them, or, if they are wriggling their way through the comb, by pricking them out with a penknife.

Received from Messrs. Edey & Son, St. Neots, Hunts, their Illustrated and Descriptive Catalogue of Hives and Bee Furniture, 48 pp. Also their Catalogue of Poultry and Game Appliances, Greenbouses, &c., 16 pp.

RECEIVED frem Mr. H. Chenevix, Hon. Secretary of the Irish Bee-keepers' Association, schedule of prizes of exhibition to be held at Salthill Gardens, near Dublin, on August 9th and 10th.

RECEIVED from Mr. Paul M'Henry, Hon. Secretary of the North-east of Ireland Bee-keepers' Association, the Annual Report. This Report contains 'Useful Hints to Bee-keepers,' extracted chiefly from the pages of the British Bee Journal; 'How can we further the Objects of the Association?' 'Invertible Hives,' 'Hints on Spring Management,' 'Directions for Packing Honey,' 'Facts for Beginners' for "These pages are well written, and will prove ginners,' &c. These papers are well written, and will prove of great service to the members of the Association.

RECEIVED from Messrs. Abbott their Price List of hives, &c., as sold at their depôt at Paris.

Show Announcements.

Giving Name and Address of Secretary, Date and Place of Show, Date of Closing Entries. Terms: Three Insertions and under, Two Shillings and Sixpence; additional insertions, Sixpence each. No charge made to those Associations whose Shows are unnounced in our general Advertising Columns.

June 15, 16.-Wilts Agricultural Show. Rev. W. E.

Burkitt, Secretary.

June 23, 21.—Suffolk Agricultural Show at Bury St.

Victorial Physics along Lynn 6, 1, Hughla Secretary. Edmunds. Entries close June 6. J. Huckle, Sceretary.

July 11-15.—Royal Agricultural Show at Newcastle-on-Tyne. Post entries to June 1st. J. Huckle, Kings Langley. July 20-22.—Lincolnshire Agricultural Society at Spalding. Entries close July 4. R. R. Godfrey, Secretary.

July 26-28. - Gloucestershire Agricultural Show at Cheltenham. Entries close July 12. W. D. Slade,

Secretary. July 26, 27.—Warwick Agricultural Society at Suttou Coldfield. J. N. Bower, Secretary.

July 27.—Bishops Waltham Show. (Hants and Isle of Wight Association.) II. W. West, Hon. Sec., Swanmore House, Dishops Waltham.

August 3-5.—Yorkshire Agricultural Society at York.

Secretary, H. L. Rickards, Poole, near Leeds.

Business Birectory.

The Name and Address and Business of any Manufacturer will be inserted in this List, under one heading, for One Pound per annum. Additional headings, Five Shillings extra. Advertisers in 'The Bee Journal,' whose orders amount to Five Pounds per annum, will be inserted Free.

SMOKE! MANIPULATE WITHOUT

Entirely supersedes the Smoker, both in Simplicity and Effectiveness. No 'going out.' No tainting or soiling of combs. Always ready for use without any preparation. Can be carried in pocket.

With Bellows, 4s. 6d.; postage, 41d. Without Bellows, 3s.; postage, 3d.

Can be adjusted to any ordinary smoker bellows.

6 oz. Bottles of Agent-carbolic acid, oil of tar, and water, proportionably mixed-6d. each.

NOW READY.

WEBSTER'S SWIVEL FRAME-LIFTER

With this appliance, frames can be removed from hive. Examined on both sides and replaced without inverting, and with one hand only, leaving the other free to perform any manipulation, at the same time preventing the soiling of hands with propolis. 1s. 6d. each. Postage 3d.

Send for ILLUSTRATED CATALOGUE of all descriptions of Appliances. Post free on receipt of post-card.

AWARDS LAST SEASON.

1st Prize, Silver Medal, Royal Counties' Agricultural Show. Highest Award, Bronze Medal, Colonial and Indian Exhibition, for Bee Subjugators.

2nd Prize Bronze Medal, Colonial and Indian Exhibition, for useful Inventions introduced since 1883,

2nd Prize, Altrincham, for useful Inventions.

Finest CYPRIAN Queens.

DIRECT by MAIL from CYPRUS to any Address in EUROPE.

From 1st MAY to 30th AUGUST.

For 1 or 2 Queens (if ordered at one time), each 14/-13/-,, 3 ,, 4 12/-,, 5 ,, 6

For Countries out of Europe add 50 ° to above prices.

All Orders to be accompanied by a Remittance.

My Queens are all very prolific, long-lived, and much larger-bodied, than the majority of those supplied by others, as they are reared naturally, under the swarming impulse, in April, May, and June, from the strongest of my forty colonies of Bees kept in double-walled moveable frame-hives, and all having choice Queens, which produce workers so gentle that they can be handled without smoke, and even without a veil on the face, just as I do myself (see Mr. S. Simmins' statements on page 37 of his work entitled, A New Era in Modern Bee-keeping). This is principally owing to the fact that I have weeded out from my Apiary all such Queens which appeared to be weak or producing troublesome workers. Address producing troublesome workers.

M. G. DERVISHIAN, Larnaca, CYPRUS. A 2375 For Reference, address Imperial Ottoman Bank, Larnaca.

STEWARTON HIVE.

JAMES ALLAN, Hive Maker, STEWARTON, N.B. Established 40 years. Maker of the famous Stewarton Honey-yielding Hive, wrought on the Storifying or Tiering principle, with instructions for use. Covers and Applianees of Apiary supplied to order. A 2572

MAY 26, 1887.

[PUBLISHED WEEKLY.]

Editorial, Hotices, &c.

PROPOSED SHOW DURING THE YEAR OF JUBILEE.

It will be seen, on reference to our report of the proceedings of the last meeting of the British Beekeepers' Association, that the subject of holding, in London, an exhibition of bees, honey, and appliances, during the present year of Jubilee, was fully discussed; and the Committee, believing that great and lasting advantages would accrue to the cause of bee-keeping from holding such an exhibition, were unanimous in their opinion of its desirability. But it would appear that the Association, having already made the necessary arrangements for holding several shows during this year (and the carrying out these arrangements will absorb the whole of their available income), are not in a position to take upon themselves the responsibility of such an undertaking without the general and generous aid of the bee-keeping public. To carry out an exhibition on the same scale, and with the hope of the same degree of success, as the South Kensington, it is estimated that about 200l. would be required. The Committee are therefore naturally desirous of ascertaining the views and the wishes of bee-keepers on this subject before proceeding to action.

Last year when the proposal was put forward to hold the exhibition at South Kensington, the Committee threw themselves with confidence on the generosity of bee-keepers. This confidence was not misplaced. The proposal was favourably and eagerly entertained; and with all promptitude a fund was opened to receive donations and subscriptions towards a guarantee fund for covering all possible charges. The result was that, through the willing assistance of the affiliated Associations and the liberality of individual bee-keepers, the Committee were encouraged to make the necessary arrangements for the exhibition; and it is with peculiar feelings of satisfaction that they are enabled to look back on the success with which their labours on that occasion were crowned.

It would be impossible, at present, to say whether the amount estimated by the Committee would be required, but we may safely say that, as probably there will be but little in the way of receipts from any source to help in reducing the expenditure, the larger portion of the expense must be met by special subscriptions; and if the Committee can have the assurance that such help will be forthcoming, they will gladly put forth all their energy, and utilise all their experience, that the exhibition may prove to be of lasting benefit to the British honey producer.

Much of the success of the proposed exhibition would depend on the locality where it would be held. Last year bee-keepers were especially fortunate in having such a location as the great Conservatory at South Kensington placed at their dis-Two localities have been mentioned as suitable, viz., the Horticultural Gardens at South Kensington, and the American Exhibition. We are of opinion that bee-keepers would prefer the latter, not only because that exhibition is the great attraction of the season to the sight-seeing public, but also, perhaps, there might be, if suggested, a friendly competition between British and American products and appliances. Such a friendly rivalry would give a character and a point to the assemblage of beekeepers, and would be perfectly in harmony with the objects of the American Exhibition. And from what we have incidentally heard, we have reason to believe that the conductors of that exhibition would not be disinclined to think favourably of the proposal.

The matter, then, rests with the bee-keepers of the United Kingdom. The success of the exhibition, on the broad principles of that of South Kensington, depends on the support which may be given to it by the affiliated Associations; by the manufacturers of bee-keeping appliances, who will chiefly be benefited by the exhibition; and by the amount of donations and subscriptions to the Guarantee Fund from bee-keepers generally.

The great object of the Exhibition will be to demonstrate to the world that Great Britain is a honey-producing country; that it is able, without foreign aid, to supply the demand of honey for this country; that British honey is equal, if not superior, to that produced in any other countries; and that in bee appliances and manufactures we are not inferior in these to any other nation.

It would at present be beside the mark to speak of the features of the Exhibition; these would be developed in proportion to the favour entertained of it by the public: but we may safely say that

all the experience of the past would be brought to bear on it by the conductors so that it may be made as perfect as possible. At the South Kensington Show the Committee had every reason to be satisfied with the assistance rendered them by the affiliated Associations and bee-keepers generally. If the same assistance be forthcoming on this occasion, we feel assured that the result would eventuate in a success which would be gratifying to all concerned; and we trust that the conduct of all may be characterised with unanimity, earnestness, and zeal. We shall be pleased to be the medium of any communications and to do all in our power to promote the effective carrying out of the wishes of the bee-keeping world.*

A REQUEST.

We notice in the communication of our correspondent 'Amateur Expert' a request that English bee-keepers should forward any spare books on beekeeping they may have to Mr. Couse, of Ontario, Canada, to help the formation of a library in connexion with the Ontario Bee-keepers' Association. The compliance with this request will in a slight degree show 'the deepening sense of brotherhood which makes all nations one,' and also will enable us to repay a debt which has been long due for the gift of one of the best works on apiculture by an American author to the library of the British Bee-keepers' Association. In June 1880 the B.B.K.A. received a book, accompanied by a letter from Mr. J. Y. Detwiler, of Toledo, Obio, saying that having read over the list of books in the library of the B.B.K.A., and having noticed the absence therefrom of Quinby's New Bee-keeping, he had forwarded it, 'trusting that those who may enjoy its perusal will find it, as I have done, a most valuable auxiliary to successful bee-keeping.' We hope that British bee-keepers will follow the example set by Mr. Detwiler, and avail themselves of the opportunity now presented of assisting our friends in Canada.

BRITISH BEE-KEEPERS' ASSOCIATION.

THE NORTHERN LECTURING TOUR.

The lecturing tour through Durham, Cumberland, and Northumberland, arranged by the British Bee-keepers' Association, will be conducted by Mr. W. B. Webster, who, on his journey to the north, will also give two lectures in Lancashire by desire of the Lancashire and Cheshire B. K. A. Starting on the morn of the 20th, the first lecture will be delivered at Lancaster, another in the same county on the 21st; Morpeth, on 24th; Felton, 25th; Alnwick, 26th; Belford, 27th; Paxton, 28th; Rothbury, 30th; Hexham, 31st; Haltwhistle, 1st June; and others on the journey home.

USEFUL HINTS.

WEATHER AND BLOOM.—We are still in the midst of gales and storms on this 20th day of May. No

chance for a bee to leave its hive, while fruit trees are laden with bloom, and all colonies are taking syrup freely to keep the masses of brood from starving. Only yesterday we saw a fine colony, having abundance of brood, perish from want of food. An occasional fine day, on which bees could work with a will, has been the exception and not the rule. The hawthorn bloom is beginning to show itself, broom, furze, apples, pears, and other fruits, show a mass of bloom, but unless we get a speedy change of weather all will be lost to the bees. Our beds of Aubrietia purpurea have formed perfect sheets of bloom for weeks, and have been covered with bees whenever the weather permitted. Limnanthes Douglasii forms the edging to our kitchen garden borders, sowing itself annually and is breaking into bloom. All this is very tantalising, but we must 'hope on, hope ever.'

Swarms.—We hear of no natural swarms at present, but if a burst of fine weather comes, no doubt they will be numerous enough, and a careful watch should be kept. Towards the close of the fruit-tree bloom swarms generally issue about the end of May. Before the white clover blooms there is a scarcity of forage, and such swarms must be liberally fed or starvation may prove fatal. Unless carefully tended, swarms issuing in the early part of June will undoubtedly surpass them, these latter being larger, enjoying warmer weather, and a

greater choice of forage.

When swarms are desired from skeps well populated, if no inclination to natural swarming appears, such may be driven, and the driving affords a good opportunity of introducing a queen of another race. The whole of the bees should be driven out, and the queen secured. They should then be divided into two portions, one containing twice as many bees as the other. To the larger lot, which forms the swarm, the queen is returned, and they are placed upon whole sheets of foundation, in a frame-hive, and located on the old stand. The smaller lot is returned to the parent skep,-which is to occupy a new position,—and the new queen is dropped into their midst as they run in. This method of introduction rarely fails, and the combs and bees may be transferred, at any time desired, to a frame-hive. From sundry indications it is likely that the present may prove a swarming season, especially if a 'burst' of hot weather succeeds to the cold, rain, sleet, and snow, now experienced. In such case it will be advisable not to attempt returning swarms, but, while gratifying the swarming instinct, to obtain through it honey in its various forms, or honey and increase together, on the systems suggested in former 'Hints.' In the hands of an amateur we are convinced that this is the most lucrative and the safest plan, if not in those of an expert. In all cases we advise placing the swarm upon the stand of the parent colony-which effectually prevents absconding-confining it to the number of frames which it is able to cover, and supering at once.

Putting on Supers. — Although many will have placed supers on the hives before this is in print, still a few general directions may prove acceptable to others. A hive should be full of bees, and honey coming in, before the attempt is made. If the outer combs are already sealed, uncap them and place them in the centre of the brood-nest, and put on the super. The bees will relieve these combs of their honey, carry it to the super, and the queen will soon fill these emptied combs with brood. Supers must be warmly covered with woollen material, and should not be disturbed until three-parts filled, when empty ones may be placed beneath, if occasion require it. As supers approach completion signs of swarming will probably be manifested, when ventilation must be given below by wedging up the hive from the floor-board, or by placing an eke under it.

REMOVING SECTIONS.—Many recommend filled sections to be removed one by one, as completed, others

 $^{^{\}ast}$ Subscriptions should be forwarded to Mr. J. Huckle, Kings Langley, Herts.

allow the whole number contained in the rack to remain on the hive until all are finished. By the latter plan the sections are worked more evenly, and there is no loss of honey if a judicious system of tiering up is practised. Before placing section cases on the hives the practice of some is to crowd the bees on a less number of frames than the usual ten by withdrawing the two outside ones, thus forcing the bees into the supers.

ENLARGING BROOD-NEST.—Our own plan is, with full colonies, to allow ten Standard frames at least, unsealing the outside ones and placing them in the centre, as advised above, or, if honey is coming in abundantly, to remove the outside frames and to place a couple of full sheets of foundation in the midst of the brood-nest. By a prolific queen such sheets will be filled with eggs long before the cells are drawn out, and in an incredibly short space of time. The objection, which prevailed some weeks ago, to dividing the broad does not hold now, since the great heat pervading the interior of the hive prevents chilling the brood. Indeed, after the departure of a swarm, the parent hive is almost deprived of working bees, yet no ill effects follow.

Doubling.—We can give no better advice, as regards doubling, to those who prefer working for extracted honey, than to refer them to Mr. Cowan's Bee-keepers' Guide Book, pp. 54-6; and to his Guide Book Pamphlet No. 1, on Doubling and Storifying. The latter contains many useful hints for the prevention of swarming, amongst them, when working for comb-honey and extracted, to place a hive containing empty combs or foundation beneath the brood-chamber, with section racks above. We advise all to procure this useful pamphlet, which is published at the nominal price of

threepeace.

Purchasing Swarms.—There is no better plan of commencing bee-keeping than by purchasing from a neighbour a good natural swarm about this time, or not later than the second week in June. Such a swarm should weigh at least 4 lbs., should be hived in a stout roomy skep, and conveyed at night to the premises of the purchaser, and transferred to a modern frame-hive well primed with full sheets of foundation. From such a swarm in a good season, a rack of sections, more than sufficient to pay its cost and that of the hive during the first year may be obtained. For the first week the swarm should be fed with about a pint of syrup every evening, and, during fine weather, the combs will be fully built out in ten or twelve days, when a super may be placed upon it. A south-east aspect, sheltered from the cold winds and open to the south, should be selected, and during bright and hot weather shade must be afforded to prevent the falling of the newly-built combs, which are fragile to a degree, and will bear no handling, except with the greatest care. An entrance stretching across the whole width of the front of the hive is desirable, and, in case of the bees clustering outside the hive, it must be slightly raised at the back to cause a current of air to pass beneath the combs. These are A B C instructions, but our readers will bear in mind that they are addressed to beginners only.

BEES AND GRAPES,—Under this heading Mr. Doolittle gives in the American Bee Journal of the 4th inst. the results of his observations, spread over a course of years, with a view to ascertaining the truth or falsehood of the charges brought against our bees of destroying grapes. Speaking of various kinds of thin-skinned grapes, subject to bursting during a damp night or moist, warm weather, he relates that he found scores of these at such times newly cracked around and near the stem' npon which he knew that no bees had been at work the day before, his examination having been made early in the morning before the bees were out, and when he found these cracked grapes afterwards covered by the bees, he knew that they were merely

sucking the jnice from the fruit, so that instead of being the cause, they come in merely as an effect. Again, on examining the tougher-skinned varieties, he discovered a triangular piece of skin, about 3 of an inch, on each side torn out of the sides of hundreds of perfectly sound grapes. Through these holes the bees were sucking the sweet juices of these sweet grapes. Carefully watching the grapes early in the morning to discover if any appeared freshly cut, as if done in the night, none were so found; he felt convinced that the bees really tore open the grapes, but, after long watching, he failed to see a single attempt at aught save sucking the juice through the holes already made, and soon became convinced that the bees were not the cause of rending the skins. These examinations were all made before noon, but it appears that the real culprit was a lazy wasp, which did not commence operations early, for on continuing his watch in the afternoon Mr. Doolittle had ocular demonstration of the actual commission of the depredations, and witnessed numbers of the triangular rents made by a species of wasp which seems plentiful in those parts. He further states that the wasps, followed by his bees, together with the cracking of the grapes, resulted in the loss of half of his grape crop. This result exactly tallies with our own experience, which we gave some ten years ago in the columns of the Times, where a lengthy discussion on the subject took place, in which the late Mr. Hunter, Mr. Carr, and Mr. Shirley Hibbert, a very keen observer in all matters relative to horticulture, gave very decided proof to the same effect. In years when wasps have been numerous, often have we watched them pierce the skins of grapes, peaches, nectarines, and other fruits, closely followed by the bees, who take advantage of the punctures made ready for their use, but never have we witnessed a single bee pierce the skin of any fruit except that of an overripe raspberry.

DECEASE OF MR. JOHN BOLTON, OF GRANTHAM,

With deep regret we have to chronicle the decease of the above-named much-respected gentleman, which took place at his residence, Grantham, on Friday last, the 20th inst., very suddenly. Mr. Godfrey writes us that he spent Thursday evening with him to chat over arrangements for the forthcoming Spalding show, when he appeared in his usual robust health except a slight lameness in one foot for which he was having treatment. An appointment was made for the following morning to examine his bees, but the weather turned out too unfavourable for the work.

On Friday evening his housekeeper took in his bedroom candle about nine o'clock, and as he required nothing more, retired, leaving him taking a book from his shelves. A short time after a lumbering noise was heard, and, this not being unusual, no notice was taken of it; his housekeeper on going in to prepare his room on Saturday merning, found him upon the floor dead, and, looking into his bedroom, saw he had not heen in bed. His doctor, after examination, stated he had been dead some hours, and that his death was instantaneous. The conclusion come to is, that death took place at the time the noise was heard the previous evening.

Apart from the well-known interest Mr. Belton took in horticulture, and his large circle of friends in that branch, we would here speak of him as having been one much interested in apiculture. His sudden removal has left a blank, more especially in Lincolnshire, where he had long and earnestly worked in our cause. Those of our friends who have been accustomed to visit the Lincolnshire shows and honey fairs, -not one of which Mr. Bolton failed to attend,—can bear testimony to the happy welcome he gave them year after year, and his constant desire to assist them; but the loss of his able assistance at his usual post,—the most laborious of all at our shows, 'staging,'-will be most felt by Mr. Godfrey, who knew, perhaps, more than any one his

valuable help.

Mr. Bolton was born on the 22nd of April, 1824, at Amerside-lau, in the county of Northumberland, and was one of a family of nine. Early in life he took to gardening as his favourite pursuit, which be continued with much success. He was engaged at Patter-dale House, afterwards at Dalkeith Castle (Duke of Buccleugh), from whence he came to Belton House (Earl Brownlow), where he remained to the time of his retirement, some few years since, having been for many years head gardener there. On his retiring the noble Earl, in recognition of his valued services, granted him a handsome pension for life. He was unmarried.

Deceased was interred in the Grantham Cemetery on Monday, his funeral being attended by four of his

brothers and many friends.

JOTTINGS BY AMATEUR EXPERT.

'Mel sapit omnia.'

Well, sir! my banner still flaunts. Thanks to my classical friend 'T. P. Atticus' we (?) have fought the battle bravely and well. I say we advisedly, just as all the snobs and tailors boast on the arrival of the news of a bravely-fought battle by our unique little army how bravely we—meaning the army and themselves—have beat them. 'Atticus' has done the fighting, and I do the shouting. If my shouting comes full late, my indulgent readers would bear with it I am sure if they knew the cause; let me say it was not because I had not recovered from the recoil of the 'first fierce shock.

I feel very keen on your 'Jubilee' project, and am sorry no one has responded to the call you have made. Our fraternization with our Canadian brethren last year was so good that I vote loudly for going in for a turn with our cousins from the States; nothing but good can come of it. Moreover, they are desirous of drawing closer in the bonds of friendship with British beekeepers; one post last week brought me five requests from them to open correspondence on apiculture with them-'they wanted to know more about us.' Here is some amusement I shall be glad to put any one on to that has the time and the will, the prospects of the usual remuneration are abundant, as Saxon blood flows as strong over yonder as it does with us.

The Ontario B. K. A. are forming a library, so here is a chance of British bee-keepers giving practical expression to their love for our 'brothers' in Canada. If you have an odd volume on bee-keeping they will be thankful for it. If you will send it on to myself, care of the Editor, I will be happy to forward it, or you can send it direct to the Secretary of the O. B. K. A., Mr. W. Couse, Meadow Vale, Ontario, Canada. 'Don't

you forget it.

Mr. Grimshawis a happy man, he is among the 'palmbearers' and recipients of 'honours and rewards.' Although I have hit Mr. Grimshaw on another issue, I have carefully refrained from appearing to detract from the efficacy of his discovery, for the simple reason that it has not been before us sufficiently long to get a fair test. I have not had a sting yet this year; I can frequently go well into the month of June without getting one. Take a few good supers off and get a cool spell and then go and test the 'Apifuge,' and you will have a better idea as to its efficacy; or, better still, wait till the month of September, and then, if I remember it, I will be happy to give my verdict and my 'palm.' Meanwhile use it fairly.

Amongst all your correspondents that have been hybernating, but have awoke with the bees and are now with them 'in full flight,' I welcome our humorous friend the Devonshire 'Rector.' My thanks are due to him not only for his bits of genuine humour, but for his calling attention to Arcady.

Another Rector's (959) positiveness as to the age of his bees is good reading. I will not attempt to refute his assertions, but give him another fact to put with his own. I have a queen-bee that is 'black' enough to suit any one short of Mr. F. Boyes, but about one-half of her progeny are as yellow-banded as many Ligurians. I have no 'yellow-jackets' in my apiary, nor have I had near me for the past three years. I can only account for it as what poultry and dog-fanciers term a 'throw back.' The remainder are brown or black or both, which you please to call them.

Mr. E. J. Gibbins stands greatly in fear of getting foul brood into his district and apiary. I can understand his almost extra precautions in face of that fear. May I tell him for his comfort (?) that it has raged around me for the past five years and yet I have escaped? How long I shall continue to do so I should not care to conjecture, but my immunity I attribute to cleanliness. I am always careful to give clean hives, &c., every spring, never to leave a lot of putrid, mouldy combs about; and although I have had condemned bees from very suspicious districts, yet I have always escaped hitherto. I think food has much to do with it also. If I fed my bees on cheap beetroot sugar, as recommended recently by 'Student,' I should soon expect to get foul brood and consider if I escaped I did not get my deserts.

I have read all Mr. F. Boyes' communications again. I give him up. All I have to say is Carniolans are the bees for timid bee-keepers, and they are Legion; and the yellow bees are only suitable for specialists whose potentiality of pain is lower than it is with—AMATEUR EXPERT.

ASSOCIATIONS.

BRITISH BEE-KEEPERS' ASSOCIATION.

The usual monthly meeting of the Committee was held at 105 Jermyn Street on Wednesday, May 18th. Present—T. W. Cowan (in the chair), the Hon. and Rev. H. Bligh, Rev. Dr. Bartrum, Captain Bush, Captain Campbell, Rev. F. S. Sclater, Dr. Walker, H. Jonas, J. M. Hooker, and the Secretary. Letters were read from the Rev. F. G. Jenyns, Rev. J. L. Seager, and the Treasurer, regretting their inability to be present. The minutes of the last meeting were read and confirmed.

The Report of the Finance Committee was considered, and various payments recommended were ordered to be made. Special attention was called to the fact that there was still a number of subscriptions outstanding.

The Secretary reported the receipt of the reports and balance-sheets of the several Associations for the past year. The Secretary was instructed to write to the Lincolnshire Association, expressing the regret of the Committee that their Association should have ceased to be in affiliation, owing to their non-compliance with the

The Exhibition Committee, having further considered the rules for the management of County Shows, as referred to them by the quarterly meeting of County Representatives, presented their report. The rules, as amended, were ordered to be printed, and the Secretary was requested to forward a copy to each County Secretary.

The subject of holding an Exhibition in London during the present season was fully discussed. The Committee were unanimously of opinion that such an exhibition would be conducive of much good to the beekeeping cause; but as the Association's work, as arranged for the year, would absorb the whole of its income, it would be necessary to have a special fund for the purpose of such an exhibition. Fully 200/. would be required to carry it out successfully. The Chairman was requested to bring the matter before the bee-keepers of the United Kingdom, and others likely to be interested, through the columns of the Bee Journal.

HANTS AND ISLE OF WIGHT BEE-KEEPERS' ASSOCIATION.

The annual general meeting of this Association was held upon Saturday, May 14th, at the rooms of the Society for Promoting Christian Knowledge in Southampton. Amongst those present were the Rev. W. E. Medlicott (chairman), Rev. J. L. Carrick, Messrs. C. Martin, J. J. Candey, A. Broom, T. Giles, H. West, E. Maberly; and Mr. and Mrs. Bellairs, who arrived that day from the Continent. The annual report and accounts were adopted with a special vote of thanks to Mr. Stokes, the manager of the Wilts and Dorset Bank, Christchurch, for acting as auditor. All the officers were re-elected with the addition of the name of the Rev. J. L. Carrick upon the Committee, and Mr. Evan Maberly as Assistant County Secretary.

The accounts show a 'turn-over' of 3771. 2s. 6d., but there is a debt amounting to 43l. 1s. 10d. owing to the Treasurer. Nearly 100/. has been distributed in prizes, and a considerable sum has been expended in local shows, experts' tours, &c. The Report deals with these at length, and alludes with legitimate pride to the special visit of the President, H.R.H. Princess Beatrice and her husband, to Southampton, to do honour to the Association. It also states that preparations are being made to arrange a joint show with the Berks B. K.A. at Reading, upon the occasion of the intended Show of the Royal Counties Agricultural Society. There are 400 members, and it is evident Hampshire has been making large strides in apiculture during the past year. The name of Mr. H. W. West, of Swanmore, is honourably mentioned in connexion with branch work, and the Association is to be congratulated in having found an Assistant Secretary in Mr. Evan Maberly.

Correspondence.

The Editor does not hold himself responsible for the opinions expressed by his correspondents. No attention will be taken of anonymous communications, and correspondents are requested to write on one side of the paper only, and give their real names and addresses, not necessarily for publication, but as a guarantee of good faith. Illustrations should be drawn on separate pieces of paper.

Communications relating to the literary department, reports of Associations, Shows, Meetings, Echoes, Queries, Books for Review, &c., must be addressed only to "The Editors of the "British Bed Journal," c/o Messrs. Strangeways and Sons, Tower Street, Upper St. Martin's Lane, London, W.C. All business communications relating to Advertisements, &c., must be addressed to Mr. J. Huckle, King's Langley, Herts (see 2nd page of Advertisements).

**In order to facilitate reference, Correspondents, when speaking of any letter or query previously inserted, will oblige by mentioning the number of the letter, as well as the page on which it appears.

OUR HONEY IMPORTS.

The value of honey imported into the United Kingdom during the month of April, 1887, amounted to 17111.— [From a Statement furnished by the Statistical Department H.M. Customs to E. H. Bellairs, Wingfield, Christchurch.]

MR. LEE'S NEW FRAME,

[974.] On the 4th of May I received one gross of Mr. Lee's new frames, with foundation to match. As the only axe I have to grind is to get best value for my money, I should much wish to give the result. Within ten minutes or so of receiving them I had put them together, and was on my way to hive number 2 with four of Lee's frames. I removed two of their frames to number 6 and gave four of the new frames. examined them on the 6th, three were worked out. One of the frames had the foundation slipped out at the

corner, and hung down like a dog's ear about four inches. As the foundation was very tough it had not broken, so I out with my pocket-knife, opened the top bar of the frame, and pushed it into place, closing it up with my thumb and finger. The frames were used without metal ends or distance-pins of any sort, and were not hammered together at the corner, which, perhaps, accounts for the corner slipping out. The foundation was worked out straight as a dart, no popholes, and firmly fixed, top, bottom, and sides. In looking over the hive yesterday I thought they wanted another frame, so I went to the box where I keep them in the flat and put a frame together and into the hive with it in no time. There was hardly a cell in the Lee frames but what had either grubs or eggs in them (not hen's eggs). I was delighted with them,—so straight and clean. I feel I shall now be able to follow the advice of Père Editor in his book Storifying and Doubling. I had previously resolved to use the W. B. C. metal ends, and no other; but judge of my disgust when they arrived and I tried to fit one on. However, I see by this week's Journal it is to be adapted to the new frames.

In my humble opinion,—and I have no interest or connexion amongst dealers,—these frames will prove a blessing to us all who, like myself, are not blessed with a lot of spare time. I make no pretensions to be a prophet, but if I did I should say this frame is the frame of the future, and think when used with the W. B. C. end it is simply perfection. I think it should be called the 'Lee Jubilee Frame.' In regard to drones, I think by cutting out a strip

12 inches from one side and 4 inches from the bottom of one or two frames, we shall get as much drone-comb and brood as will satisfy any one. I will try it. As this is how I obtained drones with the old style of frames, may I recommend these frames to 'X-Tractor?'— Charles J. Jelfs, Dodford School House, Bromsgrove,

May 17th.
P.S.—Bees here are having a glorious time on the damsons, plums, pears, &c.

AGE OF BEES.—WASPS.

[975.] I cannot allow the 'proof' by your correspondent, Mr. James, of a 'positive fact' that he has bees in his apiary 'who cannot be less than twenty months old to pass without comment. The same 'proof' could, according to my experience, be used to show that bees lived twenty years. The fact that Ligurians are seen in a hive a considerable time after a black queen has been established there may surely be accounted for by their being natives of other hives who have taken up their abode there. I have frequently noticed unmistakable Ligurians in my hives with black queens, and have always assumed that they were either trespassers or immigrants from other hives who had permanently settled there. This is a subject upon which we have yet much to learn.

It has been ascertained by experiment that wasps will, under certain circumstances, of themselves leave their native habitat and become life-members of a neighbouring colony; and if wasps—why not bees? This is one of the many points as to which bee-keepers who attempt to make the subject a science would derive profit from studying the habits of kindred insect tribes, such as wasps and humble and other bees. While mentioning wasps may I be allowed to say that it has always been a matter of regret to me to see in the Journal, as we did particularly last year, recommendations from different correspondents for the wholesale massacre of these unhappy innocents. In the first place, it should be known that the slaughter of queens in spring can have very little (if any) effect in preventing colonies being started

in the neighbourhood.

A proportion-no one knows how large-of those destroyed are probably sterile, and a large number of the fertile that survive the winter meet with violent deaths at the hands—or rather at the mouths—of their numerous enemies, prominent among these being toads that secrete themselves in holes likely to be inspected with a view to occupation. Besides these many are slain in contests for building sites, which take place when, as must frequently happen, the same site is regarded as eligible by two or more candidates.

It may not be a very consoling thought to anyone who has spent his time and trouble in slaying (it may be) his thousands to reflect that perhaps one half of the victims were sterile, one quarter would in any case have been destroyed, say, by foads or birds, and the other quarter—well, he has saved jealous rivals the trouble of disposing of them, or being disposed of by them, or

perhaps both.

But apart from these conjectures, and apart from the regret that it must be to every true lover of nature to see the wholesale slaughter of any creature recommended, I believe, Mr. Editor, that wasps, like most, if not all other insects, are not without their use, though they may be in the autumn an annoyance to the bee-keeper. It is well known that in spring they destroy vast hordes of aphides and other insects whose ravages on the buds and blossom of fruit and other trees are most serious. It may well be that by removing these pests they are doing the work for which the percentage of our fruit and honey they are apt to take without asking in the autumn is but a just recompense. - John M. Stone, Lee Park, Blackheath, 16th May.

IN THE HUT.

'There I crouch when owls do cry.'

[976.] Puck had to sip sedative soothing syrup from the poppy when his system craved for the narcotic and stimulant which nearly every nation on the face of the earth uses in some fashion or other. Unlike him, the huttites, taking full advantage of Jean Nicot's discovery by burning the leaves of Nicotiana Tabacum (perchance sophisticated with leaves of varieties of the Brassica family) in retorts of asbestos, seek comfort in the bowl, for in baccy'nalian orgies

'The bowl affords relief.'

The poor bees, too (bless'em), get their little solatinm, not sub rosu, but under the quilt, their inmost privacy being invaded for the purpose. What a jolly good smoke one does get during a manipulation!

All the huttites have 'taken the veil' and dipped it in the waters of Lethe (not the Water of Leith, Midlothians). In future they're going to do without 'em, and try to

forget they were ever used.

Hint as to fastening honey labels on tin canisters:-Mix a little honey with flour paste, and paper sticks to

I notice that the favourite prescription of a Chinese doctor is a horrible pill compounded of parts of snakes, wasps, centipedes, toads, and scorpions, ground small and mixed with honey. The Chinese are no fools, and the above is not near so nasty as was the ammonia of our forefathers in pharmacy, and as are the musk and civet of to-day; the only difference being, we do not all

know whence and how obtained.

In Emin Pasha's last letter (as late as October 1886) he says: 'Instead of sugar we use honey; instead of coffee we use the seed of a species of hibiscus; instead of stearine, candles made of wax; soap has been made from tallow and the ashes of various trees; while meat, a few vegetables, and oil got from sensum seed, have prevented us from starving. The tobacco we are growing now is very good.'

'So work the honey-bees,'

contributing to the sustenance and comfort of our pioneers of civilisation when almost in extremis,—X-Tractor, Horsforth.

HUMBLE BEES.

[977.] Your correspondent, 'D. R. Grimshaw,' says that he could not find out the name of his humble bees. There can be little doubt that they were the red-tailed bee (Bombus lapidarius). His failure to keep them through the winter probably arose from want of warmth and quiet. If he will give them a good depth of earth and plenty of moss before the cold sets in, they will build a winter nest and hybernate safely. Of course he understands that it is only the egg-laying queens that survive, and that they sleep all the winter.—Benj. Lomax, Brighton.

UNPROTECTED BEES.

[973.] I, and my bees have just past an exceptionally cold winter; the only difference in our situations being this trifling (°) circumstance, I found means wherewith to keep up two fires,—aye, and pass a great portion of my time in near proximity thereto, while my bees-bless the little gems!—were on the bleakest of the bleak elevations of the village, destitute of flannel, cork-dust, carpet, quilt, or packing of any kind. Oue of the stocks equal in point of strength to any I have—having spent the time in a cheap half-inch stuff hive, with double walls, but nothing more to cover them as roof but the half-inch stuff mentioned. I need not name the contretemps that caused this want of what is deemed necessary care and protection from inclement weather, it was unavoidable under the circumstances, and when I had my supposed tenantless hives-eleven in number -brought nearer to my domus, my surprise was great indeed, and my delight was excessive, as the ever-welcome hum sounded in my ears. Not a bee apparently any the worse for being thus 'left out in the cold,' down, down, I know not how far below zero.

Old, aged, as I am, I am not too old to learn; tell me then, O ye learned in the anatomy, the physiology, the temperature of a bee, what lesson am I to draw from the facts now related. Am I to disregard in future all the admonitions, the counsel, the cautions which our experts and bee-masters so earnestly publish; or am I to look upon the incident as constituting a marvellous escape from a violent death—a being frozen to death?-

An Aged Amateur.

P.S.—I find the stuff is not half-inch, it is only threeeighths.

Our correspondent may consider himself exceptionally fortunate; but we should not advise any one to take his experience as a precedent.—Ed.]

METAL ENDS.—TITS.

[979.] Will any one kindly inform me in the next Journal what is their opinion of metal ends versus broadshouldered? Ten of the metal ends exactly fit into a hive $14\frac{1}{2}$ in. wide, which is the width of many hives; but if there is a half bee-space at the sides of each comb when a centre comb is put to the side of the hive there will only be a half bee-space. According to this, there ought to be $\frac{1}{8}$ in. blocks at all the four corners to keep the combs off the sides, and the hive ought to be $14\frac{3}{4}$ in. wide to take ten frames. Is this right? It seems to me that $\frac{3}{8}$ in. is too thin for a top bar, and 1 think the metal ends ought to take $\frac{1}{2}$ in, tops. Are there any made that

How is it that people will write to the Journal and say that tits do not kill bees, but sometimes eat dead ones that they find on the ground? I shot exactly a dozen of the great tits last spring in two days, which were hard at work on the bces. When the snow came $_{\rm I}$

could not keep the shades over the entrances unless I used very heavy pieces of pot or sheet lead. The tits pulled anything light down, and when the bees came out to see what was the matter they were at once killed.—ARTHUR J. H. Wood, Bellwood, Ripon, May 14th.

The ends are a question of taste. Hives should be made long enough to take a division-board as well as ten frames; therefore, we think $14\frac{1}{2}$ inches not long enough. It is not very important to put in the \frac{1}{8} inch blocks, as you suggest, because in any case the bees would have \(\frac{1}{4}\) inch space, which is sufficient for their movements. We have for years used the 3 inch top bar, and have never found it too thin, or give way in the ordinary way of using .- ED.]

APIFUGE.

[980.] Does the exception prove the rule, if so, I am proud to be able, through some suffering, to bear testimony to the efficacy of Mr. Grimshaw's apifuge? Up to date I have used it on four or five occasions, notably on removing a particularly irascible colony into a clean hive with perfect success. But now comes the proof of the rule. I went last evening to put a crate of sections on a colony I had hitherto esteemed a particularly good-natured one. Being in a hurry, I omitted to smoke them. On carefully peeling off the quilt they set up a whirr of anger and astonishment at having their interior exposed, but on spreading my hands, previously rnbbed with the apifuge, over the frames, they quietly subsided under its benign influence. One bellicose individual, however, who had heard the commotion from below, came rushing up, and without waiting to learn the cause of the misunderstanding, or whether it had been, or could be, amicably settled, as indeed it had, thanks to the apifuge, so far as the majority were concerned, rushed at the nearest part of the supposed enemy's forces, which happened to be my left hand, and taking a good grip with its forefeet, applied its business end to its particular function in a business-like manner. It then made offensive demonstrations in the direction of my face, but, as I now had charge of its weapon, I merely smoled a smile of derision, and went on with my job. May I conclude from the above experience that the use of apifuge does not do away with the necessity for smoking?—Walter F. Cromey, Levens.

[One errant radical is generally to be found in an assemblage of the loyal and well-disposed.—Ed.

GRIMSHAW'S APIFUGE.

[981.] Allow me to bear testimony to the value of 'Grimshaw's Apifuge' to all bee-keepers. I have kept bees for the last thirty years, and have been stung many hundred times, and till now I have never dared to do anything to my bees without first smoking them and also wearing a bee-dress and gloves. I have lately purchased a bettle of this wenderful stuff, and cannot persuade my bees to sting me, do what I will with them. By using it the only unpleasant part of bee-keeping is done away with. If you jar or shake the hive bees are sent out at once to attack the intruder, but the moment they smell the 'apifuge' they change their minds, and either settle harmlessly on the hands or face or return to the hive. The scent is not at all unpleasant, rather the opposite. I have one very savage hive that smoke would only partially subdue; the effect of the apifuge on this hive was instantaneous, and not a bee offered to sting me. One great advantage apifuge has over smoke is that in the use of the former no time is wasted by the bees, whereas when the latter is used they glut themselves with honey out of the cells, which they return back after the manipulation is over, and this occupies a considerable time. Let me recommend all bee-keepers to try it.—NIGEL GRESLEY, Netherseale Rectory, Ashby-de-la-Zouch, May 21st.

HONEY-PRODUCING FLOWERS AND PLANTS.

[982.] Doubtless most of the readers of your valuable and esteemed Journal are aware that much has appeared in its columns in reference to many kinds of flowers and plants which are more or less valuable as honeyproducing plants, and some of the accounts given appear very contradictory. I think if our friends were to give us a few more particulars respecting the kind of soil and the treatment the various kinds of plants require to make them honey-producing, the apparent contradictions would be much lessened. I may add that I take a very great interest in the Journal and also in growing many kinds of plants which have been recommended from time to time in its columns, some of which I find entirely useless as bee-plants in my soil.

With your permission I will illustrate, in some small measure, my meaning, and to do this I will describe the soil, and follow on with a few different kinds of plants. The soil, then, is a rather strong and stiff kind of clay, top soil, and clay subsoil, it is very bad to work if much is done to it in wet weather; but if dug up rough and allow it to get well frosted, it works very well. I find that a good coating of burnt earth of any kind answers better than manure for a time and makes it work much better and prevents the cracking which often occurs in

dry weather.

Now let me give a few remarks respecting the plants which I have tried upon this kind of soil. First, Borage, this I find to be the best of all plants which I have tried; it grows very strong, each plant growing to about 3 ft. high, and many of them where they have room will measure 5 ft. through, and this will be always in bloom from the middle of June until the sharp frosts come and kill it, and it is also very thickly covered with bees all the time the weather permits them to fly; there is no slackness, and they visit it from morning till night; I have often heard them flying about it when it has been too dark for me to see them, and I believe they collect large quantities of one of the very best samples of honey from it. I find the bees leave nearly everything for it. Just to prove this; there is a meadow between my apiary and where these said plants are grown, and last summer when the Dutch clover was in full bloom I walked about the meadow several times, but I could see there were very few bees upon it, while the borage was one mass of bloom and bees, as though there were many hives hidden beneath the plants.

Next to the borage I find Nepeta Mussini. This is also a very excellent plant for bees, and is visited nearly, if not quite, as much as borage. It does not grow so high as the borage, and would suit these who had not much room to grow plants, but it grows very strong with me. I have several plants which measure 4 ft. across, and only 6 in, high; the masses of bloom and bees working upon it from morning till night would surprise those who had not seen it, and I can highly recommend it to those who wish to grow flowers which will look pretty and suit their bees at the same time. I have been told that cuttings of this plant were advertised in British Bee Journal at Is. 6d. per dozen, but I did not see it myself; be this as it may I think it a very high price. To those who would like to try its value, I shall be pleased to send them a few cuttings, but not at Is. 6d. per dozen; but I must ask them to enclose me a stamped and addressed envelope to C. H. W., Aylesford, Maidstone, or their requests cannot be attended to.

Next in value comes Limnanthes, which I find a valuable plant for the time it lasts in bloom, which is only about a fortnight, and then all is over until another

Next come crocuses and snowdreps; these are also valuable: I grow them close to my hives in large masses, and they are very pretty when in bloom. It is a pleasing sight to see how the bees roll and sport in them in early spring when they cannot get anything else.

This spring I took some pea-flour and put it into a bottle with a wide mouth and a perforated cap, and shook the flour over the crocuses. It was surprising to see what large quantities the bees would take away when found by them in this way. I have grown large quantities of pea-mint, but it is not worth much to the bees. I have also grown largely of wood sage; it is a rare thing to see any bees on it. Clarkia is also neglected by the bees, but white arabis is fairly visited until the fruit blooms appear when that is also neglected. Thyme is a fair plant while in full bloom, but the bees only visit it for a few hours in the day. Rue: I have often watched to see if I could find a bee to settle upon it, but I never could, although it is surrounded with the bees in visiting other plants. There are many other plants which I could speak upon, but I fear I have already trespassed too far upon your valuable columns, so I heg to sum up by saying that I find my bees neglect nearly, if not quite everything for borage and Nepeta Mussini, the latter is quite hardy and the cuttings strike readily with a little care in the open ground.

I have a little borage and plenty of Limnanthes seed and shall be pleased to send a little to any one on the aforesaid terms. I may also add that in very dry weather I always give my plants when I think it necessary a good soaking with water such as runs from sinks and wash-

houses, and the effect is very remarkable.

I beg pardon for trespassing so far upon your columns, but I hope it may be some little use to some of our beekeeping friends, which I am sure will give you all the satisfaction you require and I shall be well paid also.—C. II. W., Aylesford, Maidstone.

HONEY-COMB DESIGNS.

[983.] Many bee-keepers would possibly like to have nice mottoes and designs to set off their exhibits of honey after the manner described by Mr. Wm. McNally in your issue of the 12th May (948), but are debarred from the cost of purchasing the blocks or of making them themselves, and the almost utter worthlessness of the articles after the present season is over. To overcome this difficulty I suggest that 4-inch square cards be used to fit in or on to our 1-pound filled sections, with a letter cut distinctly out of the centre of the card, the ground-work of the card to be of a nice bright blue, or any other colour suitable to each individual taste, and on the coloured ground-work of the eard some pretty gilt devices, such as flowers, fruit, birds, or bees. claim for this idea economy and effectiveness, no loss of time to the bees in filling out blocks, and no detriment to the sections after being exhibited in this manner. Bee-keepers by purchasing half-a-dezen alphabets would always have it in their power to form any device they liked, and with care the cards would last for many Will some manufacturer of bee-appliances take this idea up, and issue cards after the manner I have described at a moderate price?—John Goodall, Handsworth, Woodhouse, Sheffield, May 21st.

HOW LONG DOES A WORKER-BEE LIVE?

[984.] The proof brought forward by Mr. C. C. James (p. 208) that he has some thousands of bees not less than twenty months old is far from convincing me, for, as he has had Ligurians, nothing is more likely than what you suggest, that one of his queens has been crossed with a Ligurian drone, amongst whose progeny will often be found marks of what I consider the improved strain, evidenced by many workers as yellow or orange-banded as the purest Italian Alp bees. And of this several of my own stocks are examples. Five or six years ago my friend, Mr. A. Morris, kindly sent me a swarm of cross-bred bees, who, and all whose descendants, have done well in my hives. My stocks have never been

nearer than five miles to any other bees of the Italian Alp or Ligurian strain. I have not at any time given them yellow queens or imported new blood, and yet every season during the past five years I have observed numbers of workers amongst the black population as clearly marked as if they had just come from Liguria. If Mr. James's proof is correct, I have bees not twenty but more than sixty months of age, and still as vigorons as if only born yesterday! My impression is that this appearance of yellow-banded workers where it might be expected all would be black or nearly so, is merely the occurrence of one of these genuine traits like the dark complexion or thick lips sometimes met with in human beings very many generations from the original negro father or mother.—H. W. Lett, M.A., Aghaderg Glebe, Loughbrickland, Co. Down.

FOUL BROOD.

[985.] Several letters have lately appeared in your columns in regard to the spreading of foul brood by experts in visiting apiaries, but we do not seem to get the opinions of those who, living in infected districts, ought to be able to give us some useful information in regard to the rapid means by which the disease spreads through a district, until it is an exception to find any healthy stocks. I will mention several cases which have come to my notice during the last few years. In the year 1883 I was asked by a gentleman to go and see his bees as they seemed to be rapidly dwindling away. On examination I found that the hives were simply reeking with foul brood, but although there was plenty of honey in them, there were no signs of robbers; and at the wish of the owner I completely destroyed all combs and hives, although I thought it unnecessary to do away with the latter which might have been disinfected. The same year, two other stocks about one mile off were found to be suffering from disease, one very badly, which was destroyed at once, and the other after the owner had attempted to cure with salicylic acid and failed, was destroyed in the autumn, but not until he had procured another stock in a skep, which, when transferred to a frame hive in the spring, was also found to be infected, and had to be destroyed.

During the summer of 1886, in another apiary of six stocks, two or three were found to be diseased, and I directed the owner to use phenol solution; but in consequence of the directions not being fully carried out, the cure was only partially successful, and they were put into winter quarters with the disease still in the hives, but I have had no opportunity to visit them this spring, and so

cannot say as to their present condition.

The last case I have had brought to my notice was about three weeks ago, when I found one stock diseased in an apiary of six, but apparently of recent outbreak, as it was not in an advanced state, so after reducing the brood-nest to a limited size, I gave the owner some phenol solution (the curing powers of which I have conclusively proved to my own satisfaction. See B. B. J., vol. xii., page 298), and hope to be able to make a good

rcport later on.

There are two questions now arise which I will attempt to answer; the first is, How is the disease spread through a district? and, secondly, What are the means we ought to take to eradicate it? for it is certain if we do not get rid of it, it will most assuredly exterminate all bees from the infected districts, and apiculture will in the said districts be given up in disgust. As to the first question, it is well known that the disease is spread by healthy colonies attacking those that are diseased, and carrying the Bacilli spores back with them to their hives, which in turn become infected, and also by healthy colonies being handled after those infected have been examined, and no precautions being taken to disinfect the hands and any utensils used. But, to my mind, there is another, and far more wide-spread, method

of propagation than is generally supposed, for it being undoubtedly possible for robber bees to carry the spores from colony to colony, I believe it is just as possible for the disease to be spread by bees from infected stocks visiting flowers and leaving Bacilli spores thereon, and for others from healthy stocks to revisit them and carry

the germs of disease back to their hives.

Now, if this is the case, and it seems to me quite probable, it is useless for us to go on curing individual stocks, for whilst we are so doing they are spreading the disease around to other and healthy colonies: therefore, we ought to totally destroy all those infected, and if the hives be of wood, to thoroughly disinfect them, and they could be used again. It will, no doubt, be argued that

hives be of wood, to thoroughly disinfect them, and they could be used again. It will, no doubt, be argued that those possessing only two or three stocks would be very loth to destroy them, but I think that could be met by bee-keepers in an infected district combining together and raising a kind of guarantee fund to compensate all whose stocks had to be destroyed; or, still better, by the County Associations taking the matter up, and paving any expenditure out of their funds, which would in itself be a great stimulus to bee-keepers to join them, and would do more good to bee-keeping than any shows can do. I can only say that I shall be only too happy to help in any way to rid the district of the pest, which

takes away all the pleasures, and, by the constant anxiety, makes the apiarian's life anything but a

happy one.

I would, in conclusion, strongly advise all, especially those living in an infected area, on examining stocks, to use instead of a smoker, a spray-diffuser made of a small piece of metal tube, about four inches long, and a smaller piece, two inches long, fixed at right angles at the top end of it; the longest piece is put through an ordinary cork to fit in a bottle to hold the solution of phenol, which I use the same strength as recommended by Mr. Cheshire for making phenolated syrup. When opening the stock, the diffuser is put to the mouth and a fine spray blown over all the frames, which can be repeated when necessary. To the use of the above I attribute (rightly or wrongly) my freedom from infection, as, with the exception of the case mentioned when I infected one stock (B.B.J., vol. xii., page 298), I have never had the disease in my apiary, although last year one of my stocks completely cleared a diseased hive a short distance off of their honey, but they have not shown the slightest signs of disease. J. T. HARVEYSON, Finchley, May 21st.

Echoes from the Hibes.

Ealing, May 15th.—To my great surprise, I had a fine swarm this morning.—J. Gay.

Hartlip Vicarage, near Sittingbourne, May 16th.—I have had my first swarm to-day, at 1 p.m., from a Carniolan stock, and this in spite of a north-easter, which was blowing sharp at the time, and made the gentle ones angry, so the first swarm gave me the first sting of this season. The queen must be a rare breeder, for she alone, from all my stock, swarmed last year, and provided enough bees for a second, which came out nine days after her. We have abundance of food in our cherry orchards at the present time, and only want fine warm weather to enable the bees to gather it.—Thos. Scott.

Oldcombe, Ilminster, Somerset, May 22nd.—I hoped to have been able to send an 'Echo' from this part of the country before this, but there has scarcely been sound enough from the hives to cause one, in fact on only five or six days during April and about the same number up to date in the present month have the bees been able to get out to do anything like work. I have seventeen stocks alive out of twenty that I put into winter quarters, most of my hives face south and east, but I had four facing the west; and, strange to say, three of these I found had perished from starvation previous to my first examination in the early part of March, although they were well stocked for winter, and the fourth proved to be queenless. I have re-

queened this stock in a most simple manner—about three weeks since I selected a comb of brood from one of my best stocks on which the queen was, and simply placed it, bees and all, into the centre of the queenless hive, just using a puff or two of smoke; the next day I found she had been accepted, and had filled a large portion of one of the empty combs with eggs. The apple orchards round here are one mass of bloom, but up till to-day no bees have been able to take advantage of it; but I trust before it is all gone we may have a few fine days, and be able to replace the feeding-bottle by the super.—J. Sarell.

'Honey Cott,' Weston, Leamington, May 23rd.—Black-thorn winter we are indeed having, with north wind very boisterous, hail and rain storms making it next to impossible for the poor bees to get out, while of those that do many never

return.—John Walton.

Limerick, May 23rd.—Bees in this district, as a rule, are strong. We had splendid weather from the 1st of May up to the 17th; it has been wet and cold since. Honey was coming in from apple-blossom fast, and I had them at work in the sections, but I fear they had to use all they got these past cold days. We are very late this year, apple-blossoms are only well out, and May flower in strong bud, of which there is a good show. Stocks came through winter well, they stored an exceptionally large quantity of ivy honey last autumn. I trust we shall be able to send you a good return of year's work later on. I intend to work the I\frac{3}{2} section on the storifying principle, as I find bees have more freedom without a divider, and sections are more evenly finished if the hive is perfectly level.—Alea.

NOTICES TO CORRESPONDENTS & INQUIRERS.

Letters or queries asking for addresses of manufacturers or correspondents, or where appliances can be purchased, or replies giving such information, can only be inserted as advertisements. The space devoted to letters, queries, and replies, is meant for the general good of bee-keepers, and not for advertisements. We wish our Correspondents to bear in mind that, as it is necessary for us to go to press in advance of the date of issue, queries cannot always be replied to in the issue immediately following the receipt of their communication.

- H.—Queen-cell surrounded with Drone-comb.—This is not an unusual case. If the bees have no opportunity of rearing a queen-cell from worker-brood, they will in sheer desperation endeavour to do so from drone-brood; but the contents of such will not be of any service to the bee-keeper.
- K. Drummond.—I. The bees are not likely to take the hellebore sprayed on gooseberry bushes and fruit trees.
 2. The quantity of syrup stated would be far too much, especially as honey can now be procured by the bees from natural sources.
- E. M.—The bee sent was not the queen, but a newly hatched bee with all its incipient fluffiness about it.
- D. H. D.—For the purpose of cleaning floor-boards it is preferable in small hives that they should be moveable; but bee-keepers prefer in longer hives that they should be fixed, as in cleansing them the frames can easily be moved from one end to the other. 2. The bee forwarded is a Bombus sylvarum.
- E. Gibbins.—I. Balling Queens.—Frequent examination of hives in spring often causes balling, as would also the close proximity of the entrances. 2. Distances of Entrances.—We think twelve inches apart too close for entrances, they should certainly not be nearer than two feet. 3. Effect of Cold on Queens.—Cold winds will frequently stop queens laying, more especially if the bees are short of stores. 4. Unfertilised Queen.—The queen sent is a young one. We have examined her under the microscope and have found the spermatheca filled with a clear liquid and not to contain any spermatozoa, showing that she had never successfully mated. If she has laid it could only be drone-eggs. It is possible that the bees lost the queen you say did so well last year, and the one you have sent has been raised since that time, when there were no drones about to accomplish impregnation. 5. Carpentering should not be done in a bee-house as the constant disturbance would be injurious to the bees.
- CUMBBIAN.—Third-Class Certificate.—Third-class examinations are arranged by the County Associations. Any one can compete, We are not aware than any examina-

tions have been arranged for Cumberland. We believe the Committee of the B.B.K.A. will arrange for an examination to take place at Newcastle, at the time of the Royal Agricultural Show in July next. Whether anything can be done to revive bee-keeping in Cumberland in this year of jnbilee depends entirely upon the residents of Cumberland themselves. The British Beekeepers' Association is always ready to assist a movement of this kind. For papers relating to examinations, apply to the Secretary, J. Huckle, Kings Langley, Herts.

A. H. W.—Please refer to reply given to 'Cumbrian.'

AN EARLY DRONE.—The syrup given now should consist of 10 lbs. of sugar to seven pints of water. It would be better if you gave them access to the syrnp through one hole in the feeding-stage. They will then take what they want without getting too much.

A better spur-embedder than the Woiblet:—the Heel!

Received from Abbott, Bros., some samples of capsules, stamped with very neat and appropriate designs.

Business Birectory.

All Orders to be accompanied by a Remittance.

My Queens are all very prolific, long-lived, and much larger-bodied, than the majority of those supplied by others, as they are reared naturally, under the swarming impulse, in April, May, and June, from the strongest of my forty colonies of Bees kept in double-walled moveable frame-hives, and all having choice Queens, which produce workers so gentle that they can be handled without smoke, and even without a veil on the face, just as I do myself (see Mr. S. Simmins' statements on page 37 of his work entitled, A New Era in Modern Bee-keeping). This is principally owing to the fact that I have weeded out from my Apiary all such Queens which appeared to be weak or producing troublesome workers. Address—

M. G. DERVISHIAN, Larnaca, CYPRUS. A 2375 For Reference, address Imperial Ottoman Bank, Larnaca.

STEWARTON HIVE.

JAMES ALLAN, Hive Maker, Stewarton, N.B. Established 40 years. Maker of the famous Stewarton Honey-yielding Hive, wrought on the Storifying or Tiering principle, with instructions for use. Covers and Appliances of Apiary supplied to order.

[PUBLISHED WEEKLY.]

Editorial, Notices, &c.

OUTLINES OF BEE-KEEPING FOR BEGINNERS.

(Continued from page 212.)

XI.—How to Put a Swarm into a Hive.

- 1. The bees which leave the hive to swarm fly out in large numbers, thousands of them wheeling about in circles so that the air seems alive with bees. They soon settle, usually on some bush or tree at a short distance from the hive, and form a cluster, which grows larger and larger as the straggling bees join it. As soon as most of them have settled and become quiet the swarm should be placed in a hive, or it will of its own accord seek a home and be probably lost to the beekeeper, as under such circumstances bees will sometimes fly a great distance before they settle again.
- 2. If the queen does not join the bees when clustered, they return to the old hive. They will also leave the hive if the queen be not secured with the bees when the swarm is hived. Sometimes swarms do not seem inclined to cluster; and if the bee-keeper sees that they rise higher and higher into the air, he should endeayour to stop their flight by throwing water from a syringe over them in such a way as to resemble rain. This will generally have the effect of making them settle at once,
- 3. If the bees have settled on a bush near the ground, sprinkle them with cold water from a garden syringe and close clustering will be the result. Spread a cloth under the cluster, and at one end place a floor-board, bringing the end of the cloth over the edge of the board and place the bive on it with the front, as near as possible to the cluster, propped up about one and a half inches by means of a stone or block of wood. With a sudden jerk dislodge the bees on to the cloth in front of the hive, which they will quickly enter.
- 4. If the branch on which the bees have clustered is small and not valuable, cut it off, taking care to avoid all jarring, and shake the bees on to the sheet in front of the hive.
- 5. If the bees have clustered on the branch of a tree too valuable or too thick to cut off, shake

them first into an inverted skep. Hold the skep bottom upwards in one hand under the cluster, and with the other give the branch a smart shake so as to let the bees fall into it. If they are to be kept in the skep put a floor-board over and turn the skep on to the stand the bees are to occupy. If they are to be put into a frame-hive invert the skep and with a sudden jerk throw the bees down on the cloth close to the front of the hive.

6. If they alight on the trunk of a tree brush them gently into a skep, or, if possible, place its edge near the upper part of the cluster and drive them up by blowing a little smoke, or placing a cloth dipped in carbolic solution under them. A piece of comb containing brood fixed inside the skep will induce the bees to take to it more readily.

7. If the bees settle on the ground, the hive should be set close to them, and with a spoon gently place a few near the entrance. The hum of these will entice others to follow, and in a short time they will all enter.

8. If moveable comb-hives are to be used it is best first to secure the bees in a skep or a metal pail, from which they can be poured out gently on to the cloth in front of the hive.

9. In moveable comb-hives with legs, turn up the quilt and remove three or four of the outer frames, and from the pail pour out the bees into this space. They will run in and cluster among the other frames; then return the frames which have been taken out and lay the quilt gently over them, leaving a small opening at one corner for the straggling bees to enter. Put on the cover and prop it up to allow free ventilation until the evening, when it can be put in position.

10. The bees should be taken to the stand which they are to occupy as soon as possible after they have been hived, and should be shaded while they are in the receiving hives or skeps from the heat of the sun.

11. Despatch in hiving is important as bees become more difficult to handle the longer they are out of the hive, and there is a danger of their rising and flying away.

12. If the bees are to be kept in a straw skep it will require no preparation, but should be perfectly clean. Frame-hives will require the frames furnished with guide-combs or comb-foundation, and when they are propped up during hiving care

should be taken to have the frames hang at right angles to the front, otherwise the heat and weight of the bees would displace the comb foundation, and they might possibly break away from their attachments. Great care should also be taken in moving these hives when the swarms are in them, and they should be carried very steadily and held level. The hive should be adjusted in its place, taking care that it is level across the combs.

BRITISH BEE-KEEPERS' ASSOCIATION.

BURY ST. EDMUNDS SHOW.—We desire to call the attention of our readers to the fact that entries for this Show close on June 6.

Bee-keepers and manufacturers residing in the counties of Suffolk, Norfolk, and the adjoining counties, should give this Exhibition their best support. It is hoped that this Exhibition will tend to revive the work which has been somewhat retarded in consequence of the Suffolk Association having been suffered to lapse during the past year.

A GOOD EXAMPLE.

We have much pleasure in giving insertion to the subjoined extract from the *Canadian Bee Journal*, and in calling the special attention of manufacturers to it as an act worthy of all commendation:—

'From the American Bee Journal we clip the following, relating to the Heddon Hive. Messrs. Geo, Neighbour & Sons, in a late letter, say that "Mr. Heddon and his 'new hive' are 'well known in England.'" In a recent letter, they say that as they wish to make some hives containing "some of the features" of Mr. Heddon's, and desire to "do honour" and "not be considered pirates," they send ten dollars as a "token of respect and appreciation." As the hive named is not patented in England, this shows that Messrs. Neighbour & Sons are most scrupulously honourable and just in their business relations. With pleasure, therefore, do we put this news item on record, as a pattern for beckeepers everywhere.'

SPRING MANAGEMENT BY AMATEUR EXPERT.

'Mel sapit omnia.'

If you have mismanaged your bees during the past eight weeks your prospects of a good honey crop are nil. If you have managed them so well that all your hives are crammed with bees and well filled with brood, you need not trouble to read this any further, as you do not require any advice I may be able to give you. But few of us have all our hives equally strong, and as it is yet too soon to super in these parts, the point is how can we improve the occasion and turn the time now being spent in comparative idleness by the bees to good account. I will commence by saying whatever strength your stock may be, be sure to give them too little room rather than too much while the cold weather lasts. When it is warm the bees can and do spread themselves out and cover more space of comb, but during the cold nights they crowd together and leave all the outside combs, as little short of 80° Fahr, will do to hatch brood in, and 85° will be better still.

We will suppose you have a weak stock, and one or more strong ones, and you wish to make this weak stock sufficiently strong to be of service, I purpose telling you how you may 'rob Peter to pay Paul' to accomplish it. Now I am talking about strong stocks, and by that I mean a hive that is as full of bees as it can well be, and the queen still laying. If it is not so, leave it alone, as

it is better to have one weak and one strong than two only moderate. Get a little syrup over night, and scent it, and feed the two or more hives with it that you intend to operate on. Having done so, anoint your hands with Mr. Grimshaw's 'apifuge' some time about mid-day, open the two hives—if you can get help so much the better—go gently but firmly, and do not tremble, the bees will come and smell at you, but never mind. Take out two frames of bees and brood from the strong stock, be careful not to have the queen on either of the combs, stand in front of the hive a few feet, and gently tap the top of top-bar with one hand. Most or all of the old bees will fly home to their old hive, and you can now give the combs and young bees to the weak stock. If the latter has been so weak as not to cover all their combs, you can take two empty combs from it, and having shaken off all the bees from the combs, give them to the strong stock in place of the full ones and young bees you have taken. If you think this is robbing the strong stock too much you may give only one comb or you may take one comb from more than one strong stock if you have them; or, on the other hand, you may simply shake the young bees on to a sloping board in front of the weak stock and allow them to run in. This latter is preferable to giving brood without bees, probably, as for want of sufficient bees in the weak stock to cover the brood, it may get chilled, and it is astonishing how fast a weak lot may be made strong by this method.

Why feed with scented syrup, 'A. E.?' (a.) Because the bees in the weak stock shall fail to recognise those given them from the strong one as not being their 'own kith and kin.' (b.) Because neither lot shall not ball their queens. The danger of this is greater in the weak lot than in the strong one. And, (c.), because there shall be no fighting. Now tell us why you say 'apifuge,' and make no mention of smoke? Because smoke causes the bees to gorge more fully, and consequently makes them more sluggish, whereas you want them to be so nimble that the old ones readily take wing when you 'tap' the

bar of their frame.

One word in closing. If you have not fed during the past cold spell, you must expect to find all your bees dead to-morrow morning; and if you want any profit on a season like this, you must feed! feed!! feed!!! For the present I have said my say, so au revoir.

Foreign.

HANOVER.

NATURAL OR ARTIFICIAL SWARMING?

 Λ natural swarm issues when there is an excess of population in a hive. This, however, is only found to be the case when the colony has a fertile queen, a large and healthy population, and an adequate supply of food. The departure of a swarm is, as it were, the creation of a new being of the same kind. Other animals, it is possible to propagate by breeding from a single individual, but our honey-bee cannot thus be propagated. The united efforts of the queen and thousands of workerbees are necessary to the existence of the colony. I look upon swarming as an act of reproducing or propagating the species. When bees have the opportunity of taking advantage of the necessary favourable conditions, their inherent instinct is always sure to awake. As soon, therefore, as nature sends warm weather and nectar, we find the queen actively engaged in laying eggs, the extension of the brood-nest keeping pace with the rise in temperature and the development of bee-pasture. When a colony has raised a very large number of worker-bees, and the combs down to the very edges are full of sealed and unsealed brood; when drones have made their appearance and queen-cells been commenced,

we may expect a natural swarm to issue. As a rule, the old queen with a portion of the population leaves her hive between nine o'clock in the morning and three

in the afternoon.

Most of the young bees which have to keep warm and fee I the brood, remain in the hive. In the course of a few days a young queen hatches, and if the colony has no intention of sending out further swarms, the workers, after the young queen has been impregnated, destroy all the other queen-bees which are still in the cells, and the parent hive will then be in order again. In natural swarms it seems as if the bees acted with deliberation, and what is more after the swarm has been hived and placed in position in the apiary, we find that no bee of the new colony returns to the old hive, but all enter their new home. The population of the swarm are more industrious than the other colonies which have not given off swarms. It is as if every individual bee knew that it is necessary to work hard in order that combmaking may progress and provisions be accumulated for the coming winter.

In natural swarming, the initiative proceeds from the colony. The bee-master certainly may assist and stimulate the impulse of swarming by a plentiful supply of food and increase of the temperature in the hive, &c. We bee-keepers of the province of Hanover, therefore, are in the habit of placing the parent hives in our sheltered bee-house in such a position as to be exposed to the sun from 9 a.m. to 3 p.m. We use round hives made of straw and having thick walls, and from the middle of April we stimulate our colonies by giving them plenty of honey. An artificial swarm is the work of man. As the initiative proceeds from the bee-keepers, there is a possibility of serious mistakes being

committed, to the detriment of the colonies.

From what I have said about natural swarms, it will be seen when and how artificial swarms ought to be made.

1. An artificial swarm should only be made at the proper time of the year, when there are plenty of worker-bees in the hive, when the combs are quite full of brood, and when we have either sealed royal cells or queens at our disposal.

2. Swarms made artificially ought to resemble natural

3. Some comb with brood as well as worker-bees to nurse the brood, should be left in the hive from which an artificial swarm has been taken. Care should also be taken to ensure the early reinstallation of a queen in the parent hive.

If these conditions are complied with in making artificial swarms, a bee-master is not only enabled to get swarms when he likes, but he also prevents waste of honey which is a consequence of natural swarming.

Permit me to show you the best way of making artificial swarms. You are aware there are various methods, the best of which in my opinion is that adopted by Mr. C. J. II. Gravenhorst, the most skilful living bee-master. He takes all the bees of a colony together with the old queen, and places them in a new hive in which he inserts some guide-comb, one honey-comb, and one brood-comb, but the latter for one day only.

Most of the old bees, of course, return to their old hive in the course of the day, and thus the brood receives the necessary attention. A mature royal cell or a queen is then introduced into the parent hive which is thereby placed in the position of a colony which has given off a swarm and its existence is secured. If the artificial swarm be made before the commencement of the real honey season a parent hive deprived of a swarm and managed in the way I have stated is in a position to yield incredibly large returns. The number of workerbees in such hive is increased every day by the young bees which leave their cells, and as no eggs are deposited because the queen is either still in the cell or, if hatched, has not yet become impregnated, all the worker-bees can devote themselves entirely to gathering honey. Indeed it is not uncommon for such a colony to collect 200 lbs, of honey in a season if the bees are able to

fully utilise the acacias and lime-trees.

This method, of course, necessitates a honey extractor to remove the honey from the cells frequently; if this is done at the proper time and while pasture continues abundant, a queen-excluder will be quite superfluous. Even should the queen have become fertile she will scarcely be able to deposit eggs into a great number of cells as most of them will be full of honey. The artificial swarm also makes good progress and very beautiful worker-cells are made by the bees while such a colony makes no preparation for swarming the first

Taking the brood-combs from the parent hive and leaving the queen and the old worker-bees in their old place in the apiary is in my opinion a mistake. If this is done, breeding will go on with increased energy, and in a short time the colony will again make preparation for swarming. Instead of accumulating honey, the bees will direct all their efforts to swarming, and should no autumn pasture be available the result of the beemaster's exertion will be an increase in population

instead of a good honey harvest.

The artificial swarm will also have a bad time of it. All the worker-bees which fly out to gather honey and which are old bees, return to their former hive the helpless only remaining to nurse the most helpless. Such colonies frequently become a prey of moths. This method of making artificial swarms is the most wretched one that has ever been devised. It may happen that such a colony will commence to work when there are

hardly any flowers left to visit. On whatever plan a bee-keeper makes an artificial swarm it is necessary that he should examine the colonies operated upon the following day, and again a few days later to see whether his performance has been a success. If not, he ought to assist the colonies by inserting some brood-comb, honey-comb, or empty comb. Man's work is seldom such that he is able to exclaim, like the Architect of the universe, 'It is very good;' but if he succeeds so far as to have all his colonies in a condition to follow to the fullest extent their instinct to accumulate honey when the season is at its best, then he may be called a bee-master, and will derive ample

returns from the pursuit of bee-keeping. It is a mistake, however, to suppose that artificial swarms can only be made when bees are kept in hives with moveable combs. Nowhere, perhaps, are more artificial awarms made than in the Lüneburg district. The Lüneburg bee-keepers generally allow their colonies to swarm voluntarily, but when a stock does not send out the first swarm readily, they do not wait long but drive the swarm out of the hive and they do not lose much time over this. At this time of the season the bees readily enter the empty hive which is fixed on the hive from which the swarm is to be taken. The queen is among the first bees that leave the parent hive. not necessary to drive off a large number of workerbees, as the Lüneburg Heath bee-keepers are in the habit of putting up the swarm where the parent hive has been, the latter being removed the day afterwards and put in the place of another hive which is able to part with a portion of its population. In some districts another method is adopted which is much more simple and gives good results.

A parent hive which has given off a first swarm and is about to send out a second swarm, is made to change places with a colony having a large population that is not inclined to swarm. The bees of the latter enter the hive that is going to swarm and leave it again when the first second swarm takes its departure. By means of such a colony we are able to deprive

four colonies at least of their superfluous population and to make as many large swarms; as swarming involves a great expenditure of honey, the Lüneburg beekeepers prevent the issue of swarms when no longer desirable. When a colony has furnished one large first swarm and one or two second swarms, it must not part with any more bees, for it is one of the first rules that the parent hive should retain a very large population in order to fill our honey-casks.

The colonies in an apiary of sixty hives are all in the condition of a stock with moveable combs from which swarms are obtained à la Gravenhorst. As the old hives do not give up swarming voluntarily the bees are driven off in the evening, and all the royal-cells cut away, the empty parent hives being tied up and left without bees for a night. The bees are shaken into the grass and an empty hive is placed over them. During the night the bees ascend into the crown of the hive, accepting one of the queens and killing the others. The next morning the swarm is driven back into the parent hive, and then all inclination to swarm will be found to have passed away.

It is further to be remarked that a natural swarm is rarely ever such as to satisfy bee-keepers in regard to population, and the swarm, therefore, has to be assisted. First swarms with small population are strengthened by bees from second swarms, and second swarms are added to second swarms until the hive is half full of

bees.

These few remarks of mine will show you that the bee-master will give no preference either to artificial or natural swarms. I accordingly answer the question asked as follows:—

- 1. A beginner in bee-keeping must remain satisfied with natural swarms until he has made himself thoroughly acquainted with the life and doings of bees.
- 2. A bee-master will not decide either in favour of the one or the other, but will always proceed in a manner which in any given case appears to him to be most advantageous.—Lehzen of Hanover (Translated from the Nordlingen Bienenzeitung).

AUSTRALIA.

A very curious discovery was made some time ago by a French naturalist, M. Guilmeth, in the course of one of his journeys of exploration in Australia. It was in the month of May, when one day M. Guilmeth noticed in the thickest part of the branches of a eucalyptus tree at about eighty metres from the ground a kind of a hut of a very peculiar shape, about which there was quite a swarm of black bees unknown to him. He ordered his men to proceed with the cutting down of this gigantic tree, an operation which occupied twenty-eight hours. It was then found that this peculiar object was a monster hive or bee-nest, weighing 4500 kilos, and containing 3500 kilos of an exquisite honey strongly flavoured with eucalyptus. This discovery was the subject of a lecture delivered by Dr. Thomas Caraman at one of the recent meetings of the Academy of Medicine. — From the Patriote de Bruxelles.

CALIFORNIAN HONEY IN ENGLAND.

We have before us the Annual Market Review of the honey and beeswax business of California for 1886, as issued by Messrs. Schacht & Lemcke, of San Francisco, Cal., shipping and commission merchants. From it we glean some very interesting information. We find that the number of cases of honey (each case, we believe, holds an average of 112 lbs.) shipped to England in 1885 amounted to 10,000, and in 1886 only 3475 cases, of the production of 1885. These gentlemen estimate that the total production of honey for 1886 amounted to 2000 tons extracted and 500 tons comb honey. The exports to England as given here look

well on paper, but on a closer examination we find that a very large quantity of the honey thus shipped to the British market remains unsold on the docks even to this date, so that the reason as given by Messrs. S. & L. for the small shipments of I886 is nearly in accordance with the facts as we find them. The reason they give is that 'the small shipments to Europe in 1886 were caused by the low prices ruling there in consequence of too heavy shipments in the preceding years, and by no means by the decreasing demand abroad, because Californian honey finds more and more favour everywhere. On the 14th of October last no less than 910 cases of Californian honey were put up by auction at the docks in London, England, and one-half of it only found buyers, the balance being still on hand. The commission merchants carry stocks generally about a year before disposing by auction, so that it is probable many of the 1886 shipments are still waiting for purchasers. We give in the above only the number of cases held by two tirms, and it is probable that there is in small lots at least as much more of the 1885 crop as here given. The prices at which honey was disposed of in California was 3 to $4\frac{1}{2}$ cents per pound, according to quality. It has then to be sent to England, freight paid, and stored there for nearly a year (the 910 cases reached London July, 1885), there to be sold at an average of 20s. per cwt. (112 lbs.), the lowest being 13s. 6d., and the highest 26s. Off this 20s. must be deducted for discount, commission, brokerage, trade allowances, postage, insurance, dockage, and other charges, amounting, we are told by the principal of one of those firms, to about 2s, per cwt., so that the exporter gets 18s. per cwt. nett, and out of this has to pay freights, &c. The price per pound received, on the average, for the honey which was disposed of at that time was, therefore, from 3 to 31 cents per pound. Most of you will be able to figure up the profits in these transactions. We give these particulars that some of those who still have faith in the 'commission' system of disposal of our honey in the English market may have new ideas to think upon. All the facts and figures given here are taken from written and printed matter before us,—Canadian Bee Journal,

DEVON AGRICULTURAL SHOW, AT NEWTON ABBOT 18rm, 19rm, AND 20rm MAY.

(Extract from 'Devon and Exeter Gazette.')

THE BEES AND BEE-KEEPING APPLIANCES.

The show of bee appliances and bee manipulation experiments in connexion with the Devon and Exeter Bee-keepers' Association was conducted by Mr. James Dallas (Hon. Secretary), assisted by Mr. W. N. Griffin, so well known to bee-keepers in Devon as having started the Association some thirteen years ago, and who acted as its Hon. Secretary during the first ten years of its existence. The exhibition, on the whole, may be considered a fair one. There are very good displays of hives and bee appliances exhibited by Mr. Baldwin and Mr. Butt. There are also some of this year's sections of comb honey exhibited by Mr. Tribble, and considering the lateness of the season they did much credit to the exhibitor. There is every chance of the present being a good year for honey, although there is a probability that it will be late. In the class for new appliances and articles made from the products of the apiary there were several worthy of notice. Mr. Griffin had on view his now celebrated honey dubbin, known as 'Griffin's Leather Preservative and Waterproof Compound,' which has been highly spoken of by the leading sporting papers, and a short time ago the Court Circular, in a special article devoted to it, spoke of it as a very useful composition. It has been tested by the Admiralty, and found to be of great merit as a preservative of leather. From the numerous high-class testimonials we have

perused we consider it a really good article. Passing on to the honey extractors there are several very useful machines shown. Bee-keeping, we may certainly say, is becoming a national industry, and we are pleased to see that the agricultural class are doing all they can to promote the efforts of the Devon and Exeter Association.

A short distance from the tent which contained the appliances, the bee manipulations were conducted by Mr. Baldwin, of Bromley, Kent, who is expert-in-chief of the British Bee-keepers' Association. The first day, through the severity of the wind, the manipulations could not be held; and the last day of the show the gale was so terrific the bee-tent was much injured,

together with many others.

The Association offered prizes for competition in eighteen classes, which were very well filled. The indges were the Rev. P. Williams, rector of Rewe; Mr. J. Thacker, Ottery St. Mary; and Mr. J. P. Kitson, Torquay. Amongst the prize list Mr. S. J. Baldwin was awarded first prizes for hives, collection of appliances, and comb foundation; Mr. Skinner obtaining second for bar-frame; Mr. Butt first for straw hive. Mr. J. Thacker was awarded a prize for last year's sections. A special prize for excellence was awarded to Mr. W. N. Griffin for his honey dubbin or leather preservative and waterproof compound.

Correspondence.

The Editor does not hold himself responsible for the opinions expressed by his correspondents. No attention will be taken of anonymous communications, and correspondents are requested to write on one side of the paper only, and give their real names and addresses, not necessarily for publication, but as a guarantee of good faith. Illustrations should be drawn on separate pieces of paper.

Communications relating to the literary department, reports of Associations, Shows, Meelings, Echoes, Queries, Books for Review, &c., must be addressed only to "The Editor of the "British Bee Journal," clo Messes, Strangeways and Sons, Tower Street, Cambridge Circus." All business communications relating to Advertisements, &c., must be addressed to Mr. J. Huchle, King's Langley, Herts (see 2nd page of Advertisements).

***In order to facilitate reference, Correspondents, when speaking of any letter or query previously inserted, will oblige by mentioning the number of the letter, us well as the rage on which it appears.

BEE-OLOGY.

[986.] I think 'Useful Hints' is in error when he attributes the visits of his bees on the fallen catkins of poplar-trees to searching for nectar. I have noticed the same peculiarity in their preferring the fallen to the persistent flower-buds of the balsam poplar, and have found those on the ground rich in propolis round the flower bases, for the fact is that nectar ceases to flow when the catkin breaks from the tree, the sap pressure being thus removed and the exudation of nectar thus

stopped.

I should like 'X-Tractor' to think of the wonderful and wise provision of nature which sends the scent of nectar down on the gentle gale to our bees in their huts (wooden or straw, it matters not), for the heaven-sent perfume enters the abode of the humblest peasant as as freely as it does the costly mansion of the wealthy, the picturesque skep, or the dog-kennel-like bar-frame hive (do not our gardens look like doggeries or henneries, pace Mr. U. II.?') But I am digressing. Our bees ride out against the wind empty-pouched, and are guided to their food by their never-erring sense of smell. They may dive into the shelter of a drain, tack about, port and starboard, extend themselves out full-length and rise on the airy billows, or, bending the abdomen inwards, swoop downwards and forwards against the wind, just as other barks do before the wind, but ever uncrringly on the scent-laden waves towards the nectar fields. Then when heavy laden how easily they float homeward, requiring little exertion beyond that used to just sustain them!

Omniscient critics may tell us of their bees always

flying empty with the wind, and laden against it home again; their bees always do behave differently to most others. We know that the bees from one hive gather from various quarters at the same time, but the fact remains that the infinitesimally fine sense of smell as a nectar guide, and the intensely acute telescopic vision as a colour and pollen guide, are the normal and chief stays on which our bees depend.

This morning I saw half-a-dozen bees engaged in removing a tattered piece of tape from a live, and the rapid rate they went at it along the alighting-board excited my curiosity. They looked like half-a-dozen dogs dragging a sledge, each dog having in its mouth a cord, passed longitudinally between the fore and hind legs. Sometimes we notice bees seemingly entangled in beds of ravelled string or cotton, and if we proceed to set them free with a pair of scissors we find a method in their madness,—the jaws have hold of a single thread, which passes under the thorax and abdomen, thereby not interfering with either leg or wing movement.

Do we ever wonder why the bees' gathering is circumscribed within about a two-mile radius? I came home the other night into a storm (not domesticus, but) the centre of a cyclone with hail, rain, and wind beating and blasting from 'a' the airts the wind can blaw.' As I climbed the hill I trembled for the poor bees, for everything was so fair and sunshiny three miles away, Imagine, if you can, my delight to find all right, and

not a bee abroad or stirring.

A delicate aneroid barometer falls on the approach of a bank of clouds; the sensitive petals of the daisy, the anemone, and many other flowers close on the approach of rain, in order that their pollen may be protected from the destruction wrought on its contact with moisture. Then why may not the hairs of bees, either on the body or on the antennæ, be equally hygrometric, and warn the bee of a coming storm, whilst she is comparatively near home in her gathering-ground of about twelve miles circumference? Certain is it they get a storm warning somehow, for look how they come trooping in (and none leaving) sometimes, and look, too, how soon we have to troop indoors for shelter and smoke! Bees often fly in light rain, for then the rapid vibrations of the wings beat the drops as they fall into a harmless spray; but as for the heavy thundershowers, I closely connect them with the restricted area in which the bees fly, and see another marvel of providential wisdom. — R. A. II. Grimshaw, Crag Hill, Horsforth, near Leeds.

HONEY v, SUGAR.

[987.] From a hygienic standpoint the value of honey is scarcely realised by the masses. Were it the case the use of it would have kept pace with the increased use of sugar for the past twenty-five years, which it has not. Years ago honey was to a great extent the sole sweetening medium, and the general health of civilised people was better than of the same classes to-day. The price of honey has gradually placed it among the luxuries, while sugar, from its cheapness, has been substituted in its stead. 'Had the science of bee-keeping,' says one writer, 'been in its present advanced stage when the sugar-cane industry began its rapid growth, the use of sugar would have been considerably retarded by the contemporaneous march of its more wholesome competitor, honey, which then held the field.

By modern methods employed in bee-keeping the purity and perfect cleanliness of honey are guaranteed, and had the rational culture of bees marched along with scientific sugar-making at an early date we should have heard less of cheap and nasty substitutes (as the glucose mixtures for instance, manufactured potatoes, sawdust, rags, &c., frequently) for pure sugar and whole-some honey. The latter would have been produced at so low a rate that it would have held its own as the

most delicious food, sweetmeat, and saccharine diet, either rich or poor could possess.

As some are already aware, honey is a perfect substitute for cane sugar in preserving fruits, in wine and beer making, and for cider in manufacture of vinegar, while as a medicine in many forms it is invaluable.

A leading medical and scientific journal advances the following good points in reference to its use: 'But for cane sugar there would most probably not be so many millions of artificial teeth in daily use as there are, the grape sugar of honey being at once fit for assimilation, whereas cane sugar (one has noticed how the eating of sweets increases thirst!) calls on a laggard saliva to convert it into grape sugar, and rests on nooks and corners among the teeth, fit food and breedingground for caries, schizomycetes, sphæromycetes, and what not, which turn it into acid, the said acid acting upon the lime of the teeth and dissolving them.'

Because cheap cane sugars have been taken into the stomach in unreasonable quantity, the liver has been unable to transform them, resulting in disordering both

organs

Dyspepsia and biliousness are probably caused more by the use of cane sugar than most of us think; indeed, Mr. Cheshire tells us that if cane sugar be injected into the blood, it is at once excreted, which is not the case with grape sugar. Let us then remember that it is only grape sugar which the system can at once use as heat-giving, fattening food, and this it is which honey supplies ready prepared for us by the bee in Nature's laboratory.

Honey will carry along with itself into the stomach for digestion more bread (starch, &c.) than butter, each helping the other, and a pound of honey at 8d. or 9d. per pound will consequently go as far as two pounds of butter costing 3s. Here, then, is decided economy.

It can be used for almost every purpose we now use sugar for, and by the principles of modern bee-keeping it is becoming more plentiful and cheaper year by year. A great objection to its free use in past years was its comparative high price, owing to the restricted supply caused by the annual destruction of bees. This is now removed.

Another serious objection was the fact that honey disagreed with many people. The wonder is that it agreed with any one, for a common way of obtaining it (after smothering the bees) was to cut out the comba containing young bees and pollen besides honey, and squeeze the whole in a cloth, straining the result for use.

It will thus be easily seen, without entering into details, how much objectionable matter was thus imported in the honey, which would tend to disorder delicate stomachs. All this is now changed. No brood (young bees) is now allowed by the bee-keeper to be hatched in the clean, snow-white sections we see in the shop-windows of fruiterers and grocers who sell the honey, the whole of which honey and comb may be spread on bread and caten, the cells being so thin that it takes six cell-walls to equal the thickness of ordinary note-paper.—(Dr.) W. G. l'iffire (Practical Farmer).

BEES EATING RIPE FRUIT.

[988.] I am truly surprised to read what Mr. John Moore says about wasps not eating ripe fruit. He cannot have been a very close observer of the wasp and his doings when he says that Mr. Wasp will not touch grapes indoors unless robins and tomtits first have a bite. I always have found the wasp will eat grapes and every other sort of fruit without the aid of robins or tits either. I advice Mr. Moore not to write such an article as that to any on of the gardening papers, if he do he will get a good snubbing for his pains in saying wasps will not eat grapes before 'bobby' begins his work for him.

Does Mr. Moore know the wasp was the first paper-maker, and that he can bite and chew almost anything, aye, even chew and bite Mr. Moore?—R. G.

OBSERVATORY HIVE.

[989.] Having an observatory hive, which I can examine in my house, I write to suggest that the large number of drones in a hive may be accounted for by the necessity of maintaining the heat in a hive. During the summer the workers are out collecting while the drones crawl about over the brood.

Can any correspondent explain why the queen lays her eggs in a semicircle? I would suggest this is also for warmth.—Edward Liddell, The Limes, Watford.

AGE OF WORKER BEES. (959.)

[990.] If my brown queen in No. 7 had formed, as you suggest, a mésalliance with a Ligurian bandit, surely by this time at least four-fifths of the bees in the hive would be orange-banded instead of only about one-sixth, who, I contend, must be the survivors from those horn in 1885.—C. C. James, Papworth, St. Agnes Rectory, St. Ives, Hunts, May 23rd.

[On the contrary, it is quite in accordance with the well-established fact, that if an English queen mates with an Italian drone only a few of her workers will show the yellow bands, whilst most of them will resemble the mother and show no trace of Italian blood at all.—ED.]

WILLTE EARTHEN JAR FOR HONEY.

[991.] May I suggest what I think would be a useful article for those who store a quantity of honey for family consumption in winter:—It is a pure white earthen jar, with a screw lid, in shape and size like our glass jars. They would look nice with a label even for sale purposes, but their value would be in their strength; they would be less liable to break when the honey is solid and is wanted without spending time to melt it. If such jars were obtainable, I, for one, should much like to have some.—J. E. Rosoman, Leatherhead, May 20th.

CONDEMNED BEES,—(968.)

[992.] In reply to 'Rector' and Mr. Oetzmann, condemned bees in this locality have been exceptionally good. I have, for myself and friends, taken upwards of sixty skeps last autumn; these have been wintered in lots of from one to five skeps to each bar-frame hive. I find that they have all passed through the winter in first-rate style. Those hives that were made up with the contents of only one skep have done equally well with those that contained from three up to five with a consumption of not half the quantity of stores.

Some of these were hived on foundation, others on empty combs (of course they were supplied with at least 20 lbs. of syrup), and one lot, after refusing the foundation, which was undoubtedly adulterated, built their own comb perfectly straight, though they were not taken before late in October, and are now crowded on eight frames all filled with brood, collecting honey from fruit in abundance. After this, please don't let those who have no empty or stored combs despair, as 1 find no difference between those supplied with stored or empty combs, and those with foundation.

I noticed rather a peculiar occurrence with regard to an Italian queen introduced to a black stock so late as November 10th last. While watching the hive one fine day last month, I saw her quietly leave, returning in about half-an-hour. Now, please, don't say you must have been mistaken, as twice since that time I have seen her leave; and each time I have been accompanied by a

riend, not a novice, but one that has kept bees for fifteen years and knows a queen when he sees one. Once she only stayed away five minutes. Apologising for the length of this letter-but as it is my first I have had rather a lot to tell you-hoping those who have not empty combs or stored ones will not hesitate to take condemned bees this season, and that it may thus do some small amount of good, is the hearty wish of---Nil Desperandum,

A CAUTION.

[993.] In using wired frames, will your readers kindly note that the comb-foundation, besides having the wire embedded into the mid-rib, must be firmly fixed into the saw cut of top-bar, or else fastened to the same with melted wax; if this is not done and the frame put into a strong stock, the comb-foundation will slip down the wires and form an interesting, but not a model comb? May I suggest that any one can make a wire embedder by taking a circular piece of tin, cut nicks in all round about an eighth of an inch apart and three-eighths long, break every other tooth off, and, with a pair of pliers, bend each of the others half-way round, make a hole in centre of tin, fix a handle on, and you have an embedder that will do its work as well as one costing half-a-crown. Foundation should always be warmed when using the embedder. I hope that this will be the means of saving some sheets of comb-foundation.—II. J. Sands, Harborne.

THE WAYS OF SOME · HUMBLE BEES,'

[994.] DEAR MR. EDITOR,—This is a copy of a letter which I sent to the *Leeds Mercury* on my humble bees kept during the summer of 1885:-

'I have got two chocolate-cream boxes, with a small square hole cut in the front, at which the bees go out and in as they please. I get the bees by taking their nests in the woods, and catching a few of those which could fly. gave them some sugar, moistened with water, in a little tin lid, at which they began drinking immediately, and they settled and made themselves at home in their new quarters at once. I keep the boxes out in the garden, and often watch the bees come out of their house and fly right away out of sight and over the trees, but they never forget the way home again. Although I often handle them, they never think of stinging me. Sometimes they seem quite drowsy, as if they couldn't fly. If I take one in my hand when it is in that state, and lift up my tinger on its right side, it will lift up one leg, and then if I lift up my finger on the other side, it will lift up a leg on that side. It seems as if it said, "Don't hurt me." I call them my performing bees. They express their anger by running about the box and making a buzzing noise. They do that when I lift up the lid to look in. The young bees come out of oval cases like brown paper. The bee begins to eat a small hole, and sometimes the others help it.'-Darcy Grimseaw, Crag Hill, Horsforth, near Leeds.

SECTIONS.—BEE-HOUSES.

[1995.] I hardly care to write in defence of my last letter to you, and certainly I do not wish to enter into a controversy on the subject. Allow me, however, in answer to the article in the Eee Journal, No. 965, to say that I purposely expressed myself somewhat hypothetically. There is a certain danger in writing too definitely about new inventions, which have not been fully tested, but I fully believe, as I have already stated, that these sections will be a success. I may add that three or four years ago I had considerable experience with sections corresponding somewhat in principle with Mr. Lee's. The sections I tried were clumsily made by a village carpenter, and cost more than the ordinary V sections, but I was repaid by the extra amount of honey taken. The difficulty of having them made was my only reason for discontinuing the use of them.

I am glad to see the subject of bec-houses is again brought forward by a prominent Scotch bee-master. If hives are not crowded too much, they are invaluable for wintering and supering, though one hardly dares to venture the opinion in opposition to the majority of leading apiarians.—A. G. R., Fonthill, East Grinstead,

WOODLEY'S NEW EXHIBITION CASES.

[996.] I should like, in the interest of all exhibitors, to draw their attention to this new and most useful invention to all exhibitors of comb honey.

I am a fairly large exhibitor, and on sceing Mr. A. D. Woodley's announcement of this new exhibition case in the British Bee Journal, I requested him to send me

I am very pleased to be able to say that the case bears out what Mr. Woodley said about it, and it is without doubt the most excellent of show or exhibition cases, not only for its clean and handsome appearance, but also for its cheapness, which places it within the reach of the humblest cottager, and also for the correctness of its fit for the sections, and what is much to be commended, its fair way of allowing the whole of the sections to be easily seen by the judge—the edge turned over being one quarter inch bare. With this case the tedious and time-wasting way of separate glazing with paper is done away with, and the result is a very handsome section either for exhibition or sale, and the thanks of the bee-keeping public are due to Mr. Woodley for his production.—H. W. West, Bishop Waltham.

BEE-FLORA.

[997.] In the Bee Journal for May 5th, page 198, describing my home-made bee-dress, it should have been a pair of soft leather pruning-gloves, and on the end of the gloves I have the top part of a thick pair of woollen stockings sown on fast.

I send you a small list of seeds, the flowers of which I notice my bees are very fend of, and that any poor cottager can buy cheap, and save his own seed yearly without more expense.

Wallflowers.—Pick the seed-pods when turning quite brown, dry them on paper indoors, and place when quite dry in paper bags. Sow in spring, about April. Treat

all the following seeds same way.

Mignonette.—Pick off the seed-pods when you find the seed in the pods quite or nearly brown. Place them when gathered in an old jug or tea-pot till you have picked all the pods during the season; let them rot altogether, then wash in cold water to get the pulp away from the seed; rub all of it between the hands well, the seed will then sink to the bottom of the vessel. Dry on paper.

Borage.—The seed of this will sow itself and come

up_plentifully in the spring.

Forget-me-not.—Cut off the seed branches when turning a dark brown, put in a paper bag in a warm, dry place: when quite dry rub the seed out. They are rather small, black seeds. I sow my seed about June when ripe, but the spring answers for general purposes.

Poppies.—The heads should be cut when you can hear the seed rattling about in the heads when given a gentle shake. If the seeds do not come out freely, dry on a plate, or any other thing handy. Turn the heads upside down, the seed will then fall out. The large, flowering sorts of poppies I find are what the bees are the most fond of.

Canterbury Bells.—Treat the same as for poppies. Sow the seed thinly on fine soil in a warm, sheltered situation, early in the spring. Prick the plants out as for cabbage. When large enough plant out, one foot apart

each way, in good ground for flowering the following season. I could give many more sorts, but for a poor man with the fields around him the sorts here will be sufficient.

The best hive for a poor man, who has but very little time during the summer months to look to his bees, is a flat-topped straw skep with a straw super on the top. I do not myself really think the real country cottager will be ever got to understand the modern bar-frame hives. One countryman asked me how was he to put 'the blooming bees into they things?' Another one, who had his bees put into a bar-frame hive for him, put a lot of sacks all over the outside of the hives to keep them warm during winter.

It being a very fine day down here last Sunday week, I took a walk to a friend's garden. He told me he had had a swarm of bree, and I asked how he put the bees into his bar-frame hive. He said he got a man to help him to put them in. They carried the whole of the bar-frame hive with them up into a large tree, and shook them into the

hive.—R. G., Caerleon.

COMB FOUNDATION.

[998.] I have used a large quantity of the wired foundation so highly spoken of by the writer of 'Useful llints' and, I must confess, with good results, but there is a point in connexion with it which ought to be brought before the notice of the manufacturers, who evidently have never seen natural comb, as built by the bees, otherwise they would not go on wiring the foundation the wrong way up; it must be just as easy to wire it the right way as the wrong way, but perhaps they don't care which way so long as it sells. Bees always build their combs, with perpendicular walls, the strongest possible way, and the Americans, who want teaching better, always wire their foundation, so far as I have been able to find out, the other or weaker way.

Is there no one in this country who makes this wired foundation? if not it is high time there was. Are all our manufacturers asleep? Surely the tons of this foundation imported into this country ought to be sufficient to awaken them. But there is one thing I will give the Americans credit for, and that is, the excellency of their foundation; it seems to have a tenacity about it we don't get here. Much of our English foundation is far too heavy and soft, no wonder it breaks down. Why some of it is so soft it won't bear its own weight in hot weather, how can it be expected to bear the weight of the bees, &c. in the hive?—F. Boyes.

ROYAL JELLY.—It is a nutritious material which contains nitrogenous and hydro-carbonaceous material. It is doubtless a model food, and is supposed to be the same material that is fed to the queen when she is hardest at work laying. It is already digested by the worker bees, and so is all ready for absorption.—Prof. A. J. Cook, Lancing, Mich. (Canadian Bec Journal).

Query.

[999.] Heather Honey.—Will any reader kindly say in the next issue of the Journal what is the average weight of honey a good hive of bees might be expected to collect in one season from the heather, with favourable weather and abundance of heather?—J. J. W. C.

Echoes from the Hives.

Grantham, May 21-t. -The season is very backward here, fruit-blossom only now at its best. Spring flowers are plentiful, but the weather, oh dear! bees can do nothing, feeding in most cases necessary to keep stocks well going. I hear of only one swarm this season in the neighbourhood,

and that was found on a hedge, and it took off before it could be hived. Passing the notorious hostel, 'The Living Sign,' the other day, I notice it still holds its own as one of the wonders to explorers to Grantham, and certainly the bees were right merry there, and I am assured they rarely go inside the hotel to indulge.—R. R. G.

Swineshead, May 28th.—The cold, ungenial spring, with continued frosts, N.E. and N.W. winds, and temperature 1.41 deg. below the average for April, and the bitter and sudden storms lately, causing many a pollen-laden bee to drop in attempting to clear hedges, has seriously checked the breeling and caused a great fatality among old queens, prompting and encouraging robbing, very difficult to stop in large apiaries, so that it is only the fittest that survive; hence the utility of keeping young queens and strong colonies of bees. No surplus has yet been obtained even by Fen House Apiary with seventy acres of closely-planted orehards, one and a half acre of crocus, and many bulb flowers. Yet a skep amongst others bought of a cottager lately was very strong, and it had a large hole in the bottom of the floor-board, which was rotten and near breaking. During the last five years I have driven for cottagers and others over 220 skeps in the district ranging from Cliff's Heath, Sleaford, and Fen to sea-coast, and only met with one case of foul brood (four years since), caused by wet through a mouse-hole, which I bought to experiment with, and subsequently burnt it and boiled the honey it contained to feed to a separate stock in an old hive, both of which I was prepared to sacrifice, but it did them no harm. In this district they do not, as a rule, 'fad' with their bees. - ROBERT THORPE.

North Leicestershire, May 30th.—Three really good days during the past three weeks, and that is all. The remaining days were either windy, wet, and snowy. The wind on and about the 20th instant destroyed the bees by the hundred, and stripped the currents and cherries of their bloom. The weather is still very cold, and matters get worse duily. With the bees themselves distruction of grubs and death from starvation seems the order of the day, and nothing but copious feeding keeps stocks from dwindling even at this time of the year. There is abundance of nectar if the bees could but get out. Apple-trees here are just beginning to bloom, and the maples and sycamores already show their clusters.—E. B.

Aboyne, Aberdeenshire, May 24th.—It is flattering to think that, notwithstanding the inclemency of our northern climate, we can, at least this season, boast of about as early swarms as you can in the south. We are well sheltered in the bosom of surrounding hills, with abundance of flowers and honey-producing shrubs, and far from the noisome smell of factories or other public works. About ten days ago, under the influence of a very hot sun, a bar-frame in my apiary threw a large swarm at an early hour, while on the same day, about noon, a straw skep of home con-struction followed sait. Both are doing well, as the loads of pollen by day and the strong hum by night seem amply to testify. I have heard much of the vaunted pretensions of Ligurians over the native bee, how they work late and early, how fast they breed, and how much honey they gather in the course of a season. I have had them now in my apiary for a considerable time, but I regret to say that I find them in no one point better, and in some points worse, than the hardy black (or brown) bee. I hope to be able to give a few more details of my experience with them in the course of the season.-W. S.

Lismore, May 27th.—The weather here for the past month has been, on the whole, very favourable for bees. I have not been very lucky with queens this spring. I lost one stock in the very early spring from queenlessness; another followed suit soon after. The latter swarmed last season, and had in autumn a fine young queen. Two stocks' swarms of last season next gave in, but so recently that I was able to unite them to other stocks. And now the queen of what was my best hive last year has given up, and is doing nothing; she was only a year and three-quarters old, and began to lay earliest of all this spring, so that when I left home on March 19th the hive was unusually strong; but on my return on May 5th I found scarcely any brood, and only bees to cover two bars. So my sixteen bar-hives are reduced to eleven 'effectives,' of

which three are supered—two very hard at work up above, the third just beginning operations. The remaining hives will be ready for supers in about a week or a fortnight. 1 fancy there 'is no accounting' for queens. Some of my most rapidly increasing stocks did not swarm last season, so I presume have old queens; and I have lost two stocks with young queens. Of five skeps, four are flourishing; one small stock has died out, queenlessness also. Robbing is the plague of my apiarian life. It was very bad with me last year, and I thought it was the fault of my 'condemued bees,' but this season I had no condemned bees, so I don't know what to blame. I notice that the robbers are very small bees, black and old-looking. I do not think any of my own hives have such small bees. The loss of a few stocks is perhaps a merciful dispensation. For I began last year with five stocks and three condemned lots; and at the end of the season I found the increase amounted to sixteen bar-frame hives, and five skeps. If I can manage my present lot of fifteen communities, it will be about as much as I can do. Can anyone explain how it was that the honey in the hive (which I found on January 31st tenantless, the bees having died out from queenlessness) was not granulated? The cold was extreme at night, and the door was fully open, with perforated zinc over a portion of the opening. The bars were almost all full of heather honey, with beautiful white scaling. The weather was so cold few bees were out, and there was scarcely a trace of robbing. The hive must have been empty some time, and I can't understand why the honey was not congealed .-F. W. C.

Mahon, Minorca, May 21st .- We are in full honey-flow since April 20th. So far the honey is exceeding white and beautiful. Have taken out capped honey for the extractor, and some 600 or 700 sections are rapidly being capped.-F. C. Andreu.

NOTICES TO CORRESPONDENTS & INQUIRERS.

Letters or queries asking for addresses of manufacturers or correspon Letters or queries asking for addresses of manufacturers or correspondents, or where appliances can be purchased, or replies giving such information, can only be inserted as advertisements. The space devoted to letters, queries, and replies, is meant for the general good beck-keepers, and not for advertisements. We wish our Correspondents to bear in mind that, as it is necessary for us to go to press in advance of the date of issue, queries cannot always be replied to in the issue immediately following the receipt of their communication.

All queries forwarded will be attended to, and those only of personal interest will be asserted in this column.

interest will be answered in this column.

- R. H. B.—Law on Bees.—If bees swarmed on a neighbour's garden, and were removed by the owner, the latter could not be proceeded against except for trespass. The owner might, however, be prevented from entering to take away his bees. A swarm of bees flying from a person's hive would be considered his while he kept them in sight; if the owner lost sight of them then he could not claim them.
- J.—Bces.—We are unable to discover in the bees forwarded any trace of the strain of Carniolan bees.
- M. Whittle.—I. Honey.—The sample of honey was pure and of a good flavour. The grain of the honey appeared as if it had been pounded to give the honey a better colour. 2. Wax.—The wax has been forwarded to Mr. Hehner to be analysed.
- J. J. W. C .- Dried Pollen .- The white hard substance is last year's pollen.
- 11. R.—Queen Impregnation.—If impregnation is delayed beyond the twenty-first day the queen will only lay drone eggs, although Berlepsch and Dzierzon both give examples of exceptions; in one case a queen being properly impregnated at thirty days and in another case forty-seven days. If your queens hatched on 5th April and 5th May do not lay yet, you should discard them and replace them with fertile ones, because if a queen has been properly impregnated she usually begins to lay workereggs about forty-eight hours after. We think the Kohler system very good if properly carried out.

Inquiren.—1. Fastening Foundation-strips in Bell-glass. Warm the bell-glass sufficiently to make the wax melt, and if the foundation is cut to the shape there will be no difficulty in making it adhere. 2. Preventing Untinned Treacle Valve affecting Honey .- If you dissolve propolis in spirits of wine you can varnish your treacle valve

- with it, or warm the valve and rub in some beeswax. 3. Frames.—Although the frames are better for storifying when they are completely filled, yours worked down to within half an inch of the bottom will do very well. If you wish the combs to fill the frames completely, tie two pieces of tape round the frames as in transferring, and then cut round the combs; they will drop down on to the bottom bar and will be completed by the bees and fastened to the top.
- WILLIAM PASCOE.—I. Treatment of Bees.—We are obliged to refer you for information on the treatment of bees to such works as Modern Bee-keeping and Cowan's Guide Book. 2. Time of Supering.—When the bees have swarmed, is not the right time place supers on the hive. The proper time for putting on supers is when the hive is full of bees and brood, when the weather is fine, and the honey yield abundant. It is no use specifying any date; putting on supers, which is virtually enlarging the hive, would be an injury rather than a help if placed on in cold and miserable weather, as it would tend to cool the hive when the heat should be economised. 3. Old Combs.—If the death of the bees has not been caused by any infectious disease the comb may be used again.
- R. Douglas.—Diseased Bees.—Your bees are suffering from a disease known in Germany by the name of 'Maikrankheit,' as it usually appears in May. The distention is caused by the abdomen being filled with excreta which the bees have not been able to void. It is supposed to proceed from the pollen collected baving been touched by frost, which is very prevalent in the early spring mornings. Salicylic acid in the syrup is recommended as a remedy and keeping the hive dry, and preventing any moisture accumulating inside.
- 11. P. Jones, -Diseased Bees.-See reply to R. Douglas above.
- P. P. II.—The promiseuous use of an extractor in a district where foul brood is suspected is a very possible medium for the conveyance of foul broad. Too much caution caunot be observed in thoroughly cleansing it in its passage from one apiary to another.
- J. Cole. Chitled Brood. The piece of comb forwarded was filled with chilled, not foul, brood. Chilled brood is caused by disturbing the hive at inopportune times, or by unsealing the honey-cells, or by giving the stock too much syrup, whereby the queen is stimulated to egglaying, and more brood is produced than the bees can cover and give the requisite warmth to. In foul brood the caps of the scaled brood are indented and pierced; the cells contain a sticky, coffee-coloured substance, emitting a most disagreeable smell, perceivable at some distance from the hive.
- H. B. AND BETA.—The pieces of comb forwarded are cases of chilled brood. See reply to J. Cole above.
- J. WOOD AND S. G. FIELD.—We do not sell swarms or anything in the shape of appliances. Please refer to our advertisement columns. You can get such swarms from most of the dealers in appliances.
- W. Coxon.—It depends upon the wording of the schedule. If the class is for 1-lb, sections these certainly would be disqualified. If the wording was 'not exceeding a certain weight' then they would be eligible.
- T. S. B.—1. Making the Best of Twelve Stocks in Skeps for Production of Honey.—If you transfer at once, at the same uniting two lots in one hive, you will have six stocks which will do you service and (weather permitting) store honey for you. Six strong stocks are far better than twelve weak ones. 2. Making up Stocks for Winter.-1 lb. of bees on foundation will do no good. A swarm should weigh at least 3 lbs. 3. Wax Foundation.—To obtain wax in good condition for use, we should suggest that in place of your making it yourself you purchase it it from the recognised manufacturers.
- Mater.—1. Keeping Ligarians Pure.—As you say there are black bees, you can only attempt pure fertilisation by the plan described by Mr. Raynor. The nucleus should be made up with a comb or two of hatching brood with the drones and queen, and must be kept in a dark place until brought ont for flight at a time when naturally flying drones would be at home. 2. To Ligarianise the Black

Stock, you had better remove the black queen and give the Ligurian to them, and let the Ligurians raise cells. Eight or nine days after removing the queen, make up your nuclei, giving each one or two queen-cells. 3. The Signs of Fertilsation are visible when the queen returns to the hive if you watch for her. 4. Drone Comb.—You may cut the drone comb right out, and if you like piece some worker comb into its place, secured by a few thorns or splinters; or if you wish simply to destroy the drones, cut off the projecting caps of the cells.

Show Announcements.

Giving Name and Address of Secretary, Date and Place of Show, Date of Closing Entries. Terms: Three Insertions and under, Two Shillings and Sixpence; additional insertions, Sixpence each. No charge made to Associations whose Shows are announced in our general Advertising Columns.

June 15, 16.—Wilts Agricultural Show. Rev. W. E. Burkitt, Secretary.

June 21–25.—Royal Counties' Agricultural Show at Reading.

June 23, 21.—Suffolk Agricultural Show at Bury St. Edmunds. Entries close June 6. J. Huckle, Secretary. July 11-15.—Royal Agricultural Show at Newcastle-on-

Tyne. Post entries to June 1st. J. Huckle, Kings Langley. July 21.—Prescot Horticultural Show.

Secretary, Station Road, Prescot, Lancashire. July 20-22.—Lincolnshire Agricultural Society at Spalding. Entries close July 4. R. R. Godfrey, Secretary.

July 26-28.—Gloucestershire Agricultural Show at Cheltenham. Entries close July 12. W. D. Slade, Sec.

July 26, 27.— Warwick Agricultural Society at Sutton Coldfield. J. N. Bower, Secretary.

July 27.—Bishops Waltham Show. (Hants and Isle of Wight Association.) H. W. West, Hon. Sec., Swanmore House. Bishops Waltham.

August 3-5.—Yorkshire Agricultural Society at York. Secretary, H. L. Rickards, Poole, near Leeds.

August 9, 10.—Irish Bee-keepers' Association at Salthill Gardens, near Dublin. Entries close August 2. Hon. Sec., Henry Chenevix, Blackrock, Dublin.

August 14.—Handbridge, Chester Horticultural Show. W. Little, Secretary, Eastgate Row, Chester.

August 24.—Lancaster Agricultural Show. W. Liddell, Secretary, Dale Street, Lancaster.

August 31-Sept. 3.—Royal Manchester and Liverpool Agricultural Show at Manchester. W. Lees McClure, Secretary, The Lathoms, Prescot, Lancashire.

MANIPULATE WITHOUT SMOKE!

WEBSTER'S FUMIGATOR

Entircly supersedes the Smoker, both in Simplicity and Effectiveness. No 'going out.' No tainting or soiling of combs. Always ready for use without any preparation. Can be carried in pocket.

With Bellows, 4s. 6d.; postage, 4dd. Without Bellows, 3s.; postage, 3d.

Can be adjusted to any ordinary smoker bellows.

6 oz. Bottles of Agent—carbolic acid, oil of tar, and water, proportionably mixed—6d. each.

NOW READY.

WEBSTER'S SWIVEL FRAME - LIFTER

With this appliance, frames can be removed from hive. Examined on both sides and replaced without inverting, and with one hand only, leaving the other free to perform any manipulation, at the same time preventing the soiling of hands with propolis. 1s. 6d. each. Postage 3d.

Send for ILLUSTRATED CATALOGUE of all descriptions of Appliances. Post free on receipt of post-card.

AWARDS LAST SEASON.

1st Prize, Silver Medal, Royal Counties' Agricultural Show. Highest Award, Bronze Medal, Colonial and Indian Exhibition, for Bee Subjugators.

2nd Prize Bronze Medal, Colonial and Indian Exhibition, for useful Inventions introduced since 1883.

2nd Prize, Altrincham, for useful Inventions.

IRISH BEE-KEEPING: PAST AND PRESENT.

Seven years ago, chiefly at the instigation, and largely at the expense, of the President and Hon. Secretary of the British Bee-keepers' Association, the Baroness Burdett-Coutts and the late Rev. H. R. Peel, that Society were induced to send a mission to Ireland with the purpose of stimulating bee-keepers to form themselves into associations, and of awakening the nation to the possibility of a new industry in their midst. Much judgment was displayed in the selection of two most able, experienced, and enthusiastic bee-masters to conduct this mission; these were Mr. C. N. Abbott, of Southall, and Mr. W. Carr, of Newton Heath, Manchester. The ground these gentlemen had to break up was fallow; their experiment had not been previously attempted, and many were the obstacles they had to overcome. Their mission occupied them about a month, and they were most favourably impressed with the capabilities of the country for the production of honey in large quantities. Perhaps we may not be wrong in our conjecture in attributing to the opinion formed by one of the gentlemen above mentioned during his sojourn, of his recently counselling one of his sons to locate himself in Ireland with a view of establishing a branch of his business for the supply of the growing demand for bee-appliances there.

Messrs. Abbott and Carr having fulfilled their mission, presented to the Association a very able, painstaking, and exhaustive report, which was given in extenso in the number of the Bee Journal for July 1881. It may be interesting at the present time to allude to this report, and thus to contrast the past and the present state of bee-keeping in Ireland.

The peregrinations of Messrs. Abbott and Carr extended over many hundreds of miles of country—through Munster, Leinster, and Ulster; they made their journeys on rail, car, and foot; and wherever they went they were filled with admiration of the wondrous floral beauty of the land, and the indisputable evidences it presented of its general suitability for bee-pasturage.

Notwithstanding these great advantages, they found a large portion of the country without bees,

and the people, with a very few exceptions, in sad ignorance of their value. Excepting at Clonmel and Newtownards there were no evidences of attempts made to cultivate bees. Even where bees were kept, no attempts were made to attend to them scientifically, and the sulphur match at the end of the season was lighted for their destruction. The report states:—

'Bee-keeping in Ireland consists in providing swarms with ill-made skeps of sugar-loaf shape, made of soft straw that sinks with the accruing weight, sticks being thrust across (at any angle) from below the ceutre to near the crown. They are exceedingly rough both inside and out, and when stocked are set upon a stone or stool, and very little, if any, protection is given to them; and, as a consequence, they quickly become rotten, and the bees and their enemies find an easy way through them. In a few instances ekes were added to the hives to give them more room; but even with this addition we did not find a hive, other than those containing late swarms or queenless stocks, that could contain its population; and though the country was overflowing with honey, and the hives were full (?) of it, the becs were idly clustering about their homes, having nowhere to store a surplus if they gathered it. Not anywhere, save in Clonmel and Newtownards, did we see a hive surmounted with a super, or any means in operation by which bees could be deprived of their honey without their destruction; and, as a rule, the principle of driving bees, either as a means of artificial swarming or depriving, was unknown.

The report concludes with these words:—

'Finally, we take leave to record our conviction that, with a fair knowledge of the science that governs the art, bee-farming would more than doubly increase the profits of agriculture, and smooth the way to comfortable independence to many who are now barely able to gain a livelihood in that beautiful but neglected island.'

The mission of these gentlemen has not been without result. Bee-keeping at the present day presents a very different aspect. Earnest men, having at heart the welfare of their fellow-countrymen, have not been neglectful of the advantages to be derived from the formation of Associations and the profits to be reaped from the practice of intelligent bee-keeping. From year to year we have noted the growth of Associations and the numerous well-conducted shows that have been held in various places in Ireland. Especially would we mention the efforts that have been made by the Irish Beekeepers' Association, in Dublin, and the North-east of Ireland B. K. A., in Belfast, to sustain the interest that has been awakened in their respective districts. We have before us the Prize-sheet of the August show

to be held by the former Association at Salt Hill, near Dublin, together with a supplement relating to the arrangements for disposing of any of the honey unsold at the show, and also a circular calling upon the bee-keepers in Ireland to make an effort to popularise the bee-show, so that it may not only attract those for whose benefit it is more especially intended, but also others who 'are seeking an innocent means of recreation.' The Association evidently is earnest in its desire of making this show a success, and we hope that it may lead to most valuable results.

In sending forth their Annual Report, the Irish B. K. A. published also several well-written papers on the more prominent subjects of bee-keeping. These were contributed by some of our most advanced bee-keepers, both in Britain and in Ireland. There were several pages also devoted to the statistics of bee-keeping in Ireland, which had been compiled by order of the Government in Ireland. In this matter we must allow that our sister island has taken a step in advance of this country.

We have also before us the Annual Report of the North-east of Ireland B. K. A.; this Association, too, has followed the good example set it by the Irish B. K. A., and the Report contains several instructive and well-timed articles written by the Rev. H. W. Lett, W. E. Betts, W. J. Stanford, Arthur B. Johnston, and others. This Society announces that shows in connexion with their Association will be held in Belfast, Strabane, Banbridge, Dungannon, Lisburn, and Newtownards.

Great credit is due to the Hon. Secretaries of these Associations for their exertions in disseminating a knowledge of bee-keeping, and we hope they may see that their well-meant efforts will be abundantly successful not only in their own districts but throughout Ireland.

ROYAL COUNTIES AGRICULTURAL SHOW, READING.

We would remind our readers that entries for the great show of bees, hives, and honey, to be held at Reading, in connexion with the Royal Counties Agricultural Show on June 20–24th, will close on Saturday next. Under the united efforts of joint Committees of the Berks and Hants Association a liberal prize list has been prepared, and every inducement offered for a large and attractive show. Candidates for third-class certificates should not delay in sending their application by the above date.

A WORD OF CAUTION.

A singular document, purporting to be a prospectus of a Bee-keepers' Union, has been forwarded to us. It contains no names either of the promoters or the secretary; the name of the printer is also omitted. The document is rough in arrangement, slatternly in style, ungrammatical in construction. Glowing hopes are dangled before the bee-keeper's vision; but how they are to be realised we are 'lost in conjecture.' Like some cheap medicines which

profess to be panaceas for all 'the ills that flesh is heir to,' this prospectus proposes to accomplish everything the bee-keeper can possibly require at little or no cost. We note the articles which provide for the defraying the expenses of the Council. We advise our readers to receive the statements of this prospectus with a large 'grain of salt,' and to exercise considerable caution before they part with their cash.

FOUL BROOD.

As foul brood is prevalent in various parts of the kingdom, we extract, for general benefit, from a leaflet issued by the Lancashire and Cheshire Bee-keepers' Association the directions sent forth to its members:—

'Foul Brood .- This is known to exist in our counties, therefore the committee, with the view of assisting beekeepers in freeing themselves of this terrible pest, have had a remedy put up in bottles which the hon secretary will forward to any bee-keeper on receipt of 9d. in stamps. The bottles contain an oz. of concentrated phenol; the following directions are on the label attached to the bottles:—"Directions for use.—First, add the contents of this bottle to one pint of water to make the diluted solution, then mix, with each pint of food, this small bottle, once filled, with the diluted solution." The ounce bottle of concentrated phenol, price 6d., at 2 South John Street, Liverpool, or 9d., sent per post to any address, is thus sufficient to give to bees with twenty pints of food. With this inexpensive remedy, so easily procurable, it is to be hoped all interested (and this includes every bee-keeper having even a single stock) will try to stamp out the malady. All infected combs should be burnt; and to transfer stocks to hives that have been painted inside and out can certainly do no harm, the paint to be dry before the stocks are transferred. Intending purchasers should be careful to inquire whether the disease exists in the district from which they may be negotiating for stocks.'

USEFUL HINTS.

WEATURE AND PROSPECTS.—The first week in June past, fruit bloom over, the hedges becoming white with hawthorn bloom, easterly winds, which have continued for eight weeks without intermission, still prevailingcold and copious showers, almost frosty nights, hives full of bees and brood, extensive feeding every night, hives and section-racks all in readiness for swarms, white clover expected to bloom in a week or ten days:—such is our report on this 6th day of June, 1887, and yet our hopes of a honey yield, and a good one too, are not dashed yet. Our weather-wise country friends proclaim, 'No settled weather now before the 21st,' which can hardly mean a good honey year. Still we hope. Bees are in splendid condition where they have been well looked after, and all ready to give a good account of the honey when it comes. Moreover we have great promise of a bountiful harvest in other produce. The corn-crops are looking remarkably well. Never was there a better prospect for heavy hay-crops,—in fact, the whole country is looking magnificent, robed in emerald green, and begirt with many coloured wreaths of the sweetest-scented flowers. Sun! Sun!! is all we want to start our hymenopterous treasury on their summer raids upon the nectar-yielding blooms. The old saw, 'A salivaring June keeps all things in tune,' must apply to bees and honey as well as to other things, therefore we shall continue to anticipate the beautiful sight of well-filled, evenly-wrought, straight-sided, sweet-scented sections of choicest clover honey, since a month or six weeks of fine

weather will afford to those who are well prepared a bounteous harvest.

FOUNDATION AND FRAMES.—The wired foundation cut into sheets sufficiently large to fill Lee's patent standard-frames, passing well through the bottom bars, of which we spoke several weeks ago as having been ordered by Messrs, Neighbour from the American maker, has arrived, and several frames of it have been inserted in the midst of populous colonies in our apiary. These are being worked out to perfection, and in a short space of time will be entirely filled with brood. They are the most perfect combs we have yet seen, beautifully straight and without a flaw, attached to the sides of the frames all round and free from pasaage-ways through the combs. The same may be said of unwired foundation, inserted similarly in these frames, with half-inch top bars some time since, except that the combs are not quite so even on the surface as those on the wired foundation. From the first we had no doubt in our own mind of the ultimate success of this system of inserting foundation. The rapidity and ease with which the frames are put together and filled with foundation, together with the perfect combs resulting therefrom, require merely a trial in order to convince the most sceptical of the advantages of this plan over all others. In our experiments thus far there has been neither sagging nor breaking down of the foundation. Owing to the backwardness of the season, the cold weather, and the roominess of our hives, we have not been able at present to obtain the natural swarms which we intend to place upon these frames, and thus thoroughly to test the system, but with a change of weather we shall soon expect our usual six and seven pound swarms, which in hot weather will soon prove the substantiality or the contrary of this method. With half-inch top bars and W.B.C. metal ends we have no fear of the result, but we advise a nail to be driven through the centre of the top bar to prevent the founda-tion drawing out. We entirely sympathise with Mr. Boyes in his wish expressed in our last issne (998), p. 238, that this wired foundation could be turned out by our English makers of quality equal to the American, and we are not without hope that the wish may be gratified. We never could understand why the makers insert the wires the wrong way in the foundation, but such is undoubtedly the fact. Our experience, however, does not tally with that of Mr. Boyes when he states that 'bees always build their combs with perpendicular walls,' if by that he means with the cells in straight horizontal rows parallel to the top and bottom bars of the frames. We have pleuty of combs built without foundation, or even starters, with the rows of cells ranging in various directions. No doubt the natural way of building comb, as a rule, is with horizontal rows of cells, but the American wired foundation compels a vertical arrangement of these straight rows instead of a horizontal one, inasmuch as the wires must hang vertically. But notwithstanding all this we find in actual practice that the bees draw out the combs with vertical rows of cells just as willingly and as quickly as with the horizontal, and we have not noticed any tendency to weakness in the combs thus built. During all the years we have used the American wired foundation in large quantity we have never experienced the breakage of a single comb built upon it. It is a patented article, made by Van Deusen & Sons, of New York County, United States of America; and we are in full accord with Mr. Boyes when he says that in view of the many tons of the foundation imported into this country our manufacturers must be asleep if they make no effort to produce an

equally saleable and good article.

Surplus Boxes.— When is the right time to put supers on a swarm?' is a question often asked. We reply that if zinc excluder is used between the brood and surplus compartments, it is best to super immediately the swarm is hived, confining the bees to as many

frames only as they can cover, and placing them upon full sheets of foundation, giving more space as required. By this plan, if the honey-flow is abundant, work is immediately commenced in the supers. But if excluderzinc is objected to, work must be well advanced below, and the queen laying freely, before the surplus cases are given, otherwise she will at once ascend into the supers and there deposit eggs. If after this long, cold, and moist season, we get a few weeks of bright, settled weather, swarms will be plentiful, and it behoves every bee-keeper to turn them to the best account. By no plan can this be done so well as by placing the swarm upon the parent stand, and pursuing the systems recommended in former 'Hints.'

Entrances and Shade.—As the heat increases, the entrances to the hives should be enlarged to the full width of the hive, and half an inch deep; in addition, it is well to raise the hive from the floor-board one-eighth of an inch behind, giving air all round. A greal deal of unnecessary swarming takes place from want of bottom ventilation, which is especially required when colonies are working rapidly in section-cases. During het weather shade for swarms is absolutely necessary, to prevent newly-built combs from collapsing. Here, again, bottom ventilation is most desirable and enables the bees to work with ease and comfort, and to dispense with the incessant fanning at the entrances, so often witnessed in

badly-ventilated hives.

SETTING UP SWARMS. - When placing swarms on their permanent stands the hives must stand perfectly horizontal, or level, as it is usually expressed. This can only be accomplished by the use of a spirit-level, which should be a sine qua non in every apiary. If a hive is pitched a little too much to right or left, or to front or back, it is impossible for the bees to build straight combs. The force of gravity prevents. Hence arise nine-tenths of the complaints which reach our ears on this score. The only deviation from the horizontal allowable is a pitch of half an inch from back to front, which enables the bees to carry out refuse matter with greater ease than when the hive stands perfectly level.

Thus far had we written when our factorum appeared at the study window, hatless and coatless, to proclaim the arrival of our first swarm! A pure Italian colony, domiciled in an Eelectic hive—the only one amongst fifty—has distinguished itself by leading off with at least a 6-lb. swarm. The swarm has quickly settled in the centre of a thickly-foliaged fir, and clustered closely around its stem, happily at no greater distance than some six feet from the ground. Our pen is cast aside, a sheet is spread beneath the tree, and upon it is placed a roomy skep, resting against the stem, which holds it up in front. With carbolised goose-quill we now proceed to brush off the bees, which, falling upon and around the skep, immediately commence to hurry in, and in five minutes all have entered.

Dear readers, we pray you to excuse further prosy 'Hints,' on the plea of placing our first swarm on Lee's frames filled with Van Deusen wired foundation, of which we promise a full and particular account in future prosings.

HOW TO MAKE THE BEST OF THE HEATHER HONEY CROP.

I am asked by our friend who fills the chair in Tower Street to answer the query the number of which is represented by three nines [999] in last week's Journal, put by a correspondent with long initials.

As I sat down to comply it occurred to me that the whole question of making the most of the heather honey crop might be of interest, not only to our friend 'J. J. W. C.,' but to many more of our readers.

I have yet to see the sample of heather honey that can be extracted from the combs, except probably Cornish heather, consequently it is advisable to get heather honey stored in sections; and what so toothsome or elegant as a well-filled heather honey section! On the contrary, no kind is better adapted for extracting than clover honey; and certainly there is nothing in the shape of run honey to compare with a real good sample of clover honey, with sufficient nectar from a general flora to give it a bright, gold colour, tastily put up in good white glass bottles. It is irresistible! With two such articles you are certain to get a good connexion, ready sales, and, at any rate, a fair profit. But the question before us is, How to raise them?

When you get your sections make sure that they are elean and well finished, and also strong, as they will get an extra amount of handling as you will see presently. Fill them with foundation on Mr. Corneil's plan, as illustrated in this Journal (p. 531), use a reversing erate, and if the weather is fine when you read this, they ought to be on, providing—that is always the chief factor in supering—providing your bees are ready; if they are not ready, putting on supers is worse than useless. Reverse the crate as soon as the large piece of comb is built down to meet the narrow strip, and make an effort to get as many sections built out with comb as you possibly can. I wish you to mark this point:—your chief aim must be numbers of sections built with few or no 'pop-holes.' It does not matter so much if the cells are not built out to their full depth providing the sections are well built out at the midrib and well fastened all round to bear the strain of extracting. Use vigilance and keep your bees comb-building and give as many crates of sections as you can get them in the humour to build while the flow of clover honey is on; and when that ceases take them all off, whether sealed or unsealed, and extract the whole lot. If there is a cold spell on after you have extracted, and you can give the empty sections to the bees to clear out, without getting more stings than you can endure, you may do so; it will improve the sections, but it entails labour, and probably pain.

The honey extracted from the sections is your article for bottling, and I venture to assert that nothing taken from the brood-nest combs can compare with it for appearance. Having secured your sections well filled with clean empty combs, you are ready for the heather honey Do not extract from the broad-nest if it is possible to get your stocks to the heather with heavy combs without a breakdown. With this in view it is wisest to provide tough old combs for the brood-nest, although they are objectionable on other grounds. If you extract from the brood-nest, of course the bees will first fill it with heather honey before taking to the sections. But if you have extracted or not, put on the sections at once; and being provided with combs built with clover honey, the bees are thus in a position to commence storing the heather honey as fast as they can gather it.

By this arrangement, 'with favourable weather and abundance of heather,' and plenty of bees and proper attention—do not forget the two last items, friend 'J. J. W. C.'—you may get 200 sections of heather honey from one hive; and what is more, if yon know where, get two shillings per section for them wholesale, if they are a thorough good sample.

... Do name the market, that is a dear good fellow... No! I have already given you the wrinkle how to get the sections. I am no honey factor, but only an—AMATEUR EXPENT.

Foreign.

DENMARK.

DANISH BEE-KEEPING, PAST AND PRESENT.

The changes that have taken place in Danish beekeeping during the last twenty-five years are very considerable, and this is easily explained when we

remember that it was about thirty years ago that Pastor Dzierzon, of Schlesien, invented the moveable comb hive.

The official returns of the number of hives in Denmark in 1861 have been carefully analysed by Baron Bretton, who was at that time one of our most skilful bee-keepers. According to these returns, our country had 80,000 colonies and in the previous year 40,000 had been destroyed. The returns were made on the 15th July, that is, after most of the swarms had issued so that the 80,000 may be taken as giving the greatest number of hives found in that year in Denmark. If we take the number in proportion to square miles and to 1000 inhabitants we find, according to Bretton's list for 1861, the following:—

		per square mile.*	9	per 1000 inhabitants.
Danish Islands		143		. 48
Jutland		70		. 50
Denmark		113	••••	. 49
Schleswig		425		. 171
$\mathbf{Holstein}$		489		. 140
Lauenburg		400		. 152
France		400		. 110
Hanover	*****	900		. 327

The returns in 1881 showed in Denmark 186 per

square mile and 65 per 1000 of population.

With this table in view the question arises: Is Denmark sufficiently stocked with bees, or will it support a far greater number of colonies than it at present possesses? The last part of this question we can decidedly answer with a Yes! Take, for instance, Hanover, which with almost the same condition as our country, has eight times as many hives per square mile and seven times as many in proportion to inhabitants, as we had in 1861. Holstein had three and a half times, and Schleswig three times as many as we, and yet there is no doubt that these two duchies might have supported a yet larger number. Our colonies in the next twenty years interested about sixty per cent in proportion to area, and thirty per cent to inhabitants, but have not nearly reached the number the country could support. I think at least four times as many hives could be kept.

It has been suggested that the more fertile tracts of a country were not so suitable for bee-keeping as those less fertile, and consequently less cultivated. This may be true, but if we compare Jutland with our own fertile islands we find it is just these islands that have the most colonies. We can explain this by assuming that no part of Denmark has a sufficient number of colonies, so that they would stand in more even proportion to the population than to the area. If we compare the neighbouring countries, although their conditions for beekeeping are similar, the numbers of hives kept vary greatly. On an average we find provinces with a poor population, for instance the west of Jutland, and provinces in which the land is subdivided amongst many cottagers, as in Scotland, have the largest numbers of colonies, whilst those provinces where the estates and farms are large, despise the small income to be derived from bee-keeping.

Many skilful bee-keepers are working zealously in some of the provinces to spread a knowledge of bee-keeping, and this I think is the best way I know of to advance the pursuit. It would be good if the Government would properly acknowledge the importance of bee-keeping as a pursuit for cottagers and assist more in the future than it has hitherto done.

The introduction of modern methods of bee-keeping into Denmark has resulted in advancing the pursuit considerably, partly by increasing the number of colonies and partly by enabling the bee-keeper to realise a larger income from every single colony. Rational management, enabling the bee-keeper to take the surplus honey without destroying the bees, has gradually spread

^{*} One Danish mile is equal to twenty English miles.

during the last twenty-five years, and consequently the number of colonies has increased. It is a pity that skeps and moveable comb hives are not separated in the official returns. Hewever, I believe I am not far wrong when I say that of the 130,000 colonies found here in 1881, there were at least 20,000 in meveable comb hives.

If we bear in mind that the hency extractor has improved the product, a colony in a moveable comb hive we may reckon will make a return of fourteen shillings a-year whilst the destreyed skep would only produce seven shillings. This can be proved by the fact that the income produced now is much more than that in 1861, Then we reckened 40,000 colonies destroyed equal to about 14,000? a-year. New we recken 55,000 skeps destroyed besides 20,000 moveable hives giving a total of about 24,250t. I admit that this calculation is uncertain, inasmuch as we de net knew the exact number of frame-hives, but my calculation is rather under than ever the mark. I knew that one of our hive-makers has to this date sold about 3000 such hives.

The present returns are not made at a favourable time, but as they are taken at the same time as these fer cattle this evil is not likely to be remedied. If in future the Government could be induced to separate skeps from meveable comb hives in the returns, they would be ef considerably more value in calculating the progress of bee-keeping in Denmark. The improved methods may quadruple the income of a colony, but modern beekeeping requires both knowledge and labour. It is not sufficient to persuade the skeppist to purchase good hives; he must be taught hew to manage them as well, or it is net impossible that the new method would be less remunerative than the old. It is not enough to secure more honey, it should also be of good quality so as to command a high price. I have shown that at present hee-keeping produces about 24,250l. a-year, but there is ne doubt that with the same number of colonies more than double this amount could be secured if the management was prudent, which in mest cases it is not. Every year thousands of colonies die because the bee-keeper has managed hadly, and a still larger number from the same cause give a very poor return.

Bee-keeping is now with us a source of income to between twenty and thirty thousand labourers and their families, and might be considerably increased if a knewledge of the best methods was more widely spread. Practical bee-keepers can do much to help, and it would be good if the Government could be induced to help the associations to send out experts and pamphlets on beekeeping.—Hans Ersley.

SILESIA.

On Pollen-Gathering, and Stimulative and Compulsory Feeding.

A great deal has been written on this subject. Pfarrer Deichert, Mr. Brauner, of Neudöberu, and others have given excellent advice on bee-pasture; and in No. 15 of the *Bienenzeitung*, of 1882, Tirpitz, of Mr. Wechselburg, called special attention to Epilobium montanum as a plant which is eagerly visited by bees.

Though bee-keepers cannot be reminded too often of the importance of the cultivation of hency plants, the weather unfortunately but too frequently prevents the bees from utilising them, as we have seen in the present year. This being the case, I have been endeavouring during the last few years to prevent as much as possible the disastrous visits of bees to the first flewers which make their appearance in spring, viz., the hazel (Corylus Avellana) and the alder (Alnus glutinosa), and to supply celonies with pellen inside the hive.

I cellect the pellen and give it to the bees in the fellowing manner: As seen as the catkins are se far developed as to open on sunshiny days in February and March, when the pollen begins to discharge, I engage a number of women and children to pick the catkins which I have spread out leosely on sieves, such as are used fer separating cern from chaff, er on ventilating windows, &c., and of these I place as many as a dozen, one above another, on a heated stove, or in a very warm

Between every two sieves or ventilators I place two pieces of weod, in order that the catkins may not be pressed together. Under the lowest sieve a large sheet ef smooth paste-board is put for the pollen which falls through to collect upon; from this it can be swept off easily.

When the temperature rises to about 20° R. (77° Fahrenheit), or a few degrees higher, the catkins soon open. As soon as they do so, the top sieve or ventilator with the catkins on it, is carefully taken down and placed on a large sheet of paper, previously spread out on a table; the open catkins are then shaken up with the hand, when the pollen is deposited on the paper. The remaining sieves are treated in the same manner. But as the catkins are not deprived of all their pellen the first time they are stirred up, the sieves should be replaced and expessed to the heat of the stove a second time, but the order should be reversed, so that the sieve which was first at the tep is new at the bottem. A few mements afterwards the shaking out of the pollen is repeated. Even after the catkins have been shaken repeatedly they should not be thrown away, but be carefully preserved in a dry and calm spot, where they must be turned over frequently, in order that they may not become heated or otherwise spoilt, which happens very quickly. When afterwards a sunshiny and calm day occurs allowing the bees to fly out, these catkins are spread out in front of the hives on a cleth, a doer, or other contrivance; it is a pleasure to watch the bees crowding indefatigably among the catkins in order to extract the last grain of pollen.

Bees are greatly assisted in their search for pollen by the catkins being shaken up frequently. They may be placed before the bees during a good many days, but should be kept from getting wet. When at last all the pollen has been removed from the catkins they may be treated with beiling water, and the liquid be given to

the cattle to drink.

In this manner bees are kept from starting on excursions which would prove disastrons to them, more especially if water be given them at the same time.

Although it may appear difficult and hardly worth the trouble to procure this beautiful yellow pollen in the manner indicated, yet in reality it is beth easy and remunerative.

I am paying here 25d. (3d.) for a casket ($\frac{1}{4}$ bushel) of catkins, and at this rate a child can easily earn 6d., although hazel trees are not plentiful here, and the alder catkins have to be collected in the neighbouring district; a basket of these catkins sometimes yields 1 lb. of pure pollen. Whoever has an opportunity should also have catkins collected later in May from *Pinus silvestris*, in

order to procure a supply of pellen. When the weather is still unfavourable to breeding on an extensive scale, I give this pellen to the bees on small pieces of comb which I place on the alighting beard near the entrance of the hive. I take an old comb, and with a sharp knife, previously dipped into water, I cut through the cells half-way down: I then warm thin pieces of wood or cardboard, and place the cells upon them, where they seen get fixed. Into these cells I loosely scatter the pollen, which is first passed through a good sieve. If the comb used for this purpose is quite free from the smell of honey, there need be ne fear of rebbery. But care should be taken that every colony is liberally supplied when the first distribution of pollen is made in spring. The bees set to work very eagerly to make pellets, the edges of the cells afferding them a good support. The trouble of fixing the pieces of comb is avoided if a piece of an

artificial comb is used for shaking the pollen into. When the weather permits of opening the hives frequently, and encouragement can be given to extensive breeding, the pollen is placed inside the hive, where the bees accept it just as eagerly; a special feeding apparatus is not necessary, as the portion of the comb which remains after the cells have been cut away halfway down may be used for this purpose. If a comb with cells of normal depth be filled with pollen, the latter is moistened with saliva by the bees, and gradually becomes hard, so that it can no longer be made into pellets. When all the pollen collected has been consumed by the bees before the state of the weather allows them to fly out, they may be supplied with flour in the manner I have described; it will likewise be accepted now, and thus the question asked by the late Baron von Berlepsch, as to feeding bees with flour in the hive, may be considered as solved.—A. GRUNERT, Peiskerwitz, near Kl. Bresa, Silesia.

FRANCE.

Those of our readers who have followed the reports which we have been giving from time to time upon the progress of apiculture in France, will doubtless have perceived that on that side of the Channel, no less than on this, bee-keepers have been for some time past greatly preoccupied with the growing necessity of finding increased facilities, beyond those now existing, for the ready disposal of their produce. Although it may be added that it is not only of late that this necessity has made itself felt, yet it is safe for us to say that it has become considerably more accentuated ever since our 'British Honey Company, Limited,' has been established among us; in fact, our confrères have been, ever since that event took place, seriously considering the advisability, or otherwise, of starting some such channel, and upon such a basis as would best meet the special needs of their requirements.

Accordingly, suggestions were more than once solicited from the bee-keeping community by our contemporary the Apiculteur of Paris, and now in its last number we have an outline of the constitution of an Association or Syndicate as, it is thought, might probably commend itself to the bee-keeping community of France.

We do not purpose, however, placing before our readers every point which, according to the programme before us, this 'Syndicat des Producteurs Apicols' of France would differ, in its intents and purposes, from those of our 'British Honey Company,' as they are somewhat numerous, and necessarily so, in view of the fact that this French 'Syndicat' would practically deal in everything connected with apiculture. However, our purpose here will be served if we mention one or two points which are most striking, and mostly directed to the increase of facilities for the disposal of honey. Thus, Clause 2, for instance, suggests the adoption of special hand-barrows which would perambulate the streets of Paris selling honey in attractive recipients, the shape and design of the barrow, as well as those of the pots and the labels, to be protected from becoming common property by registration and otherwise. As the Syndicate would deal only in honey of good quality, it is anticipated that such a course would soon become a most effective mode of disposing of a great deal of

According to Clause 15, the head office of the Syndicate would be established in Paris, where it is desired that further suggestions and provisional adhesions be addressed.

Clause I0 provides for a meeting of the Board of Management at least once in every six months, and suggests the 15th of July as the date for holding the general annual meeting of its members.

Clause 6 states that the annual subscription to membership would be fixed at five francs per annum, whilst lifemembership will be secured by the payment of fifty francs. Members purchasing from the Syndicate would be entitled to 5 per cent discount.

Should this project eventually take a practical form we will refer to it again at some future opportunity.

ASSOCIATIONS.

SUFFOLK AGRICULTURAL SHOW.

BURY ST. EDMUNDS.

Owing to the lateness of the season only a small quantity of honey has been entered for the Bury St. Edmunds Show, to be held on the 23rd inst. Bee-keepers having last year's produce on hand will do well to enter the same without delay. Address, J. Huckle, King's Langley.

LANCASHIRE AND CHESIIIRE BEE-KEEPERS' ASSOCIATION.

On Friday evening, May 20th, a lecture was delivered in the Market Hall Coffee Tavern, Lancaster, under the auspices of the Lancashire and Cheshire Bee-keepers' Association, by Mr. W. B. Webster, of Wokingham, Association, by Mr. W. B. Webster, of Wokingham, an expert of the British Bee-keepers' Association, on 'Bees and Bee-keeping.' There was not a very large attendance. The Rev. J. Bone presided; and amongst others present, were Mr. Win. Lees McClure, of Prescot (hon. sec. of the Lancashire and Cheshire Bee-keepers' Association), Messrs. Wm. Liddell, J. Hatch, T. Stirzaker, J. Warbrick, Gooch, Bailey, Prinkell Taylor Redmayne and others Hatch, T. Stirzaker, J. Warbrick, Drinkall, Taylor, Redmayne, and others.

The Chairman having introduced Mr. Webster, the Lecturer said he wished to give them a little information as to how they could profitably keep bees, and also keep them more humanely than had hitherto been the custom. In a hive, as most of them knew, there were three kinds of bees at certain seasons, and two at others. There was what was called the queen-bee, which was not really the queen, but simply the mother bee, the only one that bred in the hive. Then there was the drone, which was larger than any bee in the hive, and the worker, which built the combs and collected the honey and pollen with which to feed the young bees. The queen-bee laid an egg, and in twenty-one days it became a worker-bee. The same egg that produced a worker-bee would, by different feeding, produce a queen-bee in sixteen days. The queen afterwards laid another egg, which was what might be called an unfertilised one, and in twenty-five days it turned into a drone. When the services of the drones were no longer required in a hive, the other bees threw them out. Queen-bees lived four or five years, but modern bee-keepers only allowed them to remain in their hives two or three years, which was as long as they were considered useful. After exhibiting a queen and drone bee, and the cells in which the different bees were hatched, the lecturer went on to describe and condemn the old-fashioned mode of keeping bees. When a swarm took place, after the bees had been got into the hive they should be removed at once to the place where the hive was intended to remain, instead of leaving it near the place where the bees originally settled. That would prevent, in many instances, abscording swarms. The old method of obtaining the honey from a hive by means of sulphur, which generally had the effect of destroying the bees, was described as inhuman and a crime, because it was unnecessary to kill the bees to get the honey. They could take the honey from any hive in a much easier way than by killing the bees. If they had only a common straw skep, the best way was to cut a round hole, three inches in diameter, in the top, pushing a little smoke into the hive, and stopping up the

entrance. Then they could place a super or crate of sections on the top of the original hive, removing the plug from the entrance, and the bees, finding there was no furniture in the upper one, would begin to fill it with honey. They would by that means get 14lbs. or 15lbs. of honey from the top one, and leave the bees what they had collected in the bettom one to feed on. By that means they could make a profit of a guinea each year from an ordinary hive, and still have the same stock as they commenced with. The next step in bee-keeping was what was called sectional supering. A box fitted with a round hole at the bettom was fixed over the hole in the top of the hive. A piece of beeswax was placed in the section, and the bees built their comb on that foundation, and on the same lines as the beeswax ran. Then they had between each row a piece of zine, and the bees built until their backs came in contact with the zinc, and the honey was thus finished off flush. By that means he (the lecturer) obtained a prefit of 2l. 9s. from a hive last year. The frame-hive was next described, by the use of which the owner had perfect control over the bees. The method adopted to make the bees build in the frames was illustrated, and also how to make the hive larger as the bees filled the frames already in. Another advantage was that they could always see whether the bees had plenty to eat, or were starving. They could also see whether a hive was queenless, and thus going to the had, and remedy it by giving the bees a new queen. If a hive had lost its queen the bees had power to raise another from an egg which would otherwise have produced a worker, by feeding the egg in a special way, though the same process of feeding would have no effect upon an egg which produced a drene. Then if they had frame hives they could see whether their stocks were strong or weak. If they found they had two weak stocks in the winter it was always best to put them tegether and make one strong colony. Proceeding to speak of subjugating bees, the lecturer said they were not afraid of mankind, but they were irritated by a noise, and thoroughly frightened by tebacco smoke or the fumes of carbolic acid. If they had an ordinary skep hive of bees, and they wanted to take them out into another similar one, the best way was to puff a little carbolic acid into the entrance of the hive by means of a smoker, and then tap the outside of the hive smartly. The tapping and the smoke thoroughly disorganised the bees, and they proceeded to gorge themselves with honey, and almost fergot to sting. Then the hive could be turned upside down, and a few more puffs of carbolic acid would keep the bees from getting out. The second hive could then be fixed or held on the edge of the original one, and the bees would begin to crawl rapidly into it, because it was dark, and when the last bee had got into the new hive, it could be placed on the stand and the honey taken from the first one, without the loss of a single bee. After describing and illustrating the bar-frame hives, the lecturer said that the only means of preventing bees swarming was by keeping the hive a little too big for them. This could be done by taking out the frames filled with honey, and putting empty ones in their place. There was a growing and increasing demand for honey, which was not only very nutritious but a'so contained medicinal properties, and therefore bee-keepers should endeavour to get as much honey as they could from their stock. There was another aspect of bee-keeping, namely, the fertilisation of flowers. The bees, in col-lecting honey, conveyed the pollen from the male to the female flowers, and thus fertillsation took place, and seed was formed. The formation of seed was an important factor in clover, and it was therefore to the advantage of farmers to keep bees if only to produce seed by fertilisation, because seed meant weight. Farmers by keeping bees could increase their income

considerably, because they got better hay by their means, and had also the profit from the honey. He (the lecturer) did not see how any person could keep bees without them returning their owner a certain amount of profit, if they attended to them as they deserved. The more attention they devoted to bees the better they paid. Of course they must not interfere too much with them. Once a-week was quite often enough to extract honey from the hives, because taking the honey caused a commotion in the hive and interfered with the work of the bees. Many people commenced bee-keeping and found they were out of pocket. That was not the fault of the bees, but of the owner. The reason probably was because they did not attend to them properly. People who began bee-keeping should only have one hive at first, and master that before they got any more. In conclusion the lecturer spoke of the advantages to be derived from membership in the Lancashire and Cheshire Bee-keepers' Association. At the Indian and Colonial Exhibition he (the lecturer) was literally astonished at the exhibition of houey sent by the Association. People now knew that Lancashire and Cheshire could produce better honey than any other part of England. There was no honey in the exhibition that could touch that sent by the Lancashire and Cheshire Association. Therefore it was to every bee-keeper's advantage to belong to the Association.

In answer to Mr. Liddell, the lecturer described the method of doubling, the object of which was to get a very strong colony of bees just at the time honey was coming in. The same gentleman also asked a question respecting non-swarming bees, and Mr. Webster replied that it was impossible to prevent swarming altogether. They might retard it in the way he had already described, but as swarming was natural they could not altogether prevent it. In answer to further questions, the way to deal with diseased bees and the method of introducing a new queen into a hive were described. The latter method was as follows:-When a queen had got too old the frames in the hive must be lifted out in the day time until the queen was discovered, and then it must be removed. Then a new queen being in readiness must be kept in a box without food for some time, and at night, when all was quiet, and the fierce sentinel bees on guard at the entrance, the covering of the hive must be raised at the corner furthest from the entrance, and the queenbee inserted, a little smoke being puffed into the hive at the same moment. The queen-bee being hungry would call for food, and the young bees round about, who were always located at the point furthest from the entrance, would commence to feed the queen; and if once the bees could be induced to feed the stranger queen she would be accepted. By this means a new queen could be introduced forty times out of fifty without being killed, and was much superior to the old method of caging the queen when putting it into the hive.

The discussion afterwards became general, and various matters of detail respecting bee-keeping were talked about by those present, and at the close a hearty vote of thanks was passed to the lecturer, a like compliment

being paid to the Chairmon for presiding.

Swarms in Scotland.—Mr. David Malcolm, residing at Ormisten, had a fine swarm of bees on Tnesday, 24th May. Mr. Johnstone, Rose Cottage, has since had a cast from one or two of his fine hives. There was a swarm of bees at East Hopes on 31st May. There was a swarm of bees on Tuesday, 31st ult., which is the first recorded in this neighbourhood. On Wednesday, Jehn Dow, joiner, Salten, had a good swarm. Mr. David Taylor, Hardgate Street, Haddington, also reports a swarm on Wednesday. Mr. Duncan Robertson, Samuelston Mains, writes:—'As a favourable sign of the season, I beg to report that I got a very fine swarm of bees at noen on Wednesday, 1st June. I have not for some years seen the old hives so strong as they are this season, which I take as indicating a fruitful season.'

Correspondence.

The Editor does not hold himself responsible for the opinions expressed by his correspondents. No attention will be taken of anonymous communications, and correspondents are requested to write on one side of the paper only, and give their real names and addresses, not necessarily for publication, but as a guarantee of good faith. Illustrations should be drawn on separate pieces of paper.

Communications relating to the literary department, reports of Associations, Shows, Meetings, Echoes, Queries, Books for Review, &c., must be addressed only to "The Editor of the "British Bee Journal," c/o Messrs. Strangeways and Sons, Tower Street, Cambridge Circus, W.C.' All business communications relating to Advertisements, &c., must be addressed to Mr. J. Huckle. Kino's Lanalan. Hart (**e**)

Circus, N.C. An obsiness communications relating to Ambrusements, f.c., must be addressed to Mr. J. Huckle, King's Langley, Herts (see 2nd page of Advertisements).

*** In order to facilitate reference, Correspondents, when speaking of any letter or query previously inserted, will oblige by mentioning the number of the letter, as well as the page on which it appears.

A BEE TOUR THROUGH LANCASHIRE AND NORTHUMBERLAND.

[1000.] Receiving instructions from the British B.K.A., 1 commenced my journey through the above counties on After a succession of small mishaps, such as missing an important train, leaving my hat to take care of itself on a journey to Scotland, the find being no doubt greatly appreciated by some canny Scot,—I arrived in Lancaster just in time to step upon the platform,—train arrived at 7 p.m., lecture advertised at same hour, so needs must, &c. I was bound to dismiss all thoughts of dinner until I had finished my discourse. Messrs. McClure and Liddell were in a great fright at my late arrival, but everything passed off satisfactorily, when, after adjourning to the Counties' Hotel with some kindred bee-keeping spirits and refreshing the inner man, I spent an hour in very pleasant company. The next morning was spent visiting the apiaries of the district, the condition of most of the colonies was grand, all hives in a more forward condition than in the south, vegetation of all sorts being quite a week earlier than here, in Berks. Saturday I started for Poulton-le-Fylde, here the barframe hive was well understood by a few, nearly all the hives being in good condition, but scarcely as forward as those at Lancaster. There are here several gentlemen, who will, without doubt, make excellent bee-keepers. I next visited Blackpool, being driven there by a gentleman who takes considerable interest in bee-keeping. The wind of the previous Friday had played sad havec with the tender spring leaves of the trees, and instead of bright green their foliage was brown as in autumn. Monday afternoon, in company with Messrs. McClure and W. B. Carr, I attended a meeting of the Lancashire and Cheshire B.K.A. A subject of great interest was brought forward; recent advices from isolated parts had revealed the fact of the existence of 'foul brood.' Mr. McClure, in his usual energetic manner, obtained the sanction of the committee to 'go in' for a good supply of phenol and carbolic soap: these are now being distributed to those who require it. I trust the committee's efforts will be crowned with success. This is a good lesson for some of our sleepy County Associations. Tuesday morning Mr. McClure and myself unearthed a properly constructed Canadian (?) winter cellar; this subject will form such an object of interest that I purpose treating it in a separate letter, of course with Mr. Editor's permission. A hurried good-bye, and I was eff to Merpeth, Northumberland. What a ride! Smoke, coal-dust, chemical factories, iron-works, myriads of high chimney-shafts, each belching forth its volumes of black sulphurous smoke, until I arrived in Yorkshire; here we rushed through the station sacred to 'Apifuge' and hut-tites. I think this was the first pretty spot that I had seen since leaving Lancashire. Arriving at Neweastle in a drizzling rain, I thought that if there was an uninviting spot to locate a bec-keeper in England, it is Newcastle—it's black, that is all the description I can give of it. Arriving at Morpeth I was met at the station by Mr. Scholield, the organizer of the expedition, and

placing my legs under his mahogany,' I was 'at home' in fact with Mr. and Mrs. Schofield, and of course with the baby you could not feel otherwise. A lecture very well attended concluded the day's programme. next morning was too wet and cold to do anything with the bees.—W. B. Wenster, Wokingham, Berks.

APIFUGE.

[1001.] Being a novice in bee-keeping, and very desirous not only to avoid the inconvenience of stings, but to manipulate my bees with as little discomfort to them as to myself, I determined to try the far-famed 'apifuge.' The clumsy veil and gloves, and the still more barbarous practice of smoking the bees, have always been to me most objectionable, apart from the irritation caused in the hive by the process of smoking, to say nothing of the loss of time and strength on the part of the bees in loading themselves with honey, which has afterwards to be disgorged before they can settle down again to their arduous duties. I accordingly tried the 'apifuge,' and was perfectly delighted with the result. The effect upon my bees was simply charming, not one attempting to sting me. A few crawled affectionately over my fingers, and seemed to express their gratitude for the discontinuance of their enemy the smoke. Nor was there any agitation in the hive during the peaceful manipulation. But strange to say, a day or two after using the 'apifuge,' there appeared on my hands and neck, where the bee-soother had been applied, three or four irritable bumps, red and swollen. It at once occurred to me, has the apifuge caused this? but this suggestion I sought immediately to dismiss from my mind, and should have thought no more about it had it not again occurred. The next time an examination of the hive was necessary, I handed the operation over to my nephew, who after duly fortifying himself with 'apifuge,' proceeded to manipulate the bees, and with 'apifuge,' proceeded to manipulate the bees, and with the same peaceful effect upon them, not a single bee exhibiting his temper or attempting to sting. But, strange to say, the day following similar red bumps appeared on his hands and neck, causing the same itching and irritation I had experienced. Can the 'apifuge' be the cause of this? is a powerful query still resting upon our minds. Will any of my fellow-beekeepers who have used 'apifuge' kindly communicate the user the pure hear resulted. through your columns if a similar suffering has resulted from its use. It would be a grievous loss if so valuable an addition to apiarian appliances should be rendered objectionable by some powerful irritant contained in its composition .- E. Musgrove, Sideup, Kent.

We are informed that there has been a large demand for the 'apifuge' since its introduction to the public, a considerable number of bee-keepers must therefore have made trial of it. We should be glad to hear from such if they are able to confirm, or otherwise, the experiences of our correspondent. We have experimented with it on several occasions, but we have not noticed any such

results.—ED.]

BEE FLORA.

[1002.] Can you afford space for me to speak a few words to the public? It is in reference to my letter which appeared in B. B. Journal for May 26th, 1887, p. 227, No. 982. I fear very many of our bee-keeping friends will feel somewhat disappointed in the long delay which must elapse before I can send cuttings and seed to all my applicants; but when I tell them that the applications are so numerous that letters arrive nearly a hundred at a time, and considering I have to be at my work from 6 a.m. until 5.30 p.m., they will then be able to realise the delay which must occur in some cases, but I am taking them in rotation as they arrive as near as I can. But I feel bound to lay those aside for a few days which ask for a reply, in order to get those off which ask for no particulars, as the latter are very much in a majority. I also fear I have left many of our friends in doubt respecting the way in which I described the Nepeta Mussini. When I say it only grows to 6 in. high I speak of its habits of growth, as it does not stand upright, or it would be about 2 ft. high; it is now coming nicely into bloom, and I find my bees are quite aware of it also. I hope this notice will not prevent those who intend to write for cuttings and seed from doing so, as I shall be very pleased to keep on attending to them until I have completely executed my orders. If cuttings and seed fail I will communicate again.

I am very pleased to say that all my bees are doing very well indeed, considering the unsuitable weather we have had for them. There are very many friends who have been kind enough to send me some seed of various kinds. They are too numerous for me to write to privately, so I beg to take this opportunity of thanking them for the same. I will do my best to test their value, when I will, if circumstances permit, report upon the same.— C. H. W., Aylesford, Maidstone.

AGE OF WORKER-BEES.

[1003.] In your issue of the 2nd inst. I see (990) 'C. C. James' still believes he has bees two years old. I have proved to my own satisfaction that bees do not exist much longer than eight months, including the winter season; in summer time they do not exist nearly so long. I have a stock with black queen now hatching about five per cent of yellow-banded bees, which is open to the inspection of any one interested, and which confirms your foot-note to 'C. C. J.'s' letter.—Nucleus, Betley, near Crewe.

NOTES BY THE WAY.

[1004.] So Mr. Boyes has plenty of common sense. Of course he has. He says black bees are brown, American manufacturers have never seen natural comb as built by the bees, as they wire their foundation the wrong way up, as his bees always build their combs with perpendicular walls (like a factory chimney, I suppose). Surely 'F.B.' is, like our English foundation, heavy, and during the two or three warm days has naturally given

Experts are in hot water, and well they may be, seeing the expert has closed up and supered a stock of bees

belonging to a reverend gentleman close by.

What to gather we should like to be told, as our bees require feeding every night during this weather. Hailstones, we presume.—Apple Dumpling, Kent.

BEES AND RIPE FRUIT. (963.)

[1005.] Allow me, Mr. Editor, as a bee-keeper and fruit-grower, to endorse Mr. Webster's assertion, and to place it on record that bees can, and did undoubtedly, pierce the skins of sound, ripe peaches, and to a less extent plums, with us, and to a serious extent, last year.

I may here remark, and with all deferential respect for your opinion, Mr. Editor, to the contrary, that no 'wasp-prepare-the-way theory' can be admitted in our case, for the simple reason that there was not a single wasp about at the time, and that the first peaches attacked were under glass. Later on in the season they attacked peaches and plums on the walls to an alarming extent. The latter fruit was very plentiful last year, and cracked very much after the showers, as plums always do if they get the rain on them during the ripening process. I am open to the conviction that it may have been the juice oozing from the cracked plums that was the inviting attraction to the bees, and which whetted their appetites for a further onslaught of the sound fruit of peaches on the walls. But I am at a loss to understand why they should have attacked the peaches under glass in the first

As a bee-keeper of several years, and a fruit-grower of longer standing, I must confess that last year was the first time I have seen bees damage fruit to any extent worth speaking of. I believe I drew the attention of our much-respected Rector and bee-Mentor (the Rev. F. G. Jenyns) to the fact of the bees damaging the fruit in such wholesale manner. His bees shared in the treat which our orchard plums provided, for they winged their flight Rectory-wards thick and fast.—J. KIPLING Knebworth.

POLLEN-MASSES.

[1006.] Can you tell me what the substance is which grows on the heads of the enclosed bees? I saw several in two black stocks which I examined to-day, and also in one Ligarian stock. It looks beautiful under the microscope, and the bees are able to move the substance about. An answer in the Journal will oblige-T. W. Jones.

The substance is not a growth from the head of the bee. The material is a pollen mass from an orehid, which has stuck to the forehead of the bee. The mass had been dragged to pieces, and so used by the bee in the fertilisation of other blooms. See Darwin's Fertilisation of Orchids, p. 34. This excrescence has frequently been considered the effect of disease. Dzierzon, in his Rational Bee-keeping, in his chapter on 'Diseases of Bees' (p. 279), says:- The horn or tuft, formerly reckoned among bee-diseases, which appears after the fruit-bloom, deserves at least to be mentioned as a curiosity. Professor Theodor von Siebold has proved, in the Bienenzeitung, that the yellow or dark-green tufts showing on the foreheads of individual bees are not a fungoid growth at all, but are the very elastic pollinia of certain orchids that are left sticking to the bees.'-ED.]

Echoes from the Hives.

Weybridge, May 29.-I had a fine swarm on May 28th. I find bees generally late.—W. LEDGER.

Carlisle, June 2nd .-- I had yesterday a fine swarm, which I believe is about the first in this district.-John Clay STEDMAN.

Harborne, June 6th.—The long-looked for fine weather has come at last, bees working grandly, the sweat of the bees drop from the flight-boards in the early morning. What a difference from three days ago! Feeding every night to keep stocks alive, bees expelling mature as well as immature drones, no wonder a bee said as he entered the hive, 'There is no place like "comb" when the weather is like this.'-H. Sands.

Goole, June 2nd.—The late month has been a very cold one indeed, and our bees have not been able to do much work. Fruit trees began to open their bloom about the 9th, but the weather was so cold that very few bees left their hives in search of the precious nectar, and we have had very few fine, warm days since, so we have given up all hopes of any surplus until the clover blooms. I noticed the first drone flying yesterday. All our hives but two are strong in bees but have no stores, so have kept the queen breeding by The two weak stocks we intend to unite, gentle feeding. and I would ask if it would be best to unite at once, or wait until just before the clover blooms, and then add supers at the same time; also is the sample of American cloth suitable for quilts?—A. Woodhead.

[Unite without delay, and if the weather should once more become unseasonable, feed gently to get them in good form for the clover and limes. The Δ merican cloth will be found suitable.]

Graffham, near Petworth.—Weather here very dull and eloudy. Wind N. and N.E. for a fortnight. Sycamores, chestnuts, and maples, in full bloom. No swarms yet in this part.—Coltrip Gilbert.

NOTICES TO CORRESPONDENTS & INQUIRERS.

Letters or queries asking for addresses of manufacturers or correspondents, or where appliances can be purchased, or replies giving such information, can only be inserted as advertisements. The space devoted to letters, queries, and replies, is meant for the general good of bee-keepers, and not for advertisements. We wish our Correspondents to bear in mind that, as it is necessary for us to go to press in advance of the date of issue, queries cannot always be replied to in the issue immediately following the receipt of their communication.

All queries forwarded will be attended to, and those only of personal interest will be answered in this column.

- G. W. W.—Crooked Combs.—If a spirit-level is used for placing the hive perfectly horizontal, so that the frames with foundation hang perpendicularly, the bees are compelled to build straight combs and within the frames. The metal ends will keep the frames at the proper distance from each other, viz., one and half inch from centre to centre.
- W. S., Aboyne.—Bees Sluggish.—1. The queen is probably worn out and the bees are raising a young one to succeed her. Foul brood will also account for the sluggishness of the bees. Thoroughly examine the skep by driving out the bees if necessary. 2. When a colony is very small with a prolific queen at its head she will often lay several eggs in a cell, the bees being too few in number to encourage her to extend the nest.
- R. Sandall.—1. Uniting.-Remove the weak colony from its stand and in place of it set an empty skep, in front of which shake off the bees from each comb and return the empty combs to the hive. When the bees have entered the skep replace it by the frame-hive, raised slightly in front, and shake out the swarm in front of it. Shake the weak colony upon the swarm as it runs in. Either queen may be removed, or you may leave the destruction of one to the bees. All this must be done in the evening. 2. Drone Comb.—Bees will store honey in drone-comb in preference to worker-comb. 3. Doubling.—You have done right in placing an empty hive beneath the colony. The queen in the upper hive will descend and breed in the lower one. As the young bees hatch out above the bees will store honey in the combs, which can be extracted.
- A Victim.—1. Foul Brood.—We have no experience of fumigation with carbolic acid, as we always administer it in the form of phenol according to Mr. Cheshire's directions, but Calvert's No. 5 can be applied by fumigation. Sec Webster's advertisement in our columns.

 2. It may be used for disinfecting hives, washing the hands, &c.—about one part to twenty of water.

 3. It is very doubtful whether frost will destroy the bacteria.

 4. Condy's fluid is a good disinfectant, or antiseptic, and would no doubt thoroughly disinfect hives, but we never heard of its being used as a specific in foul brood.

 5. Thymol is used by fumigation and by means of any ordinary fumigator.

 6. Unslaked lime, or newly slaked, is a powerful disinfectant and may be used for hives.

 7. It is better to spray the bands with a weak solution of carbolic acid than to use it mixed with vaselin.
- II. II. H.—Fumigation.—The process you refer to is called 'Hilbert's fumigating process;' the fumes of salicylic acid have the power of penetrating everything in the hive, and destroying the germs of foul brood. The apparatus used for the purpose is M. Bertrand's fumigator, in which a spirit-lamp has the flame so regulated that the acid placed in a metal dish above it is gently evaporated. For details of process consult Cowan's Guidebook, pages 138, 139, last edition.
- E. G. V.—Castor Oil Plant.—There will be no harm in growing the castor oil plant in the vicinity of bee-hives.
- T. M.—Barrels for Storing Honey.—If you use them, take out one head, otherwise you will find when the honey poured in by the bung-hole liquid becomes set and solid it will be a difficult matter to get it out. Treacle

- barrels would be as good as any, they will only require washing to be ready.
- R. F. W.—Dcad Queen.—The queen was fertile, the spermatheca being full of spermatozoa. Exhaustion was probably the cause of death from cold and want of food.
- AGED AMATEUR.—I. Hive Descrition.—Your bees most likely left their hive for want of food. 2. Comb of previous year.—If the combs are clean and white they had better be left in the glasses, but if discoloured the honey would be of less value if they are not removed.
- H. C.—Requeening. You do not mention whether you purpose to purchase the new queens, or to rear them yourself. If the former, it may be done at once, introducing the queen in Mr. Simmins' method; if the latter, we should recommend that during the honey glut you remove the queen from the stronger stock, and let the bees raise queen-cells; one of which when almost matured insert in the weaker hive, first having taken away the queen.
- H. A.—A Vagabond Swarm.—The swarm you found was a 'vagabond' swarm, and had most likely left its hive for want of provisions. Such swarms frequently leave their new quarters when hived if there is a scarcity of stores. By inserting a comb containing unsealed brood at the time of hiving, and after that feeding liberally, such swarms are induced to take to a strange dwelling which they otherwise would abandon. We never hive a swarm without at once commencing to feed them, even if they are able to get an abundance of food naturally.
- Miss E. V.—Dividing by a Lady.—As you would have a difficulty in lifting your hives, the plan you propose,—to make the 'swarm' of frames of hatching brood from more hives than one, with a queen,—will give you a good stock; and as all the old bees will be with the old stock, and no brood to raise, you should super it at once.
- B. Kirke.—The drones, mature and immature, that the bees are casting out, are indications of starvation. Feed—feed—feed!

Show Announcements.

Giving Name and Address of Secretary, Date and Place of Show, Date of Closing Entries. Terms: Three Insertions and under, Two Shillings and Sixpence; additional insertions, Sixpence each. No charge made to Associations whose Shows are announced in our general Advertising Columns.

June 15, 16.—Wilts Agricultural Show. Rev. W. E. Burkitt, Secretary.

June 20-23.—Royal Counties' Agricultural Show at Reading. Entries close June 11th. See Advertisement.

June 23, 24.—Suffolk Agricultural Show at Bury St. Edmunds. Entries close June 6. J. Huckle, Secretary.

July 11-15.—Royal Agricultural Show at Newcastle ou-Tyne. Post entries to June 1st. J. Huckle, Kings Laugley. July 14.—Oxfordshire Association at Headington. Hon.

July 14.—Oxfordshire Association at Headington. Ho Sec., Rev. F. C. Dillon, Enstone.

July 21.—Prescot Horticultural Show. R. Rigby, Secretary, Station Road, Prescot, Lancashire.

July 20-22.—Lincolnshire Agricultural Society at Spalding. Entries close July 4. R. R. Godfrey, Secretary.

July 26-28.—Gloucestershire Agricultural Show at Cheltenham. Entries close July 12. W. D. Slade, Sec.

July 26, 27.—Warwick Agricultural Society at Sutton Coldfield. J. N. Bower, Secretary.

July 27.—Bishops Waltham Show. (Hants and Isle of Wight Association.) H. W. West, Hon. Sec., Swanmore House, Bishops Waltham.

August 3-5.—Yorkshire Agricultural Society at York. Secretary, H. L. Rickards, Poole, near Leeds.

August 9, 10.—Irish Dee-keepers' Association at Salthill Gardens, near Dublin. Entries close August 2. Hon. Sec., Henry Chenevix, Blackrock, Dublin.

August 14.—Handbridge, Chester St. Mary's Horticultural Show. W. E. Little, Hon. Secretary, Eastgate Row, Chester.

August 24.—Lancaster Agricultural Show. W. Liddell, Hon. Secretary, Dale Street, Lancaster.

Angust 31-Sept. 3.—Royal Manchester and Liverpool Agricultural Show at Manchester. W. Lees McClure, Hon. Secretary, The Lathoms, Prescot, Lancashire.

Business Directory.

For the use of Manufacturers and Purchasers of Beekeeping Appliances.

The Name and Address and Business of any Manufacturer will be inserted in this List, under one heading, for One Pound per annum. Additional headings, Five Shillings extra. Advertisers in 'The Bee Journal,' whose orders amount to Five Pounds per annum, will be inserted Free.

HIVES AND OTHER APPLIANCES.

Abbott Bros., Southall, and Merchants' Quay, Dubliu. Appleton, H. M., 256a Hotwell Road, Bristol. Baker, W. B., Muskham, Newark.

PRITISH BEE-KEEPERS' PRACTICAL NOTE BOOK. By Thomas W. Cowan, F.G.S., F.B.M.S., &c. Crown 8vo, boards, 1s.; postage 1d. Indispensable for every Bee-keeper. Published by J. Huckle, Kings Langley; may also be obtained of all Hive-dealers

IRISH BEE-KEEPERS' ASSOCIATION.

A SHOW OF

Hives, Supers, Bee-Furniture, and Honey

Will be held at SALTHILL GARDENS, DUBLIN, On 9th and 10th of August, 1887.

PRIZES in all Departments open to general competition.

Additional Prizes in the Honey Department open, without entrance Fee, to Members only.

Full particulars on application to Henry Chenevix, Hon. Sec., Blackrock, Dublin.

YORKSHIRE AGRICULTURAL SOCIETY.

PATRON: H.R.H. THE PRINCE OF WALES, K.G. PRESIDENT: THE RIGHT HON. LORD WENLOCK.

THE FIFTIETH GREAT ANNUAL SHOW

Will be held on THE KNAVESMIRE, YORK, 2nd, 3rd, and 4th days of August, 1887.

The Entries close on SATURDAY, JUNE 25th.

Prize Lists and Forms of Entry for Stock, Bee Appliances, and Implements, will be forwarded on application to Marshall Stephenson, Secretary, 176

C. T. OVERTON, Manufacturer of all kinds of Bee-keeping Appliances. The COWAN HIVE and EXTRACTORS a Speciality.

The following Goods are offered at a low price, for Cash only:—OVERTON'S IMPROVED FEEDER, 1/3 each, 12/0 doz. Best BINGHAM SMOKER, post free, 3/3. (This Smoker was awarded a Bronze Medal at the Colonial Exhibition.) CANDY for WINTER FEEDING: Sample, 1 lb., post free, 9d.; 1 lb., 6d. per lb.; 2 lbs., 5½d. per lb.; 10 lbs. 5½d. per lb. METAL SCREW CAP BOTTLES, 26/6 per gross; 25/6 per gross in crate of 5 gross. BROOD FRAMES, Plain, in flat, 8/- per 100; Broad-Shoulder, 16/- per 100.

CHARLES T. OVERTON, LOWFIELD APIARY, CRAWLEY, SUSSEX.

Our Second consignment of FOUR BEE-WAY SECTIONS, BINGHAM SMOKERS (7/6 each), and a variety of other goods just to hand. Among other new ideas in Hives, we beg to offer EDEY'S DOUBLER, complete in two chambers, 10/6. Single Parts—Bottom, 1/3; Body, 2/6; Metal Corner Frames in flat, 1/-; Dummy, 4d.; Water-proof Cover, 1/5; Invertible Crate, 2/6. In Flat—Complete Hive, 5/-; in lots of five, 23/9. If frames are wired and fitted with foundation, 5/- extra is charged: this is well worth the extra expense.

CARNIOLAN QUEENS, after June 7th, 8/-; Home Bred, as List, ENGLISH SWARMS, 12/6.

A full line of all other goods on hand, for instant delivery. See List, free.

EDEY AND SON, STEAM JOINERY WORKS, ST. NEOTS.

I have received Hundreds of Testimonials during last 5 years for my Celebrated, Genuine (Analysed) WAX FOUNDATION, 1 lb., 2s.; 4 lb. @ ls. 9d. PURE FOUNDATION, 1 lb., 1s. 10d.; 4 lb. @ ls. 7d. SUPER, 1 lb., 2s. 8d.; 2 lb. @ 2s. 6d. STRAW HIVES, 1s. 3d., 1s. 7d., and 1s. 10d. The 'BRITISH' HIVE, deep-hinged Roof, 11 wide-shoulder Frames, Dummy, Crate of 21 Sections, 8s. 3d. complete. SIMPLICITY HIVE, deep Roof, 5s. HONEY EXTRACTORS, 8s. 3d. and 22s. 6d. Bottle Feeder, 6d. Wide-shoulder Frames, 1s. 8d. per doz. Plain Frames, 1ld. and 1s, per doz. Smoker and Guard, 2s. 9d. Sections, 3s. and 2s. 6d. per 100; 500, 10s. Stocks, Bees with Italian Queen, in Standard Hive, 20s. and 30s. h. Cyprian Queens in Sept., 7s. 6d. 'Dealers quoted.' Be sure and send Card for Catalogue (110 Pictures.) Order early. G. STOTHARD, 1st Class Expert B.B.K.A., Eritish Hive Factory, Welwyn, Herts. A 2451

Send for Illustrated, Descriptive, and Instructive Circular.

SIMMINS' FACTORY, For HIVES and APPLIANCES.

CARNIOLAN
BEES have come to stay, and will hold their own wherever introduced. Good workers; amiable and beautiful; and for wintering are perfection. We are now booking Orders for SIX-FRAME STOCKS, to be delivered in July and August. STANDARD FRAMES, good sound Combs, with Brood and Stores. Also THREE-FRAME NUCLEI in like condition. SIMMINS, Rottingdean, Brighton.

Finest CYPRIAN Queens.

DIRECT by MAIL from CYPRUS to any Address in EUROPE.

From 1st MAY to 30th AUGUST.

For I or 2 Queens (if ordered at one time), each 14/-

,, 3 ,, 4 ,, ,, ,, ,, 13/-

,, 5 ,, 6 ,, ,, ,, ,, ,, 12/-For Countries out of Europe add 50 $_{\circ}/^{\circ}$ to above prices.

All Orders to be accompanied by a Remittance.

t⊕ My Queens are all very prolific, long-lived, and much larger-bodied, than the majority of those supplied by others, as they are reared naturally, under the swarming impulse, in April, May, and June, from the strongest of my forty colonies of Bees kept in double-walled moveable frame-hives, and all having choice Queens, which produce workers so gentle that they can be handled without smoke, and even without a veil on the face, just as I do myself (see Mr. S. Simmins' statements on page 37 of his work entitled, A New Era in Modern Bee-keeping). This is principally owing to the fact that I have weeded out from my Apiary all such Queens which appeared to be weak or producing troublesome workers. Address—

M. G. DERVISHIAN, Larnaca, CYPRUS. A. 2375 For Reference, address Imperial Ottoman Bank, Larnaca.

FOR USE WITHOUT SEPARATORS OR with the SIMMINS' SEPARATOR thickened at the Corners by a Half Bec-space.

20,000 4½ × 4½ × 1¾ V.CUT, Open or Close Sided, First-Class AMERICAN SECTIONS, now landed at Liverpool. Free on rail or steamer there, 20/- per 1000; 10/6 for 500. For smaller quantities apply to J. H. Howard, Holme, Peterborough; or to R. Whitze & Co., Patrickswell, Limerick. The Trade supplied.

PEES, Early Swarms for Sale, 15s. each. Orders in rotation. Address A. D. Woodley, Donnington (173)

LYON'S Patent METAL ENDS

THE only perfect pattern. The metal being flush with the inside of the Hive side, CANNOT BE FIXED TO IT BY PROPOLIS. All the so-called Improvements CAN.

The Special Alloy used allows them to be LIGHT YET STRONG. One gross weighs 5½ lbs.

Price for 1887 5/6 per gross.

DR. PINE'S VEILS.

Prize Medal, 1879, for the best Bee Dress. The only Medal ever awarded to a Veil, 2/2 each, post free. Every genuine Veil bears the Registered Trade Mark.

DR. PINE'S LOTION.

The ONLY CURE for Stings, 1/8 per bottle, post free.

CHESHIRE CURE.

Guaranteed, with Directions, 1/2 per bottle, post free.

Methyl Salicylate, or 'Sting Preventer.'

HIVE MAKERS supplied with SPRINGS, GLASSES for Sections, PHENOL, METHYL SALICYLATE, in bulk, &e., &c., at lowest prices.

OUTLINES OF BEE-KEEPING FOR BEGINNERS.

(Continued from page 232.)

XII.—How to Treat Recently-Hived Swarms.

1. The careful bee-keeper will endeavour to get his swarm to build out its combs and fill the hive as quickly as possible, and he will not leave the bees to do so without any assistance from him. Feeding gently will have the effect of keeping many bees at home comb-building who would otherwise be in the fields collecting. All swarms should be fed, even in fine weather, for the first week at any rate. At the time of hiving, give them a bottle of syrup, placed on the top of the frame in such a manner that they may have access to two or three holes in the feeding-stage. must be cut in the quilt to allow the stage to be placed over it, and care should be taken to cover over the bottle so that strange bees cannot get at it from outside, otherwise robbing may result.

2. The syrup used should consist of 10 lbs. white lump sugar, 7 pints of water, 1 oz. of vinegar, and 1 oz. of salt, and the whole boiled for a few minutes, after which 1 oz. of salicylic acid solution should be added. This solution may be made by dissolving in 1 pint of warm water $\frac{1}{4}$ oz. of salicylic acid and $\frac{1}{4}$ oz. of soda borax.

3. The swarm should only have as many frames as it can comfortably occupy, the space being closed up with a division-board, and the spare frames hung in the division at the side. From six to eight frames are usually sufficient.

4. Swarms are greatly assisted by having given to them one or two frames of comb with hatching brood. These can be taken from established stocks if the bee-keeper have them, and they be strong enough to spare any.

5. At the end of a week, examine the hive, and if the combs are built out, put in a couple more Add frames as soon as the bees require more room until the hive is filled with combs.

6. The first consideration of the bee-keeper should be to make sure worker-brood is being raised. If during the examination the queen has not been noticed, and the combs are not found to contain worker-brood, if possible, without delay,

place in the centre, amongst the combs, a frame of comb containing eggs taken from another hive. Should the swarm have lost its queen, royal cells will be at once started. Should only drone-brood be found, the queen must be removed, and the bees should be united to another swarm having a fertile

7. In ordinary seasons the bee-keeper will have to be contented if a young colony fills its hive with comb and collects enough stores to carry it through the winter without his assistance. In bad seasons it would be necessary for him to supply the bees with most of their winter provisions, and only in very good seasons can be expect to get any surplus honey.

XIII.—How to make an Artificial Swarm.

1. If, during the month of May, honey being abundant, a stock hive is found crowded with bees containing drones, and is not inclined to swarm naturally, not having therefore commenced queencells, it can be swarmed artificially.

2. Prepare a hive in the same way as for natural swarms, that is, hang in it frames furnished with guides or comb foundation. If there are frames available containing empty combs, so much the

better, as these can be used to advantage.

3. If an artificial swarm is required from a straw skep, it may be obtained by driving the bees. Remove the skep containing the stock to some quiet spot, turn it bottom upwards, and stand it in a pail for convenience. On the old stand place an empty skep. On the inverted stock put an empty skep, bringing the edges together at the point towards which the combs run. Push a skewer through the edge into the lower hive so as to form a sort of hinge, and support the upper hive by means of a couple of stout wires bent at right angles at either end. Stand in front of the opening with back to the strongest light and commence rapping on the sides of the lower hive with open hands hard enough to jar the combs, but not so hard as to run any risk of breaking them from their attachments. After a few raps, which must be kept up regularly, the bees will commence their ascent to the empty skep.

4. As the driven bees ascend a sharp look-out must be kept for the queen, and after she is seen stop the driving when about half the bees have Remove the swarm and the stock, and place them on the opposite sides of the old stand, with

an interval of about three feet between them. The bees in the skep placed on the old stand can be shaken out in front of the swarm. If the stock or swarm appear too weak, either would be strengthened by bringing one nearer to the old stand, moving the other further away.

5. If the queen be not found during driving, the bees should be returned and another attempt made. Care must be taken to leave sufficient bees in the stock to nurse the brood and build queen-cells.

6. The driven swarm can be placed in a moveable comb-hive, if the bee-keeper wishes to do so, pre-

pared as recommended above (2).

7. If the bee-keeper has one colony in a framehive, and wishes to make two, he must take a
comb of brood and bees on which the queen is
found, and place it in a hive, filling this up with
empty combs or frames with guides. Then put it
on the stand where the stock stood, and remove
this to a new position. Insert an empty comb at
the side of old stock, bringing the other frames close
together. The bees on the wing will return to the
old stand, join the queen, and form the swarm.

8. Artificial swarms should be made when the weather is fine, and many bees flying, and should always be fed. As most of the old bees will leave the old stock, this should also be fed, especially if

it be short of stores or the weather bad.

9. Care should be taken not to multiply colonies too fast, by making many swarms. Aim at having a few very strong colonies, rather than a large number of weak ones.

HOW AND WHY PLANTS PRODUCE HONEY.

(A Paper read at the Vermont Convention.)

Self-fertilisation takes place where the seed-vessel and pollen are together on the same flower, and come in contact, and cross-fertilisation occurs when pollen from one flower is carried to the seed-vessels of another flower. The reasons why nature desires to cross plants is to secure greater height, weight, and vigour, and more seeds. Most plants are spoiled by self-fertilisation, the same as close breeding in animals; some plants usually self-fertilise, as the pea, lettuce, onion, and ground-nut; but large new varieties of peas are obtained by cross-fertilisation. The means whereby nature obtains crossfertilisation are three: wind fertilisation, as in grasses; insect fertilisation, as in most flowers: as in honey-suckles. The prepotency of the pollen from another plant over that from the plant itself, is among the curious features of plant life. Plants also obtain crossfertilisation by having the pollen and seed-vessels on separate plants, as in the case of willows. On separate parts of the same plant, as in corn, when in the same flower it is attained by having pollen ripen before the seed-vessel: or vice versa, as in the plaintain, fire-weed, gentian, and verbena. There must be some great benefit in cross-fertilisation to offset the great waste of valuable pollen in some flowers, and small, closed flowers of violet have 100 grains, while the peony has three and one half million grains.

In relation to the means taken by nature to entice insects to plants, it is to be noticed that wind-fertilised plants are dull in colour, destitute of odour, and contain no honey, as in the case of pines and all conifers, hemp, hop, and grasses. Large, conspicuous flowers are visited nuch more frequently, and by a greater variety of insects, than small, inconspicuous ones. Bees probably distinguish flowers by bright-coloured leaves. When

bright blue flowers were cut off in an experiment, bees crawled over to get other flowers. When the small, upper leaves, which bees do not use to stand on, were cut off, the bees visited the flowers as usual. Odonra attract insects, as shown by flowers covered with a muslin net. When possessed of odour they do not so much need colour. Fourteen per cent of white flowers have a sweet odour, while only eight per cent of red ones have it. Honey was certainly put in flowers to entice insects. When the honey-sac was cut off a large number of flowers, more than half of them were not visited by insects, and produced no seed. Even dark-coloured streaks on coloured leaves of flowers are believed to be for guiding the insect to the honey-sac, so that it can suck a greater number of flowers in a given time, and hence produce more perfect cross-fertilisation. As honey is of use to plants only as it helps to cross-fertilise them, it is always placed where it will aid in this.

When mature, the pollen-vessels and the seed-vessels always stand in the pathway leading to the honey-sac. A certain amount of heat is necessary for the formation of honey. With some flowers, if the sun ceases to shine for half an hour, bees will cease to work on them for lack of honey. In most plants the construction and position of the pollen-glands and the seed-vessels are evidently arranged with the evident intention of making the bees rub against them when it seeks the flower for honey. In such cases the pollen is moist or glutinous. In wind-fertilised plants the pollen is dry and powdery, and the seed-vessel is usually sticking out, and hairy, to

catch the pollen.

Many flowers are irregular, one or more leaves flattened to serve as a landing-place for the bee, and their honey-sac is on that side of the flower. Violets have large conspicuous flowers adapted to cross-fertilisation, and these flowers are very fragrant, and have much honey. In the harebell the honey-sac is at the bottom of the bell. The pollen-vessels open first, and shed pollen into the bottom of the bell, around the honey-sac. The seed-vessel remains closed. Several days later, when the pollen is dead, the seed-vessel opens and receives pollen from other flowers. In the daisy, one head has many flowers. The outer white leaves serve as an attraction and resting-place, and produce no pollen. Inner flowers have pollen-vessels in the form of a hollow tube, into the middle of which the pollen falls, and is pushed up and into view by the tip of the seed-vessel. Afterward, when the seed-vessel is full grown, and most of the pollen has been brushed eff, the top opens and exposes the inner face to the seed-vessel to pollen brought from other plants.

In a common garden-bean the stamens shed pollen on the middle of the style. One of the flower leaves is wound into a tube containing both stamens and style. These remain inside the leaf until a bee alights on the wing petals, then its weight presses down the blossom, and first the end of the style touches the bee, and it gets any pollen which it has brought from the last-visited flower; next, the style sticks out still further, and the pollen on its middle hits the same spot, and prepares the

bee for the next flower.

In the lady-slipper the honey-sac is at the bottom of the slipper. The bee enters the large slit on the upper side of the slipper. Edges are inflexed, so that the hee cannot creep out the same way. There are two small holes near the stalk, through which it can get out. In doing so it must brush against the seed-vessel and pollenmasses. If the pollen-masses were first the plant would be self-fertilised, but in fact the seed-vessel comes first, and pollen is carried off to be left on the stigma of the next flower it enters.

Orchids have a sticky material that will set at once; as soon as the insect's head touches it the honey is free in the sac. When the sticky material requires more time

to harden, the honey-sac is empty, and the honey is contained in the lining of the sac, and the bee has to boro through the wall of this lining in several places before it

can get all the honey.

Bees have habits which help cross-fertilisation. They work on flowers of one kind as long as they can before changing to another kind. This is not to help the plant, but because they have learned how to stand and work better. Bees search for honey by instinct, by experience, since they work as soon as they emerge from the pupa state. They search introduced plants as readily as native flowers which do not secrete honey, and often try to suck honey out of the honey-sacs that are too long for them to reach. Bees cannot tell without entering a flower whether other bees have exhausted the honey, and hence the flower is more perfectly cross-fertilised. Mr. Miller found that in a certain set of blossoms visited by a bumble-bee, four-fifths had been previously visited.

The great number of flowers which bees can visit in a short time greatly increases the chances of any given flower being cross-fertilised. In one minute a bumblebee visited twenty-four of the closed flowers of flax. In fifteen minutes a single flower on the summit of a plant of evening primrose was visited eight times by various bees. In nineteen minutes every flower on a certain flowering plant was visited twice. In one minute six flowers of a harebell were entered by a pollen-collecting bee, for when collecting pollen they work more slowly than when collecting honey. It was estimated at one time that the flowers in a certain flower-bed were each visited thirty times daily during the week or more than there were in blossom. Bumble-bees in collecting honey fly at the rate of ten miles an hour.

Bees have other habits which are directly opposed to cross-fertilisation. In flowers having several honeysacs, if a bee finds the first one it searches is empty, it does not wait to search the others. Bees often get the honey by biting holes in the blossoms and sucking it out of the side. Whole fields of red clover have been examined in which every flower was thus bitten. The biting is done by bumble-bees, and then hive-bees suck through the holes. Bees are very successful in thus biting holes, always hitting the spot outside just over the honey-sac. In all such cases the plant is not fertilised.

The facts are that plants are very thoroughly fertilised by insects. A gentleman marked 310 plants which were incapable of self-fertilisation, and carefully put pollen on the stigmas of each day after day; he left an equal number to the insects. His produced 11,237 seeds, and the bees 10,886, a difference of but one in 35, and this difference is fully made up by the fact that he worked during a cold spell with continued rain when the bees did not. Of white clover, 10 heads unprotected gave nearly ten times as many seeds as IO heads covered with gauze; 20 heads covered produced only one poor seed, and 20 heads open gave 2290 seeds. Of red clover, 100 heads covered gave nothing, and 100 heads open produced 2720 seeds. Insects will abundantly cross-fertilise plants growing one-third to one-

half mile apart.

In the United States, hive-bees never suck red clover. In England they only suck it through holes made by bumble-bees. The clover cannot be fertilised by the hive-bee—it is too small—but it is cross-fertilised by the bumble-bee. Hence one gentleman has made this statement: The safety of England depends on the number of cats she keeps. He proves his proposition thus: Without the aid of bumble-bees the red clover could not be fertilised. Bumble-bees make their nests on the ground, where they are the prey of mice. Cats destroy the mice and give the bees a chance to live. Hence he reasons, no cats, many mice; many mice, no bumble-bees; no bees, no clover; no clover, no cattle; no cattle, no beef; and without beef where would the Englishman be?— Prof. W. W. Cooke,—(American Bee Journal.)

Foreign.

AUSTRALIA.

The people of Kangaroo Island have not yet realised what has been done for them by the Ligurian Bee Act. In these times of depression, when every new industry however small deserves attention, it seems passing strange that the islanders have not done more towards developing what should be a highly remunerative undertaking. They are in a unique and commanding position. Kangaroo Island is the one place in the world set apart for the rearing and production of pure Ligurian bees, which by an overwhelming weight of authority is pronounced to be the best race of bees known. There are several races of bees bred and manipulated for their honey. Amongst these are the common black bee, the Ligurian, the Carniolan, the Cyprian, the Syrian, and the Holy Land bee, each of which has its adherents. But no bees have so many admirers as the Ligurian, none are such general favourites, and for none is there such a constant and regular demand. When it is known that bees which are hybridised after the first cross gradually acquire the bad qualities and lose the good qualities of both stocks, and that the fashion of crossing and hybridising has become so common that in some parts purity of race has already become lost, the value of a place whence a pure race can be obtained can scarcely be over-estimated. Even in Italy the craze for hybridisation and experiment has become so great that it is feared purity of race will become a thing of the past. It must be remembered that the mating of bees cannot be controlled like the mating of horses and cattle. All attempts in that direc-tion have signally failed. If therefore there be two sorts of bees in a neighbourhood, the chance of purity being retained is at all times very uncertain, with a growing tendency to a dangerous cross.

Particulars have reached us of a case in which a gentleman, notwithstanding great attention to breeding,

had a little time ago to destroy several swarms of the second cross, which had become so fiendish in disposition that nothing could live near them. They attacked the cattle, horses, fowls, and every living creature with demoniacal fury and determination, and followed the bee-master into the house, so that had it not been for their destruction it would have become uninhabitable. They attacked strangers going along a public road fifty yards from the hives, and even settled in numbers with persistent viciousness on a toy dog that had been bought for one of the children. This victousness seems the rule with second crosses. Under these circumstances it is not to be wondered at that a pure and gentle race should be highly valued, and that Mr. Root, one of the first beemasters of America, on hearing of the dedication of the island to Ligurians, wrote to Mr. Bonney, an apiarian of whom any country might well be proud, that all the world would yet come to Kangaroo Island for its pure Ligurians. There are other facts which show the correctness of Mr. Root's anticipations. Well-known British bee-masters have called attention to the advantages which Kangaroo Island now has; and one of them, Mr. Raynor, while stating that England could not boast of anything like such advantages, has curiously enough related that thirty-five years ago, when sailing past Kangaroo Island, he exclaimed, 'What a magnificent location for an apiary!' Mr. Bonney has had frequent applications for information with regard to Kangaroo Island queens from Victoria, New Zealand, and Queens-

The islanders should remember that their greatest advantage is not in respect of the honey crop, although that would be considerable, but in respect of the rearing of pure Ligurian queens. At present considerable sums

bee trade could be done.

land, and is confident that with proper attention a large

of money are sent from all parts of Australia for the purchase of queen-bees in Italy, the whole of which would come to Kangaroo Island if the demand could be supplied with certainty and dispatch. Those bees which have been hitherto raised on the island excel the imported bees in strength and fertility, for the long voyage from Italy in a confined space is always detri-mental and often fatal. There are scores of men in America who make a handsome living out of queenrearing, and a large traffic is done by post between the States and Canada, and there would be no difficulty whatever in sending queens from South Australia even so far as New Zealand. A skilful apiarist might easily raise four or five hundred queens his first season, and 1000 queens a-year could easily be disposed of after the establishment of a proper queen-rearing apiary became known at 14s, to 1l, each. It can readily be seen, therefore, what a loss there is in the neglect of this industry by the Kangaroo Islanders. It is not necessary to say much about honey. No country in the world excels Australia in either the fineness or the yield of its honey; and the French physicians have recently discovered that eucalyptus honey is most useful in medicine. The production in America in 1881 was 200,000,000 lbs. (the value exceeding 30,000,000 dollars), of which a large quantity was exported to England. Care and attention in this matter would add no little to the farmers' profit, as the island is as prolific in honey as the mainland. But as the pleasure and profit of bee-rearing are greatly increased by the possession of good working and tractable bees, and as the island has a monopoly in this respect, it will be almost criminal neglect if the islanders continue to ignore such a great advantage.-South Australian Advertiser, April 5.

UNITED STATES.

APICULTURE AT CORNELL UNIVERSITY.—A course in apiculture under Professor Comstock has just been added to the regular work. This course is intended to supplement the Professor's lectures on the subject. Each student is given a colony of bees, and is expected to attend to it himself. The bees given to the students are Italians, and are the property of Professor Comstock. The students taking this course have just had some A swarm of black bees had taken practical work. possession of a tree near Fall Creek, just opposite the Professor's house, and had to be taken care of to prevent them from hybridising the Italians. The tree was cut down, the bees hived, their queen and drones destroyed, and an Italian queen given to them, making them now harmless neighbours. Thus it will be seen that progressive and scientific apiculture is now being taught as a practical pursuit in several of the colleges in America. American Bee Journal.

ASSOCIATIONS.

IRISH BEE-KEEPERS' ASSOCIATION.

A meeting of the committee was held on the 7th inst. Present: Dr. Allen in the chair, Dr. Knight, Dr. O'Farrell, Dr. Traill, Mr. Read, and the Hon. Secretary, Mr. Chenevix. The Hon. Secretary reported that fortythree new members had joined the Association since the last report was printed. He stated also that, in accordance with the instructions given him by the committee, he had secured the services of Mr. Green, expert of the British Bee-keepers' Association, to lecture and manipulate bees at the show in August. A sub-committee was appointed to complete the arrangements for this show. It was resolved that a conversazione be held in July.

LEICESTERSHIRE BEE-KEEPERS' ASSOCIATION.

The expert of this Association has just finished his pring tour. He has visited a large number of apiaries,

and a considerable number of new names has been added to the subscription list.

A JUBILEE OFFER.—In order to clear off the debt of the Association, Mr. J. W. Bickley, of Melton, offers a donation of one pound provided nine others can be found to imitate him. Bee-keepers of Leicestershire, to the rescue !—E. B.

Correspondence.

The Editor does not hold himself responsible for the opinions expressed by his correspondents. No attention will be taken of anonymous communications, and correspondents are requested to write on one side of the paper only, and give their real names and addresses, not necessarily for publication, but as a guarantee of good faith. Illustrations should be drawn on separate pieces of paper.

Communications relating to the literary department, reports of Associations, Shows, Meetings, Echoes, Queries, Books for Review, &c., must be addressed only to 'The Editors of the 'British Bee Journal,''c/o Messrs. Strangeways and Sons, Tower Street, Cambridge Circus, W.C.' All business communications relating to Advertisements, &c., must be addressed to Mr. J. Huckle, King's Langley, Herts (see 2nd page of Advertisements).

**In order to facilitate reference, Correspondents, when speaking of any letter or query previously inserted, will oblige by mentioning the number of the letter, as well as the page on which it appears.

OUR HONEY IMPORTS.

The value of honey imported into the United Kingdom during the month of May, ISS7, amounted to 1912. [From a return sent by the Principal of the Statistical Department H. M. Customs to E. H. Bellairs, Wingfield, Christchurch.]

A WORD FOR THE EXPERTS.

In your issue of the 9th inst., 'Apple [1007.] Dumpling ' says, 'Experts are in hot water, and well they may be, seeing the expert has closed up and supered a stock of bees, &c. In my journeyings a great many varieties of bee-keepers are met, and to the majority general advice and instruction has to be given; and I think it is far better to have supers on in readiness than to allow the hive to become crowded with bees before extra space is given, in other words, 'give room in advance of their requirements' as a preventive of swarming, &c. frequently place supers on hives long before the bees are ready rather than leave them to the tender care of some gardeners (many of whom seem to have an inborn prejudice against 'them patent hives'), or perhaps to some local expert (?). It may perhaps interest 'Apple Dumpling' to know that another reverend gentleman, in Kent too, for many years known and respected as an authority on bee-matters, remove 1 a super from a hive on the 31st ult., nearly all the sections being well filled —not with 'hailstones'—but beautiful honey from the fruit-blossoms, and from the same stock this day (11th June) about twelve more may be removed, and this has all been done in spite of cold 'nor'-easters,' lack of sunshine, and necessity for feeding (?). Apologising for trespassing on your space, Mr. Editor,—ROLAND GREEN,

WIRING FRAMES FOR FOUNDATION.

[1008.] I see in pages of B. B. J. this method of fastening foundation is gradually making way, the reason it has not already become universal is surprising when its advantages over the split top bar are apparent.

The 'tedious methods' were in use by us until about

five years ago, when a few frames roughly wired were tried, and the result was so satisfactory that the next season these wired frames obtained the exclusive use in our apiary

From that time they were offered for sale, the wire being strung through holes in the top and bottom bar, but finding this wire had an inclination to 'kink' when drawn through, our present method was arrived at.

Three half-inch wire nails are drawn through top and

bottom bars of frame, one in centre and one each an inch from ends (inside), these are partially hooked so as to hold wire by the use of a split key or turning tool (a small pair of round nosed plyers will do); the wire is then hooked over the bent nail, the diagonal braces being first put in starting from centre of top bar, the nails are then driven down tightening up wire, and the frame is ready to receive foundation.

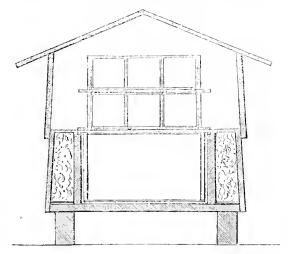

The sheets are best cut so as to touch the frame nearly all round, and are laid on a half-inch hoard with ledges projecting; the wired frame is then placed upon the sheet of foundation and embedded by the Woiblet spur. This is all that is necessary, although melted wax may be poured from a smelter on the edges if desired.

Probably fewer wires would be sufficient to keep the foundation straight and even, but when it is desired to strengthen it sufficiently to extract from soon after giving to bees, six wires (including diagonal braces) are none too much; and as thinner foundation may with economy be used, this number will really effect a saving in first cost, not taking into consideration that the comb will, when built out, stand any ordinary usage.

The objection (so called) of the bees to raise brood in cells through which wires pass is theory rather than practice. We have not noticed half-a-dozen such combs in some hundreds we have in use or stored for sale; and if it were so pollen or honey would be placed in them readily. That wired frames of foundation will take the place of wired foundation when once used is the opinion of—John Edey, St. Neots.

WATERTIGHT ROOFS.

[1009.] Seeing by several letters in the B. B. J. that some of your correspondents seem to find a difficulty in making a hive thoroughly watertight, which is at the same time interchangeable, I thought that I would send you a drawing of the hive we find best. I don't think the drawing requires any explanation, you will see the hive is perfectly watertight, and all the parts interchangeable. You can pile as many hives as you like one on the top of the other. The hive is in three parts—

floor-board, body, and roof, which is hinged to the front with a pair of pivot hinges, as recommended in B. B. J. It will take two tiers of frames—12 in. each, without alteration, of twelve frames and two tiers of sections above. It has a hinged shutter in front, and the entrances can be closed right up by two strips of zinc. The frames are quite plain, without shoulders or metal ends of any sort, resting on zinc runners. You will see the chief feature is in having the sides sloping all round instead of perpendicular.—F. F. MCKENZIE.

A LITTLE OF MY EXPERIENCE WITH CARNIOLAN BEES,

[1110.] In the year 1878, having frequent opportunies of going to see friend Martin, at Messrs. Neighbour's bee-farm at Hampstead, among other things, the Carniolan bees I especially noticed; and as I heard a good character of them as regards gentleness, combined with energy and industry, I decided to try them; so the same autumn I got an imported queen from Neighbour's for 10s. 6d. I safely introduced her, and the next year bred several queens from her. Of course, there was not much chance for the queen to mate with Carniolan drones; some got mated to Ligurian, while others got mated to English drones. Those mated with Ligurians were very nice-looking bees, but not equal in honey gathering to those mated with English drones, as the stocks bred from these were the ones that gave me more honey than ever I had from an English stock. I will not say but that in previous years I had taken as much from Ligurian stocks bred from queens got from Mr. Abbott. Of late years, Ligurians have been nowhere against the Carniolans, only that they are prettier bees.

In the summer of 188I I took 76 lbs, in sections from one of these stocks of Carniolans, while the same year I did not take more than a little over 40 lbs, from either English or Ligurians. 1 do not boast of it as a great yield, but it was the best among my stocks, and our locality is not good enough to get more, as far as I can see. In 1885 I took 76 lbs, off another stock of these Carniolans; and, what is more, I have every reason to believe the queen was one that was bred in 1881. In the autumn of same year I thought I would supersede her, but she appeared so fat and sleek that I could not find it in my heart to take her away; but in 1886 they did not do so well.

I got another imported queen in August, 1885, and raised a queen from her, and just managed to get her mated to an English drone, though I had not many left. I introduced her to a stock of English bees, where she did well, and filled up the hive last spring. And this is the peculiarity I want to be noticed particularly: the stock stood side by side with an English one, and they had both been stimulated the same; I supered them the same night, and when in about a fortnight or three weeks' time I took off the honey, judge of my snrprise to find the sections from the English stock were very dark, and thickly capped over, while the sections from the Carniolan stock were very light and transparent, and not so thickly capped either. I only had two or three pounds more than from the English stock, but it was far hetter to look at, showing to me that they had been going for the white clover, while, from the appearance of the honey, the natives had been going for, or chiefly for, the beans, of which we generally have our share in this part of the country.

I raised several queens last year, and hope to further test their work for light honey against the English. As to their quietness and docility, they are about like most bees, in my opinion; if they get thoroughly roused they can use their husiness end as well and as thoroughly as others, as on one or two occasions I have a lively recollection of them, while in a general way they are more quiet.—John Walton, Honey Cott, Weston, Learnington.

APIFUGE.

[1111.] I am sorry to say that I can confirm your correspondent's remarks as to the effects of using apifuge upon the hands. Both hands and wrists became covered with red and white eruptions of the most itching and irritating nature. I was so convinced at the time that this was the result of the apifuge that I have not used it since.—Scotus.

[1112.] Like your correspondent, E. Musgrove, I used

the apifuge with great pleasure in hiving my first swarm of the season this morning. During the afternoon I have been much irritated by two large bumps on my wrist, but I did not think of attributing them to the apifuge till I read just now of 'E. M.'s' experience. I have used it once before, and had no inconvenience. At your nequest I send this. Allow me to record my pleasure in your clever Journal.—Mary Constable, Manningtree, June 9th.

I can understand the effect of this bee-[1113.]soother on Mr. Musgrove and his nephew if there is any preparation of Arnica montana in it, for some persons are very sensitive to this drug. Maybe, it runs in families. I remember that, some years ago, Mr. Squires, one of the well-known druggists in London, telling me of his experience of it. He and I were walking under the portico of the Beau Rivage Hotel, Oudry, Lausanne, and he asked me whether the Arnica montana grew near where I lived. It was growing in the meadow before my house at Cour. In passing through Paris, Mrs. Squires, having sprained her ankle, called in a doctor, who gave her a lotion of arnica, which her husband applied. He was about to tell me the effect it had upon him, when I rudely interrupted him by saying, 'You've get erysipelas.' I had long known that in some persons the use of arnica was objectionable. Mr. Squires then told me that he could not go into a room where dry bundles of arnica were stored without suffering slight erysipelatous inflammation. I have used both arnica and apifuge. I experience no unpleasant effects. More than that, I had a sting on my wrist two or three days ago, and rubbed the place well with a finger moist with apifuge. I thought I never felt a sting less. Was it fancy?-J. Lawson-Sisson.

[1114.] Having made several trials of the useful 'apifuge,' I can say that no disagreeable effects have followed its use with me. Its application to the hands in the manipulation of two hives was most successful; in the case of the third hive it was not quite so much so, the bees on the opening of the hive flying straight at the hands and stinging viciously. Possibly the scent had faded to some extent.—C. T., Blackheath.

[Mr. Grimshaw, in a private communication, says respecting his apifuge: 'I must write and put some people right as to its use.'—ED.]

HONEY v, SUGAR.

[1115.] In your issue of June 2nd, page 235, you give a long article on this subject signed by one '(Dr.) W. G. Phelps (Practical Farmer).' I read this with considerable interest, for it touched a question on which I had written, my remarks appearing in your columns (page 493, October 21st). This interest waxed into warm appreciation when '(Dr.) W. G. Phelps' did me the honour of quoting me:—'Says one writer,' and following up with an extract from my article in the B. B. J., I felt as though I was caressed by a velvety hand. I heard the exquisitely soft drip, drip,—'sweet music's melting fall,'—as other weak mortals would who found themselves quoted. My diploma'd admirer did not, however, amend my name or initials to his excernt.

append my name or initials to his excerpt.

Further on he tells you, 'A leading medical and scientific journal advances the following good points in reference to its use,' proceeding with a long quotation from my said article, not 'Precept upon precept, line upon line, here a little and there a little,' but verbatim. I read on. Aha! what's this? Why the whole thing is my own article nearly word for word, and this appears as an original contribution by our worthy Doctor, whether of divinity, philosophy, law, or medicine, I

know nor care not!

Unlike the distraught mother who shrieked 'Me nown! me cheyild!' I murmur something not loud, but deep, and wander into a soliloquy as to whether Doctor means Debtor, seeing that this proud author is indebted to me for the very words he uses; whether '(Dr.) W. G. Phelps (Practical Farmer)' should not be designated instead 'practical plagiarist:' but anyway if any of your readers care to compare the two articles they will agree that he is certainly a distinguished man. The incense which erstwhile charmed me, now only incenses me. Mr. Phelps' réchauffé is only a hash from a joint I laid before you; his 'resurrection steak' may be a toothsome morsel, yet it is well that attention should be called to the cold joint whence it is taken. If '(Dr.) W. G. Phelps' be desirons of masquerading in foreign garb, it is but just that the protruding ears should be pointed out. I have no objection to 'Practical Farmers,' but I resent the idea of being practically farmed by the Doctor.—R. A. H. Grimshaw, Horsforth, near Leeds.

[We have taken the pains to compare Dr. Phelps' article with that of Mr. Grimshaw, and we find in it more of Mr. Grimshaw than of Dr. Phelps. The communication of Mr. Grimshaw originally appeared in the Lecds Mercury and was reprinted in our columns. We know not through how many transmutations it may have subsequently passed, probably it did find its way into some 'medical or scientific journal,' where Dr. Phelps may have seen it without having a knowledge of its source. It has also been printed, as from the Practical Farmer, in the American Bee Journal. Mr. Grimshaw may well feel flattered at the wide circulation his communication has had. A short time ago we received an apparently original article from a newspaper published in Graaf Reinet, South Africa, with a request to reprint it in the Bee Journal, but on perusal we found it was one of onr own brain-children which had somehow wandered to that distant land.—Ed.]

QUEEN INTRODUCTION: ANOTHER SUCCESS.

[1116.] Will you kindly allow me a little space in your valuable Journal to testify to the efficiency of Mr. Simmins' plan of queen introduction? On Thursday last (May 26), I received per post a Carniolan queen from Mr. Blow, and at about 3 p.m. on the afternoon of the same day I removed the queen to be superseded (from bar-frame hive). At 10 p.m. I removed 'her Carniolan majesty' from amongst her faithful subjects; and 'good gracious!' Mr. Editor, I had a job, bees running all over the box in fearful consternation, and buzzing about my ears, and I all the while in mortal agony for fear of losing such a valuable mite; but, however, after a minute or two of hunting I saw 'her ' crawling up the side of the box, and I can ladyship' crawling up the side of the box, and I can tell you it was not long till she was safely enclosed in a wine-glass, and you may guess I was truly thankful. Well to make a long story short, I got a brother beekeeper and with him repaired to the hive with the queen (after she had been enclosed for thirty minutes) and introduced her as Mr. Simmins describes, which is very simple. On Monday I examined the hive and found her all right and laying.

Swarming very much earlier here this year, one came off on the 28th, and another to-day. Hoping I have not trespassed too much on your valuable space.—BONNIE SCOTLAND, Kircudbrightshire, N.B. May 31st.

THE FLAVOUR OF HONEY.

[1117.] In all discussions in regard to ripening honey, one essential fact has been entirely ignored, and yet the quality, if not entirely, is more dependent on it than on any other. That honey must be of a certain consistency is conceded by all; so quality first, and quan-

tity next, is what we are all in pursuit of; and how to get the latter without failure of the first is yet an open question. Admitting proper consistency, quality, then, is due to its peculiar flavour, which is derived from the nectar of the flower. All flowers and plants possess a peculiar and distinct odour, which is due to a volatile, or essential, oil peculiar to itself, and this same oil we find in the nectar of the flowers; this it is that gives honey its distinct flavour. When flowers are macerated in water, then distilled, the essential oil of the flower passes off with the steam, and, if condensed, the oil is found in minute quantities floating on the water; and this, as its name indicates, is very volatile, and, if exposed to the atmosphere, in time all evaporates. Thus, the flavour of the honey is dependent on the quantity of this oil present in it. Some flowers possess more of it than others; and, as a natural result, we find some honey with more of a distinct flavour. If the retention of this oil is desirable, then that method by which there is the least loss is the one we are in search of. That we have not yet attained this is evidently a fact; but that it is attainable is beyond question, and I doubt not but that careful experimenting will yet give us a standard to go by.—G. W. BRODBECK, (American Gleanings).

THE SUSSEX ASSOCIATION.

[1118.] I have just received the balance-sheet of this Association for the years 1885 and 1886, with the intimation that subscriptions should be paid at once for 1887. I see the annual meeting was held at Horsham on the 20th January. I have generally contributed my 'mite,' but do not now see any use in belonging to it. I have never had a visit from the expert, or heard anything of the Association's work; and from the fact of the meeting being held in January for two years, and the balance-sheets not issued until June, it looks as if the

committee are 'behind' in all ways.

I have not given 2s. 6d. to the Association in the hope of getting five shillings in return in the shape of gratuitous advice from the experts (which is in some cases rather dear), but in the hope of seeing the Sussex Association come to the front again; but I am afraid we must conclude, by results, that there are more 'drones' in the committee than 'workers.' I hope soon to see a young, vigorous queen installed in our midst, or I am afraid the Association will soon come, as I have heard several say, to an inglorious end—which would be a great pity. There is honey in abundance and plenty of 'workers' amongst us, and it only requires a good prolific queen to preside over us in the shape of a good Secretary and officers to once again make our Association a prosperous colony, and the happy hum of a thriving community will be heard in this, and make itself heard in adjoining counties as well. I hope other members will take the matter to heart, and in the hands of 'workers' who have plenty of time and brains bring the Association up again to compare with others.—A Cor-TAGE BEE-KEEPER.

[There is earnestness in the piteous cry of this 'Cottage Bee-keeper,' and we hope it may reach the ear of some who are ready and willing to aid and uphold this evidently

falling cause.—ED.]

FOUL BROOD AGAIN!

[1119.] Readers of the British Bee Journal will not fail to recognise your solicitude for the general good shown in reprinting last week the extract given on page 242.

On the evening of the 9th I kept an appointment made with a neighbour, and with him examined a stock he had recently received as his start in bee-keeping from a large and well-known apiary. He was loud in praise of the fair way he had been treated, which I at first

supported; but ere long I was obliged to point out to him an irregular line of dark, sunken cells; on opening many of these, all we opened were found to contain the fateful brown jelly-like substance, all outline of the embryo being lost. Now when I add that some four years ago I started much as he did-only with a swarm getting hive and bees from this same apiary, and that for a season I endured foul brood, only eradicating it in the following spring by driving and starving out the bees, then after twenty-four hours hiving them in an entirely new hive, surely you will say that some means should be devised of preventing beginners in our interesting art being thus handicapped. It is true there were not many on each frame infected, for capped brood was abundant, with, as I describe, only a kind of broken line of these had cells on both sides of three frames, the smell being clean and pleasant; could I have been mistaken? My advice was to trust that the promised honey-flow would work a cure, but my friend having read, and evidently inwardly digested, your strictures on the subject, asked me to remove all frames tainted so that he might destroy them 'at whatever cost.'

It must be hard on the apiarist in a large way of business to know what to do; on the other hand it is harder on novices who may happen to go to him for their

start.—A B.B.K.

WIRED FOUNDATION.

[1120.] I am sorry, in pointing out that the American makers of this foundation wired it the wrong way, I did not make my meaning clear in regard to the mechanical construction of the cells-' bees always build their combs with perpendicular walls' should have been 'with perpendicular cell walls.' Your experienced correspondent's remarks in 'Useful Hints' are quite in accordance with facts, the natural disposition is with the cells in horizontal rows, with, as he justly mentions, many modifications, prompted probably in the first instance by necessity and afterwards carried on by the same impulse, nevertheless I think I am quite correct in stating, after examination of hundreds of combs, that the cells have always perpendicular walls; of course we have all seen very peculiarly shaped cells, and what may be termed abortive cells, where the bees have changed from worker to drone cells and where obstacles have impinged upon their working, &c., but these exceptions only tend to prove the rule. My experience of the practical utility of this wired foundation is quite corroborative of your correspondent, for out of between 150 and 200 combs built on it I have not had a single break-down in the hive—a happy contrast to some English flat-bottomed foundation, of which I believe I had no less than thirty sheets give way last year, and others that did not actually give way altogether stretched down to the bottom bar and bent it down nearly to the floor-board.

When we get this foundation made equally good in England and wired the right way up, I venture to predict that it will drive all other kinds out of the market, and we shall hear no more of 'breaking down,' 'sagging,' 'buckling,' &c. The objection which used to be urged against its use for the brood-nest is no longer tenable, my queens seeming not only to have that special liking which most queens have for newly-built combs but to be imbued with a strong desire to fill every cell of the wired foundation so that the combs are even slabs of broodthis may be through the regularity and evenness of the cells, for when stretching takes place many of the cells

are not used for breeding purposes.

May I be permitted to suggest the use of a small screw instead of the nail advised to be driven through the centre of the top-bar to prevent the foundation drawing out. The jar caused by driving the nail being likely to crack the foundation along the top-bar if it be at all brittle, a mishap not always readily perceptible. And, again, in the 'setting up of swarms,' where it is stated that a pitch

of half an inch from back to front is allowable; this, of course, is meant to apply only where the frames run from back to front, and not to those hives with the frames from side to side—this, of course, is understood by most of us, but beginners might get combs but rather out of the frames.

I strongly advise your readers to bear in mind what the writer states about the transfer of the super to the swarm if no excluder be used (and I never use it), the queen will undoubtedly ascend the super and breeding will be carried on there, better keep it off a day or two until the combs are sufficiently advanced to give occupation to the queen below.

Apologising to the writer of 'Useful Hints' for my intrusion on his valuable writings.—F. Boyes, Beverley.

SKELETON CASE FOR HOLDING SECTIONS.

[1121.] I have just designed a tin skeleton case for holding sections, the object being to divide the rows of sections in a crate into two parts, so that when the bees have started the middle sections they can be quickly placed at the end, and the end ones in the centre, thereby stimulating the bees to work harder and build straighter combs. They can be reversed upside down at the same time if desired. I have had them made to hold three and four sections to suit a twenty-one and twenty-four-section crate. They are made by machinery, and are therefore exactly the same size respectively and interchangeable.

Owing to the delay in the manufacture, I have been mable to get a block prepared to show them, but I hope

to have this ready in a short time.

The ends are slotted, and are $4\frac{1}{4} \times 4\frac{3}{4}$ inches, thus leaving a $\frac{1}{4}$ inch space between the rows of sections, and have strips of tin connecting the ends, angled on one side and straight on the other, keeping the sections in their places, and allowing them to slip out on one side only. By their use a crate can be quickly cleared of its sections, and are a convenient means of packing sections for sending away, as the face is completely protected.— W. H. Jenkins, Exchange Buildings, Swansea.

A REQUEST.

[1122.] Perhaps 'A. E.,' or Mr. Webster, or some of your other correspondents, or all of them, might favour me with their ideas of a cheap case in which, say, from twenty-five to lifty sections might be packed off safely for railway travelling, and which a cottager might make for himself. The difficulty of sending away sections was a source of great trouble and annoyance and loss to myself and many more in this neighbourhood last season; and if you could assist us by telling us how we may avoid a repetition of last year's troubles, I (I may as well say we again, as I have no doubt many more cottagers have felt the same difficulty) should be grateful.—Uncertificated Village Expert.

INDIAN BEES.

The quantity of honey produced in Coorg may be roughly estimated at 25,000 lbs., of which 14,000 lbs. is from the domesticated, and I1,000 lbs. from the wild bees. The price realised for the former averages 3 annas the pound, and for the latter, which is of inferior quality, 2 annas the pound. The latter is valued most for the wax. The best wax is sold at 8 annas 8 pie the pound, and that of the ordinary quality at 5 annas 9 pie the pound.

The demand for honey is small. The quantity obtained is absorbed by the local consumption, being used with food by most classes of the people, and as a cooling drink especially on festive occasions. It is used also medicinally. The ryots of Yedayanac, near Somyarpett,

who keep bees, sell the honey in the weekly markets in Mysore and South Canara, but not in any large quantity. Some boney is also imported from the Munjarabad Taluk of the Hassan District of Mysore for local consumption.

The right to collect honey in the Government reserved forests is rented out yearly for about Rs. 270. The wax from wild bees is experted by the contractors chiefly to Madras and the ports on the western coast. Bees are domesticated by villagers in several parts of Coorg, but chiefly in the Yedayanad of the Naujarajapatna Taluk, and in the Yelusavirshime Taluk. The domesticated variety is known as the Tudvé or Madiké (potjenu). It is a light black bee, with light grey wings, about the size of the common English fly, and is probably the Apis florea. It might be improved by the substitution of the Italian large vellow queen-bee, or the ordinary queen honey-bee, Apis mellifica. The Cyprian or American variety of bee might also be tried to obtain a cross. Some of the European planters might be entrusted with the experiment, and proper bee-hives should be supplied to them. At present earthen pots are used by villagers as bee-hives, with holes pierced in them. At the time the bees are expected to swarm, in the months of January and February, the inside of the pot is rubbed with wax, and they are placed with the mouth of the pot downwards in the jungle. On the bees collecting inside after ten or twelve days, the pots are carefully removed at night to the houses of the ryots, where they are kept under the eaves of houses, or under plantain trees. The bees extract honey from the bushes and creepers which are in flower in the jungle. When the honeycomb has formed in the inside of the pot in the months of May and June, the bees are removed by raising the pet up slightly, and blowing them aside while it is dark. These slightly, and blowing them aside while it is dark. bees do not sting so badly as the wild variety. Few of them are killed in the process. Another pot is usually placed afterwards over the first, into which the bees creep after the removal of the combs, but generally they effect their escape into the jungle. A portion of the honeycomb is generally left in the pot as an inducement for them to return. Occasionally larvae are found when the ryets delay too long to remove the honeycomb. These are taken and eaten. These bees are found also wild in the jungle, in the hollows of trees, and in deserted white-ant hills.

The varieties of wild bee, besides the partly domesticated Tudvé or Madiké bees, are known as the Hejjenu (the large bee), Kolu or Kaddi Jeneè (the stick bee), and Nasare or Muli Jeneè (the small bee). The Hejjenu is a thin long bee of a dark brown colour. They form numerous fine honeycombs on large trees and on rocks, in the months of Jannary, February, and March. A jungle tribe called the 'Jain' (honey) Kurubars climb the trees at night, and smoke the bees by applying torches. As much as 12 seers of honey is obtained from one comb, and as many as a hundred combs may be counted on one tree. They generally return each year to the same tree, and gather, at times, under the roofs of large buildings. A precipitous rock near Ramaswamikanvè, known as the 'Jainkal betta' (honey-hill), is covered with combs each vent.

year.

The combs are valued, however, most for the wax, which is exported to the coast. The Kolu or Kaddi Jenè is a small black bee about the size of a young fly. They are found on hedges and on the branches of small trees. The combs are small and round in shape. They give little honey, and what is obtained is used mostly medicinally as a cure for conghs.

The Nasaré or Muli Jeneè is a very diminutive black bee, which builds its comb in the hollows of trees and in the crevices of rocks. The combs are very small, the wax thin, and both it and the honey, which is slightly acid to the taste, are of a black colour. It is mostly eaten on the spot by the herd boys, who search for it when grazing their cattle. Of these varieties none are of any importance except the Hejjenu, first mentioned, which is probably the *Apis dorsata*. It might probably be domesticated. Their habits are not known to differ from those of bees on the plains.—*Asian*.

Echoes from the Hives.

Berlin House, Donegal, June 4th.—Bees have been working splendidly here since the 23rd ult., before that we had some very severe weather, cold with a good fall of suow and hail, which destroyed some of the early apple and sycamore blossoms. I have not seen such a sight of blossoms on both for years, the apple-blossom is nearly fallen now, but the sycamore is still in bloom, also the hawthorn of which there is an abundance, there is a regular smell of honey about my apiary. I had my first swarm on the 28th ult., and two more since, and several more ready any day for it. I have about 200 sections on different hives that I don't intend to let swarm, and they are working in them beautifully. So far my experience of black or brown bees is not very favourable; out of thirty stocks put up for winter, ten were black bees, the remainder Italians; at the end of March I found five of the black stocks without queens, and only two Italians without, I can hardly imagine what can be the cause, as five out of the seven were last year's queens. A friend asked me the other day to have a look at his two stocks of black bees, when I found one of them had no queen, very few bees, and any amount of honey, some of the frames completely full, she was a last year's queen, and put up strong for winter. What can be the cause? I have lost my faith in condemned bees; one of those found queenless was three stocks of condemned bees united, and there were also condemned bees united to some of the others, all queens were safe when put up for winter. I have been thinking, that perhaps, too much in-breeding has something to do with it, as I don't suppose there has been any new blood introduced into the locality for miles round since bees were known, except what I have got myself the last two years. I find that I can have swarms from Italians three weeks or a month earlier than from black bees, the queens are more prolific and the bees work better. There is here an insect, or I suppose I should call it a kind of bee, for it carries pollen, and I see it working on flowers, there is about twelve feet of a dry bank, and it is all perforated with round holes, which they go into, they are nearly as large as a small Italian, with a black body, and I see two sizes, they were flying about very early in the season and there seems to be a lot of them. I intended to have sent you some of them but perhaps from the description you will please tell me what they are, or I will send you some of them at any time. There is another kind that I see working on honey plants, smaller and of a reddish colour, I don't know where they locate themselves. I have not seen a single wasp this year, queen or otherwise, they must have completely died out.—G. Turner.

[The bees are burrowing bees, and belong to the class of Andrenidæ, of which there are many varieties; with the exception of their appearance, they have little in common with the habits of the hive bee.]

Odcombe, Ilminster, June 6th.—With the exception of the 4th and 5th inst., we have had another fortnight of most unfavourable bee-weather. It has now taken a turn for the better, which I trust may continue for a few weeks; we may then get some supers filled. The apple-bloom is nearly all gone, and in this part we must rely on the meadows, previous to their being mown, for any surplus honey; but fortunately the grass is rather late, and moving will not be general for the next fortnight or three week. I had my first swarm yesterday, from a hive of ten frames, which had just commenced work in sections, and which I have treated as I usually do, viz.: place the swarm on the stand of the parent hive, and give it two frames of brood, four empty combs, and fill up with bars guided with foundation, and put on the sections. Cut out all queencels but one from the parent hive, and put in two sheets of foundation in the place of the two frames of brood given to the swarm.—J. SARELL.

Loose, Maidstone, June 10th.—The last few days have been very favourable for the bees, and they have been

working vigorously on the sycamores, chestuuts, holly, maple, and hawthern, all of which are now in full bloom. The weather, on the whole, last month was very unsettled, but we had a few very fine days, which the bees took advantage of. I had a large swarm issue on the 9th of May, which is the first I have heard of; but as it came from a hive that I wished not to swarm I at once returned it, giving more room below (making fifteen frames in all, spaced a quarter of an inch apart), and put on a crate of partly worked-out sections, which by the 26th were three parts sealed over, so placed a second crate underneath the first, which same is now well advanced, and as the bees still crowd out behind the dummy I intend putting a third. I had two swarms on the 26th, one of which I also returned, at the same time putting on a crate of partlyfilled sections, which are now three parts full. The other swarm, which was placed in a new hive, has filled eight frames with broad and honey from starters only. I have also two other stocks working well in sections,-W. H. Dolan.

Swineshead, Lincolnshire, June 13th, — The continued frosts in May have verified the old adage, viz., 'As mauy rime frosts there are in March, there are the same number in May.' Mr. J. H. Brown, who keeps a record of the temperature of the weather, and myself, have for some years noted the fact. This year there were seventeen in March and fourteen in May, also three other mornings very near, which have very much checked the breeding of bees, and the sudden storms have caused a great fatality amongst the heavy pollen-laden workers; yet the apple-blossom, and may, and other flowers being kept back, have assisted them the last few days, having splendid weather to fully avail themselves of it, so that the hives are fast filling with pollen and honey, causing swarms from skeps; but I find the utility of my long twenty-frame hives, which have an extra entrance on the west side behind to raise nuclei and young queens in and prevent swarming, as orchard and fen-house apiaries are often not under supervision.—Robt. Thorpe.

North Leicestershire, June 13th.—To-day is the tenth successive fine day. Bees have been hard at work early and late, and have collected more than is required for present use. More room is called for, and there is a good reason to hope that stocks will be well up to the mark when clover begins to bloom. Bees at present are at work on sycamore, hawthorn, apple, charlock, 'greens,' dandelion, meadow orchis, gilliflowers, and mountain-ash.—E. B.

Honey Cott, Weston, Learnington, June 13th.—After a week's nice weather we seem fairly to have got to a yield of honey, with miles of large hawthorn hedges in full bloom, some of which are nearly twenty feet high, and clovers, and trefoil, beans, &c., blooming, too, takes me back to one of the Crystal Palace shows, where Mr. Rushridge showed honey from whitethorn and clover, which, as the Editor remarked, grew together simultaneously at Sidlesham. Have been very busy last week supering stocks. Had my first swarm only on Saturday, while to-day I have had a monster swarm of Carniolans, which, after taking out queen-cells and a frame or two of brood, I shall return, as I do not want to increase my number of stocks but little, if any at all. There is great promise of a good yield of honey if the weather keeps nice.—John Walton.

Blackheath, June 13th.—The season has been very late with us, the fruit-tree blossoms coming and going without much advantage to supers. At present the weather is glorious, and bees are beginning to take to upper boxes. A fine swarm came off on the 26th of May, and a cast, almost as good, followed a few days later.—Charles Toland.

Beverley, June 13th.—I am far too busy taking off crates of filled and completed sections to answer the remarks of your correspondent, 'Apple Dumpling.' Weather glorious here. Bees doing wonders. No swarms; but honey 'superabundant.'—F. Boyes.

Leeds District.—Since the 4th of June the bees have been working better; but very few swarms have as yet appeared. Hives are strong, and have wintered well; and with the plentiful supply of blossoms we are this year favoured with, there is every probability of a good honey harvest,—WM. DIXON BECKETT, Senr.

NOTICE!

Our practice is to have the Journal ready for press on Tuesday evening, but as next Tuesday is the day of Jubilee, we shall be compelled to finish on Monday. We should therefore be much obliged by our correspondents and advertising friends sending their communications so that they may reach us by Monday morning at latest.

NOTICES TO CORRESPONDENTS & INQUIRERS.

All queries forwarded will be attended to, and those only of personal interest will be answered in this column.

- Frater.—1. Number of Frames,—Six standard frames are not sufficient for a strong swarm; we never give less than ten. You ought to supply eight, at least. Increase the brood-nest by adding more frames. Also more sections may be given behind. Much, however, depends on the season and income. You may remove to an outhouse in October. An empty frame may be added at spring for drone-breeding. 2. Nuclei.—Workers and drones are both put into nuclei. The brood is given to keep up a supply of young bees. Sufficient honey is usually transferred to nuclei over and around the brood in the frames; but it is good policy to feed with syrup.
 3. Sycamore.—We believe that the bees gather pollen from the sycamore, but not much honey. 4. Price of Honcy.—There are no statistics which would enable us to give the weekly price of honey. 5. Honey-Flow.—You can only judge of the honey-flow by the flowers in bloom and the weather—sunshine, temperature, &c. 6. Queen-Introduction.—The plan you suggest of introducing a queen may probably succeed, but we advise you, in preference, to follow Mr. Simmins's method of direct introduction.
- E. P.—The two pieces of comb are not affected with foul brood, but only with chilled brood.
- C. C. T.—Breed of Bees.—The bees forwarded are common English bees.
- T. Cotton.—Casting out Brood.—Casting out brood at this time of the year is usually a sign of want of food, or it may be the removal of broad that has become chilled.
- A LEARNER.—Sections.—You should put one rack of sections on first, and when the bees have taken to this, raise it and place a second between it and the top of hive. If hives are sufficiently strong, you could put a third under the second, -when the bees are working well in the first two. This way of proceeding would be better than giving them the three racks at the same time, more especially as you do not expect your honey-flow for a week or two. The top rack will be completed first. Proceed in the same way with the skeps, and if strong and honey abundant they would bear two racks of sections.
- M. Lin, Essex. Burrowing Bees. The bees carrying pollen into worm-holes and into holes of the wall are not your hive-bees, but some species of Andrenidæ. The Andrenide are a section of the class Apide. Probably, the bee passing into holes is an Andrena Trimmerana. This is a burrowing and solitary-living bee. They are male and female. If you had taken the trouble to dig into the holes where you saw the bees enter, you would have discovered their cells. These cells are beautiful specimens of insect architecture. They are neat and perfect. They are shaped like a thimble, made from particles of sand, glued together by some viscid fluid which the bees are able to secrete. The outside of the cell is roughish, but the inside is perfectly smooth. In each cell is a pellet of sweetened pollen about the size of a red currant, sufficient for the sustenance of the infant bee. They collect a large amount of pollen for their family. The bee that you saw entering into the crevices of the wall of the house is another kind of solitary bee, probably what is termed Megachile muraria.
- G. Clark.—Aborted Drones.—The bees were dead on arrival, and somewhat smeared by the food (?) which you packed with them, which was unsuitable for the purpose. The bees are evidently affected with Bacillus Gaytoni. The wingless drones were aborted through chill in development.

Show Announcements.

Giving Name and Address of Secretary, Date and Place of now, Date of Closing Entries. Terms: Three Insertions Show, Date of Closing Entries. and under, Two Shillings and Sixpence; additional insertions, Sixpence each. No charge made to Associations whose Shows are announced in our general Advertising Columns,

June 15, 16.—Wilts Agricultural Show. Rev. W. E. Burkitt, Secretary.

June 20-23.—Royal Counties' Agricultural Show at Reading. Entries close June 11th. See Advertisement.

June 23, 24.—Suffolk Agricultural Show at Bury St. Edmunds. Entries close June 6. J. Huckle, Secretary.

July 11-15.—Royal Agricultural Show at Newcastle-on-Tyne. Post entries to June 1st. J. Huckle, Kings Langley.

July 14.—Oxfordshire Association at Headington. Hon. Sec., Rev. F. C. Dillon, Enstone.

July 21.—Prescot Horticultural Show. Secretary, Station Road, Present, Lancashire.

July 20-22.—Lincolnshire Agricultural Society at Spalding,

Entries close July 4. R. R. Godfrey, Secretary. July 26-28.—Gloucestershire Agricultural Show at Cheltenham. Entries close July 12. W. D. Slade, Sec.

July 26, 27.- Warwick Agricultural Society at Sutton Coldfield. J. N. Bower, Secretary.

July 27.—Bishops Waltham Show. (Hants and Isle of Wight Association.) H. W. West, Hon. Scc., Swanmore

House, Bishops Waltham. August 3-5.—Yorkshire Agricultural Society at York. Secretary, H. L. Rickards, Poole, near Leeds.

August 9, 10.—Irish Bee-keepers' Association at Salthill Gardens, near Dublin. Entries close August 2. Hon. Sec., Henry Chenevix, Blackrock, Dublin.

August 14.—Handbridge, Chester St. Mary's Horticultural Show. W. E. Little, Hon. Secretary, Eastgate Row,

August 24.—Laneaster Agricultural Show. W. Liddell, Hon. Secretary, Dale Street, Laneaster.

PRY'S Prize Medal Honey Beverages, Champagnes, Syrups, and Cordials, sell well. Assortments on Sale or Return. Lists free. Also Fry's 'Anti-sting,' 6d. and 1s. Auti-sting Soap, 6d. Tablet. Agents Wanted.

MANUFACTORY: BISHOP'S WALTHAM. A 2662

FOR USE WITHOUT SEPARATORS OR with the SIMMINS' SEPARATOR thickened at the Corners by a Half Bee-space.

20,000 $4\frac{1}{4} \times 4\frac{1}{4} \times 1\frac{3}{4}$ V-CUT, Open or Close Sided, First-Class AMERICAN SECTIONS, now landed at Liverpool. Free on rail or steamer there, 20/- per 1000; 10/6 for 500. For smaller quantities apply to J. H. HOWARD, Holme, Peterborough; or to R. White & Co., Patrickswell, Limerick. The Trade supplied.

Finest CYPRIAN Queens.

DIRECT by MAIL from CYPRUS to any Address in EUROPE. From 1st MAY to 30th AUGUST.

,, 5 ,, 6 ,, ,, ,, ,, ,, ,, 12/-

For Countries out of Europe add 50 ° to above prices.

All Orders to be accompanied by a Remittance.

My Queens are all very prolific, long-lived, and much larger-bodied, than the majority of those supplied by others, as they are reared naturally, under the swarming impulse, in April, May, and June, from the strongest of my forty colonies of Bees kept in double-walled movcable frame-hives, and all having choice Queens, which produce workers so gentle that they can be handled without smoke, and even without a veil on the face, just as I do myself (see Mr. S. Simmins' statements on page 37 of his work entitled, A New Era in Modern Bece-keeping). This is principally owing to the fact that I have weeded out from my Apiary all such Queens which appeared to be weak or producing troublesome workers. Address—

M. G. DERVISHIAN, Larnaca, CYPRUS. A 2375 For Reference, address Imperial Ottoman Bank, Larnaca.

LYON'S Patent METAL ENDS

THE only perfect pattern. The metal being flush with the inside of the Hive side, CANNOT BE FIXED TO IT BY PROPOLIS. All the so-called Improvements CAN.

The Special Alloy used allows them to be LIGHT YET STRONG. One gross weighs 5½ lbs.

Price for 1887 5/6 per gross.

DR. PINE'S VEILS.

Prize Medal, 1879, for the best Bee Dress. The only Medal ever awarded to a Veil, 2/2 each, post free. Every genuine Veil bears the Registered Trade Mark.

DR. PINE'S LOTION.

The ONLY CURE for Stings, 1/8 per bottle, post free.

CHESHIRE CURE.

Guaranteed, with Directious, 1/2 per bottle, post free.

Methyl Salicylate, or 'Sting Preventer.'

HIVE MAKERS supplied with SPRINGS, GLASSES for Sections, PHENOL, METHYL SALICYLATE, in bulk, &c., &c., at lowest prices.

F. LYON, 94 Harleyford Rd., London, S.E.

SWARMING SEASON. TIME SAVED IS MONEY EARNED!

All Goods ready for instant Delivery.

Just to hand, a Shipment of the Finest and Whitest AMERICAN SECTIONS ever imported, 11/- per 500.

YUCCA BRUSHES, 3d. Improved BRUSH (for Extracting), 9d. each.

WIRE EMBEDDER and ROLLER, 1/6 each (Root's).

WOIBLET SPUR EMBEDDER, 1/6 each.

EDEY'S Improved SMOKER, with Moveable Shutter and Flue Cleaner, 2/9 each.

BINGHAM, Imported, 7/6. Fuel for ditto, 3d. per lb.

EDEY'S Method of Fixing Foundation in Dovetailed Standard Frames, Wired. Send for WIRING OUTFIT of 1 dozen Frames, Foundation Nails, all necessary Tools, 7/6. See List. NOTE.—Special Split Key and Woiblet Spur included in price; the Key has been used by us for FOUR YEARS. Hundreds of Frames have been extracted without a breakdown. Sample Frame, 9d.

EDEY'S COTTAGER'S EXTRACTOR (52). This revolves two Combs at a time; the Honey may be emptied by the Screw-valve at foot. Not shown in engraving. Price 17/6; Crate, 2/-.

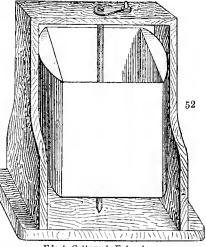

LOCK-UP TRAVELLING CAN, to hold 56 lbs. Honey. Price 5/9.

NESTED TINS for Honey, the Set of 4, holding together 35 lbs., price 1/4; postage 6d.

BEES.—English Swarms, 12/6 each; Palestine Queens, 15-; Syrian, 20/-; Home-bred ditto, half price; Black Queens, 4/-; Syrio-Carniolan Queens, the most Prolific and Best Queens in existence, price 9/- each; Imported Carniolans (BENTON'S). 8/- each.

DOUBLE your HONEY HARVEST by Using WORKED-OUT COMBS!

Clean WIRED COMBS in Frames, 10/- per doz.

Edey's Cottager's Extractor.

CHEAP, STRONG, EASILY MANIPULATED.

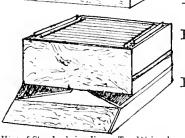

EDEY'S DOUBLER (7 A). Complete for Doubling or Tiering. As shown, with 20 Frames, 2 Dummies, Waterproof Cover, Contracting Entrances, price 10/6. In flat, each, 5/-.

For Supering: Complete Hive, 6/6; Section Crate, 2/6; Additional Body-box, 2/6; Crate of 5 Hives, 23/9.

THE UNIVERSAL (No. 7). Of superior workmanship, high outer sides. A first-class Hive for general work, with Super Crate, price 12/6.

FOUNDATION.—In addition to the ordinary Brood and Super, we have a few Parcels of very Thin and Delicate SUPER FOUNDATION, for filling Sections completely. Average weight, 20 sheets to the lb. 3/6 per lb.

EDEY'S DOVETAILED FRAMES. Best and Cheapest made. No Frame-block needed. 2/- per dozen; 12/6 per 100.

Hive of Standard size, Frame Top 151 ins. long.

For a full line of our Manufactures, see List, free.

Editorial, Aotices, &c.

THE QUEEN'S JUBILEE.

Victoria, Empress-Queen of hearts, We, loyal subjects, bring to thee The fruit of ours, from many parts, In this thy year of Jubilee.

Fruitage of love in words of love,—
Fruitage of wealth in deeds of gold,
From poor below to peer above
Our level fealty behold!

Our voices blend in unison
In the great pean raised to thee,
From myriad throats we speak as one,
In this thy year of Jubilee.

Gentle and wise, and good and great
In loyalty of womanhood,
Thy rule has blessed thy vast estate;
On virtue based, thy throne has stood.

Almighty Sovereign of the spheres,
Commend our gracious Queen to Thee;
Thou hast been with her all the years,
Graciously bless her Jubilee.
W. II., Dorking.*

'OUR QUEEN AND GOVERNOUR.'

As we take up our pen, with the sounds of 'clanging steeples,' which 'with gala-flags are hung,' and with the notes and signs of preparation for the approaching day of Jubilee meeting us on every side, it is difficult to withstand the temptation of bearing our part in the expression of loyalty which the event has evoked; and seeing the exhibition of feeling is so widespread,—we may say so world-wide and universal,—we cannot consider it our duty to be silent. There are some special reasons why bee-keepers should take their part in the general gratulations. In their twofold position as citizens of this great country and as bee-keepers, they can join as earnestly and as fervently as the most loyal in the loud shout, Long live the QUEEN!

There are many points of similitude—'to compare great things with small'—between the Royal Lady that reigns so beneficently in our midst and the hive-queen that rules over thousands of industrious, loyal, and attached subjects, whose interest bee-

* From the Commonwealth. The lines are from the pen of a bee-keeper who has frequently contributed to our pages.

keepers have so much at heart, and over whose welfare they so anxiously and sedulously watch.

We do not propose to specify with any degree of minuteness the points of resemblance that have occurred to our mind, it will suffice on the present occasion only to note the historical steps which have led to the recognition of the relation which the queen-bee bears to the other denizens of the

Our gracious Majesty now sits securely on a throne as firmly fixed as that of any monarch on the face of the earth; but as we pass upwards through the line of her ancestors, we note the many changes the dynasty has undergone. Saxons, Danes, and Normans, the houses of Plantagenet, Lancaster, York, Tudor, Stuart, and Hanover, flit before our vision,—all helping in the progress of years towards the consolidation of the kingdom as we now rejoice to view it. The hive-queen has, too, her history, and we would desire to trace it from the first faint dawnings of light which have from generation to generation led up to the full knowledge which we possess of her position and duties in the economy of the hive.

For our first knowledge of her we must hark back many ages. We must consult that repertory of the knowledge of the ancients, Aristotle, who wrote B.C. 384, to ascertain the views that were in his time entertained respecting queens, or rather, as he calls them, kings. Aristotle informs us that there were two sorts of kings, or rulers; the better sort of a red colour, the inferior black and variegated, and of a size double that of a common bee. The cells of those rulers were placed at the bottom of the combs. The king had a sting, which however he seldom used. To the king belonged a peculiar scent which had the power of attracting his subjects from a distance. The king never left the hive, even for food, or for any other purpose than swarming. When the king died, all was disturbance and ruin. But though Aristotle had some faint traces of truth he had no clear idea of the sex of the queen, and so he calls her $\beta \alpha \sigma \iota \lambda \epsilon \dot{\nu} c$, or king.

Passing on to Virgil, who flourished about the beginning of the Christian era, he styles the ruler *Rev*, or king, and describes with great spirit the attachment of the bees to their 'governor':—

'Lydian nor Mede so much his king adores, Nor those on Nilus' or Hydaspes' shores, The state united stands while he remains, But should he fall, what dire confusion reigns! Their waxen combs and honey, late their joy, With grief and rage distracted, they destroy; He guards the works, with awe they him surround, And crowd about him with triumphant sound; How frequent on their duteous shoulders bear, Bleed, fall, and die for him in glorious war.'

Georgies, iv. 211.

Pliny throws no light on the sex of the governor or ruler. After him we pass through many hundreds of years, which in many things, as well as beekeeping, may well be styled 'the dark ages,' till we arrive at the beginning of the seventeenth century. In 1609, Dr. Butler, well named 'the Father of English apiarians,' wrote his Feminine In that he gives the ruler a more Monarchy. precise designation. He says: 'I am enforced to strain the ordinary signification of the word Rex, and to translate it queen; sith the males here bear no sway at all, theirs being an Amazonian or feminine kingdom.' But Butler was not so far advanced in his knowledge as to say that the queen was the mother of the whole community; his idea was that the queen-bees bear only 'ladybees,' and that in special cells, which 'for the most part are outside of the combs; for though it be fit for princes to be near their chief cities, yet they do not love to be pestered in the midst of them. These cells were larger than the rest, to show that subjects' houses should not match their sovereign's in greatness.' Neither does he incline to the opinion that worker-bees are undeveloped females; for he says, 'Honey-bees are the females, by whom the bees of both sexes (first the females and then the males) are bred.'

We must give the honour to the Rev. Samuel Purchase for being the first to describe the ruler by her true name, namely, 'Queen-mother.' In his work, entitled A Theatre of Political Flying Insects (1657), he says, speaking of swarming:—'Signs of after-swarms are more manifest and certain, for about eight to twelve days after her first swarm is cast, the next princess will begin to tune in her treble voyce a mournful and begging note, as if she did pray her queen-mother to give her leave to begone. . . . The first day after the grant from the queen-mother,' &c., &c. Another and important step was taken by Swammerdam, whose work on Insects was published in 1669, when he stated 'that from one female, the only one in the hive, all these kinds of bees are produced,' that is queens, workers, and drones.

This great fact having been thus enunciated, the queen had now arrived at her true position as the queen-mother of all the population of the hive.

From this time, by the labours of Maraldi, Réaumur, Huber, and others, the life of the queen has been further elucidated and the arcana of the mysteries which had gathered round her have been gradually opened.

At the present day the position of the queen is higher than at any previous time. Enterprising men have gone to distant climes, have imperilled their lives, and have circled the wide earth for improved races and strains of queens. Since the introduction to the notice of the public of the

virtues of the Ligurian bee, a considerable traffic has arisen in foreign queens; and many persons have devoted their lives and their energies to provide for this want. Lately we have heard that the government of South Australia is so interested in the purity of the race of bees that it has passed an Act of Parliament and set aside an island for the purpose of keeping pure that race which they consider the most important. All bee-keepers, then, feeling how dependent the hopes of progress in bee-keeping are on the welfare and well-being of their queens, are prepared in more senses than one to 'acclaim with one glad voice' 'Vivat REGINA!'

OBSERVATIONS ON QUEENS.

'God save the Queen!' Such is the heartfelt expression from every loyal worker in this great empire, more especially in this year of Jubilee; and may the year be one of peace and prosperity to all, whatever their calling may be!

This year of Her Majesty's glorious reign is an exception, and we may be excused for mixing matters a little, though in a paper devoted exclusively to bees the mention of our own sovereign but reminds us of the great similarity between our own government and that of the hive. It has been stated that the queen-bee does not govern the hive. Well, as a matter of fact, our own Queen could not rule without the assistance of many of her subjects; and so it is with the honey bees; it is merely a question of mutual assistance—a true commonwealth. The presence of our queen, the existence of the hive queen, tends towards a condition of peace and prosperity. Let either be removed, and the community is thrown into a temporary state of dilorder, until a new head be established.

I have been asked to write something about Queens; but what? We have recently had so much about queen introduction that it is hardly advisable to start that subject again. Their natural history, too, has been treated of lately by a more able writer than myself, so I have decided to give a few general observations that may prove of interest to practical bee-keepers.

We have already seen that the queen is the life and soul of the hive, and knowing that the apiarist must be studying his own interests by ascertaining that every queen he has is deing well. Your queen may be prolific, but her bees, perhaps, do not come up to the standard for honey-gathering; they may be of bad temper, or perhaps they gather propolis in undue quantities. The mother of such bees should be superseded at the first opportunity by one known to be of better character.

When a colony does not come along in the spring as it ought, the fault can mostly be found in the queen; but it requires care and judgment before one can decide for certain. The condition of the stock during the previous autumn should be taken into consideration, also what stores they had to winter on, and whether they were properly packed. If these matters can be satisfactorily accounted for, then proceed accordingly, and do not hesitate for one moment, as everything depends first upon the queen.

It is not generally known that a queen taken from a hive while in full laying order is nearly always accepted at once by any colony that has no queen. Young queens

that have only recently commenced to lay are more restless and are not so readily taken to without precautions. Fertile queens, long confined, are frequently objected to, and, like unfertilised queens, run much risk if due care is not exercised.

The statement has been almost universally accepted that the queen leaves the hive only to be fertilised, and when going off with a swarm. For my own part I am convinced by several cases of actual observation that queens do sometimes take an airing, especially after confinement. In spring when a general flight takes place, queens are not balled so much by strange bees entering the hive as by her own bees when returning from flight, just as young queens often are after an excursion in search of drones.

Does any one know where to get queen-excluding zinc? I have tried the correct material, and yet I find not only virgin, but large laying queens go through. Certainly it excludes drones, and that is the only use I have for it. The best way to exclude queens from supers is to use all worker comb in them and to give her plenty

of room below.

Many want to know the best time to buy queens. Any time from May to August, certainly not later, though often they are inserted later, to the almost certain ruin of the stock. A young queen given late breeds late; nature will have her period of repose, consequently by the time she would lay well next spring, her bees will be dying off rapidly, in consequence of frequent flights before young bees are hatching freely. Again in spring how many there are who, finding a stock queen-less, send off for a new queen! How much better to unite at once, for what does the dealer from whom he purchases? He runs considerable risk in wintering nuclei for the sake of the young queens, as he is aware they are much sought after early in the season. As the queens are disposed of, often to be introduced to colonies (?) weaker than the nuclei they are sold from, the dealer unites, thus gaining strength while pocketing cash into the bargain, the purchaser often finding, to his regret, that his bees have not sufficient 'backbone' left to do the new queen justice. If one must try a new variety, why not give her foreign majesty a fair trial with at least an average stock in good heart, and thus be in a position to give a full and faithful report?

I am in a position to state that many queens are lost by being inserted where there already exists a virgin These are sometimes difficult to find I am fully aware, but where there is the least uncertainty, by inserting a comb with eggs, one can soon tell if a queen is in the hive. If one is present they will not complete, even if they begin to build queen-cells, though more often none are started. In the absence of a queen, cells

are rapidly completed.

In giving queens by my direct method I have been much interested to find that very often the bees exhibit personal attachment for their original queen. While accepting the new sovereign, I have noticed they behave with every sign of queenlessness, and continue to build queen-cells, such state of excitement being kept up for several days.

I have other things to mention in regard to fertilisation of queens, but this must be given in the concluding paper on the foreign races, which I am reminded remains incomplete. I hope to find time for the same at an early date.—S. SIMMINS.

USEFUL HINTS.

Weather.—'That an Englishman is always known by his remarks on the weather' has become a proverb. This, no doubt, in a great measure arises from the changeable, fickle climate of his native land. When he becomes acclimatised in other lands, with climate less fickle, he ceases to remark on the weather.

The Anglo-Australian, for instance, has little cause to

speculate on change of weather. For six monthstwelve months—one year—the Australian sky is never clouded, save by an occasional thunder-storm, and oh! how weary the eye becomes from gazing day after day on the brazen vault of heaven, on the 'never green Eucalypti,' on the arid, scorched, and burning plains. How many who have gone out there exclaim, 'England, with all thy faults, I love thee still!'

Frost, snow, hail, rain, &c., have at length given place to real summer weather. And the change has been very sudden; so much so that bees have exhibited signs of mental disorganization, not knowing whether to swarm. or to fill sections, or other supers, or to 'hang out' idly, and do nothing. In well-organized apiaries, however, they are filling sections, or swarming for increase, or raising young queens in nuclei, according to their owner's wishes, and to his heart's content. They are indeed, under sunny skies, revelling in the May bloom, on the bean-fields, on the broad yellow plains of mustard and brassica, and conveying home no stinted quantity of luscious nectar. May this pleasant realisation last. May the refreshing shower fall, 'keeping all things in tune,' causing the sweet-scented bloom of the white clover fields to fill the air all around. But the 'Mower,' with its horrible everlasting jingling, fills our ears, alas! The meadows, laden with the perfume of the blooms of their shorn flowers, are already being rendered bare and honeyless. Why cannot the farmers wait a little, and give our bees a chance, and themselves reap heavier crops? Still our hope, in the grazing districts, is the white clover. Then the limes. And then—

Sections are filling fast. Our plan has been to give small triangular pieces of the thinnest foundation in these, in preference, of late, to full sheets, on account of the 'buckling.' But in Lee's sections we have given full sheets, which are beautifully drawn out into splendidly filled sections. This is owing, no doubt, to the inserted foundation being stretched and held firmly in positionso that the bees are, in a manuer, compelled to build

straight comb.

Our only regret is, that all our sections are not of this pattern. We have also in use several of Mr. Simmins' [†]Comb-honey supers, each containing skeleton folding section frames, holding seven of the $4\frac{1}{4} \times 4\frac{1}{4} \times 1\frac{3}{4}$ inch sections, so that each super contains twenty-one sections. The whole arrangement is very neat and expeditious, a principal feature being the discarding of separators. The three skeleton folding frames are kept in position by keys, which are most easily inserted and withdrawn. These are the sole invention of Mr. Simmins, we believe, and are patented.

Wired Foundation.—Mr. Boyes' remarks on this subject, in our last issue, are very much to the point, and there is no necessity for any apology from him. We are always glad of suggestions. The insertion of screws into divided top bars is a longer process than the simple driving in of a nail, which secures the foundation equally well, and has this advantage, that the divided bar can be more easily reopened than when screwed. If the frames of foundation are prepared upon a block, resting on a firm bench, the driving in of a French nail does not perceptibly shake the foundation. For some years we have used the nail in preference to the screw, and find that it answers the purpose just as well.

Our advice as to placing the hives of swarms level, except with a slight inclination to the front, should have been qualified, as Mr. Boyes justly observes, by stating that the hint applied to those with frames ranging from back to front. Our hives being all upon this plan, we are apt to ignore the parallel system. It is evident that to raise one side of a hive having parallel frames would throw the combs out of the vertical; and this is one of the disadvantages of the system, for we count it a decided advantage that hives should have a slight inclination from back to front, not only to assist the bees in carrying out refuse matter, but also as affording an easy escape for condensed moisture. A quarter of an inch pitch is, perhaps, sufficient.

Superseding Queens is a practice often adopted by skilful apiarists, but one which, as a rule, we do not follow; although the ages of our queens being known, any queen failing in fecundity after her second year, if not superseded naturally, is removed and replaced by another. Generally speaking, an old queen is superseded by the bees, very often during the aerial flight of a natural swarm an old queen, whether from some defect in the wings or elsewhere, is lost, and the bees return to the parent hive, rarely attempting to swarm again unless the loss occurs early in the season. In such case they will cluster outside the hive in large numbers, remaining at home apparently idle. When this occurs it is best to give surplus boxes and bottom ventilation, driving the outlying bees into the hive. About twelve or fourteen days after the loss of the old queen her successor may be expected to mate when she will find plenty of empty cells for the reception of the eggs. These remarks have reference to skeps rather than to frame-hives, in which the loss of the queen can be discovered, and more easily remedied by the introduction of a fecundated queen without loss of time—a matter of great importance during the honey season. The most prolific queens, those which have produced large swarms to lead them off (for the bees lead off the queen) are those which are most often lost during the issue of a natural swarm, and such queens are usually two years old at least, and often three or more. Here, then, we have nature superseding queens without the aid of the bees or their master, and there seems to be a growing opinion amongst the greater part of experienced and able apiarists in favour of allowing the bees to supersede their queens. The general idea seems to be that a prosperous colony will not tolerate an aged or unprolific queen, and the general consensus of opinion amongst the foremost American apiarists is, that, as a general rule, it is best to allow the bees to do the superseding of their own accord. Then, again, there is the difference in queens to be considered. We have repeatedly had queens of three, and even four, years old better than others at one and two years. Another point to be considered is the time at which the change should be made. During the honey-flow, except in the case of change while swarming, would be most inopportune, hence we find that the most usual time of superseding is during the latter part of July and the month of August, and not unfrequently the old queen is tolerated until the young one commences to lay. Often have we witnessed this, but never knew the old queen to survive through the winter.

SUPERED COLONIES SWARMING.—An Italian colony, large and strong, which had received a case of sections, and before we were aware of the fact had quickly filled it, sent forth a swarm as we stood watching it. Immediately the bees began to tumble out, helter-skelter, we sat down beside the hive in order to seize the queen on her exit. At first the rush was somewhat slow and deliberate, but increased in energy, until quite at the fag end of the exodus out came the queen, which was immediately, while taking a turn or two on the alightingboard, taken in the fingers, and with half-a-dozen of her children placed in a small wire cage, which at swarming time we always carry in our fob and returned to our pocket. The swarm was now well out, and after circling around for ten minutes partially settled on a bush near by. Now was our time for action. The square framehive was raised and an eke four inches deep was placed below it. The case of beautifully filled sections was removed and an empty one took its place. By this time the bees, despairing of their que of joining them, had began to return to the hive, their entrance being expedited by carbolised goose-quill. When all had entered we placed the mother and her few attendants on the flight-board and watched her majestic entrance to her domain. And now a second case of sections is fast approaching completion, and a third has been inserted beneath it, and all goes on quietly without further sign of swarming. We excised no queen-cells, but have no doubt that the bees have done so, or at least allowed the queen to do it. Room and ventilation below and above was all we depended upon, and the bees are perfectly satisfied and are working splendidly. The queen was of last year and very prolific, and of course we did not wish for increase. The captured queen might have been utilised otherwise than by returning to the hives and the section cases would have been filled almost equally well.

Addition of Brood.—To swarms working for surplus an addition of a brood-comb or two from other colonies is very advantageous during the first ten days after swarming, since no young bees will be forthcoming for about a month after hiving, and young bees do not work in the field until a fortnight old; hence, from the loss of old bees and the non-production of young ones, the colony becomes reduced in numbers, and often the queen's domain—her brood-nest—is partly stored with

honey.

EAST WINDS AND SMOKE v. CARBOLIC.—Although the weather continues bright and fine, we still experience strong easterly winds, which always render the bees irritable and restless when bandled. Smoke, we think, is to be deprecated as causing too much disturbance in the hive. Since we gave up smoke our manipulations have been far quieter and the bees in a more natural state and less irritable, remaining quietly on their combs without clustering or rolling off during inspection. A piece of calico or house-flannel is sprayed with weak carbolic solution, and gradually takes the place of the hive quilt while being drawn aside without the escape of a single bee. The bees retire below, i.c. to the lower parts of the combs, and the frames may be quietly raised one by one as desired when an examination is necessary. If the operation is protracted, a little fresh spray may be thrown over the cloth while resting on the hive, and will effectually keep the bees quiet; indeed, this method of manipulation is the most simple and effectual of any we have tried, and is far superior to smoke. And what a relief to lay aside the dirty bellows smoker, with all its paraphernalia of fuel, lighting, relighting, &c., and, after all, finding fuel not alight just at an important moment!

Removal of Surplus Cases may be effected in a similar manner about noon on a fine day, when few bees will be found in the cases. Having removed the covering and spread the carbolised cloth over them, raise the cases slightly on wedges. Then pass a carbolised quilt between the hive and cases, and remove the latter to the manipulating room or to a shady spot, where each section may be withdrawn and the few remaining

bees brushed off. Bee-loving Hen.—In the centre of our apiary, in the midst of fifty hives, under the floor-board of a strong colony of Italian bees, standing upon a few bricks, a fine cuckoo dorking hen has made her nest. One by one eggs were deposited until the number reached twelve. Incubation then began, and the expectant mother has for ten days closely hugged her eggs within a foot of the flight-board of the hive, under which she sits with its teeming population busy all around her. A beehouse containing eight hives-two of them holding strong colonies of Cyprians-stands in rear of the hen, with other hives in front of her. Hives to the left of her, hives to the right of her! and no sting has as yet annoyed the poor patient hen. The dangerous time will be when the brood emerges. Bees hatching above, chickens below! However, we shall hope quickly to remove the latter out of harm's way. Every morning, when her fellows are fed, stealthily the hen leaves her nest; after regaling herself, stealthily she returns, causing neither commotion nor irritation amongst the

bees. For many years we have rarely kept less than fifty head of poultry located close to our apiary, of which they have the full range, and our chickens are never stung, nor did we ever see the latter attack the bees, with the exception of a few straggling drones being picked up and devoured. In these hard times then, to the well-worn 'Keep bees' of the Bishop, let us add, 'and poultry also.'

A LOWESTOFT APIARY.

Taking advantage of a day which put itself forward as the first of spring we paid a visit to an apiary of Mr. L. Wren, the expert of the local Bee-keepers' Society. Here we found a dozen hives, and learned that there were another dozen in another garden, and between thirty and forty at Beccles; the home apiary is kept expressly for raising Ligurian queens, the others for honey. The bees were somewhat torpid, but being gently stimulated by the influences of the heightened temperature. They were quartered in the bar-framed hives, which were imbedded in shavings and other things to increase the temperature. Scanty were the flowers in the neighbourhood, but the bees were 'improving the shining hour,' and every now and again a home-returning labourer negotiated the safety door of the hive. The bee has the credit for a great deal of sagacity, but it was easy to see that the bump of location or of topography, as the phrenologists would say, was not so very well developed. Frequent mistakes were made as to the hive, and the bee having tried to get 'nto 'the wrong box' was beaten off from hive to hive till it found its own. It should be said that the hives were placed very close together, and such mistakes were almost pardonable. The bees did not appear to be at all laden, and the examination of the honey-bag of one or two revealed the fact that the land was not yet abounding with honey. Over the tops of many of the hives artificially-prepared food consisting of cakes of sugar, flour, and wax, or a something which looked very much like it, were placed, and the bees had made prodigious bites out of these. The circumstances of one hive had induced an attack of dysentery or an inlet of a chilling draught, which had brought about a heavy mortality, and the carcasses of the deceased, 'uncoffined and unwept,' were plentifully scattered about. A bee, it must be understood, is an insect with very little sentiment, few affections, and no sympathy. It pays no attention to dying relatives, and if one happen to expire the bees do not stop to render succour or pay any mark of respect to the corpses. A sharp eye is kept on the queen or mother bee, who seems to be regarded with the same respect that the farmer bestows on a favourite broad mare; the drones or males come in for the harshest of usage, and the work of cell-making goes on grimly. The apiarian community would be a good subject for women's rights speakers, and we are surprised that the society has not adopted the hive as its armorial insignia. Bees are veritably brought face to face with petticoat government, although it is a mistake to suppose they are governed by the queen. The bee is like a great many people in this world: it has obtained a great reputation for all sorts of things on a very narrow basis. Mr. Wren showed us a fine-looking queen which he had obtained from Germany, and it seems that the breed of bees is to be improved by the same means that stock is improved. Her apiarian majesty now crosses the Atlantic Ocean (in boxes), and New Zealand and Australia are continually demanding good Ligurian queens. The pure Ligurian or Italian bee is the best worker, and as the aboriginal English bee is approached in breed matters go wrong. Having seen Mr. Wren take out cluster after cluster of bees and examine them (we are not certain whether he did not make them protrude their tongues and feel their pulses), we just waited to see the way in which the new wooden hives are made—by a clever adaptation of a small circular saw worked by a pretty gas engine. Any one who is

about entering on the profitable path of bee-keeping ought to pay a visit to Mr. Wren, and we prophesy that apiculture will shortly progress rapidly in Suffolk. The profits are good, and honey is of great value to the comimmity. By default of bees tons of good honey may be lost to us which flowers have produced in vain. Here is the discovery of a new harvest. Honey has qualities which admirably adapt it to beer-makers' use, and in Great Britain alone some 9,000,000 lbs. a-year are used in the breweries, being very much better than sugar for such purposes. At the present time we are importing vast quantities of honey from America, and the demand is so great that there is a great deal of adulteration resorted to. California has grown richer with her beefarming than with her gold-mining, and we think that Suffolk, at an humble distance, should follow in her wake and take to bees .- The Lowestoft Standard.

Correspondence.

The Editor does not hold himself responsible for the opinions expressed by his correspondents. No attention will be taken of anonymous communications, and correspondents are requested to write on one side of the paper only, and give their real names and addresses, not necessarily for publication, but as a guarantee of good faith. Illustrations should be drawn on separate pieces of paper.

Communications relating to the literary department, reports of Associations, Shows, Meetings, Echoes, Queries, Books for Review, &c., must be addressed only to 'The Editor of the 'British Bee Journal,' c/o Messrs. Strangeways and Sons, Tower Street, Cambridge Circus, W.C.' All business communications relating to Advertisements, &c., must be addressed to Mr. J. Huckle, King's Langley, Herts (see 2nd page of Advertisements).

******In order to facilitate reference, Correspondents, when speaking of any letter or query previously inserted, will oblige by mentioning the number of the letter, as well as the page on which it appears.

A BEE TOUR THROUGH LANCASHIRE AND NORTHUMBERLAND.
